1.2 AddToolType

```
NAME
    AddToolType -- Adds or changes a new/existing icon's tooltype (V10)
    (icon)

SYNOPSIS
    tool = AddToolType(diskobj, tooltype)

    char * = AddToolType(struct DiskObject *, char *);

FUNCTION
    This function lets you add a new tooltype to a disk object's
    tooltype list, or change already existing one.
    It is a smart routine that makes dealing with tooltypes very
    straightforward.

    The following is an example table about how a tooltype list gets
    changed based on a provided tool:
```

```
        existing tooltype | provided tooltype | result
    ----------------------------------------------------------
        NOGUI         |      (NOGUI)       | (NOGUI)
        (NOGUI)       |      NOGUI         | NOGUI
        NOGUI         |      NOGUI         | NOGUI
        SIZE=10       |      SIZE=15       | SIZE=15
        (SIZE=10)     |      SIZE=15       | SIZE=15
        SIZE=10       |      (SIZE=15)     | (SIZE=15)
        [a new one]   |      DONOTWAIT     | DONOTWAIT [added to a list]
```

INPUTS
    diskobj - points to an allocated DiskObject structure (usually
              created by GetDiskObject() function).

    tooltype - points to a new tooltype string to be added to a
               provided tooltype list

RESULT
    tool = pointer to a provided tooltype string if succeeds, otherwise
    NULL.

EXAMPLES
    This example opens a ram:test.info icon and asks a user to enter
    tooltypes to be added (until user enters 'end').

```c
#include <libraries/supra.h>
#include <clib/exec_protos.h>
#include <clib/dos_protos.h>
#include <clib/icon_protos.h>
#include <stdio.h>
#include <string.h>

#define filename "ram:test"

struct Library *IconBase = NULL;

struct DiskObject *diskobj;

char icon[50];

main()
{
    key = NULL;
        if (IntuitionBase = OpenLibrary("intuition.library",0)) {
            if (IconBase = OpenLibrary("icon.library",0)) {
                if (diskobj = GetDiskObject(filename)) {
                    do {
                        gets(icon);
                        if (strcmp(icon, "end") == 0) break;
                        AddToolType(diskobj, icon);
                    } while (TRUE);

                    PutDiskObject(filename, diskobj);
                    FreeDiskObject(diskobj);
                    FreeRemember(&key, TRUE);
```

```
                }
            }
        }

    if (IconBase) CloseLibrary(IconBase);
    if (IntuitionBase) CloseLibrary(IntuitionBase);
}
```

NOTES
    All memory allocations used by AddToolType() will be stored in
    FreeList structure that MUST be allocated right after the provided
    DiskObject structure. If you called your DiskObject by GetDiskObject()
    or GetDiskObjectNew() then FreeList is automaticly appended.
    All allocated memory is freed when you call FreeDiskObject().

    This function requires icon.library to be opened.

1.3 FCopy

NAME
    FCopy -- copies source file to destination file (V10)
    (dos V36)

SYNOPSIS
    error = FCopy(source, dest, buffer)

    UBYTE = FCopy(char *, char *, LONG);

FUNCTION
    This function works very similar to C:Copy program. It copies
    a source file to a destination file.

INPUTS
    source – pointer to a source file name (with a relative or
          absolute path)
    dest – pointer to a destination file name
    buffer – maximum size of a buffer (in bytes) to be
          allocated for copying. If this buffer is 0, FCopy()
          will try to allocate buffer a size of a source file,
          or the largest memory block available. (this is the
          fastest way).

RESULT
    error – zero if no error. Function may return one of the
    following error definitions:

        FC_ERR_EXIST – Source file does not exist
        FC_ERR_EXAM – Error during examination of a source file
        FC_ERR_MEM   – Not enough memory availabe
        FC_ERR_OPEN – Source file could not be oppened
        FC_ERR_READ – Error while reading a source file
        FC_ERR_DIR   – Source file path is a directory
        FC_ERR_DEST – Destination file could not be created
        FC_ERR_WRITE – Error while writing to a destination file

EXAMPLE

```
    /* This example will copy a file c:dir to ram: with a new name
     * list.
     */

    UBYTE err;

    if ((err = FCopy("C:Dir", "ram:list", 0)) == 0) {

        no errors...

    } else {
        printf("Error: %d\n", err); /* Error occured during FCopy()
*/

    }
```

NOTES
    If an error occurs then a destination file will not be deleted
    if it has already been partly copied.

1.4 FileType

NAME
    FileType -- Examines if a file is a directory or a file (V10)

SYNOPSIS
    type = FileType(filename)

    LONG = FileType(char *);

FUNCTION
    Will use dos.library's Examine() function to determine
    whether a specified file(path) exists, and if it is a file
    or a directory.

INPUTS
    filename - pointer to a filename string

RESULT
    returns 0 if specified file/path does not exist. If < 0, then
    it is a plain file. If > 0 a directory.
    This function actually returns fib_DirEntryType (from
    struct FileInfoBlock).

EXAMPLE

    type = FileType("SYS:System");

    type will be > 0, which means that "SYS:System" is a dir.

1.5   FreeNewImg

```
NAME
    FreeNewImg -- frees memory allocated by MakeNewImg() (V10)

SYNOPSIS
    FreeNewImg(newImage)

    void FreeNewImg(struct Image *);

FUNCTION
    You must free a new created image with this function, when
    it is no longer needed.

SEE ALSO
    MakeNewImg()
```

1.6   MakeNewImg

```
NAME
    MakeNewImg -- Remap an image to any new colours (V10)

SYNOPSIS
    newImage = MakeNewImg(oldImage, palette)

    struct Image * = MakeNewImg(struct Image *, ULONG *);

FUNCTION
    This function creates a new clone image of a provided
    image, and it remaps the new image according to a provided
    pen colour list.
    This is very useful when you need your image to use
    specific colours anywhere in the available palette.
    (e.g. you obtained some free pens from a palette, and
    you want your image to be shown with those pens).
    It is possible to modify an image's pens with PlanePick and
    PlaneOnOff fields (see Image structure), but this has a major
    limitation: most colour combinations are not possible to get.

    If your image has four colours (0,1,2,3), and you want to
    remap these to (0,16,4,7), you simply call this function,
    providing it with the image and a new colour map, and a
    new image will be created for you.

INPUTS
    oldImage - pointer to an Image structure to be remapped
    palette  - pointer to a list of new pens

    A pens list should contain the exact number of pens as
    an old image uses. (2 if image's depth is 1, 4 if image's
    depth is 2, etc.). An image's colour 0 will be remapped to the
    first pen on the list, image's colour 1 will be remapped to
    the second pen on the list and so on.
```

```
RESULT
    newImage - pointer to a newly initialized remapped old image's
              clone. If there is not enough memory, newImage will
              be NULL.
    IMPORTANT: If a new image was created you have to call
    FreeNewImg() to free the allocated memory, when you no longer
    need to use it!

EXAMPLE

    We have a depth 2 image (4 colours), and we want to use pens
    0,16,4,7 instead of 0,1,2,3:

    struct Image OldImage = {
        ....    /* This is a data of our original image */

    struct Image *NewImage;
    ULONG pal[] = {0, 16, 4, 7}; /* The new pen list */

    if (NewImage = MakeNewImg(&OldImage, &pal[0])) {
       DrawImage(rp, NewImage);
       FreeNewImg(NewImage);     /* We will no longer use it */
    }

NOTE
    A new image's depth will change to a depth that can hold
    the largest pen number from a pens list. It does not have
    any smart routine to check if the depth can be optimized
    down, by altering PlanePick and PlaneOnOff, yet.
    Bear in mind that if you provide a pen 255, then a new image's
    depth will be at least 8.

    You MUST free a new image with FreeNewImg() when it's no longer
    needed!

    This function can take much time when remapping larger images
    with more depths.

BUGS
    None found.

SEE ALSO
    FreeNewImg()
```

1.7 MakePath

```
NAME
    MakePath -- Creates all new directories in a path (V10)

SYNOPSIS
    suc = MakePath(path)

    BOOL = MakePath(char *);
```

```
FUNCTION
    This function creates a whole specified path of directories.
    It works similar to CreateDir() except that it can create
    more subdirs at once. User does not have to care if all
    sub dirs in a specified path already exist or not.

INPUTS
    path - pointer to a path string to create. A path can be
    relative to a current dir or absolute.

RESULT
    suc - TRUE if succeeds (path was created). FALSE if a path
    could not be created.

EXAMPLE

    suc = MakePath("RAM:way/to/many/dirs");

    The above function will try to make all non-existing dirs
    in a path RAM:way/to/many/dirs.

SEE ALSO
    CreateDir()
```

1.8 ObtPens

```
NAME
    ObtPens -- Obtain best pens from a list of colors (V10)
    (gfx V39)

SYNOPSIS
    number = ObtPens(cm, PalTable, PensTable, TagItem)

    ULONG  = ObtPens(struct ColorMap *, ULONG *, ULONG *,
              struct TagItem *);

FUNCTION
    This function calls ObtainBestPen() on a list of color
    entries, and puts results into a new pens list.

    It will attempt to find colors in your viewport closest to
    the provided colors list (PalTable).
    This is usefull when you want to use an image with more
    specific colors on a public screen with a sharable palette.

INPUTS
    cm = colormap
    PalTable - list of RGB entries for each color you want to use.
              The format of this table is the same as for
LoadRGB32():

          1 Word with the number of colors to obtain
          1 Word with the first color to be obtained
          3 longwords representing a left justified 32 bit RGB
triplet
```

```
                  The list is terminated by a count value of 0.

                  examples:
                    ULONG PalTable[]={2l<<16+1,0,0,0, 0xffffffff,0,0, 0};
                        two entries (black, red); obtains only red one

        PensTable - list of pen numbers on your viewport, obtained by
                    this function. First entry in PensTable will
represent
                    the first color in PalTable, and so on.
                    NOTE that entries in PensTable with count number
lower
                    than the first color to be obtained (provided in
                    PalTable) will be unaffected!

        TagItem - this tagitem will be passed to ObtainBestPen()
function,
                    that is called within ObtPens(). Please see
ObtainBestPen()
                    in order to decide what kind of precision for
obtaining
                    colors you will need. If this is NULL, PRECISION_IMAGE
will
                    be used.

   RESULT
        number = number of obtained colours (always the same as the
first
        Word in PalTable), or 0 if failed. If it succeeds you must call
        RelPens() to free obtained colors.

   EXAMPLES

        The following example will obtain red, green and blue colours in
a
        viewport, and will put obtained pens into pens[] table. pens[0]
will
        be untouched (will remain the same colour as viewport's
background).

        ULONG pal[((4<<16)+1, /* 4 entries, starting with the second one
*/
                    0, 0, 0,           /* black - will ignore this one */
                    0xffffffff, 0, 0, /* red */
                    0, 0xffffffff, 0, /* green */
                    0, 0, 0xffffffff, /* blue */
                    0};

        ULONG pens[4];

        ObtPens(cm, pal, pens, NULL);

        SetAPen(rp, pens[1]);   /* Set the primary pen to red */
        Text(rp, "I'm red!", 8);
```

```
    NOTES
        You MUST call RelPens() to free all obtained colors if ObtPens()
        have succeeded, but you must not call it if ObtPens() returns 0.
        You MUST open graphics library (V39 or higher) before calling
this
        function.

    SEE ALSO
        RelPens(), ObtainBestPen(), LoadRGB32()
```

1.9   RecDirFree

```
    NAME
        RecDirFree -- Unlocks all locked paths (V10)
        (dos V36)

    SYNOPSIS
        void RecDirFree(RecDirInfo)

        void RecDirFree(struct RecDirInfo *);

    FUNCTION
        This function is called internally when error occurs in
        RecDirNext(), so you don't have to call it then!
        You can only call it when you no longer want to use
RecDirNext(),
        before it finishes the scanning process.
        You DO NOT have to call RecDirFree() when you get any error,
        even DN_ERR_END (scanning process complete)!

    INPUTS
        RecDirInfo - pointer to struct RecDirInfo which has been
                      called with RecDirInit()

    RESULT
        none

    SEE ALSO
        RecDirInit(), RecDirNext(), RecDirNextTagList()
```

1.10   RecDirInit

```
    NAME
        RecDirInit -- Initializes recursive files scanning process (V10)
        (dos V36)

    SYNOPSIS
        error = RecDirInit(RecDirInfo)

        UBYTE = RecDirInit(struct RecDirInfo *)

    FUNCTION
```

    This function is required to start scanning files through entire
    or partial directory tree. It locks a directory path provided in
    RecDirInfo structure, then files can be examined by calling
    RecDirNext() function. Please see RecDirNext() for more
    explanation on how this is useful.
    You should initialize RecDirInfo by yourself, and you MUST set
    rdi_Path, rdi_Num, and rdi_Pattern.

INPUTS
    RecDirInfo - pointer to RecDirInfo structure, which should be
    allocated and initialized before RecDirInit() is called.
    You must set its rdi_Path field to starting directory path
    you want to scan.

    Set rdi_Num for maximum number of directories you wish to scan
    into. If you set rdi_Num to 1 it will only scan one level (that
    rdi_Path points to). If you set rdi_Num to -1 it will scan
    unlimited number of subdirectories deep.

    If rdi_Pattern field is non-NULL and points to a string then
    calling RecDirNext will only return files that match the
    pattern string. NOTE that rdi_Pattern should point to a string
    which has been parsed with ParsePattern().

RESULT
    error - 0 if no error, otherwise returns one of the following
    errors (also see libraries/supra.h):
        RDI_ERR_FILE - Path provided in rdi_Path points to a file
                        not directory.
        RDI_ERR_NONEXIST - Path provided in rdi_Path does not exist.
        RDI_ERR_MEM - not enough memory to execute RecDirInit().

EXAMPLE
    Please see an example in RecDirNext() function.

NOTES
    IMPORTANT: You MUST open dos.library before calling
RecDirInit()!
    rdi_Path is a path relative to a current path your program uses.
    That means you can set rdi_Path to "" to scan from current
    directory, or "/" to scan parent directory.

BUGS
    None found yet.

SEE ALSO
    RecDirFree(), RecDirNext(), libraries/supra.h

1.11 RecDirNext

NAME
    RecDirNext -- Gets information about the next file (V10)
    (dos V36)

SYNOPSIS

```
        error = RecDirNext(RecDirInfo, RecDirFIB);

        UBYTE = RecDirNext(struct RecDirInfo *, struct RecDirFIB *);
```

FUNCTION
        Retrieves information about the next file in a scanning process.
        Calling this function will not provide a list of sorted files
        niether by ASCII order nor by directory levels. That means
        it will scan files as they have been stored on a disk drive.

        The main advantage of using this function from using ExNext()
        is that you don't have to program a recursive scanning routine
        by yourself. You need only to provide lowest directory path,
        how deep into subdirectories you want to scan, and which
        information about files you need to be provided with.
        RecDirNext() will only return files but no directories.
        You are also able to select a matching pattern so that only
        files which match it will be returned.

        Please see RecDirInit() for more info.

INPUTS
        RecDirInfo – pointer to RecDirInfo structure. You MUST call
        RecDirInit(), providing it with this structure, before calling
        any RecDirNext() function.

        RecDirFIB – pointer to RecDirFIB structure which should be
        previousely allocated. You only set those fields in the
        structure that you want to have information about. Any field
        should point to a variable into which information will be
stored.
        Check "struct RecDirFIB" to see what each field mean.
        All field in RecDirFIB structure that are set to NULL will be
        ignored.

RESULT
        error – zero if no error. Otherwise one of the following:
            DN_ERR_END – scanning is completed. You should not call
                        any RecDirNext() again.
            DN_ERR_EXAMINE – Failure while examining a file.
            DN_ERR_MEM – not enough memory available to complete
                        the operation.
            IF any error will be resulted, RecDirFree will be called
            internally.

EXAMPLE
        This example will scan through the entire HD0: disk device, and
        will print for each file: its dir path, its name, its size.

    #include <stdio.h>
    #include <stdlib.h>
    #include <clib/exec_protos.h>
    #include <clib/dos_protos.h>
    #include <libraries/supra.h>
```

```
    struct RecDirFIB rdf;
    struct RecDirInfo rdi;
    char name[30];
    char path[100];
    LONG size;" link "TEXT_INCLUDE:exec/types.h/Main" 35} size;
    LONG err;" link "TEXT_INCLUDE:exec/types.h/Main" 35} err;

    struct DosBase *DosBase;

    void main()
    {
        if (DosBase = (struct DosBase *)OpenLibrary("dos.library",0)) {

            rdi.rdi_Path = "RAM:";  /* from path "RAM:" */
            rdi.rdi_Num = -1;        /* Unlimited subdirs deep */
            rdi.rdi_Pattern = NULL; /* Don't match files for pattern */

            if (RecDirInit(&rdi) == 0) {
                rdf.Path = path;  /* We want to get files' path, name and
size
 */
                rdf.Name = name;
                rdf.Size = &size;
                while ((err = RecDirNext(&rdi, &rdf)) == 0) {
                    printf("%s (%s) %ld\n", path, name, size);
                }

                /* Now check if DN_ERR_END or some other unexpected error
*/
                switch (err) {
                    case DN_ERR_END:
                        printf("Scanning completed\n");
                        break;
                    case DN_ERR_EXAMINE:
                        printf("Error: trouble examining a file\n");
                        break;
                    case DN_ERR_MEM:
                        printf("Error: not enough memory\n");
                }
            }

            CloseLibrary((struct Library *)DosBase);
        } else printf("Cannot open dos.library\n");
    }

    NOTES
        If you want to end scanning earlier you have to call
RecDirFree()!

    BUGS
        none found

    SEE ALSO
        RecDirInit(), RecDirTags(), RecDirFree(), libraries/supra.h
```

1.12 RecDirTags

NAME
     RecDirNextTagList -- Gets information about next file (V10)
     (dos V36)

SYNOPSIS
     error = RecDirNextTagList(RecDirInfo, RecDirFIB, TagItems)

     UBYTE = RecDirNextTagList(struct RecDirInfo *, struct RecDirFIB
*,
                 struct TagItem *);

     error = RecDirNextTags(RecDirInfo, RecDirFIB, tag1, ...)

     UBYTE = RecDirNextTags(struct RecDirInfo *, struct RecDirFIB *,
                 ULONG tag1, ...);*

FUNCTION
     This function does the same as RecDirNext() but it provides
     a TagList extension. Any additional tags will override initial
     settings in RecDirFIB structure.

INPUTS
     RecDirInfo - pointer to RecDirInfo structure which has been
                  called with RecDirInit()
     RecDirFIB - pointer to initialized and set RecDirFIB structure,
                  or NULL.
                  You can get files' information either by setting
                  variables to this structure before calling
                  RecDirNextTagList(), or by providing TagItems you
                  want.
                  NOTE: If you provide any TagItem then RecDirFIB
will
                  be changed (if it's non-NULL)!

     Tags - The following tags are available:

         RD_NAME - File name will be provided. ti_Data should carry
                   a pointer to a string buffer (char *)
         RD_PATH - Directory path where scanned file is.
         RD_FULL - Full directory path + file name
         RD_SIZE - File lenght in bytes. ti_Data must have a pointer
to
                   a LONG number (LONG *).
         RD_FLAGS - File's protection flags. ti_Data must have a
pointer
                   to LONG.
         RD_COMMENT - File's comment note. ti_Data carries a pointer
to
                   a string buffer.
         RD_DATE - File's DateStamp structure. Function will copy the
                   entire DateStamp structure into struct DateStamp
                   provided in ti_Data field that points to it.

```
            RD_BLOCKS - File size in blocks. ti_Data should have a
pointer
                      to LONG
            RD_UID - Owner's UID (not supported with all file systems).
                     ti_Data should have a pointer to UWORD variable.
            RD_GID - Owner's GID. ti_Data has a pointer to UWORD
variable.
            RD_FIB - FileInfoBlock. Function will copy examined file's
                     FileInfoBlock to a provided struct FileInfoBlock
                     via ti_Data (ti_Data has a pointer to an allocated
                     FileInfoBlock structure).

    RESULT
        Same as for RecDirNext()

    EXAMPLE

        See an example for RecDirNext(). You can replace its line

        RecDirNext(&rdi, &rdf);
            *with*
        RecDirNextTags(&rdi, NULL, RD_PATH, path,
                                   RD_NAME, name,
                                   RD_SIZE, &size,
                                   TAG_DONE);
    NOTES
        If RecDirFIB is not NULL, and you provide some tags as well then
        RecDirFIB will be changed. This may change in the future so
        that provided RecDirFIB will not change.

    BUGS
        none found

1.13 RelPens

```
    NAME
        RelPens -- Release a list of pens obtained by ObtPens (V10)
        (gfx V39)
    SYNOPSIS
        RelPens(cm, PalTable, PensTable)

        void (struct ColorMap *, ULONG *, ULONG *);

    FUNCTION
        This function repeats calls to ReleasePen() in order to
        release all pens obtained by ObtPens().

    INPUTS
        cm = colormap
        PalTable - the same PalTable called with ObtPens()
        PensTable - the same PensTable called with ObtPens()
```

NOTES
    Please DO NOT modify PalTable and PensTable between calling
    ObtPens() and RelPens(). This function uses the first long
    word from PalTable (describing number of entries and starting
    position), and all entries from PensTable (except those entries
    that are lower than a starting position).
    You MUST open graphics library (V39 or higher) before calling
    this function!

REMEMBER:

You have to #include<libraries/supra.h> in your source code when using
any of supra library functions. You have to link your object codes with
lib:supra.lib

FEW HINTS:

You will notice that some functions contain two version numbers by their
names. The one on the right is the actual function version. The one
under a name explains what version and what ROM library you have to open
before calling a function. e.g. (gfx V39) tells you that you have to
open graphics.library version 39 or higher before calling that function.
