catalogList_example

1.1 Introduction to catalogList

The catalogList object is exactly what its name suggests - a list of catalogs. It was developed for internal use of the oomodules hierarchy. Since each object can have it's own catalog and an application can use many objects there has to be a way to deal with any number of catalogs open at any time.

This is where the catalogList object comes in handy. By using the setCurrentCatalog() method one can switch between catalogs. It doesn't matter if this catalog is open or not, if this function returns non-NIL access is granted.

There is an example available

There is an autodoc file available for this object.

Again, this object was developed for internal use. Yes, you can use it in your applications, but normally there should be no need for it for an application has only one catalog.
