XML Processors

An XML Processor is a piece of software, either an application or a library, that can process XML. A good example of an XML processor is XML document validation software. There are a number of such packages available for free and for sale on the Internet. Such applications can be used to validate the contents of an XML document and make sure that it is *well-formed*. A well-formed document is one that adheres to the rules of XML and any associated DTD's.

Other good examples include XML document viewers and XML document code libraries that can be used by software that you create to manipulate XML documents.
