

TCPView for Windows NT

Copyright 1998 Mark Russinovich
<http://www.sysinternals.com>

Introduction

TCPView is a Windows program that will show you detailed listings of all TCP and UDP endpoints on your system, including the remote address and state of TCP connections. *TCPView* provides a conveniently presented subset of the *Netstat* program that ships with Windows NT.

TCPView has been tested on NT 4.0.

Using TCPView

When you start *TCPView* it will enumerate all active TCP and UDP endpoints, resolving all IP addresses to their domain name versions. A toolbar button can be used to toggle the output to not resolving names, which in some cases can speed output since there is no querying of DNS servers for translations. The Ctrl-R hotkey will toggle *TCPView* between resolving names and displaying raw IP addresses, and *TCPView* remembers the mode it was in last when it is run again.

The display can be refreshed with the F5 hot-key or the Refresh toolbar button. Finally, *TCPView*'s output window can be saved to a file using the Save functionality.

Reporting Bugs and Feedback

If you encounter a problem while running *TCPView*, please visit <http://www.sysinternals.com> to obtain the latest version. If you still have problems, please record all the information relevant to the problem. Determine if the problem is reproducible, and if so, how, and send this information to:
