## TS-Lib TS101

IEEE 754 Floating Point Optimised DSP Library  
for the TigerSHARC TS101 DSP

Cycle Performance Manual

Version 2.1.0

# TS-Lib Optimised DSP Library for the TigerSHARC

## Library Cycle Performance Tables

The TS-Lib performance tables in this document lists the cycles for each routine in the library. The given cycles assume optimial data array placement in the internal DSP memory, so that parallel read and writes to the algorithms required data does not create any data bus stalls.

Memory usage can impact upon the cycle performance, the full library documentation includes memory configuration profiles that demonstrate the affect of array placement in memory. The ADSP-TS101S libraries include dm/pm routine entry point versions that uniquely identify the impact using the two data memory blocks. The ADSP-TS20xS processors possess multiple data memory sections therefore only the best-case and worst-case memory configuration cycle counts are documented. The worst-case memory configuration occurs when all arrays are held in the same memory section. The best-case memory configuration occurs when all arrays are held in different memory sections. The majority of the routines are also described with a cycle formula that indicates the cycle performance of the code in more detail. This can be broken into two parts, an initial overhead, which is normally a constant number of cycles, and a value based upon the input dimensions.

The published cycles are based upon the results from latest ADSP TigerSHARC silicon that was available when the library was tested and released. The BTB (and Caching for TS201) is enabled for all cycle performance tests.

## Routine Naming Post-Fix

Each of the library routines is prefixed with the letters ez\_. A postfix denotes the data-type (and hence the library from which the routine originates). They are as follows:

Floating-point library:

- \_f : floating-point (using 128-bit quad-word memory access)
- \_sf : floating-point with vector stride parameter

Fixed-point library:

- \_fr16 : fixed-point 16-bit fractional (using 128-bit quad-word memory access)
- \_fr32 : fixed-point 32-bit fractional (using 128-bit quad-word memory access)

Integer library:

- \_i : integer (using 128-bit quad-word memory access)
- \_si : integer with vector stride parameter

## Memory Striding Routines

To increase functional versatility, the floating-point and 32-bit integer libraries include memory-striding versions of routines. These do not use the full quad-word data bandwidth since a stride greater than one accesses non-consecutive memory locations. The striding routines are fully optimised with this memory access overhead in-mind. The user should be aware that when using these routines, the performance may be reduced by up to four times, compared with a fully optimised routine. (All performance-metrics are documented for assessment).
