## ♦ Traces and Choice ♦

Which traces can be produced by  $P \square Q$  and  $P \square Q$ ? We know that  $P \square Q$  can do the first event of either P or Q, and then behave like the remainder of P or Q. Therefore any trace of either P or Q can be produced by  $P \square Q$ , and we have

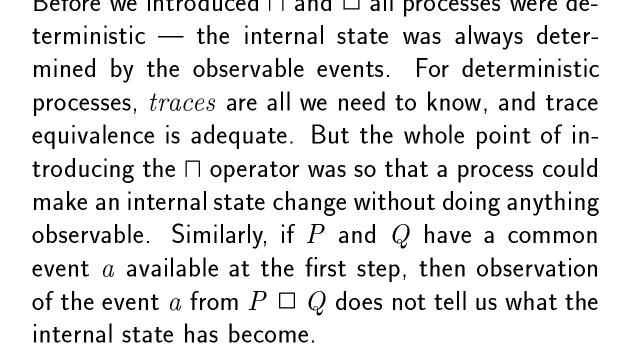

$$traces(P \square Q) = traces(P) \cup traces(Q).$$

 $P \sqcap Q$  always does  $\tau$  first, and then behaves like either P or Q. Because  $\tau$  does not appear in traces, we also have

$$traces(P \sqcap Q) = traces(P) \cup traces(Q).$$

We have previously considered  $trace\ equivalence$ , written  $P=_t Q$ , as a definition of when two processes should be considered equal or interchangeable. However, we can now see that  $P\ \square\ Q=_t P\ \square\ Q$ , even though internal and external choice have been designed to behave in different ways.

In general, trace equivalence is not suitable as a definition of process equivalence.

We will now try to say exactly what the difference between  $P \sqcap Q$  and  $P \sqcap Q$  is, and develop a new notion of process equivalence accordingly.

## $\Diamond$ Refusals $\Diamond$

Suppose we have the following definitions.

$$P = a \to P$$
$$Q = b \to Q$$

What happens if we put each of  $P \square Q$  and  $P \square Q$  in an environment consisting of P? i.e. if we look at  $(P \square Q)_{\{a,b\}}|_{\{a,b\}}P$  and  $(P \square Q)_{\{a,b\}}|_{\{a,b\}}P$ .

First, we have  $P \square Q \stackrel{a}{\longrightarrow} P$  and  $P \stackrel{a}{\longrightarrow} P$  so

$$(P \square Q)_{\{a,b\}} \|_{\{a,b\}} P \xrightarrow{a} P_{\{a,b\}} \|_{\{a,b\}} P.$$

Also,

$$P_{\{a,b\}}||_{\{a,b\}}P \xrightarrow{a} P_{\{a,b\}}||_{\{a,b\}}P$$

SO

$$P_{\{a,b\}}|_{\{a,b\}}P = P$$

(they both satisfy the same recursive definition).

So

$$(P \square Q)_{\{a,b\}} \|_{\{a,b\}} P = a \to P$$

i.e.

$$(P \square Q)_{\{a,b\}} \|_{\{a,b\}} P = P.$$

On the other hand,

$$(P \sqcap Q)_{\{a,b\}} \|_{\{a,b\}} P \xrightarrow{\tau} P_{\{a,b\}} \|_{\{a,b\}} P$$

and

$$(P \sqcap Q)_{\{a,b\}} \|_{\{a,b\}} P \xrightarrow{\tau} Q_{\{a,b\}} \|_{\{a,b\}} P$$

SO

$$(P \sqcap Q)_{\{a,b\}} \|_{\{a,b\}} P =$$

$$(P_{\{a,b\}}||_{\{a,b\}} P) \sqcap (Q_{\{a,b\}}||_{\{a,b\}} P).$$

(This is a loose statement as we haven't decided what "=" means yet.)

We know that P  $_{\{a,b\}}\|_{\{a,b\}}$  P=P and Q  $_{\{a,b\}}\|_{\{a,b\}}$  P=Stop So

$$(P \sqcap Q)_{\{a,b\}} \|_{\{a,b\}} P = P \sqcap Stop.$$

This shows that  $P \square Q$  and  $P \square Q$  behave differently when put in parallel with P. One is just P, the other can internally choose to deadlock (become Stop).

We can use this observation to develop a general approach to distinguishing between nondeterministic processes. We will consider putting a process P in an environment Q, where the alphabets of P and Q are the same, i.e. constructing  $P_{\alpha P}|_{\alpha P}Q$ .

Q. If it is possible for  $P_{\alpha P}\|_{\alpha P}$  Q to deadlock at the first step, then we say that X is a *refusal* of P. The set of all refusals of P is obtained by considering all possible sets X which could be initial event sets of Q.

Examples: 1. The empty set is a refusal of every process, because if Q=Stop then  $P_{\alpha P}\|_{\alpha P}$  Q=Stop.

- 2. Any set of events X is a refusal of Stop.
- 3. If  $a \not\in X$  then X is a refusal of  $a \to P$ . So if  $\alpha P = \{a,b,c\}$  then the refusals of  $a \to P$  are  $\{\}$ ,  $\{b\}$ ,  $\{c\}$  and  $\{b,c\}$ . Processes Q causing

$$(a \to P)_{\{a,b,c\}} \|_{\{a,b,c\}} Q$$

to deadlock include  $Stop,\ b \to Stop,\ c \to a \to Stop,\ (b \to Stop) \ \Box \ (c \to c \to Stop),\ \text{etc.}$ 

- 4. The refusals of  $(a \to c \to Stop) \ \Box \ (b \to Stop)$  are  $\{\}$  and  $\{c\}$ .
- 5. The refusals of  $(a \rightarrow c \rightarrow Stop) \sqcap (b \rightarrow Stop)$  are  $\{\}, \{a\}, \{b\}, \{c\}, \{a,c\} \text{ and } \{b,c\}.$

Week 8 5

vve can define

$$refusals(P) = \{X \mid X \subseteq \alpha P \text{ and } X \text{ is a refusal of } P\}.$$

Note that refusals(P) is a set of sets of events. For example,

$$refusals((a \to Stop) \sqcap (b \to Stop)) = \{\{\}, \{a\}, \{b\}, \{c\}, \{a, c\}, \{b, c\}\}.$$

In the examples we saw that

$$refusals((a \rightarrow Stop) \Box (b \rightarrow Stop)) \neq refusals((a \rightarrow Stop) \Box (b \rightarrow Stop)).$$

In general,  $refusals(P \square Q) \neq refusals(P \square Q)$ , and this will be the basis for a new definition of process equality which allows us to distinguish between internal and external choice.

We can now define refusals for processes defined in terms of the operators we have seen so far.

$$refusals(Stop) = \{X \mid X \subseteq \Sigma\}$$

where  $\Sigma$  is the set of all events being considered — the universal set of events.

$$refusals(a \rightarrow P) = \{X \mid X \subseteq (\alpha P - \{a\})\}$$

Both of these definitions are subsumed by the definition for menu choice: if  $P = x : A \rightarrow P(x)$  then

$$refusals(P) = \{X \mid X \subseteq (\alpha P - A)\}$$

Week 8 6

Similarly every refusal of Q is a possible refusal of  $P \sqcap Q$ .

$$refusals(P \sqcap Q) = refusals(P) \cup refusals(Q)$$

 $P \square Q$  can only refuse X if both P and Q can refuse X .

$$refusals(P \square Q) = refusals(P) \cap refusals(Q)$$

 $P_A|_A Q$  can refuse all events refused by P and all events refused by Q.

$$refusals(P_A||_A Q) = \{X \cup Y \mid X \in refusals(P) \text{ and } Y \in refusals(Q)\}$$

Refusals allow us to distinguish formally between deterministic and nondeterministic processes. If a process is deterministic then it can never refuse any event which it could possibly do. In other words, if P is deterministic and a is a possible initial event for P, then a does not appear in any refusal set of P.

Writing initials(P) for the set of possible initial events of P (so  $initials(P) = \{x \mid \langle x \rangle \in traces(P)\}$ ), we can say that if P is deterministic then

$$refusals(P) = \{X \mid X \subseteq \alpha P \text{ and } X \cap initials(P) = \{\}\}.$$

Determinism means that any event which is possible cannot be taken away by an internal state transition.

Week 8 7

Examples: IT

$$P = a \rightarrow c \rightarrow Stop \mid b \rightarrow Stop$$

then  $initials(P) = \{a,b\}$  and  $refusals(P) = \{\{\},\{c\}\}\}.$  If

$$P = (a \rightarrow c \rightarrow Stop) \sqcap (b \rightarrow Stop)$$

then  $initials(P) = \{a, b\}$  and (as before)

$$refusals(P) = \{\{\}, \{a\}, \{b\}, \{c\}, \{a, c\}, \{b, c\}\}.$$

Although a is a possible initial event for P, P could also internally choose to be  $b \to Stop$  which refuses a.

To define nondeterminism properly, we need to consider events refused not just at the first step, but after any sequence of events. For example,

$$(a \rightarrow b \rightarrow Stop) \square (a \rightarrow c \rightarrow Stop)$$

is nondeterministic, but this does not become apparent until after the first event.

So: P is deterministic if and only if  $\forall s \in traces(P)$ .  $(refusals(P / s) = \{X \subseteq \alpha P \mid X \cap initials(P / s) = \{\}\}).$ 

 $P \ / \ s$  is the process whose behaviour is whatever P could do after the trace s.
