@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@   Disclaimer (I know...):
This file is for informational purposes only.   No use of this technique   is recommended for one of many reasons: 1) It makes other Phreaks & hacks   very upset, 2) It makes the Telco VERY upset, and you could be put away for   a LONG time if you dont know what youre doing.   Telco employees could learn   something from the Copper Box. Well, anyway, off we go....   Purpose: This box can destroy a phone company, no matter how big.   You could bring   AT&T down to their knees!   Only to be used by the most irate of Phracks,   it is intended for informational purposes only.   History: This is really not a Box, but if you consider a Cheese Box a Box, then it   is.   It was first concieved back in 1986 when a Phriend and I came up with   the idea while using a Copper-coloured fone, hence, a Copper Box.   Instructions: You must obtain [1] extender, or phone company port, like an MCI or SPRINT   access number.   [2] A hell of a lot of nerve, and vendetta towards the phone   company (phriend gets busted, rates increase, etc.) [3] a computer & modem   capable of autodialing [tone.]   Dial the number of the L/D service, then enter the code.   Dial the number of   the service again, through the outdial number you are still on, enter code,   then dial again and again.   You should hear, after a while (it will take a   long time for BIG companies) a slight high-pitched, unstable tone, that grows   louder and louder w/every dial.   Once it gets so loud that it refuses to let   in any more sounds, you have just completed the first cycle of the Copper Box.   Leave line off-hook for about 10 minutes or until the tone seems to calm   down, or stop completely.   Then, dial again and repeat over and over again   until when you dial a last time, it [the port] doesnt answer.   You have just   killed a telephone company, extender, etc.   Theory of Operation: What happens is that when the tone begins to rise, it is a result of cross-   talk feedback.   The more you dial,   the more it grows.   In systems like these,   the small, sensitive equipment such as amplifiers, etc. begin to burn out as a result of the feedback, damaging the equipment, and possibly starting a fire   at the location of the equipment.
