For People New to Both FreeBSD and Unix

Annelise Anderson

andrsn@andrsn.stanford.edu

August 15, 1997

Congratulations on installing FreeBSD! This introduction is for people new to both FreeBSD *and* Un*x—so it starts with basics. It assumes you are using version 2.0.5 or later of FreeBSD as distributed by BSDi or FreeBSD.org, your system (for now) has a single user (you)—and you are probably pretty good with DOS/Windows or OS/2.

1 Logging in and Getting Out

Log in (when you see `login:`) as a user you created during installation or as *root*. (Your FreeBSD installation will already have an account for root; root can go anywhere and do anything, including deleting essential files, so be careful!) The symbols `%` and `#` in the following stand for the prompt (yours may be different), with `%` indicating an ordinary user and `#` indicating root.

To log out (and get a new `login:` prompt) type

```
# exit
```

as often as necessary. Yes, press enter after commands, and remember that Unix is case-sensitive—`exit`, not `EXIT`.

To shut down the machine type

```
# /sbin/shutdown -h now
```

Or to reboot type

```
# /sbin/shutdown -r now
```

or

```
# /sbin/reboot
```

You can also reboot with **Ctrl**-**Alt**-**Delete**. Give it a little time to do its work. This is equivalent to `/sbin/reboot` in recent releases of FreeBSD and is much, much better than hitting the reset button. You do not want to have to reinstall this thing, do you?

2 Adding A User with Root Privileges

If you did not create any users when you installed the system and are thus logged in as root, you should probably create a user now with

```
# adduser
```

The first time you use adduser, it might ask for some defaults to save. You might want to make the default shell csh(1) instead of sh(1), if it suggests sh as the default. Otherwise just press enter to accept each default. These defaults are saved in /etc/adduser.conf, an editable file.

Suppose you create a user jack with full name *Jack Benimble*. Give jack a password if security (even kids around who might pound on the keyboard) is an issue. When it asks you if you want to invite jack into other groups, type wheel

```
Login group is "jack". Invite jack into other groups: wheel
```

This will make it possible to log in as jack and use the su(1) command to become root. Then you will not get scolded any more for logging in as root.

You can quit adduser any time by typing **Ctrl-C**, and at the end you will have a chance to approve your new user or simply type **n** for no. You might want to create a second new user (jill?) so that when you edit jack's login files, you will have a hot spare in case something goes wrong.

Once you have done this, use exit to get back to a login prompt and log in as jack. In general, it is a good idea to do as much work as possible as an ordinary user who does not have the power—and risk—of root.

If you already created a user and you want the user to be able to su to root, you can log in as root and edit the file /etc/group, adding jack to the first line (the group wheel). But first you need to practice vi(1), the text editor—or use the simpler text editor, ee(1), installed on recent version of FreeBSD.

To delete a user, use the rmuser command.

3 Looking Around

Logged in as an ordinary user, look around and try out some commands that will access the sources of help and information within FreeBSD.

Here are some commands and what they do:

id

    Tells you who you are!

pwd

    Shows you where you are—the current working directory.

ls

    Lists the files in the current directory.

`ls -F`

> Lists the files in the current directory with a `*` after executables, a `/` after directories, and an `@` after symbolic links.

`ls -l`

> Lists the files in long format—size, date, permissions.

`ls -a`

> Lists hidden "dot" files with the others. If you are root, the "dot" files show up without the `-a` switch.

`cd`

> Changes directories. `cd ..` backs up one level; note the space after `cd`. `cd /usr/local` goes there. `cd ~` goes to the home directory of the person logged in—e.g., /usr/home/jack. Try `cd /cdrom`, and then `ls`, to find out if your CDROM is mounted and working.

`view filename`

> Lets you look at a file (named `filename`) without changing it. Try `view /etc/fstab`. `:q` to quit.

`cat filename`

> Displays `filename` on screen. If it is too long and you can see only the end of it, press **ScrollLock** and use the **up-arrow** to move backward; you can use **ScrollLock** with man pages too. Press **ScrollLock** again to quit scrolling. You might want to try `cat` on some of the dot files in your home directory—`cat .cshrc`, `cat .login`, `cat .profile`.

You will notice aliases in `.cshrc` for some of the `ls` commands (they are very convenient). You can create other aliases by editing `.cshrc`. You can make these aliases available to all users on the system by putting them in the system-wide `csh` configuration file, `/etc/csh.cshrc`.

4 Getting Help and Information

Here are some useful sources of help. `Text` stands for something of your choice that you type in—usually a command or filename.

`apropos text`

> Everything containing string `text` in the whatis database.

`man text`

> The man page for `text`. The major source of documentation for Un*x systems. `man ls` will tell you all the ways to use the `ls` command. Press **Enter** to move through text, **Ctrl-B** to go back a page, **Ctrl-F** to go forward, **q** or **Ctrl-C** to quit.

`which text`

> Tells you where in the user's path the command `text` is found.

```
locate text
```

    All the paths where the string `text` is found.

```
whatis text
```

    Tells you what the command `text` does and its man page. Typing `whatis *` will tell you about all the binaries in the current directory.

```
whereis text
```

    Finds the file `text`, giving its full path.

You might want to try using `whatis` on some common useful commands like `cat`, `more`, `grep`, `mv`, `find`, `tar`, `chmod`, `chown`, `date`, and `script`. `more` lets you read a page at a time as it does in DOS, e.g., `ls -l | more` or `more filename`. The * works as a wildcard—e.g., `ls w*` will show you files beginning with `w`.

Are some of these not working very well? Both locate(1) and whatis(1) depend on a database that is rebuilt weekly. If your machine is not going to be left on over the weekend (and running FreeBSD), you might want to run the commands for daily, weekly, and monthly maintenance now and then. Run them as root and give each one time to finish before you start the next one, for now.

    `# `**`periodic daily`**
    output omitted
    `# `**`periodic weekly`**
    output omitted
    `# `**`periodic monthly`**
    output omitted

If you get tired of waiting, press **Alt-F2** to get another *virtual console*, and log in again. After all, it is a multi-user, multi-tasking system. Nevertheless these commands will probably flash messages on your screen while they are running; you can type `clear` at the prompt to clear the screen. Once they have run, you might want to look at `/var/mail/root` and `/var/log/messages`.

Running such commands is part of system administration—and as a single user of a Unix system, you are your own system administrator. Virtually everything you need to be root to do is system administration. Such responsibilities are not covered very well even in those big fat books on Unix, which seem to devote a lot of space to pulling down menus in windows managers. You might want to get one of the two leading books on systems administration, either Evi Nemeth et.al.'s *UNIX System Administration Handbook* (Prentice-Hall, 1995, ISBN 0-13-15051-7)—the second edition with the red cover; or Æleen Frisch's *Essential System Administration* (O'Reilly & Associates, 1993, ISBN 0-937175-80-3). I used Nemeth.

5 Editing Text

To configure your system, you need to edit text files. Most of them will be in the `/etc` directory; and you will need to `su` to root to be able to change them. You can use the easy `ee`, but in the long run the text editor `vi` is worth learning. There is an excellent tutorial on vi in `/usr/src/contrib/nvi/docs/tutorial` if you have that installed; otherwise you can get it by FTP to `ftp.cdrom.com` in the directory FreeBSD/FreeBSD-current/src/contrib/nvi/docs/tutorial.

Before you edit a file, you should probably back it up. Suppose you want to edit `/etc/rc.conf`. You could just use `cd /etc` to get to the `/etc` directory and do:

```
# cp rc.conf rc.conf.orig
```

This would copy rc.conf to rc.conf.orig, and you could later copy rc.conf.orig to rc.conf to recover the original. But even better would be moving (renaming) and then copying back:

```
# mv rc.conf rc.conf.orig
# cp rc.conf.orig rc.conf
```

because the mv command preserves the original date and owner of the file. You can now edit rc.conf. If you want the original back, you would then **mv rc.conf rc.conf.myedit** (assuming you want to preserve your edited version) and then

```
# mv rc.conf.orig rc.conf
```

to put things back the way they were.

To edit a file, type

```
# vi filename
```

Move through the text with the arrow keys. **Esc** (the escape key) puts vi in command mode. Here are some commands:

x

    delete letter the cursor is on

dd

    delete the entire line (even if it wraps on the screen)

i

    insert text at the cursor

a

    insert text after the cursor

Once you type i or a, you can enter text. Esc puts you back in command mode where you can type

:w

    to write your changes to disk and continue editing

:wq

    to write and quit

:q!

    to quit without saving changes

/text

    to move the cursor to *text*; /**Enter** (the enter key) to find the next instance of *text*.

G

> to go to the end of the file

*n*G

> to go to line *n* in the file, where *n* is a number

Ctrl-L

> to redraw the screen

Ctrl-b and **Ctrl-f**

> go back and forward a screen, as they do with more and view.

Practice with vi in your home directory by creating a new file with vi *filename* and adding and deleting text, saving the file, and calling it up again. vi delivers some surprises because it is really quite complex, and sometimes you will inadvertently issue a command that will do something you do not expect. (Some people actually like vi—it is more powerful than DOS EDIT—find out about the :r command.) Use **Esc** one or more times to be sure you are in command mode and proceed from there when it gives you trouble, save often with :w, and use :q! to get out and start over (from your last :w) when you need to.

Now you can cd to /etc, su to root, use vi to edit the file /etc/group, and add a user to wheel so the user has root privileges. Just add a comma and the user's login name to the end of the first line in the file, press **Esc**, and use :wq to write the file to disk and quit. Instantly effective. (You did not put a space after the comma, did you?)

6 Printing Files from DOS

At this point you probably do not have the printer working, so here is a way to create a file from a man page, move it to a floppy, and then print it from DOS. Suppose you want to read carefully about changing permissions on files (pretty important). You can use man chmod to read about it. The command

```
% man chmod | col -b > chmod.txt
```

will remove formatting codes and send the man page to the chmod.txt file instead of showing it on your screen. Now put a dos-formatted diskette in your floppy drive a, su to root, and type

```
# /sbin/mount -t msdos /dev/fd0 /mnt
```

to mount the floppy drive on /mnt.

Now (you no longer need to be root, and you can type exit to get back to being user jack) you can go to the directory where you created chmod.txt and copy the file to the floppy with:

```
% cp chmod.txt /mnt
```

and use ls /mnt to get a directory listing of /mnt, which should show the file chmod.txt.

You might especially want to make a file from /sbin/dmesg by typing

```
% /sbin/dmesg > dmesg.txt
```

and copying `dmesg.txt` to the floppy. `/sbin/dmesg` is the boot log record, and it is useful to understand it because it shows what FreeBSD found when it booted up. If you ask questions on <freebsd-questions@FreeBSD.org> or on a USENET group—like "FreeBSD is not finding my tape drive, what do I do?"—people will want to know what `dmesg` has to say.

You can now dismount the floppy drive (as root) to get the disk out with

    # **/sbin/umount /mnt**

and reboot to go to DOS. Copy these files to a DOS directory, call them up with DOS EDIT, Windows Notepad or Wordpad, or a word processor, make a minor change so the file has to be saved, and print as you normally would from DOS or Windows. Hope it works! man pages come out best if printed with the DOS `print` command. (Copying files from FreeBSD to a mounted DOS partition is in some cases still a little risky.)

Getting the printer printing from FreeBSD involves creating an appropriate entry in `/etc/printcap` and creating a matching spool directory in `/var/spool/output`. If your printer is on lpt0 (what DOS calls LPT1), you may only need to go to `/var/spool/output` and (as root) create the directory `lpd` by typing: `mkdir lpd`, if it does not already exist. Then the printer should respond if it is turned on when the system is booted, and `lp` or `lpr` should send a file to the printer. Whether or not the file actually prints depends on configuring it, which is covered in the FreeBSD handbook. (../../books/handbook/index.html)

7 Other Useful Commands

df

    shows file space and mounted systems.

ps aux

    shows processes running. `ps ax` is a narrower form.

rm *filename*

    remove *filename*.

rm -R *dir*

    removes a directory *dir* and all subdirectories—careful!

ls -R

    lists files in the current directory and all subdirectories; I used a variant, `ls -AFR > where.txt`, to get a list of all the files in `/` and (separately) `/usr` before I found better ways to find files.

passwd

    to change user's password (or root's password)

man hier

    man page on the Unix file system

Use `find` to locate `filename` in `/usr` or any of its subdirectories with

```
% find /usr -name "filename"
```

You can use * as a wildcard in `"filename"` (which should be in quotes). If you tell find to search in / instead of /usr it will look for the file(s) on all mounted file systems, including the CDROM and the DOS partition.

An excellent book that explains Unix commands and utilities is Abrahams & Larson, *Unix for the Impatient* (2nd ed., Addison-Wesley, 1996). There is also a lot of Unix information on the Internet. Try the Unix Reference Desk (http://www.geek-girl.com/unix.html).

8 Next Steps

You should now have the tools you need to get around and edit files, so you can get everything up and running. There is a great deal of information in the FreeBSD handbook (which is probably on your hard drive) and FreeBSD's web site (../../../../index.html). A wide variety of packages and ports are on the CDROM as well as the web site. The handbook tells you more about how to use them (get the package if it exists, with pkg_add /cdrom/packages/All/*packagename*, where *packagename* is the filename of the package). The CDROM has lists of the packages and ports with brief descriptions in cdrom/packages/index, cdrom/packages/index.txt, and cdrom/ports/index, with fuller descriptions in /cdrom/ports/*/*/pkg/DESCR, where the *s represent subdirectories of kinds of programs and program names respectively.

If you find the handbook too sophisticated (what with lndir and all) on installing ports from the CDROM, here is what usually works:

Find the port you want, say kermit. There will be a directory for it on the CDROM. Copy the subdirectory to /usr/local (a good place for software you add that should be available to all users) with:

```
# cp -R /cdrom/ports/comm/kermit /usr/local
```

This should result in a /usr/local/kermit subdirectory that has all the files that the kermit subdirectory on the CDROM has.

Next, create the directory /usr/ports/distfiles if it does not already exist using mkdir. Now check check /cdrom/ports/distfiles for a file with a name that indicates it is the port you want. Copy that file to /usr/ports/distfiles; in recent versions you can skip this step, as FreeBSD will do it for you. In the case of kermit, there is no distfile.

Then cd to the subdirectory of /usr/local/kermit that has the file Makefile. Type

```
# make all install
```

During this process the port will FTP to get any compressed files it needs that it did not find on the CDROM or in /usr/ports/distfiles. If you do not have your network running yet and there was no file for the port in /cdrom/ports/distfiles, you will have to get the distfile using another machine and copy it to /usr/ports/distfiles from a floppy or your DOS partition. Read Makefile (with cat or more or view) to find out where to go (the master distribution site) to get the file and what its name is. Its name will be truncated when downloaded to DOS, and after you get it into /usr/ports/distfiles you will have to rename it (with the mv command) to its original name so it can be found. (Use binary file transfers!) Then go back to /usr/local/kermit, find the directory with Makefile, and type make all install.

The other thing that happens when installing ports or packages is that some other program is needed. If the installation stops with a message `can't find unzip` or whatever, you might need to install the package or port for unzip before you continue.

Once it is installed type `rehash` to make FreeBSD reread the files in the path so it knows what is there. (If you get a lot of `path not found` messages when you use `whereis` or `which`, you might want to make additions to the list of directories in the path statement in `.cshrc` in your home directory. The path statement in Unix does the same kind of work it does in DOS, except the current directory is not (by default) in the path for security reasons; if the command you want is in the directory you are in, you need to type `./` before the command to make it work; no space after the slash.)

You might want to get the most recent version of Netscape from their FTP site (ftp://ftp.netscape.com/). (Netscape requires the X Window System.) There is now a FreeBSD version, so look around carefully. Just use `gunzip` *filename* and `tar xvf` *filename* on it, move the binary to `/usr/local/bin` or some other place binaries are kept, `rehash`, and then put the following lines in `.cshrc` in each user's home directory or (easier) in `/etc/csh.cshrc`, the system-wide `csh` start-up file:

```
setenv XKEYSYMDB /usr/X11R6/lib/X11/XKeysymDB
setenv XNLSPATH /usr/X11R6/lib/X11/nls
```

This assumes that the file `XKeysymDB` and the directory `nls` are in `/usr/X11R6/lib/X11`; if they are not, find them and put them there.

If you originally got Netscape as a port using the CDROM (or FTP), do not replace `/usr/local/bin/netscape` with the new netscape binary; this is just a shell script that sets up the environment variables for you. Instead rename the new binary to `netscape.bin` and replace the old binary, which is `/usr/local/netscape/netscape`.

9 Your Working Environment

Your shell is the most important part of your working environment. In DOS, the usual shell is command.com. The shell is what interprets the commands you type on the command line, and thus communicates with the rest of the operating system. You can also write shell scripts, which are like DOS batch files: a series of commands to be run without your intervention.

Two shells come installed with FreeBSD: `csh` and `sh`. `csh` is good for command-line work, but scripts should be written with `sh` (or `bash`). You can find out what shell you have by typing `echo $SHELL`.

The `csh` shell is okay, but `tcsh` does everything `csh` does and more. It allows you to recall commands with the arrow keys and edit them. It has tab-key completion of filenames (`csh` uses the **Esc** key), and it lets you switch to the directory you were last in with `cd -`. It is also much easier to alter your prompt with `tcsh`. It makes life a lot easier.

Here are the three steps for installing a new shell:

1. Install the shell as a port or a package, just as you would any other port or package. Use `rehash` and `which tcsh` (assuming you are installing `tcsh`) to make sure it got installed.

2. As root, edit `/etc/shells`, adding a line in the file for the new shell, in this case `/usr/local/bin/tcsh`, and save the file. (Some ports may do this for you.)

3. Use the `chsh` command to change your shell to `tcsh` permanently, or type `tcsh` at the prompt to change your shell without logging in again.

> **Note:** It can be dangerous to change root's shell to something other than `sh` or `csh` on early versions of FreeBSD and many other versions of Unix; you may not have a working shell when the system puts you into single user mode. The solution is to use `su -m` to become root, which will give you the `tcsh` as root, because the shell is part of the environment. You can make this permanent by adding it to your `.tcshrc` file as an alias with
>
> ```
> alias su su -m.
> ```

When `tcsh` starts up, it will read the `/etc/csh.cshrc` and `/etc/csh.login` files, as does `csh`. It will also read the `.login` file in your home directory and the `.cshrc` file as well, unless you provide a `.tcshrc` file. This you can do by simply copying `.cshrc` to `.tcshrc`.

Now that you have installed `tcsh`, you can adjust your prompt. You can find the details in the manual page for `tcsh`, but here is a line to put in your `.tcshrc` that will tell you how many commands you have typed, what time it is, and what directory you are in. It also produces a > if you are an ordinary user and a # if you are root, but tsch will do that in any case:

set prompt = "%h %t %~ %# "

This should go in the same place as the existing set prompt line if there is one, or under "if($?prompt) then" if not. Comment out the old line; you can always switch back to it if you prefer it. Do not forget the spaces and quotes. You can get the `.tcshrc` reread by typing `source .tcshrc`.

You can get a listing of other environmental variables that have been set by typing `env` at the prompt. The result will show you your default editor, pager, and terminal type, among possibly many others. A useful command if you log in from a remote location and can not run a program because the terminal is not capable is `setenv TERM vt100`.

10 Other

As root, you can dismount the CDROM with `/sbin/umount /cdrom`, take it out of the drive, insert another one, and mount it with `/sbin/mount_cd9660 /dev/cd0a /cdrom` assuming cd0a is the device name for your CDROM drive. The most recent versions of FreeBSD let you mount the CDROM with just `/sbin/mount /cdrom`.

Using the live file system—the second of FreeBSD's CDROM disks—is useful if you have got limited space. What is on the live file system varies from release to release. You might try playing games from the CDROM. This involves using `lndir`, which gets installed with the X Window System, to tell the program(s) where to find the necessary files, because they are in the `/cdrom` file system instead of in `/usr` and its subdirectories, which is where they are expected to be. Read `man lndir`.

11 Comments Welcome

If you use this guide I would be interested in knowing where it was unclear and what was left out that you think should be included, and if it was helpful. My thanks to Eugene W. Stark, professor of computer science at SUNY-Stony Brook, and John Fieber for helpful comments.

Annelise Anderson, <andrsn@andrsn.stanford.edu>
