Introduction

The Application Kit is a framework containing all the objects you need to implement your graphical, event-driven user interface: windows, panels, buttons, menus, scrollers, and text fields. The Application Kit handles all the details for you as it efficiently draws on the screen, communicates with hardware devices and screen buffers, clears areas of the screen before drawing, and clips views. The number of classes in the Application Kit may seem daunting at first. However, most Application Kit classes are support classes that you use indirectly. You also have the choice at which level you use the Application Kit:

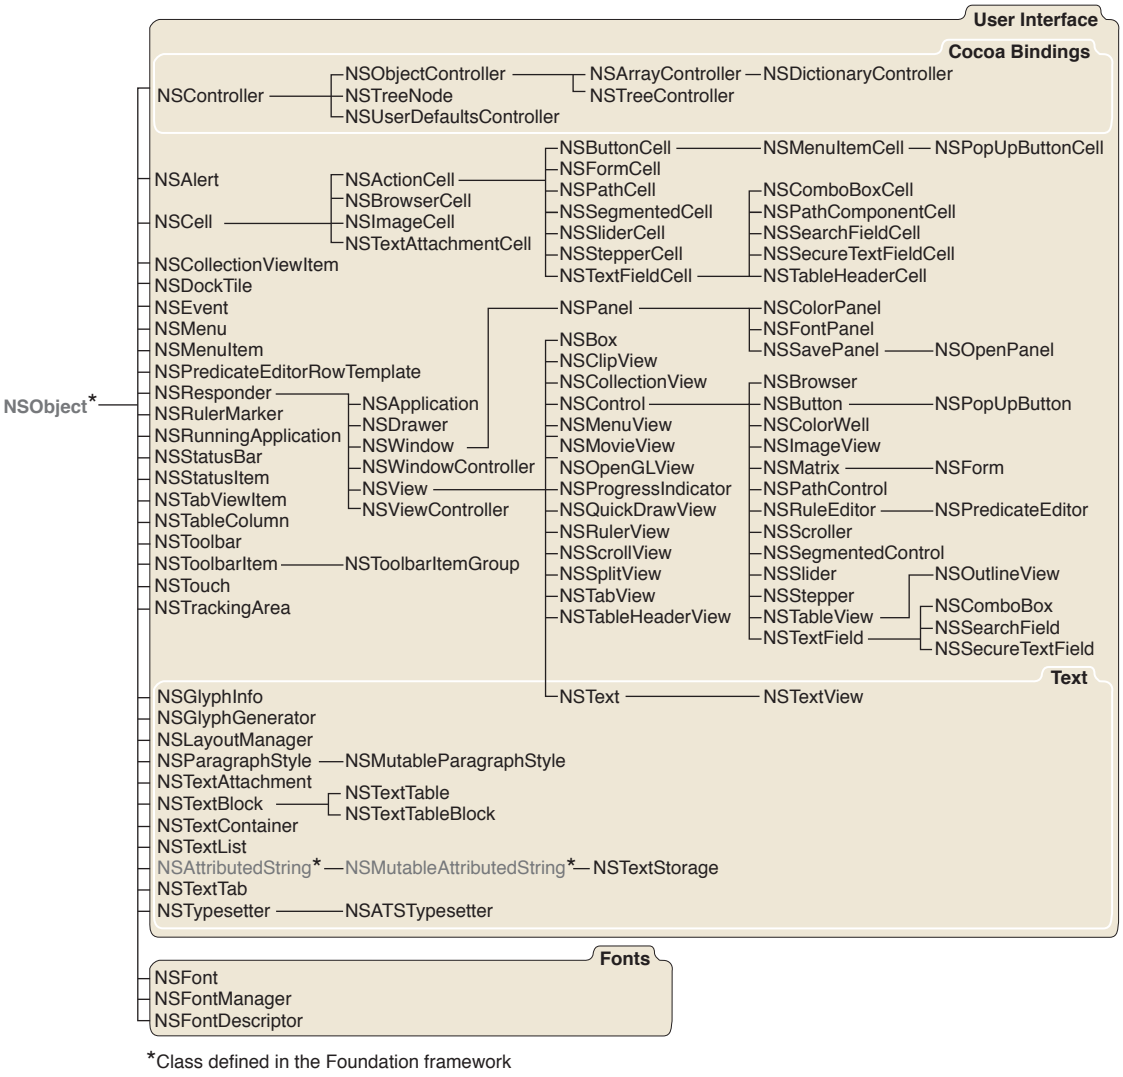
- Use Interface Builder to create connections from user interface objects to your application objects. In this case, all you need to do is implement your application classes—implement those action and delegate methods. For example, implement the method that is invoked when the user selects a menu item.
- Control the user interface programmatically, which requires more familiarity with Application Kit classes and protocols. For example, allowing the user to drag an icon from one window to another requires some programming and familiarity with the `NSDragging...` protocols.
- Implement your own objects by subclassing NSView or other classes. When subclassing NSView you write your own drawing methods using graphics functions. Subclassing requires a deeper understanding of how the Application Kit works.

To learn more about the Application Kit, review the `NSApplication`, `NSWindow`, and `NSView` class specifications, paying close attention to delegate methods. For a deeper understanding of how the Application Kit works, see the specifications for `NSResponder` and `NSRunLoop` (`NSRunLoop` is in the Foundation framework).

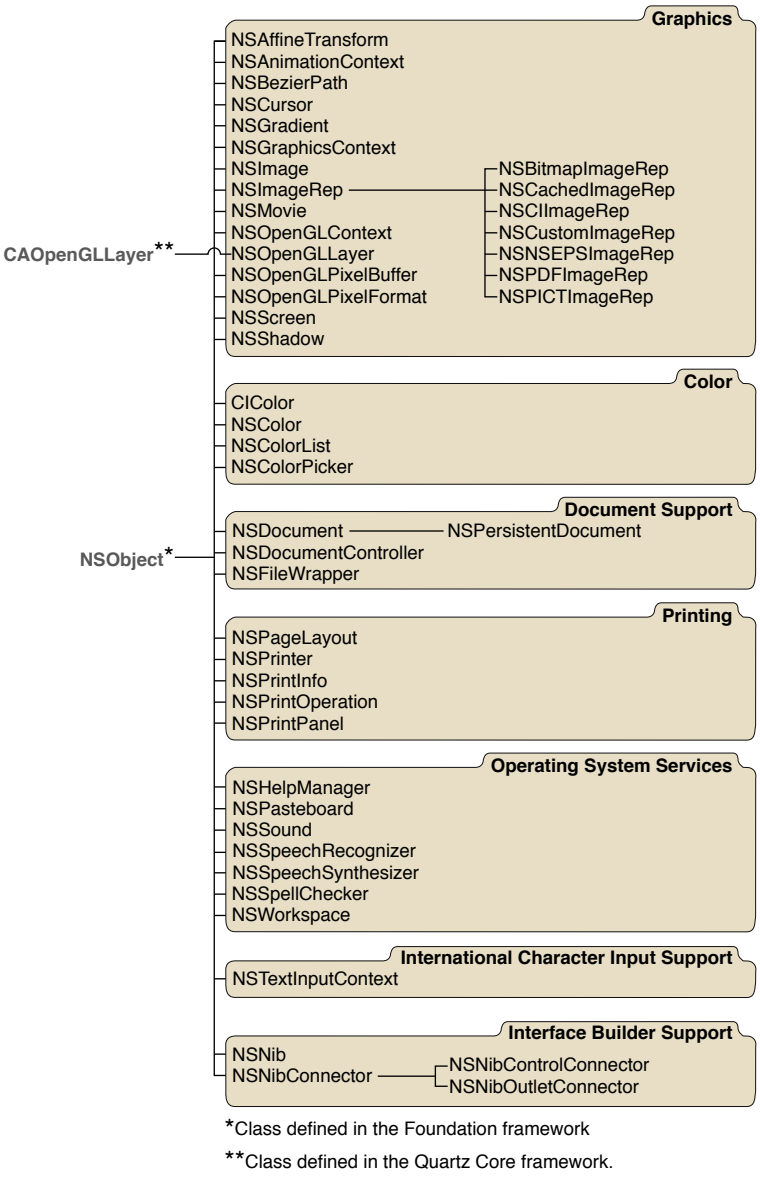
Application Kit Classes and Protocols

The Application Kit is large; it comprises more than 125 classes and protocols. The classes all descend from the Foundation framework's NSObject class (see Figure I-1 (page 47)). The following sections briefly describe some of the topics that the Application Kit addresses through its classes and protocols.

Figure I-1 Cocoa Objective-C Class Hierarchy for Application Kit



Objective-C Application Kit Continued



*Class defined in the Foundation framework

**Class defined in the Quartz Core framework.

Encapsulating an Application

Every application uses a single instance of `NSApplication` to control the main event loop, keep track of the application's windows and menus, distribute events to the appropriate objects (that is, itself or one of its windows), set up autorelease pools, and receive notification of application-level events. An `NSApplication` object has a delegate (an object that you assign) that is notified when the application starts or terminates, is hidden or activated, should open a file selected by the user, and so forth. By setting the `NSApplication` object's delegate and implementing the delegate methods, you customize the behavior of your application without having to subclass `NSApplication`.

General Event Handling and Drawing

The `NSResponder` class defines the responder chain, an ordered list of objects that respond to user events. When the user clicks the mouse button or presses a key, an event is generated and passed up the responder chain in search of an object that can "respond" to it. Any object that handles events must inherit from the `NSResponder` class. The core Application Kit classes, `NSApplication`, `NSWindow`, and NSView, inherit from `NSResponder`.

An `NSApplication` object maintains a list of `NSWindow` objects—one for each window belonging to the application—and each `NSWindow` object maintains a hierarchy of NSView objects. The view hierarchy is used for drawing and handling events within a window. An `NSWindow` object handles window-level events, distributes other events to its views, and provides a drawing area for its views. An `NSWindow` object also has a delegate allowing you to customize its behavior.

NSView is an abstract class for all objects displayed in a window. All subclasses implement a drawing method using graphics functions; `drawRect:` (page 3170) is the primary method you override when creating a new `NSView` subclass.

Panels

The `NSPanel` class is a subclass of `NSWindow` that you use to display transient, global, or pressing information. For example, you would use an instance of `NSPanel`, rather than an instance of `NSWindow`, to display error messages or to query the user for a response to remarkable or unusual circumstances. The Application Kit implements some common panels for you such as the Save, Open and Print panels, used to save, open, and print documents. Using these panels gives the user a consistent "look and feel" across applications for common operations.

Menus and Cursors

The `NSMenu`, `NSMenuItem`, and `NSCursor` classes define the look and behavior of the menus and cursors that your application displays to the user.

Grouping and Scrolling Views

The NSBox, NSScrollView, and NSSplitView classes provide graphic "accessories" to other view objects or collections of views in windows. With the NSBox class, you can group elements in windows and draw a border around the entire group. The NSSplitView class lets you "stack" views vertically or horizontally, apportioning to each view some amount of a common territory; a sliding control bar lets the user redistribute the territory among views. The NSScrollView class and its helper class, NSClipView, provide a scrolling mechanism as well as the graphic objects that let the user initiate and control a scroll. The NSRulerView class allows you to add a ruler and markers to a scroll view.

Controlling an Application

The NSControl and NSCell classes, and their subclasses, define a common set of user interface objects such as buttons, sliders, and browsers that the user can manipulate graphically to control some aspect of your application. Just what a particular control affects is up to you: When a control is "touched," it sends an action message to a target object. You typically use Interface Builder to set these targets and actions by Control-dragging from the control object to your application or other object. You can also set targets and actions programmatically.

An NSControl object is associated with one or more NSCell objects that implement the details of drawing and handling events. For example, a button comprises both an NSButton object and an NSButtonCell object. The reason for this separation of functionality is primarily to allow NSCell classes to be reused by NSControl classes. For example, NSMatrix and NSTableView can contain multiple NSCell objects of different types.

Tables

The NSTableView class displays data in row and column form. NSTableView is ideal for, but not limited to, displaying database records, where rows correspond to each record and columns contain record attributes. The user can edit individual cells and rearrange the columns. You control the behavior and content of an NSTableView object by setting its delegate and data source objects.

Text and Fonts

The NSTextField class implements a simple editable text field, and the NSTextView class provides more comprehensive editing features for larger text bodies.

NSTextView, a subclass of the abstract NSText class, defines the interface to Cocoa's extended text system. NSTextView supports rich text, attachments (graphics, file, and other), input management and key binding, and marked text attributes. NSTextView works with the font panel and menu, rulers and paragraph styles, the Services facility (for example, the spell-checking service), and the pasteboard. NSTextView also allows customizing through delegation and notifications—you rarely need to subclass NSTextView. You rarely create instances of NSTextView programmatically either, since objects on Interface Builder's palettes, such as NSTextField, NSForm, and NSScrollView, already contain NSTextView objects.

It is also possible to do more powerful and more creative text manipulation (such as displaying text in a circle) using NSTextStorage, NSLayoutManager, NSTextContainer, and related classes.

The NSFont and NSFontManager classes encapsulate and manage font families, sizes, and variations. The NSFont class defines a single object for each distinct font; for efficiency, these objects, which can be rather large, are shared by all the objects in your application. The NSFontPanel class defines the font specification panel that's presented to the user.

Graphics and Color

The classes NSImage and NSImageRep encapsulate graphics data, allowing you to easily and efficiently access images stored in files on the disk and displayed on the screen. NSImageRep subclasses each know how to draw an image from a particular kind of source data. The presentation of an image is greatly influenced by the hardware that it's displayed on. For example, a particular image may look good on a color monitor, but may be too "rich" for monochrome. Through the image classes, you can group representations of the same image, where each representation fits a specific type of display device—the decision of which representation to use can be left to the NSImage class itself.

Color is supported by the classes NSColor, NSColorPanel, NSColorList, NSColorPicker, and NSColorWell. NSColor supports a rich set of color formats and representations, including custom ones. The other classes are mostly interface classes: They define and present panels and views that allow the user to select and apply colors. For example, the user can drag colors from the color panel to any color well. The NSColorPicking protocol lets you extend the standard color panel.

Dragging

With very little programming on your part, custom view objects can be dragged and dropped anywhere. Objects become part of this dragging mechanism by conforming to NSDragging... protocols: draggable objects conform to the NSDraggingSource protocol, and destination objects (receivers of a drop) conform to the NSDraggingDestination protocol. The Application Kit hides all the details of tracking the cursor and displaying the dragged image.

Printing

The NSPrinter, NSPrintPanel, NSPageLayout, and NSPrintInfo classes work together to provide the means for printing the information that your application displays in its windows and views. You can also create an EPS representation of an NSView.

Accessing the File System

Use the NSFileWrapper class to create objects that correspond to files or directories on disk. NSFileWrapper will hold the contents of the file in memory so that it can be displayed, changed, or transmitted to another application. It also provides an icon for dragging the file or representing it as an attachment. Or use the NSFileManager class in the Foundation framework to access and enumerate file and directory contents. The NSOpenPanel and NSSavePanel classes also provide a convenient and familiar user interface to the file system.

Sharing Data With Other Applications

The NSPasteboard class defines the pasteboard, a repository for data that's copied from your application, making this data available to any application that cares to use it. NSPasteboard implements the familiar cut-copy-paste operation. The NSServicesRequest protocol uses the pasteboard to communicate data that's passed between applications by a registered service.

Checking Spelling

The NSSpellServer class lets you define a spell-checking service and provide it as a service to other applications. To connect your application to a spell-checking service, you use the NSSpellChecker class. The NSIgnoreMisspelledWords and NSChangeSpelling protocols support the spell-checking mechanism.

Localization

If an application is to be used in more than one part of the world, its resources may need to be customized, or "localized," for language, country, or cultural region. For example, an application may need to have separate Japanese, English, French, and German versions of character strings, icons, nib files, or context help. Resource files specific to a particular language are grouped together in a subdirectory of the bundle directory (the directories with the "`.lproj`" extension). Usually you set up localization resource files using Interface Builder. See the specifications for *NSBundle Additions Reference* and `NSBundle` class for more information on localization (`NSBundle` is in the Foundation framework).

Classes

CIColor Additions Reference

Inherits from	NSObject
Conforms to	NSCoding (CIColor) NSObject (NSObject)
Framework	/System/Library/Frameworks/AppKit.framework
Declared in	AppKit/NSColor.h
Availability	Available in Mac OS X v10.4 and later.

Overview

The Application Kit extends the Core Image framework's CIColor class by adding the ability to create an instance of `CIColor` from an existing `NSColor` instance.

Tasks

Creating a CIColor Instance

`- initWithColor:` (page 55)
Initializes a newly allocated `CIColor` object using an `NSColor` object.

Instance Methods

initWithColor:

Initializes a newly allocated `CIColor` object using an `NSColor` object.

```
- (id)initWithColor:(NSColor *)color
```

Parameters

color
The initial color value, which can belong to any available colorspace.

Return Value
The resulting `CIColor` object, or `nil` if the object cannot be initialized with the specified value.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`NSColor.h`

CIImage Additions Reference

Inherits from	NSObject
Conforms to	NSCoding (CIImage) NSCopying (CIImage) NSObject (NSObject)
Framework	/System/Library/Frameworks/AppKit.framework
Declared in	AppKit/NSCIImageRep.h
Availability	Available in Mac OS X v10.4 and later.

Overview

The Application Kit adds three methods to the Core Image framework's CIImage class.

Tasks

Initializing

`- initWithBitmapImageRep:` (page 59)
Initializes the receiver, a newly allocated `CIImage` object, with the specified bitmap.

Drawing Images

`- drawAtPoint:fromRect:operation:fraction:` (page 58)
Draws all or part of the image at the specified point in the current coordinate system.

`- drawInRect:fromRect:operation:fraction:` (page 58)
Draws all or part of the image in the specified rectangle in the current coordinate system

Instance Methods

drawAtPoint:fromRect:operation:fraction:

Draws all or part of the image at the specified point in the current coordinate system.

```
- (void)drawAtPoint:(NSPoint)point fromRect:(NSRect)srcRect
    operation:(NSCompositingOperation)op fraction:(CGFloat)delta
```

Parameters

point

The location in the current coordinate system at which to draw the image.

srcRect

The source rectangle specifying the portion of the image you want to draw. The coordinates of this rectangle must be specified using the image's own coordinate system.

op

The compositing operation to use when drawing the image.

delta

The opacity of the image, specified as a value from 0.0 to 1.0. Specifying a value of 0.0 draws the image as fully transparent while a value of 1.0 draws the image as fully opaque. Values greater than 1.0 are interpreted as 1.0.

Discussion

The image content is drawn at its current resolution and is not scaled unless the CTM of the current coordinate system itself contains a scaling factor. The image is otherwise positioned and oriented using the current coordinate system.

Availability

Available in Mac OS X v10.4 and later.

Declared In

`NSCIImageRep.h`

drawInRect:fromRect:operation:fraction:

Draws all or part of the image in the specified rectangle in the current coordinate system

```
- (void)drawInRect:(NSRect)dstRect fromRect:(NSRect)srcRect
    operation:(NSCompositingOperation)op fraction:(CGFloat)delta
```

Parameters

dstRect

The rectangle in which to draw the image.

srcRect

The source rectangle specifying the portion of the image you want to draw. The coordinates of this rectangle must be specified using the image's own coordinate system.

op

The compositing operation to use when drawing the image.

delta

The opacity of the image, specified as a value from 0.0 to 1.0. Specifying a value of 0.0 draws the image as fully transparent while a value of 1.0 draws the image as fully opaque. Values greater than 1.0 are interpreted as 1.0.

Discussion
If the `srcRect` and `dstRect` rectangles have different sizes, the source portion of the image is scaled to fit the specified destination rectangle. The image is otherwise positioned and oriented using the current coordinate system.

Availability
Available in Mac OS X v10.4 and later.

Related Sample Code
Reducer
SonogramViewDemo

Declared In
`NSCIImageRep.h`

initWithBitmapImageRep:

Initializes the receiver, a newly allocated `CIImage` object, with the specified bitmap.

```
- (id)initWithBitmapImageRep:(NSBitmapImageRep *)bitmapImageRep
```

Parameters

bitmapImageRep

An image representation object containing the bitmap data.

Return Value
The resulting `CIImage` object.

Availability
Available in Mac OS X v10.4 and later.

Related Sample Code
CocoaSlides
FunHouse
Reducer

Declared In
`NSCIImageRep.h`

NSActionCell Class Reference

Inherits from	NSCell : NSObject
Conforms to	NSCoding (NSCell) NSCopying (NSCell) NSObject (NSObject)
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.0 and later.
Declared in	AppKit/NSActionCell.h
Companion guide	Action Messages
Related sample code	ClockControl TrackBall

Overview

An NSActionCell defines an active area inside a control (an instance of NSControl or one of its subclasses).

As an NSControl's active area, an NSActionCell does three things: it usually performs display of text or an icon; it provides the NSControl with a target and an action; and it handles mouse (cursor) tracking by properly highlighting its area and sending action messages to its target based on cursor movement.

Tasks

Configuring an NSActionCell Object

- `setAlignment:` (page 65)
  Sets the alignment of text in the receiver.
- `setEnabled:` (page 67)
  Sets whether the receiver is enabled or disabled.
- `setFloatingPointFormat:left:right:` (page 67)
  Sets the receiver's floating-point format.
- `setImage:` (page 69)
  Sets the image to be displayed in the receiver.

- `setBezeled:` (page 66) Available in Mac OS X v10.0 through Mac OS X v10.5
  Sets whether the receiver draws itself with a bezeled border.
- `setBordered:` (page 66) Available in Mac OS X v10.0 through Mac OS X v10.5
  Sets whether the receiver draws itself outlined with a plain border.
- `setFont:` (page 68) Available in Mac OS X v10.0 through Mac OS X v10.5
  Sets the font to be used when the receiver displays text.

Obtaining and Setting Cell Values

- `doubleValue` (page 63)
  Returns the receiver's value as a `double` after validating any editing of cell content.
- `integerValue` (page 64)
  Returns the receiver's value as a 64-bit compatible integer after validating any editing of cell content.
- `setObjectValue:` (page 69)
  Discards any editing of the receiver's text and sets its object value to *`object`*.
- `floatValue` (page 64) Available in Mac OS X v10.0 through Mac OS X v10.5
  Returns the receiver's value as a `float` after validating any editing of cell content.
- `intValue` (page 65) Available in Mac OS X v10.0 through Mac OS X v10.5
  Returns the receiver's value as an `int` after validating any editing of cell content.
- `stringValue` (page 70) Available in Mac OS X v10.0 through Mac OS X v10.5
  Returns the receiver's value as a string object as converted by the cell's formatter, if one exists.

Managing the Cell's View

- `setControlView:` (page 67)
  Sets the receiver's control view, the view in which it is drawn.
- `controlView` (page 63) Available in Mac OS X v10.0 through Mac OS X v10.5
  Returns the view in which the receiver was last drawn.

Assigning the Target and Action

- `setAction:` (page 65)
  Sets the selector used for action messages sent by the receiver's control.
- `action` (page 63)
  Returns the receiver's action-message selector.
- `setTarget:` (page 70)
  Sets the receiver's target object.
- `target` (page 71)
  Returns the receiver's target object.

Assigning a Tag

- `setTag:` (page 69)
  Sets the receiver's tag.
- `tag` (page 71)
  Returns the receiver's tag.

Instance Methods

action

Returns the receiver's action-message selector.

```
- (SEL)action
```

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setAction:` (page 65)
- `setTarget:` (page 70)
- `target` (page 71)

Declared In
`NSActionCell.h`

controlView

Returns the view in which the receiver was last drawn. (Available in Mac OS X v10.0 through Mac OS X v10.5.)

```
- (NSView *)controlView
```

Return Value
The returned view is normally an `NSControl` object. The method returns `nil` if the receiver has no control view (usually because it hasn't yet been placed in the view hierarchy).

Availability
Available in Mac OS X v10.0 through Mac OS X v10.5.

Declared In
`NSActionCell.h`

doubleValue

Returns the receiver's value as a `double` after validating any editing of cell content. (Available in Mac OS X v10.0 through Mac OS X v10.5.)

```
- (double)doubleValue
```

Discussion
If the receiver is not a text-type cell or the cell value is not scannable, the method returns 0.

Availability
Available in Mac OS X v10.0 through Mac OS X v10.5.

See Also
- `validateEditing` (page 845) (NSControl)

Declared In
`NSActionCell.h`

floatValue

Returns the receiver's value as a `float` after validating any editing of cell content. (Available in Mac OS X v10.0 through Mac OS X v10.5.)

```
- (float)floatValue
```

Discussion
If the receiver is not a text-type cell or the cell value is not scannable, the method returns 0.

Availability
Available in Mac OS X v10.0 through Mac OS X v10.5.

See Also
- `validateEditing` (page 845) (NSControl)

Declared In
`NSActionCell.h`

integerValue

Returns the receiver's value as a 64-bit compatible integer after validating any editing of cell content.

```
- (NSInteger)integerValue
```

Return Value
A 64-bit compatible integer value, as defined by the `NSInteger` type.

Discussion
If the receiver is not a text-type cell or the cell value is not scannable, the method returns 0.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSActionCell.h`

intValue

Returns the receiver's value as an `int` after validating any editing of cell content. (Available in Mac OS X v10.0 through Mac OS X v10.5.)

```
- (int)intValue
```

Discussion
If the receiver is not a text-type cell or the cell value is not scannable, the method returns 0.

Availability
Available in Mac OS X v10.0 through Mac OS X v10.5.

See Also
- `validateEditing` (page 845) (NSControl)

Declared In
`NSActionCell.h`

setAction:

Sets the selector used for action messages sent by the receiver's control.

```
- (void)setAction:(SEL)aSelector
```

Parameters
aSelector
The selector that identifies the action method to invoke.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `action` (page 63)
- `setTarget:` (page 70)
- `target` (page 71)

Related Sample Code
Quartz Composer WWDC 2005 TextEdit

Declared In
`NSActionCell.h`

setAlignment:

Sets the alignment of text in the receiver. (Available in Mac OS X v10.0 through Mac OS X v10.5.)

```
- (void)setAlignment:(NSTextAlignment)mode
```

Parameters

mode

One of five constants that specifies alignment within the cell: `NSLeftTextAlignment`, `NSRightTextAlignment`, `NSCenterTextAlignment`, `NSJustifiedTextAlignment`, and `NSNaturalTextAlignment` (the default alignment for the text).

Discussion

The method marks the receiver as needing redisplay after discarding any editing changes that were being made to cell text.

Availability

Available in Mac OS X v10.0 through Mac OS X v10.5.

Declared In

`NSActionCell.h`

setBezeled:

Sets whether the receiver draws itself with a bezeled border. (Available in Mac OS X v10.0 through Mac OS X v10.5.)

```
- (void)setBezeled:(BOOL)flag
```

Parameters

flag

`YES` if the cell is to be drawn with a bezeled border, `NO` otherwise.

Discussion

After setting the attribute the method marks the receiver as needing redisplay. The `setBezeled:` and `setBordered:` (page 66) methods are mutually exclusive—that is, a border can be only plain or bezeled.

Availability

Available in Mac OS X v10.0 through Mac OS X v10.5.

Declared In

`NSActionCell.h`

setBordered:

Sets whether the receiver draws itself outlined with a plain border. (Available in Mac OS X v10.0 through Mac OS X v10.5.)

```
- (void)setBordered:(BOOL)flag
```

Parameters

flag

`YES` if the cell is to be drawn with a plain border, `NO` otherwise.

Discussion

After setting the attribute the method marks the receiver as needing redisplay. The `setBezeled:` (page 66) and `setBordered:` methods are mutually exclusive—that is, a border can be only plain or bezeled.

Availability

Available in Mac OS X v10.0 through Mac OS X v10.5.

Declared In
NSActionCell.h

setControlView:

Sets the receiver's control view, the view in which it is drawn.

```
- (void)setControlView:(NSView *)view
```

Parameters

view

The view object, which is normally an NSControl *view*. Pass in `nil` if the receiver has no control view (usually because it hasn't yet been placed in the view hierarchy).

Discussion
The control view is typically set in the receiver's implementation of `drawWithFrame:inView:` (page 554) (`NSCell`).

Availability
Available in Mac OS X v10.4 and later.

Declared In
NSActionCell.h

setEnabled:

Sets whether the receiver is enabled or disabled. (Available in Mac OS X v10.0 through Mac OS X v10.5.)

```
- (void)setEnabled:(BOOL)flag
```

Parameters

flag

`YES` if the cell is to be enabled, `NO` otherwise

Discussion
The text of disabled cells is changed to gray. If a cell is disabled, it cannot be highlighted, cannot be edited, and does not support mouse tracking (and thus cannot participate in target-action behavior). The method marks the receiver as needing redisplay after discarding any editing changes that were being made to cell text.

Availability
Available in Mac OS X v10.0 through Mac OS X v10.5.

Declared In
NSActionCell.h

setFloatingPointFormat:left:right:

Sets the receiver's floating-point format. (Available in Mac OS X v10.0 through Mac OS X v10.5.)

```
- (void)setFloatingPointFormat:(BOOL)autoRange left:(NSUInteger)leftDigits
    right:(NSUInteger)rightDigits
```

Parameters

autoRange

NO if you want the receiver to places digits to the right and left of the decimal point as specified (in leftDigits and rightDigits; YES if you want it to place the digits flexibly.

leftDigits

The maximum number of digits to the left of the decimal point. The receiver might interpret this value flexibly if autoRange is YES.

rightDigits

The maximum number of digits to the right of the decimal point. The receiver might interpret this value flexibly if autoRange is YES.

Discussion

The implementation of this method is based on the NSCell method setFloatingPointFormat:left:right: (page 586). See the description of that method for details.

The NSActionCell implementation of the method supplements the NSCell implementation by marking the receiver as needing redisplay after discarding any editing changes that were being made to cell text.

Note: This method is being deprecated in favor of NSFormatter objects. For more information, see NSFormatter. This documentation is provided only for developers who need to modify older applications.

Availability

Available in Mac OS X v10.0 through Mac OS X v10.5.

Declared In

NSActionCell.h

setFont:

Sets the font to be used when the receiver displays text. (Available in Mac OS X v10.0 through Mac OS X v10.5.)

```
- (void)setFont:(NSFont *)fontObj
```

Parameters

fontObj

The font object encapsulating information about the new font. If *fontObj* is nil and the receiver is a text-type cell, the font object currently held by the receiver is autoreleased.

Discussion

If the receiver is not a text-type cell, the method converts it to that type. NSActionCell supplements the NSCell implementation of this method by marking the updated cell as needing redisplay. If the receiver was converted to a text-type cell and is selected, it also updates the field editor with *fontObj*.

Availability

Available in Mac OS X v10.0 through Mac OS X v10.5.

Declared In

NSActionCell.h

setImage:

Sets the image to be displayed in the receiver. (Available in Mac OS X v10.0 through Mac OS X v10.5.)

```
- (void)setImage:(NSImage *)image
```

Parameters

image

The image for the receiver to display. If *image* is `nil`, the image currently displayed by the receiver is removed.

Availability
Available in Mac OS X v10.0 through Mac OS X v10.5.

Declared In
`NSActionCell.h`

setObjectValue:

Discards any editing of the receiver's text and sets its object value to *object*. (Available in Mac OS X v10.0 through Mac OS X v10.5.)

```
- (void)setObjectValue:(id < NSCopying >)object
```

Parameters

object

The object value to assign to the receiver.

Discussion
If the object value is afterward different from what it was before the method was invoked, the method marks the receiver as needing redisplay.

Availability
Available in Mac OS X v10.0 through Mac OS X v10.5.

Declared In
`NSActionCell.h`

setTag:

Sets the receiver's tag.

```
- (void)setTag:(NSInteger)anInt
```

Parameters

anInt

An integer tag to be associated with the receiver.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `tag` (page 71)

Declared In
NSActionCell.h

setTarget:

Sets the receiver's target object.

```
- (void)setTarget:(id)anObject
```

Parameters

anObject
The object that is the target of action messages sent by the receiver's control.

Availability
Available in Mac OS X v10.0 and later.

See Also
- action (page 63)
- setAction: (page 65)
- target (page 71)

Related Sample Code
Quartz Composer WWDC 2005 TextEdit

Declared In
NSActionCell.h

stringValue

Returns the receiver's value as a string object as converted by the cell's formatter, if one exists. (Available in Mac OS X v10.0 through Mac OS X v10.5.)

```
- (NSString *)stringValue
```

Discussion
If no formatter exists and the value is an NSString, returns the value as a plain, attributed, or localized formatted string. If the value is not an NSString or cannot be converted to one, returns an empty string. The method supplements the NSCell implementation by validating and retaining any editing changes being made to cell text.

Availability
Available in Mac OS X v10.0 through Mac OS X v10.5.

See Also
- validateEditing (page 845) (NSControl)

Declared In

NSAffineTransform Additions Reference

Inherits from	NSObject
Conforms to	NSCoding NSCopying NSObject (NSObject)
Framework	/System/Library/Frameworks/AppKit.framework
Declared in	AppKit/NSAffineTransform.h
Companion guide	Cocoa Drawing Guide

Overview

The Application Kit extends Foundation's NSAffineTransform class by adding:

- Methods for applying affine transformations to the current graphics context.
- A method for applying an affine transformation to an `NSBezierPath`.

Note: In Mac OS X v10.3 and earlier the `NSAffineTransform` class was declared and implemented entirely in the Application Kit framework. As of Mac OS X v10.4 the `NSAffineTransform` class has been split across the Foundation Kit and Application Kit frameworks.

Tasks

Setting and Building the Current Transformation Matrix

- `set` (page 74)
  Sets the current transformation matrix to the receiver's transformation matrix.
- `concat` (page 74)
  Appends the receiver's matrix to the current transformation matrix stored in the current graphics context, replacing the current transformation matrix with the result.

Transforming Bezier Paths

- `transformBezierPath:` (page 75)
  Creates and returns a new `NSBezierPath` object with each point in the given path transformed by the receiver.

Instance Methods

concat

Appends the receiver's matrix to the current transformation matrix stored in the current graphics context, replacing the current transformation matrix with the result.

```
- (void)concat
```

Discussion
Concatenation is performed by matrix multiplication—see "Manipulating Transform Values".

If this method is invoked from within an `NSView` `drawRect:` (page 3170) method, then the current transformation matrix is an accumulation of the screen, window, and any superview's transformation matrices. Invoking this method defines a new user coordinate system whose coordinates are mapped into the former coordinate system according to the receiver's transformation matrix. To undo the concatenation, you must invert the receiver's matrix and invoke this method again.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `set` (page 74)
- `invert`

Related Sample Code
DockTile
Sketch+Accessibility
Sketch-112
WebKitPluginStarter
WebKitPluginWithJavaScript

Declared In
`NSAffineTransform.h`

set

Sets the current transformation matrix to the receiver's transformation matrix.

```
- (void)set
```

Discussion
The current transformation is stored in the current graphics context and is applied to subsequent drawing operations. You should use this method sparingly because it removes the existing transformation matrix, which is an accumulation of transformation matrices for the screen, window, and any superviews. Instead use the `concat` (page 74) method to add this transformation matrix to the current transformation matrix.

Availability
Available in Mac OS X v10.0 and later.

Overview

You use an `NSAlert` object to display an alert, either as an application-modal dialog or as a sheet attached to a document window. The methods of the `NSAlert` class allow you to specify alert level, icon, button titles, and alert text. The class also lets your alerts display help buttons and provides ways for applications to offer help specific to an alert. To display an alert as a sheet, invoke the `beginSheetModalForWindow:modalDelegate:didEndSelector:contextInfo:` (page 84) method; to display one as an application-modal dialog, use the `runModal` (page 88) method.

By design, an `NSAlert` object is intended for a single alert—that is, an alert with a unique combination of title, buttons, and so on—that is displayed upon a particular condition. You should create an `NSAlert` object for each alert dialog. Normally you should create an `NSAlert` object when you need to display an alert, and release it when you are done. If you have a particular alert dialog that you need to show repeatedly, you can retain and reuse an instance of `NSAlert` for this dialog.

After creating an alert using one of the alert creation methods, you can customize it further prior to displaying it by customizing its attributes. See "Instance Attributes" (page 78)

Note: The `NSAlert` class, which was introduced in Mac OS X v10.3, supersedes the functional Application Kit API for displaying alerts (`NSRunAlertPanel`, `NSBeginAlertSheet`, and so on). The former API is still supported, but you should use the `NSAlert` class for your application's alert dialogs.

Instance Attributes

`NSAlert` objects have the following attributes:

- **Type.** An alert's type helps convey the importance or gravity of its message to the user. Specified with `setAlertStyle:` (page 89).
- **Message text.** The main message of the alert. Specified with `setMessageText:` (page 92).
- **Informative text.** Additional information about the alert. Specified with `informativeText` (page 86).
- **icon.** The icon displayed in the alert. Specified with : `setIcon:` (page 91).
- **Help.** Alerts can let the user get help about them. Use `setHelpAnchor:` (page 90) and `setShowsHelp:` (page 92).
- **Response buttons.** By default an alert has one response button: the OK button. You can add more response buttons using: `addButtonWithTitle:` (page 83).
- **Suppression checkbox.** A suppression checkbox allows the user to suppress the display of a particular alert in subsequent occurrences of the event that triggers it. Use `setShowsSuppressionButton:` (page 93), `suppressionButton` (page 95).
- **Accessory view.** An accessory view lets you add additional information to an alert; for example, a text field with contact information. Use `setAccessoryView:` (page 88), `layout` (page 87).

Subclassing Notes

The `NSAlert` class is not designed for subclassing.

Tasks

Creating Alerts

`+ alertWithError:` (page 80)

Returns an alert initialized from information in an error object.

`+ alertWithMessageText:defaultButton:alternateButton:otherButton:informativeTextWithFormat:` (page 81)

Creates an alert compatible with alerts created using the `NSRunAlertPanel` (page 3998) function for display as a warning-style alert.

Configuring Alerts

- `layout` (page 87)
  Specifies that the receiver must do immediate layout instead of lazily just before display.
- `alertStyle` (page 83)
  Returns the `NSAlertStyle` constant identifying the receiver's alert style.
- `setAlertStyle:` (page 89)
  Sets the alert style of the receiver.
- `accessoryView` (page 82)
  Returns the receiver's accessory view.
- `setAccessoryView:` (page 88)
  Sets the receiver's accessory view.
- `showsHelp` (page 94)
  Indicates whether the receiver has a help button.
- `setShowsHelp:` (page 92)
  Specifies whether the receiver has a help button.
- `helpAnchor` (page 86)
  Returns the receiver's HTML help anchor.
- `setHelpAnchor:` (page 90)
  Associates the receiver to a given anchor.
- `delegate` (page 85)
  Returns the receiver's delegate.
- `setDelegate:` (page 90)
  Sets the receiver's delegate.

Displaying Alerts

- `runModal` (page 88)
  Runs the receiver as an application-modal dialog and returns the constant positionally identifying the button clicked.
- `beginSheetModalForWindow:modalDelegate:didEndSelector:contextInfo:` (page 84)
  Runs the receiver modally as an alert sheet attached to a specified window.
- `suppressionButton` (page 95)
  Returns the receiver's suppression checkbox.
- `showsSuppressionButton` (page 94)
  Indicates whether the receiver shows a suppression button.
- `setShowsSuppressionButton:` (page 93)
  Specifies whether the receiver includes a suppression checkbox.

Accessing Alert Text

- `informativeText` (page 86)
  Returns the receiver's informative text.

- `setInformativeText:` (page 91)
  Sets the receiver's informative text to a given text.
- `messageText` (page 87)
  Returns the receiver's message text (or title).
- `setMessageText:` (page 92)
  Sets the receiver's message text, or title, to a given text.

Accessing Alert Icons

- `icon` (page 86)
  Returns the icon displayed in the receiver.
- `setIcon:` (page 91)
  Sets the icon to be displayed in the alert to a given icon.

Accessing Alert Buttons

- `buttons` (page 85)
  Returns the receiver's buttons.
- `addButtonWithTitle:` (page 83)
  Adds a button with a given title to the receiver.

Getting Alert Panels

- `window` (page 95)
  Provides the application-modal panel associated with the receiver.

Class Methods

alertWithError:

Returns an alert initialized from information in an error object.

```
+ (NSAlert *)alertWithError:(NSError *)error
```

Parameters

error
  Error information to display.

Return Value
Initialized alert.

Discussion
The `NSAlert` class extracts the localized error description, recovery suggestion, and recovery options from *error* and uses them as the alert's message text, informative text, and button titles, respectively.

Availability
Available in Mac OS X v10.4 and later.

Declared In
NSAlert.h

alertWithMessageText:defaultButton:alternateButton:otherButton: informativeTextWithFormat:

Creates an alert compatible with alerts created using the NSRunAlertPanel (page 3998) function for display as a warning-style alert.

```
+ (NSAlert *)alertWithMessageText:(NSString *)messageTitle defaultButton:(NSString
    *)defaultButtonTitle alternateButton:(NSString *)alternateButtonTitle
   otherButton:(NSString *)otherButtonTitle informativeTextWithFormat:(NSString
   *)informativeText, ...
```

Parameters

messageTitle
Title of the alert. When nil or an empty string, a default localized title is used (“Alert” in English).

defaultButtonTitle
Title for the default button. When nil or an empty string, a default localized button title (“OK” in English) is used.

alternateButtonTitle
Title for the alternate button. When nil, the alternate button is not created.

otherButtonTitle
Title for the other button. When nil, the other button is not created.

informativeText
Informative text. This is optional but must be an empty string (@"") not nil. Can embed variable values using a format string; list any necessary arguments for this formatted string at the end of the method’s argument list. For more information on format strings, see Formatting String Objects.

Return Value
Initialized alert.

Discussion
For languages that read left to right, the buttons are laid out on the bottom-right corner of the alert sheet or window, with *defaultButtonTitle* on the right, *alternateButtonTitle* on the left, and *otherButtonTitle* in the middle. The return values identifying these buttons are constants—NSAlertDefaultReturn, NSAlertAlternateReturn, and NSAlertOtherReturn—that correspond to the keywords.

By default, the first button has a key equivalent of Return, any button with a title of "Cancel" has a key equivalent of Escape, and any button with the title "Don't Save" has a key equivalent of Command-D (but only if it is not the first button). You can also assign different key equivalents for the buttons using the `setKeyEquivalent:` (page 483) method of the `NSButton` class. To access the alert's buttons, use the `buttons` (page 85) method.

Special Considerations

This is a compatibility method. It is designed for easy adoption by applications migrating from the corresponding function-based API. This method uses earlier return values—`NSAlertDefaultReturn`, `NSAlertAlternateReturn`, and `NSAlertOtherReturn`—compatible with the earlier API, rather than the return values defined by the `NSAlert` class, described in "Button Return Values" (page 96).

Unless you must maintain compatibility with existing alert-processing code that uses the function-based API, you should allocate (`alloc`) and initialize (`init`) the object, and then set its attributes using the appropriate methods of the `NSAlert` class. However, using `init` results in no default buttons being provided, in which case you must call `addButtonWithTitle:` (page 83) explicitly.

Availability
Available in Mac OS X v10.3 and later.

Instance Methods

accessoryView

Returns the receiver's accessory view.

```
- (NSView *)accessoryView
```

Return Value
The alert's accessory view.

Availability
Available in Mac OS X v10.5 and later.

See Also
`- setAccessoryView:` (page 88)

Declared In
`NSAlert.h`

addButtonWithTitle:

Adds a button with a given title to the receiver.

```
- (NSButton *)addButtonWithTitle:(NSString *)buttonTitle
```

Parameters

buttonTitle

Title of the button to add to the alert. Must not be `nil`.

Return Value

Button added to the alert.

Discussion

Buttons are placed starting near the right side of the alert and going toward the left side (for languages that read left to right). The first three buttons are identified positionally as `NSAlertFirstButtonReturn`, `NSAlertSecondButtonReturn`, `NSAlertThirdButtonReturn` in the return-code parameter evaluated by the modal delegate. Subsequent buttons are identified as `NSAlertThirdButtonReturn` +*n*, where *n* is an integer

By default, the first button has a key equivalent of Return, any button with a title of "Cancel" has a key equivalent of Escape, and any button with the title "Don't Save" has a key equivalent of Command-D (but only if it is not the first button). You can also assign different key equivalents for the buttons using the `setKeyEquivalent:` (page 483) method of the `NSButton` class. In addition, you can use the `setTag:` (page 838) method of the `NSButton` class to set the return value.

`NSAlert` instances created with the `init` method lack any buttons. You must call `addButtonWithTitle:` (page 83) to add a minimum of one button.

Availability

Available in Mac OS X v10.3 and later.

`NSAlert.h`

alertStyle

Returns the `NSAlertStyle` constant identifying the receiver's alert style.

```
- (NSAlertStyle)alertStyle
```

Return Value

Alert style for the alert. See NSAlertStyle (page 96) for the list of alert style constants.

Availability

Available in Mac OS X v10.3 and later.

See Also
- `setAlertStyle:` (page 89)

Declared In
`NSAlert.h`

beginSheetModalForWindow:modalDelegate:didEndSelector:contextInfo:

Runs the receiver modally as an alert sheet attached to a specified window.

```
- (void)beginSheetModalForWindow:(NSWindow *)window modalDelegate:(id)modalDelegate
    didEndSelector:(SEL)alertDidEndSelector contextInfo:(void *)contextInfo
```

Parameters

window
The parent window for the sheet.

modalDelegate
The delegate for the modal-dialog session.

alertDidEndSelector
Message the alert sends to *modalDelegate* after the user responds but before the sheet is dismissed.

contextInfo
Contextual data passed to *modalDelegate* in *didEndSelector* message.

Discussion
You can create the required `NSAlert` object either through the standard allocate-initialize procedure or by using the compatibility method `alertWithMessageText:defaultButton:alternateButton:otherButton:informativeTextWithFormat:` (page 81).

The *alertDidEndSelector* argument must be a selector that takes three arguments, and the corresponding method should have a declaration modeled on the following example:

```
- (void) alertDidEnd:(NSAlert *)alert returnCode:(NSInteger)returnCode
contextInfo:(void *)contextInfo;
```

where *alert* is the `NSAlert` object, *returnCode* specifies which button the user pressed, and *contextInfo* is the same *contextInfo* passed in the original message. The *returnCode* argument identifies which button was used to dismiss the alert (see this method's "Special Considerations" section). The modal delegate determines which button was clicked ("OK", "Cancel", and so on) and proceeds accordingly.

If you want to dismiss the sheet from within the *alertDidEndSelector* method before the modal delegate carries out an action in response to the return value, send `orderOut:` (page 3352) (`NSWindow`) to the window object obtained by sending `window` (page 95) to the *alert* argument. This allows you to chain sheets, for example, by dismissing one sheet before showing the next from within the *alertDidEndSelector* method. Note that you should be careful not to call `orderOut:` on the sheet from elsewhere in your program before the *alertDidEndSelector* method is invoked.

Special Considerations

When you use `alertWithMessageText:defaultButton:alternateButton:otherButton:informativeTextWithFormat:` (page 81) to create an alert, these are the constants used to identify the button used to dismiss the alert: `NSAlertDefaultReturn`, `NSAlertAlternateReturn`, and `NSAlertOtherReturn`. Otherwise, the constants used are the ones described in "Button Return Values" (page 96).

Availability
Available in Mac OS X v10.3 and later.

`NSAlert.h`

informativeText

Returns the receiver's informative text.

```
- (NSString *)informativeText
```

Return Value
The alert's informative text.

Availability
Available in Mac OS X v10.3 and later.

See Also
- `setInformativeText:` (page 91)
- `messageText` (page 87)

Declared In
`NSAlert.h`

layout

Specifies that the receiver must do immediate layout instead of lazily just before display.

```
- (void)layout
```

Discussion
You need to call this method only when you need to customize the alert's layout. Call this method after all the alert's attributes have been customized, including the suppression checkbox and the accessory layout. After the method returns, you can make the necessary layout changes; for example, adjusting the frame of the accessory view.

Note: The standard alert layout is subject to change in future system software versions. Therefore, if you rely on custom alert layout, you should make sure your layouts work as expected in future releases of Mac OS.

Availability
Available in Mac OS X v10.5 and later.

See Also
- `setAccessoryView:` (page 88)

Declared In
`NSAlert.h`

messageText

Returns the receiver's message text (or title).

```
- (NSString *)messageText
```

Return Value
The alert's message text.

Availability
Available in Mac OS X v10.3 and later.

See Also
- `setMessageText:` (page 92)

- informativeText (page 86)

Declared In
NSAlert.h

runModal

Runs the receiver as an application-modal dialog and returns the constant positionally identifying the button clicked.

```
- (NSInteger)runModal
```

Return Value
Response to the alert. See this method's "Special Considerations" section for details.

Discussion
You can create the alert either through the standard allocate–initialize procedure or by using the compatibility method alertWithMessageText:defaultButton:alternateButton:otherButton:informativeTextWithFormat: (page 81).

Special Considerations

When you use alertWithMessageText:defaultButton:alternateButton:otherButton:informativeTextWithFormat: (page 81) to create an alert, these are the constants used to identify the button used to dismiss the alert: NSAlertDefaultReturn, NSAlertAlternateReturn, and NSAlertOtherReturn. Otherwise, the constants used are the ones described in "Button Return Values" (page 96).

Availability
Available in Mac OS X v10.3 and later.

setAccessoryView:

Sets the receiver's accessory view.

```
- (void)setAccessoryView:(NSView *)accessoryView
```

Parameters
accessoryView
View that is to be the alert's accessory view.

Discussion

The `NSAlert` class places the accessory view between the informative text or suppression checkbox (if present) and the response buttons. To change the location of the accessory view, you must first call the `layout` (page 87) method.

Listing 5-1 shows an example of adding an accessory view to an alert. Figure 5-1 shows the alert generated.

Listing 5-1 Adding an accessory view to an alert

```
NSTextView *accessory = [[NSTextView alloc] initWithFrame:NSMakeRect(0,0,200,15)];
NSFont *font = [NSFont systemFontOfSize:[NSFont systemFontSize]];
NSDictionary *textAttributes = [NSDictionary dictionaryWithObject:font
forKey:NSFontAttributeName];
[accessory insertText:[[NSAttributedString alloc] initWithString:@"Text in
accessory view"
                                                        attributes:textAttributes]];
[accessory setEditable:NO];
[accessory setDrawsBackground:NO];

NSAlert* alert = [NSAlert alertWithMessageText:@"Message text" defaultButton:nil
 alternateButton:nil otherButton:nil informativeTextWithFormat:@"Informative
text"];
[alert setAccessoryView:accessory];
[alert runModal];
```

setIcon:

Sets the icon to be displayed in the alert to a given icon.

```
- (void)setIcon:(NSImage *)icon
```

Parameters

icon

Icon for the alert. `nil` restores the application icon.

Discussion
By default, the image is the application icon, accessed via the application bundle's `NSApplicationIcon` property.

Availability
Available in Mac OS X v10.3 and later.

See Also
- `icon` (page 86)

Declared In
`NSAlert.h`

setInformativeText:

Sets the receiver's informative text to a given text.

```
- (void)setInformativeText:(NSString *)informativeText
```

Parameters

informativeText

Informative text for the alert. The value must not be `nil`.

Availability
Available in Mac OS X v10.3 and later.

See Also
- `informativeText` (page 86)
- `setMessageText:` (page 92)

Related Sample Code
CocoaDVDPlayer

UIElementInspector

XMLBrowser

Declared In
NSAlert.h

setMessageText:

Sets the receiver's message text, or title, to a given text.

```
- (void)setMessageText:(NSString *)messageText
```

Parameters

messageText
Message text for the alert.

Availability
Available in Mac OS X v10.3 and later.

See Also
- messageText (page 87)
- setInformativeText: (page 91)

Related Sample Code
CocoaDVDPlayer

Declared In
NSAlert.h

setShowsHelp:

Specifies whether the receiver has a help button.

```
- (void)setShowsHelp:(BOOL)showsHelp
```

Parameters

showsHelp
YES for a help button, NO for no help button.

Discussion
When the help button is pressed, the alert delegate (delegate (page 85)) is first sent a alertShowHelp: (page 3551) message. If there is no delegate, or the delegate does not implement alertShowHelp: (page 3551) or returns NO, then the openHelpAnchor:inBook: (page 1318) message is sent to the application's help manager with a nil book and the anchor specified by setHelpAnchor: (page 90), if any. An exception is raised if the delegate returns NO and no help anchor is set.

Availability
Available in Mac OS X v10.3 and later.

See Also
- `setDelegate:` (page 90)
- `showsHelp` (page 94)

Declared In
`NSAlert.h`

setShowsSuppressionButton:

Specifies whether the receiver includes a suppression checkbox.

```
- (void)setShowsSuppressionButton:(BOOL)showButton
```

Parameters

showButton

When `YES` the alert includes the suppression checkbox.

Discussion

You can set the title of the checkbox with the following code:

```
[[alert suppressionButton] setTitle:title];
```

Listing 5-2 shows how to add a suppression checkbox (with the default suppression-checkbox title) to a modal alert. Figure 5-2 shows the corresponding dialog.

Listing 5-2 Creating an alert with a suppression checkbox

```
NSString *exampleAlertSuppress = @"ExampleAlertSuppress";
NSUserDefaults *defaults = [NSUserDefaults standardUserDefaults];
if ([defaults boolForKey:exampleAlertSuppress]) {
    NSLog(@"ExampleAlert suppressed");
}
else {
    NSAlert* alert = [NSAlert alertWithMessageText:@"Message text"
defaultButton:nil alternateButton:nil
                                        otherButton:nil
informativeTextWithFormat:@"Informative text"];
    [alert setShowsSuppressionButton:YES];
    [alert runModal];
    if ([[alert suppressionButton] state] == NSOnState) {
        // Suppress this alert from now on.
        [defaults setBool:YES forKey:exampleAlertSuppress];
    }
    [alert release];
}
```

Figure 5-2 Alert dialog with a suppression checkbox

Availability
Available in Mac OS X v10.5 and later.

See Also
- `suppressionButton` (page 95)

Declared In
`NSAlert.h`

showsHelp

Indicates whether the receiver has a help button.

```
- (BOOL)showsHelp
```

Return Value
`YES` if the alert has a help button, `NO` otherwise.

Availability
Available in Mac OS X v10.3 and later.

See Also
- `setShowsHelp:` (page 92)

Declared In
`NSAlert.h`

showsSuppressionButton

Indicates whether the receiver shows a suppression button.

```
- (BOOL)showsSuppressionButton
```

Return Value
`YES` when the alert shows a suppression button, `NO` otherwise. The default is `NO`.

Availability
Available in Mac OS X v10.5 and later.

See Also
- setShowsSuppressionButton: (page 93)

Declared In
NSAlert.h

suppressionButton

Returns the receiver's suppression checkbox.

```
- (NSButton *)suppressionButton
```

Return Value
The alert's suppression button.

Discussion
You can use this method to customize the alert's suppression checkbox before the alert is displayed. For example, you can change the title of the checkbox or specify its initial state, which is unselected by default.

Availability
Available in Mac OS X v10.5 and later.

Declared In
NSAlert.h

window

Provides the application-modal panel associated with the receiver.

```
- (id)window
```

Return Value
The receiver's associated NSPanel object.

Discussion
This method is useful when you want to dismiss an alert created with beginSheetModalForWindow:modalDelegate:didEndSelector:contextInfo: (page 84) within the method identified by the didEndSelector: parameter.

Availability
Available in Mac OS X v10.3 and later.

Declared In
NSAlert.h

Constants

NSAlertStyle

The `NSAlert` class defines the alert styles used by `setAlertStyle:` (page 89) and `alertStyle` (page 83).

```
enum {
    NSWarningAlertStyle = 0,
    NSInformationalAlertStyle = 1,
    NSCriticalAlertStyle = 2
};
typedef NSUInteger NSAlertStyle;
```

Constants

`NSWarningAlertStyle`

An alert used to warn the user about a current or impending event. The purpose is more than informational but not critical. This is the default alert style.

Available in Mac OS X v10.3 and later.

Declared in `NSAlert.h`.

`NSInformationalAlertStyle`

An alert used to inform the user about a current or impending event.

Available in Mac OS X v10.3 and later.

Declared in `NSAlert.h`.

`NSCriticalAlertStyle`

Reserved this style for critical alerts, such as when there might be severe consequences as a result of a certain user response (for example, a "clean install" will erase all data on a volume). This style causes the icon to be badged with a caution icon.

Available in Mac OS X v10.3 and later.

Declared in `NSAlert.h`.

Discussion

Currently, there is no visual difference between informational and warning alerts. You should only use the critical (or "caution") alert style if warranted, as specified in the "Alerts" chapter in *Apple Human Interface Guidelines*.

Availability

Available in Mac OS X v10.3 and later.

Declared In

`NSAlert.h`

Button Return Values

An alert's return values for buttons are position dependent. The following constants describe the return values for the first three buttons on an alert (assuming a language that reads left to right).

```
enum {
   NSAlertFirstButtonReturn  = 1000,
   NSAlertSecondButtonReturn  = 1001,
   NSAlertThirdButtonReturn  = 1002
};
```

Constants

`NSAlertFirstButtonReturn`

The user clicked the first (rightmost) button on the dialog or sheet.

Available in Mac OS X v10.3 and later.

Declared in `NSAlert.h`.

`NSAlertSecondButtonReturn`

The user clicked the second button from the right edge of the dialog or sheet.

Available in Mac OS X v10.3 and later.

Declared in `NSAlert.h`.

`NSAlertThirdButtonReturn`

The user clicked the third button from the right edge of the dialog or sheet.

Available in Mac OS X v10.3 and later.

Declared in `NSAlert.h`.

Discussion

If you have more than three buttons on your alert, the button-position return value is `NSAlertThirdButtonReturn` + *n*, where *n* is an integer. For languages that read right to left, the first button's position is closest to the left edge of the dialog or sheet.

Declared In

`NSAlert.h`

Overview

Objects of the `NSAnimation` class manage the timing and progress of animations in the user interface. The class also lets you link together multiple animations so that when one animation ends another one starts. It does not provide any drawing support for animation and does not directly deal with views, targets, or actions.

Note: For simple tasks requiring a timing mechanism, consider using `NSTimer`.

`NSAnimation` objects have several characteristics, including duration, frame rate, and animation curve, which describes the relative speed of the animation over its course. You can set progress marks in an animation, each of which specifies a percentage of the animation completed; when an animation reaches a progress mark, it notifies its delegate and posts a notification to any observers. Animations execute in one of three blocking modes: blocking, non-blocking on the main thread, and non-blocking on a separate thread. The non-blocking modes permit the handling of user events while the animation is running.

Subclassing Notes

The usual usage pattern for `NSAnimation` is to make a subclass that overrides (at least) the setCurrentProgress: (page 109) method to invoke the superclass implementation and then perform whatever animation action is needed. The method implementation might invoke currentValue (page 104) and then use that value to update some drawing; as a consequence of invoking currentValue (page 104), the method

`animation:valueForProgress:` (page 3560) is sent to the delegate (if there is a delegate that implements the method). For more information on subclassing `NSAnimation`, see *Animation Programming Guide for Cocoa*.

Tasks

Initializing an NSAnimation Object

- `initWithDuration:animationCurve:` (page 106)
  Returns an `NSAnimation` object initialized with the specified duration and animation-curve values.

Configuring an Animation

- `setAnimationBlockingMode:` (page 108)
  Sets the blocking mode of the receiver.
- `animationBlockingMode` (page 102)
  Returns the blocking mode the receiver is next scheduled to run under.
- `runLoopModesForAnimating` (page 107)
  Overridden to return the run-loop modes that the receiver uses to run the animation timer in.
- `setAnimationCurve:` (page 108)
  Sets the receiver's animation curve.
- `animationCurve` (page 103)
  Returns the animation curve the receiver is running under.
- `setDuration:` (page 110)
  Sets the duration of the animation to a specified number of seconds.
- `duration` (page 105)
  Returns the duration of the animation, in seconds.
- `setFrameRate:` (page 110)
  Sets the frame rate of the receiver.
- `frameRate` (page 105)
  Returns the frame rate of the animation.

Managing the Delegate

- `setDelegate:` (page 109)
  Sets the delegate of the receiver.
- `delegate` (page 105)
  Returns the delegate of the receiver.

Controlling and Monitoring an Animation

- `startAnimation` (page 111)
  Starts the animation represented by the receiver.
- `stopAnimation` (page 112)
  Stops the animation represented by the receiver.
- `isAnimating` (page 106)
  Returns a Boolean value that indicates whether the receiver is currently animating.
- `setCurrentProgress:` (page 109)
  Sets the current progress of the receiver.
- `currentProgress` (page 104)
  Returns the current progress of the receiver.
- `currentValue` (page 104)
  Returns the current value of the effect based on the current progress.

Managing Progress Marks

- `addProgressMark:` (page 102)
  Adds the progress mark to the receiver.
- `removeProgressMark:` (page 107)
  Removes progress mark from the receiver.
- `setProgressMarks:` (page 111)
  Sets the receiver's progress marks to the values specified in the passed-in array.
- `progressMarks` (page 107)
  Returns the receiver's progress marks.

Linking Animations Together

- `startWhenAnimation:reachesProgress:` (page 112)
  Starts running the animation represented by the receiver when another animation reaches a specific progress mark.
- `stopWhenAnimation:reachesProgress:` (page 113)
  Stops running the animation represented by the receiver when another animation reaches a specific progress mark.
- `clearStartAnimation` (page 103)
  Clears linkage to another animation that causes the receiver to start.
- `clearStopAnimation` (page 103)
  Clears linkage to another animation that causes the receiver to stop.

Instance Methods

addProgressMark:

Adds the progress mark to the receiver.

```
- (void)addProgressMark:(NSAnimationProgress)progressMark
```

Parameters

progressMark

A `float` value (typed as `NSAnimationProgress`) between 0.0 and 1.0. Values outside that range are pinned to 0.0 or 1.0, whichever is nearest.

Discussion

A progress mark represents a percentage of the animation completed. When the animation reaches a progress mark, an `animation:didReachProgressMark:` (page 3560) message is sent to the delegate and an `NSAnimationProgressMarkNotification` (page 116) is broadcast to all observers. You might receive multiple notifications of progress advances over multiple marks.

Availability

Available in Mac OS X v10.4 and later.

See Also

- `currentProgress` (page 104)
- `removeProgressMark:` (page 107)

Declared In

`NSAnimation.h`

animationBlockingMode

Returns the blocking mode the receiver is next scheduled to run under.

```
- (NSAnimationBlockingMode)animationBlockingMode
```

Return Value

A constant representing the receiver's blocking mode. See "NSAnimationBlockingMode" (page 114) for valid values.

Discussion

The animation can run in blocking mode or non-blocking mode; non-blocking mode can be either on the main thread or on a separate thread. The default mode is `NSAnimationBlocking`.

Availability

Available in Mac OS X v10.4 and later.

See Also

- `setAnimationBlockingMode:` (page 108)

Declared In

`NSAnimation.h`

animationCurve

Returns the animation curve the receiver is running under.

```
- (NSAnimationCurve)animationCurve
```

Return Value
An `NSAnimationCurve` constant indicating the animation curve.

Discussion
The animation curve describes the relative frame rate over the course of the animation. See "NSAnimationCurve" (page 113) for valid `NSAnimationCurve` constants.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `setAnimationCurve:` (page 108)

Declared In
`NSAnimation.h`

clearStartAnimation

Clears linkage to another animation that causes the receiver to start.

```
- (void)clearStartAnimation
```

Discussion
The linkage to the other animation is made with `startWhenAnimation:reachesProgress:` (page 112).

Availability
Available in Mac OS X v10.4 and later.

See Also
- `startAnimation` (page 111)

Declared In
`NSAnimation.h`

clearStopAnimation

Clears linkage to another animation that causes the receiver to stop.

```
- (void)clearStopAnimation
```

Discussion
The linkage to the other animation is made with `stopWhenAnimation:reachesProgress:` (page 113).

Availability
Available in Mac OS X v10.4 and later.

See Also
- `stopAnimation` (page 112)

Declared In
NSAnimation.h

currentProgress

Returns the current progress of the receiver.

```
- (NSAnimationProgress)currentProgress
```

Return Value
A float value typed as NSAnimationProgress that indicates the current progress of the animation.

Discussion
The current progress is a value between 0.0 and 1.0 that represents the percentage of the animation currently completed.

Availability
Available in Mac OS X v10.4 and later.

See Also
- setCurrentProgress: (page 109)

Declared In
NSAnimation.h

currentValue

Returns the current value of the effect based on the current progress.

```
- (float)currentValue
```

Return Value
A float value that indicates the current value of the animation effect.

Discussion
NSAnimation gets the current value from the delegate in animation:valueForProgress: (page 3560) or, if that method is not implemented, computes it from the current progress by factoring in the animation curve. NSAnimation itself does not invoke this method currently. Instances of NSAnimation subclasses or other objects can invoke this method on a periodic basis to get the current value.

Although this method has no corresponding setter method, those NSAnimation subclasses may override this method to return a custom curve value instead of implementing animation:valueForProgress: (page 3560), thereby saving on the overhead of using a delegate. The current value can be less than 0.0 or greater than 1.0. For example, if you make the value greater than 1.0 you can achieve a "rubber effect" where the size of a view is temporarily larger before its final size.

Availability
Available in Mac OS X v10.4 and later.

See Also
- currentProgress (page 104)
- setAnimationCurve: (page 108)

Declared In
NSAnimation.h

delegate

Returns the delegate of the receiver.

```
- (id < NSAnimationDelegate >)delegate
```

Return Value
The receiver's delegate.

Availability
Available in Mac OS X v10.4 and later.

See Also
- setDelegate: (page 109)

Declared In
NSAnimation.h

duration

Returns the duration of the animation, in seconds.

```
- (NSTimeInterval)duration
```

Return Value
An NSTimeInterval value indicating the duration.

Availability
Available in Mac OS X v10.4 and later.

See Also
- setDuration: (page 110)

Declared In
NSAnimation.h

frameRate

Returns the frame rate of the animation.

```
- (float)frameRate
```

Discussion
The frame rate is the number of updates per second. It is not guaranteed to be accurate because of differences between systems on the time needed to process a frame.

Availability
Available in Mac OS X v10.4 and later.

Declared In
NSAnimation.h

initWithDuration:animationCurve:

Returns an NSAnimation object initialized with the specified duration and animation-curve values.

```
- (id)initWithDuration:(NSTimeInterval)duration
    animationCurve:(NSAnimationCurve)animationCurve
```

Parameters

duration

The number of seconds over which the animation occurs. Specifying a negative number raises an exception.

animationCurve

An NSAnimationCurve constant that describes the relative speed of the animation over its course; if it is zero, the default curve (NSAnimationEaseInOut) is used.

Return Value
An initialized NSAnimation instance. Returns nil if the object could not be initialized.

Discussion
You can always later change the duration of an NSAnimation object by sending it a setDuration: (page 110) message, even while the animation is running. See "Constants" for descriptions of the NSAnimationCurve constants.

Availability
Available in Mac OS X v10.4 and later.

Related Sample Code
Reducer

Declared In
NSAnimation.h

isAnimating

Returns a Boolean value that indicates whether the receiver is currently animating.

```
- (BOOL)isAnimating
```

Return Value
YES if the receiver is animating, NO otherwise.

Availability
Available in Mac OS X v10.4 and later.

Declared In
NSAnimation.h

progressMarks

Returns the receiver's progress marks.

```
- (NSArray *)progressMarks
```

Return Value
An array of `NSNumber` objects, each encapsulating a `float` value (typed as `NSAnimationProgress`) that represents a current progress mark. If the receiver has no progress marks, an empty array is returned.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `addProgressMark:` (page 102)
- `setProgressMarks:` (page 111)

Declared In
`NSAnimation.h`

removeProgressMark:

Removes progress mark from the receiver.

```
- (void)removeProgressMark:(NSAnimationProgress)progressMark
```

Parameters
progressMark
A `float` value (typed as `NSAnimationProgress`) that indicates the portion of the animation completed. The value should correspond to a progress mark set with addProgressMark: (page 102) or setProgressMarks: (page 111).

Availability
Available in Mac OS X v10.4 and later.

See Also
- `addProgressMark:` (page 102)

Declared In
`NSAnimation.h`

runLoopModesForAnimating

Overridden to return the run-loop modes that the receiver uses to run the animation timer in.

```
- (NSArray *)runLoopModesForAnimating
```

Return Value
An array of constants that indicate the modes the animation's run loop can be in. By default, the method returns `nil`, which indicates that the animation can be run in default, modal, or event-tracking mode. See the `NSRunLoop` class reference for information about the mode constants

Discussion
The value returned from this method is ignored if the animation blocking mode is something other than `NSAnimationNonblocking`.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- setAnimationBlockingMode:` (page 108)

Declared In
`NSAnimation.h`

setAnimationBlockingMode:

Sets the blocking mode of the receiver.

```
- (void)setAnimationBlockingMode:(NSAnimationBlockingMode)animationBlockingMode
```

Parameters

animationBlockingMode

A constant representing the blocking mode the animation is next scheduled to run under. See "NSAnimationBlockingMode" (page 114) for valid values.

If the constant is `NSAnimationNonblocking`, the animation runs in the main thread in one of the standard run-loop modes or in a mode returned from `runLoopModesForAnimating` (page 107). If *animationBlockingMode* is `NSAnimationNonblockingThreaded`, a new thread is spawned to run the animation.

Discussion
The default mode is `NSAnimationBlocking`, which means that the animation runs on the main thread in a custom run-loop mode that blocks user events. The new blocking mode takes effect the next time the receiver is started and has no effect on an animation underway.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- animationBlockingMode` (page 102)

Related Sample Code
From A View to A Movie
Reducer

Declared In
`NSAnimation.h`

setAnimationCurve:

Sets the receiver's animation curve.

```
- (void)setAnimationCurve:(NSAnimationCurve)curve
```

Parameters

curve

An `NSAnimationCurve` constant specifying the animation curve. Invalid values raise an exception.

Discussion

The animation curve describes the relative frame rate over the course of the animation; predefined curves are linear, ease in (slow down near end), ease out (slowly speed up at start), and ease in-ease out (S-curve). Sending this message affects animations already in progress. The `NSAnimationCurve` setting is ignored if the delegate implements `animation:valueForProgress:` (page 3560). See "NSAnimationCurve" (page 113) for valid `NSAnimationCurve` constants.

Availability

Available in Mac OS X v10.4 and later.

Related Sample Code

From A View to A Movie

QTCoreVideo301

Declared In

`NSAnimation.h`

setCurrentProgress:

Sets the current progress of the receiver.

```
- (void)setCurrentProgress:(NSAnimationProgress)progress
```

Parameters

progress

A `float` value typed as `NSAnimationProgress` that specifies the current progress of the animation. This value should be between 0.0 and 1.0; values that are out of range are pinned to 0.0 or 1.0, whichever is closer.

Discussion

You can use this method to adjust the progress of a running animation. The `NSAnimation` class invokes this method while the animation is running to change the progress for the next frame. Subclasses can override this method to get the latest value and perform their action with it, possibly in a secondary thread. Alternatively, you can implement the delegation method `animation:valueForProgress:` (page 3560).

Availability

Available in Mac OS X v10.4 and later.

See Also

`- currentProgress` (page 104)

Declared In

`NSAnimation.h`

setDelegate:

Sets the delegate of the receiver.

```
- (void)setDelegate:(id < NSAnimationDelegate >)delegate
```

Parameters

delegate

The delegate for the receiver.

Availability
Available in Mac OS X v10.4 and later.

See Also
- delegate (page 105)

Declared In
NSAnimation.h

setDuration:

Sets the duration of the animation to a specified number of seconds.

```
- (void)setDuration:(NSTimeInterval)duration
```

Parameters

duration

An NSTimeInterval value specifying the duration of the animation. Negative values raise an exception.

Discussion
You can change the duration of an animation while it is running. However, setting the duration of a running animation to an interval shorter than the current progress ends the animation.

Availability
Available in Mac OS X v10.4 and later.

See Also
- duration (page 105)

Related Sample Code
From A View to A Movie
QTCoreVideo301
Reducer

Declared In
NSAnimation.h

setFrameRate:

Sets the frame rate of the receiver.

```
- (void)setFrameRate:(float)framesPerSecond
```

Parameters

framesPerSecond

A float value specifying the number of updates per second for the animation. This value must be positive; negative values raise an exception. A frame rate of 0.0 means to go as fast as possible.

Discussion
The frame rate is not guaranteed due to differences among systems for the time needed to process a frame. You can change the frame rate while an animation is running and the new value is used at the next frame. The default frame rate is set to a reasonable value (which is subject to future change).

Availability
Available in Mac OS X v10.4 and later.

See Also
- `frameRate` (page 105)

Declared In
`NSAnimation.h`

setProgressMarks:

Sets the receiver's progress marks to the values specified in the passed-in array.

```
- (void)setProgressMarks:(NSArray *)progressMarks
```

Parameters

progressMarks
An array of `NSNumber` objects, each encapsulating a `float` value (typed as `NSAnimationProgress`) that represents a current progress mark. Passing in `nil` clears all progress marks.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `progressMarks` (page 107)

Declared In
`NSAnimation.h`

startAnimation

Starts the animation represented by the receiver.

```
- (void)startAnimation
```

Discussion
The receiver retains itself and is then autoreleased at the end of the animation or when it receives `stopAnimation` (page 112). If the blocking mode is `NSAnimationBlocking`, the method only returns after the animation has completed or the delegate sends it `stopAnimation` (page 112). If the receiver has a progress of 1.0, it starts again at 0.0.

Availability
Available in Mac OS X v10.4 and later.

Declared In
NSAnimation.h

startWhenAnimation:reachesProgress:

Starts running the animation represented by the receiver when another animation reaches a specific progress mark.

```
- (void)startWhenAnimation:(NSAnimation *)animation
    reachesProgress:(NSAnimationProgress)startProgress
```

Parameters

animation
The other NSAnimation object with which the receiver is linked.

startProgress
A float value (typed as NSAnimationProgress) that specifies a progress mark of the other animation.

Discussion
This method links the running of two animations together. You can set only one NSAnimation object as a start animation and one as a stop animation at any one time. Setting a new start animation removes any animation previously set.

Availability
Available in Mac OS X v10.4 and later.

See Also
- clearStartAnimation (page 103)
- startAnimation (page 111)
- stopWhenAnimation:reachesProgress: (page 113)

Declared In
NSAnimation.h

stopAnimation

Stops the animation represented by the receiver.

```
- (void)stopAnimation
```

Discussion
The current progress of the receiver is not reset. When this method is sent to instances of NSViewAnimation (a subclass of NSAnimation) the receiver moves to the end frame location.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `startAnimation` (page 111)
- `stopWhenAnimation:reachesProgress:` (page 113)

Related Sample Code
From A View to A Movie

Declared In
`NSAnimation.h`

stopWhenAnimation:reachesProgress:

Stops running the animation represented by the receiver when another animation reaches a specific progress mark.

```
- (void)stopWhenAnimation:(NSAnimation *)animation
    reachesProgress:(NSAnimationProgress)stopProgress
```

Parameters

animation
The other `NSAnimation` object with which the receiver is linked.

stopProgress
A `float` value (typed as `NSAnimationProgress`) that specifies a progress mark of the other animation.

Discussion
This method links the running of two animations together. You can set only one `NSAnimation` object as a start animation and one as a stop animation at any one time. Setting a new stop animation removes any animation previously set.

Availability
Available in Mac OS X v10.4 and later.

- `startWhenAnimation:reachesProgress:` (page 112)
- `stopAnimation` (page 112)

Declared In
`NSAnimation.h`

Constants

NSAnimationCurve

These constants describe the curve of an animation—that is, the relative speed of an animation from start to finish.

```
enum {
    NSAnimationEaseInOut,
    NSAnimationEaseIn,
    NSAnimationEaseOut,
    NSAnimationLinear
};
typedef NSUInteger NSAnimationCurve;
```

Constants

`NSAnimationEaseInOut`

Describes an S-curve in which the animation slowly speeds up and then slows down near the end of the animation. This constant is the default.

Available in Mac OS X v10.4 and later.

Declared in `NSAnimation.h`.

`NSAnimationEaseIn`

Describes an animation that slows down as it reaches the end.

Available in Mac OS X v10.4 and later.

Declared in `NSAnimation.h`.

`NSAnimationEaseOut`

Describes an animation that slowly speeds up from the start.

Available in Mac OS X v10.4 and later.

Declared in `NSAnimation.h`.

`NSAnimationLinear`

Describes an animation in which there is no change in frame rate.

Available in Mac OS X v10.4 and later.

Declared in `NSAnimation.h`.

Discussion

You initialize an `NSAnimation` object using one of these constants with `initWithDuration:animationCurve:` (page 106) and you can set it thereafter with `setAnimationCurve:` (page 108).

NSAnimationBlockingMode

These constants indicate the blocking mode of an `NSAnimation` object when it is running.

```
enum {
    NSAnimationBlocking,
    NSAnimationNonblocking,
    NSAnimationNonblockingThreaded
};
typedef NSUInteger NSAnimationBlockingMode;
```

Constants

`NSAnimationBlocking`

Requests the animation to run in the main thread in a custom run-loop mode that blocks user input.

This is the default.

Available in Mac OS X v10.4 and later.

Declared in `NSAnimation.h`.

`NSAnimationNonblocking`
Requests the animation to run in a standard or specified run-loop mode that allows user input.

Available in Mac OS X v10.4 and later.

Declared in `NSAnimation.h`.

`NSAnimationNonblockingThreaded`
Requests the animation to run in a separate thread that is spawned by the `NSAnimation` object.

The secondary thread has its own run loop.

Available in Mac OS X v10.4 and later.

Declared in `NSAnimation.h`.

Discussion
You specify one of these constants in `setAnimationBlockingMode:` (page 108).

NSAnimationProgress

`NSAnimationProgress` is returned in the userInfo dictionary of an `NSAnimationProgressMarkNotification` (page 116) notification. It will have a value between 0.0 and 1.0

```
typedef float NSAnimationProgress;
```

Availability
Available in Mac OS X v10.4 and later.

Declared In
`NSAnimation.h`

Animation action triggers

These constants are used by the `NSAnimatablePropertyContainer` methods `defaultAnimationForKey:` (page 3554) and `animationForKey:` (page 3555).

```
NSString *NSAnimationTriggerOrderIn;
NSString *NSAnimationTriggerOrderOut;
```

Constants
`NSAnimationTriggerOrderIn`
The trigger that represents the action taken when a view becomes visible, either as a result of being inserted into the visible view hierarchy or the view is no longer set as hidden.

Available in Mac OS X v10.5 and later.

Declared in `NSAnimation.h`.

`NSAnimationTriggerOrderOut`
The trigger that represents the action taken when the view is either removed from the view hierarchy or is hidden.

Available in Mac OS X v10.5 and later.

Declared in `NSAnimation.h`.

NSAnimationProgressMark Notification Key

This constant is returned in the userInfo dictionary of the `NSAnimationProgressMarkNotification` (page 116) notification.

```
NSString*    NSAnimationProgressMark;
```

Constants

`NSAnimationProgressMark`

Contains the value of an `NSAnimationProgress` (page 115) as an `NSNumber` instance that indicates the current animation progress. The value will be between 0.0 and 1.0.

Available in Mac OS X v10.4 and later.

Declared in `NSAnimation.h`.

Notifications

NSAnimationProgressMarkNotification

Posted when the current progress of a running animation reaches one of its progress marks.

The notification object is a running `NSAnimation` object. The `userInfo` dictionary contains the current progress mark, accessed via the key `NSAnimationProgressMark`.

Availability

Available in Mac OS X v10.4 and later.

Overview

`NSAnimationContext` is analogous to `CATransaction` and are similar in overall concept to `NSGraphicsContext`. Each thread maintains its own stack of nestable `NSAnimationContext` instances, with each new instance initialized as a copy of the instance below (so, inheriting its current properties).

Multiple `NSAnimationContext` instances can be nested, allowing a given block of code to initiate animations using its own specified duration without affecting animations initiated by surrounding code.

```
[NSAnimationContext beginGrouping];
// Animate enclosed operations with a duration of 1 second
[[NSAnimationContext currentContext] setDuration:1.0];
[[aView animator] setFrame:newFrame];
...
    [NSAnimationContext beginGrouping];
    // Animate alpha fades with half-second duration
    [[NSAnimationContext currentContext] setDuration:0.5];
    [[aView animator] setAlphaValue:0.75];
    [[bView animator] setAlphaValue:0.75];
    [NSAnimationContext endGrouping];
...
// Will animate with a duration of 1 second
[[bView animator] setFrame:secondFrame];
[NSAnimationContext endGrouping];
```

Tasks

Grouping Transactions

`+ beginGrouping` (page 118)
Creates a new animation grouping.

`+ endGrouping` (page 119)
Ends the current animation grouping.

Getting the Current Animation Context

`+ currentContext` (page 119)
Returns the current animation context.

Modifying the Animation Duration

`- setDuration:` (page 120)
Sets the duration used by animations created as a result of setting new values for an animatable property.

`- duration` (page 119)
Returns the duration used when animating object properties that support animation.

Class Methods

beginGrouping

Creates a new animation grouping.

```
+ (void)beginGrouping
```

Availability
Available in Mac OS X v10.5 and later.

`NSAnimationContext.h`

Instance Methods

duration

Returns the duration used when animating object properties that support animation.

```
- (NSTimeInterval)duration
```

Return Value
The duration in seconds.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSAnimationContext.h`

setDuration:

Sets the duration used by animations created as a result of setting new values for an animatable property.

```
- (void)setDuration:(NSTimeInterval)duration
```

Parameters

duration
The duration in seconds.

Discussion
Any animations that occur as a result of setting the values of animatable properties in the current context will run for this duration.

Availability
Available in Mac OS X v10.5 and later.

NSAppleScript Additions Reference

Inherits from	NSObject
Framework	/System/Library/Frameworks/AppKit.framework
Declared in	AppKit/NSAppleScriptExtensions.h
Companion guide	Cocoa Scripting Guide

Overview

The Application Kit adds a method to the Foundation Framework's `NSAppleScript` class to handle rich text source. This method becomes part of the `NSAppleScript` class only for those applications that use the Application Kit.

For more information, see `NSAppleScript` in the *Foundation Framework API Reference*.

Tasks

Obtaining Source

`- richTextSource` (page 121)
Returns the syntax-highlighted source code of the receiver if the receiver has been compiled and its source code is available.

Instance Methods

richTextSource

Returns the syntax-highlighted source code of the receiver if the receiver has been compiled and its source code is available.

```
- (NSAttributedString *)richTextSource
```

Discussion
Returns `nil` otherwise. It is possible for an instance of `NSAppleScript` that has been instantiated with `initWithContentsOfURL:error:` to be a script for which the source code is not available, but is nonetheless executable.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`NSAppleScriptExtensions.h`

Class at a Glance

An `NSApplication` object manages an application's main event loop in addition to resources used by all of that application's objects.

Principal Attributes

- Delegate
- Key window

- Display context
- List of windows
- Main window

Commonly Used Methods

`keyWindow` (page 150)
Returns an `NSWindow` object representing the key window.

`mainWindow` (page 151)
Returns the application's main window.

`registerServicesMenuSendTypes:returnTypes:` (page 158)
Specifies which services are valid for this application.

`runModalForWindow:` (page 163)
Runs a modal event loop for the specified `NSWindow` object.

Overview

The `NSApplication` class provides the central framework for your application's execution.

Every application must have exactly one instance of `NSApplication` (or a subclass of `NSApplication`). Your program's `main()` function should create this instance by invoking the `sharedApplication` (page 135) class method. After creating the `NSApplication` object, the `main()` function should load your application's main nib file and then start the event loop by sending the `NSApplication` object a `run` (page 162) message. If you create an Application project in Xcode, this `main()` function is created for you. The `main()` function Xcode creates begins by calling a function named `NSApplicationMain()`, which is functionally similar to the following:

```
void NSApplicationMain(int argc, char *argv[]) {
    [NSApplication sharedApplication];
    [NSBundle loadNibNamed:@"myMain" owner:NSApp];
    [NSApp run];
}
```

The `sharedApplication` (page 135) class method initializes the display environment and connects your program to the window server and the display server. The `NSApplication` object maintains a list of all the `NSWindow` objects the application uses, so it can retrieve any of the application's `NSView` objects. `sharedApplication` (page 135) also initializes the global variable `NSApp`, which you use to retrieve the `NSApplication` instance. `sharedApplication` (page 135) only performs the initialization once; if you invoke it more than once, it simply returns the `NSApplication` object it created previously.

`NSApplication` performs the important task of receiving events from the window server and distributing them to the proper `NSResponder` objects. `NSApp` translates an event into an `NSEvent` object, then forwards the `NSEvent` object to the affected `NSWindow` object. All keyboard and mouse events go directly to the `NSWindow` object associated with the event. The only exception to this rule is if the Command key is pressed when a key-down event occurs; in this case, every `NSWindow` object has an opportunity to respond to the event. When an `NSWindow` object receives an `NSEvent` object from `NSApp`, it distributes it to the objects in its view hierarchy.

NSApplication is also responsible for dispatching certain Apple events received by the application. For example, Mac OS X sends Apple events to your application at various times, such as when the application is launched or reopened. NSApplication installs Apple event handlers to handle these events by sending a message to the appropriate object. You can also use the NSAppleEventManager class to register your own Apple event handlers. The applicationWillFinishLaunching: (page 3578) method is generally the best place to do so. For more information on how events are handled and how you can modify the default behavior, including information on working with Apple events in scriptable applications, see How Cocoa Applications Handle Apple Events in *Cocoa Scripting Guide*.

The NSApplication class sets up autorelease pools (instances of the NSAutoreleasePool class) during initialization and inside the event loop—specifically, within its initialization (or sharedApplication (page 135)) and run (page 162) methods. Similarly, the methods the Application Kit adds to NSBundle employ autorelease pools during the loading of nib files. These autorelease pools aren't accessible outside the scope of the respective NSApplication and NSBundle methods. Typically, an application creates objects either while the event loop is running or by loading objects from nib files, so this lack of access usually isn't a problem. However, if you do need to use Cocoa classes within the main() function itself (other than to load nib files or to instantiate NSApplication), you should create an autorelease pool before using the classes and then release the pool when you're done. For more information, see NSAutoreleasePool in the *Foundation Framework Reference*.

The Delegate and Notifications

You can assign a delegate to NSApp. The delegate responds to certain messages on behalf of NSApp. Some of these messages, such as application:openFile: (page 3566), ask the delegate to perform an action. Another message, applicationShouldTerminate: (page 3576), lets the delegate determine whether the application should be allowed to quit. The NSApplication class sends these messages directly to its delegate.

The NSApp also posts notifications to the application's default notification center. Any object may register to receive one or more of the notifications posted by NSApp by sending the message addObserver:selector:name:object: to the default notification center (an instance of the NSNotificationCenter class). The delegate of NSApp is automatically registered to receive these notifications if it implements certain delegate methods. For example, NSApp posts notifications when it is about to be done launching the application and when it is done launching the application (NSApplicationWillFinishLaunchingNotification (page 195) and NSApplicationDidFinishLaunchingNotification (page 194)). The delegate has an opportunity to respond to these notifications by implementing the methods applicationWillFinishLaunching: (page 3578) and applicationDidFinishLaunching: (page 3571). If the delegate wants to be informed of both events, it implements both methods. If it needs to know only when the application is finished launching, it implements only applicationDidFinishLaunching: (page 3571).

System Services

NSApplication interacts with the system services architecture to provide services to your application through the Services menu.

Subclassing Notes

You rarely should find a real need to create a custom `NSApplication` subclass. Unlike some object-oriented libraries, Cocoa does not require you to create a custom application class to customize application behavior. Instead it gives you many other ways to customize an application. This section discusses both some of the possible reasons to subclass `NSApplication` and some of the reasons *not* to subclass `NSApplication`.

To use a custom subclass of `NSApplication`, simply send `sharedApplication` (page 135) to your subclass rather than directly to `NSApplication`. If you create your application in Xcode, you can accomplish this by setting your custom application class to be the principal class. In Xcode, double-click the application target in the Groups and Files list to open the Info window for the target. Then display the Properties pane of the window and replace "NSApplication" in the Principal Class field with the name of your custom class. The `NSApplicationMain` function sends `sharedApplication` (page 135) to the principal class to obtain the global application instance (`NSApp`)—which in this case will be an instance of your custom subclass of `NSApplication`.

Important: Many Application Kit classes rely on the `NSApplication` class and may not work properly until this class is fully initialized. As a result, you should not, for example, attempt to invoke methods of other Application Kit classes from an initialization method of an `NSApplication` subclass.

Methods to Override

Generally, you subclass `NSApplication` to provide your own special responses to messages that are routinely sent to the global application object (`NSApp`). `NSApplication` does not have primitive methods in the sense of methods that you must override in your subclass. Here are four methods that are possible candidates for overriding:

- Override `run` (page 162) if you want the application to manage the main event loop differently than it does by default. (This a critical and complex task, however, that you should only attempt with good reason.)
- Override `sendEvent:` (page 167) if you want to change how events are dispatched or perform some special event processing.
- Override `requestUserAttention:` (page 161) if you want to modify how your application attracts the attention of the user (for example, offering an alternative to the bouncing application icon in the Dock).
- Override `targetForAction:` (page 174) to substitute another object for the target of an action message.

Special Considerations

The global application object uses autorelease pools in its `run` (page 162) method; if you override this method, you'll need to create your own autorelease pools.

Do not override `sharedApplication` (page 135). The default implementation, which is essential to application behavior, is too complex to duplicate on your own.

Alternatives to Subclassing

`NSApplication` defines over twenty delegate methods that offer opportunities for modifying specific aspects of application behavior. Instead of making a custom subclass of `NSApplication`, your application delegate may be able to implement one or more of these methods to accomplish your design goals. In general, a better design than subclassing `NSApplication` is to put the code that expresses your application's special behavior into one or more custom objects called controllers. Methods defined in your controllers can be invoked from a small dispatcher object without being closely tied to the global application object. For more about application architectures, see Cocoa Design Patterns and The Core Application Architecture on Mac OS X.

Tasks

Getting the Application

`+ sharedApplication` (page 135)
Returns the application instance, creating it if it doesn't exist yet.

Configuring Applications

`- applicationIconImage` (page 138)
Returns the image used for the receiver's icon.

`- setApplicationIconImage:` (page 168)
Sets the receiver's icon to the specified image.

`- delegate` (page 144)
Returns the receiver's delegate.

`- setDelegate:` (page 169)
Makes the given object the receiver's delegate.

Launching Applications

`- finishLaunching` (page 147)
Activates the receiver, opens any files specified by the `NSOpen` user default, and unhighlights the application's icon.

Terminating Applications

`- terminate:` (page 176)
Terminates the receiver.

`- replyToApplicationShouldTerminate:` (page 160)
Responds to `NSTerminateLater` once the application knows whether it can terminate.

Managing Active Status

- `isActive` (page 149)
  Returns a Boolean value indicating whether this is the active application.
- `activateIgnoringOtherApps:` (page 136)
  Makes the receiver the active application.
- `deactivate` (page 143)
  Deactivates the receiver.

Hiding Applications

- `hideOtherApplications:` (page 148)
  Hides all applications, except the receiver.
- `unhideAllApplications:` (page 178)
  Unhides all applications, including the receiver.

Managing the Event Loop

- `isRunning` (page 150)
  Returns a Boolean value indicating whether the main event loop is running.
- `run` (page 162)
  Starts the main event loop.
- `stop:` (page 173)
  Stops the main event loop.
- `runModalForWindow:` (page 163)
  Starts a modal event loop for a given window.
- `stopModal` (page 174)
  Stops a modal event loop.
- `stopModalWithCode:` (page 174)
  Stops a modal event loop, allowing you to return a custom result code.
- `abortModal` (page 135)
  Aborts the event loop started by `runModalForWindow:` (page 163) or `runModalSession:` (page 164).
- `beginModalSessionForWindow:` (page 139)
  Sets up a modal session with the given window and returns an `NSModalSession` structure representing the session.
- `runModalSession:` (page 164)
  Runs a given modal session, as defined in a previous invocation of `beginModalSessionForWindow:`.
- `modalWindow` (page 153)
  Returns the modal window that the receiver is displaying.
- `endModalSession:` (page 146)
  Finishes a modal session.
- `sendEvent:` (page 167)
  Dispatches an event to other objects.

Handling Events

- `currentEvent` (page 142)
  Returns the current event, the last event the receiver retrieved from the event queue.
- `nextEventMatchingMask:untilDate:inMode:dequeue:` (page 153)
  Returns the next event matching a given mask, or `nil` if no such event is found before a specified expiration date.
- `discardEventsMatchingMask:beforeEvent:` (page 144)
  Removes all events matching the given mask and generated before the specified event.

Posting Events

- `postEvent:atStart:` (page 157)
  Adds a given event to the receiver's event queue.

Managing Sheets

- `beginSheet:modalForWindow:modalDelegate:didEndSelector:contextInfo:` (page 140)
  Starts a document modal session.
- `endSheet:` (page 146)
  Ends a document modal session by specifying the sheet window.
- `endSheet:returnCode:` (page 146)
  Ends a document modal session by specifying the sheet window.

Managing Windows

- `keyWindow` (page 150)
  Returns the window that currently receives keyboard events.
- `mainWindow` (page 151)
  Returns the main window.
- `windowWithWindowNumber:` (page 182)
  Returns the window corresponding to the specified window number.
- `windows` (page 181)
  Returns an array containing the receiver's window objects.
- `makeWindowsPerform:inOrder:` (page 152)
  Sends the specified message to each of the application's window objects until one returns a non-`nil` value.

Minimizing Windows

- `miniaturizeAll:` (page 152)
  Miniaturizes all the receiver's windows.

User Interface Layout Direction

- `userInterfaceLayoutDirection` (page 180)
  Returns the layout direction of the user interface.

Hiding Windows

- `isHidden` (page 150)
  Returns a Boolean value indicating whether the receiver is hidden.
- `hide:` (page 148)
  Hides all the receiver's windows, and the next application in line is activated.
- `unhide:` (page 177)
  Restores hidden windows to the screen and makes the receiver active.
- `unhideWithoutActivation` (page 178)
  Restores hidden windows without activating their owner (the receiver).

Updating Windows

- `updateWindows` (page 179)
  Sends an `update` (page 3405) message to each onscreen window.
- `setWindowsNeedUpdate:` (page 172)
  Sets whether the receiver's windows need updating when the receiver has finished processing the current event.

Managing Window Layers

- `preventWindowOrdering` (page 158)
  Suppresses the usual window ordering in handling the most recent mouse-down event.
- `arrangeInFront:` (page 138)
  Arranges windows listed in the Window menu in front of all other windows.

Accessing the Main Menu

- `mainMenu` (page 151)
  Returns the receiver's main menu.
- `setMainMenu:` (page 170)
  Makes the given menu the receiver's main menu.

Managing the Window Menu

- `windowsMenu` (page 181)
  Returns the Window menu of the application.

- `setWindowsMenu:` (page 172)
  Makes the given menu the receiver's Window menu.
- `addWindowsItem:title:filename:` (page 137)
  Adds an item to the Window menu for a given window.
- `changeWindowsItem:title:filename:` (page 141)
  Changes the item for a given window in the Window menu to a given string.
- `removeWindowsItem:` (page 160)
  Removes the Window menu item for a given window.
- `updateWindowsItem:` (page 179)
  Updates the Window menu item for a given window to reflect the edited status of that window.

Accessing the Dock Tile

- `dockTile` (page 145)
  Returns the application's Dock tile.

Managing the Services Menu

- `registerServicesMenuSendTypes:returnTypes:` (page 158)
  Registers the pasteboard types the receiver can send and receive in response to service requests.
- `servicesMenu` (page 167)
  Returns the Services menu.
- `setServicesMenu:` (page 171)
  Makes a given menu the receiver's Services menu.

Providing Services

- `validRequestorForSendType:returnType:` (page 180)
  Indicates whether the receiver can send and receive the specified pasteboard types.
- `servicesProvider` (page 167)
  Returns the object that provides the services the receiver advertises in the Services menu of other applications.
- `setServicesProvider:` (page 171)
  Registers a given object as the service provider.

Managing Panels

- `orderFrontColorPanel:` (page 155)
  Brings up the color panel, an instance of `NSColorPanel`.
- `orderFrontStandardAboutPanel:` (page 156)
  Displays a standard About window.
- `orderFrontStandardAboutPanelWithOptions:` (page 156)
  Displays a standard About window with information from a given options dictionary.

- `orderFrontCharacterPalette:` (page 155)
  Opens the character palette.
- `runPageLayout:` (page 165)
  Displays the receiver's page layout panel, an instance of `NSPageLayout`.

Displaying Help

- `showHelp:` (page 172)
  If your project is properly registered, and the necessary keys have been set in the property list, this method launches Help Viewer and displays the first page of your application's help book.
- `activateContextHelpMode:` (page 136)
  Places the receiver in context-sensitive help mode.
- `helpMenu` (page 147)
  Returns the help menu used by the application.
- `setHelpMenu:` (page 169)
  Sets the application's help menu.

Managing Threads

+ `detachDrawingThread:toTarget:withObject:` (page 134)
  Creates and executes a new thread based on the specified target and selector.

Posting Actions

- `tryToPerform:with:` (page 177)
  Dispatches an action message to the specified target.
- `sendAction:to:from:` (page 166)
  Sends the given action message to the given target.
- `targetForAction:` (page 174)
  Returns the object that receives the action message specified by the given selector
- `targetForAction:to:from:` (page 175)
  Finds an object that can receive the message specified by the given selector.

Drawing Windows

- `context` (page 142)
  Returns the receiver's display context.

Logging Exceptions

- `reportException:` (page 161)
  Logs a given exception by calling `NSLog()`.

Scripting

- `application:delegateHandlesKey:` (page 182) *delegate method*
  Sent by Cocoa's built-in scripting support during execution of `get` or `set` script commands to find out if the delegate can handle operations on the specified key-value key.
- `orderedDocuments` (page 154)
  Returns an array of document objects arranged according to the front-to-back ordering of their associated windows.
- `orderedWindows` (page 155)
  Returns an array of window objects arranged according to their front-to-back ordering on the screen.

Managing User Attention Requests

- `requestUserAttention:` (page 161)
  Starts a user attention request.
- `cancelUserAttentionRequest:` (page 141)
  Cancels a previous user attention request.
- `replyToOpenOrPrint:` (page 161)
  Handles errors that might occur when the user attempts to open or print files.

Keyboard Accessibility

- `isFullKeyboardAccessEnabled` (page 149)
  Returns that status of Full Keyboard Access set in the Keyboard preference pane.

Presentation Options

- `currentSystemPresentationOptions` (page 143)
  Returns the set of application presentation options that are currently in effect for the system.
- `presentationOptions` (page 158)
  Returns the presentation options that should be in effect for the system when this application is active.
- `setPresentationOptions:` (page 170)
  Sets the application presentation options to use when this application is active.

Activation Policy

- `activationPolicy` (page 137)
  Returns the application's activation policy.
- `setActivationPolicy:` (page 168)
  Attempts to modify the application's activation policy.

Deprecated

- `application:printFiles:` (page 183) *delegate method*
  (Deprecated. Use `application:printFiles:withSettings:showPrintPanels:` (page 3569) instead.)
- `beginModalSessionForWindow:relativeToWindow:` (page 140) Deprecated in Mac OS X v10.0
  (Deprecated. Use `beginSheet:modalForWindow:modalDelegate:didEndSelector:contextInfo:` (page 140) instead.)
- `runModalForWindow:relativeToWindow:` (page 163) Deprecated in Mac OS X v10.0
  (Deprecated. Use `beginSheet:modalForWindow:modalDelegate:didEndSelector:contextInfo:` (page 140) instead.)

Spotlight for Help

- `registerUserInterfaceItemSearchHandler:` (page 159)
  Register an an object that provides help data to your application.
- `searchString:inUserInterfaceItemString:searchRange:foundRange:` (page 165)
  Searches for the string in the user interface.
- `unregisterUserInterfaceItemSearchHandler:` (page 178)
  Unregister an an object that provides help data to your application.

Class Methods

detachDrawingThread:toTarget:withObject:

Creates and executes a new thread based on the specified target and selector.

```
+ (void)detachDrawingThread:(SEL)selector toTarget:(id)target withObject:(id)argument
```

Parameters

selector
The selector whose code you want to execute in the new thread.

target
The object that defines the specified selector.

argument
An optional argument you want to pass to the selector.

Discussion
This method is a convenience wrapper for the `detachNewThreadSelector:toTarget:withObject:` method of `NSThread`. This method automatically creates an `NSAutoreleasePool` object for the new thread before invoking *selector*.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSApplication.h

sharedApplication

Returns the application instance, creating it if it doesn't exist yet.

```
+ (NSApplication *)sharedApplication
```

Return Value
The shared application object.

Discussion
This method also makes a connection to the window server and completes other initialization. Your program should invoke this method as one of the first statements in `main()`; this invoking is done for you if you create your application with Xcode. To retrieve the `NSApplication` instance after it has been created, use the global variable `NSApp` or invoke this method.

Availability
Available in Mac OS X v10.0 and later.

NSApplication.h

Instance Methods

abortModal

Aborts the event loop started by `runModalForWindow:` (page 163) or `runModalSession:` (page 164).

```
- (void)abortModal
```

Discussion
When stopped with this method, `runModalForWindow:` and `runModalSession:` return `NSRunAbortedResponse`.

`abortModal` must be used instead of `stopModal` (page 174) or `stopModalWithCode:` (page 174) when you need to stop a modal event loop from anywhere other than a callout from that event loop. In other words, if you want to stop the loop in response to a user's actions within the modal window, use `stopModal`;

otherwise, use `abortModal`. For example, use `abortModal` when running in a different thread from the Application Kit's main thread or when responding to an `NSTimer` that you have added to the `NSModalPanelRunLoopMode` mode of the default `NSRunLoop`.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- endModalSession:` (page 146)

Declared In
`NSApplication.h`

activateContextHelpMode:

Places the receiver in context-sensitive help mode.

```
- (void)activateContextHelpMode:(id)sender
```

Parameters

sender
The object that sent the command.

Discussion
In this mode, the cursor becomes a question mark, and help appears for any user interface item the user clicks.

Most applications don't use this method. Instead, applications enter context-sensitive mode when the user presses the Help key. Applications exit context-sensitive help mode upon the first event after a help window is displayed.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- showHelp:` (page 172)

Declared In
`NSHelpManager.h`

activateIgnoringOtherApps:

Makes the receiver the active application.

```
- (void)activateIgnoringOtherApps:(BOOL)flag
```

Parameters

flag
If `NO`, the application is activated only if no other application is currently active. If `YES`, the application activates regardless.

Discussion
The *flag* parameter is normally set to NO. When the Finder launches an application, using a value of NO for *flag* allows the application to become active if the user waits for it to launch, but the application remains unobtrusive if the user activates another application. Regardless of the setting of *flag*, there may be a time lag before the application activates—you should not assume the application will be active immediately after sending this message.

You rarely need to invoke this method. Under most circumstances, the Application Kit takes care of proper activation. However, you might find this method useful if you implement your own methods for inter-application communication.

You don't need to send this message to make one of the application's NSWindows key. When you send a makeKeyWindow (page 3345) message to an NSWindow object, you ensure that it is the key window when the application is active.

Availability
Available in Mac OS X v10.0 and later.

See Also
- deactivate (page 143)
- isActive (page 149)

Declared In
NSApplication.h

activationPolicy

Returns the application's activation policy.

```
- (NSApplicationActivationPolicy)activationPolicy
```

Return Value
The application's current activation policy.

Availability
Available in Mac OS X v10.6 and later.

See Also
- setActivationPolicy: (page 168)

Declared In
NSApplication.h

addWindowsItem:title:filename:

Adds an item to the Window menu for a given window.

```
- (void)addWindowsItem:(NSWindow *)aWindow title:(NSString *)aString
    filename:(BOOL)isFilename
```

Parameters

aWindow

The window being added to the menu. If this window object already exists in the Window menu, this method has no effect.

aString

The string to display for the window's menu item. How the string is interpreted is dependent on the value in the *isFilename* parameter.

isFilename

If NO, *aString* appears literally in the menu; otherwise, *aString* is assumed to be a converted pathname with the name of the file preceding the path (the way the NSWindow method setTitleWithRepresentedFilename: (page 3399) shows a title)

Discussion

You rarely need to invoke this method directly because Cocoa places an item in the Window menu automatically whenever you set the title of an NSWindow object.

Availability

Available in Mac OS X v10.0 and later.

See Also

- changeWindowsItem:title:filename: (page 141)
- setTitle: (page 3398) (NSWindow)

QTAudioExtractionPanel

Declared In

NSApplication.h

applicationIconImage

Returns the image used for the receiver's icon.

```
- (NSImage *)applicationIconImage
```

Return Value

An image containing the application's icon.

Availability

Available in Mac OS X v10.0 and later.

See Also

- setApplicationIconImage: (page 168)

Declared In

NSApplication.h

arrangeInFront:

Arranges windows listed in the Window menu in front of all other windows.

```
- (void)arrangeInFront:(id)sender
```

Parameters

sender

The object that sent the command.

Discussion

Windows associated with the application but not listed in the Window menu are not ordered to the front.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `addWindowsItem:title:filename:` (page 137)
- `removeWindowsItem:` (page 160)
- `makeKeyAndOrderFront:` (page 3345) (`NSWindow`)

Declared In

`NSApplication.h`

beginModalSessionForWindow:

Sets up a modal session with the given window and returns an `NSModalSession` structure representing the session.

```
- (NSModalSession)beginModalSessionForWindow:(NSWindow *)aWindow
```

Parameters

aWindow

The window for the session.

Return Value

The `NSModalSession` structure that represents the session.

Discussion

In a modal session, the application receives mouse events only if they occur in *aWindow*. The window is made key, and if not already visible is placed onscreen using the `NSWindow` method `center` (page 3307).

The `beginModalSessionForWindow:` method only sets up the modal session. To actually run the session, use `runModalSession:` (page 164). `beginModalSessionForWindow:` should be balanced by `endModalSession:` (page 146). Make sure these two messages are sent within the same exception-handling scope. That is, if you send `beginModalSessionForWindow:` inside an `NS_DURING` construct, you must send `endModalSession:` before `NS_ENDHANDLER`.

If an exception is raised, `beginModalSessionForWindow:` arranges for proper cleanup. Do not use `NS_DURING` constructs to send an `endModalSession:` message in the event of an exception.

A loop using these methods is similar to a modal event loop run with `runModalForWindow:` (page 163), except the application can continue processing between method invocations.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSApplication.h`

beginModalSessionForWindow:relativeToWindow:

(Deprecated in Mac OS X v10.0. Use beginSheet:modalForWindow:modalDelegate:didEndSelector:contextInfo: (page 140) instead.)

```
- (NSModalSession)beginModalSessionForWindow:(NSWindow *)theWindow
    relativeToWindow:(NSWindow *)docWindow
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.0.

Declared In
NSApplication.h

beginSheet:modalForWindow:modalDelegate:didEndSelector:contextInfo:

Starts a document modal session.

```
- (void)beginSheet:(NSWindow *)sheet modalForWindow:(NSWindow *)docWindow
    modalDelegate:(id)modalDelegate didEndSelector:(SEL)didEndSelector
    contextInfo:(void *)contextInfo
```

Parameters

sheet
The window object representing the sheet you want to display.

docWindow
The window object to which you want to attach the sheet.

modalDelegate
The delegate object that defines your *didEndSelector* method. If nil, the method in *didEndSelector* is not called.

didEndSelector
An optional method to call when the sheet's modal session has ended. This method must be defined on the object in the *modalDelegate* parameter and have the following signature:

```
- (void)sheetDidEnd:(NSWindow *)sheet returnCode:(NSInteger)returnCode
contextInfo:(void *)contextInfo;
```

contextInfo
A pointer to the context info you want passed to the *didEndSelector* method when the sheet's modal session ends.

Discussion
This method runs the modal event loop for the specified sheet synchronously. It displays the sheet, makes it key, starts the run loop, and processes events for it. While the application is in the run loop, it does not respond to any other events (including mouse, keyboard, or window-close events) unless they are associated with the sheet. It also does not perform any tasks (such as firing timers) that are not associated with the modal run loop. In other words, this method consumes only enough CPU time to process events and dispatch them to the action methods associated with the modal window.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `endSheet:` (page 146)
- `endSheet:returnCode:` (page 146)

Declared In
`NSApplication.h`

cancelUserAttentionRequest:

Cancels a previous user attention request.

```
- (void)cancelUserAttentionRequest:(NSInteger)request
```

Parameters

request
The request identifier returned by the `requestUserAttention:` method.

Discussion
A request is also canceled automatically by user activation of the application.

Availability
Available in Mac OS X v10.1 and later.

See Also
- `requestUserAttention:` (page 161)

Declared In
`NSApplication.h`

changeWindowsItem:title:filename:

Changes the item for a given window in the Window menu to a given string.

```
- (void)changeWindowsItem:(NSWindow *)aWindow title:(NSString *)aString
    filename:(BOOL)isFilename
```

Parameters

aWindow
The window whose title you want to change in the Window menu. If *aWindow* is not in the Window menu, this method adds it.

aString
The string to display for the window's menu item. How the string is interpreted is dependent on the value in the *isFilename* parameter.

isFilename
If NO, *aString* appears literally in the menu; otherwise, *aString* is assumed to be a converted pathname with the name of the file preceding the path (the way the NSWindow method setTitleWithRepresentedFilename: (page 3399) shows a title)

Availability
Available in Mac OS X v10.0 and later.

See Also
- addWindowsItem:title:filename: (page 137)
- removeWindowsItem: (page 160)
- setTitle: (page 3398) (NSWindow)

Declared In
NSApplication.h

context

Returns the receiver's display context.

```
- (NSGraphicsContext *)context
```

Return Value
The current display context for the application.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSApplication.h

currentEvent

Returns the current event, the last event the receiver retrieved from the event queue.

```
- (NSEvent *)currentEvent
```

Return Value
The last event object retrieved by the application.

Discussion
NSApp receives events and forwards them to the affected NSWindow objects, which then distribute them to the objects in its view hierarchy.

Availability
Available in Mac OS X v10.0 and later.

See Also
- discardEventsMatchingMask:beforeEvent: (page 144)
- postEvent:atStart: (page 157)
- sendEvent: (page 167)

Related Sample Code
ClockControl

Declared In
`NSApplication.h`

currentSystemPresentationOptions

Returns the set of application presentation options that are currently in effect for the system.

```
- (NSApplicationPresentationOptions)currentSystemPresentationOptions
```

Return Value
The presentation options. The constants are listed in "NSApplicationPresentationOptions" (page 187) and can combined using a C bitwise OR operator.

Discussion
These are the presentation options that have been put into effect by the currently active application.

This method is key-value observable.

A client that observes `currentSystemPresentationOptions` will receive notifications when

- The client is the active application, and makes a change itself using either `setPresentationOptions:` (page 170) or `SetSystemUIMode`.
- Another application is active, and makes presentation changes of its own.
- Another application becomes active and causes the active set of presentation options to change.

Key-value observing notifications are not sent when one of the above conditions occur, but has the same set of presentation options as the previously active application.

Availability
Available in Mac OS X v10.6 and later.

See Also
- `presentationOptions` (page 158)
- `setPresentationOptions` (page 170)

Declared In
`NSApplication.h`

deactivate

Deactivates the receiver.

```
- (void)deactivate
```

Discussion
Normally, you shouldn't invoke this method—the Application Kit is responsible for proper deactivation.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `activateIgnoringOtherApps:` (page 136)

Declared In
`NSApplication.h`

delegate

Returns the receiver's delegate.

```
- (id < NSApplicationDelegate >)delegate
```

Return Value
The application delegate object.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setDelegate:` (page 169)

Declared In
`NSApplication.h`

discardEventsMatchingMask:beforeEvent:

Removes all events matching the given mask and generated before the specified event.

```
- (void)discardEventsMatchingMask:(NSUInteger)mask beforeEvent:(NSEvent *)lastEvent
```

Parameters

mask
Contains one or more flags indicating the types of events to discard. The constants section of the `NSEvent` class defines the constants you can add together to create this mask. The discussion section also lists some of the constants that are typically used.

lastEvent
A marker event that you use to indicate which events should be discarded. Events that occurred before this event are discarded but those that occurred after it are not.

Discussion
Use this method to ignore any events that occurred before a specific event. For example, suppose your application has a tracking loop that you exit when the user releases the mouse button. You could use this method, specifying `NSAnyEventMask` as the mask argument and the ending mouse-up event as the *lastEvent* argument, to discard all events that occurred while you were tracking mouse movements in your loop. Passing the mouse-up event as *lastEvent* ensures that any events that might have occurred after the mouse-up event (that is, that appear in the queue after the mouse-up event) are not discarded.

Note: Typically, you send this message to an `NSWindow` object, rather than to the application object. Discarding events for a window clears out all of the events for that window only, leaving events for other windows in place.

For the *mask* parameter, you can add together event type constants such as the following:

```
NSLeftMouseDownMask
NSLeftMouseUpMask
NSRightMouseDownMask
NSRightMouseUpMask
NSMouseMovedMask
NSLeftMouseDraggedMask
NSRightMouseDraggedMask
NSMouseEnteredMask
NSMouseExitedMask
NSKeyDownMask
NSKeyUpMask
NSFlagsChangedMask
NSPeriodicMask
NSCursorUpdateMask
NSAnyEventMask
```

This method can also be called in subthreads. Events posted in subthreads bubble up in the main thread event queue.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- nextEventMatchingMask:untilDate:inMode:dequeue:` (page 153)

Declared In
`NSApplication.h`

dockTile

Returns the application's Dock tile.

```
- (NSDockTile *)dockTile
```

Return Value
The application's Dock tile.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSApplication.h`

endModalSession:

Finishes a modal session.

```
- (void)endModalSession:(NSModalSession)session
```

Parameters

session

A modal session structure returned by a previous invocation of `beginModalSessionForWindow:`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `beginModalSessionForWindow:` (page 139)
- `runModalSession:` (page 164)

Declared In
`NSApplication.h`

endSheet:

Ends a document modal session by specifying the sheet window.

```
- (void)endSheet:(NSWindow *)sheet
```

Parameters

sheet

The sheet whose modal session you want to end.

Discussion
This method ends the modal session with the return code `NSRunStoppedResponse`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `beginSheet:modalForWindow:modalDelegate:didEndSelector:contextInfo:` (page 140)
- `endSheet:returnCode:` (page 146)

ImageClient

Declared In
`NSApplication.h`

finishLaunching

Activates the receiver, opens any files specified by the `NSOpen` user default, and unhighlights the application's icon.

```
- (void)finishLaunching
```

Discussion
The `run` (page 162) method invokes this method before it starts the event loop. When this method begins, it posts an `NSApplicationWillFinishLaunchingNotification` (page 195) to the default notification center. If you override `finishLaunching` (page 147), the subclass method should invoke the superclass method.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `applicationWillFinishLaunching:` (page 3578) (NSApplicationDelegate)
- `applicationDidFinishLaunching:` (page 3571) (NSApplicationDelegate)

Related Sample Code
GLUT

Declared In
`NSApplication.h`

helpMenu

Returns the help menu used by the application.

```
- (NSMenu *)helpMenu
```

Return Value
Returns the application's help menu.

Discussion
If `helpMenu` is `nil`, the system will append the help to an appropriate menu and will not return a reference to that menu when this method is called.,

Availability
Available in Mac OS X v10.6 and later.

See Also
`- setHelpMenu:` (page 169)

Declared In
`NSApplication.h`

hide:

Hides all the receiver's windows, and the next application in line is activated.

```
- (void)hide:(id)sender
```

Parameters

sender

The object that sent the command.

Discussion
This method is usually invoked when the user chooses Hide in the application's main menu. When this method begins, it posts an `NSApplicationWillHideNotification` (page 195) to the default notification center. When it completes successfully, it posts an `NSApplicationDidHideNotification` (page 194).

Availability
Available in Mac OS X v10.0 and later.

See Also
`- miniaturizeAll:` (page 152)
`- unhide:` (page 177)
`- unhideWithoutActivation` (page 178)

`- applicationWillHide:` (page 3578) (NSApplicationDelegate)

Declared In
`NSApplication.h`

hideOtherApplications:

Hides all applications, except the receiver.

```
- (void)hideOtherApplications:(id)sender
```

Parameters

sender

The object that sent this message.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSApplication.h

isActive

Returns a Boolean value indicating whether this is the active application.

```
- (BOOL)isActive
```

Return Value
YES if this is the active application; NO otherwise.

Availability
Available in Mac OS X v10.0 and later.

See Also
- activateIgnoringOtherApps: (page 136)
- deactivate (page 143)

Declared In
NSApplication.h

isFullKeyboardAccessEnabled

Returns that status of Full Keyboard Access set in the Keyboard preference pane.

```
- (BOOL)isFullKeyboardAccessEnabled
```

Return Value
YES if Full Keyboard Access is enabled, otherwise NO.

Discussion
You may use this status to implement your own key loop or to implement in-control tabbing behavior similar to NSTableView. Because of the nature of the preference storage, you will not be notified of changes to the key if you attempt to observe it via key-value observing; however, calling this method is fairly inexpensive, so you should always call it when you need the underlying value instead of caching it.

Availability
Available in Mac OS X v10.6 and later.

Declared In
NSApplication.h

isHidden

Returns a Boolean value indicating whether the receiver is hidden.

```
- (BOOL)isHidden
```

Return Value
`YES` if the receiver is hidden, `NO` otherwise.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `hide:` (page 148)
- `unhide:` (page 177)
- `unhideWithoutActivation` (page 178)

Declared In
`NSApplication.h`

isRunning

Returns a Boolean value indicating whether the main event loop is running.

```
- (BOOL)isRunning
```

Return Value
`YES` if the main event loop is running; `NO` otherwise.

Discussion
`NO` means the `stop:` (page 173) method was invoked.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `run` (page 162)
- `terminate:` (page 176)

Related Sample Code

Declared In
`NSApplication.h`

keyWindow

Returns the window that currently receives keyboard events.

```
- (NSWindow *)keyWindow
```

Return Value
The window object currently receiving keyboard events or `nil` if there is no key window.

Discussion
This method might return `nil` if the application's nib file hasn't finished loading yet or if the receiver is not active.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `mainWindow` (page 151)
- `isKeyWindow` (page 3338) (NSWindow)

Declared In
`NSApplication.h`

mainMenu

Returns the receiver's main menu.

```
- (NSMenu *)mainMenu
```

Return Value
The menu object representing the application's menu bar.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setMainMenu:` (page 170)

Declared In
`NSApplication.h`

mainWindow

Returns the main window.

```
- (NSWindow *)mainWindow
```

Return Value
The application's main window or `nil` if there is no main window.

Discussion
This method might return `nil` if the application's nib file hasn't finished loading, if the receiver is not active, or if the application is hidden.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `keyWindow` (page 150)
- `isMainWindow` (page 3338) (NSWindow)

Related Sample Code
PDFKitLinker2

Declared In
NSApplication.h

makeWindowsPerform:inOrder:

Sends the specified message to each of the application's window objects until one returns a non-nil value.

```
- (NSWindow *)makeWindowsPerform:(SEL)aSelector inOrder:(BOOL)flag
```

Parameters

aSelector

The selector to perform on each window. This method must not take any arguments and must return a value whose type that can be compared to nil.

flag

If YES, the *aSelector* message is sent to each of the window server's onscreen windows, going in z-order, until one returns a non-nil value. A minimized window is not considered to be onscreen for this check. If NO, the message is sent to all windows in NSApp's window list, regardless of whether or not they are onscreen. This order is unspecified.

Return Value
The window that returned a non-nil value or nil if all windows returned nil from *aSelector*.

Availability
Available in Mac OS X v10.0 and later.

See Also
- sendAction:to:from: (page 166)
- tryToPerform:with: (page 177)
- windows (page 181)

Declared In
NSApplication.h

miniaturizeAll:

Miniaturizes all the receiver's windows.

```
- (void)miniaturizeAll:(id)sender
```

Parameters

sender

The object that sent the command.

Availability
Available in Mac OS X v10.0 and later.

See Also
- hide: (page 148)

Declared In
NSApplication.h

modalWindow

Returns the modal window that the receiver is displaying.

```
- (NSWindow *)modalWindow
```

Return Value
The modal window being displayed or nil if no modal window is being displayed.

Discussion
This method returns the current standalone modal window. It does not return sheets that are attached to other windows. If you need to retrieve a sheet window, use the attachedSheet (page 3300) method of NSWindow.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSApplication.h

nextEventMatchingMask:untilDate:inMode:dequeue:

Returns the next event matching a given mask, or nil if no such event is found before a specified expiration date.

```
- (NSEvent *)nextEventMatchingMask:(NSUInteger)mask untilDate:(NSDate *)expiration
    inMode:(NSString *)mode dequeue:(BOOL)flag
```

Parameters

mask
Contains one or more flags indicating the types of events to return. The constants section of the NSEvent class defines the constants you can add together to create this mask. The discardEventsMatchingMask:beforeEvent: (page 144) method also lists several of these constants.

expiration
The expiration date for the current event request. Specifying nil for this parameter is equivalent to returning a date object using the distantPast method.

mode
The run loop mode in which to run while looking for events. The mode you specify also determines which timers and run-loop observers may fire while the application waits for the event.

flag
Specify YES if you want the event removed from the queue.

Return Value
The event object whose type matches one of the event types specified by the *mask* parameter.

Discussion
You can use this method to short circuit normal event dispatching and get your own events. For example, you may want to do this in response to a mouse-down event in order to track the mouse while its button is down. (In such an example, you would pass the appropriate event types for mouse-dragged and mouse-up events to the *mask* parameter and specify the `NSEventTrackingRunLoopMode` run loop mode.) Events that do not match one of the specified event types are left in the queue.

You can specify one of the run loop modes defined by the Application Kit or a custom run loop mode used specifically by your application. Application Kit defines the following run-loop modes:

```
NSDefaultRunLoopMode
NSEventTrackingRunLoopMode
NSModalPanelRunLoopMode
NSConnectionReplyMode
```

Availability
Available in Mac OS X v10.0 and later.

See Also
- `postEvent:atStart:` (page 157)
- `run` (page 162)
- `runModalForWindow:` (page 163)

Declared In
`NSApplication.h`

orderedDocuments

Returns an array of document objects arranged according to the front-to-back ordering of their associated windows.

```
- (NSArray *)orderedDocuments
```

Return Value
An array of `NSDocument` objects, where the position of a document is based on the front-to-back ordering of its associated window.

Discussion
This method is called during script command evaluation—for example, while finding the document in the script statement `the third rectangle in the first document`. For information on how your application can return its own array of ordered documents, see `application:delegateHandlesKey:`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `orderedWindows` (page 155)

Declared In
`NSApplicationScripting.h`

orderedWindows

Returns an array of window objects arranged according to their front-to-back ordering on the screen.

```
- (NSArray *)orderedWindows
```

Return Value
An array of `NSWindow` objects, where the position of each window in the array corresponds to the front-to-back ordering of the windows on the screen.

Discussion
Only windows that are typically scriptable are included in the returned array. For example, panels are not included.

This method is called during script command evaluation—for example, while finding the window in the script statement `close the second window`. For information on how your application can return its own array of ordered windows, see `application:delegateHandlesKey:`.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- orderedDocuments` (page 154)

Declared In
`NSApplicationScripting.h`

orderFrontCharacterPalette:

Opens the character palette.

```
- (void)orderFrontCharacterPalette:(id)sender
```

Parameters
sender
The object that sent the command.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`NSApplication.h`

orderFrontColorPanel:

Brings up the color panel, an instance of `NSColorPanel`.

```
- (void)orderFrontColorPanel:(id)sender
```

Parameters
sender
The object that sent the command.

Discussion
If the `NSColorPanel` object does not exist yet, this method creates one. This method is typically invoked when the user chooses Colors from a menu.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSColorPanel.h`

orderFrontStandardAboutPanel:

Displays a standard About window.

```
- (void)orderFrontStandardAboutPanel:(id)sender
```

Parameters

sender
The object that sent the command.

Discussion
This method calls `orderFrontStandardAboutPanelWithOptions:` (page 156) with a `nil` argument. See `orderFrontStandardAboutPanelWithOptions:` for a description of what's displayed.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
MenuItemView

Declared In
`NSApplication.h`

orderFrontStandardAboutPanelWithOptions:

Displays a standard About window with information from a given options dictionary.

```
- (void)orderFrontStandardAboutPanelWithOptions:(NSDictionary *)optionsDictionary
```

Parameters

optionsDictionary
A dictionary whose keys define the contents of the About window. See the discussion for a description of the available keys.

Discussion
The following strings are keys that can occur in *optionsDictionary*:

- `@"Credits"`: An NSAttributedString displayed in the info area of the panel. If not specified, this method then looks for a file named "`Credits.html`", "`Credits.rtf`", and "`Credits.rtfd`", in that order, in the bundle returned by the `NSBundle` class method `mainBundle`. The first file found is used. If none is found, the info area is left blank.

- `@"ApplicationName"`: An `NSString` object displayed as the application's name. If not specified, this method then uses the value of `CFBundleName` (localizable). If neither is found, this method uses `[[NSProcessInfo processInfo] processName]`.
- `@"ApplicationIcon"`: An `NSImage` object displayed as the application's icon. If not specified, this method then looks for an image named "`NSApplicationIcon`", using `[NSImage imageNamed:@"NSApplicationIcon"]`. If neither is available, this method uses the generic application icon.
- `@"Version"`: An `NSString` object with the build version number of the application ("58.4"), displayed as "(v58.4)". If not specified, obtain from the `CFBundleVersion` key in `infoDictionary`; if not specified, leave blank (the "(v)" is not displayed).
- `@"Copyright"`: An `NSString` object with a line of copyright information. If not specified, this method then looks for the value of `NSHumanReadableCopyright` in the localized version `infoDictionary`. If neither is available, this method leaves the space blank.
- `@"ApplicationVersion"`: An `NSString` object with the application version ("Mac OS X", "3", "WebObjects 4.5", "AppleWorks 6",...). If not specified, obtain from the `CFBundleShortVersionString` key in `infoDictionary`. If neither is available, the build version, if available, is printed alone, as "Version x.x".

Availability
Available in Mac OS X v10.0 and later.

See Also
`- orderFrontStandardAboutPanel:` (page 156)

Declared In
`NSApplication.h`

postEvent:atStart:

Adds a given event to the receiver's event queue.

```
- (void)postEvent:(NSEvent *)anEvent atStart:(BOOL)flag
```

Parameters

anEvent
The event object to post to the queue.

flag
Specify `YES` to add the event to the front of the queue; otherwise, specify `NO` to add the event to the back of the queue.

Discussion
This method can also be called in subthreads. Events posted in subthreads bubble up in the main thread event queue.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- currentEvent` (page 142)
`- sendEvent:` (page 167)

Declared In
NSApplication.h

presentationOptions

Returns the presentation options that should be in effect for the system when this application is active.

```
- (NSApplicationPresentationOptions)presentationOptions
```

Return Value
The application's presentation options. The constants are listed in "NSApplicationPresentationOptions" (page 187) and they combined using a C bitwise OR operator.

Discussion
This method is key-value observable.

Availability
Available in Mac OS X v10.6 and later.

See Also
- currentSystemPresentationOptions (page 143)
- setPresentationOptions (page 170)

Declared In
NSApplication.h

preventWindowOrdering

Suppresses the usual window ordering in handling the most recent mouse-down event.

```
- (void)preventWindowOrdering
```

Discussion
This method is only useful for mouse-down events when you want to prevent the window that receives the event from being ordered to the front.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSApplication.h

registerServicesMenuSendTypes:returnTypes:

Registers the pasteboard types the receiver can send and receive in response to service requests.

```
- (void)registerServicesMenuSendTypes:(NSArray *)sendTypes returnTypes:(NSArray
    *)returnTypes
```

Parameters

sendTypes

An array of `NSString` objects, each of which corresponds to a particular pasteboard type that the application can send.

returnTypes

An array of `NSString` objects, each of which corresponds to a particular pasteboard type that the application can receive.

Discussion

If the receiver has a Services menu, a menu item is added for each service provider that can accept one of the specified *sendTypes* or return one of the specified *returnTypes*. You should typically invoke this method at application startup time or when an object that can use services is created. You can invoke it more than once—its purpose is to ensure there is a menu item for every service the application can use. The event-handling mechanism will dynamically enable the individual items to indicate which services are currently appropriate. All the `NSResponder` objects in your application (typically `NSView` objects) should register every possible type they can send and receive by sending this message to `NSApp`.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `validRequestorForSendType:returnType:` (page 180)
- `readSelectionFromPasteboard:` (page 3797) (NSServicesRequests protocol)
- `writeSelectionToPasteboard:types:` (page 3798) (NSServicesRequests protocol)

Declared In

`NSApplication.h`

registerUserInterfaceItemSearchHandler:

Register an an object that provides help data to your application.

```
- (void)registerUserInterfaceItemSearchHandler:(id < NSUserInterfaceItemSearching
    >)handler
```

Parameters

handler

The class instance that conforms to `NSUserInterfaceItemSearching` and provides help content.

Discussion

You can register as many search handlers as you like. If you register the same instance more than once the subsequent registrations are ignored.

Availability

Available in Mac OS X v10.6 and later.

See Also

- `unregisterUserInterfaceItemSearchHandler:` (page 178)
- `searchString:inUserInterfaceItemString:searchRange:foundRange:` (page 165)

Declared In

`NSUserInterfaceItemSearching.h`

removeWindowsItem:

Removes the Window menu item for a given window.

```
- (void)removeWindowsItem:(NSWindow *)aWindow
```

Parameters

aWindow

The window whose menu item is to be removed.

Discussion

This method doesn't prevent the item from being automatically added again. Use the `setExcludedFromWindowsMenu:` (page 3380) method of `NSWindow` if you want the item to remain excluded from the Window menu.

Availability

Available in Mac OS X v10.0 and later.

See Also

`- addWindowsItem:title:filename:` (page 137)

`- changeWindowsItem:title:filename:` (page 141)

Declared In

`NSApplication.h`

replyToApplicationShouldTerminate:

Responds to `NSTerminateLater` once the application knows whether it can terminate.

```
- (void)replyToApplicationShouldTerminate:(BOOL)shouldTerminate
```

Parameters

shouldTerminate

Specify `YES` if you want the application to terminate; otherwise, specify `NO`.

Discussion

If your application delegate returns `NSTerminateLater` from its `applicationShouldTerminate:` (page 3576) method, your code must subsequently call this method to let the `NSApplication` object know whether it can actually terminate itself.

Availability

Available in Mac OS X v10.0 and later.

Related Sample Code

ExtractMovieAudioToAIFF

QTExtractAndConvertToAIFF

QTExtractAndConvertToMovieFile

Declared In

`NSApplication.h`

replyToOpenOrPrint:

Handles errors that might occur when the user attempts to open or print files.

```
- (void)replyToOpenOrPrint:(NSApplicationDelegateReply)reply
```

Parameters

reply

The error that occurred. For a list of possible values, see "Constants" (page 184).

Discussion

Delegates should invoke this method if an error is encountered in the `application:openFiles:` (page 3566) or `application:printFiles:withSettings:showPrintPanels:` (page 3569) delegate methods.

Availability

Available in Mac OS X v10.3 and later.

Declared In

`NSApplication.h`

reportException:

Logs a given exception by calling `NSLog()`.

```
- (void)reportException:(NSException *)anException
```

Parameters

anException

The exception whose contents you want to write to the log file.

Discussion

This method does not raise *anException*. Use it inside of an exception handler to record that the exception occurred.

Availability

Available in Mac OS X v10.0 and later.

See Also

`NSSetUncaughtExceptionHandler` (Foundation Functions)

Declared In

`NSApplication.h`

requestUserAttention:

Starts a user attention request.

```
- (NSInteger)requestUserAttention:(NSRequestUserAttentionType)requestType
```

Parameters

requestType

The severity of the request. For a list of possible values, see "Constants" (page 184).

Return Value
The identifier for the request. You can use this value to cancel the request later using the `cancelUserAttentionRequest:` method.

Discussion
Activating the application cancels the user attention request. A spoken notification will occur if spoken notifications are enabled. Sending `requestUserAttention:` to an application that is already active has no effect.

If the inactive application presents a modal panel, this method will be invoked with `NSCriticalRequest` automatically. The modal panel is not brought to the front for an inactive application.

Availability
Available in Mac OS X v10.1 and later.

See Also
- `cancelUserAttentionRequest:` (page 141)

Declared In
`NSApplication.h`

run

Starts the main event loop.

```
- (void)run
```

Discussion
The loop continues until a `stop:` (page 173) or `terminate:` (page 176) message is received. Upon each iteration through the loop, the next available event from the window server is stored and then dispatched by sending it to `NSApp` using `sendEvent:` (page 167).

After creating the `NSApplication` object, the `main` function should load your application's main nib file and then start the event loop by sending the `NSApplication` object a `run` message. If you create an Cocoa application project in Xcode, this `main` function is implemented for you.

Availability
Available in Mac OS X v10.0 and later.

See Also

NumberInput_IMKit_Sample

Declared In
`NSApplication.h`

runModalForWindow:

Starts a modal event loop for a given window.

```
- (NSInteger)runModalForWindow:(NSWindow *)aWindow
```

Parameters

aWindow

The window to be displayed modally. If it is not already visible, the window is centered on the screen using the value in its `center` (page 3307)method and made visible and key. If it is already visible, it is simply made key.

Return Value

An integer indicating the reason that this method returned. See the discussion for a description of possible return values.

Discussion

This method runs a modal event loop for the specified window synchronously. It displays the specified window, makes it key, starts the run loop, and processes events for that window. (You do not need to show the window yourself.) While the application is in that loop, it does not respond to any other events (including mouse, keyboard, or window-close events) unless they are associated with the window. It also does not perform any tasks (such as firing timers) that are not associated with the modal run loop. In other words, this method consumes only enough CPU time to process events and dispatch them to the action methods associated with the modal window.

You can exit the modal loop by calling the `stopModal`, `stopModalWithCode:`, or `abortModal` methods from your modal window code. If you use the `stopModalWithCode:` method to stop the modal event loop, this method returns the argument passed to `stopModalWithCode:`. If you use `stopModal` instead, this method returns the constant `NSRunStoppedResponse`. If you use `abortModal`, this method returns the constant `NSRunAbortedResponse`.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `run` (page 162)
- `runModalSession:` (page 164)

Related Sample Code

WhackedTV

Declared In

`NSApplication.h`

runModalForWindow:relativeToWindow:

(Deprecated in Mac OS X v10.0. Use `beginSheet:modalForWindow:modalDelegate:didEndSelector:contextInfo:` (page 140) instead.)

```
- (NSInteger)runModalForWindow:(NSWindow *)theWindow relativeToWindow:(NSWindow
    *)docWindow
```

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.0.

Declared In
NSApplication.h

runModalSession:

Runs a given modal session, as defined in a previous invocation of `beginModalSessionForWindow:`.

```
- (NSInteger)runModalSession:(NSModalSession)session
```

Parameters

session

The modal session structure returned by the `beginModalSessionForWindow:` method for the window to be displayed.

Return Value
An integer indicating the reason that this method returned. See the discussion for a description of possible return values.

Discussion
A loop that uses this method is similar in some ways to a modal event loop run with `runModalForWindow:`, except with this method your code can do some additional work between method invocations. When you invoke this method, events for the `NSWindow` object of this session are dispatched as normal. This method returns when there are no more events. You must invoke this method frequently enough in your loop that the window remains responsive to events. However, you should not invoke this method in a tight loop because it returns immediately if there are no events, and consequently you could end up polling for events rather than blocking.

Typically, you use this method in situations where you want to do some additional processing on the current thread while the modal loop runs. For example, while processing a large data set, you might want to use a modal dialog to display progress and give the user a chance to cancel the operation. If you want to display a modal dialog and do not need to do any additional work in parallel, use `runModalForWindow:` instead. When there are no pending events, that method waits idly instead of consuming CPU time.

The following code shows a sample loop you can use in your code:

```
NSModalSession session = [NSApp beginModalSessionForWindow:theWindow];
for (;;) {
    if ([NSApp runModalSession:session] != NSRunContinuesResponse)
        break;
    [self doSomeWork];
}
[NSApp endModalSession:session];
```

If the modal session was not stopped, this method returns `NSRunContinuesResponse`. At this point, your application can do some work before the next invocation of `runModalSession:` (as indicated in the example's `doSomeWork` call). If `stopModal` (page 174) was invoked as the result of event processing, `runModalSession:` returns `NSRunStoppedResponse`. If `stopModalWithCode:` (page 174) was invoked, this method returns the value passed to `stopModalWithCode:`. If `abortModal` (page 135) was invoked, this method returns `NSRunAbortedResponse`.

The window is placed on the screen and made key as a result of the `runModalSession:` message. Do not send a separate `makeKeyAndOrderFront:` (page 3345) message.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `beginModalSessionForWindow:` (page 139)
- `endModalSession:` (page 146)
- `run` (page 162)
- `runModalForWindow:` (page 163)

Declared In
`NSApplication.h`

runPageLayout:

Displays the receiver's page layout panel, an instance of `NSPageLayout`.

```
- (void)runPageLayout:(id)sender
```

Parameters

sender
The object that sent the command.

Discussion
If the `NSPageLayout` instance does not exist, this method creates one. This method is typically invoked when the user chooses Page Setup from the application's FIle menu.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSPageLayout.h`

searchString:inUserInterfaceItemString:searchRange:foundRange:

Searches for the string in the user interface.

```
- (BOOL)searchString:(NSString *)searchString inUserInterfaceItemString:(NSString
    *)stringToSearch searchRange:(NSRange)searchRange foundRange:(NSRange
   *)foundRange
```

Parameters

searchString
The search string.

stringToSearch
The string to search.

searchRange
The subrange of the *stringToSearch* to restrict the search to.

foundRange
Returns, by-reference, the range of the *searchString* within *stringToSearch*.

Return Value
`YES` if the searchString is matched, otherwise `NO`.

Discussion
The search uses the default matching rules for Spotlight for Help.

Availability
Available in Mac OS X v10.6 and later.

See Also
- `registerUserInterfaceItemSearchHandler:` (page 159)

Declared In
`NSUserInterfaceItemSearching.h`

sendAction:to:from:

Sends the given action message to the given target.

```
- (BOOL)sendAction:(SEL)anAction to:(id)aTarget from:(id)sender
```

Parameters

anAction
The action message you want to send.

aTarget
The target object that defines the specified action message.

sender
The object to pass for the action message's parameter.

Return Value
`YES` if the action was successfully sent; otherwise `NO`. This method also returns `NO` if *anAction* is `nil`.

Discussion
If *aTarget* is `nil`, `sharedApplication` (page 135) looks for an object that can respond to the message—that is, an object that implements a method matching *anAction*. It begins with the first responder of the key window. If the first responder can't respond, it tries the first responder's next responder and continues following next responder links up the responder chain. If none of the objects in the key window's responder chain can handle the message, `sharedApplication` (page 135) attempts to send the message to the key window's delegate.

If the delegate doesn't respond and the main window is different from the key window, `sharedApplication` (page 135) begins again with the first responder in the main window. If objects in the main window can't respond, `sharedApplication` (page 135) attempts to send the message to the main window's delegate. If still no object has responded, `sharedApplication` (page 135) tries to handle the message itself. If `sharedApplication` (page 135) can't respond, it attempts to send the message to its own delegate.

Availability
Available in Mac OS X v10.0 and later.

- `makeWindowsPerform:inOrder:` (page 152)

Declared In
NSApplication.h

sendEvent:

Dispatches an event to other objects.

```
- (void)sendEvent:(NSEvent *)anEvent
```

Parameters

anEvent
The event object to dispatch.

Discussion
You rarely invoke `sendEvent:` directly, although you might want to override this method to perform some action on every event. `sendEvent:` messages are sent from the main event loop (the `run` (page 162) method). `sendEvent:` is the method that dispatches events to the appropriate responders—`NSApp` handles application events, the `NSWindow` object indicated in the event record handles window-related events, and mouse and key events are forwarded to the appropriate `NSWindow` object for further dispatching.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `currentEvent` (page 142)
- `postEvent:atStart:` (page 157)

Declared In
NSApplication.h

servicesMenu

Returns the Services menu.

```
- (NSMenu *)servicesMenu
```

Return Value
The Services menu or `nil` if no Services menu has been created

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setServicesMenu:` (page 171)

Declared In
NSApplication.h

servicesProvider

Returns the object that provides the services the receiver advertises in the Services menu of other applications.

```
- (id)servicesProvider
```

Return Value
The application's service provider object.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setServicesProvider: (page 171)

Declared In
NSApplication.h

setActivationPolicy:

Attempts to modify the application's activation policy.

```
- (BOOL)setActivationPolicy:(NSApplicationActivationPolicy)activationPolicy
```

Parameters
activationPolicy
The desired activation policy.

Return Value
YES if the policy switch was successful, otherwise NO.

Discussion
Currently, NSApplicationActivationPolicyNone and NSApplicationActivationPolicyAccessory may be changed to NSApplicationActivationPolicyRegular, but other modifications are not supported.Needs links to running application

Availability
Available in Mac OS X v10.6 and later.

See Also
- activationPolicy (page 137)

Declared In
NSApplication.h

setApplicationIconImage:

Sets the receiver's icon to the specified image.

```
- (void)setApplicationIconImage:(NSImage *)anImage
```

Parameters
anImage
The image to use as the new application icon.

Discussion
This method sets the icon in the dock application tile. This method scales the image as necessary so that it fits in the dock tile. You can use this method to change your application icon while running. To restore your application's original icon, you pass `nil` to this method.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- applicationIconImage` (page 138)

Declared In
`NSApplication.h`

setDelegate:

Makes the given object the receiver's delegate.

```
- (void)setDelegate:(id < NSApplicationDelegate >)anObject
```

Parameters
anObject
The application delegate object.

Discussion
The messages a delegate can expect to receive are listed at the end of this specification. The delegate doesn't need to implement all the methods.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- delegate` (page 144)

Related Sample Code
CocoaDVDPlayer
PictureSharing

Declared In
`NSApplication.h`

setHelpMenu:

Sets the application's help menu.

```
- (void)setHelpMenu:(NSMenu *)helpMenu
```

Parameters
helpMenu
The menu to use as the application's help menu.

Discussion
If *helpMenu* is a non-nil menu it is set as the Help menu, and Spotlight for Help will be installed in it. If *helpMenu* is nil, AppKit will install Spotlight for Help into a menu of its choosing, and that menu is not returned from helpMenu.

If you wish to completely suppress Spotlight for Help, you can set a menu that does not appear in the menu bar.

NSApplication retains its Help menu and releases it when a different menu is set.

Availability
Available in Mac OS X v10.6 and later.

Declared In
NSApplication.h

setMainMenu:

Makes the given menu the receiver's main menu.

```
- (void)setMainMenu:(NSMenu *)aMenu
```

Parameters

aMenu

The new menu bar for the application.

Availability
Available in Mac OS X v10.0 and later.

See Also
- mainMenu (page 151)

Declared In
NSApplication.h

setPresentationOptions:

Sets the application presentation options to use when this application is active.

```
- (void)setPresentationOptions:(NSApplicationPresentationOptions)newOptions
```

Parameters

newOptions

The presentation options. The possible constants, and combination restrictions, are listed in "NSApplicationPresentationOptions" (page 187) and they combined using a C bitwise OR operator.

Discussion
Only certain combinations of "NSApplicationPresentationOptions" (page 187) flags are supported. When given an invalid combination of option flags this method raises an exception NSInvalidArgumentException exception..

Availability
Available in Mac OS X v10.6 and later.

See Also
- `currentSystemPresentationOptions` (page 143)
- `presentationOptions` (page 158)

Declared In
`NSApplication.h`

setServicesMenu:

Makes a given menu the receiver's Services menu.

```
- (void)setServicesMenu:(NSMenu *)aMenu
```

Parameters

aMenu

The new Services menu.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `servicesMenu` (page 167)

Declared In
`NSApplication.h`

setServicesProvider:

Registers a given object as the service provider.

```
- (void)setServicesProvider:(id)aProvider
```

Parameters

aProvider

The new service provider object.

Discussion
The service provider is an object that performs all services the application provides to other applications. When another application requests a service from the receiver, it sends the service request to *aProvider*. Service requests can arrive immediately after the service provider is set, so invoke this method only when your application is ready to receive requests.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `servicesProvider` (page 167)

Declared In
`NSApplication.h`

setWindowsMenu:

Makes the given menu the receiver's Window menu.

```
- (void)setWindowsMenu:(NSMenu *)aMenu
```

Parameters

aMenu

The new Window menu for the application.

Availability
Available in Mac OS X v10.0 and later.

See Also
- windowsMenu (page 181)

Declared In
NSApplication.h

setWindowsNeedUpdate:

Sets whether the receiver's windows need updating when the receiver has finished processing the current event.

```
- (void)setWindowsNeedUpdate:(BOOL)flag
```

Parameters

flag

If YES, the receiver's windows are updated after an event is processed.

Discussion
This method is especially useful for making sure menus are updated to reflect changes not initiated by user actions, such as messages received from remote objects.

Availability
Available in Mac OS X v10.0 and later.

See Also
- updateWindows (page 179)

Declared In
NSApplication.h

showHelp:

If your project is properly registered, and the necessary keys have been set in the property list, this method launches Help Viewer and displays the first page of your application's help book.

```
- (void)showHelp:(id)sender
```

Parameters

sender

The object that sent the command.

Discussion
For information on how to set up your project to take advantage of having Help Viewer display your help book, see Specifying the Comprehensive Help File.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `activateContextHelpMode:` (page 136)

Related Sample Code
HelpHook

Declared In
`NSHelpManager.h`

stop:

Stops the main event loop.

```
- (void)stop:(id)sender
```

Parameters

sender

The object that sent this message.

Discussion
This method notifies the application that you want to exit the current run loop as soon as it finishes processing the current `NSEvent` object. This method does not forcibly exit the current run loop. Instead it sets a flag that the application checks only after it finishes dispatching an actual event object. For example, you could call this method from an action method responding to a button click or from one of the many methods defined by the `NSResponder` class. However, calling this method from a timer or run-loop observer routine would not stop the run loop because they do not result in the p of an `NSEvent` object.

If you call this method from an event handler running in your main run loop, the application object exits out of the `run` method, thereby returning control to the `main()` function. If you call this method from within a modal event loop, it will exit the modal loop instead of the main event loop.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `run` (page 162)
- `runModalForWindow:` (page 163)
- `runModalSession:` (page 164)
- `terminate:` (page 176)

Declared In
`NSApplication.h`

stopModal

Stops a modal event loop.

```
- (void)stopModal
```

Discussion
This method should always be paired with a previous invocation of `runModalForWindow:` (page 163) or `beginModalSessionForWindow:` (page 139). When `runModalForWindow:` (page 163) is stopped with this method, it returns `NSRunStoppedResponse`. This method stops the loop only if it's executed by code responding to an event. If you need to stop a `runModalForWindow:` (page 163) loop outside of one of its event callbacks (for example, a method repeatedly invoked by an `NSTimer` object or a method running in a different thread), use the `abortModal` (page 135) method.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `runModalSession:` (page 164)
- `stopModalWithCode:` (page 174)

Related Sample Code
WhackedTV

Declared In
`NSApplication.h`

stopModalWithCode:

Stops a modal event loop, allowing you to return a custom result code.

```
- (void)stopModalWithCode:(NSInteger)returnCode
```

Parameters

returnCode
The result code you want returned from the `runModalForWindow:` or `runModalSession:` method. The meaning of this result code is up to you.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `abortModal` (page 135)
- `runModalForWindow:` (page 163)

Declared In
`NSApplication.h`

targetForAction:

Returns the object that receives the action message specified by the given selector

```
- (id)targetForAction:(SEL)aSelector
```

Parameters

aSelector

The desired action message.

Return Value

The object that would receive the specified action message or `nil` if no target object would receive the message. This method also returns `nil` if *aSelector* is `nil`.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `sendAction:to:from:` (page 166)
- `tryToPerform:with:` (page 177)
- `targetForAction:to:from:` (page 175)

Declared In

`NSApplication.h`

targetForAction:to:from:

Finds an object that can receive the message specified by the given selector.

```
- (id)targetForAction:(SEL)anAction to:(id)aTarget from:(id)sender
```

Parameters

anAction

The desired action message.

aTarget

The first target object to check. Specify `nil` if you want the application to search the responder chain.

sender

The parameter to send to the action message.

Return Value

The object that can accept the specified action message or `nil` if no target object can receive the message. This method also returns `nil` if *anAction* is `nil`.

Discussion

If *aTarget* is not `nil`, *aTarget* is returned. If *aTarget* is `nil`, `NSApp` looks for an object that can respond to the message—that is, an object that implements a method matching *anAction*. The search begins with the first responder of the key window. If the first responder does not handle the message, it tries the first responder's next responder and continues following next responder links up the responder chain. If none of the objects in the key window's responder chain can handle the message, `NSApp` asks the key window's delegate whether it can handle the message.

If the delegate cannot handle the message and the main window is different from the key window, `NSApp` begins searching again with the first responder in the main window. If objects in the main window cannot handle the message, `NSApp` tries the main window's delegate. If it cannot handle the message, `NSApp` asks itself. If `NSApp` doesn't handle the message, it asks the application delegate. If there is no object capable of handling the message, `nil` is returned.

Availability

Available in Mac OS X v10.0 and later.

See Also
- `sendAction:to:from:` (page 166)
- `tryToPerform:with:` (page 177)
- `targetForAction:` (page 174)

Declared In
`NSApplication.h`

terminate:

Terminates the receiver.

```
- (void)terminate:(id)sender
```

Parameters

sender

Typically, this parameter contains the object that initiated the termination request.

Discussion
This method is typically invoked when the user chooses Quit or Exit from the application's menu.

When invoked, this method performs several steps to process the termination request. First, it asks the application's document controller (if one exists) to save any unsaved changes in its documents. During this process, the document controller can cancel termination in response to input from the user. If the document controller does not cancel the operation, this method then calls the delegate's `applicationShouldTerminate:` (page 3576) method. If `applicationShouldTerminate:` (page 3576) returns NSTerminateCancel, the termination process is aborted and control is handed back to the main event loop. If the method returns `NSTerminateLater`, the application runs its run loop in the `NSModalPanelRunLoopMode` mode until the `replyToApplicationShouldTerminate:` method is called with the value `YES` or `NO`. If the `applicationShouldTerminate:` (page 3576) method returns NSTerminateNow, this method posts a `NSApplicationWillTerminateNotification` notification to the default notification center.

Do not bother to put final cleanup code in your application's `main()` function—it will never be executed. If cleanup is necessary, perform that cleanup in the delegate's `applicationWillTerminate:` (page 3579) method.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `run` (page 162)
- `stop:` (page 173)
- `applicationShouldTerminate:` (page 3576) (NSApplicationDelegate)
- `applicationWillTerminate:` (page 3579) (NSApplicationDelegate)
- `replyToApplicationShouldTerminate:` (page 160)

`NSApplicationWillTerminateNotification` (page 196)

WhackedTV

Declared In
NSApplication.h

tryToPerform:with:

Dispatches an action message to the specified target.

```
- (BOOL)tryToPerform:(SEL)aSelector with:(id)anObject
```

Parameters

aSelector
The action message you want to dispatch.

anObject
The target object that defines the specified selector.

Return Value
YES if either the receiver or its delegate can accept the specified selector; otherwise, NO. This method also returns NO if *aSelector* is nil.

Discussion
The receiver tries to perform the method *aSelector* using its inherited tryToPerform:with: (page 2202) method of NSResponder. If the receiver doesn't perform *aSelector*, the delegate is given the opportunity to perform it using its inherited performSelector:withObject: method of NSObject.

Availability
Available in Mac OS X v10.0 and later.

See Also
respondsToSelector: (NSObject protocol)

Declared In
NSApplication.h

unhide:

Restores hidden windows to the screen and makes the receiver active.

```
- (void)unhide:(id)sender
```

Parameters

sender
The object that sent the command.

Discussion
Invokes unhideWithoutActivation (page 178).

Availability
Available in Mac OS X v10.0 and later.

See Also
- activateIgnoringOtherApps: (page 136)

- hide: (page 148)

Declared In
NSApplication.h

unhideAllApplications:

Unhides all applications, including the receiver.

- (void)unhideAllApplications:(id)*sender*

Parameters

sender

The object that sent this message.

Discussion
This action causes each application to order its windows to the front, which could obscure the currently active window in the active application.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSApplication.h

unhideWithoutActivation

Restores hidden windows without activating their owner (the receiver).

- (void)unhideWithoutActivation

Discussion
When this method begins, it posts an NSApplicationWillUnhideNotification (page 196) to the default notification center. If it completes successfully, it posts an NSApplicationDidUnhideNotification (page 195).

Availability
Available in Mac OS X v10.0 and later.

See Also
- activateIgnoringOtherApps: (page 136)
- hide: (page 148)
- applicationDidUnhide: (page 3573) (NSApplicationDelegate)
- applicationWillUnhide: (page 3579) (NSApplicationDelegate)

Declared In
NSApplication.h

unregisterUserInterfaceItemSearchHandler:

Unregister an an object that provides help data to your application.

```
- (void)unregisterUserInterfaceItemSearchHandler:(id < NSUserInterfaceItemSearching
    >)handler
```

Parameters

handler

The class instance that conforms to `NSUserInterfaceItemSearching` and provides help content.

Discussion

If you unregister the same instance more than once the subsequent invocations are ignored. Unregistering an instance that was never registered is ignored.

Availability

Available in Mac OS X v10.6 and later.

See Also

- `registerUserInterfaceItemSearchHandler:` (page 159)

Declared In

`NSUserInterfaceItemSearching.h`

updateWindows

Sends an `update` (page 3405) message to each onscreen window.

```
- (void)updateWindows
```

Discussion

This method is invoked automatically in the main event loop after each event when running in `NSDefaultRunLoopMode` or `NSModalRunLoopMode`. This method is not invoked automatically when running in `NSEventTrackingRunLoopMode`.

When this method begins, it posts an `NSApplicationWillUpdateNotification` (page 196) to the default notification center. When it successfully completes, it posts an `NSApplicationDidUpdateNotification` (page 195).

Availability

Available in Mac OS X v10.0 and later.

See Also

- `update` (page 3405) (NSWindow)
- `setWindowsNeedUpdate:` (page 172)
- `applicationDidUpdate:` (page 3573) (NSApplicationDelegate)
- `applicationWillUpdate:` (page 3580) (NSApplicationDelegate)

Declared In

`NSApplication.h`

updateWindowsItem:

Updates the Window menu item for a given window to reflect the edited status of that window.

```
- (void)updateWindowsItem:(NSWindow *)aWindow
```

Parameters

aWindow

The window whose menu item is to be updated.

Discussion

You rarely need to invoke this method because it is invoked automatically when the edit status of an `NSWindow` object is set.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `changeWindowsItem:title:filename:` (page 141)
- `setDocumentEdited:` (page 3379) (`NSWindow`)

Declared In

`NSApplication.h`

userInterfaceLayoutDirection

Returns the layout direction of the user interface.

```
- (NSUserInterfaceLayoutDirection)userInterfaceLayoutDirection
```

Return Value

The direction of the user interface layout. See "NSUserInterfaceLayoutDirection" (page 184) for possible values.

Discussion

This method specifies the general user interface layout flow directions.

Availability

Available in Mac OS X v10.6 and later.

Declared In

`NSApplication.h`

validRequestorForSendType:returnType:

Indicates whether the receiver can send and receive the specified pasteboard types.

```
- (id)validRequestorForSendType:(NSString *)sendType returnType:(NSString
    *)returnType
```

Parameters

sendType

The pasteboard type the application needs to send.

returnType

The pasteboard type the application needs to receive.

Return Value

The object that can send and receive the specified types or `nil` if the receiver knows of no object that can send and receive data of that type.

Discussion
This message is sent to all responders in a responder chain. `NSApp` is typically the last item in the responder chain, so it usually receives this message only if none of the current responders can send *`sendType`* data and accept back *`returnType`* data.

The receiver passes this message on to its delegate if the delegate can respond (and isn't an `NSResponder` object with its own next responder). If the delegate cannot respond or returns `nil`, this method returns `nil`. If the delegate can find an object that can send *`sendType`* data and accept back *`returnType`* data, it returns that object.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `registerServicesMenuSendTypes:returnTypes:` (page 158)
- `validRequestorForSendType:returnType:` (page 2204) (NSResponder)

- `writeSelectionToPasteboard:types:` (page 3798) (NSServicesRequests protocol)

Declared In
`NSApplication.h`

windows

Returns an array containing the receiver's window objects.

```
- (NSArray *)windows
```

Return Value
An array of `NSWindow` objects. This array includes both onscreen and offscreen windows.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
GLUT
Quartz Composer WWDC 2005 TextEdit

Declared In
`NSApplication.h`

windowsMenu

Returns the Window menu of the application.

```
- (NSMenu *)windowsMenu
```

Return Value
The window menu or `nil` if such a menu does not exist or has not yet been created.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setWindowsMenu: (page 172)

Declared In
NSApplication.h

windowWithWindowNumber:

Returns the window corresponding to the specified window number.

```
- (NSWindow *)windowWithWindowNumber:(NSInteger)windowNum
```

Parameters

windowNum
The unique window number associated with the desired NSWindow object.

Return Value
The desired window object or nil if the window could not be found.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSApplication.h

Delegate Methods

application:delegateHandlesKey:

Sent by Cocoa's built-in scripting support during execution of get or set script commands to find out if the delegate can handle operations on the specified key-value key.

```
- (BOOL)application:(NSApplication *)sender delegateHandlesKey:(NSString *)key
```

Parameters

sender
The application object associated with the delegate.

key
The key to be handled.

Return Value
YES if your delegate handles the key or NO if it does not.

Discussion
The method should return YES if the delegate for the application *sender* handles the key specified by *key*, which means it can get or set the scriptable property or element that corresponds to that key. The application implements methods for each of the keys that it handles, where the method name matches the key.

For example, a scriptable application that doesn't use Cocoa's document-based application architecture can implement this method to supply its own document ordering. Such an application might want to do this because the standard application delegate expects to work with a document-based application. The TextEdit application (whose source is distributed with Mac OS X developer tools) provides the following implementation:

```
return [key isEqualToString:@"orderedDocuments"];
```

TextEdit then implements the `orderedDocuments` method in its controller class to return an ordered list of documents. An application with its own window ordering might add a test for the key `orderedWindows` so that its delegate can provide its own version of `orderedWindows`.

Important: Cocoa scripting does not invoke this method for script commands other than `get` or `set`. For information on working with other commands, see Script Commands in *Cocoa Scripting Guide*.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `orderedDocuments` (page 154) (NSApplication)
- `orderedWindows` (page 155) (NSApplication)

Declared In
`NSApplicationScripting.h`

application:printFiles:

(Available in Mac OS X v10.3 through Mac OS X v10.5. Use `application:printFiles:withSettings:showPrintPanels:` (page 3569) instead.)

```
- (void)application:(NSApplication *)sender
    printFiles:(NSArray *)filenames
```

Discussion
Identical to `application:printFile:` (page 3568) except that the receiver prints multiple files corresponding to the file names in the *`filenames`* array.

Delegates should invoke the `replyToOpenOrPrint:` (page 161) method upon success or failure, or when the user cancels the operation.

Availability
Available in Mac OS X v10.3 through Mac OS X v10.5.

Declared In
`NSApplication.h`

Constants

NSUserInterfaceLayoutDirection

Specifies the directional flow of the user interface. These constants are returned by `userInterfaceLayoutDirection` (page 180).

```
enum {
    NSUserInterfaceLayoutDirectionLeftToRight = 0,
    NSUserInterfaceLayoutDirectionRightToLeft = 1
};
typedef NSInteger NSUserInterfaceLayoutDirection;
```

Constants

`NSUserInterfaceLayoutDirectionLeftToRight`

Layout direction is left to right.

Available in Mac OS X v10.6 and later.

Declared in `NSApplication.h`.

`NSUserInterfaceLayoutDirectionRightToLeft`

Layout direction is right to left. This is appropriate when running with localizations such as Arabic or Hebrew that should have the user interface layout origin on the right edge of the coordinate system.

Available in Mac OS X v10.6 and later.

Declared in `NSApplication.h`.

Return values for modal operations

These are possible return values for `runModalForWindow:` (page 163) and `runModalSession:` (page 164).

```
enum {
    NSRunStoppedResponse    = (-1000),
    NSRunAbortedResponse    = (-1001),
    NSRunContinuesResponse  = (-1002)
};
```

Constants

`NSRunStoppedResponse`

Modal session was broken with `stopModal` (page 174).

Available in Mac OS X v10.0 and later.

Declared in `NSApplication.h`.

`NSRunAbortedResponse`

Modal session was broken with `abortModal` (page 135).

Available in Mac OS X v10.0 and later.

Declared in `NSApplication.h`.

`NSRunContinuesResponse`

Modal session is continuing (returned by `runModalSession:` (page 164) only).

Available in Mac OS X v10.0 and later.

Declared in `NSApplication.h`.

Discussion
The system also reserves all values below these.

NSUpdateWindowsRunLoopOrdering

This constant is used by the `NSRunLoop` method `performSelector:target:argument:order:modes:`.

```
enum {
    NSUpdateWindowsRunLoopOrdering = 500000
};
```

Constants
`NSUpdateWindowsRunLoopOrdering`
Run-loop message priority for handling window updates.

Available in Mac OS X v10.0 and later.

Declared in `NSApplication.h`.

NSApp

A global constant for the shared application instance.

```
id NSApp
```

Constants
`NSApp`
Global constant for the shared application instance. This is the same as sending the `NSApplication` class the method `sharedApplication` (page 135) message.

Available in Mac OS X v10.0 and later.

Declared in `NSApplication.h`.

Discussion
This variable designates the shared application object, created by the sharedApplication (page 135) method.

Declared In
`NSApplication.h`

NSRequestUserAttentionType

These constants specify the level of severity of a user attention request and are used by `cancelUserAttentionRequest:` (page 141) and `requestUserAttention:` (page 161).

```
enum {
    NSCriticalRequest = 0,
    NSInformationalRequest = 10
}
typedef NSUInteger NSRequestUserAttentionType;
```

Constants

`NSCriticalRequest`

The user attention request is a critical request.

The dock icon will bounce until either the application becomes active or the request is canceled.

Available in Mac OS X v10.1 and later.

Declared in `NSApplication.h`.

`NSInformationalRequest`

The user attention request is an informational request.

The dock icon will bounce for one second. The request, though, remains active until either the application becomes active or the request is canceled.

Available in Mac OS X v10.1 and later.

Declared in `NSApplication.h`.

Declared In

`NSApplication.h`

NSApplicationDelegateReply

These constants indicate whether or not a copy or print operation was successful, was cancelled, or failed. These constants are used by the `replyToOpenOrPrint:` (page 161) method.

```
enum NSApplicationDelegateReply {
    NSApplicationDelegateReplySuccess = 0,
    NSApplicationDelegateReplyCancel = 1,
    NSApplicationDelegateReplyFailure = 2
}
typedef NSUInteger NSApplicationDelegateReply;
```

Constants

`NSApplicationDelegateReplySuccess`

Indicates the operation succeeded.

Available in Mac OS X v10.3 and later.

Declared in `NSApplication.h`.

`NSApplicationDelegateReplyCancel`

Indicates the user cancelled the operation.

Available in Mac OS X v10.3 and later.

Declared in `NSApplication.h`.

`NSApplicationDelegateReplyFailure`

Indicates an error occurred processing the operation.

Available in Mac OS X v10.3 and later.

Declared in `NSApplication.h`.

NSApplicationPresentationOptions

The constants control the presentation of the application. Typically, in fullscreen applications such as games or kiosks. They are used by the methods `presentationOptions` (page 158), `currentSystemPresentationOptions` (page 143), and `setPresentationOptions` (page 170).

```
enum {
    NSApplicationPresentationDefault                    = 0,
    NSApplicationPresentationAutoHideDock               = (1 <<  0),
    NSApplicationPresentationHideDock                   = (1 <<  1),
    NSApplicationPresentationAutoHideMenuBar            = (1 <<  2),
    NSApplicationPresentationHideMenuBar                = (1 <<  3),
    NSApplicationPresentationDisableAppleMenu           = (1 <<  4),
    NSApplicationPresentationDisableProcessSwitching    = (1 <<  5),
    NSApplicationPresentationDisableForceQuit           = (1 <<  6),
    NSApplicationPresentationDisableSessionTermination  = (1 <<  7),
    NSApplicationPresentationDisableHideApplication     = (1 <<  8),
    NSApplicationPresentationDisableMenuBarTransparency = (1 <<  9)
};
typedef NSUInteger NSApplicationPresentationOptions;
```

Constants

`NSApplicationPresentationDefault`

This is the default presentation mode. The application is displayed as normal, including dock, menu bar, process switching is enabled, force quit is enabled, session termination is enabled, the hide menu is enabled, and the menu bar transparency is normal.

Available in Mac OS X v10.6 and later.

Declared in `NSApplication.h`.

`NSApplicationPresentationAutoHideDock`

The dock is normally hidden, but automatically appears when moused near.

Available in Mac OS X v10.6 and later.

Declared in `NSApplication.h`.

`NSApplicationPresentationHideDock`

The dock is entirely hidden and disabled.

Available in Mac OS X v10.6 and later.

Declared in `NSApplication.h`.

`NSApplicationPresentationAutoHideMenuBar`

The menu bar is normally hidden, but automatically appears when moused near.

Available in Mac OS X v10.6 and later.

Declared in `NSApplication.h`.

`NSApplicationPresentationHideMenuBar`

The menu bar is entirely hidden and disabled.

Available in Mac OS X v10.6 and later.

Declared in `NSApplication.h`.

`NSApplicationPresentationDisableAppleMenu`

All Apple Menu items are disabled.

Available in Mac OS X v10.6 and later.

Declared in `NSApplication.h`.

`NSApplicationPresentationDisableProcessSwitching`
The process switching user interface (Command + Tab to cycle through applications) is disabled.

Available in Mac OS X v10.6 and later.

Declared in `NSApplication.h`.

`NSApplicationPresentationDisableForceQuit`
The force quit panel (displayed by pressing Command + Option + Esc) is disabled

Available in Mac OS X v10.6 and later.

Declared in `NSApplication.h`.

`NSApplicationPresentationDisableSessionTermination`
The panel that shows the Restart, Shut Down, and Log Out options that are displayed as a result of pushing the power key is disabled.

Available in Mac OS X v10.6 and later.

Declared in `NSApplication.h`.

`NSApplicationPresentationDisableHideApplication`
The application's "Hide" menu item is disabled.

Available in Mac OS X v10.6 and later.

Declared in `NSApplication.h`.

`NSApplicationPresentationDisableMenuBarTransparency`
The menu bar transparency appearance is disabled.

Available in Mac OS X v10.6 and later.

Declared in `NSApplication.h`.

Discussion
There are restrictions on the combination of presentation options that can be set simultaneously:

- `NSApplicationPresentationAutoHideDock` (page 187) and `NSApplicationPresentationHideDock` (page 187) are mutually exclusive: You may specify one or the other, but not both.
- `NSApplicationPresentationAutoHideMenuBar` (page 187) and `NSApplicationPresentationHideMenuBar` (page 187) are mutually exclusive: You may specify one or the other, but not both.
- If you specify `NSApplicationPresentationHideMenuBar` (page 187), it must be accompanied by `NSApplicationPresentationHideDock` (page 187).
- If you specify `NSApplicationPresentationAutoHideMenuBar` (page 187), it must be accompanied by either `NSApplicationPresentationHideDock` (page 187) or `NSApplicationPresentationAutoHideDock` (page 187).
- If you specify any of `NSApplicationPresentationDisableProcessSwitching` (page 188), `NSApplicationPresentationDisableForceQuit` (page 188), `NSApplicationPresentationDisableSessionTermination` (page 188), or `NSApplicationPresentationDisableMenuBarTransparency` (page 188), it must be accompanied by either `NSApplicationPresentationHideDock` (page 187) or `NSApplicationPresentationAutoHideDock` (page 187).

When `setPresentationOptions:` (page 170) receives a parameter value that does not conform to these requirements, it raises an `NSInvalidArgumentException`.

NSApplicationTerminateReply

These constants define whether an application should terminate and are used by the delegate method `applicationShouldTerminate:` (page 3576).

```
enum {
    NSTerminateCancel = 0,
    NSTerminateNow    = 1,
    NSTerminateLater  = 2
}
typedef NSUInteger NSApplicationTerminateReply;
```

Constants

`NSTerminateNow`

It is OK to proceed with termination.

Available in Mac OS X v10.0 and later.

Declared in `NSApplication.h`.

`NSTerminateCancel`

The application should not be terminated.

Available in Mac OS X v10.0 and later.

Declared in `NSApplication.h`.

`NSTerminateLater`

It may be OK to proceed with termination later. Returning this value causes Cocoa to run the run loop in the `NSModalPanelRunLoopMode` until your application subsequently calls `replyToApplicationShouldTerminate:` (page 160) with the value `YES` or `NO`. This return value is for delegates that need to provide document modal alerts (sheets) in order to decide whether to quit.

Available in Mac OS X v10.0 and later.

Declared in `NSApplication.h`.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSApplication.h`

NSApplicationPrintReply

These constants are returned by the delegate method `application:printFiles:withSettings:showPrintPanels:` (page 3569).

```
enum {
    NSPrintingCancelled  = 0,
    NSPrintingSuccess    = 1,
    NSPrintingFailure    = 3,
    NSPrintingReplyLater = 2
}
typedef NSUInteger NSApplicationPrintReply;
```

Constants

`NSPrintingCancelled`

Printing was cancelled.

Available in Mac OS X v10.4 and later.

Declared in `NSApplication.h`.

`NSPrintingSuccess`

Printing was successful.

Available in Mac OS X v10.4 and later.

Declared in `NSApplication.h`.

`NSPrintingFailure`

Printing failed.

Available in Mac OS X v10.4 and later.

Declared in `NSApplication.h`.

`NSPrintingReplyLater`

The result of printing cannot be returned immediately, for example, if printing will cause the presentation of a sheet. If your method returns `NSPrintingReplyLater` it must always invoke `replyToOpenOrPrint:` (page 161) when the entire print operation has been completed, successfully or not.

Available in Mac OS X v10.4 and later.

Declared in `NSApplication.h`.

Declared In

`NSApplication.h`

Run loop modes

These loop mode constants are defined by `NSApplication`.

```
NSString *NSModalPanelRunLoopMode;
NSString *NSEventTrackingRunLoopMode;
```

Constants

`NSEventTrackingRunLoopMode`

A run loop should be set to this mode when tracking events modally, such as a mouse-dragging loop.

Available in Mac OS X v10.0 and later.

Declared in `NSApplication.h`.

`NSModalPanelRunLoopMode`

A run loop should be set to this mode when waiting for input from a modal panel, such as `NSSavePanel` or `NSOpenPanel`.

Available in Mac OS X v10.0 and later.

Declared in `NSApplication.h`.

Declared In
NSApplication.h

NSAppKitVersionNumber

This constant identifies the installed version of the Application Kit framework.

```
const double NSAppKitVersionNumber;
```

Constants

NSAppKitVersionNumber

This value corresponds to one of the constants defined in "Application Kit framework version numbers" (page 191).

Available in Mac OS X v10.1 and later.

Declared in NSApplication.h.

Application Kit framework version numbers

You can use the following constants to determine if you are using a version of the Application Kit framework newer than the version delivered in Mac OS X v10.0.

```
#define NSAppKitVersionNumber10_0   577
#define NSAppKitVersionNumber10_1   620
#define NSAppKitVersionNumber10_2   663
#define NSAppKitVersionNumber10_2_3 663.6
#define NSAppKitVersionNumber10_3   743
#define NSAppKitVersionNumber10_3_2 743.14
#define NSAppKitVersionNumber10_3_3 743.2
#define NSAppKitVersionNumber10_3_5 743.24
#define NSAppKitVersionNumber10_3_7 743.33
#define NSAppKitVersionNumber10_3_9 743.36
#define NSAppKitVersionNumber10_4   824
#define NSAppKitVersionNumber10_4_1 824.1
#define NSAppKitVersionNumber10_4_3 824.23
#define NSAppKitVersionNumber10_4_4 824.33
#define NSAppKitVersionNumber10_4_7 824.41
#define NSAppKitVersionNumber10_5   949
#define NSAppKitVersionNumber10_5_2 949.27
#define NSAppKitVersionNumber10_5_3 949.33
```

Constants

NSAppKitVersionNumber10_0

The Application Kit framework included in Mac OS X v10.0.

Available in Mac OS X v10.1 and later.

Declared in NSApplication.h.

NSAppKitVersionNumber10_1

The Application Kit framework included in Mac OS X v10.1.

Available in Mac OS X v10.2 and later.

Declared in NSApplication.h.

`NSAppKitVersionNumber10_2`
The Application Kit framework included in Mac OS X v10.2.
Available in Mac OS X v10.3 and later.
Declared in `NSApplication.h`.

`NSAppKitVersionNumber10_2_3`
The Application Kit framework included in Mac OS X v10.2.3.
Available in Mac OS X v10.3 and later.
Declared in `NSApplication.h`.

`NSAppKitVersionNumber10_3`
The Application Kit framework included in Mac OS X v10.3.
Available in Mac OS X v10.4 and later.
Declared in `NSApplication.h`.

`NSAppKitVersionNumber10_3_2`
The Application Kit framework included in Mac OS X v10.3.2.
Available in Mac OS X v10.4 and later.
Declared in `NSApplication.h`.

`NSAppKitVersionNumber10_3_3`
The Application Kit framework included in Mac OS X v10.3.3.
Available in Mac OS X v10.4 and later.
Declared in `NSApplication.h`.

`NSAppKitVersionNumber10_3_5`
The Application Kit framework included in Mac OS X v10.3.5.
Available in Mac OS X v10.4 and later.
Declared in `NSApplication.h`.

`NSAppKitVersionNumber10_3_7`
The Application Kit framework included in Mac OS X v10.3.7.
Available in Mac OS X v10.5 and later.
Declared in `NSApplication.h`.

`NSAppKitVersionNumber10_3_9`
The Application Kit framework included in Mac OS X v10.3.9.
Available in Mac OS X v10.5 and later.
Declared in `NSApplication.h`.

`NSAppKitVersionNumber10_4`
The Application Kit framework included in Mac OS X v10.4.
Available in Mac OS X v10.5 and later.
Declared in `NSApplication.h`.

`NSAppKitVersionNumber10_4_1`
The Application Kit framework included in Mac OS X v10.4.1.
Available in Mac OS X v10.6 and later.
Declared in `NSApplication.h`.

`NSAppKitVersionNumber10_4_3`
The Application Kit framework included in Mac OS X v10.4.3.

Available in Mac OS X v10.6 and later.

Declared in `NSApplication.h`.

`NSAppKitVersionNumber10_4_4`
The Application Kit framework included in Mac OS X v10.4.4.

Available in Mac OS X v10.6 and later.

Declared in `NSApplication.h`.

`NSAppKitVersionNumber10_4_7`
The Application Kit framework included in Mac OS X v10.4.7.

Available in Mac OS X v10.6 and later.

Declared in `NSApplication.h`.

`NSAppKitVersionNumber10_5`
The Application Kit framework included in Mac OS X v10.5.

Available in Mac OS X v10.6 and later.

Declared in `NSApplication.h`.

`NSAppKitVersionNumber10_5_2`
The Application Kit framework included in Mac OS X v10.5.2.

Available in Mac OS X v10.6 and later.

Declared in `NSApplication.h`.

`NSAppKitVersionNumber10_5_3`
The Application Kit framework included in Mac OS X v10.5.3.

Available in Mac OS X v10.6 and later.

Declared in `NSApplication.h`.

Notifications

These notifications apply to `NSApplication`. See `Notifications` in *NSWorkspace Class Reference* for additional, similar notifications.

NSApplicationDidBecomeActiveNotification

Posted immediately after the application becomes active.

The notification object is `sharedApplication` (page 135). This notification does not contain a *`userInfo`* dictionary.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSApplication.h`

NSApplicationDidChangeScreenParametersNotification

Posted when the configuration of the displays attached to the computer is changed.

The configuration change can be made either programmatically or when the user changes settings in the Displays control panel. The notification object is `sharedApplication` (page 135). This notification does not contain a *`userInfo`* dictionary.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSApplication.h`

NSApplicationDidFinishLaunchingNotification

Posted at the end of the `finishLaunching` (page 147) method to indicate that the application has completed launching and is ready to run.

The notification object is `sharedApplication` (page 135). This notification does not contain a *`userInfo`* dictionary.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSApplication.h`

NSApplicationDidHideNotification

Posted at the end of the `hide:` (page 148) method to indicate that the application is now hidden.

The notification object is `NSApp`. This notification does not contain a *`userInfo`* dictionary.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSApplication.h`

NSApplicationDidResignActiveNotification

Posted immediately after the application gives up its active status to another application.

The notification object is `NSApp`. This notification does not contain a *`userInfo`* dictionary.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSApplication.h`

NSApplicationDidUnhideNotification

Posted at the end of the `unhideWithoutActivation` (page 178) method to indicate that the application is now visible.

The notification object is `NSApp`. This notification does not contain a *`userInfo`* dictionary.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSApplication.h`

NSApplicationDidUpdateNotification

Posted at the end of the `updateWindows` (page 179) method to indicate that the application has finished updating its windows.

The notification object is `NSApp`. This notification does not contain a *`userInfo`* dictionary.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSApplication.h`

NSApplicationWillBecomeActiveNotification

Posted immediately after the application becomes active.

The notification object is `NSApp`. This notification does not contain a *`userInfo`* dictionary.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSApplication.h`

NSApplicationWillFinishLaunchingNotification

Posted at the start of the `finishLaunching` (page 147) method to indicate that the application has completed its initialization process and is about to finish launching.

The notification object is `NSApp`. This notification does not contain a *`userInfo`* dictionary.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSApplication.h`

NSApplicationWillHideNotification

Posted at the start of the `hide:` (page 148) method to indicate that the application is about to be hidden.

The notification object is `NSApp`. This notification does not contain a *`userInfo`* dictionary.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSApplication.h`

NSApplicationWillResignActiveNotification

Posted immediately before the application gives up its active status to another application.

The notification object is `sharedApplication` (page 135). This notification does not contain a *`userInfo`* dictionary.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSApplication.h`

NSApplicationWillTerminateNotification

Posted by the `terminate:` (page 176) method to indicate that the application will terminate.

Posted only if the delegate method `applicationShouldTerminate:` (page 3576) returns `YES`. The notification object is `sharedApplication` (page 135). This notification does not contain a *`userInfo`* dictionary.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSApplication.h`

NSApplicationWillUnhideNotification

Posted at the start of the `unhideWithoutActivation` (page 178) method to indicate that the application is about to become visible.

The notification object is `sharedApplication` (page 135). This notification does not contain a *`userInfo`* dictionary.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSApplication.h`

NSApplicationWillUpdateNotification

Posted at the start of the `updateWindows` (page 179) method to indicate that the application is about to update its windows.

The notification object is `sharedApplication` (page 135). This notification does not contain a *`userInfo`* dictionary.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSApplication.h`

NSArrayController Class Reference

Inherits from	NSObjectController : NSController : NSObject
Conforms to	NSCoding (NSController) NSObject (NSObject)
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.3 and later.
Declared in	AppKit/NSArrayController.h
Companion guides	Cocoa Bindings Programming Topics Predicate Programming Guide Core Data Programming Guide
Related sample code	CoreRecipes DemoMonkey GridCalendar LightTable XMLBrowser

Overview

`NSArrayController` is a bindings compatible class that manages a collection of objects. Typically the collection is an array, however, if the controller manages a relationship of a managed object (see `NSManagedObject`) the collection may be a set. `NSArrayController` provides selection management and sorting capabilities.

Tasks

Managing Sort Descriptors

`- setSortDescriptors:` (page 224)
Sets the sort descriptors for the receiver.

`- sortDescriptors` (page 224)
Returns the receiver's array of sort descriptors.

Arranging Objects

- `arrangeObjects:` (page 206)
  Returns a given array, appropriately sorted and filtered.
- `arrangedObjects` (page 205)
  Returns an array containing the receiver's content objects arranged using `arrangeObjects:` (page 206).
- `rearrangeObjects` (page 213)
  Triggers filtering of the receiver's content.

Managing Content

- `add:` (page 203)
  Creates and adds a new object to the receiver's content and arranged objects.
- `setAutomaticallyPreparesContent:` (page 219)
  Sets whether the receiver automatically creates and inserts new content objects automatically.
- `automaticallyPreparesContent` (page 206)
  Returns a Boolean value that indicates whether the receiver automatically prepares its content when it is loaded from a nib.

Selection Attributes

- `setAvoidsEmptySelection:` (page 220)
  Sets whether the receiver attempts to avoid an empty selection.
- `avoidsEmptySelection` (page 208)
  Returns a Boolean value that indicates whether if the receiver requires that the content array attempt to maintain a selection.
- `setClearsFilterPredicateOnInsertion:` (page 221)
  Sets whether the receiver automatically clears an existing filter predicate when a new object is inserted or added to the content array.
- `preservesSelection` (page 212)
  Returns a Boolean value that indicates whether the receiver will attempt to preserve the current selection when the content changes.
- `setPreservesSelection:` (page 222)
  Sets whether the receiver attempts to preserve selection when the content changes.
- `alwaysUsesMultipleValuesMarker` (page 205)
  Returns a Boolean value that indicates whether the receiver always returns the multiple values marker when multiple objects are selected.
- `setAlwaysUsesMultipleValuesMarker:` (page 219)
  Sets whether the receiver always returns the multiple values marker when multiple objects are selected.

Managing Selections

- `selectionIndex` (page 217)
  Returns the index of the first object in the receiver's selection.
- `setSelectionIndex:` (page 222)
  Sets the receiver's selection to the given index, and returns a Boolean value that indicates whether the selection was changed.
- `setSelectsInsertedObjects:` (page 224)
  Sets whether the receiver will automatically select objects as they are inserted.
- `selectsInsertedObjects` (page 219)
  Returns whether the receiver automatically selects inserted objects.
- `setSelectionIndexes:` (page 223)
  Sets the receiver's selection indexes and returns a Boolean value that indicates whether the selection changed.
- `selectionIndexes` (page 217)
  Returns an index set containing the indexes of the receiver's currently selected objects in the content array.
- `addSelectionIndexes:` (page 205)
  Adds the objects at the specified indexes in the receiver's content array to the current selection, returning `YES` if the selection was changed.
- `removeSelectionIndexes:` (page 216)
  Removes the object as the specified *`indexes`* from the receiver's current selection, returning `YES` if the selection was changed.
- `setSelectedObjects:` (page 222)
  Sets *`objects`* as the receiver's current selection, returning `YES` if the selection was changed.
- `selectedObjects` (page 216)
  Returns an array containing the receiver's selected objects.
- `addSelectedObjects:` (page 204)
  Adds *`objects`* from the receiver's content array to the current selection, returning `YES` if the selection was changed.
- `removeSelectedObjects:` (page 215)
  Removes *`objects`* from the receiver's current selection, returning `YES` if the selection was changed.
- `selectNext:` (page 218)
  Selects the next object, relative to the current selection, in the receiver's arranged content.
- `canSelectNext` (page 209)
  Returns `YES` if the next object, relative to the current selection, in the receiver's content array can be selected.
- `selectPrevious:` (page 218)
  Selects the previous object, relative to the current selection, in the receiver's arranged content.
- `canSelectPrevious` (page 209)
  Returns `YES` if the previous object, relative to the current selection, in the receiver's content array can be selected.

Inserting

- `canInsert` (page 208)
  Returns a Boolean value that indicates whether an object can be inserted into the receiver's content collection.
- `insert:` (page 211)
  Creates a new object and inserts it into the receiver's content array.

Adding and Removing Objects

- `addObject:` (page 203)
  Adds *object* to the receiver's content collection and the arranged objects array.
- `addObjects:` (page 204)
  Adds *objects* to the receiver's content collection.
- `insertObject:atArrangedObjectIndex:` (page 211)
  Inserts *object* into the receiver's arranged objects array at the location specified by *index*, and adds it to the receiver's content collection.
- `insertObjects:atArrangedObjectIndexes:` (page 212)
  Inserts *objects* into the receiver's arranged objects array at the locations specified in *indexes*, and adds it to the receiver's content collection.
- `removeObjectAtArrangedObjectIndex:` (page 214)
  Removes the object at the specified *index* in the receiver's arranged objects from the receiver's content array.
- `removeObjectsAtArrangedObjectIndexes:` (page 215)
  Removes the objects at the specified *indexes* in the receiver's arranged objects from the content array.
- `remove:` (page 213)
  Removes the receiver's selected objects from the content collection.
- `removeObject:` (page 214)
  Removes *object* from the receiver's content collection.
- `removeObjects:` (page 215)
  Removes *objects* from the receiver's content collection.

Filtering Content

- `clearsFilterPredicateOnInsertion` (page 209)
  Returns a Boolean value that indicates whether the receiver automatically clears an existing filter predicate when new items are inserted or added to the content.
- `filterPredicate` (page 210)
  Returns the predicate used by the receiver to filter the array controller contents.
- `setFilterPredicate:` (page 221)
  Sets the predicate used to filter the contents of the receiver.

Automatic Content Rearranging

- `setAutomaticallyRearrangesObjects:` (page 220)
  Sets whether or not the receiver automatically rearranges its content to correspond to the current sort descriptors and filter predicates.
- `automaticallyRearrangesObjects` (page 207)
  Returns a Boolean that indicates if the receiver automatically rearranges its content to correspond to the current sort descriptors and filter predicates.
- `automaticRearrangementKeyPaths` (page 207)
  Returns an array of key paths that trigger automatic content sorting or filtering.
- `didChangeArrangementCriteria` (page 210)
  Invoked when any criteria for arranging objects change.

Instance Methods

add:

Creates and adds a new object to the receiver's content and arranged objects.

```
- (void)add:(id)sender
```

Parameters

sender
  Typically the object that invoked this method.

Special Considerations

Beginning with Mac OS X v10.4 the result of this method is deferred until the next iteration of the runloop so that the error presentation mechanism (see Error Responders and Error Recovery) can provide feedback as a sheet.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`NSArrayController.h`

addObject:

Adds *object* to the receiver's content collection and the arranged objects array.

```
- (void)addObject:(id)object
```

Availability
Available in Mac OS X v10.3 and later.

See Also
- `addObjects:` (page 204)
- `insertObject:atArrangedObjectIndex:` (page 211)

- removeObject: (page 214)

Related Sample Code
Aperture Edit Plugin - Borders & Titles
QTCompressionOptionsWindow
XMLBrowser

Declared In
NSArrayController.h

addObjects:

Adds *objects* to the receiver's content collection.

```
- (void)addObjects:(NSArray *)objects
```

Discussion
If selectsInsertedObjects (page 219) returns YES (the default), the added objects are selected in the array controller.

It is important to note that inserting many objects with selectsInsertedObjects on can cause a significant performance penalty. In this case it is more efficient to use the setContent: (page 1756) method to set the array, or to set selectsInsertedObjects to NO before adding the objects with addObjects:.

Availability
Available in Mac OS X v10.3 and later.

See Also
- addObject: (page 203)
- insertObjects:atArrangedObjectIndexes: (page 212)
- removeObjects: (page 215)

Declared In
NSArrayController.h

addSelectedObjects:

Adds *objects* from the receiver's content array to the current selection, returning YES if the selection was changed.

```
- (BOOL)addSelectedObjects:(NSArray *)objects
```

Discussion
Attempting to change the selection may cause a commitEditing (page 850) message which fails, thus denying the selection change.

Availability
Available in Mac OS X v10.3 and later.

See Also
- removeSelectedObjects: (page 215)
- setSelectedObjects: (page 222)

Declared In
NSArrayController.h

addSelectionIndexes:

Adds the objects at the specified indexes in the receiver's content array to the current selection, returning YES if the selection was changed.

```
- (BOOL)addSelectionIndexes:(NSIndexSet *)indexes
```

Discussion
Attempting to change the selection may cause a commitEditing (page 850) message which fails, thus denying the selection change.

Availability
Available in Mac OS X v10.3 and later.

See Also
- removeSelectionIndexes: (page 216)

Declared In
NSArrayController.h

alwaysUsesMultipleValuesMarker

Returns a Boolean value that indicates whether the receiver always returns the multiple values marker when multiple objects are selected.

```
- (BOOL)alwaysUsesMultipleValuesMarker
```

Return Value
YES if the receiver always returns the multiple values marker when multiple objects are selected—even if the selected items have the same value, otherwise NO.

Discussion
The default is NO.

This property is observable using key-value observing.

Availability
Available in Mac OS X v10.4 and later.

See Also
- setAlwaysUsesMultipleValuesMarker: (page 219)

Declared In
NSArrayController.h

arrangedObjects

Returns an array containing the receiver's content objects arranged using arrangeObjects: (page 206).

```
- (id)arrangedObjects
```

Return Value
An array containing the receiver's content objects arranged using `arrangeObjects:` (page 206).

Discussion
This property is observable using key-value observing.

Availability
Available in Mac OS X v10.3 and later.

See Also
- `arrangeObjects:` (page 206)

Related Sample Code
CoreRecipes
DemoMonkey
QTCompressionOptionsWindow
With and Without Bindings

Declared In
`NSArrayController.h`

arrangeObjects:

Returns a given array, appropriately sorted and filtered.

```
- (NSArray *)arrangeObjects:(NSArray *)objects
```

Return Value
An array containing *objects* filtered using the receiver's filter predicate (see filterPredicate (page 210)) and sorted according to the receiver's `sortDescriptors` (page 224).

Discussion
Subclasses should override this method to use a different sort mechanism, provide custom object arrangement, or (typically only prior to Mac OS X version 10.4, which provides a filter predicate) filter the objects.

Availability
Available in Mac OS X v10.3 and later.

See Also
- `arrangedObjects` (page 205)
- `rearrangeObjects` (page 213)
- `sortDescriptors` (page 224)

Declared In
`NSArrayController.h`

automaticallyPreparesContent

Returns a Boolean value that indicates whether the receiver automatically prepares its content when it is loaded from a nib.

```
- (BOOL)automaticallyPreparesContent
```

Return Value
`YES` if the receiver automatically prepares its content when loaded from a nib, otherwise `NO`.

Discussion
See `setAutomaticallyPreparesContent:` (page 219) for a full explanation of "automatically prepares content."

The default is `YES`.

See Also
- `setAutomaticallyPreparesContent:` (page 219)
- `prepareContent` (page 1753)

automaticallyRearrangesObjects

Returns a Boolean that indicates if the receiver automatically rearranges its content to correspond to the current sort descriptors and filter predicates.

```
- (BOOL)automaticallyRearrangesObjects
```

Return Value
`YES` if the receiver automatically rearranges objects upon changes to the content, `NO` if the content does not automatically rearrange.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSArrayController.h`

automaticRearrangementKeyPaths

Returns an array of key paths that trigger automatic content sorting or filtering.

```
- (NSArray *)automaticRearrangementKeyPaths
```

Return Value
An array of key paths that trigger automatic content sorting or filtering.

Discussion
Subclasses can override this method to customize the default behavior of the sort descriptors and filtering predicates, for example, if additional arrangement criteria are used in a custom implementation of `rearrangeObjects` (page 213).

Availability
Available in Mac OS X v10.5 and later.

See Also
- `rearrangeObjects` (page 213)

Declared In
NSArrayController.h

avoidsEmptySelection

Returns a Boolean value that indicates whether if the receiver requires that the content array attempt to maintain a selection.

```
- (BOOL)avoidsEmptySelection
```

Return Value
YES if the receiver requires that the content array attempt to maintain a selection at all times, otherwise NO.

Discussion
The default is YES.

This property is observable using key-value observing.

Availability
Available in Mac OS X v10.3 and later.

See Also
- setAvoidsEmptySelection: (page 220)

Declared In
NSArrayController.h

canInsert

Returns a Boolean value that indicates whether an object can be inserted into the receiver's content collection.

```
- (BOOL)canInsert
```

Return Value
YES if an object can be inserted into the receiver's content collection, otherwise NO.

Discussion
The result of this method can be used by a binding to enable user interface items.

This property is observable using key-value observing.

Availability
Available in Mac OS X v10.3 and later.

See Also
- insert: (page 211)

Declared In
NSArrayController.h

canSelectNext

Returns `YES` if the next object, relative to the current selection, in the receiver's content array can be selected.

```
- (BOOL)canSelectNext
```

Discussion
The result of this method can be used by a binding to enable user interface items.

This property is observable using key-value observing.

Availability
Available in Mac OS X v10.3 and later.

See Also
- `selectNext:` (page 218)
- `canSelectPrevious` (page 209)

Declared In
`NSArrayController.h`

canSelectPrevious

Returns `YES` if the previous object, relative to the current selection, in the receiver's content array can be selected.

```
- (BOOL)canSelectPrevious
```

Discussion
The result of this method can be used by a binding to enable user interface items.

This property is observable using key-value observing.

Availability
Available in Mac OS X v10.3 and later.

See Also
- `canSelectNext` (page 209)
- `selectPrevious:` (page 218)

Declared In
`NSArrayController.h`

clearsFilterPredicateOnInsertion

Returns a Boolean value that indicates whether the receiver automatically clears an existing filter predicate when new items are inserted or added to the content.

```
- (BOOL)clearsFilterPredicateOnInsertion
```

Return Value
`YES` if the receiver automatically clears an existing filter predicate when new items are inserted or added to the content, otherwise `NO`.

Discussion
The default is `YES`.

This property is observable using key-value observing.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- setClearsFilterPredicateOnInsertion:` (page 221)

Declared In
`NSArrayController.h`

didChangeArrangementCriteria

Invoked when any criteria for arranging objects change.

```
- (void)didChangeArrangementCriteria
```

Discussion
This method is invoked by the controller itself when any criteria for arranging objects change (sort descriptors or filter predicates) to reset the key paths for automatic rearranging.

Special Considerations

If you implement a subclass of `NSArrayController` and override `rearrangeObjects` (page 213) to use additional arrangement criteria, you should invoke this method if those criteria change.

Availability
Available in Mac OS X v10.5 and later.

See Also
`- rearrangeObjects` (page 213)

Declared In
`NSArrayController.h`

filterPredicate

Returns the predicate used by the receiver to filter the array controller contents.

```
- (NSPredicate *)filterPredicate
```

Return Value
The predicate used by the receiver to filter the array controller contents. Returns `nil` if no filter predicate is set.

Discussion
This property is observable using key-value observing.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `setClearsFilterPredicateOnInsertion:` (page 221)
- `setFilterPredicate:` (page 221)

Declared In
`NSArrayController.h`

insert:

Creates a new object and inserts it into the receiver's content array.

```
- (void)insert:(id)sender
```

Parameters

sender

Typically the object that invoked this method.

Discussion
If an entity name is specified (see `entityName` (page 1749)), this method creates an instance of the of the class specified by the entity, otherwise this method creates an instance of the class specified by `objectClass` (page 1753).

Special Considerations

Beginning with Mac OS X v10.4 the result of this method is deferred until the next iteration of the runloop so that the error presentation mechanism (see Error Responders and Error Recovery) can provide feedback as a sheet.

Availability
Available in Mac OS X v10.3 and later.

See Also
- `canInsert` (page 208)

Declared In
`NSArrayController.h`

insertObject:atArrangedObjectIndex:

Inserts *object* into the receiver's arranged objects array at the location specified by *index*, and adds it to the receiver's content collection.

```
- (void)insertObject:(id)object atArrangedObjectIndex:(NSUInteger)index
```

Discussion
Subclasses can override this method to provide customized arranged objects support.

Availability
Available in Mac OS X v10.3 and later.

See Also
- `insertObjects:atArrangedObjectIndexes:` (page 212)
- `addObject:` (page 203)
- `removeObjectAtArrangedObjectIndex:` (page 214)

Related Sample Code
With and Without Bindings

Declared In
NSArrayController.h

insertObjects:atArrangedObjectIndexes:

Inserts *objects* into the receiver's arranged objects array at the locations specified in *indexes*, and adds it to the receiver's content collection.

```
- (void)insertObjects:(NSArray *)objects atArrangedObjectIndexes:(NSIndexSet
    *)indexes
```

Availability
Available in Mac OS X v10.3 and later.

See Also
- `insertObject:atArrangedObjectIndex:` (page 211)
- `addObjects:` (page 204)
- `removeObjectsAtArrangedObjectIndexes:` (page 215)

Related Sample Code
DemoMonkey

Declared In
NSArrayController.h

preservesSelection

Returns a Boolean value that indicates whether the receiver will attempt to preserve the current selection when the content changes.

```
- (BOOL)preservesSelection
```

Return Value
`YES` if the receiver attempts to preserve the current selection when the content changes, otherwise `NO`.

Discussion
The default is `YES`.

This property is observable using key-value observing.

Availability
Available in Mac OS X v10.3 and later.

See Also
- `setClearsFilterPredicateOnInsertion:` (page 221)

Declared In
NSArrayController.h

rearrangeObjects

Triggers filtering of the receiver's content.

```
- (void)rearrangeObjects
```

Discussion
This method invokes `arrangeObjects:` (page 206).

When you detect that filtering criteria change (such as when listening to the text sent by an `NSSearchField` instance), invoke this method on `self`.

Availability
Available in Mac OS X v10.3 and later.

See Also
- `arrangeObjects:` (page 206)
- `didChangeArrangementCriteria` (page 210)
- `automaticRearrangementKeyPaths` (page 207)

iSpend

Declared In
`NSArrayController.h`

remove:

Removes the receiver's selected objects from the content collection.

```
- (void)remove:(id)sender
```

Parameters
sender
Typically the object that invoked this method.

Discussion
See removeObject: (page 214) for a discussion of the semantics of removing objects when using Core Data.

Special Considerations

Beginning with Mac OS X v10.4 the result of this method is deferred until the next iteration of the runloop so that the error presentation mechanism (see Error Responders and Error Recovery) can provide feedback as a sheet.

Availability
Available in Mac OS X v10.4 and later.

Declared In
NSArrayController.h

removeObject:

Removes *object* from the receiver's content collection.

```
- (void)removeObject:(id)object
```

Special Considerations

If you are using Core Data, the exact semantics of this method differ depending on the settings for the array controller. If the receiver's content is fetched automatically, removed objects are marked for deletion by the managed object context (and hence removal from the object graph). If, however, the receiver's `contentSet` is bound to a relationship, `removeObject:` by default only removes the object from the relationship (not from the object graph). You can, though, set the "Deletes Object on Remove" option for the `contentSet` binding, in which case objects are marked for deletion as well as being removed from the relationship.

Availability
Available in Mac OS X v10.3 and later.

removeObjectAtArrangedObjectIndex:

Removes the object at the specified *index* in the receiver's arranged objects from the receiver's content array.

```
- (void)removeObjectAtArrangedObjectIndex:(NSUInteger)index
```

Discussion
See removeObject: (page 214) for a discussion of the semantics of removing objects when using Core Data.

Availability
Available in Mac OS X v10.3 and later.

See Also
- `removeObjectsAtArrangedObjectIndexes:` (page 215)

- removeObjects: (page 215)

Declared In
NSArrayController.h

removeSelectedObjects:

Removes *objects* from the receiver's current selection, returning YES if the selection was changed.

```
- (BOOL)removeSelectedObjects:(NSArray *)objects
```

Discussion
Attempting to change the selection may cause a `commitEditing` (page 850) message which fails, thus denying the selection change.

Availability
Available in Mac OS X v10.3 and later.

See Also
`- addSelectedObjects:` (page 204)

Declared In
`NSArrayController.h`

removeSelectionIndexes:

Removes the object as the specified *indexes* from the receiver's current selection, returning `YES` if the selection was changed.

```
- (BOOL)removeSelectionIndexes:(NSIndexSet *)indexes
```

Discussion
Attempting to change the selection may cause a `commitEditing` (page 850) message which fails, thus denying the selection change.

Availability
Available in Mac OS X v10.3 and later.

See Also
`- addSelectionIndexes:` (page 205)

Declared In
`NSArrayController.h`

selectedObjects

Returns an array containing the receiver's selected objects.

```
- (NSArray *)selectedObjects
```

Discussion
This property is observable using key-value observing.

Availability
Available in Mac OS X v10.3 and later.

See Also
`- setSelectedObjects:` (page 222)

selectionIndexes

Returns an index set containing the indexes of the receiver's currently selected objects in the content array.

```
- (NSIndexSet *)selectionIndexes
```

Return Value
An index set containing the indexes of the receiver's currently selected objects in the content array.

Discussion
This property is observable using key-value observing.

Availability
Available in Mac OS X v10.3 and later.

See Also
- `setSelectionIndexes:` (page 223)

- selectionIndex (page 217)

Declared In
NSArrayController.h

selectNext:

Selects the next object, relative to the current selection, in the receiver's arranged content.

```
- (void)selectNext:(id)sender
```

Discussion
The *sender* is typically the object that invoked this method.

Special Considerations

Beginning with Mac OS X v10.4 the result of this method is deferred until the next iteration of the runloop so that the error presentation mechanism (see Error Responders and Error Recovery) can provide feedback as a sheet.

Availability
Available in Mac OS X v10.3 and later.

See Also
- selectPrevious: (page 218)
- canSelectNext (page 209)

Declared In
NSArrayController.h

selectPrevious:

Selects the previous object, relative to the current selection, in the receiver's arranged content.

```
- (void)selectPrevious:(id)sender
```

Discussion
The *sender* is typically the object that invoked this method.

Special Considerations

Beginning with Mac OS X v10.4 the result of this method is deferred until the next iteration of the runloop so that the error presentation mechanism (see Error Responders and Error Recovery) can provide feedback as a sheet.

Availability
Available in Mac OS X v10.3 and later.

See Also
- selectNext: (page 218)
- canSelectPrevious (page 209)

Declared In
NSArrayController.h

selectsInsertedObjects

Returns whether the receiver automatically selects inserted objects.

```
- (BOOL)selectsInsertedObjects
```

Return Value
`YES` if the receiver automatically selects inserted objects, otherwise `NO`.

Discussion
The default is `YES`.

This property is observable using key-value observing.

Availability
Available in Mac OS X v10.3 and later.

See Also
`- setSelectsInsertedObjects:` (page 224)

Declared In
`NSArrayController.h`

setAlwaysUsesMultipleValuesMarker:

Sets whether the receiver always returns the multiple values marker when multiple objects are selected.

```
- (void)setAlwaysUsesMultipleValuesMarker:(BOOL)flag
```

Parameters

flag

If `YES`, the receiver always returns the multiple values marker when multiple objects are selected, even if they have the same value.

Discussion
Setting *flag* to `YES` can increase performance if your application doesn't allow editing multiple values. The default is `NO`.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- alwaysUsesMultipleValuesMarker` (page 205)

Declared In
`NSArrayController.h`

setAutomaticallyPreparesContent:

Sets whether the receiver automatically creates and inserts new content objects automatically.

```
- (void)setAutomaticallyPreparesContent:(BOOL)flag
```

Parameters

flag

If YES, the receiver automatically prepares its content.

Discussion

If *flag* is YES and the receiver is not using a managed object context, prepareContent (page 1753) is used to create the content object.

If *flag* is YES and a managed object context is set, the initial content is fetched from the managed object context using the current fetch predicate. The controller also registers as an observer of its managed object context. It then tracks insertions and deletions of its entity using the context's notifications, and updates its content array as appropriate.

Setting *flag* to YES is the same as checking the "Automatically Prepares Content" option in the Interface Builder controller inspector.

See Also

- automaticallyPreparesContent (page 206)
- prepareContent (page 1753)

setAutomaticallyRearrangesObjects:

Sets whether or not the receiver automatically rearranges its content to correspond to the current sort descriptors and filter predicates.

```
- (void)setAutomaticallyRearrangesObjects:(BOOL)flag
```

Parameters

flag

A Boolean value that indicates whether the receiver automatically rearranges its content (YES) or not (NO).

Discussion

The default is NO.

Availability

Available in Mac OS X v10.5 and later.

Declared In

NSArrayController.h

setAvoidsEmptySelection:

Sets whether the receiver attempts to avoid an empty selection.

```
- (void)setAvoidsEmptySelection:(BOOL)flag
```

Parameters

flag

If YES, the receiver maintains a selection unless there are no objects in the content array.

Discussion

The default is YES.

Availability
Available in Mac OS X v10.3 and later.

See Also
- `avoidsEmptySelection` (page 208)

Declared In
`NSArrayController.h`

setClearsFilterPredicateOnInsertion:

Sets whether the receiver automatically clears an existing filter predicate when a new object is inserted or added to the content array.

```
- (void)setClearsFilterPredicateOnInsertion:(BOOL)flag
```

Parameters

flag

If `YES`, the receiver automatically clears an existing filter predicate when a new object is inserted or added to the content array.

Discussion
The default is `YES`.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `clearsFilterPredicateOnInsertion` (page 209)

Declared In
`NSArrayController.h`

setFilterPredicate:

Sets the predicate used to filter the contents of the receiver.

```
- (void)setFilterPredicate:(NSPredicate *)filterPredicate
```

Parameters

filterPredicate

The predicate used to filter the contents of the receiver.

Discussion
If *filterPredicate* is `nil`, any existing filter predicate is removed.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `filterPredicate` (page 210)

Declared In
`NSArrayController.h`

setPreservesSelection:

Sets whether the receiver attempts to preserve selection when the content changes.

```
- (void)setPreservesSelection:(BOOL)flag
```

Parameters

flag

If YES, the receiver attempts to preserve selection when the content changes.

Discussion
The default is YES.

Availability
Available in Mac OS X v10.3 and later.

See Also
- preservesSelection (page 212)

Declared In
NSArrayController.h

setSelectedObjects:

Sets *objects* as the receiver's current selection, returning YES if the selection was changed.

```
- (BOOL)setSelectedObjects:(NSArray *)objects
```

Discussion
Attempting to change the selection may cause a commitEditing (page 850) message which fails, thus denying the selection change.

Availability
Available in Mac OS X v10.3 and later.

See Also
- selectedObjects (page 216)
- addSelectedObjects: (page 204)

setSelectionIndex:

Sets the receiver's selection to the given index, and returns a Boolean value that indicates whether the selection was changed.

```
- (BOOL)setSelectionIndex:(NSUInteger)index
```

Parameters

index

The index for the selection.

Return Value

`YES` if the selection was changed, otherwise `NO`.

Discussion

Attempting to change the selection may cause a `commitEditing` (page 850) message which fails, thus denying the selection change.

Availability

Available in Mac OS X v10.3 and later.

GridCalendar

QTCompressionOptionsWindow

Declared In

`NSArrayController.h`

setSelectionIndexes:

Sets the receiver's selection indexes and returns a Boolean value that indicates whether the selection changed.

```
- (BOOL)setSelectionIndexes:(NSIndexSet *)indexes
```

Parameters

indexes

The set of selection indexes for the receiver.

Return Value

`YES` if the selection was changed, otherwise `NO`.

Discussion

Attempting to change the selection may cause a `commitEditing` (page 850) message which fails, thus denying the selection change.

To select all the receiver's objects, indexes should be an index set with indexes `[0...count -1]`. To deselect all indexes, pass an empty index set.

Availability

Available in Mac OS X v10.3 and later.

See Also

- `selectionIndexes` (page 217)
- `setSelectionIndex:` (page 222)

Related Sample Code
DemoMonkey

Declared In
`NSArrayController.h`

setSelectsInsertedObjects:

Sets whether the receiver will automatically select objects as they are inserted.

```
- (void)setSelectsInsertedObjects:(BOOL)flag
```

Parameters

flag
If `YES` then items will be selected upon insertion.

Discussion
The default is `YES`.

Availability
Available in Mac OS X v10.3 and later.

See Also
`- selectsInsertedObjects` (page 219)

Declared In
`NSArrayController.h`

setSortDescriptors:

Sets the sort descriptors for the receiver.

```
- (void)setSortDescriptors:(NSArray *)sortDescriptors
```

Parameters

sortDescriptors
An array of `NSSortDescriptor` objects, used by the receiver to arrange its content.

Availability
Available in Mac OS X v10.3 and later.

See Also
`- sortDescriptors` (page 224)
`- arrangeObjects:` (page 206)

Declared In
`NSArrayController.h`

sortDescriptors

Returns the receiver's array of sort descriptors.

```
- (NSArray *)sortDescriptors
```

Return Value
The array of `NSSortDescriptor` objects used by the receiver to arrange its content.

Discussion
This property is observable using key-value observing.

Availability
Available in Mac OS X v10.3 and later.

NSATSTypesetter Class Reference

Inherits from	NSTypesetter : NSObject
Conforms to	NSObject (NSObject)
Framework	/System/Library/Frameworks/AppKit.framework
Declared in	AppKit/NSATSTypesetter.h
Availability	Available in Mac OS X v10.3 and later.
Companion guides	Text System Overview Text Layout Programming Guide

Overview

`NSATSTypesetter` is a concrete subclass of `NSTypesetter` that places glyphs during the text layout process. The typesetter creates line fragment rectangles, positions glyphs within the line fragments, determines line breaks by word wrapping and hyphenation, and handles tab positioning.

`NSATSTypesetter` encapsulates the advanced typesetting capabilities of Core Text. `NSATSTypesetter` provides enhanced line and character spacing accuracy and supports more languages, including bidirectional languages, than the original, built-in typesetter class `NSSimpleHorizontalTypesetter` (which is deprecated in Mac OS X version 10.4 and later).

Subclassing Notes

`NSATSTypesetter` introduced a set of interfaces in Mac OS X version 10.3 that facilitated subclassing and made it possible to substitute a custom layout engine into the Cocoa text system. In Mac OS X version 10.4, those interfaces moved to `NSTypesetter`, which you can subclass to the same effect. See the `NSTypesetter` reference documentation for relevant subclassing notes.

Tasks

Getting a Typesetter

`+ sharedTypesetter` (page 231)
Returns a shared instance of `NSATSTypesetter`.

Managing the Layout Manager

- `layoutManager` (page 237)
  Returns the layout manager for the text being typeset.
- `setUsesFontLeading:` (page 245)
  Sets a Boolean value controlling whether the typesetter uses the leading (or line gap) value specified in the font metric information.
- `usesFontLeading` (page 247)
  Returns a Boolean value indicating whether the typesetter uses the leading (or line gap) value specified in the font metric information of the current font.
- `setTypesetterBehavior:` (page 244)
  Sets the default typesetter behavior, which affects glyph spacing and line height.
- `typesetterBehavior` (page 247)
  Returns the current typesetter behavior value.
- `setHyphenationFactor:` (page 242)
  Sets the threshold controlling when hyphenation is attempted
- `hyphenationFactor` (page 235)
  Returns the current hyphenation factor.

Managing the Text Container

- `currentTextContainer` (page 233)
  Returns the text container for the text being typeset.
- `setLineFragmentPadding:` (page 242)
  Sets the amount (in points) by which text is inset within line fragment rectangles
- `lineFragmentPadding` (page 237)
  Returns the current line fragment padding amount; that is, the portion on each end of the line fragment rectangle left blank.

Mapping Screen and Printer Fonts

- `substituteFontForFont:` (page 246)
  Returns a screen font suitable for use in place of the specified original font, or simply returns the original font if a screen font can't be used or isn't available.

Managing Text Tabs

- `textTabForGlyphLocation:writingDirection:maxLocation:` (page 247)
  Returns the text tab next closest to a given glyph location, indexing in the specified direction but not beyond a given glyph location.

Bidirectional Text Processing

- `setBidiProcessingEnabled:` (page 241)
  Sets a Boolean value controlling whether the typesetter performs bidirectional text processing.
- `bidiProcessingEnabled` (page 232)
  Returns a Boolean value indicating the bidirectional text processing setting currently in effect.

Accessing Paragraph Typesetting Information

- `setAttributedString:` (page 240)
  Sets the text backing store on which this typesetter operates.
- `attributedString` (page 231)
  Returns the text backing store, usually an instance of `NSTextStorage`.
- `setParagraphGlyphRange:separatorGlyphRange:` (page 244)
  Sets the current glyph range being processed and the paragraph separator glyph range (the range of the paragraph separator character or characters).
- `paragraphGlyphRange` (page 238)
  Returns the glyph range currently being processed.
- `paragraphSeparatorGlyphRange` (page 239)
  Returns the current paragraph separator range, which is the full range that contains the current glyph range and that extends from one paragraph separator character to the next.

Paragraph Layout

- `layoutParagraphAtPoint:` (page 237)
  Lays out glyphs in the current glyph range until the next paragraph separator is reached.

Line and Paragraph Spacing

- `lineSpacingAfterGlyphAtIndex:withProposedLineFragmentRect:` (page 238)
  Returns the line spacing in effect following the specified glyph.
- `paragraphSpacingAfterGlyphAtIndex:withProposedLineFragmentRect:` (page 239)
  Returns the paragraph spacing, the number of points of space added following a paragraph, which is in effect after the specified glyph.
- `paragraphSpacingBeforeGlyphAtIndex:withProposedLineFragmentRect:` (page 240)
  Returns the number of points of space added before a paragraph, which is in effect before the specified glyph.

Glyph Caching

- `setHardInvalidation:forGlyphRange:` (page 242)
  Sets a Boolean value controlling whether to force the layout manager to invalidate the portion of the glyph cache in the given glyph range when invalidating layout.

Laying out Glyphs

`- boundingBoxForControlGlyphAtIndex:forTextContainer:proposedLineFragment:glyphPosition:characterIndex:` (page 232)

Returns the bounding rectangle for the given control glyph, at the given glyph position and character index, in the given text container.

`- getLineFragmentRect:usedRect:forParagraphSeparatorGlyphRange:atProposedOrigin:` (page 234)

Calculates the line fragment rectangle and line fragment used rectangle for blank lines.

`- hyphenCharacterForGlyphAtIndex:` (page 236)

Returns the hyphen character to be inserted after the given glyph when hyphenation is enabled in the layout manager.

`- hyphenationFactorForGlyphAtIndex:` (page 235)

Returns the hyphenation factor in effect at the given glyph index.

`- shouldBreakLineByHyphenatingBeforeCharacterAtIndex:` (page 245)

The typesetter calls this method, if implemented by a subclass, before breaking a line by hyphenating before the character at the given character index, enabling the subclass to control line breaking.

`- shouldBreakLineByWordBeforeCharacterAtIndex:` (page 246)

The typesetter calls this method, if implemented by a subclass, before breaking a line by word wrapping before the character at the given character index, enabling the subclass to control line breaking.

`- willSetLineFragmentRect:forGlyphRange:usedRect:baselineOffset:` (page 248)

Called by the typesetter just prior to calling `setLineFragmentRect:forGlyphRange:usedRect:baselineOffset:` (page 243) which stores the actual line fragment rectangle location in the layout manager.

Interfacing with Glyph Storage

`- characterRangeForGlyphRange:actualGlyphRange:` (page 232)

Returns the range for the characters in the receiver's text store that are mapped to the glyphs in the given glyph range.

`- deleteGlyphsInRange:` (page 233)

Deletes the glyphs in the given glyph range from the glyph cache maintained by the layout manager.

`- getGlyphsInRange:glyphs:characterIndexes:glyphInscriptions:elasticBits:` (page 233)

Extracts the information needed to lay out the glyphs in the given glyph buffer from the given glyph range.

`- glyphRangeForCharacterRange:actualCharacterRange:` (page 234)

Returns the range for the glyphs mapped to the characters of the text store in the given character range.

`- insertGlyph:atGlyphIndex:characterIndex:` (page 236)

Enables the typesetter to insert a new glyph into the stream.

`- setAttachmentSize:forGlyphRange:` (page 240)

Sets the size the glyphs in the given glyph range (assumed to be attachments) will be asked to draw themselves.

`- setBidiLevels:forGlyphRange:` (page 241)

Sets the direction of the glyphs in the given glyph range for bidirectional text to the given levels.

- `setDrawsOutsideLineFragment:forGlyphRange:` (page 241)
  Sets a Boolean value controlling whether the glyphs in the given glyph range exceed the bounds of the line fragment in which they are laid out.
- `setLineFragmentRect:forGlyphRange:usedRect:baselineOffset:` (page 243)
  Sets the line fragment rectangle where the glyphs in in the given glyph range are laid out to the given line fragment rectangle.
- `setLocation:withAdvancements:forStartOfGlyphRange:` (page 243)
  Sets the location where the glyphs in the given glyph range are laid out to the specified location.
- `setNotShownAttribute:forGlyphRange:` (page 244)
  Sets a Boolean value controlling whether the glyphs in the given glyph rangeare not shown.
- `substituteGlyphsInRange:withGlyphs:` (page 246)
  Replaces the glyphs in the given glyph range with the given glyphs.
- `lineFragmentRectForProposedRect:remainingRect:` (page 238) Deprecated in Mac OS X v10.4
  This method has been deprecated. Use the NSTypesetter method `getLineFragmentRect:usedRect:remainingRect:forStartingGlyphAtIndex:proposedRect:lineSpacing:paragraphSpacingBefore:paragraphSpacingAfter:` (page 3090) instead.

Class Methods

sharedTypesetter

Returns a shared instance of `NSATSTypesetter`.

```
+ (id)sharedTypesetter
```

Availability
Available in Mac OS X v10.3 and later.

Declared In
`NSATSTypesetter.h`

Instance Methods

attributedString

Returns the text backing store, usually an instance of `NSTextStorage`.

```
- (NSAttributedString *)attributedString
```

Availability
Available in Mac OS X v10.3. Moved to NSTypesetter in Mac OS X v10.4 and later.

See Also
- `setAttributedString:` (page 240)

Declared In
NSATSTypesetter.h

bidiProcessingEnabled

Returns a Boolean value indicating the bidirectional text processing setting currently in effect.

```
- (BOOL)bidiProcessingEnabled
```

Availability
Available in Mac OS X v10.3. Moved to NSTypesetter in Mac OS X v10.4 and later.

See Also
- setBidiProcessingEnabled: (page 241)

Declared In
NSATSTypesetter.h

boundingBoxForControlGlyphAtIndex:forTextContainer:proposedLineFragment:glyphPosition:characterIndex:

Returns the bounding rectangle for the given control glyph, at the given glyph position and character index, in the given text container.

```
- (NSRect)boundingBoxForControlGlyphAtIndex:(NSUInteger)glyphIndex
    forTextContainer:(NSTextContainer *)textContainer
    proposedLineFragment:(NSRect)proposedRect glyphPosition:(NSPoint)glyphPosition
     characterIndex:(NSUInteger)charIndex
```

Discussion
Returns the bounding rectangle for the control glyph at *glyphIndex*, at the given *glyphPosition* and character index *charIndex*, in *textContainer*. The proposed line fragment rectangle is specified by *proposedRect*.

The typesetter calls this method when it encounters an NSControlGlyph. The default behavior is to return zero width for control glyphs. A subclass can override this method to do something different, such as implement a way to display control characters.

NSGlyphGenerator can choose whether or not to map control characters to NSControlGlyph. Tab characters, for example, do not use this facility.

Availability
Available in Mac OS X v10.3. Moved to NSTypesetter in Mac OS X v10.4 and later.

Declared In
NSATSTypesetter.h

characterRangeForGlyphRange:actualGlyphRange:

Returns the range for the characters in the receiver's text store that are mapped to the glyphs in the given glyph range.

```
- (NSRange)characterRangeForGlyphRange:(NSRange)glyphRange
    actualGlyphRange:(NSRangePointer)actualGlyphRange
```

Discussion
If *actualGlyphRange* is non-NULL, expands the requested range as needed so that it identifies all glyphs mapped to those characters and returns the new range by reference in *actualGlyphRange*.

A subclass can override this method to interact with custom glyph storage.

Availability
Available in Mac OS X v10.3. Moved to NSTypesetter in Mac OS X v10.4 and later.

See Also
- glyphRangeForCharacterRange:actualCharacterRange: (page 234)

Declared In
NSATSTypesetter.h

currentTextContainer

Returns the text container for the text being typeset.

```
- (NSTextContainer *)currentTextContainer
```

Availability
Available in Mac OS X v10.3. Moved to NSTypesetter in Mac OS X v10.4 and later.

Declared In
NSATSTypesetter.h

deleteGlyphsInRange:

Deletes the glyphs in the given glyph range from the glyph cache maintained by the layout manager.

```
- (void)deleteGlyphsInRange:(NSRange)glyphRange
```

Discussion
A subclass can override this method to interact with custom glyph storage.

Availability
Available in Mac OS X v10.3. Moved to NSTypesetter in Mac OS X v10.4 and later.

See Also
insertGlyph:atGlyphIndex:characterIndex: (page 236)

Declared In
NSATSTypesetter.h

getGlyphsInRange:glyphs:characterIndexes:glyphInscriptions:elasticBits:

Extracts the information needed to lay out the glyphs in the given glyph buffer from the given glyph range.

```
- (NSUInteger)getGlyphsInRange:(NSRange)glyphsRange glyphs:(NSGlyph *)glyphBuffer
    characterIndexes:(NSUInteger *)charIndexBuffer
  glyphInscriptions:(NSGlyphInscription *)inscribeBuffer elasticBits:(BOOL
  *)elasticBuffer
```

Discussion
The *charIndexBuffer* contains the original characters for the glyphs. Note that a glyph at index 1 is not necessarily mapped to the character at index 1, since a glyph may be for a ligature or accent.

The *inscribeBuffer* contains the inscription attributes for each glyph, which are used to layout characters that are combined together. The possible values are described in the "Constants" (page 1525) section of the NSLayoutManager reference.

The *elasticBuffer* contains a Boolean value indicating whether a glyph is elastic for each glyph. An elastic glyph can be made longer at the end of a line or when needed for justification.

A subclass can override this method to interact with custom glyph storage.

Availability
Available in Mac OS X v10.3. Moved to NSTypesetter in Mac OS X v10.4 and later.

Declared In
NSATSTypesetter.h

getLineFragmentRect:usedRect:forParagraphSeparatorGlyphRange:atProposedOrigin:

Calculates the line fragment rectangle and line fragment used rectangle for blank lines.

```
- (void)getLineFragmentRect:(NSRect *)lineFragmentRect usedRect:(NSRect
  *)lineFragmentUsedRect
  forParagraphSeparatorGlyphRange:(NSRange)paragraphSeparatorGlyphRange
  atProposedOrigin:(NSPoint)lineOrigin
```

Discussion
The method returns the calculated line fragment rectangle in *lineFragmentRect*, and it returns the used rectangle (the portion of the line fragment rectangle that actually contains marks) in *lineFragmentUsedRect*. The *paragraphSeparatorGlyphRange* is the range of glyphs under consideration, and *lineOrigin* is the origin point of the line fragment rectangle. A *paragraphSeparatorGlyphRange* with length 0 indicates an extra line fragment (which occurs if the last character in the paragraph is a line separator.)

Availability
Available in Mac OS X v10.3. Moved to NSTypesetter in Mac OS X v10.4 and later.

Declared In
NSATSTypesetter.h

glyphRangeForCharacterRange:actualCharacterRange:

Returns the range for the glyphs mapped to the characters of the text store in the given character range.

```
- (NSRange)glyphRangeForCharacterRange:(NSRange)charRange
    actualCharacterRange:(NSRangePointer)actualCharRange
```

Discussion
If *actualCharRange* is non-NULL, expands the requested range as needed so that it identifies all characters mapped to those glyphs and returns the new range by reference in *actualCharRange*.

A subclass can override this method to interact with custom glyph storage.

Availability
Available in Mac OS X v10.3. Moved to NSTypesetter in Mac OS X v10.4 and later.

See Also
- characterRangeForGlyphRange:actualGlyphRange: (page 232)

Declared In
NSATSTypesetter.h

hyphenationFactor

Returns the current hyphenation factor.

```
- (float)hyphenationFactor
```

Discussion
The hyphenation factor is a value ranging from 0.0 to 1.0 that controls when hyphenation is attempted. By default, the value is 0.0, meaning hyphenation is off. A factor of 1.0 causes hyphenation to be attempted always.

Availability
Available in Mac OS X v10.3. Moved to NSTypesetter in Mac OS X v10.4 and later.

See Also
- setHyphenationFactor: (page 242)

Declared In
NSATSTypesetter.h

hyphenationFactorForGlyphAtIndex:

Returns the hyphenation factor in effect at the given glyph index.

```
- (float)hyphenationFactorForGlyphAtIndex:(NSUInteger)glyphIndex
```

Discussion
The hyphenation factor is a value ranging from 0.0 to 1.0 that controls when hyphenation is attempted. By default, the value is 0.0, meaning hyphenation is off. A factor of 1.0 causes hyphenation to be attempted always.

The typesetter calls this method with a proposed hyphenation point for a line break to find the hyphenation factor in effect at that time. A subclass can override this method to customize the text layout process.

Availability
Available in Mac OS X v10.3. Moved to NSTypesetter in Mac OS X v10.4 and later.

See Also
- hyphenCharacterForGlyphAtIndex: (page 236)

Declared In
NSATSTypesetter.h

hyphenCharacterForGlyphAtIndex:

Returns the hyphen character to be inserted after the given glyph when hyphenation is enabled in the layout manager.

```
- (UTF32Char)hyphenCharacterForGlyphAtIndex:(NSUInteger)glyphIndex
```

Discussion
The typesetter calls this method before hyphenating. A subclass can override this method to return a different hyphen glyph.

Availability
Available in Mac OS X v10.3. Moved to NSTypesetter in Mac OS X v10.4 and later.

See Also
- hyphenationFactorForGlyphAtIndex: (page 235)

Declared In
NSATSTypesetter.h

insertGlyph:atGlyphIndex:characterIndex:

Enables the typesetter to insert a new glyph into the stream. (Available in Mac OS X v10.3 through Mac OS X v10.3.)

```
- (void)insertGlyph:(NSGlyph)glyph atGlyphIndex:(NSUInteger)glyphIndex
    characterIndex:(NSUInteger)charIndex
```

Discussion
Inserts *glyph* into the glyph cache at *glyphIndex* and maps it to the character at *charIndex*. If the glyph is mapped to several characters, *charIndex* should indicate the first character to which it's mapped.

The standard typesetter uses this method for inserting hyphenation glyphs. Because this method keeps the glyph caches synchronized, subclasses should always use this method to insert glyphs instead of calling layoutManager (page 237) directly.

A subclass can override this method to interact with custom glyph storage.

Availability
Available in Mac OS X v10.3 through Mac OS X v10.3.

Declared In
NSATSTypesetter.h

layoutManager

Returns the layout manager for the text being typeset.

```
- (NSLayoutManager *)layoutManager
```

Availability
Available in Mac OS X v10.3. Moved to NSTypesetter in Mac OS X v10.4 and later.

Declared In
NSATSTypesetter.h

layoutParagraphAtPoint:

Lays out glyphs in the current glyph range until the next paragraph separator is reached.

```
- (NSUInteger)layoutParagraphAtPoint:(NSPoint *)lineFragmentOrigin
```

Discussion
The *lineFragmentOrigin* specifies the upper-left corner of line fragment rectangle. On return, *lineFragmentOrigin* contains the next origin. This method returns the next glyph index. Usually it's the index right after the paragraph separator, but it can be inside the paragraph range if, for example, the end of the text container is reached before the paragraph separator.

Availability
Available in Mac OS X v10.3. Moved to NSTypesetter in Mac OS X v10.4 and later.

Declared In
NSATSTypesetter.h

lineFragmentPadding

Returns the current line fragment padding amount; that is, the portion on each end of the line fragment rectangle left blank.

```
- (CGFloat)lineFragmentPadding
```

Discussion
Text is inset within the line fragment rectangle by this amount.

Availability
Available in Mac OS X v10.3. Moved to NSTypesetter in Mac OS X v10.4 and later.

See Also
- setLineFragmentPadding: (page 242)

Declared In
NSATSTypesetter.h

lineFragmentRectForProposedRect:remainingRect:

This method has been deprecated. Use the NSTypesetter method `getLineFragmentRect:usedRect:remainingRect:forStartingGlyphAtIndex:proposedRect:lineSpacing:paragraphSpacingBefore:paragraphSpacingAfter:` (page 3090) instead. (Deprecated in Mac OS X v10.4.)

```
- (NSRect)lineFragmentRectForProposedRect:(NSRect)proposedRect
    remainingRect:(NSRectPointer)remainingRect
```

Discussion
Returns the largest rectangle available for the proposed rectangle *proposedRect*. It also returns a rectangle in *remainingRect* containing any remaining space, such as that left on the other side of a hole or gap in the text container.

A subclass can override this method to interact with custom glyph storage.

Availability
Available in Mac OS X v10.3 and later.
Deprecated in Mac OS X v10.4.

Declared In
`NSATSTypesetter.h`

lineSpacingAfterGlyphAtIndex:withProposedLineFragmentRect:

Returns the line spacing in effect following the specified glyph.

```
- (CGFloat)lineSpacingAfterGlyphAtIndex:(NSUInteger)glyphIndex
    withProposedLineFragmentRect:(NSRect)rect
```

Discussion
The NSATSTypesetter calls this method to determine the number of points of space to include below the descenders in the used rectangle for the proposed line fragment rectangle *rect*.

Line spacing, also called leading, is an attribute of NSParagraphStyle, which you can set on an NSMutableParagraphStyle object. A font typically includes a default minimum line spacing metric used if none is set in the paragraph style.

If the typesetter behavior specified in the NSLayoutManager is `NSTypesetterOriginalBehavior`, the text system uses the original, private typesetter NSSimpleHorizontalTypesetter, which adds the line spacing above the ascender. Similarly, NSATSTypesetter adds the line spacing above the ascender if the value is negative.

Availability
Available in Mac OS X v10.3. Moved to NSTypesetter in Mac OS X v10.4 and later.

Declared In
`NSATSTypesetter.h`

paragraphGlyphRange

Returns the glyph range currently being processed.

```
- (NSRange)paragraphGlyphRange
```

Availability
Available in Mac OS X v10.3. Moved to NSTypesetter in Mac OS X v10.4 and later.

See Also
- `setParagraphGlyphRange:separatorGlyphRange:` (page 244)
- `paragraphSeparatorGlyphRange` (page 239)

Declared In
`NSATSTypesetter.h`

paragraphSeparatorGlyphRange

Returns the current paragraph separator range, which is the full range that contains the current glyph range and that extends from one paragraph separator character to the next.

```
- (NSRange)paragraphSeparatorGlyphRange
```

Availability
Available in Mac OS X v10.3. Moved to NSTypesetter in Mac OS X v10.4 and later.

See Also
- `setParagraphGlyphRange:separatorGlyphRange:` (page 244)
- `paragraphGlyphRange` (page 238)

Declared In
`NSATSTypesetter.h`

paragraphSpacingAfterGlyphAtIndex:withProposedLineFragmentRect:

Returns the paragraph spacing, the number of points of space added following a paragraph, which is in effect after the specified glyph.

```
- (CGFloat)paragraphSpacingAfterGlyphAtIndex:(NSUInteger)glyphIndex
    withProposedLineFragmentRect:(NSRect)rect
```

Discussion
The *rect* argument specifies the line fragment rectangle of the last line in the paragraph.

The typesetter adds the number of points specified in the return value to the bottom of the line fragment rectangle specified by *rect* (but not to the used line fragment rectangle for that line). Paragraph spacing added after a paragraph correlates to the value returned by the `paragraphSpacing` method of NSParagraphStyle, which you can set using the `setParagraphSpacing:` method of NSMutableParagraphStyle.

Availability
Available in Mac OS X v10.3. Moved to NSTypesetter in Mac OS X v10.4 and later.

See Also
- `paragraphSpacingBeforeGlyphAtIndex:withProposedLineFragmentRect:` (page 240)

Declared In
`NSATSTypesetter.h`

paragraphSpacingBeforeGlyphAtIndex:withProposedLineFragmentRect:

Returns the number of points of space added before a paragraph, which is in effect before the specified glyph.

```
- (CGFloat)paragraphSpacingBeforeGlyphAtIndex:(NSUInteger)glyphIndex
    withProposedLineFragmentRect:(NSRect)rect
```

Discussion
The *rect* argument specifies the line fragment rectangle of the first line in the paragraph.

The typesetter adds the number of points specified in the return value to the top of the line fragment rectangle specified by *rect* (but not to the used line fragment rectangle for that line). Paragraph spacing added before a paragraph correlates to the value returned by the `paragraphSpacingBefore` method of NSParagraphStyle, which you can set using the `setParagraphSpacingBefore:` method of NSMutableParagraphStyle.

Availability
Available in Mac OS X v10.3. Moved to NSTypesetter in Mac OS X v10.4 and later.

See Also
`- paragraphSpacingAfterGlyphAtIndex:withProposedLineFragmentRect:` (page 239)

Declared In
`NSATSTypesetter.h`

setAttachmentSize:forGlyphRange:

Sets the size the glyphs in the given glyph range (assumed to be attachments) will be asked to draw themselves.

```
- (void)setAttachmentSize:(NSSize)attachmentSize forGlyphRange:(NSRange)glyphRange
```

Discussion
A subclass can override this method to interact with custom glyph storage.

Availability
Available in Mac OS X v10.3. Moved to NSTypesetter in Mac OS X v10.4 and later.

Declared In
`NSATSTypesetter.h`

setAttributedString:

Sets the text backing store on which this typesetter operates.

```
- (void)setAttributedString:(NSAttributedString *)attrString
```

Discussion
The string object is not retained.

Availability
Available in Mac OS X v10.3. Moved to NSTypesetter in Mac OS X v10.4 and later.

See Also
- attributedString (page 231)

Declared In
NSATSTypesetter.h

setBidiLevels:forGlyphRange:

Sets the direction of the glyphs in the given glyph range for bidirectional text to the given levels.

```
- (void)setBidiLevels:(const uint8_t *)levels forGlyphRange:(NSRange)glyphRange
```

Discussion
The value of *levels* can range from 0 to 61 as defined by Unicode Standard Annex #9.

A subclass can override this method to interact with custom glyph storage.

Availability
Available in Mac OS X v10.3. Moved to NSTypesetter in Mac OS X v10.4 and later.

Declared In
NSATSTypesetter.h

setBidiProcessingEnabled:

Sets a Boolean value controlling whether the typesetter performs bidirectional text processing.

```
- (void)setBidiProcessingEnabled:(BOOL)flag
```

Discussion
You can use this method to disable the bidirectional layout stage if you know the paragraph does not need this stage; that is, if the characters in the backing store are in display order.

Availability
Available in Mac OS X v10.3. Moved to NSTypesetter in Mac OS X v10.4 and later.

See Also
- bidiProcessingEnabled (page 232)

Declared In
NSATSTypesetter.h

setDrawsOutsideLineFragment:forGlyphRange:

Sets a Boolean value controlling whether the glyphs in the given glyph range exceed the bounds of the line fragment in which they are laid out.

```
- (void)setDrawsOutsideLineFragment:(BOOL)flag forGlyphRange:(NSRange)glyphRange
```

Discussion
This can happen when text is set at a fixed line height. For example, if the user specifies a fixed line height of 12 points and sets the font size to 24 points, the glyphs will exceed their layout rectangles.

A subclass can override this method to interact with custom glyph storage.

Availability
Available in Mac OS X v10.3. Moved to NSTypesetter in Mac OS X v10.4 and later.

Declared In
NSATSTypesetter.h

setHardInvalidation:forGlyphRange:

Sets a Boolean value controlling whether to force the layout manager to invalidate the portion of the glyph cache in the given glyph range when invalidating layout.

```
- (void)setHardInvalidation:(BOOL)flag forGlyphRange:(NSRange)glyphRange
```

Availability
Available in Mac OS X v10.3. Moved to NSTypesetter in Mac OS X v10.4 and later.

Declared In
NSATSTypesetter.h

setHyphenationFactor:

Sets the threshold controlling when hyphenation is attempted

```
- (void)setHyphenationFactor:(float)factor
```

Discussion
The *factor* argument is in the range of 0.0 to 1.0. By default, the value is 0.0, meaning hyphenation is off. A *factor* of 1.0 causes hyphenation to be attempted always.

Availability
Available in Mac OS X v10.3. Moved to NSTypesetter in Mac OS X v10.4 and later.

See Also
- hyphenationFactor (page 235)

Declared In
NSATSTypesetter.h

setLineFragmentPadding:

Sets the amount (in points) by which text is inset within line fragment rectangles

```
- (void)setLineFragmentPadding:(CGFloat)padding
```

Discussion
Note that line fragment padding isn't a suitable means for expressing margins; you should set the NSTextView object's position and size for document margins or the paragraph margin attributes for text margins.

Availability
Available in Mac OS X v10.3. Moved to NSTypesetter in Mac OS X v10.4 and later.

See Also
- `lineFragmentPadding` (page 237)

Declared In
`NSATSTypesetter.h`

setLineFragmentRect:forGlyphRange:usedRect:baselineOffset:

Sets the line fragment rectangle where the glyphs in in the given glyph range are laid out to the given line fragment rectangle.

```
- (void)setLineFragmentRect:(NSRect)fragmentRect forGlyphRange:(NSRange)glyphRange
    usedRect:(NSRect)usedRect baselineOffset:(CGFloat)baselineOffset
```

Discussion
The exact positions of the glyphs must be set after the line fragment rectangle with `setLocation:forStartOfGlyphRange:`.

The *usedRect* argument indicates the portion of *fragmentRect*, in the NSTextContainer object's coordinate system, that actually contains glyphs or other marks that are drawn (including the text container's line fragment padding). The *usedRect* must be equal to or contained within *fragmentRect*. The *baselineOffset* argument is the vertical distance in pixels from the line fragment origin to the baseline on which the glyphs align.

A subclass can override this method to interact with custom glyph storage.

Availability
Available in Mac OS X v10.3. Moved to NSTypesetter in Mac OS X v10.4 and later.

Declared In
`NSATSTypesetter.h`

setLocation:withAdvancements:forStartOfGlyphRange:

Sets the location where the glyphs in the given glyph range are laid out to the specified location.

```
- (void)setLocation:(NSPoint)location withAdvancements:(const CGFloat *)advancements
    forStartOfGlyphRange:(NSRange)glyphRange
```

Discussion
The x-coordinate of *location* is expressed relative to the line fragment rectangle origin, and the y-coordinate is expressed relative to the baseline previously specified by `setLineFragmentRect:forGlyphRange:usedRect:baselineOffset:` (page 243). The *glyphRange* defines a series of glyphs that can be displayed with a single PostScript `show` operation (a nominal range). Setting the location for a series of glyphs implies that the glyphs preceding it can't be included in a single `show` operation. The *advancements* argument is the nominal glyph advance width specified in the font metric information.

Before setting the location for a glyph range, you must specify line fragment rectangle with `setLineFragmentRect:forGlyphRange:usedRect:baselineOffset:`.

A subclass can override this method to interact with custom glyph storage.

Availability
Available in Mac OS X v10.3. Moved to NSTypesetter in Mac OS X v10.4 and later.

Declared In
NSATSTypesetter.h

setNotShownAttribute:forGlyphRange:

Sets a Boolean value controlling whether the glyphs in the given glyph rangeare not shown.

```
- (void)setNotShownAttribute:(BOOL)flag forGlyphRange:(NSRange)glyphRange
```

Discussion
For example, a tab or newline character doesn't leave any marks; it just indicates where following glyphs are laid out.

A subclass can override this method to interact with custom glyph storage.

Availability
Available in Mac OS X v10.3. Moved to NSTypesetter in Mac OS X v10.4 and later.

Declared In
NSATSTypesetter.h

setParagraphGlyphRange:separatorGlyphRange:

Sets the current glyph range being processed and the paragraph separator glyph range (the range of the paragraph separator character or characters).

```
- (void)setParagraphGlyphRange:(NSRange)paragraphRange
    separatorGlyphRange:(NSRange)paragraphSeparatorRange
```

Parameters

paragraphRange
The glyph range that becomes current.

paragraphSeparatorRange
The paragraph separator glyph range that becomes current.

Availability
Available in Mac OS X v10.3. Moved to NSTypesetter in Mac OS X v10.4 and later.

See Also
- paragraphGlyphRange (page 238)
- paragraphSeparatorGlyphRange (page 239)

Declared In
NSATSTypesetter.h

setTypesetterBehavior:

Sets the default typesetter behavior, which affects glyph spacing and line height.

```
- (void)setTypesetterBehavior:(NSTypesetterBehavior)behavior
```

Discussion
The possible values for *behavior* are described in the "Constants" (page 1525) section of the NSLayoutManager reference.

Availability
Available in Mac OS X v10.3. Moved to NSTypesetter in Mac OS X v10.4 and later.

See Also
- typesetterBehavior (page 247)

Declared In
NSATSTypesetter.h

setUsesFontLeading:

Sets a Boolean value controlling whether the typesetter uses the leading (or line gap) value specified in the font metric information.

```
- (void)setUsesFontLeading:(BOOL)flag
```

Availability
Available in Mac OS X v10.3. Moved to NSTypesetter in Mac OS X v10.4 and later.

See Also
- usesFontLeading (page 247)

Declared In
NSATSTypesetter.h

shouldBreakLineByHyphenatingBeforeCharacterAtIndex:

The typesetter calls this method, if implemented by a subclass, before breaking a line by hyphenating before the character at the given character index, enabling the subclass to control line breaking.

```
- (BOOL)shouldBreakLineByHyphenatingBeforeCharacterAtIndex:(NSUInteger)charIndex
```

Discussion
A subclass can override this method to customize the text layout process. If the method returns NO, the typesetter continues looking for a break point.

Availability
Available in Mac OS X v10.3. Moved to NSTypesetter in Mac OS X v10.4 and later.

See Also
- shouldBreakLineByWordBeforeCharacterAtIndex: (page 246)

Declared In
NSATSTypesetter.h

shouldBreakLineByWordBeforeCharacterAtIndex:

The typesetter calls this method, if implemented by a subclass, before breaking a line by word wrapping before the character at the given character index, enabling the subclass to control line breaking.

```
- (BOOL)shouldBreakLineByWordBeforeCharacterAtIndex:(NSUInteger)charIndex
```

Discussion
A subclass can override this method to customize the text layout process. If the method returns `NO`, the typesetter continues looking for a break point.

Availability
Available in Mac OS X v10.3. Moved to NSTypesetter in Mac OS X v10.4 and later.

See Also
- shouldBreakLineByHyphenatingBeforeCharacterAtIndex: (page 245)

Declared In
NSATSTypesetter.h

substituteFontForFont:

Returns a screen font suitable for use in place of the specified original font, or simply returns the original font if a screen font can't be used or isn't available.

```
- (NSFont *)substituteFontForFont:(NSFont *)originalFont
```

Discussion
A screen font can be substituted if the receiver is set to use screen fonts and if no NSTextView associated with the receiver is scaled or rotated.

Availability
Available in Mac OS X v10.3. Moved to NSTypesetter in Mac OS X v10.4 and later.

Declared In
NSATSTypesetter.h

substituteGlyphsInRange:withGlyphs:

Replaces the glyphs in the given glyph range with the given glyphs.

```
- (void)substituteGlyphsInRange:(NSRange)glyphRange withGlyphs:(NSGlyph *)glyphs
```

Discussion
This method does not alter the glyph-to-character mapping or invalidate layout information.

A subclass can override this method to interact with custom glyph storage.

Availability
Available in Mac OS X v10.3 and later.

Declared In
NSATSTypesetter.h

textTabForGlyphLocation:writingDirection:maxLocation:

Returns the text tab next closest to a given glyph location, indexing in the specified direction but not beyond a given glyph location.

```
- (NSTextTab *)textTabForGlyphLocation:(CGFloat)glyphLocation
    writingDirection:(NSWritingDirection)direction maxLocation:(CGFloat)maxLocation
```

Discussion
The typesetter calls this method whenever it finds a tab character. To determine the width to advance the next glyph, the typesetter examines the NSParagraphStyle tab array and the default tab interval.

Availability
Available in Mac OS X v10.3. Moved to NSTypesetter in Mac OS X v10.4 and later.

Declared In
NSATSTypesetter.h

typesetterBehavior

Returns the current typesetter behavior value.

```
- (NSTypesetterBehavior)typesetterBehavior
```

Discussion
The possible return values are described in the "Constants" (page 1525) section of the `NSLayoutManager` reference.

Availability
Available in Mac OS X v10.3. Moved to NSTypesetter in Mac OS X v10.4 and later.

See Also
- `setTypesetterBehavior:` (page 244)

Declared In
NSATSTypesetter.h

usesFontLeading

Returns a Boolean value indicating whether the typesetter uses the leading (or line gap) value specified in the font metric information of the current font.

```
- (BOOL)usesFontLeading
```

Availability
Available in Mac OS X v10.3. Moved to NSTypesetter in Mac OS X v10.4 and later.

See Also
- `setUsesFontLeading:` (page 245)

Declared In
NSATSTypesetter.h

willSetLineFragmentRect:forGlyphRange:usedRect:baselineOffset:

Called by the typesetter just prior to calling `setLineFragmentRect:forGlyphRange:usedRect:baselineOffset:` (page 243) which stores the actual line fragment rectangle location in the layout manager.

```
- (void)willSetLineFragmentRect:(NSRect *)lineRect forGlyphRange:(NSRange)glyphRange
    usedRect:(NSRect *)usedRect baselineOffset:(CGFloat *)baselineOffset
```

Discussion

The *lineRect* argument is the rectangle in which the glyphs in *glyphRange* are laid out. The *usedRect* argument indicates the portion of *lineRect*, in the NSTextContainer object's coordinate system, that actually contains glyphs or other marks that are drawn (including the text container's line fragment padding). The *usedRect* must be equal to or contained within *lineRect*. The *baselineOffset* argument is the vertical distance in pixels from the line fragment origin to the baseline on which the glyphs align.

A subclass can override this method to customize the text layout process. For example, it could change the shape of the line fragment rectangle. The subclass is responsible for ensuring that the modified rectangle remains valid (for example, that it lies within the text container).

Availability

Available in Mac OS X v10.3. Moved to NSTypesetter in Mac OS X v10.4 and later.

Declared In

`NSATSTypesetter.h`

NSAttributedString Application Kit Additions Reference

Inherits from	NSObject
Framework	/System/Library/Frameworks/AppKit.framework
Declared in	AppKit/NSAttributedString.h AppKit/NSStringDrawing.h AppKit/NSTextAttachment.h
Companion guide	Attributed String Programming Guide

Overview

The Application Kit extends Foundation's `NSAttributedString` class by adding support for RTF (with or without attachments), graphics attributes (including font and ruler attributes), methods for drawing attributed strings, and methods for calculating significant linguistic units.

Tasks

Creating an NSAttributedString

`+ attributedStringWithAttachment:` (page 252)
Creates an attributed string with an attachment.

`- initWithData:options:documentAttributes:error:` (page 260)
Initializes and returns a new `NSAttributedString` object from the data contained in the given `NSData` object.

`- initWithDocFormat:documentAttributes:` (page 261)
Initializes and returns a new `NSAttributedString` object from Microsoft Word format data contained in the given `NSData` object.

`- initWithHTML:documentAttributes:` (page 261)
Initializes and returns a new `NSAttributedString` object from HTML contained in the given data object.

`- initWithHTML:baseURL:documentAttributes:` (page 261)
Initializes and returns a new `NSAttributedString` object from the HTML contained in the given object and base URL.

`- initWithHTML:options:documentAttributes:` (page 262)
Initializes and returns a new `NSAttributedString` object from HTML contained in the given data object.

- `initWithPath:documentAttributes:` (page 262)
  Initializes a new `NSAttributedString` object from RTF or RTFD data contained in the file at the given path.
- `initWithRTF:documentAttributes:` (page 263)
  Initializes a new `NSAttributedString` object by decoding the stream of RTF commands and data contained in the given data object.
- `initWithRTFD:documentAttributes:` (page 263)
  Initializes a new `NSAttributedString` object by decoding the stream of RTFD commands and data contained in the given data object.
- `initWithRTFDFileWrapper:documentAttributes:` (page 263)
  Initializes a new `NSAttributedString` object from the given `NSFileWrapper` object containing an RTFD document.
- `initWithURL:documentAttributes:` (page 264)
  Initializes a new `NSAttributedString` object from the data at the given URL.
- `initWithURL:options:documentAttributes:error:` (page 264)
  Initializes a new `NSAttributedString` object from the contents of the given URL.

Retrieving Font Attribute Information

- `containsAttachments` (page 256)
  Returns `YES` if the receiver contains any attachment attributes, `NO` otherwise.
- `fontAttributesInRange:` (page 260)
  Returns the font attributes in effect for the character at the given location.
- `rulerAttributesInRange:` (page 269)
  Returns the ruler (paragraph) attributes in effect for the characters within the given range.

Calculating Linguistic Units

- `URLAtIndex:effectiveRange:` (page 270)
  Returns a URL, either from a link attribute or from text at the given location that appears to be a URL string, for use in automatic link detection.
- `doubleClickAtIndex:` (page 257)
  Returns the range of characters that form a word (or other linguistic unit) surrounding the given index, taking language characteristics into account.
- `lineBreakBeforeIndex:withinRange:` (page 265)
  Returns the index of the closest character before the given index, and within the given range, that can be placed on a new line when laying out text.
- `lineBreakByHyphenatingBeforeIndex:withinRange:` (page 265)
  Returns the index of the closest character before the given index, and within the given range, that can be placed on a new line by hyphenating.
- `nextWordFromIndex:forward:` (page 266)
  Returns the index of the first character of the word after or before the given index.

Calculating Ranges

- `itemNumberInTextList:atIndex:` (page 265)
  Returns the range of the item at the given index within the given list.
- `rangeOfTextBlock:atIndex:` (page 266)
  Returns the range of the individual text block that contains the given location.
- `rangeOfTextList:atIndex:` (page 267)
  Returns the range of the given text list that contains the given location.
- `rangeOfTextTable:atIndex:` (page 267)
  Returns the range of the given text table that contains the given location

Generating Data

- `dataFromRange:documentAttributes:error:` (page 256)
  Returns an `NSData` object that contains a text stream corresponding to the characters and attributes within the given range.
- `fileWrapperFromRange:documentAttributes:error:` (page 259)
  Returns an `NSFileWrapper` object that contains a text stream corresponding to the characters and attributes within the given range.
- `docFormatFromRange:documentAttributes:` (page 257)
  Returns an `NSData` object that contains a Microsoft Word–format stream corresponding to the characters and attributes within the specified range.
- `RTFFromRange:documentAttributes:` (page 269)
  Returns an `NSData` object that contains an RTF stream corresponding to the characters and attributes within the given range, omitting all attachment attributes.
- `RTFDFromRange:documentAttributes:` (page 268)
  Returns an NSData object that contains an RTFD stream corresponding to the characters and attributes within *aRange*.
- `RTFDFileWrapperFromRange:documentAttributes:` (page 268)
  Returns an `NSFileWrapper` object that contains an RTFD document corresponding to the characters and attributes within the given range.

Drawing the String

- `drawAtPoint:` (page 257)
  Draws the receiver with its font and other display attributes at the given point in the currently focused `NSView`.
- `drawInRect:` (page 258)
  Draws the receiver with its font and other display attributes within the given rectangle in the currently focused `NSView`, clipping the text layout to this rectangle.
- `drawWithRect:options:` (page 259)
  Draws the receiver with the specified options, within the given rectangle in the current graphics context.
- `size` (page 270)
  Returns the bounding box of the marks that the receiver draws.

Getting the Bounding Rectangle of Rendered Strings

`- boundingRectWithSize:options:` (page 255)
Calculates and returns bounding rectangle for the receiver drawn using the options specified, within the given rectangle in the current graphics context.

Testing String Data Sources

`+ textTypes` (page 254)
Returns an array of UTI strings identifying the file types supported by the receiver, either directly or through a user-installed filter service.

`+ textUnfilteredTypes` (page 255)
Returns an array of UTI strings identifying the file types supported directly by the receiver.

Deprecated Methods

`+ textFileTypes` (page 253) Deprecated in Mac OS X v10.5
Returns an array of strings representing those file types that can be loaded as text. (Deprecated. Use `textTypes` (page 254) instead.)

`+ textPasteboardTypes` (page 253) Deprecated in Mac OS X v10.5
Returns an array of pasteboard types that can be loaded as text. (Deprecated. Use `textTypes` (page 254) instead.)

`+ textUnfilteredFileTypes` (page 254) Deprecated in Mac OS X v10.5
Returns an array of strings representing those file types that can be loaded as a text. (Deprecated. Use `textUnfilteredTypes` (page 255) instead.)

`+ textUnfilteredPasteboardTypes` (page 255) Deprecated in Mac OS X v10.5
Returns an array of pasteboard types that can be loaded as text. (Deprecated. Use `textUnfilteredTypes` (page 255) instead.)

Class Methods

attributedStringWithAttachment:

Creates an attributed string with an attachment.

```
+ (NSAttributedString *)attributedStringWithAttachment:(NSTextAttachment *)attachment
```

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
CoreRecipes

Declared In
`NSTextAttachment.h`

textFileTypes

Returns an array of strings representing those file types that can be loaded as text. (Deprecated in Mac OS X v10.5. Use `textTypes` (page 254) instead.)

```
+ (NSArray *)textFileTypes
```

Discussion
This list includes all file types supported by text classes, plus those types that can be converted to supported file types through a user-installed filter service. The array returned by this method may be passed directly to *NSOpenPanel* method `runModalForTypes:` (page 1821).

File types are identified by extension and HFS file types. By default, the list returned by this method includes "`txt`", "`rtf`", "`rtfd`", and "`html`".

When creating a subclass of `NSAttributedString` that accepts text data from non-default file types, override `textUnfilteredFileTypes` (page 254) to notify `NSAttributedString` of the file types your class supports.

Availability
Available in Mac OS X v10.1 and later.
Deprecated in Mac OS X v10.5.

See Also
`+ textUnfilteredFileTypes` (page 254)

Declared In
`NSAttributedString.h`

textPasteboardTypes

Returns an array of pasteboard types that can be loaded as text. (Deprecated in Mac OS X v10.5. Use `textTypes` (page 254) instead.)

```
+ (NSArray *)textPasteboardTypes
```

Discussion
This list includes all pasteboard types supported by text classes and those that can be converted to supported pasteboard types through a user-installed filter service.

By default, the list returned by this method includes `NSHTMLPboardType`, `NSRTFPboardType`, `NSRTFDPboardType`, and `NSStringPboardType`.

When creating a subclass of `NSAttributedString` that accepts text data from non-default pasteboard types, override `textUnfilteredPasteboardTypes` (page 255) to notify `NSAttributedString` of the pasteboard types your class supports.

Availability
Available in Mac OS X v10.1 and later.
Deprecated in Mac OS X v10.5.

See Also
`+ textUnfilteredPasteboardTypes` (page 255)

Related Sample Code
GLUT

Declared In
NSAttributedString.h

textTypes

Returns an array of UTI strings identifying the file types supported by the receiver, either directly or through a user-installed filter service.

```
+ (NSArray *)textTypes
```

Return Value
An array of `NSString` objects, each of which contains a UTI identifying a supported file type.

Discussion
The returned list includes UTIs all file types supported by the receiver plus those that can be opened by the receiver after being converted by a user-installed filter service. You can use the returned UTI strings with any method that supports UTIs.

Availability
Available in Mac OS X v10.5 and later.

Declared In
NSAttributedString.h

textUnfilteredFileTypes

Returns an array of strings representing those file types that can be loaded as a text. (Deprecated in Mac OS X v10.5. Use `textUnfilteredTypes` (page 255) instead.)

```
+ (NSArray *)textUnfilteredFileTypes
```

Discussion
This list consists of all file types supported by text classes, but does not include those types that can be converted to supported file types through a user-installed filter service. The array returned by this method may be passed directly to `NSOpenPanel` method `runModalForTypes:` (page 1821).

Availability
Available in Mac OS X v10.1 and later.
Deprecated in Mac OS X v10.5.

See Also
`+ textFileTypes` (page 253)

Declared In
NSAttributedString.h

textUnfilteredPasteboardTypes

Returns an array of pasteboard types that can be loaded as text. (Deprecated in Mac OS X v10.5. Use `textUnfilteredTypes` (page 255) instead.)

```
+ (NSArray *)textUnfilteredPasteboardTypes
```

Discussion
This list consists of all pasteboard types supported by text classes, but does not include those that can be converted to supported pasteboard types through a user-installed filter service.

Availability
Available in Mac OS X v10.1 and later.
Deprecated in Mac OS X v10.5.

See Also
`+ textPasteboardTypes` (page 253)

Declared In
`NSAttributedString.h`

textUnfilteredTypes

Returns an array of UTI strings identifying the file types supported directly by the receiver.

```
+ (NSArray *)textUnfilteredTypes
```

Return Value
An array of `NSString` objects, each of which contains a UTI identifying a supported file type.

Discussion
The returned list includes UTI strings only for those file types that are supported directly by the receiver. It does not include types that are supported through user-installed filter services. You can use the returned UTI strings with any method that supports UTIs.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSAttributedString.h`

Instance Methods

boundingRectWithSize:options:

Calculates and returns bounding rectangle for the receiver drawn using the options specified, within the given rectangle in the current graphics context.

```
- (NSRect)boundingRectWithSize:(NSSize)size options:(NSStringDrawingOptions)options
```

Discussion
The origin of the rectangle returned from this method is the first glyph origin.

The values of `NSStringDrawingOptions` are listed in the `String Drawing Options` (page 2585) section of NSString Additions.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- drawInRect:` (page 258)

Declared In
`NSStringDrawing.h`

containsAttachments

Returns `YES` if the receiver contains any attachment attributes, `NO` otherwise.

```
- (BOOL)containsAttachments
```

Discussion
This method checks only for attachment attributes, not for `NSAttachmentCharacter`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSAttributedString.h`

dataFromRange:documentAttributes:error:

Returns an `NSData` object that contains a text stream corresponding to the characters and attributes within the given range.

```
- (NSData *)dataFromRange:(NSRange)range documentAttributes:(NSDictionary *)dict
    error:(NSError **)error
```

Discussion
Requires a document attributes dictionary *`dict`* specifying at least the `NSDocumentTypeDocumentAttribute` to determine the format to write. Raises an `NSRangeException` if any part of *`range`* lies beyond the end of the receiver's characters. If unsuccessful, returns `nil` after setting *`error`* to point to an `NSError` object that encapsulates the reason why the object could not be created.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- fileWrapperFromRange:documentAttributes:error:` (page 259)

Related Sample Code
Quartz Composer WWDC 2005 TextEdit

Declared In
`NSAttributedString.h`

docFormatFromRange:documentAttributes:

Returns an `NSData` object that contains a Microsoft Word–format stream corresponding to the characters and attributes within the specified range.

```
- (NSData *)docFormatFromRange:(NSRange)range documentAttributes:(NSDictionary
    *)dict
```

Discussion
The range is passed in the *range* parameter. Also writes the document-level attributes in *dict*, as explained in "Constants" (page 271). If there are no document-level attributes, *dict* can be `nil`. Raises an `NSRangeException` if any part of *range* lies beyond the end of the receiver's characters.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`NSAttributedString.h`

doubleClickAtIndex:

Returns the range of characters that form a word (or other linguistic unit) surrounding the given index, taking language characteristics into account.

```
- (NSRange)doubleClickAtIndex:(NSUInteger)index
```

Discussion
Raises an `NSRangeException` if *index* lies beyond the end of the receiver's characters.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- nextWordFromIndex:forward:` (page 266)

Declared In
`NSAttributedString.h`

drawAtPoint:

Draws the receiver with its font and other display attributes at the given point in the currently focused `NSView`.

```
- (void)drawAtPoint:(NSPoint)point
```

Discussion
The width (height for vertical layout) of the rendering area is unlimited, unlike `drawInRect:` (page 258), which uses a bounding rectangle. As a result, this method renders the text in a single line.

Don't invoke this method while no `NSView` is focused.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `lockFocus` (page 3187) (NSView)
- `size` (page 270)
- `drawInRect:` (page 258)

ComplexBrowser
FunHouse
Movie Overlay

Declared In
`NSStringDrawing.h`

drawInRect:

Draws the receiver with its font and other display attributes within the given rectangle in the currently focused `NSView`, clipping the text layout to this rectangle.

```
- (void)drawInRect:(NSRect)rect
```

Discussion
Text is drawn within *`rect`* according to its line sweep direction; for example, Arabic text will begin at the right edge and potentially be clipped on the left.

The *`rect`* parameter determines how many glyphs are typeset within the width of a line, but it's possible for a portion of a glyph to appear outside the area of *`rect`* if the image bounding box of the particular glyph exceeds its typographic bounding box.

If the focus view is flipped, the text origin is set at the upper-left corner of the drawing bounding box; otherwise the origin is set at the lower-left corner. For text rendering, whether the view coordinates are flipped or not doesn't affect the flow of line layout, which goes from top to bottom. However, it affects the interpretation of the text origin. So, for example, if the *`rect`* argument is `{0.0, 0.0, 100.0, 100.0}`, the text origin is {0.0, 0.0} when the view coordinates are flipped and {0.0, 100.0} when not.

Don't invoke this method while no `NSView` is focused.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSStringDrawing.h

drawWithRect:options:

Draws the receiver with the specified options, within the given rectangle in the current graphics context.

```
- (void)drawWithRect:(NSRect)rect options:(NSStringDrawingOptions)options
```

Discussion
The *rect* argument's origin field specifies the rendering origin. The point is interpreted as the baseline origin by default. With NSStringDrawingUsesLineFragmentOrigin, it is interpreted as the upper left corner of the line fragment rect. The size field specifies the text container size. The width part of the size field specifies the maximum line fragment width if larger than 0.0. The height defines the maximum size that can be occupied with text if larger than 0.0 and NSStringDrawingUsesLineFragmentOrigin is specified. If NSStringDrawingUsesLineFragmentOrigin is not specified, height is ignored and considered to be single-line rendering (NSLineBreakByWordWrapping and NSLineBreakByCharWrapping are treated as NSLineBreakByClipping).

The values of NSStringDrawingOptions are listed in the String Drawing Options (page 2585) section of NSString Additions.

You should only invoke this method when there is a current graphics context.

Availability
Available in Mac OS X v10.4 and later.

See Also
- drawAtPoint: (page 257) (NSView)
- lockFocus (page 3187)

Declared In
NSStringDrawing.h

fileWrapperFromRange:documentAttributes:error:

Returns an NSFileWrapper object that contains a text stream corresponding to the characters and attributes within the given range.

```
- (NSFileWrapper *)fileWrapperFromRange:(NSRange)range
    documentAttributes:(NSDictionary *)dict error:(NSError **)error
```

Discussion
Requires a document attributes dictionary *dict* specifying at least the NSDocumentTypeDocumentAttribute to determine the format to write. Raises an NSRangeException if any part of *range* lies beyond the end of the receiver's characters. Returns a directory file wrapper for those document types for which it is appropriate; otherwise a regular file wrapper. If unsuccessful, returns nil after setting *error* to point to an NSError object that encapsulates the reason why the object could not be created.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `dataFromRange:documentAttributes:error:` (page 256)

Declared In
`NSAttributedString.h`

fontAttributesInRange:

Returns the font attributes in effect for the character at the given location.

```
- (NSDictionary *)fontAttributesInRange:(NSRange)aRange
```

Discussion
Returns the font attributes in effect for the character at *aRange*.*location*. Font attributes are all those listed in "Standard Attributes" (page 271), except `NSLinkAttributeName`, `NSParagraphStyleAttributeName`, and `NSAttachmentAttributeName`. Use this method to obtain font attributes that are to be copied or pasted with "copy font" operations. Raises an `NSRangeException` if any part of *aRange* lies beyond the end of the receiver's characters.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `rulerAttributesInRange:` (page 269)

Declared In
`NSAttributedString.h`

initWithData:options:documentAttributes:error:

Initializes and returns a new `NSAttributedString` object from the data contained in the given `NSData` object.

```
- (id)initWithData:(NSData *)data options:(NSDictionary *)options
    documentAttributes:(NSDictionary **)dict error:(NSError **)error
```

Discussion
The *options* dictionary can contain the values described in "Option keys for importing documents" (page 285) to specify how the document should be loaded. If `NSDocumentTypeDocumentOption` is specified, the document is treated as being in the specified format. If `NSDocumentTypeDocumentOption` is not specified, the method examines the document and loads it using whatever format it seems to contain. Also returns by reference in *dict* a dictionary containing document-level attributes described in "Constants" (page 271). The *dict* parameter may be nil, in which case no document attributes are returned. Returns `nil` if *data* can't be decoded, after setting *error* to point to an NSError that encapsulates the reason why the attributed string object could not be created.

Availability
Available in Mac OS X v10.4 and later.

NSAttributedString.h

initWithDocFormat:documentAttributes:

Initializes and returns a new NSAttributedString object from Microsoft Word format data contained in the given NSData object.

```
- (id)initWithDocFormat:(NSData *)data documentAttributes:(NSDictionary
    **)docAttributes
```

Discussion
Also returns by reference in *docAttributes* a dictionary containing document-level attributes described in "Document Attributes" (page 279). *docAttributes* may be NULL, in which case no document attributes are returned. Returns nil if *data* can't be decoded.

Availability
Available in Mac OS X v10.3 and later.

Declared In
NSAttributedString.h

initWithHTML:baseURL:documentAttributes:

Initializes and returns a new NSAttributedString object from the HTML contained in the given object and base URL.

```
- (id)initWithHTML:(NSData *)data baseURL:(NSURL *)aURL
    documentAttributes:(NSDictionary **)docAttributes
```

Discussion
Also returns by reference in *docAttributes* a dictionary containing document-level attributes described in "Document Attributes" (page 279). *docAttributes* may be NULL, in which case no document attributes are returned. Returns an initialized object, or nil if the file at *aURL* can't be decoded.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSAttributedString.h

initWithHTML:documentAttributes:

Initializes and returns a new NSAttributedString object from HTML contained in the given data object.

```
- (id)initWithHTML:(NSData *)data documentAttributes:(NSDictionary **)docAttributes
```

Discussion
Also returns by reference in *docAttributes* a dictionary containing document-level attributes described in "Document Attributes" (page 279). *docAttributes* may be NULL, in which case no document attributes are returned. Returns nil if *data* can't be decoded.

Availability
Available in Mac OS X v10.0 and later.

initWithHTML:options:documentAttributes:

Initializes and returns a new `NSAttributedString` object from HTML contained in the given data object.

```
- (id)initWithHTML:(NSData *)data options:(NSDictionary *)options
    documentAttributes:(NSDictionary **)dict
```

Discussion
The *options* dictionary can contain the values described in "Option keys for importing documents" (page 285).

Also returns by reference in *docAttributes* a dictionary containing document-level attributes described in "Document Attributes" (page 279). *docAttributes* may be `NULL`, in which case no document attributes are returned. Returns `nil` if *data* can't be decoded.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`NSAttributedString.h`

initWithPath:documentAttributes:

Initializes a new `NSAttributedString` object from RTF or RTFD data contained in the file at the given path.

```
- (id)initWithPath:(NSString *)path documentAttributes:(NSDictionary **)docAttributes
```

Discussion
The contents of *path* will be examined to best load the file in whatever format it's in. Filter services can be used to convert the file into a format recognized by Cocoa. Also returns by reference in *docAttributes* a dictionary containing document-level attributes described in "Document Attributes" (page 279). *docAttributes* may be `NULL`, in which case no document attributes are returned. Returns an initialized object, or `nil` if the file at *path* can't be decoded.

Availability
Available in Mac OS X v10.0 and later.

initWithRTFDFileWrapper:documentAttributes:

Initializes a new NSAttributedString object from the given NSFileWrapper object containing an RTFD document.

```
- (id)initWithRTFDFileWrapper:(NSFileWrapper *)wrapper
    documentAttributes:(NSDictionary **)docAttributes
```

Discussion
Also returns by reference in *docAttributes* a dictionary containing document-level attributes described in "Document Attributes" (page 279). *docAttributes* may be NULL, in which case no document attributes are returned. Returns an initialized object, or nil if *wrapper* can't be interpreted as an RTFD document.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSAttributedString.h

initWithURL:documentAttributes:

Initializes a new NSAttributedString object from the data at the given URL.

```
- (id)initWithURL:(NSURL *)aURL documentAttributes:(NSDictionary **)docAttributes
```

Discussion
The contents of *aURL* are examined to best load the file in whatever format it's in. Filter services can be used to convert the file into a format recognized by Cocoa. Also returns by reference in *docAttributes* a dictionary containing document-level attributes described in "Document Attributes" (page 279). *docAttributes* may be NULL, in which case no document attributes are returned. Returns an initialized object, or nil if the file at *path* can't be decoded.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSAttributedString.h

initWithURL:options:documentAttributes:error:

Initializes a new NSAttributedString object from the contents of the given URL.

```
- (id)initWithURL:(NSURL *)url options:(NSDictionary *)options
    documentAttributes:(NSDictionary **)dict error:(NSError **)error
```

Discussion
Filter services can be used to convert the file into a format recognized by Cocoa. The *options* dictionary specifies how the document should be loaded and can contain the values described in "Option keys for importing documents" (page 285).

If NSDocumentTypeDocumentOption is specified, the document is treated as being in the specified format. If NSDocumentTypeDocumentOption is not specified, the method examines the document and loads it using whatever format it seems to contain.

Also returns by reference in *dict* a dictionary containing document-level attributes described in "Document Attributes" (page 279). The *dict* parameter may be nil, in which case no document attributes are returned. Returns an initialized object, or nil if the file at *url* can't be decoded, after setting *error* to point to an NSError object that encapsulates the reason why the attributed string object could not be created.

- rangeOfTextTable:atIndex: (page 267)

Declared In
NSAttributedString.h

lineBreakBeforeIndex:withinRange:

Returns the index of the closest character before the given index, and within the given range, that can be placed on a new line when laying out text.

```
- (NSUInteger)lineBreakBeforeIndex:(NSUInteger)index withinRange:(NSRange)aRange
```

Discussion
In other words, finds the appropriate line break when the character at *index* won't fit on the same line as the character at the beginning of *aRange*. Returns NSNotFound if no line break is possible before *index*.Raises an NSRangeException if *index* or any part of *aRange* lies beyond the end of the receiver's characters.

Availability
Available in Mac OS X v10.0 and later.

See Also
- lineBreakByHyphenatingBeforeIndex:withinRange: (page 265)

Declared In
NSAttributedString.h

lineBreakByHyphenatingBeforeIndex:withinRange:

Returns the index of the closest character before the given index, and within the given range, that can be placed on a new line by hyphenating.

```
- (NSUInteger)lineBreakByHyphenatingBeforeIndex:(NSUInteger)location
    withinRange:(NSRange)aRange
```

Discussion
In other words, during text layout, finds the appropriate line break by hyphenation (the character index at which the hyphen glyph should be inserted) when the character at `index` won't fit on the same line as the character at the beginning of `aRange`. Returns `NSNotFound` if no line break by hyphenation is possible before `index`.Raises an `NSRangeException` if `index` or any part of `aRange` lies beyond the end of the receiver's characters.

Availability
Available in Mac OS X v10.3 and later.

See Also
`- lineBreakBeforeIndex:withinRange:` (page 265)

Declared In
`NSAttributedString.h`

nextWordFromIndex:forward:

Returns the index of the first character of the word after or before the given index.

```
- (NSUInteger)nextWordFromIndex:(NSUInteger)index forward:(BOOL)flag
```

Discussion
If `flag` is `YES`, this is the first character after `index` that begins a word; if `flag` is `NO`, it's the first character before `index` that begins a word, whether `index` is located within a word or not. If `index` lies at either end of the string and the search direction would progress past that end, it's returned unchanged. This method is intended for moving the insertion point during editing, not for linguistic analysis or parsing of text.Raises an `NSRangeException` if `index` lies beyond the end of the receiver's characters.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- lineBreakBeforeIndex:withinRange:` (page 265)

RTFDFileWrapperFromRange:documentAttributes:

Returns an NSFileWrapper object that contains an RTFD document corresponding to the characters and attributes within the given range.

```
- (NSFileWrapper *)RTFDFileWrapperFromRange:(NSRange)aRange
    documentAttributes:(NSDictionary *)docAttributes
```

Discussion
The file wrapper also includes the document-level attributes in *docAttributes*, as explained in RTF Files and Attributed Strings. If there are no document-level attributes, *docAttributes* can be nil. Raises an NSRangeException if any part of *aRange* lies beyond the end of the receiver's characters.You can save the file wrapper using the NSFileWrapper method writeToFile:atomically:updateFilenames: (page 1137).

Availability
Available in Mac OS X v10.0 and later.

GLUT

Declared In
NSAttributedString.h

RTFFromRange:documentAttributes:

Returns an NSData object that contains an RTF stream corresponding to the characters and attributes within the given range, omitting all attachment attributes.

```
- (NSData *)RTFFromRange:(NSRange)aRange documentAttributes:(NSDictionary
    *)docAttributes
```

Discussion
Also writes the document-level attributes in *docAttributes*, as explained in RTF Files and Attributed Strings. If there are no document-level attributes, *docAttributes* can be nil. Raises an NSRangeException if any part of *aRange* lies beyond the end of the receiver's characters.When writing data to the pasteboard, you can use the NSData object as the first argument to the NSPasteboard method setData:forType: (page 1898), with a second argument of NSRTFPboardType. Although this method strips attachments, it leaves the attachment characters in the text itself. The NSText method RTFFromRange: (page 2732), on the other hand, does strip attachment characters when extracting RTF.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSAttributedString.h

rulerAttributesInRange:

Returns the ruler (paragraph) attributes in effect for the characters within the given range.

```
- (NSDictionary *)rulerAttributesInRange:(NSRange)aRange
```

Discussion
The only ruler attribute currently defined is that named by NSParagraphStyleAttributeName. Use this method to obtain attributes that are to be copied or pasted with "copy ruler" operations. Raises an NSRangeException if any part of *aRange* lies beyond the end of the receiver's characters.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `fontAttributesInRange:` (page 260)

Declared In
`NSAttributedString.h`

size

Returns the bounding box of the marks that the receiver draws.

```
- (NSSize)size
```

Availability
Available in Mac OS X v10.0 and later.

See Also
- `drawAtPoint:` (page 257)
- `drawInRect:` (page 258)

Declared In
`NSStringDrawing.h`

URLAtIndex:effectiveRange:

Returns a URL, either from a link attribute or from text at the given location that appears to be a URL string, for use in automatic link detection.

```
- (NSURL *)URLAtIndex:(NSUInteger)location
    effectiveRange:(NSRangePointer)effectiveRange
```

Parameters

location
The character index in the string at which the method checks for a link.

effectiveRange
The actual range covered by the link attribute or URL string, or of non-URL text if no apparent URL is found.

Return Value
The URL found at *location*.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSAttributedString.h`

Constants

Standard Attributes

Attributed strings support the following standard attributes for text. If the key is not in the dictionary, then use the default values described below.

```
NSString *NSFontAttributeName;
NSString *NSParagraphStyleAttributeName;
NSString *NSForegroundColorAttributeName;
NSString *NSUnderlineStyleAttributeName;
NSString *NSSuperscriptAttributeName;
NSString *NSBackgroundColorAttributeName;
NSString *NSAttachmentAttributeName;
NSString *NSLigatureAttributeName;
NSString *NSBaselineOffsetAttributeName;
NSString *NSKernAttributeName;
NSString *NSLinkAttributeName;
NSString *NSStrokeWidthAttributeName;
NSString *NSStrokeColorAttributeName;
NSString *NSUnderlineColorAttributeName;
NSString *NSStrikethroughStyleAttributeName;
NSString *NSStrikethroughColorAttributeName;
NSString *NSShadowAttributeName;
NSString *NSObliquenessAttributeName;
NSString *NSExpansionAttributeName;
NSString *NSCursorAttributeName;
NSString *NSToolTipAttributeName;
NSString *NSMarkedClauseSegmentAttributeName;
NSString *NSWritingDirectionAttributeName;
```

Constants

`NSFontAttributeName`
`NSFont`

Default Helvetica 12-point

Available in Mac OS X v10.0 and later.

Declared in `NSAttributedString.h`.

`NSParagraphStyleAttributeName`
`NSParagraphStyle`

Default as returned by the `NSParagraphStyle` method `defaultParagraphStyle`

Available in Mac OS X v10.0 and later.

Declared in `NSAttributedString.h`.

`NSForegroundColorAttributeName`
`NSColor`

Default `blackColor`

Available in Mac OS X v10.0 and later.

Declared in `NSAttributedString.h`.

`NSUnderlineStyleAttributeName`
`NSNumber` containing integer

Default `0`, no underline. See "`Underlining Patterns`" (page 275), "`Underlining Styles`" (page 274), and "`Underline Masks`" (page 276) for mask values.

Available in Mac OS X v10.0 and later.

Declared in `NSAttributedString.h`.

`NSSuperscriptAttributeName`
`NSNumber` containing integer

Default `0`

Available in Mac OS X v10.0 and later.

Declared in `NSAttributedString.h`.

`NSBackgroundColorAttributeName`
`NSColor`

Default `nil`, no background

Available in Mac OS X v10.0 and later.

Declared in `NSAttributedString.h`.

`NSAttachmentAttributeName`
`NSTextAttachment`

Default `nil`, no attachment

Available in Mac OS X v10.0 and later.

Declared in `NSAttributedString.h`.

`NSLigatureAttributeName`
`NSNumber` containing integer

Default `1`, standard ligatures; `0`, no ligatures; `2`, all ligatures

Available in Mac OS X v10.0 and later.

Declared in `NSAttributedString.h`.

`NSBaselineOffsetAttributeName`
`NSNumber` containing floating point value, as points offset from baseline

Default `0.0`

Available in Mac OS X v10.0 and later.

Declared in `NSAttributedString.h`.

`NSKernAttributeName`
`NSNumber` containing floating point value, as points by which to modify default kerning

Default `nil`, use default kerning specified in font file; `0.0`, kerning off; non-zero, points by which to modify default kerning

Available in Mac OS X v10.0 and later.

Declared in `NSAttributedString.h`.

`NSLinkAttributeName`
`NSURL` (preferred) or `NSString`

Default `nil`, no link

Available in Mac OS X v10.0 and later.

Declared in `NSAttributedString.h`.

`NSStrokeWidthAttributeName`
`NSNumber` containing floating point value, as percent of font point size

Default `0`, no stroke; positive, stroke alone; negative, stroke and fill (a typical value for outlined text would be `3.0`)

Available in Mac OS X v10.3 and later.

Declared in `NSAttributedString.h`.

`NSStrokeColorAttributeName`
`NSColor`

Default `nil`, same as foreground color

Available in Mac OS X v10.3 and later.

Declared in `NSAttributedString.h`.

`NSUnderlineColorAttributeName`
`NSColor`

Default `nil`, same as foreground color

Available in Mac OS X v10.3 and later.

Declared in `NSAttributedString.h`.

`NSStrikethroughStyleAttributeName`
`NSNumber` containing integer

Default `0`, no strikethrough. See "Underlining Patterns" (page 275), "Underlining Styles" (page 274), and "Underline Masks" (page 276) for mask values.

Available in Mac OS X v10.3 and later.

Declared in `NSAttributedString.h`.

`NSStrikethroughColorAttributeName`
`NSColor`

Default `nil`, same as foreground color

Available in Mac OS X v10.3 and later.

Declared in `NSAttributedString.h`.

`NSShadowAttributeName`
`NSShadow`

Default `nil`, no shadow

Available in Mac OS X v10.3 and later.

Declared in `NSAttributedString.h`.

`NSObliquenessAttributeName`
`NSNumber` containing floating point value, as skew to be applied to glyphs

Default `0.0`, no skew

Available in Mac OS X v10.3 and later.

Declared in `NSAttributedString.h`.

`NSExpansionAttributeName`
`NSNumber` containing floating point value, as log of expansion factor to be applied to glyphs

Default `0.0`, no expansion

Available in Mac OS X v10.3 and later.

Declared in `NSAttributedString.h`.

`NSCursorAttributeName`
`NSCursor`

Default as returned by the `NSCursor` method `IBeamCursor`

Available in Mac OS X v10.3 and later.

Declared in `NSAttributedString.h`.

`NSToolTipAttributeName`
`NSString`

Default `nil`, no tooltip

Available in Mac OS X v10.3 and later.

Declared in `NSAttributedString.h`.

`NSMarkedClauseSegmentAttributeName`
`NSNumber` containing an integer, as an index in marked text indicating clause segments

Available in Mac OS X v10.5 and later.

Declared in `NSAttributedString.h`.

`NSWritingDirectionAttributeName`
An `NSArray` of `NSNumbers`.

This provides a means to override the default bidi algorithm, equivalent to the use of bidi control characters LRE, RLE, LRO, or RLO paired with PDF, as a higher-level attribute. This is the NSAttributedString equivalent of HTML's dir attribute and/or BDO element. The array represents nested embeddings or overrides, in order from outermost to innermost. The values of the NSNumbers should be 0, 1, 2, or 3, for LRE, RLE, LRO, or RLO respectively; these should be regarded as `NSWritingDirectionLeftToRight` (page 2748) or `NSWritingDirectionRightToLeft` (page 2748) plus `NSTextWritingDirectionEmbedding` or `NSTextWritingDirectionOverride`.

Available in Mac OS X v10.6 and later.

Declared in `NSAttributedString.h`.

Underlining Styles

These constants define underlining style values for `NSUnderlineStyleAttributeName` (page 272) and `NSStrikethroughStyleAttributeName` (page 273).

```
enum {
    NSUnderlineStyleNone   = 0x00,
    NSUnderlineStyleSingle   = 0x01,
    NSUnderlineStyleThick   = 0x02,
    NSUnderlineStyleDouble   = 0x09
};
```

Constants

`NSUnderlineStyleNone`
Do not draw an underline.

Available in Mac OS X v10.3 and later.

Declared in `NSAttributedString.h`.

`NSUnderlineStyleSingle`
Draw an underline consisting of a single line.

Available in Mac OS X v10.3 and later.

Declared in `NSAttributedString.h`.

`NSUnderlineStyleThick`
Draw an underline consisting of a thick line.

Available in Mac OS X v10.3 and later.

Declared in `NSAttributedString.h`.

`NSUnderlineStyleDouble`
Draw an underline consisting of a double line.

Available in Mac OS X v10.3 and later.

Declared in `NSAttributedString.h`.

Discussion
See also "Underline Masks" (page 276) and "Underlining Patterns" (page 275). The style, pattern, and optionally by-word mask are OR'd together to produce the value for `NSUnderlineStyleAttributeName` (page 272) and `NSStrikethroughStyleAttributeName` (page 273).

Declared In
`NSAttributedString.h`

Underlining Patterns

These constants define underlining pattern values for `NSUnderlineStyleAttributeName` (page 272) and `NSStrikethroughStyleAttributeName` (page 273).

```
enum {
    NSUnderlinePatternSolid   = 0x0000,
    NSUnderlinePatternDot   = 0x0100,
    NSUnderlinePatternDash   = 0x0200,
    NSUnderlinePatternDashDot   = 0x0300,
    NSUnderlinePatternDashDotDot  = 0x0400
};
```

Constants
`NSUnderlinePatternSolid`
Draw a solid underline.

Available in Mac OS X v10.3 and later.

Declared in `NSAttributedString.h`.

`NSUnderlinePatternDot`
Draw an underline using a pattern of dots.

Available in Mac OS X v10.3 and later.

Declared in `NSAttributedString.h`.

`NSUnderlinePatternDash`
Draw an underline using a pattern of dashes.

Available in Mac OS X v10.3 and later.

Declared in `NSAttributedString.h`.

`NSUnderlinePatternDashDot`
Draw an underline using a pattern of alternating dashes and dots.

Available in Mac OS X v10.3 and later.

Declared in `NSAttributedString.h`.

`NSUnderlinePatternDashDotDot`
Draw an underline using a pattern of a dash followed by two dots.

Available in Mac OS X v10.3 and later.

Declared in `NSAttributedString.h`.

Discussion
See also "`Underline Masks`" (page 276) and "`Underlining Styles`" (page 274). The style, pattern, and optionally by-word mask are OR'd together to produce the value for `NSUnderlineStyleAttributeName` (page 272) and `NSStrikethroughStyleAttributeName` (page 273).

Deprecated Underlining Styles

Deprecated constants previously used for underline style. (Deprecated. See "Underlining Patterns" (page 275) for the correct replacements.)

```
enum {
    NSNoUnderlineStyle = 0,
    NSSingleUnderlineStyle
};
NSUInteger NSUnderlineStrikethroughMask;
```

Constants
`NSNoUnderlineStyle`
Deprecated see "Underlining Patterns" (page 275) for the correct replacements.

Available in Mac OS X v10.0 and later.

Declared in `NSAttributedString.h`.

`NSSingleUnderlineStyle`
Deprecated see "Underlining Patterns" (page 275) for the correct replacements.

Available in Mac OS X v10.0 and later.

Declared in `NSAttributedString.h`.

Underline Masks

This constant defines the underlining style for `NSUnderlineStyleAttributeName` (page 272) and `NSStrikethroughStyleAttributeName` (page 273).

```
unsigned NSUnderlineByWordMask;
```

Constants
`NSUnderlineByWordMask`
Draw the underline only underneath words, not underneath whitespace.

Available in Mac OS X v10.0 and later.

Declared in `NSAttributedString.h`.

Discussion
Use this constant with the desired underline style to create the given effect. For example, to get a thick underline only underneath words, set `NSUnderlineStyleAttribute` to `(NSUnderlineStyleThick | NSUnderlineByWordMask)`. Also see "Underlining Styles" (page 274) and "Underlining Patterns" (page 275).

Declared In
`NSAttributedString.h`

Glyph Info Attribute

This object provides a means to override the standard glyph generation.

```
NSString *NSGlyphInfoAttributeName;
```

Constants
`NSGlyphInfoAttributeName`
The name of an `NSGlyphInfo` object.

`NSLayoutManager` assigns the glyph specified by this glyph info to the entire attribute range, provided that its contents match the specified base string, and that the specified glyph is available in the font specified by `NSFontAttributeName`.

Available in Mac OS X v10.2 and later.

Declared in `NSAttributedString.h`.

Declared In
`NSAttributedString.h`

Character Shape Attribute

The character shape feature type (`kCharacterShapeType`) is used when a single font contains different appearances for the same character shape, and these shapes are not traditionally treated as swashes. It is needed for languages such as Chinese that have both traditional and simplified character sets.

```
NSString *NSCharacterShapeAttributeName;
```

Constants
`NSCharacterShapeAttributeName`
An integer value. The value is interpreted as Apple Type Services `kCharacterShapeType selector + 1`.

The default value is 0 (disable). 1 is `kTraditionalCharactersSelector`, and so on. Refer to `<ATS/SFNTLayoutTypes.h>` and Font Features in *ATSUI Programming Guide* for additional information.

Available in Mac OS X v10.0 and later.

Declared in `NSAttributedString.h`.

Declared In
`NSAttributedString.h`

Document Types

The following values can be returned for the `NSDocumentTypeDocumentAttribute` (page 281) key in the document attributes dictionary.

```
NSString *NSPlainTextDocumentType;
NSString *NSRTFTextDocumentType;
NSString *NSRTFDTextDocumentType;
NSString *NSMacSimpleTextDocumentType;
NSString *NSHTMLTextDocumentType;
NSString *NSDocFormatTextDocumentType;
NSString *NSWordMLTextDocumentType;
NSString *NSWebArchiveTextDocumentType;
NSString *NSOfficeOpenXMLTextDocumentType;
NSString *NSOpenDocumentTextDocumentType;
```

Constants

`NSPlainTextDocumentType`
Plain text document.
Available in Mac OS X v10.0 and later.
Declared in `NSAttributedString.h`.

`NSRTFTextDocumentType`
Rich text format document.
Available in Mac OS X v10.0 and later.
Declared in `NSAttributedString.h`.

`NSRTFDTextDocumentType`
Rich text format with attachments document.
Available in Mac OS X v10.0 and later.
Declared in `NSAttributedString.h`.

`NSMacSimpleTextDocumentType`
Macintosh SimpleText document.
Available in Mac OS X v10.0 and later.
Declared in `NSAttributedString.h`.

`NSHTMLTextDocumentType`
Hypertext Markup Language (HTML) document.
Available in Mac OS X v10.0 and later.
Declared in `NSAttributedString.h`.

`NSDocFormatTextDocumentType`
Microsoft Word document.
Available in Mac OS X v10.3 and later.
Declared in `NSAttributedString.h`.

`NSWordMLTextDocumentType`
Microsoft Word XML (WordML schema) document.
Available in Mac OS X v10.3 and later.
Declared in `NSAttributedString.h`.

`NSWebArchiveTextDocumentType`
Web Kit WebArchive document.
Available in Mac OS X v10.4 and later.
Declared in `NSAttributedString.h`.

`NSOfficeOpenXMLTextDocumentType`
ECMA Office Open XML text document format.

Available in Mac OS X v10.5 and later.

Declared in `NSAttributedString.h`.

`NSOpenDocumentTextDocumentType`
OASIS Open Document text document format.

Available in Mac OS X v10.5 and later.

Declared in `NSAttributedString.h`.

Discussion
See also NSDocumentTypeDocumentOption (page 285).

Declared In
`NSAttributedString.h`

Document Attributes

The `init...` methods can return a dictionary with the following document-wide attributes (attribute identifiers available on Mac OS X v10.4 and later; use actual string value keys for earlier systems):

```
NSString *NSAuthorDocumentAttribute;
NSString *NSBackgroundColorDocumentAttribute;
NSString *NSBottomMarginDocumentAttribute;
NSString *NSCharacterEncodingDocumentAttribute;
NSString *NSCategoryDocumentAttribute;
NSString *NSCocoaVersionDocumentAttribute;
NSString *NSCommentDocumentAttribute;
NSString *NSCompanyDocumentAttribute;
NSString *NSConvertedDocumentAttribute;
NSString *NSCopyrightDocumentAttribute;
NSString *NSCreationTimeDocumentAttribute;
NSString *NSDefaultTabIntervalDocumentAttribute;
NSString *NSDocumentTypeDocumentAttribute;
NSString *NSEditorDocumentAttribute;
NSString *NSFileTypeDocumentAttribute;
NSString *NSFileTypeDocumentOption;
NSString *NSHyphenationFactorDocumentAttribute;
NSString *NSKeywordsDocumentAttribute;
NSString *NSLeftMarginDocumentAttribute;
NSString *NSManagerDocumentAttribute;
NSString *NSModificationTimeDocumentAttribute;
NSString *NSPaperSizeDocumentAttribute;
NSString *NSReadOnlyDocumentAttribute;
NSString *NSRightMarginDocumentAttribute;
NSString *NSSubjectDocumentAttribute;
NSString *NSTitleDocumentAttribute;
NSString *NSTopMarginDocumentAttribute;
NSString *NSViewModeDocumentAttribute;
NSString *NSViewSizeDocumentAttribute;
NSString *NSViewZoomDocumentAttribute;
```

Constants

`NSPaperSizeDocumentAttribute`

NSValue, containing NSSize.

Mac OS X v10.3 and earlier string constant is `@"PaperSize"`.

Available in Mac OS X v10.4 and later.

Declared in `NSAttributedString.h`.

`NSLeftMarginDocumentAttribute`

NSNumber, containing a float, in points.

Mac OS X v10.3 and earlier string constant is `@"LeftMargin"`.

Available in Mac OS X v10.4 and later.

Declared in `NSAttributedString.h`.

`NSRightMarginDocumentAttribute`

NSNumber, containing a float, in points.

Mac OS X v10.3 and earlier string constant is `@"RightMargin"`.

Available in Mac OS X v10.4 and later.

Declared in `NSAttributedString.h`.

`NSTopMarginDocumentAttribute`
NSNumber, containing a float, in points.

Mac OS X v10.3 and earlier string constant is `@"TopMargin"`.

Available in Mac OS X v10.4 and later.

Declared in `NSAttributedString.h`.

`NSBottomMarginDocumentAttribute`
NSNumber, containing a float, in points.

Mac OS X v10.3 and earlier string constant is `@"BottomMargin"`.

Available in Mac OS X v10.4 and later.

Declared in `NSAttributedString.h`.

`NSHyphenationFactorDocumentAttribute`
NSNumber, containing a float; 0 = off, 1 = full hyphenation.

Mac OS X v10.3 and earlier string constant is `@"HyphenationFactor"`.

Available in Mac OS X v10.4 and later.

Declared in `NSAttributedString.h`.

`NSDocumentTypeDocumentAttribute`
How the document was interpreted; one of the values in "Document Types" (page 277).

Mac OS X v10.3 and earlier string constant is `@"DocumentType"`.

Available in Mac OS X v10.4 and later.

Declared in `NSAttributedString.h`.

`NSCharacterEncodingDocumentAttribute`
NSNumber, containing an int specifying the `NSStringEncoding` for the file; for reading and writing plain text files and writing HTML; default for plain text is the default encoding; default for HTML is UTF-8.

Mac OS X v10.3 and earlier string constant is `@"CharacterEncoding"`.

Available in Mac OS X v10.4 and later.

Declared in `NSAttributedString.h`.

`NSViewSizeDocumentAttribute`
NSValue, containing NSSize.

Mac OS X v10.3 and earlier string constant is `@"ViewSize"`.

Available in Mac OS X v10.4 and later.

Declared in `NSAttributedString.h`.

`NSViewZoomDocumentAttribute`
Mac OS X v10.3 and earlier string constant is `@"ViewZoom"`.

NSValue, containing a float; 100 = 100% zoom.

Available in Mac OS X v10.4 and later.

Declared in `NSAttributedString.h`.

`NSViewModeDocumentAttribute`
NSValue, containing an int; 0 = normal; 1 = page layout (use value of `@"PaperSize"`).

Mac OS X v10.3 and earlier string constant is `@"ViewMode"`.

Available in Mac OS X v10.4 and later.

Declared in `NSAttributedString.h`.

`NSBackgroundColorDocumentAttribute`

NSColor, representing the document-wide page background color.

Mac OS X v10.3 and earlier string constant is `@"BackgroundColor"`.

For applications linked on versions prior to Mac OS X v10.5, HTML import sets the `NSBackgroundColorDocumentAttribute` to `[NSColor whiteColor]` in cases in which the HTML does not specify a background color. For applications linked on Mac OS X v10.5 and later, no `NSBackgroundColorDocumentAttribute` is set in these cases.

Available in Mac OS X v10.4 and later.

Declared in `NSAttributedString.h`.

`NSCocoaVersionDocumentAttribute`

NSNumber, containing a float. For RTF files only, stores the version of Cocoa with which the file was created. Absence of this value indicates RTF file not created by Cocoa or its predecessors.

Values less than 100 are pre–Mac OS X; 100 is Mac OS X v10.0 or v10.1; 102 is Mac OS X v10.2 and 10.3; values greater than 102 correspond to values of `NSAppKitVersionNumber` on Mac OS X v10.4 and later.

Mac OS X v10.3 and earlier string constant is `@"CocoaRTFVersion"`.

Available in Mac OS X v10.4 and later.

Declared in `NSAttributedString.h`.

`NSReadOnlyDocumentAttribute`

NSNumber, containing int. If missing or 0 or negative, not read only; 1 or more, read only.

Note that this has nothing to do with the file system protection on the file, but instead can affect how the file should be displayed to the user.

Mac OS X v10.3 and earlier string constant is `@"ReadOnly"`.

Available in Mac OS X v10.4 and later.

Declared in `NSAttributedString.h`.

`NSConvertedDocumentAttribute`

NSNumber, containing an int. Indicates whether the file was converted by a filter service.

If missing or 0, the file was originally in the format specified by document type. If negative, the file was originally in the format specified by document type, but the conversion to NSAttributedString may have been lossy. If 1 or more, it was converted to this type by a filter service.

Mac OS X v10.3 and earlier string constant is `@"Converted"`.

Available in Mac OS X v10.4 and later.

Declared in `NSAttributedString.h`.

`NSDefaultTabIntervalDocumentAttribute`

NSNumber containing a float. Represents the document-wide default tab stop interval.

Mac OS X v10.3 and earlier string constant is `@"DefaultTabInterval"`.

Available in Mac OS X v10.4 and later.

Declared in `NSAttributedString.h`.

`NSTitleDocumentAttribute`

NSString containing document title.

Available in Mac OS X v10.4 and later.

Declared in `NSAttributedString.h`.

`NSCompanyDocumentAttribute`
NSString containing company or organization name.

Available in Mac OS X v10.4 and later.

Declared in `NSAttributedString.h`.

`NSCopyrightDocumentAttribute`
NSString containing document copyright info.

Available in Mac OS X v10.4 and later.

Declared in `NSAttributedString.h`.

`NSSubjectDocumentAttribute`
NSString containing subject of document.

Available in Mac OS X v10.4 and later.

Declared in `NSAttributedString.h`.

`NSAuthorDocumentAttribute`
`NSString` containing author name.

Available in Mac OS X v10.4 and later.

Declared in `NSAttributedString.h`.

`NSKeywordsDocumentAttribute`
`NSArray` of `NSString`, containing keywords.

Available in Mac OS X v10.4 and later.

Declared in `NSAttributedString.h`.

`NSCommentDocumentAttribute`
`NSString` containing document comments.

Available in Mac OS X v10.4 and later.

Declared in `NSAttributedString.h`.

`NSEditorDocumentAttribute`
`NSString` containing name of person who last edited the document.

Available in Mac OS X v10.4 and later.

Declared in `NSAttributedString.h`.

`NSCreationTimeDocumentAttribute`
`NSDate` containing the creation date of the document; note that this is not the file system creation date of the file, but of the document.

Available in Mac OS X v10.4 and later.

Declared in `NSAttributedString.h`.

`NSModificationTimeDocumentAttribute`
`NSDate` containing the modification date of the document contents.

Available in Mac OS X v10.4 and later.

Declared in `NSAttributedString.h`.

`NSManagerDocumentAttribute`
`NSString` containing the name of the author's manager.

Available in Mac OS X v10.6 and later.

Declared in `NSAttributedString.h`.

`NSCategoryDocumentAttribute`
`NSString` containing the document's category.

Available in Mac OS X v10.6 and later.

Declared in `NSAttributedString.h`.

`NSFileTypeDocumentAttribute`
`NSString` indicating which document type was used to interpret the document, specified as a UTI; for reading, this is available along with `NSDocumentTypeDocumentAttribute` (page 281), but for writing the two are mutually exclusive.

Available in Mac OS X v10.6 and later.

Declared in `NSAttributedString.h`.

`NSFileTypeDocumentOption`
`NSString` indicating a document type to be forced when loading the document, specified as a UTI string; mutually exclusive with `NSDocumentTypeDocumentOption` (page 285).

Available in Mac OS X v10.6 and later.

Declared in `NSAttributedString.h`.

Attributes for generating HTML

These document-wide attributes provide control over the form of generated HTML—you use them only for writing HTML

```
NSString *NSExcludedElementsDocumentAttribute;
NSString *NSTextEncodingNameDocumentAttribute;
NSString *NSPrefixSpacesDocumentAttribute;
```

Constants

`NSExcludedElementsDocumentAttribute`
An `NSArray` object containing `NSString` objects, representing HTML elements not to be used in generated HTML.

Available in Mac OS X v10.4 and later.

Declared in `NSAttributedString.h`.

`NSTextEncodingNameDocumentAttribute`
An `NSString` object containing the name, IANA or otherwise, of a text encoding to be used; mutually exclusive with `NSCharacterEncodingDocumentAttribute`.

Available in Mac OS X v10.4 and later.

Declared in `NSAttributedString.h`.

`NSPrefixSpacesDocumentAttribute`
An `NSNumber` containing an integer (default 0) representing the number of spaces per level by which to indent certain nested HTML elements.

Available in Mac OS X v10.4 and later.

Declared in `NSAttributedString.h`.

Discussion

`NSExcludedElementsDocumentAttribute` allows control over the tags used. The recognized values in the `NSExcludedElementsDocumentAttribute` array are (case-insensitive) HTML tags, plus DOCTYPE (representing a doctype declaration) and XML (representing an XML declaration). By default, if this attribute is not present, the excluded elements will be those deprecated in HTML 4 (APPLET, BASEFONT, CENTER, DIR, FONT, ISINDEX, MENU, S, STRIKE, and U) plus XML. If XML is on the list, HTML forms are used; if XML is not

on the list, XHTML forms are used where there is a distinction. Either `NSCharacterEncodingDocumentAttribute` or `NSTextEncodingNameDocumentAttribute` may be used to control the encoding used for generated HTML; character entities are used for characters not representable in the specified encoding. `NSPrefixSpacesDocumentAttribute` allows some control over formatting.

Declared In
`NSAttributedString.h`

Option keys for importing documents

These option keys are recognized for importing documents using initWithData:options:documentAttributes:error: (page 260), initWithHTML:options:documentAttributes: (page 262), initWithURL:options:documentAttributes:error: (page 264), or the `readFrom...` methods (such as `readFromData:options:documentAttributes:` (page 1710)) implemented by `NSMutableAttributedString`.

```
NSString *NSBaseURLDocumentOption;
NSString *NSCharacterEncodingDocumentOption;
NSString *NSDefaultAttributesDocumentOption;
NSString *NSDocumentTypeDocumentOption;
NSString *NSTextEncodingNameDocumentOption;
NSString *NSTextSizeMultiplierDocumentOption;
NSString *NSTimeoutDocumentOption;
NSString *NSWebPreferencesDocumentOption;
NSString *NSWebResourceLoadDelegateDocumentOption;
```

Constants

`NSCharacterEncodingDocumentOption`
For plain text documents; NSNumber containing the unsigned int `NSStringEncoding` to override any encoding specified in an HTML document. Previous string constant was `@"CharacterEncoding"`.

Available in Mac OS X v10.4 and later.

Declared in `NSAttributedString.h`.

`NSBaseURLDocumentOption`
For HTML documents; `NSURL` containing base URL. Previous string constant was `@"BaseURL"`

Available in Mac OS X v10.4 and later.

Declared in `NSAttributedString.h`.

`NSDefaultAttributesDocumentOption`
For plain text documents; NSDictionary containing attributes to be applied to plain files. Previous string constant was `@"DefaultAttributes"`.

Available in Mac OS X v10.4 and later.

Declared in `NSAttributedString.h`.

`NSDocumentTypeDocumentOption`
One of the document types described in "Document Types" (page 277), indicating a document type to be forced when loading the document. Previous string constant was `@"DocumentType"`.

Available in Mac OS X v10.4 and later.

Declared in `NSAttributedString.h`.

`NSTextEncodingNameDocumentOption`
: NSString containing the name, IANA or otherwise, of a text encoding to override any encoding specified in an HTML document. Mutually exclusive with `@"CharacterEncoding"`. Previous string constant was `@"TextEncodingName"`.

  Available in Mac OS X v10.4 and later.

  Declared in `NSAttributedString.h`.

`NSTimeoutDocumentOption`
: NSNumber containing float. Time in seconds to wait for a document to finish loading. Previous string constant was `@"Timeout"`.

  Available in Mac OS X v10.4 and later.

  Declared in `NSAttributedString.h`.

`NSWebPreferencesDocumentOption`
: WebPreferences; for HTML only, specifies a WebPreferences object. If not present, a default set of preferences is used. Previous string constant was `@"WebPreferences"`.

  Available in Mac OS X v10.4 and later.

  Declared in `NSAttributedString.h`.

`NSWebResourceLoadDelegateDocumentOption`
: `NSObject`; for HTML only, specifies an object to serve as the web resource loading delegate.

  If not present, a default delegate is used that permits the loading of subsidiary resources but does not respond to authentication challenges. Previous string constant was `@"WebResourceLoadDelegate"`.

  Available in Mac OS X v10.4 and later.

  Declared in `NSAttributedString.h`.

`NSTextSizeMultiplierDocumentOption`
: Specifies a scale factor for font sizes.. `NSNumber` containing float, default 1.0; for HTML only, corresponding to WebView's `textSizeMultiplier`.

  There is no textual equivalent for Mac OS X v10.3.

  Available in Mac OS X v10.4 and later.

  Declared in `NSAttributedString.h`.

Discussion
In Mac OS X v10.3, the options key `@"UseWebKit"` specifies that WebKit–based HTML importing be used (and must be specified for the other options to be recognized). In Mac OS X v10.4 and later, WebKit is always used for HTML documents, and all of the options except `@"UseWebKit"` are recognized (attribute identifiers are available on Mac OS X v10.4 and later; use actual string value keys for Mac OS X v10.3):

NSSpellingStateAttributeName

This constant is used as, and recognized only as, a temporary attribute. It indicates that spelling and/or grammar indicators should be shown for the specified characters.

```
NSString *NSSpellingStateAttributeName;
```

Constants

`NSSpellingStateAttributeName`

An integer value. Defaults to 0, indicating no grammar or spelling error. See "NSSpellingStateAttributeName Flags" (page 287) for possible values.

This key is available in Mac OS X v10.2 and later, but its interpretation changed in Mac OS X v10.5. Previously, any non-zero value caused the spelling indicator to be displayed. For Mac OS X v10.5 and later, the (integer) value is treated as being composed of the spelling and grammar flags. See "NSSpellingStateAttributeName Flags" (page 287) for possible values.

Available in Mac OS X v10.5 and later.

Declared in `NSAttributedString.h`.

NSSpellingStateAttributeName Flags

These constants control the display of the spelling and grammar indicators on text, highlighting portions of the text that are flagged for spelling or grammar issues. These regions are denoted by a temporary attribute on the layout manager, using the `NSSpellingStateAttributeName` (page 287) key.

```
enum {
    NSSpellingStateSpellingFlag = (1 << 0),
    NSSpellingStateGrammarFlag  = (1 << 1)
};
```

Constants

`NSSpellingStateSpellingFlag`

Flag for spelling issues.

Available in Mac OS X v10.5 and later.

Declared in `NSAttributedString.h`.

`NSSpellingStateGrammarFlag`

Flag for grammar issues.

Available in Mac OS X v10.5 and later.

Declared in `NSAttributedString.h`.

Overview

An `NSBezierPath` object allows you to create paths using PostScript-style commands. Paths consist of straight and curved line segments joined together. Paths can form recognizable shapes such as rectangles, ovals, arcs, and glyphs; they can also form complex polygons using either straight or curved line segments. A single path can be closed by connecting its two endpoints, or it can be left open.

An `NSBezierPath` object can contain multiple disconnected paths, whether they are closed or open. Each of these paths is referred to as a subpath. The subpaths of an `NSBezierPath` object must be manipulated as a group. The only way to manipulate subpaths individually is to create separate `NSBezierPath` objects for each.

For a given `NSBezierPath` object, you can stroke the path's outline or fill the region occupied by the path. You can also use the path as a clipping region for views or other regions. Using methods of `NSBezierPath`, you can also perform hit detection on the filled or stroked path. Hit detection is needed to implement interactive graphics, as in rubberbanding and dragging operations.

The current graphics context is automatically saved and restored for all drawing operations involving `NSBezierPath` objects, so your application does not need to worry about the graphics settings changing across invocations.

Adopted Protocols

NSCoding
- `encodeWithCoder:`
- `initWithCoder:`

NSCopying
- `copyWithZone:`

Tasks

Creating an NSBezierPath Object

`+ bezierPath` (page 294)
Creates and returns a new `NSBezierPath` object.

`+ bezierPathWithOvalInRect:` (page 295)
Creates and returns a new `NSBezierPath` object initialized with an oval path inscribed in the specified rectangle.

`+ bezierPathWithRect:` (page 295)
Creates and returns a new `NSBezierPath` object initialized with a rectangular path.

`+ bezierPathWithRoundedRect:xRadius:yRadius:` (page 296)
Creates and returns a new `NSBezierPath` object initialized with a rounded rectangular path.

`- bezierPathByFlatteningPath` (page 313)
Creates and returns a “flattened” copy of the receiver.

`- bezierPathByReversingPath` (page 314)
Creates and returns a new `NSBezierPath` object with the reversed contents of the receiver’s path.

Constructing Paths

`- moveToPoint:` (page 324)
Moves the receiver’s current point to the specified location.

`- lineToPoint:` (page 322)
Appends a straight line to the receiver’s path

`- curveToPoint:controlPoint1:controlPoint2:` (page 317)
Adds a Bezier cubic curve to the receiver’s path.

`- closePath` (page 315)
Closes the most recently added subpath.

`- relativeMoveToPoint:` (page 326)
Moves the receiver’s current point to a new point whose location is the specified distance from the current point.

- `relativeLineToPoint:` (page 325)
  Appends a straight line segment to the receiver's path starting at the current point and moving towards the specified point, relative to the current location.
- `relativeCurveToPoint:controlPoint1:controlPoint2:` (page 325)
  Adds a Bezier cubic curve to the receiver's path from the current point to a new location, which is specified as a relative distance from the current point.

Appending Common Shapes to a Path

- `appendBezierPath:` (page 307)
  Appends the contents of the specified path object to the receiver's path.
- `appendBezierPathWithPoints:count:` (page 312)
  Appends a series of line segments to the receiver's path.
- `appendBezierPathWithOvalInRect:` (page 311)
  Appends an oval path to the receiver, inscribing the oval in the specified rectangle.
- `appendBezierPathWithArcFromPoint:toPoint:radius:` (page 307)
  Appends an arc to the receiver's path.
- `appendBezierPathWithArcWithCenter:radius:startAngle:endAngle:` (page 308)
  Appends an arc of a circle to the receiver's path.
- `appendBezierPathWithArcWithCenter:radius:startAngle:endAngle:clockwise:` (page 309)
  Appends an arc of a circle to the receiver's path.
- `appendBezierPathWithGlyph:inFont:` (page 309)
  Appends an outline of the specified glyph to the receiver's path.
- `appendBezierPathWithGlyphs:count:inFont:` (page 310)
  Appends the outlines of the specified glyphs to the receiver's path.
- `appendBezierPathWithPackedGlyphs:` (page 311)
  Appends an array of packed glyphs to the receiver's path.
- `appendBezierPathWithRect:` (page 312)
  Appends a rectangular path to the receiver's path.
- `appendBezierPathWithRoundedRect:xRadius:yRadius:` (page 313)
  Appends a rounded rectangular path to the receiver's path.

Accessing Path Attributes

+ `defaultWindingRule` (page 299)
  Returns the default winding rule used to fill all paths.
+ `setDefaultWindingRule:` (page 304)
  Sets the default winding rule used to fill all paths.
- `windingRule` (page 334)
  Returns the winding rule used to fill the receiver's path.
- `setWindingRule:` (page 332)
  Sets the winding rule used to fill the receiver's path.
+ `defaultLineCapStyle` (page 298)
  Returns the default line cap style for all paths.

+ `setDefaultLineCapStyle:` (page 302)
  Sets the default line cap style for all paths.
- `lineCapStyle` (page 322)
  Returns the line cap style for the receiver's path.
- `setLineCapStyle:` (page 329)
  Sets the line cap style for the receiver's path.
+ `defaultLineJoinStyle` (page 298)
  Returns the default line join style for all paths.
+ `setDefaultLineJoinStyle:` (page 302)
  Sets the default line join style for all paths.
- `lineJoinStyle` (page 322)
  Returns the receiver's line join style.
- `setLineJoinStyle:` (page 330)
  Sets the line join style for the receiver's path.
+ `defaultLineWidth` (page 299)
  Returns the default line width for the all paths.
+ `setDefaultLineWidth:` (page 303)
  Sets the default line width for all paths.
- `lineWidth` (page 323)
  Returns the line width of the receiver's path.
- `setLineWidth:` (page 331)
  Sets the line width of the receiver's path.
+ `defaultMiterLimit` (page 299)
  Returns the default miter limit for all paths.
+ `setDefaultMiterLimit:` (page 304)
  Sets the default miter limit for all paths.
- `miterLimit` (page 323)
  Returns the miter limit of the receiver's path.
- `setMiterLimit:` (page 332)
  Sets the miter limit for the receiver's path.
+ `defaultFlatness` (page 297)
  Returns the default flatness value for all paths.
+ `setDefaultFlatness:` (page 301)
  Sets the default flatness value for all paths.
- `flatness` (page 320)
  Returns the flatness value of the receiver's path.
- `setFlatness:` (page 329)
  Sets the flatness value for the receiver's path.
- `getLineDash:count:phase:` (page 321)
  Returns the line-stroking pattern for the receiver.
- `setLineDash:count:phase:` (page 330)
  Sets the line-stroking pattern for the receiver.

Drawing Paths

- `stroke` (page 333)
  Draws a line along the receiver's path using the current stroke color and drawing attributes.
- `fill` (page 320)
  Paints the region enclosed by the receiver's path.
+ `fillRect:` (page 300)
  Fills the specified rectangular path with the current fill color.
+ `strokeRect:` (page 306)
  Strokes the path of the specified rectangle using the current stroke color and the default drawing attributes.
+ `strokeLineFromPoint:toPoint:` (page 305)
  Strokes a line between two points using the current stroke color and the default drawing attributes.
+ `drawPackedGlyphs:atPoint:` (page 300)
  Draws a set of packed glyphs at the specified point in the current coordinate system.

Clipping Paths

- `addClip` (page 306)
  Intersects the area enclosed by the receiver's path with the clipping path of the current graphics context and makes the resulting shape the current clipping path.
- `setClip` (page 328)
  Replaces the clipping path of the current graphics context with the area inside the receiver's path.
+ `clipRect:` (page 297)
  Intersects the specified rectangle with the clipping path of the current graphics context and makes the resulting shape the current clipping path

Hit Detection

- `containsPoint:` (page 316)
  Returns a Boolean value indicating whether the receiver contains the specified point.

Querying Paths

- `bounds` (page 314)
  Returns the bounding box of the receiver's path.
- `controlPointBounds` (page 316)
  Returns the bounding box of the receiver's path, including any control points.
- `currentPoint` (page 317)
  Returns the receiver's current point (the trailing point or ending point in the most recently added segment).
- `isEmpty` (page 321)
  Returns a Boolean value indicating whether the receiver is empty.

Applying Transformations

- `transformUsingAffineTransform:` (page 333)
  Transforms all points in the receiver using the specified transform.

Accessing Elements of a Path

- `elementCount` (page 319)
  Returns the total number of path elements in the receiver's path.
- `elementAtIndex:` (page 318)
  Returns the type of path element at the specified index.
- `elementAtIndex:associatedPoints:` (page 318)
  Gets the element type and (and optionally) the associated points for the path element at the specified index.
- `removeAllPoints` (page 326)
  Removes all path elements from the receiver, effectively clearing the path.
- `setAssociatedPoints:atIndex:` (page 327)
  Changes the points associated with the specified path element.

Caching Paths

- `cachesBezierPath` (page 315) Deprecated in Mac OS X v10.0
  Returns a Boolean value indicating whether this object maintains a cached image of its path.
- `setCachesBezierPath:` (page 328) Deprecated in Mac OS X v10.0
  Sets whether the receiver should cache its path information.

Class Methods

bezierPath

Creates and returns a new `NSBezierPath` object.

```
+ (NSBezierPath *)bezierPath
```

Return Value
A new empty path object.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
DockTile
Sketch-112
SpeedometerView
WebKitPluginStarter

WebKitPluginWithJavaScript

Declared In
NSBezierPath.h

bezierPathWithOvalInRect:

Creates and returns a new NSBezierPath object initialized with an oval path inscribed in the specified rectangle.

```
+ (NSBezierPath *)bezierPathWithOvalInRect:(NSRect)aRect
```

Parameters

aRect

The rectangle in which to inscribe an oval.

Return Value
An NSBezierPath new path object with the oval path.

Discussion
If the *aRect* parameter specifies a square, the inscribed path is a circle. The path is constructed by starting in the lower-right quadrant of the rectangle and adding arc segments counterclockwise to complete the oval.

Availability
Available in Mac OS X v10.0 and later.

See Also
+ bezierPath (page 294)
- appendBezierPathWithOvalInRect: (page 311)

Declared In
NSBezierPath.h

bezierPathWithRect:

Creates and returns a new NSBezierPath object initialized with a rectangular path.

```
+ (NSBezierPath *)bezierPathWithRect:(NSRect)aRect
```

Parameters

aRect

The rectangle describing the path to create.

Return Value
A new path object with the rectangular path.

Discussion
The path is constructed by starting at the origin of *aRect* and adding line segments in a counterclockwise direction.

Availability
Available in Mac OS X v10.0 and later.

See Also
+ bezierPath (page 294)
- appendBezierPathWithRect: (page 312)
+ fillRect: (page 300)

Declared In
NSBezierPath.h

bezierPathWithRoundedRect:xRadius:yRadius:

Creates and returns a new NSBezierPath object initialized with a rounded rectangular path.

```
+ (NSBezierPath *)bezierPathWithRoundedRect:(NSRect)rect xRadius:(CGFloat)xRadius
     yRadius:(CGFloat)yRadius
```

Parameters

rect
The rectangle that defines the basic shape of the path.

xRadius
The radius of each corner oval along the x-axis. Values larger than half the rectangle's width are clamped to half the width.

yRadius
The radius of each corner oval along the y-axis. Values larger than half the rectangle's height are clamped to half the height.

Return Value
A new path object with the rounded rectangular path.

Discussion
The path is constructed in a counter-clockwise direction, starting at the top-left corner of the rectangle. If either one of the radius parameters contains the value 0.0, the returned path is a plain rectangle without rounded corners.

Availability
Available in Mac OS X v10.5 and later.

clipRect:

Intersects the specified rectangle with the clipping path of the current graphics context and makes the resulting shape the current clipping path

```
+ (void)clipRect:(NSRect)aRect
```

Parameters
aRect
The rectangle to intersect with the current clipping path.

Availability
Available in Mac OS X v10.0 and later.

See Also
- addClip (page 306)
- setClip (page 328)

Declared In
NSBezierPath.h

defaultFlatness

Returns the default flatness value for all paths.

```
+ (CGFloat)defaultFlatness
```

Return Value
The default value for determining the smoothness of curved paths, or 0.6 if no other value has been set.

Availability
Available in Mac OS X v10.0 and later.

See Also
+ setDefaultFlatness: (page 301)
- flatness (page 320)

Declared In
NSBezierPath.h

defaultLineCapStyle

Returns the default line cap style for all paths.

```
+ (NSLineCapStyle)defaultLineCapStyle
```

Return Value
The default line cap style or NSButtLineCapStyle if no other style has been set. For a list of values, see "Constants" (page 335).

Discussion
The default line cap style can be overridden for individual paths by setting a custom style for that path using the setLineCapStyle: (page 329) method.

Availability
Available in Mac OS X v10.0 and later.

See Also
+ setDefaultLineCapStyle: (page 302)
+ defaultLineJoinStyle (page 298)
+ defaultLineWidth (page 299)
- lineCapStyle (page 322)

Declared In
NSBezierPath.h

defaultLineJoinStyle

Returns the default line join style for all paths.

```
+ (NSLineJoinStyle)defaultLineJoinStyle
```

Return Value
The default line join style or NSMiterLineJoinStyle if no other value has been set. For a list of values, see "Constants" (page 335).

Availability
Available in Mac OS X v10.0 and later.

See Also
+ setDefaultLineJoinStyle: (page 302)
+ defaultLineCapStyle (page 298)
+ defaultLineWidth (page 299)
- lineJoinStyle (page 322)

Declared In
NSBezierPath.h

defaultLineWidth

Returns the default line width for the all paths.

```
+ (CGFloat)defaultLineWidth
```

Return Value
The default line width, measured in points in the user coordinate space, or 1.0 if no other value has been set.

Availability
Available in Mac OS X v10.0 and later.

See Also
+ setDefaultLineWidth: (page 303)
+ defaultLineCapStyle (page 298)
+ defaultLineJoinStyle (page 298)
- lineWidth (page 323)

Declared In
NSBezierPath.h

defaultMiterLimit

Returns the default miter limit for all paths.

```
+ (CGFloat)defaultMiterLimit
```

Return Value
The default miter limit for all paths, or 10.0 if no other value has been set.

Availability
Available in Mac OS X v10.0 and later.

See Also
+ setDefaultMiterLimit: (page 304)
- miterLimit (page 323)

Declared In
NSBezierPath.h

defaultWindingRule

Returns the default winding rule used to fill all paths.

```
+ (NSWindingRule)defaultWindingRule
```

Return Value
The current default winding rule or `NSNonZeroWindingRule` if no default rule has been set. This value may be either `NSNonZeroWindingRule` or `NSEvenOddWindingRule`.

Availability
Available in Mac OS X v10.0 and later.

See Also
`+ setDefaultWindingRule:` (page 304)
`- windingRule` (page 334)

Declared In
`NSBezierPath.h`

drawPackedGlyphs:atPoint:

Draws a set of packed glyphs at the specified point in the current coordinate system.

```
+ (void)drawPackedGlyphs:(const char *)packedGlyphs atPoint:(NSPoint)aPoint
```

Parameters
packedGlyphs
A C-style array containing one or more `CGGlyph` data types terminated by a `NULL` character.
aPoint
The starting point at which to draw the glyphs.

Discussion
This method draws the glyphs immediately.

You should avoid using this method directly. Instead, use the `appendBezierPathWithGlyph:inFont:` (page 309) and `appendBezierPathWithGlyphs:count:inFont:` (page 310) methods to create a path with one or more glyphs.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- appendBezierPathWithPackedGlyphs:` (page 311)
`- set` (page 711) (NSColor)

Declared In
`NSBezierPath.h`

fillRect:

Fills the specified rectangular path with the current fill color.

```
+ (void)fillRect:(NSRect)aRect
```

Parameters
aRect
A rectangle in the current coordinate system.

Discussion
This method fills the specified region immediately. This method uses the compositing operation returned by the `compositingOperation` method of `NSGraphicsContext`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `- appendBezierPathWithRect:` (page 312)
- `+ bezierPathWithRect:` (page 295)
- `+ strokeRect:` (page 306)
- `- compositingOperation` (page 1304) (NSGraphicsContext)
- `- set` (page 711) (NSColor)

SampleRaster
WhackedTV

Declared In
`NSBezierPath.h`

setDefaultFlatness:

Sets the default flatness value for all paths.

```
+ (void)setDefaultFlatness:(CGFloat)flatness
```

Parameters
flatness
The default flatness value.

Discussion
The flatness value specifies the accuracy (or smoothness) with which curves are rendered. It is also the maximum error tolerance (measured in pixels) for rendering curves, where smaller numbers give smoother curves at the expense of more computation. The exact interpretation may vary slightly on different rendering devices.

The default flatness value is 0.6, which yields smooth curves.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `+ defaultFlatness` (page 297)
- `- setFlatness:` (page 329)

Declared In
`NSBezierPath.h`

setDefaultLineCapStyle:

Sets the default line cap style for all paths.

```
+ (void)setDefaultLineCapStyle:(NSLineCapStyle)lineCap
```

Parameters

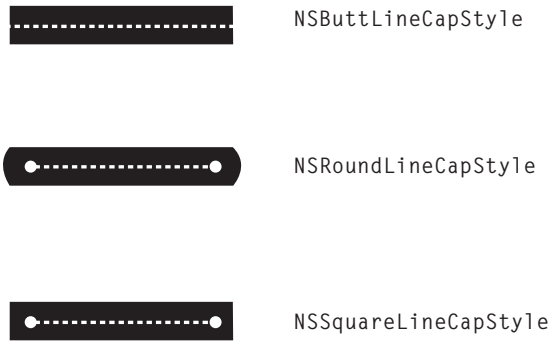
lineCap

The default line cap style. For a list of values, see "Constants" (page 335).

Discussion

The line cap style specifies the shape of the endpoints of an open path when stroked. Figure 13-1 (page 302) shows the appearance of the available line cap styles.

Figure 13-1 Line cap styles



Availability

Available in Mac OS X v10.0 and later.

See Also

+ defaultLineCapStyle (page 298)
+ setDefaultLineJoinStyle: (page 302)
+ setDefaultLineWidth: (page 303)
- setLineCapStyle: (page 329)

Declared In

NSBezierPath.h

setDefaultLineJoinStyle:

Sets the default line join style for all paths.

```
+ (void)setDefaultLineJoinStyle:(NSLineJoinStyle)lineJoinStyle
```

Parameters

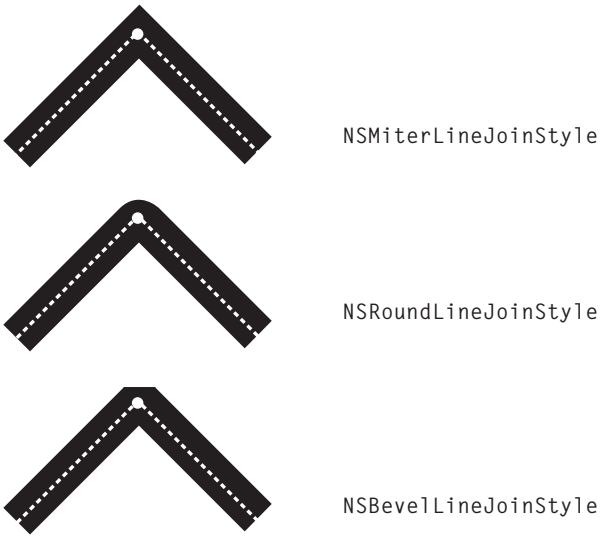
lineJoinStyle

The default line join style. For a list of values, see "Constants" (page 335).

Discussion

The line join style specifies the shape of the joints between connected segments of a stroked path. Figure 13-2 (page 303) shows the appearance of the available line join styles.

Figure 13-2 Line join styles



Availability
Available in Mac OS X v10.0 and later.

See Also
+ defaultLineJoinStyle (page 298)
+ setDefaultLineCapStyle: (page 302)
+ setDefaultLineWidth: (page 303)
+ setDefaultMiterLimit: (page 304)
- setLineJoinStyle: (page 330)

Declared In
NSBezierPath.h

setDefaultLineWidth:

Sets the default line width for all paths.

```
+ (void)setDefaultLineWidth:(CGFloat)width
```

Parameters

width

The default line width, measured in points in the user coordinate space.

Discussion
The line width defines the thickness of stroked paths. A width of 0 is interpreted as the thinnest line that can be rendered on a particular device. The actual rendered line width may vary from the specified width by as much as 2 device pixels, depending on the position of the line with respect to the pixel grid and the current anti-aliasing settings. The width of the line may also be affected by scaling factors specified in the current transformation matrix of the active graphics context.

Availability
Available in Mac OS X v10.0 and later.

See Also
+ defaultLineWidth (page 299)
+ setDefaultLineCapStyle: (page 302)
+ setDefaultLineJoinStyle: (page 302)
- setLineWidth: (page 331)

ClockControl
CocoaDragAndDrop

Declared In
NSBezierPath.h

setDefaultMiterLimit:

Sets the default miter limit for all paths.

```
+ (void)setDefaultMiterLimit:(CGFloat)limit
```

Parameters
limit
The default limit at which miter joins are converted to bevel joins.

Discussion
The miter limit helps you avoid spikes at the junction of two line segments connected by a miter join (NSMiterLineJoinStyle). If the ratio of the miter length—the diagonal length of the miter join—to the line thickness exceeds the miter limit, the joint is converted to a bevel join. The default miter limit value is 10, which converts miters whose angle at the joint is less than 11 degrees.

Availability
Available in Mac OS X v10.0 and later.

See Also
+ defaultMiterLimit (page 299)
+ setDefaultLineJoinStyle: (page 302)
- setMiterLimit: (page 332)

Declared In
NSBezierPath.h

setDefaultWindingRule:

Sets the default winding rule used to fill all paths.

```
+ (void)setDefaultWindingRule:(NSWindingRule)windingRule
```

Parameters
windingRule
The winding rule to use if no winding rule is set explicitly for a path object. This value may be either NSNonZeroWindingRule or NSEvenOddWindingRule.

Discussion
Winding rules determine how to paint (or fill) the region enclosed by a path. You use this method to set the default rule that is applied to paths that do not have a custom winding rule assigned.

For more information on how winding rules affect the appearance of filled paths, see "Winding Rules and Filling Paths".

Availability
Available in Mac OS X v10.0 and later.

See Also
`+ defaultWindingRule` (page 299)
`- setWindingRule:` (page 332)

Declared In
`NSBezierPath.h`

strokeLineFromPoint:toPoint:

Strokes a line between two points using the current stroke color and the default drawing attributes.

```
+ (void)strokeLineFromPoint:(NSPoint)point1 toPoint:(NSPoint)point2
```

Parameters
point1
The starting point of the line.
point2
The ending point of the line.

Discussion
This method strokes the specified path immediately.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- lineToPoint:` (page 322)
`- moveToPoint:` (page 324)
`+ setDefaultLineCapStyle:` (page 302)

`NSBezierPath.h`

strokeRect:

Strokes the path of the specified rectangle using the current stroke color and the default drawing attributes.

```
+ (void)strokeRect:(NSRect)aRect
```

Parameters

aRect

A rectangle in the current coordinate system.

Discussion

The path is drawn beginning at the rectangle's origin and proceeding in a counterclockwise direction. This method strokes the specified path immediately.

Availability

Available in Mac OS X v10.0 and later.

SampleRaster

Declared In

`NSBezierPath.h`

Instance Methods

addClip

Intersects the area enclosed by the receiver's path with the clipping path of the current graphics context and makes the resulting shape the current clipping path.

```
- (void)addClip
```

Discussion

This method uses the current winding rule to determine the clipping shape of the receiver. This method does not affect the receiver's path.

Availability

Available in Mac OS X v10.0 and later.

See Also

Declared In
`NSBezierPath.h`

appendBezierPath:

Appends the contents of the specified path object to the receiver's path.

```
- (void)appendBezierPath:(NSBezierPath *)aPath
```

Parameters

aPath
The path to add to the receiver.

Discussion
This method adds the commands used to create *aPath* to the end of the receiver's path. This method does not explicitly try to connect the subpaths in the two objects, although the operations in *aPath* may still cause that effect.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSBezierPath.h`

appendBezierPathWithArcFromPoint:toPoint:radius:

Appends an arc to the receiver's path.

```
- (void)appendBezierPathWithArcFromPoint:(NSPoint)fromPoint toPoint:(NSPoint)toPoint
    radius:(CGFloat)radius
```

Parameters

fromPoint
The middle point of the angle.

toPoint
The end point of the angle.

radius
The radius of the circle inscribed in the angle.

Discussion
The created arc is defined by a circle inscribed inside the angle specified by three points: the current point, the `fromPoint` parameter, and the `toPoint` parameter (in that order). The arc itself lies on the perimeter of the circle, whose radius is specified by the `radius` parameter. The arc is drawn between the two points of the circle that are tangent to the two legs of the angle.

The arc usually does not contain the points in the *fromPoint* and *toPoint* parameters. If the starting point of the arc does not coincide with the current point, a line is drawn between the two points. The starting point of the arc lies on the line defined by the current point and the *fromPoint* parameter.

You must set the path's current point (using the `moveToPoint:` (page 324) method or through the creation of a preceding line or curve segment) before you invoke this method. If the path is empty, this method raises an `NSGenericException` exception.

Depending on the length of the arc, this method may add multiple connected curve segments to the path.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
IBFragmentView

Declared In
`NSBezierPath.h`

appendBezierPathWithArcWithCenter:radius:startAngle:endAngle:

Appends an arc of a circle to the receiver's path.

```
- (void)appendBezierPathWithArcWithCenter:(NSPoint)center radius:(CGFloat)radius
    startAngle:(CGFloat)startAngle endAngle:(CGFloat)endAngle
```

Parameters

center
Specifies the center point of the circle used to define the arc.

radius
Specifies the radius of the circle used to define the arc.

startAngle
Specifies the starting angle of the arc, measured in degrees counterclockwise from the x-axis.

endAngle
Specifies the end angle of the arc, measured in degrees counterclockwise from the x-axis.

Discussion
The created arc lies on the perimeter of the circle, between the angles specified by the *startAngle* and *endAngle* parameters. The arc is drawn in a counterclockwise direction. If the receiver's path is empty, this method sets the current point to the beginning of the arc before adding the arc segment. If the receiver's path is not empty, a line is drawn from the current point to the starting point of the arc.

Depending on the length of the arc, this method may add multiple connected curve segments to the path.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSBezierPath.h

appendBezierPathWithArcWithCenter:radius:startAngle:endAngle:clockwise:

Appends an arc of a circle to the receiver's path.

```
- (void)appendBezierPathWithArcWithCenter:(NSPoint)center radius:(CGFloat)radius
    startAngle:(CGFloat)startAngle endAngle:(CGFloat)endAngle
    clockwise:(BOOL)clockwise
```

Parameters

center
Specifies the center point of the circle used to define the arc.

radius
Specifies the radius of the circle used to define the arc.

startAngle
Specifies the starting angle of the arc, measured in degrees counterclockwise from the x-axis.

endAngle
Specifies the end angle of the arc, measured in degrees counterclockwise from the x-axis.

clockwise
YES if you want the arc to be drawn in a clockwise direction; otherwise NO to draw the arc in a counterclockwise direction.

Discussion
The created arc lies on the perimeter of the circle, between the angles specified by the *startAngle* and *endAngle* parameters. The arc is drawn in the direction indicated by the *clockwise* parameter. If the receiver's path is empty, this method sets the current point to the beginning of the arc before adding the arc segment. If the receiver's path is not empty, a line is drawn from the current point to the starting point of the arc.

Depending on the length of the arc, this method may add multiple connected curve segments to the path.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSBezierPath.h

appendBezierPathWithGlyph:inFont:

Appends an outline of the specified glyph to the receiver's path.

```
- (void)appendBezierPathWithGlyph:(NSGlyph)aGlyph inFont:(NSFont *)fontObj
```

Parameters

aGlyph

The glyph to add to the path.

fontObj

The font in which the glyph is encoded.

Discussion

If the glyph is not encoded in the font specified by the *fontObj* parameter—that is, the font does not have an entry for the specified glyph—then no path is appended to the receiver.

You must set the path's current point (using the `moveToPoint:` (page 324) method or through the creation of a preceding line or curve segment) before you invoke this method. If the path is empty, this method raises an `NSGenericException` exception.

Availability

Available in Mac OS X v10.0 and later.

- `appendBezierPathWithGlyphs:count:inFont:` (page 310)
- `appendBezierPathWithPackedGlyphs:` (page 311)
+ `drawPackedGlyphs:atPoint:` (page 300)

Declared In

`NSBezierPath.h`

appendBezierPathWithGlyphs:count:inFont:

Appends the outlines of the specified glyphs to the receiver's path.

```
- (void)appendBezierPathWithGlyphs:(NSGlyph *)glyphs count:(NSInteger)count
    inFont:(NSFont *)fontObj
```

Parameters

glyphs

A C-style array of `NSGlyph` data types to add to the path.

count

The number of glyphs in the *glyphs* parameter.

fontObj

The font in which the glyphs are encoded.

Discussion

If the glyphs are not encoded in the font specified by the *fontObj* parameter—that is, the font does not have an entry for one of the specified glyphs—then no path is appended to the receiver.

You must set the path's current point (using the `moveToPoint:` (page 324) method or through the creation of a preceding line or curve segment) before you invoke this method. If the path is empty, this method raises an `NSGenericException` exception.

Availability

Available in Mac OS X v10.0 and later.

Declared In
NSBezierPath.h

appendBezierPathWithOvalInRect:

Appends an oval path to the receiver, inscribing the oval in the specified rectangle.

```
- (void)appendBezierPathWithOvalInRect:(NSRect)aRect
```

Parameters

aRect

The rectangle in which to inscribe the oval.

Discussion
Before adding the oval, this method moves the current point, which implicitly closes the current subpath. If the *aRect* parameter specifies a square, the inscribed path is a circle. The path is constructed by starting in the lower-right quadrant of the rectangle and adding arc segments counterclockwise to complete the oval.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
CompositeLab
Grady
SonOfSillyBalls

Declared In
NSBezierPath.h

appendBezierPathWithPackedGlyphs:

Appends an array of packed glyphs to the receiver's path.

```
- (void)appendBezierPathWithPackedGlyphs:(const char *)packedGlyphs
```

Parameters

packedGlyphs

A C-style array containing one or more CGGlyph data types terminated by a NULL character.

Discussion
You should avoid using this method directly. Instead, use the appendBezierPathWithGlyph:inFont: (page 309) and appendBezierPathWithGlyphs:count:inFont: (page 310) methods to append glyphs to a path.

Availability
Available in Mac OS X v10.0 and later.

WebKitPluginWithJavaScript

Declared In
NSBezierPath.h

appendBezierPathWithPoints:count:

Appends a series of line segments to the receiver's path.

```
- (void)appendBezierPathWithPoints:(NSPointArray)points count:(NSInteger)count
```

Parameters

points
A C-style array of NSPoint data types, each of which contains the end point of the next line segment.

count
The number of points in the *points* parameter.

Discussion
This method interprets the points as a set of connected line segments. If the current path contains an open subpath, a line is created from the last point in that subpath to the first point in the points array. If the current path is empty, the first point in the points array is used to set the starting point of the line segments. Subsequent line segments are added using the remaining points in the array.

This method does not close the path that is created. If you wish to create a closed path, you must do so by explicitly invoking the receiver's closePath (page 315) method.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSBezierPath.h

appendBezierPathWithRect:

Appends a rectangular path to the receiver's path.

```
- (void)appendBezierPathWithRect:(NSRect)aRect
```

Parameters

aRect
The rectangle describing the path to create.

Discussion
Before adding the rectangle, this method moves the current point to the origin of the rectangle, which implicitly closes the current subpath (if any). The path is constructed by starting at the origin of *aRect* and adding line segments in a counterclockwise direction. The final segment is added using a closePath (page 315) message.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSBezierPath.h`

appendBezierPathWithRoundedRect:xRadius:yRadius:

Appends a rounded rectangular path to the receiver's path.

```
- (void)appendBezierPathWithRoundedRect:(NSRect)rect xRadius:(CGFloat)xRadius
    yRadius:(CGFloat)yRadius
```

Parameters

rect
The rectangle that defines the basic shape of the path.

xRadius
The radius of each corner oval along the x-axis. Values larger than half the rectangle's width are clamped to half the width.

yRadius
The radius of each corner oval along the y-axis. Values larger than half the rectangle's height are clamped to half the height.

Discussion
The path is constructed in a counter-clockwise direction, starting at the top-left corner of the rectangle. If either one of the radius parameters contains the value `0.0`, the returned path is a plain rectangle without rounded corners.

Availability
Available in Mac OS X v10.5 and later.

See Also
`+ bezierPathWithRoundedRect:xRadius:yRadius:` (page 296)

Declared In
`NSBezierPath.h`

bezierPathByFlatteningPath

Creates and returns a "flattened" copy of the receiver.

```
- (NSBezierPath *)bezierPathByFlatteningPath
```

Return Value
A new path object whose contents are a flattened version of the receiver's path.

Discussion
Flattening a path converts all curved line segments into straight line approximations. The granularity of the approximations is controlled by the path's current flatness value, which is set using the `setDefaultFlatness:` (page 301) method.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSBezierPath.h`

bezierPathByReversingPath

Creates and returns a new `NSBezierPath` object with the reversed contents of the receiver's path.

```
- (NSBezierPath *)bezierPathByReversingPath
```

Return Value
A new path object whose contents are a reversed version of the receiver's path.

Discussion
Reversing a path does not necessarily change the appearance of the path when rendered. Instead, it changes the direction in which path segments are drawn. For example, reversing the path of a rectangle (whose line segments are normally drawn starting at the origin and proceeding in a counterclockwise direction) causes its line segments to be drawn in a clockwise direction instead. Drawing a reversed path could affect the appearance of a filled pattern, depending on the pattern and the fill rule in use.

This method reverses each whole or partial subpath in the path object individually.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSBezierPath.h`

bounds

Returns the bounding box of the receiver's path.

```
- (NSRect)bounds
```

Return Value
The rectangle that encloses the path of the receiver. If the path contains curve segments, the bounding box encloses the curve but may not enclose the control points used to calculate the curve.

Availability
Available in Mac OS X v10.0 and later.

See Also
- controlPointBounds (page 316)

Declared In
NSBezierPath.h

cachesBezierPath

Returns a Boolean value indicating whether this object maintains a cached image of its path. (Deprecated in Mac OS X v10.0.)

```
- (BOOL)cachesBezierPath
```

Return Value
YES if the path maintains a cached image; otherwise, NO.

Discussion
Caching of paths currently has no effect, so method always returns NO.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.0.

See Also
- setCachesBezierPath: (page 328)

Declared In
NSBezierPath.h

closePath

Closes the most recently added subpath.

```
- (void)closePath
```

Discussion
This method closes the current subpath by creating a line segment between the first and last points in the subpath. This method subsequently updates the current point to the end of the newly created line segment, which is also the first point in the now closed subpath.

Availability
Available in Mac OS X v10.0 and later.

See Also

Declared In
`NSBezierPath.h`

containsPoint:

Returns a Boolean value indicating whether the receiver contains the specified point.

```
- (BOOL)containsPoint:(NSPoint)aPoint
```

Parameters
aPoint
The point to test against the path, specified in the path object's coordinate system.

Return Value
`YES` if the path's enclosed area contains the specified point; otherwise, `NO`.

Discussion
This method checks the point against the path itself and the area it encloses. When determining hits in the enclosed area, this method uses the non-zero winding rule (`NSNonZeroWindingRule`). It does not take into account the line width used to stroke the path.

Availability
Available in Mac OS X v10.0 and later.

`NSBezierPath.h`

controlPointBounds

Returns the bounding box of the receiver’s path, including any control points.

```
- (NSRect)controlPointBounds
```

Return Value
The rectangle that encloses the receiver's path. If the path contains curve segments, the bounding box encloses the control points of the curves as well as the curves themselves.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `bounds` (page 314)

Declared In
`NSBezierPath.h`

currentPoint

Returns the receiver's current point (the trailing point or ending point in the most recently added segment).

```
- (NSPoint)currentPoint
```

Return Value
The point from which the next drawn line or curve segment begins.

Discussion
If the receiver is empty, this method raises `NSGenericException`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `closePath` (page 315)

- `moveToPoint:` (page 324)

Declared In
`NSBezierPath.h`

curveToPoint:controlPoint1:controlPoint2:

Adds a Bezier cubic curve to the receiver's path.

```
- (void)curveToPoint:(NSPoint)aPoint controlPoint1:(NSPoint)controlPoint1
    controlPoint2:(NSPoint)controlPoint2
```

Parameters
aPoint
The destination point of the curve segment, specified in the current coordinate system

controlPoint1
The point that determines the shape of the curve near the current point.

controlPoint2
The point that determines the shape of the curve near the destination point.

Discussion
You must set the path's current point (using the `moveToPoint:` (page 324) method or through the creation of a preceding line or curve segment) before you invoke this method. If the path is empty, this method raises an `NSGenericException` exception.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSBezierPath.h`

elementAtIndex:

Returns the type of path element at the specified index.

```
- (NSBezierPathElement)elementAtIndex:(NSInteger)index
```

Parameters

index
The index of the desired path element.

Return Value
The type of the path element. For a list of constants, see "NSBezierPathElement" (page 335).

Discussion
Path elements describe the commands used to define a path and include basic commands such as moving to a specific point, creating a line segment, creating a curve, or closing the path. The elements are stored in the order of their execution.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `- elementCount` (page 319)
- `- elementAtIndex:associatedPoints:` (page 318)
- `- bezierPathByReversingPath` (page 314)

Declared In
`NSBezierPath.h`

elementAtIndex:associatedPoints:

Gets the element type and (and optionally) the associated points for the path element at the specified index.

```
- (NSBezierPathElement)elementAtIndex:(NSInteger)index
    associatedPoints:(NSPointArray)points
```

Parameters

index

The index of the desired path element.

points

On input, a C-style array containing up to three `NSPoint` data types, or `NULL` if you do not want the points. On output, the data points associated with the specified path element.

Return Value

The type of the path element. For a list of constants, see "NSBezierPathElement" (page 335).

Discussion

If you specify a value for the points parameter, your array must be large enough to hold the number of points for the given path element. Move, close path, and line segment commands return one point. Curve operations return three points.

For curve operations, the order of the points is controlPoint1 (*points*[0]), controlPoint2 (*points*[1]), endPoint (*points*[2]).

Availability

Available in Mac OS X v10.0 and later.

See Also

- `elementCount` (page 319)
- `elementAtIndex:` (page 318)

Declared In

`NSBezierPath.h`

elementCount

Returns the total number of path elements in the receiver's path.

```
- (NSInteger)elementCount
```

Return Value

The number of path elements.

Discussion

Each element type corresponds to one of the operations described in "Path Elements".

Availability

Available in Mac OS X v10.0 and later.

Related Sample Code

Cropped Image

Declared In

`NSBezierPath.h`

fill

Paints the region enclosed by the receiver's path.

```
- (void)fill
```

Discussion
This method fills the path using the current fill color and the receiver's current winding rule. If the path contains any open subpaths, this method implicitly closes them before painting the fill region.

The painted region includes the pixels right up to, but not including, the path line itself. For paths with large line widths, this can result in overlap between the fill region and the stroked path (which is itself centered on the path line).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSBezierPath.h`

flatness

Returns the flatness value of the receiver's path.

```
- (CGFloat)flatness
```

Return Value
The flatness value of the path. If no value is set, this method returns the default flatness value.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setFlatness:` (page 329)
+ `defaultFlatness` (page 297)

Declared In
`NSBezierPath.h`

getLineDash:count:phase:

Returns the line-stroking pattern for the receiver.

```
- (void)getLineDash:(CGFloat *)pattern count:(NSInteger *)count phase:(CGFloat
    *)phase
```

Parameters

pattern

On input, a C-style array of floating point values, or `nil` if you do not want the pattern values. On output, this array contains the lengths (measured in points) of the line segments and gaps in the pattern. The values in the array alternate, starting with the first line segment length, followed by the first gap length, followed by the second line segment length, and so on.

count

On input, a pointer to an integer or `nil` if you do not want the number of pattern entries. On output, the number of entries written to *pattern*.

phase

On input, a pointer to a floating point value or `nil` if you do not want the phase. On output, this value contains the offset at which to start drawing the pattern, measured in points along the dashed-line pattern. For example, a phase of 6 in the pattern 5-2-3-2 would cause drawing to begin in the middle of the first gap.

Discussion

The array in the *pattern* parameter must be large enough to hold all of the returned values in the pattern. If you are not sure how many values there might be, you can call this method twice. The first time you call it, do not pass a value for *pattern* but use the returned value in *count* to allocate an array of floating-point numbers that you can then pass in the second time.

Availability

Available in Mac OS X v10.0 and later.

See Also

`- setLineDash:count:phase:` (page 330)

Declared In

`NSBezierPath.h`

isEmpty

Returns a Boolean value indicating whether the receiver is empty.

```
- (BOOL)isEmpty
```

Return Value

`YES` if the receiver contains no path elements; otherwise, `NO`.

Availability

Available in Mac OS X v10.0 and later.

lineJoinStyle

Returns the receiver's line join style.

```
- (NSLineJoinStyle)lineJoinStyle
```

Return Value
The receiver's line join style. For a list of values, see "Constants" (page 335). If this value is not set for the receiver, the default line join style is returned.

Availability
Available in Mac OS X v10.0 and later.

See Also
+ defaultLineJoinStyle (page 298)
+ setDefaultLineJoinStyle: (page 302)
- setLineJoinStyle: (page 330)

Declared In
NSBezierPath.h

lineToPoint:

Appends a straight line to the receiver's path

```
- (void)lineToPoint:(NSPoint)aPoint
```

Parameters
aPoint
The destination point of the line segment, specified in the current coordinate system.

Discussion
This method creates a straight line segment starting at the current point and ending at the point specified by the *aPoint* parameter. The current point is the last point in the receiver's most recently added segment.

You must set the path's current point (using the `moveToPoint:` (page 324) method or through the creation of a preceding line or curve segment) before you invoke this method. If the path is empty, this method raises an `NSGenericException` exception.

Availability
Available in Mac OS X v10.0 and later.

miterLimit

Returns the miter limit of the receiver's path.

```
- (CGFloat)miterLimit
```

Return Value
The miter limit of the path. If no value is set, this method returns the default miter limit.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setMiterLimit:` (page 332)
+ `defaultMiterLimit` (page 299)

Declared In
`NSBezierPath.h`

moveToPoint:

Moves the receiver's current point to the specified location.

```
- (void)moveToPoint:(NSPoint)aPoint
```

Parameters

aPoint
A point in the current coordinate system.

Discussion
This method implicitly closes the current subpath (if any) and sets the current point to the value in *aPoint*. When closing the previous subpath, this method does not cause a line to be created from the first and last points in the subpath.

For many path operations, you must invoke this method before issuing any commands that cause a line or curve segment to be drawn.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSBezierPath.h`

relativeCurveToPoint:controlPoint1:controlPoint2:

Adds a Bezier cubic curve to the receiver's path from the current point to a new location, which is specified as a relative distance from the current point.

```
- (void)relativeCurveToPoint:(NSPoint)aPoint controlPoint1:(NSPoint)controlPoint1
    controlPoint2:(NSPoint)controlPoint2
```

Parameters

aPoint

The destination point of the curve segment, interpreted as a relative offset from the current point.

controlPoint1

The point that determines the shape of the curve near the current point, interpreted as a relative offset from the current point.

controlPoint2

The point that determines the shape of the curve near the destination point, interpreted as a relative offset from the current point.

Discussion

You must set the path's current point (using the `moveToPoint:` (page 324) method or through the creation of a preceding line or curve segment) before you invoke this method. If the path is empty, this method raises an `NSGenericException` exception.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSBezierPath.h`

relativeLineToPoint:

Appends a straight line segment to the receiver's path starting at the current point and moving towards the specified point, relative to the current location.

```
- (void)relativeLineToPoint:(NSPoint)aPoint
```

Parameters

aPoint

A point whose coordinates are interpreted as a relative offset from the current point.

Discussion

The destination point is relative to the current point. For example, if the current point is (1, 1) and *aPoint* contains the value (1, 2), a line segment is created between the points (1, 1) and (2, 3).

You must set the path's current point (using the `moveToPoint:` (page 324) method or through the creation of a preceding line or curve segment) before you invoke this method. If the path is empty, this method raises an `NSGenericException` exception.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `closePath` (page 315)
- `lineToPoint:` (page 322)
- `relativeLineToPoint:` (page 325)
- `relativeMoveToPoint:` (page 326)

SampleRaster

Declared In
`NSBezierPath.h`

relativeMoveToPoint:

Moves the receiver's current point to a new point whose location is the specified distance from the current point.

```
- (void)relativeMoveToPoint:(NSPoint)aPoint
```

Parameters

aPoint

A point whose coordinates are interpreted as a relative offset from the current point.

Discussion
This method implicitly closes the current subpath (if any) and updates the location of the current point. For example, if the current point is (1, 1) and *aPoint* contains the value (1, 2), the previous subpath would be closed and the current point would become (2, 3). When closing the previous subpath, this method does not cause a line to be created from the first and last points in the subpath.

You must set the path's current point (using the `moveToPoint:` (page 324) method or through the creation of a preceding line or curve segment) before you invoke this method. If the path is empty, this method raises an `NSGenericException` exception.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `closePath` (page 315)

- `relativeLineToPoint:` (page 325)

Declared In
`NSBezierPath.h`

removeAllPoints

Removes all path elements from the receiver, effectively clearing the path.

```
- (void)removeAllPoints
```

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
Cropped Image

Declared In
`NSBezierPath.h`

setAssociatedPoints:atIndex:

Changes the points associated with the specified path element.

```
- (void)setAssociatedPoints:(NSPointArray)points atIndex:(NSInteger)index
```

Parameters

points

A C-style array containing up to three `NSPoint` data types. This parameter must contain the correct number of points for the path element at the specified index. Move, close path, and line segment commands require one point. Curve operations require three points.

index

The index of the path element you want to modify.

Discussion
You can use this method to change the points associated with a path quickly and without recreating the path. You cannot use this method to change the type of the path element.

The following example shows you how you would modify the point associated with a line path element. The path created by this example results in a path with two elements. The first path element specifies a move to point (0, 0) while the second creates a line to point (100, 100). It then changes the line to go only to the point (50,50) using this method:

```
NSBezierPath *bezierPath = [NSBezierPath bezierPath];
NSPoint newPoint = NSMakePoint(50.0, 50.0);

[bezierPath moveToPoint: NSMakePoint(0.0, 0.0)];
[bezierPath lineToPoint: NSMakePoint(100.0, 100.0)];

// Modifies the point added by lineToPoint: method (100.0, 100.0)
// to the new point (50.0, 50.0)
[bezierPath setAssociatedPoints: &newPoint atIndex: 1];
```

Note: If you specify too few points for a path element of type `NSCurveToBezierPathElement`, the behavior of this method is undefined.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSBezierPath.h`

setCachesBezierPath:

Sets whether the receiver should cache its path information. (Deprecated in Mac OS X v10.0.)

```
- (void)setCachesBezierPath:(BOOL)flag
```

Parameters

flag

YES if the receiver should cache its path information; otherwise, NO.

Discussion
Caching of paths currently has no effect.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.0.

See Also
- cachesBezierPath (page 315)

Declared In
NSBezierPath.h

setClip

Replaces the clipping path of the current graphics context with the area inside the receiver's path.

```
- (void)setClip
```

Discussion
You should avoid using this method as a way of adjusting the clipping path, as it may expand the clipping path beyond the bounds set by the enclosing view. If you do use this method, be sure to save the graphics state prior to modifying the clipping path and restore the graphics state when you are done.

This method uses the current winding rule to determine the clipping shape of the receiver. This method does not affect the receiver's path.

Availability
Available in Mac OS X v10.0 and later.

See Also

NSBezierPath.h

setFlatness:

Sets the flatness value for the receiver's path.

```
- (void)setFlatness:(CGFloat)flatness
```

Parameters

flatness

The flatness value for the path.

Discussion

The flatness value specifies the accuracy (or smoothness) with which curves are rendered. It is also the maximum error tolerance (measured in pixels) for rendering curves, where smaller numbers give smoother curves at the expense of more computation. The exact interpretation may vary slightly on different rendering devices.

The default flatness value is 0.6, which yields smooth curves.

Availability

Available in Mac OS X v10.0 and later.

See Also

- flatness (page 320)
+ setDefaultFlatness: (page 301)

Declared In

NSBezierPath.h

setLineCapStyle:

Sets the line cap style for the receiver's path.

```
- (void)setLineCapStyle:(NSLineCapStyle)lineCapStyle
```

Parameters

lineCapStyle

The line cap style to use with the receiver. For a list of values, see "Constants" (page 335).

Discussion

The line cap style specifies the shape of the endpoints of an open path when stroked. Figure 13-1 (page 302) shows the appearance of the available line cap styles.

Availability

Available in Mac OS X v10.0 and later.

See Also

+ defaultLineCapStyle (page 298)

NSBezierPath.h

setLineDash:count:phase:

Sets the line-stroking pattern for the receiver.

```
- (void)setLineDash:(const CGFloat *)pattern count:(NSInteger)count
    phase:(CGFloat)phase
```

Parameters

pattern

A C-style array of floating point values that contains the lengths (measured in points) of the line segments and gaps in the pattern. The values in the array alternate, starting with the first line segment length, followed by the first gap length, followed by the second line segment length, and so on

count

The number of values in *pattern*.

phase

The offset at which to start drawing the pattern, measured in points along the dashed-line pattern. For example, a phase of 6 in the pattern 5-2-3-2 would cause drawing to begin in the middle of the first gap

Discussion
For example, to produce a supermarket coupon type of dashed line:

```
array[0] = 5.0; //segment painted with stroke color
array[1] = 2.0; //segment not painted with a color

[path setLineDash: array count: 2 phase: 0.0];
```

In the above example, if you set *phase* to 6.0, the line dash would begin exactly six units into *pattern*, which would start the pattern in the middle of the first gap.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `getLineDash:count:phase:` (page 321)

Declared In
NSBezierPath.h

setLineJoinStyle:

Sets the line join style for the receiver's path.

```
- (void)setLineJoinStyle:(NSLineJoinStyle)lineJoinStyle
```

Parameters

lineJoinStyle

The line join style to use for the receiver's path. For a list of values, see "Constants" (page 335).

Discussion

The line join style specifies the shape of the joints between connected segments of a stroked path. Figure 13-2 (page 303) shows the appearance of the available line join styles.

Availability

Available in Mac OS X v10.0 and later.

Declared In

NSBezierPath.h

setLineWidth:

Sets the line width of the receiver's path.

```
- (void)setLineWidth:(CGFloat)lineWidth
```

Parameters

lineWidth

The line width to use for the receiver, measured in points in the user coordinate space.

Discussion

The line width defines the thickness of the receiver's stroked path. A width of 0 is interpreted as the thinnest line that can be rendered on a particular device. The actual rendered line width may vary from the specified width by as much as 2 device pixels, depending on the position of the line with respect to the pixel grid and the current anti-aliasing settings. The width of the line may also be affected by scaling factors specified in the current transformation matrix of the active graphics context.

Availability

Available in Mac OS X v10.0 and later.

Declared In
NSBezierPath.h

setMiterLimit:

Sets the miter limit for the receiver's path.

```
- (void)setMiterLimit:(CGFloat)miterLimit
```

Parameters
miterLimit
A value indicating the limit at which miter joins are converted to bevel joins.

Discussion
The miter limit helps you avoid spikes at the junction of two line segments connected by a miter join (NSMiterLineJoinStyle). If the ratio of the miter length—the diagonal length of the miter join—to the line thickness exceeds the miter limit, the joint is converted to a bevel join. The default miter limit value is 10, which converts miters whose angle at the joint is less than 11 degrees.

Availability
Available in Mac OS X v10.0 and later.

See Also
- miterLimit (page 323)
+ setDefaultMiterLimit: (page 304)

Declared In
NSBezierPath.h

setWindingRule:

Sets the winding rule used to fill the receiver's path.

```
- (void)setWindingRule:(NSWindingRule)aWindingRule
```

Parameters
aWindingRule
The winding rule to use for the path. This value may be either NSNonZeroWindingRule or NSEvenOddWindingRule.

Discussion
For more information on how winding rules affect the appearance of filled paths, see "Winding Rules and Filling Paths".

Availability
Available in Mac OS X v10.0 and later.

Cropped Image

Declared In
NSBezierPath.h

stroke

Draws a line along the receiver's path using the current stroke color and drawing attributes.

```
- (void)stroke
```

Discussion
The drawn line is centered on the path with its sides parallel to the path segment. This method uses the current drawing attributes associated with the receiver. If a particular attribute is not set for the receiver, this method uses the corresponding default attribute.

Availability
Available in Mac OS X v10.0 and later.

See Also
- fill (page 320)
+ setDefaultLineCapStyle: (page 302)
+ setDefaultLineJoinStyle: (page 302)

transformUsingAffineTransform:

Transforms all points in the receiver using the specified transform.

```
- (void)transformUsingAffineTransform:(NSAffineTransform *)aTransform
```

Parameters
aTransform
The transform to apply to the path.

Discussion
This method applies the transform to the path's points immediately. The following code translates a line from 0,0 to 100,100 to a line from 10,10 to 110,110.

```
NSBezierPath *bezierPath = [NSBezierPath bezierPath];
NSAffineTransform *transform = [NSAffineTransform transform];

[bezierPath moveToPoint: NSMakePoint(0.0, 0.0)];
[bezierPath lineToPoint: NSMakePoint(100.0, 100.0)];

[transform translateXBy: 10.0 yBy: 10.0];
[bezierPath transformUsingAffineTransform: transform];
```

Availability
Available in Mac OS X v10.0 and later.

- `setWindingRule:` (page 332)
+ `defaultWindingRule` (page 299)

Declared In
`NSBezierPath.h`

Constants

NSBezierPathElement

Basic path element commands.

```
typedef enum {
    NSMoveToBezierPathElement,
    NSLineToBezierPathElement,
    NSCurveToBezierPathElement,
    NSClosePathBezierPathElement
} NSBezierPathElement;
```

Constants

`NSMoveToBezierPathElement`

Moves the path object's current drawing point to the specified point.

This path element does not result in any drawing. Using this command in the middle of a path results in a disconnected line segment.

Contains 1 point.

Available in Mac OS X v10.0 and later.

Declared in `NSBezierPath.h`.

`NSLineToBezierPathElement`

Creates a straight line from the current drawing point to the specified point.

Lines and rectangles are specified using this path element.

Contains 1 point.

Available in Mac OS X v10.0 and later.

Declared in `NSBezierPath.h`.

`NSCurveToBezierPathElement`

Creates a curved line segment from the current point to the specified endpoint using two control points to define the curve.

The points are stored in the following order: controlPoint1, controlPoint2, endPoint. Ovals, arcs, and Bezier curves all use curve elements to specify their geometry.

Contains 3 points.

Available in Mac OS X v10.0 and later.

Declared in `NSBezierPath.h`.

`NSClosePathBezierPathElement`

Marks the end of the current subpath at the specified point.

Note that the point specified for the Close Path element is essentially the same as the current point.

Available in Mac OS X v10.0 and later.

Declared in `NSBezierPath.h`.

Discussion

These commands are enough to define all of the possible path shapes. Each command has one or more points that contain information needed to position the path element. Most path elements use the current drawing point as the starting point for drawing. For more details, see Paths.

Declared In
NSBezierPath.h

NSLineJoinStyle

These constants specify the shape of the joints between connected segments of a stroked path.

```
typedef enum {
    NSMiterLineJoinStyle = 0,
    NSRoundLineJoinStyle = 1,
    NSBevelLineJoinStyle = 2
} NSLineJoinStyle;
```

Constants

`NSBevelLineJoinStyle`
Specifies a bevel line shape of the joints between connected segments of a stroked path.
See the `setDefaultLineJoinStyle:` (page 302) method for an example of the appearance.
Available in Mac OS X v10.0 and later.
Declared in `NSBezierPath.h`.

`NSMiterLineJoinStyle`
Specifies a miter line shape of the joints between connected segments of a stroked path.
See the `setDefaultLineJoinStyle:` (page 302) method for an example of the appearance.
Available in Mac OS X v10.0 and later.
Declared in `NSBezierPath.h`.

`NSRoundLineJoinStyle`
Specifies a round line shape of the joints between connected segments of a stroked path.
See the `setDefaultLineJoinStyle:` (page 302) method for an example of the appearance.
Available in Mac OS X v10.0 and later.
Declared in `NSBezierPath.h`.

Declared In
NSBezierPath.h

NSLineCapStyle

These constants specify the shape of endpoints for an open path when stroked.

```
typedef enum {
    NSButtLineCapStyle   = 0,
    NSRoundLineCapStyle  = 1,
    NSSquareLineCapStyle = 2
} NSLineCapStyle;
```

Constants

`NSButtLineCapStyle`
Specifies a butt line cap style for endpoints for an open path when stroked.
See the `setDefaultLineCapStyle:` (page 302) method for an example of the appearance.
Available in Mac OS X v10.0 and later.
Declared in `NSBezierPath.h`.

`NSSquareLineCapStyle`
: Specifies a square line cap style for endpoints for an open path when stroked.

  See the `setDefaultLineCapStyle:` (page 302) method for an example of the appearance.

  Available in Mac OS X v10.0 and later.

  Declared in `NSBezierPath.h`.

`NSRoundLineCapStyle`
: Specifies a round line cap style for endpoints for an open path when stroked.

  See the `setDefaultLineCapStyle:` (page 302) method for an example of the appearance.

  Available in Mac OS X v10.0 and later.

  Declared in `NSBezierPath.h`.

Declared In
`NSBezierPath.h`

NSWindingRule

These constants are used to specify the winding rule a Bezier path should use.

```
typedef enum {
    NSNonZeroWindingRule = 0,
    NSEvenOddWindingRule = 1
} NSWindingRule;
```

Constants
`NSNonZeroWindingRule`
: Specifies the non-zero winding rule.

  Count each left-to-right path as +1 and each right-to-left path as -1. If the sum of all crossings is 0, the point is outside the path. If the sum is nonzero, the point is inside the path and the region containing it is filled. This is the default winding rule.

  Available in Mac OS X v10.0 and later.

  Declared in `NSBezierPath.h`.

`NSEvenOddWindingRule`
: Specifies the even-odd winding rule.

  Count the total number of path crossings. If the number of crossings is even, the point is outside the path. If the number of crossings is odd, the point is inside the path and the region containing it should be filled.

  Available in Mac OS X v10.0 and later.

  Declared in `NSBezierPath.h`.

Discussion
These constants are described in more detail in Paths.

Declared In
`NSBezierPath.h`

NSBitmapImageRep Class Reference

Inherits from	NSImageRep : NSObject
Conforms to	NSCoding (NSImageRep) NSCopying (NSImageRep) NSObject (NSObject)
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.0 and later.
Declared in	AppKit/NSBitmapImageRep.h
Companion guide	Cocoa Drawing Guide
Related sample code	GLSLShowpiece GLUT Image Difference Quartz EB Reducer

Overview

The `NSBitmapImageRep` class renders an image from bitmap data. Bitmap data formats supported include GIF, JPEG, TIFF, PNG, and various permutations of raw bitmap data.

Alpha Premultiplication

If a coverage (alpha) plane exists, a bitmap's color components are premultiplied with it. If you modify the contents of the bitmap, you are therefore responsible for premultiplying the data. For this reason, though, if you want to manipulate the actual data, an `NSBitmapImageRep` object is not recommended for storage. If you need to work with data that is not premultiplied, you should use Quartz, specifically `CGImageCreate` with `kCGImageAlphaLast`.

Note that premultiplying does not affect the output quality. Given source bitmap pixel `s`, destination pixel `d`, and alpha value `a`, a blend is basically

```
d' = a * s + (1 - a) * d
```

All premultiplication does is precalculate `a * s`.

Tasks

Creating an NSBitmapImageRep Object

`+ imageRepWithData:` (page 344)
Creates and returns an `NSBitmapImageRep` object initialized with the first image in the supplied data.

`+ imageRepsWithData:` (page 343)
Creates and returns an array of initialized `NSBitmapImageRep` objects corresponding to the images in the supplied data.

`- colorizeByMappingGray:toColor:blackMapping:whiteMapping:` (page 351)
Colorizes a grayscale image.

`- initWithBitmapDataPlanes:pixelsWide:pixelsHigh:bitsPerSample:samplesPerPixel:hasAlpha:isPlanar:colorSpaceName:bitmapFormat:bytesPerRow:bitsPerPixel:` (page 356)
Initializes the receiver, a newly allocated `NSBitmapImageRep` object, so it can render the specified image.

`- initWithBitmapDataPlanes:pixelsWide:pixelsHigh:bitsPerSample:samplesPerPixel:hasAlpha:isPlanar:colorSpaceName:bytesPerRow:bitsPerPixel:` (page 358)
Initializes the receiver, a newly allocated `NSBitmapImageRep` object, so it can render the specified image.

`- initWithCGImage:` (page 360)
Returns an `NSBitmapImageRep` object created from a Core Graphics image object.

`- initWithCIImage:` (page 361)
Returns an `NSBitmapImageRep` object created from a Core Image object.

`- initWithData:` (page 362)
Initializes a newly allocated `NSBitmapImageRep` from the provided data.

`- initWithFocusedViewRect:` (page 362)
Initializes the receiver, a newly allocated `NSBitmapImageRep` object, with bitmap data read from a rendered image.

`- initForIncrementalLoad` (page 355)
Initializes and returns the receiver, a newly allocated `NSBitmapImageRep` object, for incremental loading.

Getting Information About the Image

`- bitmapFormat` (page 347)
Returns the bitmap format of the receiver.

`- bitsPerPixel` (page 348)
Returns the number of bits allocated for each pixel in each plane of data.

`- bytesPerPlane` (page 349)
Returns the number of bytes in each plane or channel of data.

`- bytesPerRow` (page 349)
Returns the minimum number of bytes required to specify a scan line (a single row of pixels spanning the width of the image) in each data plane.

- `isPlanar` (page 363)
  Returns `YES` if image data is a planar configuration and `NO` if its in a meshed configuration.
- `numberOfPlanes` (page 363)
  Returns the number of separate planes image data is organized into.
- `samplesPerPixel` (page 364)
  Returns the number of components in the data.

Getting Image Data

- `bitmapData` (page 346)
  Returns a pointer to the bitmap data.
- `getBitmapDataPlanes:` (page 352)
  Returns by indirection bitmap data of the receiver separated into planes.

Producing Representations of the Image

+ `TIFFRepresentationOfImageRepsInArray:` (page 345)
  Returns a TIFF representation of the given images
+ `TIFFRepresentationOfImageRepsInArray:usingCompression:factor:` (page 346)
  Returns a TIFF representation of the given images using a specified compression scheme and factor.
- `TIFFRepresentation` (page 366)
  Returns a TIFF representation of the receiver.
- `TIFFRepresentationUsingCompression:factor:` (page 367)
  Returns a TIFF representation of the image using the specified compression.
+ `representationOfImageRepsInArray:usingType:properties:` (page 345)
  Formats the specified bitmap images using the specified storage type and properties and returns them in a data object.
- `representationUsingType:properties:` (page 363)
  Formats the receiver's image data using the specified storage type and properties and returns it in a data object.

Managing Compression Types

+ `getTIFFCompressionTypes:count:` (page 343)
  Returns by indirection an array of all available compression types that can be used when writing a TIFF image.
+ `localizedNameForTIFFCompressionType:` (page 344)
  Returns an autoreleased string containing the localized name for the specified compression type.
- `canBeCompressedUsing:` (page 350)
  Tests whether the receiver can be compressed by the specified compression scheme.
- `setCompression:factor:` (page 365)
  Sets the receiver's compression type and compression factor.

- `getCompression:factor:` (page 353)
  Returns by indirection the receiver's compression type and compression factor.
- `setProperty:withValue:` (page 366)
  Sets the image's *property* to *value*.
- `valueForProperty:` (page 368)
  Returns the value for the specified property.

Loading Image Incrementally

- `incrementalLoadFromData:complete:` (page 354)
  Loads the current image data into an incrementally-loaded image representation and returns the current status of the image.

Managing Pixel Values

- `setColor:atX:y:` (page 364)
  Changes the color of the pixel at the specified coordinates.
- `colorAtX:y:` (page 351)
  Returns the color of the pixel at the specified coordinates.
- `setPixel:atX:y:` (page 366)
  Sets the receiver's pixel at the specified coordinates to the specified raw pixel values.
- `getPixel:atX:y:` (page 354)
  Returns by indirection the pixel data for the specified location in the receiver.

Getting a Core Graphics Image

- `CGImage` (page 350)
  Returns a Core Graphics image object from the receiver's current bitmap data.

Managing ColorSpaces

- `bitmapImageRepByConvertingToColorSpace:renderingIntent:` (page 347)
  Converts the image rep to the specified colorspace
- `bitmapImageRepByRetaggingWithColorSpace:` (page 348)
  Changes the colorSpace tag of the receiver.
- `colorSpace` (page 352)
  Returns the image rep's colorSpace

Class Methods

getTIFFCompressionTypes:count:

Returns by indirection an array of all available compression types that can be used when writing a TIFF image.

```
+ (void)getTIFFCompressionTypes:(const NSTIFFCompression **)list count:(NSInteger
    *)numTypes
```

Parameters

list

On return, a C array of `NSTIFFCompression` constants. This array belongs to the `NSBitmapImageRep` class; it shouldn't be freed or altered. See "Constants" (page 368) for the supported TIFF compression types.

numTypes

The number of constants in list.

Discussion

Note that not all compression types can be used for all images: `NSTIFFCompressionNEXT` can be used only to retrieve image data. Because future releases may include other compression types, always use this method to get the available compression types—for example, when you implement a user interface for selecting compression types.

Availability

Available in Mac OS X v10.0 and later.

See Also

Declared In

`NSBitmapImageRep.h`

imageRepsWithData:

Creates and returns an array of initialized `NSBitmapImageRep` objects corresponding to the images in the supplied data.

```
+ (NSArray *)imageRepsWithData:(NSData *)bitmapData
```

Parameters

bitmapData

A data object containing one or more bitmapped images or `nil` if the class is unable to create an image representation. The *bitmapData* parameter can contain data in any supported bitmap format.

Return Value

An array of `NSBitmapImageRep` instances or an empty array if the class is unable to create any image representations.

Availability

Available in Mac OS X v10.0 and later.

Declared In
NSBitmapImageRep.h

imageRepWithData:

Creates and returns an NSBitmapImageRep object initialized with the first image in the supplied data.

```
+ (id)imageRepWithData:(NSData *)bitmapData
```

Parameters

bitmapData

A data object containing one or more bitmapped images. The *bitmapData* parameter can contain data in any supported bitmap format.

Return Value
An NSBitmapImageRep instance or nil if the class is unable to create an image representation.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSBitmapImageRep.h

localizedNameForTIFFCompressionType:

Returns an autoreleased string containing the localized name for the specified compression type.

```
+ (NSString *)localizedNameForTIFFCompressionType:(NSTIFFCompression)compression
```

Parameters

compression

A TIFF compression type. NSTIFFCompression types are described in "Constants" (page 368).

Return Value
A localized name for *compression* or nil if *compression* is unrecognized.

Discussion
When implementing a user interface for selecting TIFF compression types, use getTIFFCompressionTypes:count: (page 343) to get the list of supported compression types, then use this method to get the localized names for each compression type.

Availability
Available in Mac OS X v10.0 and later.

See Also
+ getTIFFCompressionTypes:count: (page 343)

Declared In
NSBitmapImageRep.h

representationOfImageRepsInArray:usingType:properties:

Formats the specified bitmap images using the specified storage type and properties and returns them in a data object.

```
+ (NSData *)representationOfImageRepsInArray:(NSArray *)imageReps
    usingType:(NSBitmapImageFileType)storageType properties:(NSDictionary
    *)properties
```

Parameters

imageReps

An array of NSBitmapImageRep objects.

storageType

An enum constant specifying a file type for bitmap images. It can be NSBMPFileType, NSGIFFileType, NSJPEGFileType, NSPNGFileType, or NSTIFFFileType.

properties

A dictionary that contains key-value pairs specifying image properties. These string constants used as keys and the valid values are described in "Bitmap image properties" (page 370).

Return Value
A data object containing the bitmap image data in the specified format. You can write this data to a file or use it to create a new NSBitmapImageRep object.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSBitmapImageRep.h

TIFFRepresentationOfImageRepsInArray:

Returns a TIFF representation of the given images

```
+ (NSData *)TIFFRepresentationOfImageRepsInArray:(NSArray *)array
```

Parameters

array

An array containing objects representing bitmap image representations.

Return Value
A data object containing a TIFF image representation.

Discussion
This method uses the compression returned by getCompression:factor: (page 353) (if applicable). If a problem is encountered during generation of the TIFF, this method raises an NSTIFFException or an NSBadBitmapParametersException.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `TIFFRepresentation` (page 366)

Declared In
`NSBitmapImageRep.h`

TIFFRepresentationOfImageRepsInArray:usingCompression:factor:

Returns a TIFF representation of the given images using a specified compression scheme and factor.

```
+ (NSData *)TIFFRepresentationOfImageRepsInArray:(NSArray *)array
    usingCompression:(NSTIFFCompression)compression factor:(float)factor
```

Parameters

array

An array containing objects representing bitmap image representations.

compression

An enum constant that represents a TIFF data-compression scheme. Legal values for *compression* can be found in `NSBitmapImageRep.h` and are described in "Constants" (page 368).

factor

A `float` value that provides a hint for those compression types that implement variable compression ratios.

Currently only JPEG compression uses a compression factor. JPEG compression in TIFF files is not supported, and *factor* is ignored.

Return Value
A data object containing a TIFF image representation.

Discussion
If the specified compression isn't applicable, no compression is used. If a problem is encountered during generation of the TIFF, the method raises an `NSTIFFException` or an `NSBadBitmapParametersException`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `TIFFRepresentationUsingCompression:factor:` (page 367)

Declared In
`NSBitmapImageRep.h`

Instance Methods

bitmapData

Returns a pointer to the bitmap data.

```
- (unsigned char *)bitmapData
```

Discussion
If the data is planar, returns a pointer to the first plane.

Availability
Available in Mac OS X v10.0 and later.

See Also

Declared In
`NSBitmapImageRep.h`

bitmapFormat

Returns the bitmap format of the receiver.

```
- (NSBitmapFormat)bitmapFormat
```

Discussion
Returns 0 by default. The return value can indicate several different attributes, which are described in "Constants" (page 368).

Availability
Available in Mac OS X v10.4 and later.

See Also
- `bytesPerRow` (page 349)

Declared In
`NSBitmapImageRep.h`

bitmapImageRepByConvertingToColorSpace:renderingIntent:

Converts the image rep to the specified colorspace

```
- (NSBitmapImageRep *)bitmapImageRepByConvertingToColorSpace:(NSColorSpace
    *)targetSpace renderingIntent:(NSColorRenderingIntent)renderingIntent
```

Parameters
targetSpace
The new colorSpace

renderingIntent
The rendering intent specifies how to handle colors that are not located within the target color space. The supported values are `NSColorRenderingIntent` (page 1313).

Return Value
An `NSBitmapImageRep`, or `nil`, if the conversion fails. If the original `NSBitmapImageRep` already uses that colorSpace, it is returned as is.

Availability
Available in Mac OS X v10.6 and later.

See Also
- `bitmapImageRepByRetaggingWithColorSpace:` (page 348)
- `colorSpace` (page 352)

Declared In
`NSBitmapImageRep.h`

bitmapImageRepByRetaggingWithColorSpace:

Changes the colorSpace tag of the receiver.

```
- (NSBitmapImageRep *)bitmapImageRepByRetaggingWithColorSpace:(NSColorSpace
    *)newSpace
```

Parameters
newSpace
The desired colorSpace.

Return Value
An `NSBitmapImageRep`, or `nil`, if the conversion fails. If the original `NSBitmapImageRep` already uses that colorSpace, it is returned as is.

Discussion
This method will definitely fail if you pass a colorSpace that has a different color space model than the receiver. That is, if your original image is sRGB, you can only retag with some other RGB colorspace.

Availability
Available in Mac OS X v10.6 and later.

See Also
- `bitmapImageRepByRetaggingWithColorSpace:` (page 348)
- `colorSpace` (page 352)

Declared In
`NSBitmapImageRep.h`

bitsPerPixel

Returns the number of bits allocated for each pixel in each plane of data.

```
- (NSInteger)bitsPerPixel
```

Discussion
This number is normally equal to the number of bits per sample or, if the data is in meshed configuration, the number of bits per sample times the number of samples per pixel. It can be explicitly set to another value (in `initWithBitmapDataPlanes:pixelsWide:pixelsHigh:bitsPerSample:samplesPerPixel:hasAlpha:isPlanar:colorSpaceName:bytesPerRow:bitsPerPixel:` (page 358)) in case extra memory is allocated for each pixel. This may be the case, for example, if pixel data is aligned on byte boundaries.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
Quartz EB

Declared In
`NSBitmapImageRep.h`

bytesPerPlane

Returns the number of bytes in each plane or channel of data.

```
- (NSInteger)bytesPerPlane
```

Discussion
This number is calculated from the number of bytes per row and the height of the image.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- bytesPerRow` (page 349)

Declared In
`NSBitmapImageRep.h`

bytesPerRow

Returns the minimum number of bytes required to specify a scan line (a single row of pixels spanning the width of the image) in each data plane.

```
- (NSInteger)bytesPerRow
```

Discussion
If not explicitly set to another value (in `initWithBitmapDataPlanes:pixelsWide:pixelsHigh:bitsPerSample:samplesPerPixel:hasAlpha:isPlanar:colorSpaceName:bytesPerRow:bitsPerPixel:` (page 358)), this number will be figured from the width of the image, the number of bits per sample, and, if the data is in a meshed configuration, the number of samples per pixel. It can be set to another value to indicate that each row of data is aligned on word or other boundaries.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSBitmapImageRep.h

canBeCompressedUsing:

Tests whether the receiver can be compressed by the specified compression scheme.

```
- (BOOL)canBeCompressedUsing:(NSTIFFCompression)compression
```

Parameters
compression
A TIFF compression type. NSTIFFCompression types are defined in "Constants" (page 368).

Return Value
YES if the receiver's data matches compression with this type, NO if the data doesn't match *compression* or if *compression* is unsupported..

Discussion
Legal values for *compression* can be found in NSBitmapImageRep.h and are described in TIFF Compression in NSBitmapImageReps. This method returns YES if the receiver's data matches *compression*; for example, if *compression* is NSTIFFCompressionCCITTFAX3, then the data must be 1 bit per sample and 1 sample per pixel.

Availability
Available in Mac OS X v10.0 and later.

See Also
+ getTIFFCompressionTypes:count: (page 343)

Declared In
NSBitmapImageRep.h

CGImage

Returns a Core Graphics image object from the receiver's current bitmap data.

```
- (CGImageRef)CGImage
```

Return Value
Returns an autoreleased CGImageRef opaque type based on the receiver's current bitmap data.

Discussion
The returned `CGImageRef` has pixel dimensions that are identical to the receiver's. This method might return a preexisting `CGImageRef` opaque type or create a new one. If the receiver is later modified, subsequent invocations of this method might return different `CGImageRef` opaque types.

Availability
Available in Mac OS X version 10.5.

See Also
`- initWithCGImage:` (page 360)

Declared In
`NSBitmapImageRep.h`

colorAtX:y:

Returns the color of the pixel at the specified coordinates.

```
- (NSColor *)colorAtX:(NSInteger)x y:(NSInteger)y
```

Parameters

x
The x-axis coordinate.

y
The y-axis coordinate.

Return Value
A color object representing the color at the specified coordinates.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- setColor:atX:y:` (page 364)

Related Sample Code
RadiantColorPicker

Declared In
`NSBitmapImageRep.h`

colorizeByMappingGray:toColor:blackMapping:whiteMapping:

Colorizes a grayscale image.

```
- (void)colorizeByMappingGray:(CGFloat)midPoint toColor:(NSColor *)midPointColor
    blackMapping:(NSColor *)shadowColor whiteMapping:(NSColor *)lightColor
```

Parameters

midPoint
A float value representing the midpoint of the grayscale image.

midPointColor
A color object representing the midpoint of the color to map the image to.

shadowColor
A color object representing the black mapping to use for shadows.

lightColor
A color object representing the white mapping to be used in the image.

Discussion
This method maps the receiver such that:

Gray value of *midPoint* –> *midPointColor*;
black –> *shadowColor*;
white –> *lightColor*.

It works on images with 8-bit SPP, and thus supports either 8-bit gray or 24-bit color (with optional alpha).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSBitmapImageRep.h`

colorSpace

Returns the image rep's colorSpace

```
- (NSColorSpace *)colorSpace
```

Return Value
The colorSpace.

Availability
Available in Mac OS X v10.6 and later.

`- bitmapImageRepByRetaggingWithColorSpace:` (page 348)
`- bitmapImageRepByConvertingToColorSpace:renderingIntent:` (page 347)

Declared In
`NSBitmapImageRep.h`

getBitmapDataPlanes:

Returns by indirection bitmap data of the receiver separated into planes.

```
- (void)getBitmapDataPlanes:(unsigned char **)data
```

Parameters

data

On return, a C array of five character pointers. If the bitmap data is in planar configuration, each pointer will be initialized to point to one of the data planes. If there are less than five planes, the remaining pointers will be set to `NULL`. If the bitmap data is in meshed configuration, only the first pointer will be initialized; the others will be `NULL`.

Discussion

Color components in planar configuration are arranged in the expected order—for example, red before green before blue for RGB color. All color planes precede the coverage plane. If a coverage plane exists, the bitmap's color components are premultiplied with it. If you modify the contents of the bitmap, you are responsible for premultiplying the data.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSBitmapImageRep.h`

getCompression:factor:

Returns by indirection the receiver's compression type and compression factor.

```
- (void)getCompression:(NSTIFFCompression *)compression factor:(float *)factor
```

Parameters

compression

On return, an `enum` constant that represents the compression type used on the data; it corresponds to one of the values returned by the class method `getTIFFCompressionTypes:count:` (page 343).

factor

A float value that is specific to the compression type. Many types of compression don't support varying degrees of compression and thus ignore *factor*. JPEG compression allows a compression factor ranging from 0.0 to 1.0, with 0.0 being the lowest and 1.0 being the highest.

Discussion

Use this method to get information on the compression type for the source image data.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSBitmapImageRep.h`

getPixel:atX:y:

Returns by indirection the pixel data for the specified location in the receiver.

```
- (void)getPixel:(NSUInteger[])pixelData atX:(NSInteger)x y:(NSInteger)y
```

Parameters

pixelData

On return, an array of integers containing raw pixel data in the appropriate order for the receiver's `bitmapFormat` (page 347). Smaller integer samples, such as 4-bit, are returned as an integer. Floating point values are cast to integer values and returned.

x

The x-axis coordinate of the pixel.

y

The y-axis coordinate of the pixel.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- setPixel:atX:y:` (page 366)

Declared In
`NSBitmapImageRep.h`

incrementalLoadFromData:complete:

Loads the current image data into an incrementally-loaded image representation and returns the current status of the image.

```
- (NSInteger)incrementalLoadFromData:(NSData *)data complete:(BOOL)complete
```

Parameters

data

A data object that contains the image to be loaded.

complete

`YES` if the image is entirely downloaded, `NO` otherwise.

Return Value
An integer constant indicating the status of the image during the load operation. See the discussion for details.

Discussion
After initializing the receiver with `initForIncrementalLoad` (page 355), you should call this method to incrementally load the image. Call this method each time new data becomes available. Always pass the entire image data buffer in *data*, not just the newest data, because the image decompressor may need the original data in order to backtrack. This method will block until the data is decompressed; it will decompress as much of the image as possible based on the length of the data. The image rep does not retain *data*, so you must ensure that *data* is not released for the duration of this method call. Pass `NO` for *complete* until the entire image is downloaded, at which time you should pass `YES`. You should also pass `YES` for *complete* if you have only partially downloaded the data, but cannot finish the download.

This method returns `NSImageRepLoadStatusUnknownType` if you did not pass enough data to determine the image format; you should continue to invoke this method with additional data.

This method returns `NSImageRepLoadStatusReadingHeader` if it has enough data to determine the image format, but needs more data to determine the size and depth and other characteristics of the image. You should continue to invoke this method with additional data.

This method returns `NSImageRepLoadStatusWillNeedAllData` if the image format does not support incremental loading or the Application Kit does not yet implement incremental loading for the image format. You may continue to invoke this method in this case, but until you pass `YES` for *`complete`*, this method will continue to return `NSImageRepLoadStatusWillNeedAllData`, and will perform no decompression. Once you pass `YES`, the image will be decompressed and one of the final three status messages will be returned.

If the image format does support incremental loading, then once enough data has been read, the image is decompressed from the top down a row at a time. In this case, instead of a status value, this method returns the number of pixel rows that have been decompressed, starting from the top of the image. You can use this information to draw the part of the image that is valid. The rest of the image is filled with opaque white. Note that if the image is progressive (as in a progressive JPEG or 2D interlaced PNG), this method may quickly return the full height of the image, but the image may still be loading, so do not use this return value as an indication of how much of the image remains to be decompressed.

If an error occurred while decompressing, this method returns `NSImageRepLoadStatusInvalidData`. If *`complete`* is `YES` but not enough data was available for decompression, `NSImageRepLoadStatusUnexpectedEOF` is returned. If enough data has been provided (regardless of the *`complete`* flag), then `NSImageRepLoadStatusCompleted` is returned. When any of these three status results are returned, this method has adjusted the `NSBitmapImageRep` so that `pixelsHigh` (page 1419) and `size` (page 1424), as well as the bitmap data, only contains the pixels that are valid, if any.

To cancel decompression, just pass in the existing data or `nil` and `YES` for *`complete`*. This method stops decompression immediately, adjusts the image size, and returns `NSImageRepLoadStatusUnexpectedEOF`. This method returns `NSImageRepLoadStatusCompleted` if you call it after receiving any error results (`NSImageRepLoadStatusInvalidData` or `NSImageRepLoadStatusUnexpectedEOF`) or if you call it on an `NSBitmapImageRep` that was not initialized with `initForIncrementalLoad` (page 355).

Availability
Available in Mac OS X v10.2 and later.

See Also
`- initForIncrementalLoad` (page 355)

Declared In
`NSBitmapImageRep.h`

initForIncrementalLoad

Initializes and returns the receiver, a newly allocated `NSBitmapImageRep` object, for incremental loading.

```
- (id)initForIncrementalLoad
```

Discussion
The receiver returns itself after setting its size and data buffer to zero. You can then call `incrementalLoadFromData:complete:` (page 354) to incrementally add image data.

Availability
Available in Mac OS X v10.2 and later.

See Also
`- incrementalLoadFromData:complete:` (page 354)

Declared In
`NSBitmapImageRep.h`

initWithBitmapDataPlanes:pixelsWide:pixelsHigh:bitsPerSample:samplesPerPixel:hasAlpha:isPlanar:colorSpaceName:bitmapFormat:bytesPerRow:bitsPerPixel:

Initializes the receiver, a newly allocated `NSBitmapImageRep` object, so it can render the specified image.

```
- (id)initWithBitmapDataPlanes:(unsigned char **)planes pixelsWide:(NSInteger)width
    pixelsHigh:(NSInteger)height bitsPerSample:(NSInteger)bps
   samplesPerPixel:(NSInteger)spp hasAlpha:(BOOL)alpha isPlanar:(BOOL)isPlanar
   colorSpaceName:(NSString *)colorSpaceName
   bitmapFormat:(NSBitmapFormat)bitmapFormat bytesPerRow:(NSInteger)rowBytes
   bitsPerPixel:(NSInteger)pixelBits
```

Parameters

planes

An array of character pointers, each of which points to a buffer containing raw image data. If the data is in planar configuration, each buffer holds one component—one plane—of the data. Color planes are arranged in the standard order—for example, red before green before blue for RGB color. All color planes precede the coverage plane. If a coverage plane exists, the bitmap's color components must be premultiplied with it. If the data is in meshed configuration (that is, *isPlanar* is `NO`), only the first buffer is read.

If *planes* is `NULL` or an array of `NULL` pointers, this method allocates enough memory to hold the image described by the other arguments. You can then obtain pointers to this memory (with the `getPixel:atX:y:` (page 354) or `bitmapData` (page 346) method) and fill in the image data. In this case, the allocated memory will belong to the object and will be freed when it's freed.

If *planes* is not `NULL` and the array contains at least one data pointer, the returned object will only reference the image data; it will not copy it. The object treats the image data in the buffers as immutable and will not attempt to alter it. When the object itself is freed, it will not attempt to free the buffers.

width

The width of the image in pixels. This value must be greater than 0.

height

The height of the image in pixels. This value must be greater than 0.

bps

The number of bits used to specify one pixel in a single component of the data. All components are assumed to have the same bits per sample. *bps* should be one of these values: 1, 2, 4, 8, 12, or 16.

spp

The number of data components, or samples per pixel. This value includes both color components and the coverage component (alpha), if present. Meaningful values range from 1 through 5. An image with cyan, magenta, yellow, and black (CMYK) color components plus a coverage component would have an *spp* of 5; a grayscale image that lacks a coverage component would have an *spp* of 1.

alpha

YES if one of the components counted in the number of samples per pixel (*spp*) is a coverage (alpha) component, and NO if there is no coverage component. If YES, the color components in the bitmap data must be premultiplied with their coverage component.

isPlanar

YES if the data components are laid out in a series of separate "planes" or channels ("planar configuration") and NO if component values are interwoven in a single channel ("meshed configuration"). If NO, only the first buffer of planes is read.

For example, in meshed configuration, the red, green, blue, and coverage values for the first pixel of an image would precede the red, green, blue, and coverage values for the second pixel, and so on. In planar configuration, red values for all the pixels in the image would precede all green values, which would precede all blue values, which would precede all coverage values.

colorSpaceName

A string constant that indicates how data values are to be interpreted. It should be one of the following values:

- NSCalibratedWhiteColorSpace
- NSCalibratedBlackColorSpace
- NSCalibratedRGBColorSpace
- NSDeviceWhiteColorSpace
- NSDeviceBlackColorSpace
- NSDeviceRGBColorSpace
- NSDeviceCMYKColorSpace
- NSNamedColorSpace
- NSCustomColorSpace

If *bps* is 12, you cannot specify the monochrome color space.

bitmapFormat

An integer that specifies the ordering of the bitmap components. It is a mask created by combining the NSBitmapFormat constants NSAlphaFirstBitmapFormat, NSAlphaNonpremultipliedBitmapFormat and NSFloatingPointSamplesBitmapFormat using the C bitwise OR operator.

rowBytes

The number of bytes that are allocated for each scan line in each plane of data. A scan line is a single row of pixels spanning the width of the image.

Normally, *rowBytes* can be figured from the width of the image, the number of bits per pixel in each sample (*bps*), and, if the data is in a meshed configuration, the number of samples per pixel (*spp*). However, if the data for each row is aligned on word or other boundaries, it may have been necessary to allocate more memory for each row than there is data to fill it. *rowBytes* lets the object know whether that's the case.

If you pass in a *rowBytes* value of 0, the bitmap data allocated may be padded to fall on long word or larger boundaries for performance. If your code wants to advance row by row, use bytesPerRow (page 349) and do not assume the data is packed. Passing in a non-zero value allows you to specify exact row advances.

pixelBits

This integer value informs NSBitmapImageRep how many bits are actually allocated per pixel in each plane of data. If the data is in planar configuration, this normally equals *bps* (bits per sample). If the data is in meshed configuration, it normally equals *bps* times *spp* (samples per pixel). However, it's possible for a pixel specification to be followed by some meaningless bits (empty space), as may happen, for example, if pixel data is aligned on byte boundaries. NSBitmapImageRep supports only a limited number of *pixelBits* values (other than the default): for RGB images with 4 *bps*, *pixelBits* may be 16; for RGB images with 8 *bps*, *pixelBits* may be 32. The legal values for *pixelBits* are system dependent.

If you specify 0 for this parameter, the object interprets the number of bits per pixel using the values in the *bps* and *spp* parameters, as described in the preceding paragraph, without any meaningless bits.

Return Value
An initialized NSBitmapImageRep object or nil if the object cannot be initialized.

Availability
Available in Mac OS X v10.4 and later.

Related Sample Code
Quartz Composer Offline Rendering

Declared In
NSBitmapImageRep.h

initWithBitmapDataPlanes:pixelsWide:pixelsHigh:bitsPerSample:samplesPerPixel:hasAlpha:isPlanar:colorSpaceName:bytesPerRow:bitsPerPixel:

Initializes the receiver, a newly allocated NSBitmapImageRep object, so it can render the specified image.

```
- (id)initWithBitmapDataPlanes:(unsigned char **)planes pixelsWide:(NSInteger)width
    pixelsHigh:(NSInteger)height bitsPerSample:(NSInteger)bps
   samplesPerPixel:(NSInteger)spp hasAlpha:(BOOL)alpha isPlanar:(BOOL)isPlanar
   colorSpaceName:(NSString *)colorSpaceName bytesPerRow:(NSInteger)rowBytes
   bitsPerPixel:(NSInteger)pixelBits
```

Parameters

planes

An array of character pointers, each of which points to a buffer containing raw image data. If the data is in planar configuration, each buffer holds one component—one plane—of the data. Color planes are arranged in the standard order—for example, red before green before blue for RGB color. All color planes precede the coverage plane. If a coverage plane exists, the bitmap's color components must be premultiplied with it. If the data is in meshed configuration (that is, *isPlanar* is NO), only the first buffer is read.

If *planes* is NULL or an array of NULL pointers, this method allocates enough memory to hold the image described by the other arguments. You can then obtain pointers to this memory (with the getPixel:atX:y: (page 354) or bitmapData (page 346) method) and fill in the image data. In this case, the allocated memory will belong to the object and will be freed when it's freed.

If *planes* is not NULL and the array contains at least one data pointer, the returned object will only reference the image data; it will not copy it. The object treats the image data in the buffers as immutable and will not attempt to alter it. When the object itself is freed, it will not attempt to free the buffers.

width

The width of the image in pixels. This value must be greater than 0.

height

The height of the image in pixels. This value must be greater than 0.

bps

The number of bits used to specify one pixel in a single component of the data. All components are assumed to have the same bits per sample. *bps* should be one of these values: 1, 2, 4, 8, 12, or 16.

spp

The number of data components, or samples per pixel. This value includes both color components and the coverage component (alpha), if present. Meaningful values range from 1 through 5. An image with cyan, magenta, yellow, and black (CMYK) color components plus a coverage component would have an *spp* of 5; a grayscale image that lacks a coverage component would have an *spp* of 1.

alpha

`YES` if one of the components counted in the number of samples per pixel (*spp*) is a coverage (alpha) component, and `NO` if there is no coverage component. If `YES`, the color components in the bitmap data must be premultiplied with their coverage component.

isPlanar

`YES` if the data components are laid out in a series of separate "planes" or channels ("planar configuration") and `NO` if component values are interwoven in a single channel ("meshed configuration"). If `NO`, only the first buffer of `planes` is read.

For example, in meshed configuration, the red, green, blue, and coverage values for the first pixel of an image would precede the red, green, blue, and coverage values for the second pixel, and so on. In planar configuration, red values for all the pixels in the image would precede all green values, which would precede all blue values, which would precede all coverage values.

colorSpaceName

A string constant that indicates how data values are to be interpreted. It should be one of the following values:

- `NSCalibratedWhiteColorSpace`
- `NSCalibratedBlackColorSpace`
- `NSCalibratedRGBColorSpace`
- `NSDeviceWhiteColorSpace`
- `NSDeviceBlackColorSpace`
- `NSDeviceRGBColorSpace`
- `NSDeviceCMYKColorSpace`
- `NSNamedColorSpace`
- `NSCustomColorSpace`

If *bps* is 12, you cannot specify the monochrome color space.

rowBytes

The number of bytes that are allocated for each scan line in each plane of data. A scan line is a single row of pixels spanning the width of the image.

Normally, *rowBytes* can be figured from the width of the image, the number of bits per pixel in each sample (*bps*), and, if the data is in a meshed configuration, the number of samples per pixel (*spp*). However, if the data for each row is aligned on word or other boundaries, it may have been necessary to allocate more memory for each row than there is data to fill it. *rowBytes* lets the object know whether that's the case.

If you pass in a *rowBytes* value of 0, the bitmap data allocated may be padded to fall on long word or larger boundaries for performance. If your code wants to advance row by row, use `bytesPerRow` (page 349) and do not assume the data is packed. Passing in a non-zero value allows you to specify exact row advances.

pixelBits

This integer value informs `NSBitmapImageRep` how many bits are actually allocated per pixel in each plane of data. If the data is in planar configuration, this normally equals *bps* (bits per sample). If the data is in meshed configuration, it normally equals *bps* times *spp* (samples per pixel). However, it's possible for a pixel specification to be followed by some meaningless bits (empty space), as may happen, for example, if pixel data is aligned on byte boundaries. `NSBitmapImageRep` supports only a limited number of *pixelBits* values (other than the default): for RGB images with 4 *bps*, *pixelBits* may be 16; for RGB images with 8 *bps*, *pixelBits* may be 32. The legal values for *pixelBits* are system dependent.

If you specify 0 for this parameter, the object interprets the number of bits per pixel using the values in the *bps* and *spp* parameters, as described in the preceding paragraph, without any meaningless bits.

Return Value
An initialized `NSBitmapImageRep` object or `nil` if the object cannot be initialized.

Availability
Available in Mac OS X v10.0 and later.

Transformed Image

Declared In
`NSBitmapImageRep.h`

initWithCGImage:

Returns an `NSBitmapImageRep` object created from a Core Graphics image object.

```
- (id)initWithCGImage:(CGImageRef)cgImage
```

Parameters

cgImage

A Core Graphics image object (an opaque type) from which to create the receiver. This opaque type is retained.

Return Value
An `NSBitmapImageRep` object initialized from the contents of the Core Graphics image or `nil` if the `NSBitmapImageRep` couldn't be created.

Discussion
If you use this method, you should treat the resulting bitmap `NSBitmapImageRep` object as read only. Because it only retains the value in the *`cgImage`* parameter, rather than unpacking the data, accessing the pixel data requires the creation of a copy of that data in memory. Changes to that data are not saved back to the Core Graphics image.

Availability
Available in Mac OS X v10.5 and later.

See Also
- `CGImage` (page 350)

Declared In
`NSBitmapImageRep.h`

initWithCIImage:

Returns an `NSBitmapImageRep` object created from a Core Image object.

```
- (id)initWithCIImage:(CIImage *)ciImage
```

Parameters

`ciImage`

A Core Image object whose contents are to be copied to the receiver. This image rectangle must be of a finite size.

Return Value
An `NSBitmapImageRep` object initialized from the contents of the Core Image (`CIImage`) object or `nil` if the `NSBitmapImageRep` couldn't be created.

Discussion
The image in the *`ciImage`* parameter must be fully rendered before the receiver can be initialized. If you specify an object whose rendering was deferred (and thus does not have any pixels available now), this method forces the image to be rendered immediately. Rendering the image could result in a performance penalty if the image has a complex rendering chain or accelerated rendering hardware is not available. By the time this method returns, however, the resultant `NSBitmapImageRep` object can have its raw pixel data inspected, can be put on the pasteboard, and can be encoded to any of the standard image formats that `NSBitmapImageRep` supports (JPEG, TIFF, and so on.)

If you pass in a `CIImage` object whose extents are not finite, this method raises an exception.

Availability
Available in Mac OS X v10.5 and later.

See Also
- `initWithBitmapImageRep:` (page 59) (CIImage)

Declared In
`NSBitmapImageRep.h`

initWithData:

Initializes a newly allocated `NSBitmapImageRep` from the provided data.

```
- (id)initWithData:(NSData *)bitmapData
```

Parameters

bitmapData

A data object containing image data. The contents of *bitmapData* can be any supported bitmap format. For TIFF data, the `NSBitmapImageRep` is initialized from the first header and image data found in *bitmapData*.

Return Value

Returns an initialized `NSBitmapImageRep` if the initialization was successful or `nil` if it was unable to interpret the contents of *bitmapData*.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSBitmapImageRep.h`

initWithFocusedViewRect:

Initializes the receiver, a newly allocated `NSBitmapImageRep` object, with bitmap data read from a rendered image.

```
- (id)initWithFocusedViewRect:(NSRect)rect
```

Parameters

rect

A rectangle that specifies an area of the current window in the current coordinate system.

Return Value

Returns the initialized object or `nil` If for any reason the new object can't be initialized.

Discussion

This method uses imaging operators to read the image data into a buffer; the object is then created from that data. The object is initialized with information about the image obtained from the window server.

Availability

Available in Mac OS X v10.0 and later.

FunHouse

Reducer

Declared In

`NSBitmapImageRep.h`

isPlanar

Returns YES if image data is a planar configuration and NO if its in a meshed configuration.

```
- (BOOL)isPlanar
```

Discussion
In a planar configuration, the image data is segregated into a separate plane for each color and coverage component. In a meshed configuration, the data is integrated into a single plane.

Availability
Available in Mac OS X v10.0 and later.

See Also
- samplesPerPixel (page 364)

Declared In
NSBitmapImageRep.h

numberOfPlanes

Returns the number of separate planes image data is organized into.

```
- (NSInteger)numberOfPlanes
```

Discussion
This number is the number of samples per pixel if the data has a separate plane for each component (isPlanar (page 363) returns YES) and 1 if the data is meshed (isPlanar (page 363) returns NO).

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSBitmapImageRep.h

representationUsingType:properties:

Formats the receiver's image data using the specified storage type and properties and returns it in a data object.

```
- (NSData *)representationUsingType:(NSBitmapImageFileType)storageType
    properties:(NSDictionary *)properties
```

Parameters

storageType

An enum constant specifying a file type for bitmap images. It can be NSBMPFileType, NSGIFFileType, NSJPEGFileType, NSPNGFileType, or NSTIFFFileType.

properties

A dictionary that contains key-value pairs specifying image properties. These string constants used as keys and the valid values are described in "Bitmap image properties" (page 370).

Return Value
A data object containing the receiver's image data in the specified format. You can write this data to a file or use it to create a new `NSBitmapImageRep` object.

Availability
Available in Mac OS X v10.0 and later.

See Also

setColor:atX:y:

Changes the color of the pixel at the specified coordinates.

```
- (void)setColor:(NSColor *)color atX:(NSInteger)x y:(NSInteger)y
```

Parameters

color

A color object representing the color to be set.

x

The x-axis coordinate of the pixel.

y

The y-axis coordinate of the pixel.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `colorAtX:y:` (page 351)

Related Sample Code
RadiantColorPicker

Declared In
`NSBitmapImageRep.h`

setCompression:factor:

Sets the receiver's compression type and compression factor.

```
- (void)setCompression:(NSTIFFCompression)compression factor:(float)factor
```

Parameters

compression

An `enum` constant that identifies one of the supported compression types as described in "Constants" (page 368).

factor

A floating point value that is specific to the compression type. Many types of compression don't support varying degrees of compression and thus ignore *factor*. JPEG compression allows a compression factor ranging from 0.0 to 1.0, with 0.0 being the lowest and 1.0 being the highest.

Discussion
When an `NSBitmapImageRep` is created, the instance stores the compression type and factor for the source data. `TIFFRepresentation` (page 366) and `TIFFRepresentationOfImageRepsInArray:` (page 345) (class method) try to use the stored compression type and factor. Use this method to change the compression type and factor.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `canBeCompressedUsing:` (page 350)

Declared In
`NSBitmapImageRep.h`

setPixel:atX:y:

Sets the receiver's pixel at the specified coordinates to the specified raw pixel values.

```
- (void)setPixel:(NSUInteger[])pixelData atX:(NSInteger)x y:(NSInteger)y
```

Parameters

pixelData

An array of integers representing the raw pixel values. The values must be in an order appropriate to the receiver's `bitmapFormat` (page 347). Small pixel sample values should be passed as an integer value. Floating point values should be cast `int[]`.

x

The x-axis coordinate of the pixel.

y

The y-axis coordinate of the pixel.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- getPixel:atX:y:` (page 354)

Declared In
`NSBitmapImageRep.h`

setProperty:withValue:

Sets the image's *property* to *value*.

```
- (void)setProperty:(NSString *)property withValue:(id)value
```

Parameters

property

A string constant used as a key for an image property. These properties are described in "Constants" (page 368).

value

A value specific to `property`. If *value* is `nil`, the value of the property is cleared.

Discussion
The properties can affect how the image is read in and saved to file.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSBitmapImageRep.h`

TIFFRepresentation

Returns a TIFF representation of the receiver.

```
- (NSData *)TIFFRepresentation
```

Discussion
This method invokes `TIFFRepresentationUsingCompression:factor:` (page 367) using the stored compression type and factor retrieved from the initial image data or changed using `setCompression:factor:` (page 365). If the stored compression type isn't supported for writing TIFF data (for example, `NSTIFFCompressionNEXT`), the stored compression is changed to `NSTIFFCompressionNone` before invoking `TIFFRepresentationUsingCompression:factor:` (page 367). receiver, using the compression that's returned by `getCompression:factor:` (page 353) (if applicable).

If a problem is encountered during generation of the TIFF, `TIFFRepresentation` raises an `NSTIFFException` or an `NSBadBitmapParametersException`.

Availability
Available in Mac OS X v10.0 and later.

See Also
`+ TIFFRepresentationOfImageRepsInArray:` (page 345)
`- TIFFRepresentationUsingCompression:factor:` (page 367)
`- representationUsingType:properties:` (page 363)
`- TIFFRepresentation` (page 1372) (NSImage)
`- TIFFRepresentationUsingCompression:factor:` (page 1373) (NSImage)

Declared In
`NSBitmapImageRep.h`

TIFFRepresentationUsingCompression:factor:

Returns a TIFF representation of the image using the specified compression.

```
- (NSData *)TIFFRepresentationUsingCompression:(NSTIFFCompression)compression
    factor:(float)factor
```

Parameters

compression

An enum constant that represents a TIFF data-compression scheme. Legal values for *compression* can be found in `NSBitmapImageRep.h` and are described in "Constants" (page 368).

factor

A `float` value that provides a hint for those compression types that implement variable compression ratios.

Currently only JPEG compression uses a compression factor. JPEG compression in TIFF files is not supported, and *factor* is ignored.

Discussion
If the compression type isn't supported for writing TIFF data (for example, `NSTIFFCompressionNEXT`), the stored compression is changed to `NSTIFFCompressionNone` before the TIFF representation is generated.

If a problem is encountered during generation of the TIFF, `TIFFRepresentationUsingCompression:factor:` raises an `NSTIFFException` or an `NSBadBitmapParametersException`.

Availability
Available in Mac OS X v10.0 and later.

valueForProperty:

Returns the value for the specified property.

```
- (id)valueForProperty:(NSString *)property
```

Parameters

property

A string constant used as a key for an image property. These properties are described in "Constants" (page 368).

Return Value
A value specific to `property`, or `nil` if the property is not set for the bitmap.

Discussion
Image properties can affect how an image is read in and saved to file. When retrieving the bitmap image properties defined in "Bitmap image properties" (page 370), be sure to check the return value of this method for a `nil` value. If a particular value is not set for the image, this method may return `nil`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSBitmapImageRep.h`

Constants

NSImageRepLoadStatus

These constants represent the various status values returned by `incrementalLoadFromData:complete:` (page 354).

```
enum {
    NSImageRepLoadStatusUnknownType     = -1,
    NSImageRepLoadStatusReadingHeader   = -2,
    NSImageRepLoadStatusWillNeedAllData = -3,
    NSImageRepLoadStatusInvalidData     = -4,
    NSImageRepLoadStatusUnexpectedEOF   = -5,
    NSImageRepLoadStatusCompleted       = -6
};
typedef NSInteger NSImageRepLoadStatus;
```

Constants

`NSImageRepLoadStatusUnknownType`

Not enough data to determine image format. You should continue to provide more data.

Available in Mac OS X v10.2 and later.

Declared in `NSBitmapImageRep.h`.

`NSImageRepLoadStatusReadingHeader`

The image format is known, but not enough data has been read to determine the size, depth, etc., of the image. You should continue to provide more data.

Available in Mac OS X v10.2 and later.

Declared in `NSBitmapImageRep.h`.

`NSImageRepLoadStatusWillNeedAllData`

Incremental loading cannot be supported. Until you call `incrementalLoadFromData:complete:` (page 354) with `YES`, this status will be returned. You can continue to call the method but no decompression will take place. Once you do call the method with `YES`, then the image will be decompressed and one of the final three status messages will be returned.

Available in Mac OS X v10.2 and later.

Declared in `NSBitmapImageRep.h`.

`NSImageRepLoadStatusInvalidData`

An error occurred during image decompression. The image contains the portions of the data that have already been successfully decompressed, if any

Available in Mac OS X v10.2 and later.

Declared in `NSBitmapImageRep.h`.

`NSImageRepLoadStatusUnexpectedEOF`

`incrementalLoadFromData:complete:` (page 354) was called with `YES`, but not enough data was available for decompression. The image contains the portions of the data that have already been successfully decompressed, if any.

Available in Mac OS X v10.2 and later.

Declared in `NSBitmapImageRep.h`.

`NSImageRepLoadStatusCompleted`

Enough data has been provided to successfully decompress the image (regardless of the complete: flag).

Available in Mac OS X v10.2 and later.

Declared in `NSBitmapImageRep.h`.

Bitmap image properties

These constants identify properties that are used by `representationOfImageRepsInArray:usingType:properties:` (page 345), `representationUsingType:properties:` (page 363), `setPixel:atX:y:` (page 366), and `valueForProperty:` (page 368).

```
NSString *NSImageCompressionMethod;
NSString *NSImageCompressionFactor;
NSString *NSImageDitherTransparency;
NSString *NSImageRGBColorTable;
NSString *NSImageInterlaced;
NSString *NSImageColorSyncProfileData;
NSString *NSImageFrameCount;
NSString *NSImageCurrentFrame;
NSString *NSImageCurrentFrameDuration;
NSString *NSImageLoopCount;
NSString *NSImageGamma;
NSString *NSImageProgressive;
NSString *NSImageEXIFData;
NSString *NSImageFallbackBackgroundColor;
```

Constants

`NSImageColorSyncProfileData`

Identifies an `NSData` object containing the ColorSync profile data.

It can be used for TIFF, JPEG, GIF, and PNG files. This value is set when reading in and used when writing out image data. You can get the profile data for a particular color space from the corresponding `NSColorSpace` object or from the ColorSync Manager.

Available in Mac OS X v10.0 and later.

Declared in `NSBitmapImageRep.h`.

`NSImageCompressionFactor`

Identifies an `NSNumber` object containing the compression factor of the image.

Used only for JPEG files. JPEG compression in TIFF files is not supported, and the factor is ignored. The value is a float between 0.0 and 1.0, with 1.0 resulting in no compression and 0.0 resulting in the maximum compression possible. It's set when reading in and used when writing out the image.

Available in Mac OS X v10.0 and later.

Declared in `NSBitmapImageRep.h`.

`NSImageCompressionMethod`

Identifies an `NSNumber` object identifying the compression method of the image.

Used only for TIFF files. The value corresponds to one of the `NSTIFFCompression` constants, described below. It's set when reading in and used when writing out.

Available in Mac OS X v10.0 and later.

Declared in `NSBitmapImageRep.h`.

`NSImageDitherTransparency`

Identifies an `NSNumber` object containing a boolean that indicates whether the image is dithered.

Used only when writing GIF files.

Available in Mac OS X v10.0 and later.

Declared in `NSBitmapImageRep.h`.

`NSImageInterlaced`

Identifies an `NSNumber` object containing a Boolean value that indicates whether the image is interlaced.

Used only when writing out PNG files.

Available in Mac OS X v10.0 and later.

Declared in `NSBitmapImageRep.h`.

`NSImageRGBColorTable`

Identifies an `NSData` object containing the RGB color table.

Used only for GIF files. It's stored as packed RGB. It's set when reading in and used when writing out.

Available in Mac OS X v10.0 and later.

Declared in `NSBitmapImageRep.h`.

`NSImageEXIFData`

Identifies an `NSDictionary` object containing the EXIF data for the image.

This property is used only when reading or writing JPEG files. The dictionary contains the EXIF keys and values. Th standard dictionary keys (that is, those that are not specific to camera vendors) are identical to those for `kCGImagePropertyExifDictionary` declared in the `CGImageSource` API. See `kCGImagePropertyExifDictionary` Keys for details.

Available in Mac OS X v10.4 and later.

Declared in `NSBitmapImageRep.h`.

`NSImageFallbackBackgroundColor`

Specifies the background color to use when writing to an image format (such as JPEG) that doesn't support alpha. The color's alpha value is ignored. The default background color, when this property is not specified, is white. The value of the property should be an `NSColor` object. This constant corresponds to the `kCGImageDestinationBackgroundColor` constant in Quartz.

Available in Mac OS X v10.5 and later.

Declared in `NSBitmapImageRep.h`.

`NSImageFrameCount`

Identifies an `NSNumber` object containing the number of frames in an animated GIF file.

This value is used when reading in data.

Available in Mac OS X v10.2 and later.

Declared in `NSBitmapImageRep.h`.

`NSImageGamma`

Identifies an `NSNumber` object containing the gamma value for the image.

Used only for PNG files. The gamma values is a floating-point number between 0.0 and 1.0, with 0.0 being black and 1.0 being the maximum color. It's set when reading in and used when writing out.

Available in Mac OS X v10.4 and later.

Declared in `NSBitmapImageRep.h`.

`NSImageCurrentFrame`

Identifies an `NSNumber` object containing the current frame for an animated GIF file.

The first frame is 0.

Available in Mac OS X v10.2 and later.

Declared in `NSBitmapImageRep.h`.

`NSImageCurrentFrameDuration`
: Identifies an `NSNumber` object containing the duration (in seconds) of the current frame for an animated GIF image.

  The frame duration can be a floating-point value. It is used when reading in, but not when writing out.

  Available in Mac OS X v10.2 and later.

  Declared in `NSBitmapImageRep.h`.

`NSImageProgressive`
: Identifies an `NSNumber` object containing a boolean that indicates whether the image uses progressive encoding.

  Used only for JPEG files. It's set when reading in and used when writing out.

  Available in Mac OS X v10.4 and later.

  Declared in `NSBitmapImageRep.h`.

`NSImageLoopCount`
: Identifies an `NSNumber` object containing the number of loops to make when animating a GIF image.

  A value of 0 indicates the animation should loop indefinitely. Values should be specified as integer numbers. It is used when reading in but not when writing out the image.

  Available in Mac OS X v10.3 and later.

  Declared in `NSBitmapImageRep.h`.

Discussion
When using the `valueForProperty:` method to retrieve the the value for any of these keys, be sure to check that the returned value is non-`nil` before you attempt to use it. A bitmap image representation may return `nil` for any values that have not yet been set.

NSBitmapImageFileType

The following file type constants are provided as a convenience by `NSBitmapImageRep`:

```
enum {
    NSTIFFFileType,
    NSBMPFileType,
    NSGIFFileType,
    NSJPEGFileType,
    NSPNGFileType,
    NSJPEG2000FileType
};
typedef NSUInteger NSBitmapImageFileType;
```

Constants
`NSTIFFFileType`
: Tagged Image File Format (TIFF)

  Available in Mac OS X v10.0 and later.

  Declared in `NSBitmapImageRep.h`.

`NSBMPFileType`
: Windows bitmap image (BMP) format

  Available in Mac OS X v10.0 and later.

  Declared in `NSBitmapImageRep.h`.

`NSGIFFileType`
Graphics Image Format (GIF), originally created by CompuServe for online downloads

Available in Mac OS X v10.0 and later.

Declared in `NSBitmapImageRep.h`.

`NSJPEGFileType`
JPEG format

Available in Mac OS X v10.0 and later.

Declared in `NSBitmapImageRep.h`.

`NSPNGFileType`
Portable Network Graphics (PNG) format

Available in Mac OS X v10.0 and later.

Declared in `NSBitmapImageRep.h`.

`NSJPEG2000FileType`
JPEG 2000 file format.

Available in Mac OS X v10.4 and later.

Declared in `NSBitmapImageRep.h`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSBitmapImageRep.h`

NSTIFFCompression

These constants represent the various TIFF data-compression schemes supported by `NSBitmapImageRep`.

```
enum {
    NSTIFFCompressionNone = 1,
    NSTIFFCompressionCCITTFAX3 = 3,
    NSTIFFCompressionCCITTFAX4 = 4,
    NSTIFFCompressionLZW = 5,
    NSTIFFCompressionJPEG = 6,
    NSTIFFCompressionNEXT = 32766,
    NSTIFFCompressionPackBits = 32773,
    NSTIFFCompressionOldJPEG = 32865
};
typedef NSUInteger NSTIFFCompression;
```

Constants
`NSTIFFCompressionNone`
No compression.

Available in Mac OS X v10.0 and later.

Declared in `NSBitmapImageRep.h`.

`NSTIFFCompressionCCITTFAX3`
CCITT Fax Group 3 compression.

Used for 1-bit fax images sent over telephone lines.

Available in Mac OS X v10.0 and later.

Declared in `NSBitmapImageRep.h`.

`NSTIFFCompressionCCITTFAX4`
CCITT Fax Group 4 compression.
Used for 1-bit fax images sent over ISDN lines.
Available in Mac OS X v10.0 and later.
Declared in `NSBitmapImageRep.h`.

`NSTIFFCompressionLZW`
LZW compression.
Available in Mac OS X v10.0 and later.
Declared in `NSBitmapImageRep.h`.

`NSTIFFCompressionJPEG`
JPEG compression. No longer supported for input or output.
Available in Mac OS X v10.0 and later.
Declared in `NSBitmapImageRep.h`.

`NSTIFFCompressionNEXT`
NeXT compressed. Supported for input only.
Available in Mac OS X v10.0 and later.
Declared in `NSBitmapImageRep.h`.

`NSTIFFCompressionPackBits`
PackBits compression.
Available in Mac OS X v10.0 and later.
Declared in `NSBitmapImageRep.h`.

`NSTIFFCompressionOldJPEG`
Old JPEG compression. No longer supported for input or output.
Available in Mac OS X v10.0 and later.
Declared in `NSBitmapImageRep.h`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSBitmapImageRep.h`

NSBitmapFormat

These constants represent the various bitmap component formats supported by `NSBitmapImageRep`. These values are combined using the C bitwise OR operator and passed to `initWithBitmapDataPlanes:pixelsWide:pixelsHigh:bitsPerSample:samplesPerPixel:hasAlpha:isPlanar:colorSpaceName:bitmapFormat:bytesPerRow:bitsPerPixel:` (page 356) as the bitmap format and are returned by `bitmapFormat` (page 347).

```
enum {
    NSAlphaFirstBitmapFormat            = 1 << 0,
    NSAlphaNonpremultipliedBitmapFormat = 1 << 1,
    NSFloatingPointSamplesBitmapFormat  = 1 << 2
};
typedef NSUInteger NSBitmapFormat;
```

Constants

`NSAlphaFirstBitmapFormat`

If 0, alpha values are the last component.

For example, CMYKA and RGBA.

Available in Mac OS X v10.4 and later.

Declared in `NSBitmapImageRep.h`.

`NSAlphaNonpremultipliedBitmapFormat`

If 0, alpha values are premultiplied.

Available in Mac OS X v10.4 and later.

Declared in `NSBitmapImageRep.h`.

`NSFloatingPointSamplesBitmapFormat`

If 0, samples are integer values.

Available in Mac OS X v10.4 and later.

Declared in `NSBitmapImageRep.h`.

Availability

Available in Mac OS X v10.4 and later.

Declared In

`NSBitmapImageRep.h`

NSBox Class Reference

Inherits from	NSView : NSResponder : NSObject

Overview

The `NSBox` class implements simple views that can title themselves and draw a border around their content. These objects are known as **boxes**. You can use box to group, visually, some number of other views.

Subclassing Notes

An `NSBox` object is a view that draws a line around its rectangular bounds and that displays a title on or near the line (or might display neither line nor title). You can adjust the style of the line (bezel, grooved, or plain) as well as the placement and font of the title. An `NSBox` also has a content view to which other views can be added; it thus offers a way for an application to group related views. You could create a custom subclass of `NSBox` that alters or augments its appearance or that modifies its grouping behavior. For example, you might add color to the lines or background, add a new line style, or have the views in the group automatically snap to an invisible grid when added.

Methods to Override

You must override the `drawRect:` (page 3170) method (inherited from `NSView`) if you want to customize the appearance of your `NSBox` objects. Depending on the visual effect you're trying to achieve, you may have to invoke `super`'s implementation first. For example, if you are compositing a small image in a corner of the

box, you would invoke the superclass implementation first. If you're adding a new style of line, you would provide a way to store a request for this line type (such as a boolean instance variable and related accessor methods). Then, in `drawRect:` (page 3170), if a request for this line type exists, you would draw the entire view yourself (that is, without calling `super`). Otherwise, you would invoke the superclass implementation.

If you wish to change grouping behavior or other behavioral characteristics of the `NSBox` class, consider overriding `setContentView:` (page 385), `sizeToFit` (page 390), or `addSubview:` (page 3139) (inherited from `NSView`).

Special Considerations

If you are drawing the custom `NSBox` entirely by yourself, and you want it to look exactly like the superclass object (except for your changes), it may take some effort and time to get the details right.

Tasks

Configuring Boxes

- `borderRect` (page 380)
  Returns the rectangle in which the receiver's border is drawn.
- `boxType` (page 381)
  Returns the receiver's box type.
- `setBoxType:` (page 385)
  Sets the box type.
- `borderType` (page 380)
  Returns the receiver's border type.
- `setBorderType:` (page 384)
  Sets the border type to *`aType`*, which must be a valid border type.
- `isTransparent` (page 383)
  Indicates whether the receiver is transparent.
- `setTransparent:` (page 390)
  Specifies whether the receiver is transparent.
- `title` (page 391)
  Returns the receiver's title.
- `setTitle:` (page 388)
  Sets the title of the box and marks the region of the receiver within the title rectangle as needing display.
- `titleFont` (page 391)
  Returns the font object used to draw the receiver's title.
- `setTitleFont:` (page 388)
  Sets the font object used to draw the receiver's title and marks the region of the receiver within the title rectangle as needing display.
- `titlePosition` (page 392)
  Returns a constant representing the title position.

- `setTitlePosition:` (page 389)
  Sets the position of the box's title.
- `setTitleWithMnemonic:` (page 389)
  Sets the title of the receiver with a character denoted as an access key.
- `titleCell` (page 391)
  Returns the cell used to display the receiver's title.
- `titleRect` (page 392)
  Returns the rectangle in which the receiver's title is drawn.

Customizing

- `borderColor` (page 380)
  Returns the color of the receiver's border when the receiver is a custom box with a simple line border.
- `setBorderColor:` (page 384)
  Specifies the receiver's border color.
- `borderWidth` (page 381)
  Returns the width of the receiver's border when the receiver is a custom box with a simple line border.
- `setBorderWidth:` (page 385)
  Specifies the receiver's border width.
- `cornerRadius` (page 382)
  Returns the radius of the receiver's corners when the receiver is a custom box with a simple line border.
- `setCornerRadius:` (page 386)
  Specifies the receiver's corner radius.
- `fillColor` (page 383)
  Returns the color of the receiver's background when the receiver is a custom box with a simple line border.
- `setFillColor:` (page 387)
  Specifies the receiver's fill color.

Managing Content

- `contentView` (page 382)
  Returns the receiver's content view.
- `setContentView:` (page 385)
  Sets the receiver's content view.
- `contentViewMargins` (page 382)
  Returns the distances between the border and the content view.
- `setContentViewMargins:` (page 386)
  Sets the horizontal and vertical distance between the border of the receiver and its content view.

Sizing

- `setFrameFromContentFrame:` (page 387)
  Places the receiver so its content view lies on the specified frame.
- `sizeToFit` (page 390)
  Resizes and moves the receiver's content view so it just encloses its subviews.

Instance Methods

borderColor

Returns the color of the receiver's border when the receiver is a custom box with a simple line border.

```
- (NSColor *)borderColor
```

Return Value
The receiver's border color. It must be a custom box—that is, it has a type of `NSBoxCustom` (page 394)—and it must have a border style of `NSLineBorder` (page 3250).

Availability
Available in Mac OS X v10.5 and later.

See Also
- `setBorderColor:` (page 384)

Declared In
`NSBox.h`

borderRect

Returns the rectangle in which the receiver's border is drawn.

```
- (NSRect)borderRect
```

Return Value
The rectangle in which the border of the `NSBox` is drawn.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSBox.h`

borderType

Returns the receiver's border type.

```
- (NSBorderType)borderType
```

Return Value
A constant describing the type of border. Border types are defined in `NSView.h`. Currently, the following border types are defined: `NSNoBorder`,`NSLineBorder`,`NSBezelBorder`, `NSGrooveBorder`.

By default, the border type of an `NSBox` is `NSGrooveBorder`.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setBorderType:` (page 384)

Declared In
`NSBox.h`

borderWidth

Returns the width of the receiver's border when the receiver is a custom box with a simple line border.

```
- (CGFloat)borderWidth
```

Return Value
The receiver's border width. It must be a custom box—that is, it has a type of `NSBoxCustom` (page 394)—and it must have a border style of `NSLineBorder` (page 3250).

Availability
Available in Mac OS X v10.5 and later.

See Also
`- setBorderWidth:` (page 385)

Declared In
`NSBox.h`

boxType

Returns the receiver's box type.

```
- (NSBoxType)boxType
```

Return Value
A constant describing the type of box. These constants are described in `NSBoxType` (page 394). By default, the box type of an `NSBox` is `NSBoxPrimary`.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setBoxType:` (page 385)

Declared In
`NSBox.h`

contentView

Returns the receiver's content view.

```
- (id)contentView
```

Return Value
The content view of the `NSBox` object. The content view is created automatically when the box is created and resized as the box is resized (you should never send frame-altering messages directly to a box's content view). You can replace it with an `NSView` of your own through the `setContentView:` (page 385) method.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setContentView:` (page 385)

Related Sample Code
EnhancedDataBurn
Quartz Composer QCTV
TextSizingExample

Declared In
`NSBox.h`

contentViewMargins

Returns the distances between the border and the content view.

```
- (NSSize)contentViewMargins
```

Return Value
The width (the horizontal distance between the innermost edge of the border and the content view) and height (the vertical distance between the innermost edge of the border and the content view) describing the distance between the border and the content view. By default, these are both 5.0 in the box's coordinate system.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setContentViewMargins:` (page 386)

Declared In
`NSBox.h`

cornerRadius

Returns the radius of the receiver's corners when the receiver is a custom box with a simple line border.

```
- (CGFloat)cornerRadius
```

Return Value
The receiver's corner radius. It must be a custom box—that is, it has a type of `NSBoxCustom` (page 394)—and it must have a border style of `NSLineBorder` (page 3250).

Availability
Available in Mac OS X v10.5 and later.

See Also
`- setCornerRadius:` (page 386)

Declared In
`NSBox.h`

fillColor

Returns the color of the receiver's background when the receiver is a custom box with a simple line border.

```
- (NSColor *)fillColor
```

Return Value
The receiver's fill color. It must be a custom box—that is, it has a type of `NSBoxCustom` (page 394)—and it must have a border style of `NSLineBorder` (page 3250).

Availability
Available in Mac OS X v10.5 and later.

See Also
`- setFillColor:` (page 387)

Declared In
`NSBox.h`

isTransparent

Indicates whether the receiver is transparent.

```
- (BOOL)isTransparent
```

Return Value
`YES` when the receiver is transparent, `NO` otherwise.

Availability
Available in Mac OS X v10.5 and later.

See Also
`- setTransparent:` (page 390)

Declared In
`NSBox.h`

setBorderColor:

Specifies the receiver's border color.

```
- (void)setBorderColor:(NSColor *)borderColor
```

Parameters

borderColor

Border color for the receiver.

Special Considerations

Functional only when the receiver's box type (`boxType` (page 381)) is `NSBoxCustom` and its border type (`borderType` (page 380)) is `NSLineBorder`.

Availability
Available in Mac OS X v10.5 and later.

See Also
- `borderColor` (page 380)

Declared In
`NSBox.h`

setBorderType:

Sets the border type to *aType*, which must be a valid border type.

```
- (void)setBorderType:(NSBorderType)aType
```

Parameters

aType

A constant describing the type of border. Border types are defined in `NSView.h`. Currently, the following border types are defined: `NSNoBorder`,`NSLineBorder`,`NSBezelBorder`, `NSGrooveBorder`.

Discussion
If the size of the new border is different from that of the old border, the content view is resized to absorb the difference, and the box is marked for redisplay.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `borderType` (page 380)
- `setNeedsDisplay:` (page 3225) (`NSView`)

FunHouse

Declared In
`NSBox.h`

setBorderWidth:

Specifies the receiver's border width.

```
- (void)setBorderWidth:(CGFloat)borderWidth
```

Parameters

borderWidth

Border width for the receiver.

Special Considerations

Functional only when the receiver's box type (`boxType` (page 381)) is `NSBoxCustom` and its border type (`borderType` (page 380)) is `NSLineBorder`.

Availability
Available in Mac OS X v10.5 and later.

See Also
- `borderWidth` (page 381)

Declared In
`NSBox.h`

setBoxType:

Sets the box type.

```
- (void)setBoxType:(NSBoxType)boxType
```

Parameters

boxType

A constant describing the type of box; this must be a valid box type. These constants are described in `NSBoxType` (page 394).

Availability
Available in Mac OS X v10.0 and later.

See Also
- `boxType` (page 381)

Related Sample Code
AnimatingViews
FunHouse

Declared In
`NSBox.h`

setContentView:

Sets the receiver's content view.

```
- (void)setContentView:(NSView *)aView
```

Parameters

aView

The new content view. The `NSView` object is resized to fit within the box's current content area and the box is marked for redisplay.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `contentView` (page 382)
- `setFrameFromContentFrame:` (page 387)
- `sizeToFit` (page 390)
- `setNeedsDisplay:` (page 3225) (`NSView`)

Related Sample Code
Quartz Composer QCTV

Declared In
`NSBox.h`

setContentViewMargins:

Sets the horizontal and vertical distance between the border of the receiver and its content view.

```
- (void)setContentViewMargins:(NSSize)offsetSize
```

Parameters

offsetSize

The width and height of the offset between the box's border and content view. The horizontal value is applied (reckoned in the box's coordinate system) fully and equally to the left and right sides of the box. The vertical value is similarly applied to the top and bottom.

Discussion
Unlike changing a box's other attributes, such as its title position or border type, changing the offsets doesn't automatically resize the content view. In general, you should send a `sizeToFit` (page 390) message to the box after changing the size of its offsets. This message causes the content view to remain unchanged while the box is sized to fit around it.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `contentViewMargins` (page 382)

Declared In
`NSBox.h`

setCornerRadius:

Specifies the receiver's corner radius.

```
- (void)setCornerRadius:(CGFloat)cornerRadius
```

Parameters

cornerRadius

Corner radius for the receiver.

Special Considerations

Functional only when the receiver's box type (`boxType` (page 381)) is `NSBoxCustom` and its border type (`borderType` (page 380)) is `NSLineBorder`.

Availability
Available in Mac OS X v10.5 and later.

See Also
`- cornerRadius` (page 382)

Declared In
`NSBox.h`

setFillColor:

Specifies the receiver's fill color.

```
- (void)setFillColor:(NSColor *)fillColor
```

Parameters

fillColor

Fill color for the receiver.

Special Considerations

Functional only when the receiver's box type (`boxType` (page 381)) is `NSBoxCustom` and its border type (`borderType` (page 380)) is `NSLineBorder`.

Availability
Available in Mac OS X v10.5 and later.

AnimatingViews

Declared In
`NSBox.h`

setFrameFromContentFrame:

Places the receiver so its content view lies on the specified frame.

```
- (void)setFrameFromContentFrame:(NSRect)contentFrame
```

Parameters

contentFrame

The rectangle specifying the frame of the box's content view, reckoned in the coordinate system of the box's superview. The box is marked for redisplay.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setContentViewMargins:` (page 386)
- `setFrame:` (page 3218) (`NSView`)
- `setNeedsDisplay:` (page 3225) (`NSView`)

Declared In
`NSBox.h`

setTitle:

Sets the title of the box and marks the region of the receiver within the title rectangle as needing display.

```
- (void)setTitle:(NSString *)aString
```

Parameters

aString

The new title of the `NSBox`. The default title of an `NSBox` is "Title." If the size of the new title is different from that of the old title, the content view is resized to absorb the difference.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `title` (page 391)
- `titleRect` (page 392)
- `setNeedsDisplayInRect:` (page 3225) (`NSView`)

Related Sample Code
Quartz Composer QCTV

Declared In
`NSBox.h`

setTitleFont:

Sets the font object used to draw the receiver's title and marks the region of the receiver within the title rectangle as needing display.

```
- (void)setTitleFont:(NSFont *)aFont
```

Parameters

aFont

The `NSFont` object used to draw the box's title.

Discussion
By default, the title is drawn using the small system font (obtained using (`smallSystemFontSize` (page 1157) as the parameter of `systemFontOfSize:` (page 1157), both `NSFont` class methods). If the size of the new font is different from that of the old font, the content view is resized to absorb the difference.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `titleFont` (page 391)
- `setNeedsDisplayInRect:` (page 3225) (`NSView`)

Declared In
`NSBox.h`

setTitlePosition:

Sets the position of the box's title.

```
- (void)setTitlePosition:(NSTitlePosition)aPosition
```

Parameters

aPosition

A constant describing the position of the box's title. These constants are described in `NSTitlePosition` (page 392). The default position is `NSAtTop`.

Discussion
If the new title position changes the size of the box's border area, the content view is resized to absorb the difference, and the box is marked as needing redisplay.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `titlePosition` (page 392)
- `setNeedsDisplay:` (page 3225) (`NSView`)

AnimatingViews
FunHouse

Declared In
`NSBox.h`

setTitleWithMnemonic:

Sets the title of the receiver with a character denoted as an access key.

```
- (void)setTitleWithMnemonic:(NSString *)aString
```

Discussion
Mnemonics are not supported in Mac OS X.

By default, a box's title is "Title." The content view is not automatically resized, and the box is not marked for redisplay.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setTitleWithMnemonic:` (page 599) (`NSCell`)

Declared In
`NSBox.h`

setTransparent:

Specifies whether the receiver is transparent.

```
- (void)setTransparent:(BOOL)transparent
```

Parameters

transparent

`YES` makes the receiver transparent.

`NO` makes the receiver opaque.

Availability
Available in Mac OS X v10.5 and later.

See Also
- `isTransparent` (page 383)

Declared In
`NSBox.h`

sizeToFit

Resizes and moves the receiver's content view so it just encloses its subviews.

```
- (void)sizeToFit
```

Discussion
The receiver is then moved and resized to wrap around the content view. The receiver's width is constrained so its title will be fully displayed.

You should invoke this method after:

- Adding a subview (to the content view)
- Altering the size or location of such a subview
- Setting the margins around the content view

The mechanism by which the content view is moved and resized depends on whether the object responds to its own `sizeToFit` message: If it does respond, then that message is sent, and the content view is expected to be so modified. If the content view doesn't respond, the box moves and resizes the content view itself.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSBox.h`

title

Returns the receiver's title.

```
- (NSString *)title
```

Return Value
The title of the `NSBox`. By default, a box's title is "Title."

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setTitle:` (page 388)

Related Sample Code
Quartz Composer QCTV

Declared In
`NSBox.h`

titleCell

Returns the cell used to display the receiver's title.

```
- (id)titleCell
```

Return Value
The `NSCell` object used to display the title.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSBox.h`

titleFont

Returns the font object used to draw the receiver's title.

```
- (NSFont *)titleFont
```

Return Value
The `NSFont` object used to draw the title.

Discussion
By default, the title is drawn using the small system font (obtained using (`smallSystemFontSize` (page 1157) as the parameter of `systemFontOfSize:` (page 1157), both `NSFont` class methods).

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setTitleFont:` (page 388)

Declared In
NSBox.h

titlePosition

Returns a constant representing the title position.

```
- (NSTitlePosition)titlePosition
```

Return Value
A constant representing the position of the receiver's title. See `NSTitlePosition` (page 392) for a list of these constants.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setTitlePosition:` (page 389)

Declared In
NSBox.h

titleRect

Returns the rectangle in which the receiver's title is drawn.

```
- (NSRect)titleRect
```

Return Value
The rectangle in which the title is drawn.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setTitlePosition:` (page 389)
- `setTitle:` (page 388)
- `setTitleFont:` (page 388)

Declared In
NSBox.h

Constants

NSTitlePosition

Specify the location of a box's title with respect to its border.

```
typedef enum _NSTitlePosition {
    NSNoTitle     = 0,
    NSAboveTop    = 1,
    NSAtTop       = 2,
    NSBelowTop    = 3,
    NSAboveBottom = 4,
    NSAtBottom    = 5,
    NSBelowBottom = 6
} NSTitlePosition;
```

Constants

`NSNoTitle`
The box has no title.
Available in Mac OS X v10.0 and later.
Declared in `NSBox.h`.

`NSAboveTop`
Title positioned above the box's top border.
Available in Mac OS X v10.0 and later.
Declared in `NSBox.h`.

`NSAtTop`
Title positioned within the box's top border.
Available in Mac OS X v10.0 and later.
Declared in `NSBox.h`.

`NSBelowTop`
Title positioned below the box's top border.
Available in Mac OS X v10.0 and later.
Declared in `NSBox.h`.

`NSAboveBottom`
Title positioned above the box's bottom border.
Available in Mac OS X v10.0 and later.
Declared in `NSBox.h`.

`NSAtBottom`
Title positioned within the box's bottom border.
Available in Mac OS X v10.0 and later.
Declared in `NSBox.h`.

`NSBelowBottom`
Title positioned below the box's bottom border.
Available in Mac OS X v10.0 and later.
Declared in `NSBox.h`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSBox.h`

NSBoxType

These constants and data type identifies box types, which, in conjunction with a box's border type, define the appearance of the box.

```
enum {
    NSBoxPrimary   = 0,
    NSBoxSecondary = 1,
    NSBoxSeparator = 2,
    NSBoxOldStyle  = 3,
    NSBoxCustom    = 4
};
typedef NSUInteger NSBoxType;
```

Constants

`NSBoxPrimary`

Specifies the primary box appearance. This is the default box type.

Available in Mac OS X v10.0 and later.

Declared in `NSBox.h`.

`NSBoxSecondary`

Specifies the secondary box appearance.

Available in Mac OS X v10.0 and later.

Declared in `NSBox.h`.

`NSBoxSeparator`

Specifies that the box is a separator.

Available in Mac OS X v10.0 and later.

Declared in `NSBox.h`.

`NSBoxOldStyle`

Specifies that the box is a Mac OS X v10.2–style box.

Available in Mac OS X v10.0 and later.

Declared in `NSBox.h`.

`NSBoxCustom`

Specifies that the appearance of the box is determined entirely by the by box-configuration methods, without automatically applying Apple human interface guidelines. See "`Customizing`" (page 379) for details.

Available in Mac OS X v10.5 and later.

Declared in `NSBox.h`.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSBox.h`

Overview

This class provides a user interface for displaying and selecting items from a list of data or from hierarchically organized lists of data such as directory paths. Instances of this class are known as browsers. When working with a hierarchy of data, the levels are displayed in columns, which are indexed from left to right.

This class uses the `NSBrowserCell` class to implement its user interface.

Browsers have the following components:

- Columns
- Scroll views
- Matrices
- Browser cells

To the user, browsers display data in columns and rows within each column. These components are arranged in the following component hierarchy:

```
Browser
|---Columns [1..*]
    |---Scroll view
```

```
    |---Matrix
        |---Rows [0..*]
```

Tasks

Configuring Browsers

- `reusesColumns` (page 427)
  Indicates whether the browser reuses matrix objects after their columns are unloaded.
- `setReusesColumns:` (page 444)
  Specifies whether matrices can be reused.
- `maxVisibleColumns` (page 422)
  Returns the maximum number of visible columns.
- `setMaxVisibleColumns:` (page 442)
  Sets the maximum number of columns that can be displayed.
- `autohidesScroller` (page 406)
  Returns whether the browser automatically hides its scroller.
- `setAutohidesScroller:` (page 437)
  Allows the browser to hide its scroller automatically.
- `backgroundColor` (page 406)
  Provides the browser's background color.
- `setBackgroundColor:` (page 437)
  Specifies the browser's background color.
- `minColumnWidth` (page 423)
  Returns the minimum column width.
- `setMinColumnWidth:` (page 443)
  Sets the minimum column width.
- `separatesColumns` (page 435)
  Indicates whether columns are separated by bezeled borders.
- `setSeparatesColumns:` (page 446)
  Separates columns with bezeled borders.
- `takesTitleFromPreviousColumn` (page 448)
  Indicates whether a column takes its title from the selected cell in the previous column.
- `setTakesTitleFromPreviousColumn:` (page 447)
  Sets whether the title of a column is set to the string value of the selected cell in the previous column.
- `tile` (page 449)
  Adjusts the various subviews of the browser—scrollers, columns, titles, and so on—without redrawing.
- `delegate` (page 411)
  Returns the browser's delegate.
- `setDelegate:` (page 440)
  Sets the browser's delegate.

- `acceptsArrowKeys` (page 404) Deprecated in Mac OS X v10.6
  Indicates whether the browser allows navigation using the arrow keys. (Deprecated. There is no replacement.)
- `setAcceptsArrowKeys:` (page 435) Deprecated in Mac OS X v10.6
  Specifies whether the browser allows navigation using the arrow keys. (Deprecated. There is no replacement.)

Getting Browser Information

- `isOpaque` (page 418)
  Indicates whether the browser is opaque.

Managing Component Types

+ `cellClass` (page 403)
  Returns the `NSBrowserCell` class.
- `setCellClass:` (page 438)
  Sets the class of the cell to be used by the matrices in the columns of the browser.
- `cellPrototype` (page 407)
  Returns the browser's prototype `NSCell`.
- `setCellPrototype:` (page 438)
  Sets the prototype cell for displaying items in the matrices in the columns of the browser.
- `matrixClass` (page 421)
  Returns the matrix class used in the browser's columns.
- `setMatrixClass:` (page 442)
  Sets the matrix class to be used in the browser's columns.

Managing Selection Behavior

- `allowsBranchSelection` (page 404)
  Indicates whether the user can select branch items.
- `setAllowsBranchSelection:` (page 435)
  Allows the user to select branch items.
- `allowsEmptySelection` (page 405)
  Indicates whether there can be nothing selected.
- `setAllowsEmptySelection:` (page 436)
  Allows the user to select nothing.
- `allowsMultipleSelection` (page 405)
  Indicates whether the user can select multiple items.
- `setAllowsMultipleSelection:` (page 436)
  Allows the user to select multiple items.
- `selectedRowIndexesInColumn:` (page 432)
  Provides the indexes of the selected rows in a given column of the browser.

- `selectRowIndexes:inColumn:` (page 434)
  Specifies the selected rows in a given column of the browser.
- `allowsTypeSelect` (page 405)
  Indicates whether the browser allows keystroke-based selection (type select).
- `setAllowsTypeSelect:` (page 437)
  Allows the browser to accept keystroke-based selection.

Managing Selection

- `selectedCell` (page 430)
  Returns the last (rightmost and lowest) selected cell.
- `selectedCellInColumn:` (page 430)
  Returns the last (lowest) cell selected in the given column.
- `selectedCells` (page 431)
  Returns all cells selected in the rightmost column.
- `selectAll:` (page 430)
  Selects all cells in the last column of the browser.
- `selectedRowInColumn:` (page 432)
  Returns the row index of the selected cell in the specified column.
- `selectRow:inColumn:` (page 433)
  Selects the cell at the specified row and column index.
- `selectionIndexPath` (page 433)
  Returns the index path of the item selected in the browser.
- `setSelectionIndexPath:` (page 445)
  Sets the browser's selection to the item with the specified path.
- `selectionIndexPaths` (page 433)
  Returns an array containing the index paths of all items selected in the browser.
- `setSelectionIndexPaths:` (page 446)
  Sets the browser's selection to the items whose index paths are in the specified array.

Accessing Components

- `loadedCellAtRow:column:` (page 421)
  Loads, if necessary, and returns the cell at the specified row and column location.
- `matrixInColumn:` (page 422)
  Returns the matrix located in the specified column.
- `editItemAtIndexPath:withEvent:select:` (page 414)
  Begins editing the item at the specified path.
- `itemAtIndexPath:` (page 419)
  Returns the item at the specified index path.
- `itemAtRow:inColumn:` (page 420)
  Returns the item located at the specified row and column.

- `indexPathForColumn:` (page 417)
  Returns the index path of the item whose children are displayed in the given column.
- `isLeafItem:` (page 418)
  Returns whether the specified item is a leaf item.
- `parentForItemsInColumn:` (page 424)
  Returns the item that contains the children located in the specified column.

Managing the Path

- `path` (page 425)
  Returns a string representing the browser's current path.
- `setPath:` (page 443)
  Sets the path to be displayed by the browser.
- `pathToColumn:` (page 425)
  Returns a string representing the path from the first column up to, but not including, the column at the given index.
- `pathSeparator` (page 425)
  Returns the path separator.
- `setPathSeparator:` (page 444)
  Sets the path separator.

Managing Columns

- `addColumn` (page 404)
  Adds a column to the right of the last column.
- `columnOfMatrix:` (page 409)
  Returns the column number in which the given matrix is located.
- `selectedColumn` (page 431)
  Returns the index of the last column with a selected item.
- `lastColumn` (page 420)
  Returns the index of the last column loaded.
- `setLastColumn:` (page 442)
  Sets the last column.
- `firstVisibleColumn` (page 415)
  Returns the index of the first visible column.
- `numberOfVisibleColumns` (page 424)
  Returns the number of columns that are visible.
- `lastVisibleColumn` (page 420)
  Returns the index of the last visible column.
- `validateVisibleColumns` (page 451)
  Validates the browser's visible columns.
- `isLoaded` (page 418)
  Returns whether column 0 is loaded.

- `loadColumnZero` (page 421)
  Loads column 0; unloads previously loaded columns.
- `reloadColumn:` (page 426)
  Reloads the given column if it exists and sets it to be the last column.
- `displayAllColumns` (page 411) Deprecated in Mac OS X v10.3
  Updates the browser to display all loaded columns. (Deprecated. Use `setNeedsDisplayInRect:` (page 3225))
- `displayColumn:` (page 411) Deprecated in Mac OS X v10.3
  Updates the browser to display the given column. (Deprecated. Use `setNeedsDisplayInRect:` (page 3225) instead.)

Accessing Column Titles

- `titleOfColumn:` (page 450)
  Returns the title displayed for the given column.
- `setTitle:ofColumn:` (page 447)
  Sets the title of the given column.
- `isTitled` (page 419)
  Indicates whether columns display titles.
- `setTitled:` (page 447)
  Sets columns to display titles.
- `drawTitleOfColumn:inRect:` (page 414)
  Draws the title for the specified column within the given rectangle.
- `titleHeight` (page 450)
  Returns the height of the column titles.
- `titleFrameOfColumn:` (page 449)
  Returns the bounds of the title frame for the specified column.

Updating Browsers

- `noteHeightOfRowsWithIndexesChanged:inColumn:` (page 423)
  Immediately retiles the browser's columns using row heights specified by the browser's delegate.
- `reloadDataForRowIndexes:inColumn:` (page 427)
  Updates the rows in the column with the specified column index with indexes in the specified set.

Scrolling

- `hasHorizontalScroller` (page 417)
  Indicates whether the browser has a horizontal scroller.
- `setHasHorizontalScroller:` (page 441)
  Sets whether the browser has a scroller to scroll horizontally.
- `scrollColumnToVisible:` (page 428)
  Scrolls to make the specified column visible.

- `scrollColumnsLeftBy:` (page 428)
  Scrolls columns left by the specified number of columns.
- `scrollColumnsRightBy:` (page 428)
  Scrolls columns right by the specified number of columns.
- `scrollRowToVisible:inColumn:` (page 429)
  Scrolls the specified row to be visible within the specified column.
- `scrollViaScroller:` (page 429) Deprecated in Mac OS X v10.3
  Scrolls columns left or right based on an `NSScroller`. (Deprecated. There is no replacement.)
- `updateScroller` (page 450) Deprecated in Mac OS X v10.3
  Updates the horizontal scroller to reflect column positions. (Deprecated. There is no replacement.)

Dragging

- `draggingSourceOperationMaskForLocal:` (page 413)
  Indicates the types of dragging operations the source object allows on the dragged image's data.
- `setDraggingSourceOperationMask:forLocal:` (page 441)
  Specifies the drag-operation mask for dragging operations with local or external destinations.
- `canDragRowsWithIndexes:inColumn:withEvent:` (page 407)
  Indicates whether the browser can attempt to initiate a drag of the given rows for the given event.
- `draggingImageForRowsWithIndexes:inColumn:withEvent:offset:` (page 413)
  Provides an image to represent dragged rows during a drag operation on the browser.
- `namesOfPromisedFilesDroppedAtDestination:` (page 423)
  Provides the names of the files that the browser promises to create at a specified location.

Getting Column Frames

- `frameOfColumn:` (page 415)
  Returns the rectangle containing the given column.
- `frameOfInsideOfColumn:` (page 415)
  Returns the rectangle containing the specified column, not including borders.

Getting Row Frames

- `frameOfRow:inColumn:` (page 416)
  Returns the frame of the cell at the specified location, including the expandable arrow.
- `getRow:column:forPoint:` (page 416)
  Gets the row and column coordinates for the specified point, if a cell exists at that point.

Managing Actions

- `doubleAction` (page 412)
  Returns the browser's double-click action method.

- `setDoubleAction:` (page 440)
  Sets the browser's double-click action.
- `sendsActionOnArrowKeys` (page 434)
  Returns whether pressing an arrow key causes an action message to be sent.
- `setSendsActionOnArrowKeys:` (page 446)
  Allows the specified action message to be sent when the user presses an arrow key.
- `sendAction` (page 434)
  Sends the action message to the target.

Handling Mouse-Click Events

- `doClick:` (page 412)
  Responds to (single) mouse clicks in a column of the browser.
- `doDoubleClick:` (page 412)
  Responds to double clicks in a column of the browser.
- `clickedColumn` (page 407)
  Returns the column number of the cell that the user clicked to display a context menu.
- `clickedRow` (page 408)
  Returns the row number of the cell that the user clicked to display a context menu.

Sizing

+ `removeSavedColumnsWithAutosaveName:` (page 403)
  Removes the column configuration data stored under the given name from the application's user defaults.
- `columnsAutosaveName` (page 409)
  Returns the name used to automatically save the browser's column configuration.
- `setColumnsAutosaveName:` (page 439)
  Sets the name used to automatically save the browser's column configuration.
- `columnContentWidthForColumnWidth:` (page 408)
  Returns the content width for a given column width.
- `columnWidthForColumnContentWidth:` (page 410)
  Returns the column width for the width of the given column's content.
- `columnResizingType` (page 409)
  Returns the browser's column resizing type.
- `setColumnResizingType:` (page 438)
  Sets the browser's column resizing type.
- `prefersAllColumnUserResizing` (page 426)
  Returns whether the browser is set to resize all columns simultaneously rather than resizing a single column at a time.
- `setPrefersAllColumnUserResizing:` (page 444)
  Causes the browser to resize all column simultaneously rather than resize a single column at a time.
- `widthOfColumn:` (page 451)
  Returns the width of the specified column.

- `setWidth:ofColumn:` (page 448)
  Sets the width of the specified column.
- `defaultColumnWidth` (page 410)
  Returns the default column width of the browser's columns.
- `setDefaultColumnWidth:` (page 439)
  Sets the default column width for new browser columns that do not otherwise have an initial width from defaults or the browser's delegate.
- `rowHeight` (page 427)
  Returns the height of the browser's rows.
- `setRowHeight:` (page 445)
  Sets the height of the browser's rows to the specified value.

Class Methods

cellClass

Returns the `NSBrowserCell` class.

```
+ (Class)cellClass
```

Return Value
Always returns the `NSBrowserCell` class (even if the developer has sent a `setCellClass:` (page 438) message to a particular instance).

Discussion
This method is used by `NSControl` during initialization and is not meant to be used by applications.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `cellPrototype` (page 407)
- `setCellPrototype:` (page 438)

Declared In
`NSBrowser.h`

removeSavedColumnsWithAutosaveName:

Removes the column configuration data stored under the given name from the application's user defaults.

```
+ (void)removeSavedColumnsWithAutosaveName:(NSString *)name
```

Parameters
name
The name of the column configuration data to remove.

Availability
Available in Mac OS X v10.3 and later.

See Also
- `setColumnsAutosaveName:` (page 439)

Declared In
`NSBrowser.h`

Instance Methods

acceptsArrowKeys

Indicates whether the browser allows navigation using the arrow keys. (Deprecated in Mac OS X v10.6. There is no replacement.)

```
- (BOOL)acceptsArrowKeys
```

Return Value
`YES` if the arrow keys are enabled; otherwise, `NO`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.6.

See Also
- `setAcceptsArrowKeys:` (page 435)

Declared In
`NSBrowser.h`

addColumn

Adds a column to the right of the last column.

```
- (void)addColumn
```

Availability
Available in Mac OS X v10.0 and later.

See Also
- `selectedColumn` (page 431)

Declared In
`NSBrowser.h`

allowsBranchSelection

Indicates whether the user can select branch items.

```
- (BOOL)allowsBranchSelection
```

Return Value
YES if the user can select branch items when multiple selection is enabled; otherwise, NO.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setAllowsBranchSelection: (page 435)

Declared In
NSBrowser.h

allowsEmptySelection

Indicates whether there can be nothing selected.

```
- (BOOL)allowsEmptySelection
```

Return Value
YES if the browser allows the selection to be empty; otherwise, NO.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setAllowsEmptySelection: (page 436)

Declared In
NSBrowser.h

allowsMultipleSelection

Indicates whether the user can select multiple items.

```
- (BOOL)allowsMultipleSelection
```

Return Value
YES if the browser allows the user to select multiple items at once; otherwise, NO.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setAllowsMultipleSelection: (page 436)

Declared In
NSBrowser.h

allowsTypeSelect

Indicates whether the browser allows keystroke-based selection (type select).

```
- (BOOL)allowsTypeSelect
```

Return Value
`YES` (default) when the browser allows keystroke-based selection; otherwise, `NO`.

Availability
Available in Mac OS X v10.5 and later.

See Also
`- setAllowsTypeSelect:` (page 437)

Declared In
`NSBrowser.h`

autohidesScroller

Returns whether the browser automatically hides its scroller.

```
- (BOOL)autohidesScroller
```

Return Value
`YES` if the scroller is automatically hidden; otherwise, `NO`.

Availability
Available in Mac OS X v10.6 and later.

See Also
`- setAutohidesScroller:` (page 437)

Declared In
`NSBrowser.h`

backgroundColor

Provides the browser's background color.

```
- (NSColor *)backgroundColor
```

Return Value
The browser's background color.

Discussion
The default value is `[NSColor whiteColor]`

Availability
Available in Mac OS X v10.5 and later.

See Also
`- setBackgroundColor:` (page 437)

Declared In
`NSBrowser.h`

canDragRowsWithIndexes:inColumn:withEvent:

Indicates whether the browser can attempt to initiate a drag of the given rows for the given event.

```
- (BOOL)canDragRowsWithIndexes:(NSIndexSet *)rowIndexes
    inColumn:(NSInteger)columnIndex withEvent:(NSEvent *)dragEvent
```

Parameters

rowIndexes

Rows the user is dragging

columnIndex

Column containing the rows the user is dragging.

dragEvent

Mouse-drag event.

Return Value

`YES` when *rowIndexes* identifies at least one row and all the identified rows are enabled; otherwise, `NO`.

Availability

Available in Mac OS X v10.5 and later.

See Also

- `browser:canDragRowsWithIndexes:inColumn:withEvent:` (page 3585) (`NSBrowserDelegate`)

Declared In

`NSBrowser.h`

cellPrototype

Returns the browser's prototype `NSCell`.

```
- (id)cellPrototype
```

Return Value

The prototype `NSCell`. The prototype `NSCell` instance is copied to display items in the matrices of the browser.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `setCellPrototype:` (page 438)
- `setCellClass:` (page 438)

Declared In

`NSBrowser.h`

clickedColumn

Returns the column number of the cell that the user clicked to display a context menu.

```
- (NSInteger)clickedColumn
```

Return Value
The column number of the clicked cell, or `-1` if no context menu is active.

Availability
Available in Mac OS X v10.6 and later.

See Also
`- clickedRow` (page 408)

Declared In
`NSBrowser.h`

clickedRow

Returns the row number of the cell that the user clicked to display a context menu.

```
- (NSInteger)clickedRow
```

Return Value
The row number of the clicked cell, or `-1` if no context menu is active.

Availability
Available in Mac OS X v10.6 and later.

See Also
`- clickedColumn` (page 407)

Declared In
`NSBrowser.h`

columnContentWidthForColumnWidth:

Returns the content width for a given column width.

```
- (CGFloat)columnContentWidthForColumnWidth:(CGFloat)columnWidth
```

Parameters
columnWidth
The width of the column. This width is the entire scrolling text view.

Return Value
The width of the content for the column. This is the width of the matrix in the column.

Availability
Available in Mac OS X v10.3 and later.

See Also
`- columnWidthForColumnContentWidth:` (page 410)

Declared In
`NSBrowser.h`

columnOfMatrix:

Returns the column number in which the given matrix is located.

```
- (NSInteger)columnOfMatrix:(NSMatrix *)matrix
```

Parameters

matrix

The matrix for which to return the column number.

Return Value

The index of the column in which the specified matrix appears.

Availability

Available in Mac OS X v10.0 and later.

See Also

- matrixInColumn: (page 422)

Declared In

NSBrowser.h

columnResizingType

Returns the browser's column resizing type.

```
- (NSBrowserColumnResizingType)columnResizingType
```

Return Value

A constant indicating the column resizing type. Possible return values are described in "NSBrowserColumnResizingType" (page 451). The default is NSBrowserAutoColumnResizing (page 452)

Availability

Available in Mac OS X v10.3 and later.

See Also

- setColumnResizingType: (page 438)

Declared In

NSBrowser.h

columnsAutosaveName

Returns the name used to automatically save the browser's column configuration.

```
- (NSString *)columnsAutosaveName
```

Return Value

The name used to save the column configuration.

Availability

Available in Mac OS X v10.3 and later.

See Also
- setColumnsAutosaveName: (page 439)

Declared In
NSBrowser.h

columnWidthForColumnContentWidth:

Returns the column width for the width of the given column's content.

```
- (CGFloat)columnWidthForColumnContentWidth:(CGFloat)columnContentWidth
```

Parameters

columnContentWidth
The width of the column's content (the width of the the matrix in the column).

Return Value
The width of the column (the width of the entire scrolling text view).

Discussion
For example, to guarantee that 16 pixels of your browser cell are always visible, call:

```
[browser setMinColumnWidth: [browser columnWidthForColumnContentWidth:16]]
```

Availability
Available in Mac OS X v10.3 and later.

See Also
- columnContentWidthForColumnWidth: (page 408)

Declared In
NSBrowser.h

defaultColumnWidth

Returns the default column width of the browser's columns.

```
- (CGFloat)defaultColumnWidth
```

Return Value
The default column width.

Availability
Available in Mac OS X v10.6 and later.

See Also
- setDefaultColumnWidth: (page 439)

Declared In
NSBrowser.h

delegate

Returns the browser's delegate.

```
- (id <NSBrowserDelegate>)delegate
```

Return Value
The browser's delegate.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setDelegate: (page 440)

Declared In
NSBrowser.h

displayAllColumns

Updates the browser to display all loaded columns. (Deprecated in Mac OS X v10.3. Use setNeedsDisplayInRect: (page 3225))

```
- (void)displayAllColumns
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.3.

See Also
- addColumn (page 404)
- validateVisibleColumns (page 451)

Declared In
NSBrowser.h

displayColumn:

Updates the browser to display the given column. (Deprecated in Mac OS X v10.3. Use setNeedsDisplayInRect: (page 3225) instead.)

```
- (void)displayColumn:(NSInteger)column
```

Parameters
column
The index of the column to display.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.3.

See Also
- addColumn (page 404)

- validateVisibleColumns (page 451)

Declared In
NSBrowser.h

doClick:

Responds to (single) mouse clicks in a column of the browser.

```
- (void)doClick:(id)sender
```

Availability
Available in Mac OS X v10.0 and later.

See Also
- sendAction (page 434)

Declared In
NSBrowser.h

doDoubleClick:

Responds to double clicks in a column of the browser.

```
- (void)doDoubleClick:(id)sender
```

Availability
Available in Mac OS X v10.0 and later.

See Also
- setDoubleAction: (page 440)

Declared In
NSBrowser.h

doubleAction

Returns the browser's double-click action method.

```
- (SEL)doubleAction
```

Return Value
The action method invoked when the user double-clicks on the browser.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setDoubleAction: (page 440)

Declared In
NSBrowser.h

draggingImageForRowsWithIndexes:inColumn:withEvent:offset:

Provides an image to represent dragged rows during a drag operation on the browser.

```
- (NSImage *)draggingImageForRowsWithIndexes:(NSIndexSet *)rowIndexes
    inColumn:(NSInteger)columnIndex withEvent:(NSEvent *)dragEvent
    offset:(NSPointPointer)dragImageOffset
```

Parameters

rowIndexes

Rows the user is dragging.

columnIndex

Column with the rows the user is dragging.

dragEvent

Mouse drag event.

dragImageOffset

Offset for the returned image:

- `NSZeroPoint`: The image is centered under the pointer.

Return Value

Image representing the visible cells identified by rowIndexes.

Availability

Available in Mac OS X v10.5 and later.

See Also

`- browser:draggingImageForRowsWithIndexes:inColumn:withEvent:offset:` (page 3587) (`NSBrowserDelegate`)

Related Sample Code

ComplexBrowser

ZipBrowser

Declared In

`NSBrowser.h`

draggingSourceOperationMaskForLocal:

Indicates the types of dragging operations the source object allows on the dragged image's data.

```
- (NSDragOperation)draggingSourceOperationMaskForLocal:(BOOL)localDestination
```

Parameters

localDestination

Indicates the location of the dragging operation's destination object: `YES` for this application, `NO` for another application.

Return Value

- `NSDragOperationEvery` (page 3665) when localDestination is `YES`.
- `NSDragOperationNone` (page 3666) when localDestination is `NO`.

Discussion
This method overrides `NSDraggingSource draggingSourceOperationMaskForLocal:` (page 3670).

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setDraggingSourceOperationMask:forLocal:` (page 441)

Declared In
`NSDragging.h`

drawTitleOfColumn:inRect:

Draws the title for the specified column within the given rectangle.

```
- (void)drawTitleOfColumn:(NSInteger)column inRect:(NSRect)aRect
```

Parameters

column
The index of the column for which to draw the title.

aRect
The rectangle within which to draw the title.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setTitle:ofColumn:` (page 447)
`- titleFrameOfColumn:` (page 449)
`- titleHeight` (page 450)

Declared In
`NSBrowser.h`

editItemAtIndexPath:withEvent:select:

Begins editing the item at the specified path.

```
- (void)editItemAtIndexPath:(NSIndexPath *)indexPath
    withEvent:(NSEvent *)theEvent
    select:(BOOL)select
```

Parameters

indexPath
The path of the item.

theEvent
The event to use when beginning the edit.

select
If `YES`, the cells contents will be selected; if `NO`, they will not be selected.

Availability
Available in Mac OS X v10.6 and later.

Declared In
NSBrowser.h

firstVisibleColumn

Returns the index of the first visible column.

```
- (NSInteger)firstVisibleColumn
```

Return Value
The index of the first visible column.

Availability
Available in Mac OS X v10.0 and later.

See Also
- lastVisibleColumn (page 420)

Declared In
NSBrowser.h

frameOfColumn:

Returns the rectangle containing the given column.

```
- (NSRect)frameOfColumn:(NSInteger)column
```

Parameters
column
The index of the column for which to retrieve the frame.

Return Value
The rectangle containing the specified column.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSBrowser.h

frameOfInsideOfColumn:

Returns the rectangle containing the specified column, not including borders.

```
- (NSRect)frameOfInsideOfColumn:(NSInteger)column
```

Parameters
column
The index of the column for which to retrieve the inside frame.

Return Value
The rectangle containing the column, not including the column borders.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSBrowser.h

frameOfRow:inColumn:

Returns the frame of the cell at the specified location, including the expandable arrow.

```
- (NSRect)frameOfRow:(NSInteger)row
    inColumn:(NSInteger)column
```

Parameters

row
The row of the cell.

column
The column of the cell.

Return Value
The frame of the cell, in the `NSBrowser` coordinate space.

Availability
Available in Mac OS X v10.6 and later.

Declared In
NSBrowser.h

getRow:column:forPoint:

Gets the row and column coordinates for the specified point, if a cell exists at that point.

```
- (BOOL)getRow:(NSInteger *)row
    column:(NSInteger *)column
    forPoint:(NSPoint)point
```

Parameters

row
On output, the row number of the cell at the specified point, or `-1` if there is no cell at the point.

column
On output, he column number of the cell at the specified point, or `-1` if there is no cell at the point.

point
The point to test.

Return Value
`YES` if a cell exists at the specified point; otherwise, `NO`.

Discussion
If a row does not exist at *point*, then `-1` is set for the row. If a column does not exist at *point*, then `-1` is set for the column.

Availability
Available in Mac OS X v10.6 and later.

Declared In
NSBrowser.h

hasHorizontalScroller

Indicates whether the browser has a horizontal scroller.

```
- (BOOL)hasHorizontalScroller
```

Return Value
YES if the browser uses an NSScroller object to scroll horizontally; otherwise, NO.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setHasHorizontalScroller: (page 441)

Declared In
NSBrowser.h

indexPathForColumn:

Returns the index path of the item whose children are displayed in the given column.

```
- (NSIndexPath *)indexPathForColumn:(NSInteger)column
```

Parameters

column
The column to find the index path for.

Return Value
The index path of the column.

Discussion
This method can only be used if the delegate implements the item data source methods.

Availability
Available in Mac OS X v10.6 and later.

Related Sample Code
ComplexBrowser
ZipBrowser

Declared In
NSBrowser.h

isLeafItem:

Returns whether the specified item is a leaf item.

```
- (BOOL)isLeafItem:(id)item
```

Parameters

item

The item to be checked.

Return Value

`YES` if the item is a leaf item; otherwise, `NO`.

Discussion

This method may return `NO` if the item has never been displayed in the browser or accessed via `itemAtIndexPath:` (page 419). Overriding this method has no effect. It may be used only if the browser's delegate implements the item data source methods.

Availability

Available in Mac OS X v10.6 and later.

Declared In

`NSBrowser.h`

isLoaded

Returns whether column 0 is loaded.

```
- (BOOL)isLoaded
```

Return Value

`YES` if column 0 is loaded; otherwise, `NO`.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `loadColumnZero` (page 421)
- `reloadColumn:` (page 426)

Declared In

`NSBrowser.h`

isOpaque

Indicates whether the browser is opaque.

```
- (BOOL)isOpaque
```

Return Value

`YES` when the browser doesn't have a title and its background color's alpha component is `1.0`; otherwise, `NO`.

Discussion
This method overrides the `isOpaque` (page 3183) method of `NSView`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSView.h`

isTitled

Indicates whether columns display titles.

```
- (BOOL)isTitled
```

Return Value
`YES` if the columns in a browser display titles; otherwise, `NO`.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setTitled:` (page 447)

Declared In
`NSBrowser.h`

itemAtIndexPath:

Returns the item at the specified index path.

```
- (id)itemAtIndexPath:(NSIndexPath *)indexPath
```

Parameters
indexPath
The index path of the item to return.

Return Value
The item.

Discussion
This method can only be used if the delegate implements the item data source methods. The specified index path must be displayable in the browser.

Availability
Available in Mac OS X v10.6 and later.

Related Sample Code
ComplexBrowser
ZipBrowser

Declared In
`NSBrowser.h`

itemAtRow:inColumn:

Returns the item located at the specified row and column.

```
- (id)itemAtRow:(NSInteger)row
    inColumn:(NSInteger)column
```

Parameters

row

The row of the item.

column

The column of the item.

Return Value
The item.

Availability
Available in Mac OS X v10.6 and later.

Declared In
NSBrowser.h

lastColumn

Returns the index of the last column loaded.

```
- (NSInteger)lastColumn
```

Return Value
The index of the last loaded column.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setLastColumn: (page 442)

Declared In
NSBrowser.h

lastVisibleColumn

Returns the index of the last visible column.

```
- (NSInteger)lastVisibleColumn
```

Return Value
The index of the last visible column.

Availability
Available in Mac OS X v10.0 and later.

See Also
- firstVisibleColumn (page 415)

Declared In
NSBrowser.h

loadColumnZero

Loads column 0; unloads previously loaded columns.

```
- (void)loadColumnZero
```

Availability
Available in Mac OS X v10.0 and later.

See Also
- isLoaded (page 418)
- reloadColumn: (page 426)

Related Sample Code
ZipBrowser

Declared In
NSBrowser.h

loadedCellAtRow:column:

Loads, if necessary, and returns the cell at the specified row and column location.

```
- (id)loadedCellAtRow:(NSInteger)row column:(NSInteger)column
```

Parameters
row
The row index of the cell to return.
column
The column index of the cell to return.

Availability
Available in Mac OS X v10.0 and later.

See Also
- selectedCellInColumn: (page 430)
- selectRow:inColumn: (page 433)

Declared In
NSBrowser.h

matrixClass

Returns the matrix class used in the browser's columns.

```
- (Class)matrixClass
```

Return Value
The class of `NSMatrix` used in the browser's columns.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setMatrixClass:` (page 442)

Declared In
`NSBrowser.h`

matrixInColumn:

Returns the matrix located in the specified column.

```
- (NSMatrix *)matrixInColumn:(NSInteger)column
```

Parameters
column
The column index of the matrix to obtain.

Return Value
The matrix located in the column.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- columnOfMatrix:` (page 409)

Declared In
`NSBrowser.h`

maxVisibleColumns

Returns the maximum number of visible columns.

```
- (NSInteger)maxVisibleColumns
```

Return Value
The maximum number of visible columns.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setMaxVisibleColumns:` (page 442)

Declared In
`NSBrowser.h`

minColumnWidth

Returns the minimum column width.

```
- (CGFloat)minColumnWidth
```

Return Value
The minimum column width, in pixels.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setMinColumnWidth: (page 443)

Declared In
NSBrowser.h

namesOfPromisedFilesDroppedAtDestination:

Provides the names of the files that the browser promises to create at a specified location.

```
- (NSArray *)namesOfPromisedFilesDroppedAtDestination:(NSURL *)dropDestination
```

Return Value
Result of sending
browser:namesOfPromisedFilesDroppedAtDestination:forDraggedRowsWithIndexes:inColumn:
to the delegate.

Discussion
Implementation of NSDraggingSource namesOfPromisedFilesDroppedAtDestination: (page 3671).

Availability
Available in Mac OS X v10.2 and later.

See Also
- browser:namesOfPromisedFilesDroppedAtDestination:forDraggedRowsWithIndexes:inColumn: (page 3589) (NSBrowserDelegate)

Declared In
NSDragging.h

noteHeightOfRowsWithIndexesChanged:inColumn:

Immediately retiles the browser's columns using row heights specified by the browser's delegate.

```
- (void)noteHeightOfRowsWithIndexesChanged:(NSIndexSet *)indexSet
    inColumn:(NSInteger)columnIndex
```

Parameters
indexSet
The indexes of the rows to resize.

columnIndex
The column to retile.

Discussion
The browser's delegate must implement

Availability
Available in Mac OS X v10.6 and later.

Declared In
NSBrowser.h

numberOfVisibleColumns

Returns the number of columns that are visible.

```
- (NSInteger)numberOfVisibleColumns
```

Return Value
The number of visible columns.

Availability
Available in Mac OS X v10.0 and later.

See Also
- validateVisibleColumns (page 451)

Declared In
NSBrowser.h

parentForItemsInColumn:

Returns the item that contains the children located in the specified column.

```
- (id)parentForItemsInColumn:(NSInteger)column
```

Parameters
column
The column.

Return Value
The parent item for the specified column.

Availability
Available in Mac OS X v10.6 and later.

Related Sample Code
AnimatedTableView
ComplexBrowser

Declared In
NSBrowser.h

path

Returns a string representing the browser's current path.

```
- (NSString *)path
```

Return Value
The path representing the current selection. The components of this path are separated with the string returned by `pathSeparator` (page 425).

Discussion
Invoking this method is equivalent to invoking `pathToColumn:` (page 425) for all columns.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setPath:` (page 443)
- `pathToColumn:` (page 425)

Declared In
`NSBrowser.h`

pathSeparator

Returns the path separator.

```
- (NSString *)pathSeparator
```

Return Value
The path separator. The default is "/".

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setPathSeparator:` (page 444)

Declared In
`NSBrowser.h`

pathToColumn:

Returns a string representing the path from the first column up to, but not including, the column at the given index.

```
- (NSString *)pathToColumn:(NSInteger)column
```

Parameters
column
The index of the column at which the path stops.

Return Value
The path of the current selection up to, but not including, the specified column. The components of this path are separated with the string returned by `pathSeparator` (page 425).

Availability
Available in Mac OS X v10.0 and later.

See Also
- `path` (page 425)
- `setPath:` (page 443)

Declared In
`NSBrowser.h`

prefersAllColumnUserResizing

Returns whether the browser is set to resize all columns simultaneously rather than resizing a single column at a time.

```
- (BOOL)prefersAllColumnUserResizing
```

Return Value
`YES` if the browser is set to resize all columns simultaneously; otherwise, `NO`. The default is `NO`.

Discussion
This setting applies only to browsers that allow the user to resize columns (see the constant `NSBrowserUserColumnResizing` (page 452). Holding down the Option key while resizing switches the type of resizing used.

Availability
Available in Mac OS X v10.3 and later.

See Also
- `setPrefersAllColumnUserResizing:` (page 444)

Declared In
`NSBrowser.h`

reloadColumn:

Reloads the given column if it exists and sets it to be the last column.

```
- (void)reloadColumn:(NSInteger)column
```

Parameters
column
The index of the column to reload.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `isLoaded` (page 418)

- loadColumnZero (page 421)

Related Sample Code
NewsReader
ZipBrowser

Declared In
NSBrowser.h

reloadDataForRowIndexes:inColumn:

Updates the rows in the column with the specified column index with indexes in the specified set.

```
- (void)reloadDataForRowIndexes:(NSIndexSet *)rowIndexes
    inColumn:(NSInteger)column
```

Parameters

rowIndexes
The set of row indexes of the rows to be updated.

column
The column containing the rows to be updated.

Availability
Available in Mac OS X v10.6 and later.

Declared In
NSBrowser.h

reusesColumns

Indicates whether the browser reuses matrix objects after their columns are unloaded.

```
- (BOOL)reusesColumns
```

Return Value
YES if NSMatrix objects aren't freed when their columns are unloaded; otherwise, NO.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setReusesColumns: (page 444)

Declared In
NSBrowser.h

rowHeight

Returns the height of the browser's rows.

```
- (CGFloat)rowHeight
```

Return Value
The row height.

Discussion
The default value is 17.0. `rowHeight` and `setRowHeight:` (page 445) are only available when using the item delegate methods. An exception is thrown if you are using the matrix delegate methods.

Availability
Available in Mac OS X v10.6 and later.

See Also
`- setRowHeight:` (page 445)

Declared In
`NSBrowser.h`

scrollColumnsLeftBy:

Scrolls columns left by the specified number of columns.

```
- (void)scrollColumnsLeftBy:(NSInteger)shiftAmount
```

Parameters
shiftAmount
The number of columns by which to scroll the browser.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSBrowser.h`

scrollColumnsRightBy:

Scrolls columns right by the specified number of columns.

```
- (void)scrollColumnsRightBy:(NSInteger)shiftAmount
```

Parameters
shiftAmount
The number of columns by which to scroll the browser.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSBrowser.h`

scrollColumnToVisible:

Scrolls to make the specified column visible.

```
- (void)scrollColumnToVisible:(NSInteger)column
```

Parameters

column

The index of the column to scroll to.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `scrollRowToVisible:inColumn:` (page 429)

Declared In
`NSBrowser.h`

scrollRowToVisible:inColumn:

Scrolls the specified row to be visible within the specified column.

```
- (void)scrollRowToVisible:(NSInteger)row
    inColumn:(NSInteger)column
```

Parameters

row

The index of the row to scroll.

column

The index of the column containing the row to scroll.

Discussion
The row's column will not be scrolled to visible via this method. To scroll the column to visible, use `scrollColumnToVisible:` (page 428).

Availability
Available in Mac OS X v10.6 and later.

See Also
- `scrollColumnToVisible:` (page 428)

Declared In
`NSBrowser.h`

scrollViaScroller:

Scrolls columns left or right based on an `NSScroller`. (Deprecated in Mac OS X v10.3. There is no replacement.)

```
- (void)scrollViaScroller:(NSScroller *)sender
```

Parameters

sender

The `NSScroller` object that determines the scrolling of the browser columns.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.3.

See Also
- `updateScroller` (page 450)

Declared In
`NSBrowser.h`

selectAll:

Selects all cells in the last column of the browser.

```
- (void)selectAll:(id)sender
```

Availability
Available in Mac OS X v10.0 and later.

See Also
- `selectedCell` (page 430)
- `selectedCells` (page 431)
- `selectedColumn` (page 431)

Declared In
`NSBrowser.h`

selectedCell

Returns the last (rightmost and lowest) selected cell.

```
- (id)selectedCell
```

Return Value
The selected cell (`NSCell`).

Availability
Available in Mac OS X v10.0 and later.

See Also
- `selectAll:` (page 430)
- `selectedCells` (page 431)

Declared In
`NSBrowser.h`

selectedCellInColumn:

Returns the last (lowest) cell selected in the given column.

```
- (id)selectedCellInColumn:(NSInteger)column
```

Parameters
column
The column whose last selected cell is to be returned.

Return Value
The last (or lowest) selected cell.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `- loadedCellAtRow:column:` (page 421)
- `- selectedRowInColumn:` (page 432)

Related Sample Code
NewsReader

Declared In
`NSBrowser.h`

selectedCells

Returns all cells selected in the rightmost column.

```
- (NSArray *)selectedCells
```

Return Value
An array of `NSCell` objects representing the selected cells in the rightmost browser column.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `- selectAll:` (page 430)
- `- selectedCell` (page 430)

Declared In
`NSBrowser.h`

selectedColumn

Returns the index of the last column with a selected item.

```
- (NSInteger)selectedColumn
```

Return Value
The index of the last column with a selected item, or `-1` if there is no column selected.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `- columnOfMatrix:` (page 409)
- `- selectAll:` (page 430)

Related Sample Code
ZipBrowser

Declared In
NSBrowser.h

selectedRowInColumn:

Returns the row index of the selected cell in the specified column.

```
- (NSInteger)selectedRowInColumn:(NSInteger)column
```

Parameters

column
The column index specifying the column for which to return the selected row.

Return Value
The row index of the selected cell in the specified column.

Availability
Available in Mac OS X v10.0 and later.

See Also
- loadedCellAtRow:column: (page 421)
- selectedCellInColumn: (page 430)

Related Sample Code
NewsReader

Declared In
NSBrowser.h

selectedRowIndexesInColumn:

Provides the indexes of the selected rows in a given column of the browser.

```
- (NSIndexSet *)selectedRowIndexesInColumn:(NSInteger)columnIndex
```

Parameters

columnIndex
The column whose selected rows are provided.

Return Value
Rows selected in column *columnIndex*.

Availability
Available in Mac OS X v10.5 and later.

See Also
- selectRowIndexes:inColumn: (page 434)

Declared In
NSBrowser.h

selectionIndexPath

Returns the index path of the item selected in the browser.

```
- (NSIndexPath *)selectionIndexPath
```

Return Value
The index path of the selected item, or `nil` if there is no selection.

Availability
Available in Mac OS X v10.6 and later.

See Also
`- setSelectionIndexPath:` (page 445)

Declared In
`NSBrowser.h`

selectionIndexPaths

Returns an array containing the index paths of all items selected in the browser.

```
- (NSArray *)selectionIndexPaths
```

Return Value
The array containing the index paths of the selected items.

Availability
Available in Mac OS X v10.6 and later.

See Also
`- setSelectionIndexPaths:` (page 446)

Declared In
`NSBrowser.h`

selectRow:inColumn:

Selects the cell at the specified row and column index.

```
- (void)selectRow:(NSInteger)row inColumn:(NSInteger)column
```

Parameters

row
The row index of the cell to select.

column
The column index of the cell to select.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- loadedCellAtRow:column:` (page 421)

Declared In
NSBrowser.h

selectRowIndexes:inColumn:

Specifies the selected rows in a given column of the browser.

```
- (void)selectRowIndexes:(NSIndexSet *)rowIndexes inColumn:(NSInteger)columnIndex
```

Parameters

rowIndexes
Rows to be selected in column *columnIndex*.

columnIndex
Column in which to select rows *rowIndexes*.

Availability
Available in Mac OS X v10.5 and later.

See Also
- selectedRowIndexesInColumn: (page 432)

Declared In
NSBrowser.h

sendAction

Sends the action message to the target.

```
- (BOOL)sendAction
```

Return Value
YES if successful; NO if no target for the message could be found.

Availability
Available in Mac OS X v10.0 and later.

See Also
- doClick: (page 412)
- doDoubleClick: (page 412)

Declared In
NSBrowser.h

sendsActionOnArrowKeys

Returns whether pressing an arrow key causes an action message to be sent.

```
- (BOOL)sendsActionOnArrowKeys
```

Return Value
NO if pressing an arrow key scrolls the browser; YES if it also sends the action message specified by setAction: (page 828).

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setSendsActionOnArrowKeys:` (page 446)

Declared In
`NSBrowser.h`

separatesColumns

Indicates whether columns are separated by bezeled borders.

```
- (BOOL)separatesColumns
```

Return Value
`YES` if the browser's columns are separated by bezeled borders; otherwise, `NO`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setSeparatesColumns:` (page 446)

Declared In
`NSBrowser.h`

setAcceptsArrowKeys:

Specifies whether the browser allows navigation using the arrow keys. (Deprecated in Mac OS X v10.6. There is no replacement.)

```
- (void)setAcceptsArrowKeys:(BOOL)flag
```

Parameters
flag
`YES` to enable the use of the arrow keys for navigating within and between browsers; otherwise, `NO`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.6.

See Also
- `acceptsArrowKeys` (page 404)
- `sendsActionOnArrowKeys` (page 434)

Declared In
`NSBrowser.h`

setAllowsBranchSelection:

Allows the user to select branch items.

```
- (void)setAllowsBranchSelection:(BOOL)flag
```

Parameters

flag

YES if the user can select branch items when multiple selection is enabled; otherwise, NO.

Availability
Available in Mac OS X v10.0 and later.

See Also
- allowsBranchSelection (page 404)

Declared In
NSBrowser.h

setAllowsEmptySelection:

Allows the user to select nothing.

```
- (void)setAllowsEmptySelection:(BOOL)flag
```

Parameters

flag

YES if the browser allows an empty selection; otherwise, NO.

Availability
Available in Mac OS X v10.0 and later.

See Also
- allowsEmptySelection (page 405)

Declared In
NSBrowser.h

setAllowsMultipleSelection:

Allows the user to select multiple items.

```
- (void)setAllowsMultipleSelection:(BOOL)flag
```

Parameters

flag

YES if the user can select multiple items at once; otherwise, NO.

Availability
Available in Mac OS X v10.0 and later.

See Also
- allowsMultipleSelection (page 405)

Declared In
NSBrowser.h

setAllowsTypeSelect:

Allows the browser to accept keystroke-based selection.

```
- (void)setAllowsTypeSelect:(BOOL)allowsTypeSelection
```

Parameters

allowsTypeSelection

YES to allow type selection; NO to disallow it.

Availability
Available in Mac OS X v10.5 and later.

See Also
- allowsTypeSelect (page 405)

Declared In
NSBrowser.h

setAutohidesScroller:

Allows the browser to hide its scroller automatically.

```
- (void)setAutohidesScroller:(BOOL)flag
```

Parameters

flag

If YES, the browser hides its scroller automatically; if NO, it does not.

Availability
Available in Mac OS X v10.6 and later.

See Also
- autohidesScroller (page 406)

Declared In
NSBrowser.h

setBackgroundColor:

Specifies the browser's background color.

```
- (void)setBackgroundColor:(NSColor *)backgroundColor
```

Parameters

backgroundColor

[NSColor clearColor] specifies a transparent background.

Availability
Available in Mac OS X v10.5 and later.

See Also
- backgroundColor (page 406)

Declared In
NSBrowser.h

setCellClass:

Sets the class of the cell to be used by the matrices in the columns of the browser.

```
- (void)setCellClass:(Class)factoryId
```

Parameters

factoryId

The class of NSCell used by the matrices in the columns of the browser. This method creates an instance of the class and calls setCellPrototype: (page 438).

Availability
Available in Mac OS X v10.0 and later.

See Also
+ cellClass (page 403)
- cellPrototype (page 407)
- setCellPrototype: (page 438)

Declared In
NSBrowser.h

setCellPrototype:

Sets the prototype cell for displaying items in the matrices in the columns of the browser.

```
- (void)setCellPrototype:(NSCell *)aCell
```

Parameters

aCell

The prototype NSCell instance.

Availability
Available in Mac OS X v10.0 and later.

See Also
+ cellClass (page 403)
- cellPrototype (page 407)
- setCellClass: (page 438)

Declared In
NSBrowser.h

setColumnResizingType:

Sets the browser's column resizing type.

```
- (void)setColumnResizingType:(NSBrowserColumnResizingType)columnResizingType
```

Parameters

columnResizingType

The column resizing type. Possible values are described in "NSBrowserColumnResizingType" (page 451). The default is NSBrowserAutoColumnResizing (page 452). This setting is persistent.

Availability
Available in Mac OS X v10.3 and later.

See Also
- columnResizingType (page 409)

Declared In
NSBrowser.h

setColumnsAutosaveName:

Sets the name used to automatically save the browser's column configuration.

```
- (void)setColumnsAutosaveName:(NSString *)name
```

Parameters

name

The name used to save the column configuration. If *name* is different from the current name, this method also reads in any column configuration data previously saved under *name* and applies the values to the browser.

Discussion
Column configuration is defined as an array of column content widths. One width is saved for each level the user has reached. That is, the browser saves column width based on depth, not on unique paths. To do more complex column persistence, you should register for NSBrowserColumnConfigurationDidChangeNotification (page 453) and handle persistence yourself. This setting is persistent.

Availability
Available in Mac OS X v10.3 and later.

See Also
- columnsAutosaveName (page 409)
+ removeSavedColumnsWithAutosaveName: (page 403)

Declared In
NSBrowser.h

setDefaultColumnWidth:

Sets the default column width for new browser columns that do not otherwise have an initial width from defaults or the browser's delegate.

```
- (void)setDefaultColumnWidth:(CGFloat)columnWidth
```

Parameters

columnWidth

The default column width to set.

Availability
Available in Mac OS X v10.6 and later.

See Also
- `defaultColumnWidth` (page 410)

Declared In
`NSBrowser.h`

setDelegate:

Sets the browser's delegate.

```
- (void)setDelegate:(id <NSBrowserDelegate>)anObject
```

Parameters

anObject
The object to set at the browser's delegate.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `delegate` (page 411)

Declared In
`NSBrowser.h`

setDoubleAction:

Sets the browser's double-click action.

```
- (void)setDoubleAction:(SEL)aSelector
```

Parameters

aSelector
The action method to invoke when the browser is double-clicked.

Discussion
For the method to have any effect, the browser's action and target must be set to the class in which the selector is declared. See *Action Messages* for additional information on action messages.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `doubleAction` (page 412)
- `sendAction` (page 434)
- `doDoubleClick:` (page 412)

Related Sample Code
NewsReader

Declared In
NSBrowser.h

setDraggingSourceOperationMask:forLocal:

Specifies the drag-operation mask for dragging operations with local or external destinations.

```
- (void)setDraggingSourceOperationMask:(NSDragOperation)dragOperationMask
    forLocal:(BOOL)localDestination
```

Parameters

dragOperationMask

Dragging operation mask to use for either local or external drag operations, as specified by localDestination.

localDestination

Indicates the location of the dragging operation's destination object:

YES for this application; NO for another application.

Discussion

Important: Do not override this method.

Availability
Available in Mac OS X v10.5 and later.

See Also
- draggingSourceOperationMaskForLocal: (page 413)

Declared In
NSBrowser.h

setHasHorizontalScroller:

Sets whether the browser has a scroller to scroll horizontally.

```
- (void)setHasHorizontalScroller:(BOOL)flag
```

Parameters

flag

YES if the browser uses an NSScroller object to scroll horizontally; otherwise, NO.

Availability
Available in Mac OS X v10.0 and later.

See Also
- hasHorizontalScroller (page 417)

Declared In
NSBrowser.h

setLastColumn:

Sets the last column.

```
- (void)setLastColumn:(NSInteger)column
```

Parameters

column

The index of the last column.

Availability

Available in Mac OS X v10.0 and later.

See Also

- lastColumn (page 420)

Declared In

NSBrowser.h

setMatrixClass:

Sets the matrix class to be used in the browser's columns.

```
- (void)setMatrixClass:(Class)factoryId
```

Parameters

factoryId

The matrix class (NSMatrix or an NSMatrix subclass) used in the browser's columns.

Availability

Available in Mac OS X v10.0 and later.

See Also

- matrixClass (page 421)

Declared In

NSBrowser.h

setMaxVisibleColumns:

Sets the maximum number of columns that can be displayed.

```
- (void)setMaxVisibleColumns:(NSInteger)columnCount
```

Parameters

columnCount

The maximum number of visible columns.

Availability

Available in Mac OS X v10.0 and later.

See Also

- maxVisibleColumns (page 422)

Declared In
NSBrowser.h

setMinColumnWidth:

Sets the minimum column width.

```
- (void)setMinColumnWidth:(CGFloat)columnWidth
```

Parameters

columnWidth

The minimum column width, in pixels.

Availability
Available in Mac OS X v10.0 and later.

See Also
- minColumnWidth (page 423)

Declared In
NSBrowser.h

setPath:

Sets the path to be displayed by the browser.

```
- (BOOL)setPath:(NSString *)path
```

Parameters

path

The path to display. If *path* is prefixed by the path separator, the path is absolute, containing the full path from the browser's first column. Otherwise, the path is relative, extending the browser's current path starting at the last column.

Return Value
YES if the given path is valid; otherwise, NO.

Discussion
While parsing *path*, the browser compares each component with the entries in the current column. If an exact match is found, the matching entry is selected, and the next component is compared to the next column's entries. If no match is found for a component, the method exits and returns NO; the final path is set to the valid portion of *path*. If each component of *path* specifies a valid branch or leaf in the browser's hierarchy, the method returns YES.

Availability
Available in Mac OS X v10.0 and later.

See Also
- path (page 425)
- pathToColumn: (page 425)

Declared In
NSBrowser.h

setPathSeparator:

Sets the path separator.

```
- (void)setPathSeparator:(NSString *)newString
```

Parameters

newString

The new path separator.

Availability
Available in Mac OS X v10.0 and later.

See Also
- pathSeparator (page 425)

Declared In
NSBrowser.h

setPrefersAllColumnUserResizing:

Causes the browser to resize all column simultaneously rather than resize a single column at a time.

```
- (void)setPrefersAllColumnUserResizing:(BOOL)prefersAllColumnResizing
```

Parameters

prefersAllColumnResizing

YES to cause the browser to resize all columns simultaneously; the default is single column resizing (NO). This setting applies only to browsers that allow the user to resize columns (see NSBrowserUserColumnResizing (page 452). Holding down the Option key while resizing switches the type of resizing used. This setting is persistent.

Availability
Available in Mac OS X v10.3 and later.

See Also
- prefersAllColumnUserResizing (page 426)

Declared In
NSBrowser.h

setReusesColumns:

Specifies whether matrices can be reused.

```
- (void)setReusesColumns:(BOOL)flag
```

Parameters

flag

YES to prevent NSMatrix objects from being freed when their columns are unloaded, so they can be reused; otherwise, NO.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `reusesColumns` (page 427)

Declared In
`NSBrowser.h`

setRowHeight:

Sets the height of the browser's rows to the specified value.

```
- (void)setRowHeight:(CGFloat)height
```

Parameters

height
The new height to set.

Discussion
The value must be greater than 0. Any fractional value will be forced to an integral value for drawing. For variable row height browsers (ones whose delegates implement `browser:heightOfRow:inColumn:` (page 3588)), the row height will be used to draw alternating rows past the last row in each browser column. `rowHeight` and `setRowHeight:` (page 445) are only available when using the item delegate methods. An exception is thrown if you are using the matrix delegate methods.

Availability
Available in Mac OS X v10.6 and later.

See Also
- `rowHeight` (page 427)

Declared In
`NSBrowser.h`

setSelectionIndexPath:

Sets the browser's selection to the item with the specified path.

```
- (void)setSelectionIndexPath:(NSIndexPath *)path
```

Parameters

path
The path of the item to select.

Availability
Available in Mac OS X v10.6 and later.

See Also
- `selectionIndexPath` (page 433)

Declared In
`NSBrowser.h`

setSelectionIndexPaths:

Sets the browser's selection to the items whose index paths are in the specified array.

```
- (void)setSelectionIndexPaths:(NSArray *)paths
```

Parameters

paths

The array containing the index paths of the items to select.

Availability
Available in Mac OS X v10.6 and later.

See Also
- selectionIndexPaths (page 433)

Declared In
NSBrowser.h

setSendsActionOnArrowKeys:

Allows the specified action message to be sent when the user presses an arrow key.

```
- (void)setSendsActionOnArrowKeys:(BOOL)flag
```

Parameters

flag

YES if pressing an arrow key should send the action message specified by setAction: (page 828) in addition to scrolling the browser; NO if it should only scroll the browser.

Availability
Available in Mac OS X v10.0 and later.

See Also
- sendsActionOnArrowKeys (page 434)

Declared In
NSBrowser.h

setSeparatesColumns:

Separates columns with bezeled borders.

```
- (void)setSeparatesColumns:(BOOL)flag
```

Parameters

flag

YES if the browser's columns should be separated by bezeled borders; otherwise, NO. This value is ignored if isTitled (page 419) does not return NO.

Availability
Available in Mac OS X v10.0 and later.

See Also
- separatesColumns (page 435)

Declared In
NSBrowser.h

setTakesTitleFromPreviousColumn:

Sets whether the title of a column is set to the string value of the selected cell in the previous column.

```
- (void)setTakesTitleFromPreviousColumn:(BOOL)flag
```

Parameters

flag

YES if the title of a column should be set to the string value of the selected NSCell in the previous column; otherwise, NO.

Availability
Available in Mac OS X v10.0 and later.

See Also
- takesTitleFromPreviousColumn (page 448)

Declared In
NSBrowser.h

setTitle:ofColumn:

Sets the title of the given column.

```
- (void)setTitle:(NSString *)aString ofColumn:(NSInteger)column
```

Parameters

aString

The title of the column.

column

The index of the column whose title should be set.

Availability
Available in Mac OS X v10.0 and later.

See Also
- drawTitleOfColumn:inRect: (page 414)
- titleOfColumn: (page 450)

Declared In
NSBrowser.h

setTitled:

Sets columns to display titles.

```
- (void)setTitled:(BOOL)flag
```

Parameters

flag

YES if the columns in a browser display titles; otherwise, NO.

Availability
Available in Mac OS X v10.0 and later.

See Also
- isTitled (page 419)

Declared In
NSBrowser.h

setWidth:ofColumn:

Sets the width of the specified column.

```
- (void)setWidth:(CGFloat)columnWidth ofColumn:(NSInteger)columnIndex
```

Parameters

columnWidth

The new width of the specified column.

columnIndex

The index of the column for which to set the width.

Discussion
This method can be used to set the initial width of browser columns unless the column sizing is automatic; setWidth:ofColumn: does nothing if columnResizingType (page 409) is NSBrowserAutoColumnResizing (page 452). To set the default width for new columns (that don't otherwise have initial widths from defaults or via the delegate), use a *columnIndex* of –1. A value set for *columnIndex* of –1 is persistent. An NSBrowserColumnConfigurationDidChangeNotification (page 453) notification is posted (not immediately), if necessary, so that the browser can autosave the new column configuration.

Availability
Available in Mac OS X v10.3 and later.

See Also
- widthOfColumn: (page 451)
- browser:shouldSizeColumn:forUserResize:toWidth: (page 3596) (NSBrowserDelegate)

Declared In
NSBrowser.h

takesTitleFromPreviousColumn

Indicates whether a column takes its title from the selected cell in the previous column.

```
- (BOOL)takesTitleFromPreviousColumn
```

Return Value
`YES` if the title of a column is set to the string value of the selected `NSCell` in the previous column; otherwise, `NO`.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setTakesTitleFromPreviousColumn:` (page 447)

Declared In
`NSBrowser.h`

tile

Adjusts the various subviews of the browser—scrollers, columns, titles, and so on—without redrawing.

```
- (void)tile
```

Discussion
Your code shouldn't send this message. It's invoked any time the appearance of the browser changes.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSBrowser.h`

titleFrameOfColumn:

Returns the bounds of the title frame for the specified column.

```
- (NSRect)titleFrameOfColumn:(NSInteger)column
```

Parameters
column
The index of the column for which to return the title frame.

Return Value
The rectangle specifying the bounds of the column's title frame.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- drawTitleOfColumn:inRect:` (page 414)

Declared In
`NSBrowser.h`

titleHeight

Returns the height of the column titles.

```
- (CGFloat)titleHeight
```

Return Value
The height of the column titles for the browser.

Availability
Available in Mac OS X v10.0 and later.

See Also
- drawTitleOfColumn:inRect: (page 414)

Declared In
NSBrowser.h

titleOfColumn:

Returns the title displayed for the given column.

```
- (NSString *)titleOfColumn:(NSInteger)column
```

Parameters
column
The index of the column for which to get the title.

Return Value
The title of the specified column.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setTitle:ofColumn: (page 447)

Declared In
NSBrowser.h

updateScroller

Updates the horizontal scroller to reflect column positions. (Deprecated in Mac OS X v10.3. There is no replacement.)

```
- (void)updateScroller
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.3.

See Also
- scrollViaScroller: (page 429)

Declared In
NSBrowser.h

validateVisibleColumns

Validates the browser's visible columns.

```
- (void)validateVisibleColumns
```

Discussion
This method invokes the delegate method `browser:isColumnValid:` (page 3589)

Availability
Available in Mac OS X v10.0 and later.

See Also
`- numberOfVisibleColumns` (page 424)

Declared In
NSBrowser.h

widthOfColumn:

Returns the width of the specified column.

```
- (CGFloat)widthOfColumn:(NSInteger)column
```

Parameters
column
The index of the column for which to retrieve the width.

Return Value
The width of the column.

Availability
Available in Mac OS X v10.3 and later.

See Also
`- setWidth:ofColumn:` (page 448)

Declared In
NSBrowser.h

Constants

NSBrowserColumnResizingType

Types of browser column resizing.

```
enum {
    NSBrowserNoColumnResizing   = 0,
    NSBrowserAutoColumnResizing = 1,
    NSBrowserUserColumnResizing = 2
};
typedef NSUInteger NSBrowserColumnResizingType;
```

Constants

`NSBrowserNoColumnResizing`

Neither `NSBrowser` nor the user can change the column width. The developer must explicitly set all column widths.

Available in Mac OS X v10.3 and later.

Declared in `NSBrowser.h`.

`NSBrowserAutoColumnResizing`

All columns have the same width, calculated using a combination of the minimum column width and maximum number of visible columns settings. The column width changes as the window size changes. The user cannot resize columns.

Available in Mac OS X v10.3 and later.

Declared in `NSBrowser.h`.

`NSBrowserUserColumnResizing`

The developer chooses the initial column widths, but users can resize all columns simultaneously or each column individually.

Available in Mac OS X v10.3 and later.

Declared in `NSBrowser.h`.

Discussion

These constants are used by the `setColumnResizingType:` (page 438) and `columnResizingType` (page 409) methods.

NSBrowserDropOperation

The type used to specify the drop type of a drag-and-drop operation. See `browser:validateDrop:proposedRow:column:dropOperation:` (page 3600) for more information.

```
enum {
   NSBrowserDropOn,
   NSBrowserDropAbove
};
typedef NSUInteger NSBrowserDropOperation;
```

Constants

`NSBrowserDropOn`

The drop occurs at the row to which the item was dragged.

Available in Mac OS X v10.5 and later.

Declared in `NSBrowser.h`.

`NSBrowserDropAbove`

The drop occurs above the row to which the item was dragged.

Available in Mac OS X v10.5 and later.

Declared in `NSBrowser.h`.

Declared In
NSBrowser.h

Application Kit Versions for NSBrowser Functionality

The version of the AppKit.framework containing a specific bug fix or capability.

```
#define NSAppKitVersionNumberWithContinuousScrollingBrowser 680.0
#define NSAppKitVersionNumberWithColumnResizingBrowser      685.0
```

Constants

`NSAppKitVersionNumberWithContinuousScrollingBrowser`

The specific version of the AppKit framework that introduced support the continuous scrolling in NSBrowser. Developers should not need to use this constant unless they are writing applications for Mac OS X v10.3 and earlier.

Available in Mac OS X v10.3 and later.

Declared in `NSBrowser.h`.

`NSAppKitVersionNumberWithColumnResizingBrowser`

The specific version of the AppKit framework that introduced support for resizing individual browser columns. Developers should not need to use this constant unless they are writing applications for Mac OS X v10.3 and earlier.

Available in Mac OS X v10.3 and later.

Declared in `NSBrowser.h`.

Notifications

NSBrowserColumnConfigurationDidChangeNotification

Notifies the delegate when the width of a browser column has changed. The notification object is the browser whose column sizes need to be made persistent. This notification does not contain a *`userInfo`* dictionary. If the user resizes more than one column, a single notification is posted when the user is finished resizing.

Availability
Available in Mac OS X v10.3 and later.

See Also
`- browserColumnConfigurationDidChange:` (page 3602)

Declared In
NSBrowser.h

NSBrowserCell Class Reference

Inherits from	NSCell : NSObject
Conforms to	NSCoding (NSCell) NSCopying (NSCell) NSObject (NSObject)
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.0 and later.
Declared in	AppKit/NSBrowserCell.h
Companion guide	Browsers
Related sample code	NewsReader SimpleCocoaBrowser

Overview

The `NSBrowserCell` class is the subclass of `NSCell` used by default to display data in the columns of an `NSBrowser` object. (Each column contains an `NSMatrix` filled with `NSBrowserCell` objects.)

The `NSBrowserCell` class implements the user interface of `NSBrowser`.

Tasks

Getting Browser Cell Information

`+ branchImage` (page 456)
Returns the default image for branch cells in a browser.

`+ highlightedBranchImage` (page 457)
Returns the default image for branch browser cells that are highlighted.

Configuring Browser Cells

`- image` (page 458)
Returns the receiver's image.

- `setImage:` (page 460)
  Sets the receiver's image, retaining the image.
- `alternateImage` (page 457)
  Returns the receiver's image for the highlighted state.
- `setAlternateImage:` (page 460)
  Sets the receiver's image for the highlighted state, retaining the image.

Managing Browser Cell State

- `reset` (page 459)
  Unhighlights the receiver and unsets its state.
- `set` (page 459)
  Highlights the receiver and sets its state.
- `isLeaf` (page 458)
  Returns whether the receiver is a leaf or a branch cell.
- `setLeaf:` (page 461)
  Sets whether the receiver is a leaf or a branch cell.
- `isLoaded` (page 459)
  Returns a Boolean value indicating whether the cell is ready to display.
- `setLoaded:` (page 461)
  Sets whether the receiver's state has been set and the cell is ready to display.
- `highlightColorInView:` (page 458)
  Returns the highlight color that the receiver wants to display.

Class Methods

branchImage

Returns the default image for branch cells in a browser.

```
+ (NSImage *)branchImage
```

Return Value
The default image used for branch `NSBrowserCell` objects. The default image is a right-pointing triangle.

Discussion
Override this method if you want a different image. To have a branch `NSBrowserCell` with no image (and no space reserved for an image), override this method to return `nil`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `highlightedBranchImage` (page 457)
- `alternateImage` (page 457)
- `setAlternateImage:` (page 460)

Declared In
NSBrowserCell.h

highlightedBranchImage

Returns the default image for branch browser cells that are highlighted.

```
+ (NSImage *)highlightedBranchImage
```

Return Value
The default image used for branch NSBrowserCell objects that are highlighted. This is a lighter version of the image returned by branchImage (page 456).

Discussion
Override this method if you want a different image.

Availability
Available in Mac OS X v10.0 and later.

See Also
+ branchImage (page 456)
- alternateImage (page 457)
- setAlternateImage: (page 460)

Declared In
NSBrowserCell.h

Instance Methods

alternateImage

Returns the receiver's image for the highlighted state.

```
- (NSImage *)alternateImage
```

Return Value
The image used for the browser cell in its highlighted state or nil if no image is set.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setAlternateImage: (page 460)

Declared In
NSBrowserCell.h

highlightColorInView:

Returns the highlight color that the receiver wants to display.

```
- (NSColor *)highlightColorInView:(NSView *)controlView
```

Parameters

controlView

The view for which to return the highlight color.

Return Value

The highlight color.

Availability

Available in Mac OS X v10.0 and later.

Declared In

NSBrowserCell.h

image

Returns the receiver's image.

```
- (NSImage *)image
```

Return Value

The image of the receiver or `nil` if no image is set.

Availability

Available in Mac OS X v10.2 and later.

See Also

`- setImage:` (page 460)

Declared In

NSBrowserCell.h

isLeaf

Returns whether the receiver is a leaf or a branch cell.

```
- (BOOL)isLeaf
```

Return Value

`YES` if the receiver is a leaf cell; otherwise `NO`.

Discussion

A branch `NSBrowserCell` has an image near its right edge indicating that more, hierarchically related information is available; when the user selects the cell, the `NSBrowser` displays a new column of `NSBrowserCell` objects. A leaf `NSBrowserCell` has no image, indicating that the user has reached a terminal piece of information; it doesn't point to additional information.

Availability

Available in Mac OS X v10.0 and later.

See Also
- `setLeaf:` (page 461)

Declared In
`NSBrowserCell.h`

isLoaded

Returns a Boolean value indicating whether the cell is ready to display.

```
- (BOOL)isLoaded
```

Return Value
`YES` if the receiver's state has been set and the cell is ready to display; otherwise `NO`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setLoaded:` (page 461)

Declared In
`NSBrowserCell.h`

reset

Unhighlights the receiver and unsets its state.

```
- (void)reset
```

Availability
Available in Mac OS X v10.0 and later.

See Also
- `set` (page 459)

Declared In
`NSBrowserCell.h`

set

Highlights the receiver and sets its state.

```
- (void)set
```

Availability
Available in Mac OS X v10.0 and later.

See Also
- `reset` (page 459)

Declared In
NSBrowserCell.h

setAlternateImage:

Sets the receiver's image for the highlighted state, retaining the image.

```
- (void)setAlternateImage:(NSImage *)newAltImage
```

Parameters

newAltImage

The new image for the browser cell in its highlighted state. If *newAltImage* is `nil`, it removes the alternate image for the receiver. *newAltImage* is drawn vertically centered on the left edge of the browser cell.

Note that *newAltImage* is drawn at the given size of the image. `NSBrowserCell` does not set the size of the image, nor does it clip the drawing of the image. Make sure *newAltImage* is the correct size for drawing in the browser cell.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `alternateImage` (page 457)

Declared In
NSBrowserCell.h

setImage:

Sets the receiver's image, retaining the image.

```
- (void)setImage:(NSImage *)newImage
```

Parameters

newImage

The new image. If *newImage* is `nil`, it removes the image for the receiver. *newImage* is drawn vertically centered on the left edge of the browser cell.

Note that *newImage* is drawn at the given size of the image. `NSBrowserCell` does not set the size of the image, nor does it clip the drawing of the image. Make sure *newImage* is the correct size for drawing in the browser cell.

Availability
Available in Mac OS X v10.2 and later.

See Also
- `image` (page 458)

Declared In
NSBrowserCell.h

setLeaf:

Sets whether the receiver is a leaf or a branch cell.

```
- (void)setLeaf:(BOOL)flag
```

Parameters

flag

`YES` if the receiver is a leaf cell; otherwise `NO`.

Discussion

A branch `NSBrowserCell` has an image near its right edge indicating that more, hierarchically related information is available; when the user selects the cell, the `NSBrowser` displays a new column of `NSBrowserCell` objects. A leaf `NSBrowserCell` has no image, indicating that the user has reached a terminal piece of information; it doesn't point to additional information.

Availability

Available in Mac OS X v10.0 and later.

NSBundle Additions Reference

Inherits from	NSObject
Framework	/System/Library/Frameworks/AppKit.framework
Declared in	AppKit/NSHelpManager.h AppKit/NSImage.h AppKit/NSNibLoading.h AppKit/NSSound.h
Companion guide	Resource Programming Guide

Overview

The Application Kit extends the behavior of the Foundation framework's NSBundle class to support the loading of specific resource types.

The `NSBundle` additions add support for the following tasks:

- Loading nib files
- Locating image and sound resources
- Accessing context help from a `Help.plist` file

These methods become part of the `NSBundle` class only for those applications that use the Application Kit.

Tasks

Loading Nib Files

`+ loadNibFile:externalNameTable:withZone:` (page 464)
Unarchives the contents of the nib file and links them to objects in your program.

`+ loadNibNamed:owner:` (page 465)
Unarchives the contents of the nib file and links them to a specific owner object.

`- loadNibFile:externalNameTable:withZone:` (page 466)
Unarchives the contents of a nib file located in the receiver's bundle.

Locating Image Resources

- `URLForImageResource:` (page 468)
  Returns the location of the specified image resource as an NSURL.
- `pathForImageResource:` (page 467)
  Returns the location of the specified image resource file.

Accessing Context Help

- `contextHelpForKey:` (page 465)
  Returns the context-sensitive help for the specified key from the bundle's help file.

Locating Sound Resources

- `pathForSoundResource:` (page 467)
  Returns the location of the specified sound resource file.

Class Methods

loadNibFile:externalNameTable:withZone:

Unarchives the contents of the nib file and links them to objects in your program.

```
+ (BOOL)loadNibFile:(NSString *)fileName externalNameTable:(NSDictionary *)context
     withZone:(NSZone *)zone
```

Parameters

fileName
The location of the nib file specified as an absolute path in the file system.

context
A name table whose keys identify objects associated with your program or the nib file. The newly unarchived objects from the nib file use this table to connect to objects in your program. For example, the nib file uses the object associated with the `NSNibOwner` constant as the nib file's owning object. If you associate an empty `NSMutableArray` object with the `NSNibTopLevelObjects` constant, on output, the array contains the top level objects from the nib file. For descriptions of these constants, see *NSNib Class Reference*.

zone
The memory zone in which to allocate the nib file objects.

Return Value
`YES` if the nib file was loaded successfully; otherwise, `NO`.

Discussion
This method is declared in `NSNibLoading.h`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSNibLoading.h

loadNibNamed:owner:

Unarchives the contents of the nib file and links them to a specific owner object.

```
+ (BOOL)loadNibNamed:(NSString *)aNibName owner:(id)owner
```

Parameters

aNibName

The name of the nib file, which need not include the `.nib` extension. The file name should not include path information. The object in the *owner* parameter determines the location in which to look for the nib file.

owner

The object to assign as the nib FIle's Owner. If the class of this object has an associated bundle, that bundle is searched for the specified nib file; otherwise, this method looks in the main bundle.

Return Value
`YES` if the nib file was loaded successfully; otherwise, `NO`.

Discussion
This method is declared in `NSNibLoading.h`.

Availability
Available in Mac OS X v10.0 and later.

See Also
`+ bundleForClass:` (NSBundle)

Reducer
WhackedTV

Declared In
NSNibLoading.h

Instance Methods

contextHelpForKey:

Returns the context-sensitive help for the specified key from the bundle's help file.

```
- (NSAttributedString *)contextHelpForKey:(NSString *)key
```

Parameters

key

A key in your application's `Help.plist` file that identifies the context-sensitive help to return.

Return Value

The help string or `nil` if the application does not have a `Help.plist` file or the file does not contain an entry for the specified *key*.

Discussion

When you build your application, you can merge multiple RTF-based help files together using the `/usr/bin/compileHelp` tool, which then packages your help file information into a property list named `Help.plist`. After placing this property-list file in your application bundle, you can use this method to extract context help information from it. To look up a particular entry, you specify the name of the original RTF help file in the *key* parameter of this method. For example, if your application project contains a help file named `Copy.rtf`, you would retrieve the text from this file by passing the value `@"Copy.rtf"` to the *key* parameter.

This method is declared in `NSHelpManager.h`.

Availability

Available in Mac OS X v10.0 and later.

See Also

`- contextHelpForObject:` (page 1317) (NSHelpManager)

Declared In

`NSHelpManager.h`

loadNibFile:externalNameTable:withZone:

Unarchives the contents of a nib file located in the receiver's bundle.

```
- (BOOL)loadNibFile:(NSString *)fileName externalNameTable:(NSDictionary *)context
    withZone:(NSZone *)zone
```

Parameters

fileName

The name of the nib file, which need not include the `.nib` extension.

context

A name table whose keys identify objects associated with your program or the nib file. The newly unarchived objects from the nib file use this table to connect to objects in your program. For example, the nib file uses the object associated with the `NSNibOwner` constant as the nib file's owning object. If you associate an empty `NSMutableArray` object with the `NSNibTopLevelObjects` constant, on output, the array contains the top level objects from the nib file. For descriptions of these constants, see *NSNib Class Reference*.

zone

The memory zone in which to allocate the nib file objects.

Return Value

`YES` if the nib file was loaded successfully; otherwise, `NO`.

Discussion

This method searches the language-specific project (`.lproj`) directories for the specified nib file. If the file is not there, it searches the bundle's `Resources` directory for a nonlocalized version of the file.

This method is declared in `NSNibLoading.h`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSNibLoading.h`

pathForImageResource:

Returns the location of the specified image resource file.

```
- (NSString *)pathForImageResource:(NSString *)name
```

Parameters

name

The name of the image resource file, without any pathname information. Including a filename extension is optional.

Return Value
The absolute pathname of the resource file or `nil` if the file was not found.

Discussion
Image resources are those files in the bundle that are recognized by the `NSImage` class, including those that can be converted using the Image IO framework.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `pathForResource:ofType:` (NSBundle)
- `URLForImageResource:` (page 468)

Related Sample Code

FilterDemo
LayerBackedOpenGLView

Declared In
`NSImage.h`

pathForSoundResource:

Returns the location of the specified sound resource file.

```
- (NSString *)pathForSoundResource:(NSString *)name
```

Parameters

name

The name of the sound resource file, without any pathname information. Including a filename extension is optional

Return Value
The absolute pathname of the resource file or `nil` if the file was not found.

Discussion
Sound resources are those files in the bundle that are recognized by the `NSSound` class. The types of sound files can be determined by calling the `soundUnfilteredFileTypes` (page 2467) method of `NSSound`.

This method is declared in `NSSound.h`.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- pathForResource:ofType:` (NSBundle)

Declared In
`NSSound.h`

URLForImageResource:

Returns the location of the specified image resource as an NSURL.

```
- (NSURL *)URLForImageResource:(NSString *)name
```

Parameters

name

The name of the image resource file. Including a filename extension is optional.

Return Value
An `NSURL` for the resource file or `nil` if the file was not found.

Availability
Available in Mac OS X v10.6 and later.

Overview

The `NSButton` class is a subclass of `NSControl` that intercepts mouse-down events and sends an action message to a target object when it's clicked or pressed.

The `NSButton` class uses NSButtonCell to implement its user interface.

`NSButton` and `NSMatrix` both provide a control view, which is needed to display an `NSButtonCell` object. However, while `NSMatrix` requires you to access the `NSButtonCell` objects directly, most of the `NSButton` class' methods are "covers" for identically declared methods in `NSButtonCell`. (In other words, the implementation of the `NSButton` method invokes the corresponding `NSButtonCell` method for you, allowing you to be unconcerned with the existence of the `NSButtonCell`.) The only `NSButtonCell` methods that don't have covers relate to the font used to display the key equivalent and to specific methods for highlighting or showing the state of the `NSButton` (these last are usually set together with the `NSButton setButtonType:` (page 482) method).

Tasks

Configuring Buttons

- `setButtonType:` (page 482)
  Sets how the receiver button highlights while pressed and how it shows its state.
- `getPeriodicDelay:interval:` (page 474)
  Returns by reference the delay and interval periods for a continuous button.
- `setPeriodicDelay:interval:` (page 485)
  Sets the message delay and interval periods for a continuous button.
- `alternateTitle` (page 473)
  Returns the title that the button displays when it's in its alternate state.
- `setAlternateTitle:` (page 479)
  Sets the title that appears on the button when it's in its alternate state.
- `attributedTitle` (page 474)
  Returns the title that the button displays in its normal state as an attributed string.
- `setAttributedTitle:` (page 480)
  Sets the string that appears on the button when it's in its normal state to the given attributed string and redraws the button.
- `attributedAlternateTitle` (page 473)
  Returns the title that the button displays when it's in its alternate state as an attributed string.
- `setAttributedAlternateTitle:` (page 480)
  Sets the title that appears on the button when it's in its alternate state to the given attributed string.
- `title` (page 490)
  Returns the title displayed on the button when it's in its normal state.
- `setTitle:` (page 487)
  Sets the title displayed by the receiver when in its normal state and, if necessary, redraws the button's contents.
- `setTitleWithMnemonic:` (page 488)
  Sets the title of a button with a character denoting an access key.
- `setSound:` (page 486)
  Sets the sound played when the user presses the button.
- `sound` (page 489)
  Returns the sound that's played when the user presses the button.

Configuring Button Images

- `image` (page 475)
  Returns the image that appears on the receiver when it's in its normal state.
- `setImage:` (page 482)
  Sets the receiver's image and redraws the button.
- `alternateImage` (page 472)
  Returns the image that appears on the button when it's in its alternate state.

- `setAlternateImage:` (page 479)
  Sets the image displayed by the button when it's in its alternate state and, if necessary, redraws the contents of the button.
- `imagePosition` (page 476)
  Returns the position of the receiver's image relative to its title.
- `setImagePosition:` (page 483)
  Sets the position of the button's image relative to its title.
- `isBordered` (page 476)
  Returns a Boolean value indicating whether the button has a border.
- `setBordered:` (page 481)
  Sets whether the receiver has a bezeled border.
- `isTransparent` (page 477)
  Returns a Boolean value indicating whether the button is transparent.
- `setTransparent:` (page 488)
  Sets whether the receiver is transparent and redraws the receiver if necessary.
- `bezelStyle` (page 474)
  Returns the appearance of the receiver's border.
- `setBezelStyle:` (page 481)
  Sets the appearance of the border, if the receiver has one.
- `showsBorderOnlyWhileMouseInside` (page 489)
  Returns a Boolean value indicating whether the button displays its border only when the cursor is over it.
- `setShowsBorderOnlyWhileMouseInside:` (page 485)
  Sets whether the receiver's border is displayed only when the cursor is over the button.

Managing Button State

- `allowsMixedState` (page 472)
  Returns a Boolean value indicating whether the button allows a mixed state.
- `setAllowsMixedState:` (page 478)
  Sets whether the button allows a mixed state.
- `state` (page 489)
  Returns the receiver's state.
- `setState:` (page 486)
  Sets the cell's state to the specified value.
- `setNextState` (page 484)
  Sets the receiver to its next state.
- `highlight:` (page 475)
  Highlights (or unhighlights) the receiver.

Accessing Key Equivalents

- `keyEquivalent` (page 477)
  Returns the key-equivalent character of the receiver.

- `setKeyEquivalent:` (page 483)
  Sets the key equivalent character of the receiver to the given character.
- `keyEquivalentModifierMask` (page 477)
  Returns the mask specifying the modifier keys for the receiver's key equivalent.
- `setKeyEquivalentModifierMask:` (page 484)
  Sets the mask indicating the modifier keys used by the receiver's key equivalent.

Handling Keyboard Events

- `performKeyEquivalent:` (page 478)
  Checks the button's key equivalent against the specified event and, if they match, simulates the button being clicked.

Instance Methods

allowsMixedState

Returns a Boolean value indicating whether the button allows a mixed state.

```
- (BOOL)allowsMixedState
```

Return Value
`YES` if the receiver has three states: on, off, and mixed. `NO` if the receiver has two states: on and off. The default is `NO`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setAllowsMixedState:` (page 478)
- `setNextState` (page 484)

Declared In
`NSButton.h`

alternateImage

Returns the image that appears on the button when it's in its alternate state.

```
- (NSImage *)alternateImage
```

Return Value
The image displayed by the button when it's in its alternate state, or `nil` if there is no alternate image. Note that some button types don't display an alternate image. Buttons don't display images by default.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setAlternateImage:` (page 479)
- `image` (page 475)
- `imagePosition` (page 476)
- `keyEquivalent` (page 477)
- `setButtonType:` (page 482)

Declared In
`NSButton.h`

alternateTitle

Returns the title that the button displays when it's in its alternate state.

```
- (NSString *)alternateTitle
```

Return Value
The string that appears on the receiver when it's in its alternate state, or the empty string if the receiver doesn't display an alternate title. By default, a button's alternate title is "Button."

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setAlternateTitle:` (page 479)
- `attributedAlternateTitle` (page 473)
- `setButtonType:` (page 482)
- `title` (page 490)

Declared In
`NSButton.h`

attributedAlternateTitle

Returns the title that the button displays when it's in its alternate state as an attributed string.

```
- (NSAttributedString *)attributedAlternateTitle
```

Return Value
The string that appears on the receiver when it's in its alternate state, as an `NSAttributedString`, or the empty string if the receiver doesn't display an alternate title. By default, a button's alternate title is "Button."

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setAttributedAlternateTitle:` (page 480)
- `attributedTitle` (page 474)
- `setButtonType:` (page 482)

Declared In
NSButton.h

attributedTitle

Returns the title that the button displays in its normal state as an attributed string.

```
- (NSAttributedString *)attributedTitle
```

Return Value
The string that appears on the receiver when it's in its normal state as an `NSAttributedString`, or an empty attributed string if the receiver doesn't display a title.

A button's title is always displayed if the button doesn't use its alternate contents for highlighting or displaying the alternate state. By default, a button's title is "Button."

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setAttributedTitle:` (page 480)
- `attributedAlternateTitle` (page 473)
- `setButtonType:` (page 482)

Declared In
NSButton.h

bezelStyle

Returns the appearance of the receiver's border.

```
- (NSBezelStyle)bezelStyle
```

Return Value
The bezel style of the button. See the "Constants" (page 521) section of NSButtonCell (page 491) for the list of possible values.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setBezelStyle:` (page 481)

Declared In
NSButton.h

getPeriodicDelay:interval:

Returns by reference the delay and interval periods for a continuous button.

```
- (void)getPeriodicDelay:(float *)delay interval:(float *)interval
```

Parameters

delay

On return, the amount of time (in seconds) the button will pause before starting to periodically send action messages to the target object. The default delay is taken from a user's default (60 seconds maximum). If the user hasn't specified a default value, *delay* defaults to 0.4 seconds,

interval

On return, the amount of time (in seconds) between each action message that is sent. The default interval is taken from a user's default (60 seconds maximum). If the user hasn't specified a default value, *interval* defaults to 0.075 seconds.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `isContinuous` (page 822) (NSControl)

Declared In
`NSButton.h`

highlight:

Highlights (or unhighlights) the receiver.

```
- (void)highlight:(BOOL)flag
```

Parameters

flag

`YES` to highlight the button; `NO` to unhighlight the button. If the current state of the button matches *flag*, no action is taken.

Discussion
Highlighting may involve the button appearing "pushed in" to the screen, displaying its alternate title or image, or causing the button to appear to be "lit."

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setButtonType:` (page 482)

Declared In
`NSButton.h`

image

Returns the image that appears on the receiver when it's in its normal state.

```
- (NSImage *)image
```

Return Value
The image displayed by the button when it's in its normal state, or `nil` if there is no such image. This image is always displayed on a button that doesn't change its contents when highlighting or showing its alternate state. Buttons don't display images by default.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setImage:` (page 482)
- `alternateImage` (page 472)
- `setButtonType:` (page 482)

Declared In
`NSButton.h`

imagePosition

Returns the position of the receiver's image relative to its title.

```
- (NSCellImagePosition)imagePosition
```

Return Value
The position of the button's image. This is one of the image positions described in the "Constants" (page 613) section of NSCell (page 533).

Discussion
If the title is above, below, or overlapping the image, or if there is no image, the text is horizontally centered within the button.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setImagePosition:` (page 483)
- `setButtonType:` (page 482)
- `setImage:` (page 482)
- `setTitle:` (page 487)

Declared In
`NSButton.h`

isBordered

Returns a Boolean value indicating whether the button has a border.

```
- (BOOL)isBordered
```

Return Value
`YES` if the receiver has a border, `NO` otherwise. A button's border isn't the single line of most other controls' borders—instead, it's a raised bezel. By default, buttons are bordered.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setBordered:` (page 481)

Declared In
NSButton.h

isTransparent

Returns a Boolean value indicating whether the button is transparent.

```
- (BOOL)isTransparent
```

Return Value
YES if the receiver is transparent, NO otherwise. A transparent button never draws itself, but it receives mouse-down events and tracks the mouse properly.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setTransparent: (page 488)

Declared In
NSButton.h

keyEquivalent

Returns the key-equivalent character of the receiver.

```
- (NSString *)keyEquivalent
```

Return Value
The button's key equivalent, or the empty string if one hasn't been defined. Buttons don't have a default key equivalent.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setKeyEquivalent: (page 483)
- performKeyEquivalent: (page 478)
- keyEquivalentFont (page 504) (NSButtonCell)

Declared In
NSButton.h

keyEquivalentModifierMask

Returns the mask specifying the modifier keys for the receiver's key equivalent.

```
- (NSUInteger)keyEquivalentModifierMask
```

Return Value
The mask specifying the modifier keys that are applied to the button's key equivalent. Mask bits are defined in `NSEvent.h`. The only mask bits relevant in button key-equivalent modifier masks are `NSControlKeyMask`, `NSAlternateKeyMask`, and `NSCommandKeyMask`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setKeyEquivalentModifierMask:` (page 484)
- `keyEquivalent` (page 477)

Declared In
`NSButton.h`

performKeyEquivalent:

Checks the button's key equivalent against the specified event and, if they match, simulates the button being clicked.

```
- (BOOL)performKeyEquivalent:(NSEvent *)anEvent
```

Parameters
anEvent
The event containing the key equivalent.

Return Value
`YES` if the key equivalent in anEvent matches the button's key equivalent; `NO` if it does not. This method also returns `NO` if he receiver is blocked by a modal panel or the button is disabled.

Discussion
If the character in *anEvent* matches the receiver's key equivalent, and the modifier flags in *anEvent* match the key-equivalent modifier mask, `performKeyEquivalent:` simulates the user clicking the button and returning `YES`. Otherwise, `performKeyEquivalent:` does nothing and returns `NO`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `keyEquivalent` (page 477)
- `keyEquivalentModifierMask` (page 477)

Declared In
`NSButton.h`

setAllowsMixedState:

Sets whether the button allows a mixed state.

```
- (void)setAllowsMixedState:(BOOL)flag
```

Parameters

flag

YES to indicate that the receiver has three states: on, off, and mixed. If flag is NO, the receiver has two states: on and off.

Availability
Available in Mac OS X v10.0 and later.

See Also
- allowsMixedState (page 472)
- setNextState (page 484)

Quartz Composer WWDC 2005 TextEdit

Declared In
NSButton.h

setAlternateImage:

Sets the image displayed by the button when it's in its alternate state and, if necessary, redraws the contents of the button.

```
- (void)setAlternateImage:(NSImage *)image
```

Parameters

image

The image that appears on the receiver when it's in its alternate state. Note that some button types don't display an alternate image.

Availability
Available in Mac OS X v10.0 and later.

See Also
- alternateImage (page 472)
- setButtonType: (page 482)
- setImage: (page 482)

Declared In
NSButton.h

setAlternateTitle:

Sets the title that appears on the button when it's in its alternate state.

```
- (void)setAlternateTitle:(NSString *)aString
```

Parameters

aString

The string to set as the button's alternate title. Note that some button types don't display an alternate title.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `alternateTitle` (page 473)
- `setTitle:` (page 487)
- `setTitleWithMnemonic:` (page 488)
- `setButtonType:` (page 482)
- `setFont:` (page 511) (`NSButtonCell`)

Declared In
`NSButton.h`

setAttributedAlternateTitle:

Sets the title that appears on the button when it's in its alternate state to the given attributed string.

```
- (void)setAttributedAlternateTitle:(NSAttributedString *)aString
```

Parameters

aString

The attributed string to set as the button's alternate title. Note that some button types don't display an alternate title.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `attributedAlternateTitle` (page 473)
- `setAttributedTitle:` (page 480)
- `setButtonType:` (page 482)
- `setFont:` (page 511) (`NSButtonCell`)

Declared In
`NSButton.h`

setAttributedTitle:

Sets the string that appears on the button when it's in its normal state to the given attributed string and redraws the button.

```
- (void)setAttributedTitle:(NSAttributedString *)aString
```

Parameters

aString

The attributed string to set as the button's title. The title is always shown on buttons that don't use their alternate contents when highlighting or displaying their alternate state.

Discussion

Availability
Available in Mac OS X v10.0 and later.

See Also
- `attributedTitle` (page 474)
- `setAttributedAlternateTitle:` (page 480)
- `setButtonType:` (page 482)
- `setFont:` (page 511) (`NSButtonCell`)

Declared In
`NSButton.h`

setBezelStyle:

Sets the appearance of the border, if the receiver has one.

```
- (void)setBezelStyle:(NSBezelStyle)bezelStyle
```

Parameters

`bezelStyle`

The bezel style of the button. This must be one of the bezel styles described in the "Constants" (page 521) section of NSButtonCell (page 491).

If the button is not bordered, the bezel style is ignored.

Discussion
The button uses shading to look like it's sticking out or pushed in. You can set the shading with the `NSButtonCell` method `setGradientType:` (page 512).

Availability
Available in Mac OS X v10.0 and later.

See Also
- `bezelStyle` (page 474)

Related Sample Code
FunHouse

Declared In
`NSButton.h`

setBordered:

Sets whether the receiver has a bezeled border.

```
- (void)setBordered:(BOOL)flag
```

Parameters

`flag`

`YES` if the receiver should display a border; `NO` if it should not. A button's border is not the single line of most other controls' borders—instead, it's a raised bezel.

Discussion
This method redraws the button if `setBordered:` causes the bordered state to change.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `isBordered` (page 476)

Related Sample Code
FunHouse

Declared In
`NSButton.h`

setButtonType:

Sets how the receiver button highlights while pressed and how it shows its state.

```
- (void)setButtonType:(NSButtonType)aType
```

Parameters

aType

A constant specifying the type of the button—one of the constants described in the Constants section of `NSButtonCell`.

Discussion
`setButtonType:` redisplays the button before returning.

The types available are for the most common button types, which are also accessible in Interface Builder. You can configure different behavior with the `NSButtonCell` methods `setHighlightsBy:` (page 512) and `setShowsStateBy:` (page 517).

Note that there is no `-buttonType` method. The set method sets various button properties that together establish the behavior of the type.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setAlternateImage:` (page 479)
- `setImage:` (page 482)
- `setButtonType:` (page 511) (`NSButtonCell`)

Related Sample Code
FunHouse

Declared In
`NSButton.h`

setImage:

Sets the receiver's image and redraws the button.

```
- (void)setImage:(NSImage *)anImage
```

Parameters

anImage

The button's image. A button's image is displayed when the button is in its normal state, or all the time for a button that doesn't change its contents when highlighting or displaying its alternate state.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `image` (page 475)
- `setImagePosition:` (page 483)
- `setAlternateImage:` (page 479)
- `setButtonType:` (page 482)

Declared In
`NSButton.h`

setImagePosition:

Sets the position of the button's image relative to its title.

```
- (void)setImagePosition:(NSCellImagePosition)aPosition
```

Parameters

aPosition

A constant specifying the position of the button's image. See the "Constants" (page 613) section of NSCell (page 533) for a listing of possible values.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `imagePosition` (page 476)

Related Sample Code
ButtonMadness
FunHouse

Declared In
`NSButton.h`

setKeyEquivalent:

Sets the key equivalent character of the receiver to the given character.

```
- (void)setKeyEquivalent:(NSString *)charCode
```

Parameters

charCode

The character to set as the button's key equivalent.

Discussion

This method redraws the button's interior if it displays a key equivalent instead of an image. The key equivalent isn't displayed if the image position is set to `NSNoImage`, `NSImageOnly`, or `NSImageOverlaps`; that is, the button must display both its title and its "image" (the key equivalent in this case), and they must not overlap.

To display a key equivalent on a button, set the image and alternate image to `nil`, then set the key equivalent, then set the image position.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `keyEquivalent` (page 477)
- `performKeyEquivalent:` (page 478)
- `setAlternateImage:` (page 479)
- `setImage:` (page 482)
- `setImagePosition:` (page 483)
- `setKeyEquivalentFont:` (page 515) (NSButtonCell)

Declared In

`NSButton.h`

setKeyEquivalentModifierMask:

Sets the mask indicating the modifier keys used by the receiver's key equivalent.

```
- (void)setKeyEquivalentModifierMask:(NSUInteger)mask
```

Parameters

mask

The mask identifying the modifier keys to be applied to the button's key equivalent.

Mask bits are defined in `NSEvent.h`. The only mask bits relevant in button key-equivalent modifier masks are `NSControlKeyMask`, `NSAlternateKeyMask`, and `NSCommandKeyMask`.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `keyEquivalentModifierMask` (page 477)
- `setKeyEquivalent:` (page 483)

Declared In

`NSButton.h`

setNextState

Sets the receiver to its next state.

```
- (void)setNextState
```

Discussion
If the button has three states, it cycles through them in this order: on, off, mixed, on, and so forth. If the button has two states, it toggles between them.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `allowsMixedState` (page 472)
- `setAllowsMixedState:` (page 478)

Declared In
`NSButton.h`

setPeriodicDelay:interval:

Sets the message delay and interval periods for a continuous button.

```
- (void)setPeriodicDelay:(float)delay interval:(float)interval
```

Parameters

delay

The amount of time (in seconds) that a continuous button will pause before starting to periodically send action messages to the target object. The maximum allowed value is 60.0 seconds; if a larger value is supplied, it is ignored, and 60.0 seconds is used.

interval

The amount of time (in seconds) between each action message. The maximum value is 60.0 seconds; if a larger value is supplied, it is ignored, and 60.0 seconds is used.

Discussion
The delay and interval values are used if the button is configured (by a `setContinuous:` (page 830) message) to continuously send the action message to the target object while tracking the mouse.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setContinuous:` (page 830) (`NSControl`)

Declared In
`NSButton.h`

setShowsBorderOnlyWhileMouseInside:

Sets whether the receiver's border is displayed only when the cursor is over the button.

```
- (void)setShowsBorderOnlyWhileMouseInside:(BOOL)show
```

Parameters

show

YES to display the border only when the cursor is within the button's border and the button is active. NO, to continue to display the button's border when the cursor is outside the button's bounds.

Discussion

If isBordered (page 476) returns NO, the border is never displayed, regardless of what this method returns.

Availability

Available in Mac OS X v10.0 and later.

See Also

- showsBorderOnlyWhileMouseInside (page 489)

Declared In

NSButton.h

setSound:

Sets the sound played when the user presses the button.

```
- (void)setSound:(NSSound *)aSound
```

Parameters

aSound

The sound that should be played when the user presses the button. The sound is played during a mouse-down event, such as NSLeftMouseDown.

Availability

Available in Mac OS X v10.0 and later.

See Also

- sound (page 489)

Declared In

NSButton.h

setState:

Sets the cell's state to the specified value.

```
- (void)setState:(NSInteger)value
```

Parameters

value

The state of the button. This can be NSOnState, NSOffState,NSMixedState. See the discussion for a more detailed explanation.

Discussion

If necessary, this method also redraws the receiver.

The cell can have two or three states. If it has two, *value* can be NSOffState (the normal or unpressed state) and NSOnState (the alternate or pressed state). If it has three, *value* can be NSOnState (the feature is in effect everywhere), NSOffState (the feature is in effect nowhere), or NSMixedState (the feature is in effect somewhere). Note that if the cell has only two states and *value* is NSMixedState, this method sets the cell's state to NSOnState.

Although using the enumerated constants is preferred, *value* can also be an integer. If the cell has two states, 0 is treated as NSOffState, and a nonzero value is treated as NSOnState. If the cell has three states, 0 is treated as NSOffState; a negative value, as NSMixedState; and a positive value, as NSOnState.

To check whether the button uses the mixed state, use the method allowsMixedState (page 472).

Availability
Available in Mac OS X v10.0 and later.

See Also
- state (page 489)

Declared In
NSButton.h

setTransparent:

Sets whether the receiver is transparent and redraws the receiver if necessary.

```
- (void)setTransparent:(BOOL)flag
```

Parameters
flag
YES if the button is transparent; otherwise NO.

Discussion
A transparent button tracks the mouse and sends its action, but doesn't draw. A transparent button is useful for sensitizing an area on the screen so that an action gets sent to a target when the area receives a mouse click.

Availability
Available in Mac OS X v10.0 and later.

See Also
- isTransparent (page 477)

NSButton.h

showsBorderOnlyWhileMouseInside

Returns a Boolean value indicating whether the button displays its border only when the cursor is over it.

```
- (BOOL)showsBorderOnlyWhileMouseInside
```

Return Value
`YES` if the receiver's border is displayed only when the cursor is over the button and the button is active; `NO` if the border is displayed all the time.

By default, this method returns `NO`.

Discussion
If `isBordered` (page 476) returns `NO`, the border is never displayed, regardless of what this method returns.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setShowsBorderOnlyWhileMouseInside:` (page 485)

Declared In
`NSButton.h`

sound

Returns the sound that's played when the user presses the button.

```
- (NSSound *)sound
```

Return Value
The sound played when the user presses the button.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setSound:` (page 486)

Declared In
`NSButton.h`

state

Returns the receiver's state.

```
- (NSInteger)state
```

Return Value
The button's state. A button can have two or three states. If it has two, this value is either `NSOffState` (the normal or unpressed state) or `NSOnState` (the alternate or pressed state). If it has three, this value can be `NSOnState` (the feature is in effect everywhere), `NSOffState` (the feature is in effect nowhere), or `NSMixedState` (the feature is in effect somewhere).

Discussion
To check whether the button uses the mixed state, use the method `allowsMixedState` (page 472).

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setState:` (page 486)

Related Sample Code
DatePicker

FinalCutPro_AppleEvents
GLUT
WhackedTV

Declared In
`NSButton.h`

title

Returns the title displayed on the button when it's in its normal state.

```
- (NSString *)title
```

Return Value
The title displayed on the receiver when it's in its normal state or the empty string if the button doesn't display a title. This title is always displayed if the button doesn't use its alternate contents for highlighting or displaying the alternate state. By default, a button's title is "Button."

Availability
Available in Mac OS X v10.0 and later.

NSButtonCell Class Reference

Inherits from	NSActionCell : NSCell : NSObject
Conforms to	NSCoding (NSCell) NSCopying (NSCell) NSObject (NSObject)
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.0 and later.
Declared in	AppKit/NSButtonCell.h
Companion guide	Button Programming Topics
Related sample code	ButtonMadness DragNDropOutlineView FunkyOverlayWindow MyMediaPlayer QTAudioContextInsert

Overview

The `NSButtonCell` class is a subclass of `NSActionCell` used to implement the user interfaces of push buttons, checkboxes (switches), and radio buttons. It can also be used for any other region of a view that's designed to send a message to a target when clicked. The `NSButton` subclass of `NSControl` uses a single `NSButtonCell`.

The `NSButtonCell` class implements the user interface of `NSButton`.

Setting the integer, float, double, or object value of an `NSButtonCell` object results in a call to `setState:` (page 596) with the value converted to integer. In the case of `setObjectValue:` (page 592), `nil` is equivalent to 0, and a non-`nil` object that doesn't respond to `intValue` (page 565) sets the state to 1. Otherwise, the state is set to the object's `intValue` (page 565). Similarly, querying the integer, float, double, or object value of an `NSButtonCell` returns the current state in the requested representation. In the case of `objectValue` (page 572), this is an `NSNumber` containing `YES` for on, `NO` for off, and integer value -1 for the mixed state.

For more information on the behavior of `NSButtonCell`, see the `NSButton` and `NSMatrix` class specifications, and *Button Programming Topics*.

Exceptions

In its implementation of the `compare:` (page 550) method (declared in `NSCell`), `NSButtonCell` raises an `NSBadComparisonException` if the *`otherCell`* argument is not of the `NSButtonCell` class.

Tasks

Setting Titles

- `alternateMnemonic` (page 496)
  Returns the character in the alternate title that's marked as the "keyboard mnemonic."
- `alternateMnemonicLocation` (page 496)
  Returns an unsigned integer indicating the character in the alternate title that's marked as the "keyboard mnemonic."
- `alternateTitle` (page 497)
  Returns the string displayed by the button when it's in its alternate state.
- `attributedAlternateTitle` (page 497)
  Returns the title displayed by the button when it's in its alternate state, as an attributed string.
- `attributedTitle` (page 498)
  Returns the title displayed by the button when it's in its normal state as an attributed string.
- `setAlternateMnemonicLocation:` (page 507)
  Sets the character in the alternate title that should be the "keyboard mnemonic."
- `setAlternateTitle:` (page 507)
  Sets the title the button displays when it's in its alternate state.
- `setAlternateTitleWithMnemonic:` (page 508)
  Sets the title the button displays when it's in its alternate state to the given string with an embedded mnemonic.
- `setAttributedAlternateTitle:` (page 508)
  Sets the string the button displays when it's in its alternate state to the given attributed string.
- `setAttributedTitle:` (page 509)
  Sets the string the button displays when it's in its normal state to the given attributed string and redraws the button.
- `setFont:` (page 511)
  Sets the font used to display the button's title and alternate title.
- `setTitle:` (page 518)
  Sets the title the button displays when in its normal state and, if necessary, redraws the receiver's contents.
- `setTitleWithMnemonic:` (page 519)
  Sets the title the button displays when it's in its normal state to the given string with an embedded mnemonic.
- `title` (page 521)
  Returns the title displayed on the receiver when it's in its normal state.

Managing Images

- `alternateImage` (page 495)
  Returns the image the button displays in its alternate state.
- `imagePosition` (page 502)
  Returns the position of the receiver's image relative to its title.
- `setAlternateImage:` (page 506)
  Sets the image the button displays in its alternate state and, if necessary, redraws its contents.
- `setImagePosition:` (page 513)
  Sets the position of the receiver's image relative to its title.
- `imageScaling` (page 503)
  Returns the scale factor for the receiver's image.
- `setImageScaling:` (page 514)
  Sets the scale factor for the receiver's image.

Managing the Repeat Interval

- `getPeriodicDelay:interval:` (page 501)
  Returns by reference the delay and interval periods for a continuous button.
- `setPeriodicDelay:interval:` (page 516)
  Sets the message delay and interval for the receiver.

Managing the Key Equivalent

- `keyEquivalent` (page 504)
  Returns the receiver's key-equivalent character.
- `keyEquivalentFont` (page 504)
  Returns the font used to draw the key equivalent.
- `keyEquivalentModifierMask` (page 505)
  Returns the mask identifying the modifier keys for the button's key equivalent.
- `setKeyEquivalent:` (page 514)
  Sets the key equivalent character of the receiver.
- `setKeyEquivalentModifierMask:` (page 516)
  Sets the mask identifying the modifier keys to use with the button's key equivalent.
- `setKeyEquivalentFont:` (page 515)
  Sets the font used to draw the key equivalent and redisplays the receiver if necessary.
- `setKeyEquivalentFont:size:` (page 515)
  Sets by name and size of the font used to draw the key equivalent.

Managing Graphics Attributes

- `backgroundColor` (page 498)
  Returns the background color of the receiver.

- `setBackgroundColor:` (page 510)
  Sets the background color of the receiver.
- `bezelStyle` (page 499)
  Returns the appearance of the receiver's border.
- `setBezelStyle:` (page 510)
  Sets the appearance of the border, if the receiver has one.
- `gradientType` (page 501)
  Returns the gradient of the receiver's border.
- `setGradientType:` (page 512)
  Sets the type of gradient to use for the receiver.
- `imageDimsWhenDisabled` (page 502)
  Returns a Boolean value that indicates whether the receiver's image and text appear "dim" when the receiver is disabled.
- `setImageDimsWhenDisabled:` (page 513)
  Sets whether the receiver's image appears "dim" when the button cell is disabled.
- `isOpaque` (page 503)
  Returns a Boolean value that indicates whether the receiver is opaque.
- `isTransparent` (page 504)
  Returns a Boolean value that indicates whether the receiver is transparent.
- `setTransparent:` (page 519)
  Sets whether the receiver is transparent.
- `showsBorderOnlyWhileMouseInside` (page 520)
  Returns a Boolean value indicating whether the button displays its border only when the cursor is over it.
- `setShowsBorderOnlyWhileMouseInside:` (page 517)
  Sets whether the receiver's border is displayed only when the cursor is over the button.

Displaying the Cell

- `highlightsBy` (page 501)
  Returns flags indicating how the button highlights when it receives a mouse-down event.
- `setHighlightsBy:` (page 512)
  Sets the way the receiver highlights itself while pressed.
- `setShowsStateBy:` (page 517)
  Sets the way the receiver indicates its alternate state.
- `setButtonType:` (page 511)
  Sets how the receiver highlights while pressed and how it shows its state.
- `showsStateBy` (page 520)
  Returns the flags indicating how the button cell shows its alternate state.

Managing the Sound

- `sound` (page 520)
  Returns the sound that's played when the user presses the receiver.

- `setSound:` (page 518)
  Sets the sound that's played when the user presses the receiver.

Handling Events and Action Messages

- `mouseEntered:` (page 505)
  Draws the receiver's border.
- `mouseExited:` (page 506)
  Erases the receiver's border.
- `performClick:` (page 506)
  Simulates the user clicking the receiver with the cursor.

Drawing the Button Content

- `drawBezelWithFrame:inView:` (page 499)
  Draws the border of the button using the current bezel style.
- `drawImage:withFrame:inView:` (page 499)
  Draws the image associated with the button's current state.
- `drawTitle:withFrame:inView:` (page 500)
  Draws the button's title centered vertically in a specified rectangle.

Instance Methods

alternateImage

Returns the image the button displays in its alternate state.

```
- (NSImage *)alternateImage
```

Return Value
The image displayed by the button when it's in its alternate state, or `nil` if there is no alternate image.

Discussion
Note that some button types don't display an alternate image. Buttons don't display images by default.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setAlternateImage:` (page 506)
- `imagePosition` (page 502)
- `keyEquivalent` (page 504)
- `setButtonType:` (page 511)
- `image` (page 562) (`NSCell`)

Declared In
NSButtonCell.h

alternateMnemonic

Returns the character in the alternate title that's marked as the "keyboard mnemonic."

```
- (NSString *)alternateMnemonic
```

Return Value
The character in the alternate title (the title displayed on the receiver when it's in its alternate state) marked as the "keyboard mnemonic."

Discussion
Mnemonics are not supported in Mac OS X.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `alternateMnemonicLocation` (page 496)
- `setAlternateTitleWithMnemonic:` (page 508)
- `mnemonic` (page 571) (`NSCell`)

Declared In
NSButtonCell.h

alternateMnemonicLocation

Returns an unsigned integer indicating the character in the alternate title that's marked as the "keyboard mnemonic."

```
- (NSUInteger)alternateMnemonicLocation
```

Return Value
An unsigned integer indicating the character in the alternate title (the title displayed on the receiver when it's in its alternate state) that's marked as the "keyboard mnemonic." If the alternate title doesn't have a keyboard mnemonic, returns `NSNotFound`.

Discussion
Mnemonics are not supported in Mac OS X.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setAlternateMnemonicLocation:` (page 507)
- `alternateMnemonic` (page 496)
- `setAlternateTitleWithMnemonic:` (page 508)
- `mnemonicLocation` (page 571) (`NSCell`)

Declared In
NSButtonCell.h

alternateTitle

Returns the string displayed by the button when it's in its alternate state.

```
- (NSString *)alternateTitle
```

Return Value
The string that appears on the button when it's in its alternate state, or the empty string if the receiver doesn't display an alternate title.

Discussion
Note that some button types don't display an alternate title. By default, a button's alternate title is "Button."

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setAlternateTitle:` (page 507)
- `alternateMnemonic` (page 496)
- `attributedAlternateTitle` (page 497)
- `setButtonType:` (page 511)
- `title` (page 521)

Declared In
NSButtonCell.h

attributedAlternateTitle

Returns the title displayed by the button when it's in its alternate state, as an attributed string.

```
- (NSAttributedString *)attributedAlternateTitle
```

Return Value
The attributed string that appears on the button when it's in its alternate state, or the empty string if the receiver doesn't display an alternate title.

Discussion
Note that some button types don't display an alternate title. By default, a button's alternate title is "Button."

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setAttributedAlternateTitle:` (page 508)
- `alternateMnemonic` (page 496)
- `attributedTitle` (page 498)
- `setButtonType:` (page 511)

Declared In
NSButtonCell.h

attributedTitle

Returns the title displayed by the button when it's in its normal state as an attributed string.

```
- (NSAttributedString *)attributedTitle
```

Return Value
The attributes string that appears on the button when it's in its normal state, or an empty attributed string if the receiver doesn't display a title.

Discussion
A button's title is always displayed if the button doesn't use its alternate contents for highlighting or displaying the alternate state. By default, a button's title is "Button."

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setAttributedTitle:` (page 509)
- `attributedAlternateTitle` (page 497)
- `setButtonType:` (page 511)
- `mnemonic` (page 571) (`NSCell`)

Declared In
NSButtonCell.h

backgroundColor

Returns the background color of the receiver.

```
- (NSColor *)backgroundColor
```

Return Value
The receiver's background color.

Discussion
The background color is used only when drawing borderless buttons.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `setBackgroundColor:` (page 510)

Declared In
NSButtonCell.h

bezelStyle

Returns the appearance of the receiver's border.

```
- (NSBezelStyle)bezelStyle
```

Return Value
A constant specifying the bezel style used by the button. See "Bezel Styles" (page 522) for a list of possible values.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setBezelStyle: (page 510)

Declared In
NSButtonCell.h

drawBezelWithFrame:inView:

Draws the border of the button using the current bezel style.

```
- (void)drawBezelWithFrame:(NSRect)frame inView:(NSView *)controlView
```

Parameters

frame
The bounding rectangle of the button.

controlView
The control being drawn.

Discussion
This method is called automatically when the button is redrawn; you should not call it directly.

Availability
Available in Mac OS X v10.4 and later.

See Also
- setBezelStyle: (page 510)

Declared In
NSButtonCell.h

drawImage:withFrame:inView:

Draws the image associated with the button's current state.

```
- (void)drawImage:(NSImage *)image withFrame:(NSRect)frame inView:(NSView
    *)controlView
```

Parameters

image
The image associated with the button's current state.

frame
The bounding rectangle of the button.

controlView
The control being drawn.

Discussion
This method is called automatically when the button is redrawn; you should not call it directly.

You specify the primary and alternate images for the button using Interface Builder.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `setAlternateImage:` (page 506)

Declared In
`NSButtonCell.h`

drawTitle:withFrame:inView:

Draws the button's title centered vertically in a specified rectangle.

```
- (NSRect)drawTitle:(NSAttributedString *)title withFrame:(NSRect)frame
    inView:(NSView *)controlView
```

Parameters
title
The title of the button.

frame
The rectangle in which to draw the title.

controlView
The control being drawn.

Return Value
The bounding rectangle for the text of the title.

Discussion
This method is called automatically when the button is redrawn; you should not call it directly.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `setAlternateTitle:` (page 507)
- `setAttributedTitle:` (page 509)

Declared In
`NSButtonCell.h`

getPeriodicDelay:interval:

Returns by reference the delay and interval periods for a continuous button.

```
- (void)getPeriodicDelay:(float *)delay interval:(float *)interval
```

Parameters

delay

On return, the amount of time (in seconds) that the button will pause before starting to periodically send action messages to the target object. Default values are taken from the user's defaults (60 seconds maximum); if the user hasn't specified a default value, this defaults to 0.4 seconds.

interval

On return, the amount of time (in seconds) between each action message. Default values are taken from the user's defaults (60 seconds maximum); if the user hasn't specified a default value, this defaults to 0.075 seconds.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `isContinuous` (page 566)
- `isContinuous` (page 566) (`NSCell`)

Declared In
`NSButtonCell.h`

gradientType

Returns the gradient of the receiver's border.

```
- (NSGradientType)gradientType
```

Return Value
A constant specifying the gradient used for the button's border. See "Gradient Types" (page 526) for a list of possible values.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setGradientType:` (page 512)

Declared In
`NSButtonCell.h`

highlightsBy

Returns flags indicating how the button highlights when it receives a mouse-down event.

```
- (NSInteger)highlightsBy
```

Return Value
The logical OR of flags that indicate the way the receiver highlights when it receivers a mouse-down event. See the "Constants" (page 613) section of NSCell (page 533) for the list of flags.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setHighlightsBy:` (page 512)
- `showsStateBy` (page 520)

Related Sample Code
MyMediaPlayer

Declared In
`NSButtonCell.h`

imageDimsWhenDisabled

Returns a Boolean value that indicates whether the receiver's image and text appear "dim" when the receiver is disabled.

```
- (BOOL)imageDimsWhenDisabled
```

Return Value
`YES` if the button's image and text are dimmed when the button is disabled, otherwise `NO`.

Discussion
By default, all button types except `NSSwitchButton` and `NSRadioButton` do dim when disabled. When buttons of type `NSSwitchButton` and `NSRadioButton` are disabled, only the associated text dims.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setButtonType:` (page 511)
- `setImageDimsWhenDisabled:` (page 513)

Declared In
`NSButtonCell.h`

imagePosition

Returns the position of the receiver's image relative to its title.

```
- (NSCellImagePosition)imagePosition
```

Return Value
The position of the button's image. This is one of the image positions described in the "Constants" (page 613) section of NSCell (page 533).

Discussion
If the title is above, below, or overlapping the image, or if there is no image, the text is horizontally centered within the button.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setImagePosition:` (page 513)
- `setButtonType:` (page 511)
- `setTitle:` (page 518)
- `setImage:` (page 589) (`NSCell`)

Declared In
`NSButtonCell.h`

imageScaling

Returns the scale factor for the receiver's image.

```
- (NSImageScaling)imageScaling
```

Return Value
The scale factor for the receiver's image.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSButtonCell.h`

isOpaque

Returns a Boolean value that indicates whether the receiver is opaque.

```
- (BOOL)isOpaque
```

Return Value
`YES` if the receiver draws over every pixel in its frame, otherwise `NO`.

Discussion
A button cell is opaque only if it isn't transparent and if it has a border.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `isTransparent` (page 504)
- `setTransparent:` (page 519)

Declared In
`NSButtonCell.h`

isTransparent

Returns a Boolean value that indicates whether the receiver is transparent.

```
- (BOOL)isTransparent
```

Return Value
`YES` if the receiver is transparent, `NO` otherwise.

Discussion
A transparent button never draws itself, but it receives mouse-down events and tracks the mouse properly.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setTransparent:` (page 519)
- `isOpaque` (page 503)

Declared In
`NSButtonCell.h`

keyEquivalent

Returns the receiver's key-equivalent character.

```
- (NSString *)keyEquivalent
```

Return Value
The string containing the key equivalent character of the button, or the empty string if one hasn't been defined.

Discussion
Buttons don't have a default key equivalent.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setKeyEquivalent:` (page 514)
- `keyEquivalentFont` (page 504)

Declared In
`NSButtonCell.h`

keyEquivalentFont

Returns the font used to draw the key equivalent.

```
- (NSFont *)keyEquivalentFont
```

Return Value
The font object describing the font used to draw the button's key equivalent, or `nil` if the receiver doesn't have a key equivalent.

Discussion
The default font is the same as that used to draw the title.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setKeyEquivalentFont:` (page 515)
- `setKeyEquivalentFont:size:` (page 515)
- `setFont:` (page 511)

Declared In
`NSButtonCell.h`

keyEquivalentModifierMask

Returns the mask identifying the modifier keys for the button's key equivalent.

```
- (NSUInteger)keyEquivalentModifierMask
```

Return Value
A mask indicating the modifier keys that are applied to the receiver's key equivalent.

Mask bits are defined in `NSEvent.h`. The only mask bits relevant in button key-equivalent modifier masks are `NSControlKeyMask`, `NSAlternateKeyMask`, and `NSCommandKeyMask` bits.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setKeyEquivalentModifierMask:` (page 516)
- `keyEquivalent` (page 504)

Declared In
`NSButtonCell.h`

mouseEntered:

Draws the receiver's border.

```
- (void)mouseEntered:(NSEvent *)event
```

Parameters
event
The event object generated by the mouse movement.

Discussion
This method is called only when the cursor moves onto the receiver and `showsBorderOnlyWhileMouseInside` (page 520) returns `YES`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSButtonCell.h

mouseExited:

Erases the receiver's border.

```
- (void)mouseExited:(NSEvent *)event
```

Parameters

event
The event object generated by the mouse movement.

Discussion
This method is called only when the cursor moves off the receiver and `showsBorderOnlyWhileMouseInside` (page 520) returns `YES`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSButtonCell.h

performClick:

Simulates the user clicking the receiver with the cursor.

```
- (void)performClick:(id)sender
```

Parameters

sender
The sender of the message.

Discussion
This method essentially highlights the button, sends the button's action message to the target object, and then unhighlights the button. If an exception is raised while the target object is processing the action message, the button is unhighlighted before the exception is propagated out of `performClick:`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSButtonCell.h

setAlternateImage:

Sets the image the button displays in its alternate state and, if necessary, redraws its contents.

```
- (void)setAlternateImage:(NSImage *)image
```

Parameters

image

The image displayed by the button when it's in its alternate state.

Discussion

Note that some button types don't display an alternate image.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `alternateImage` (page 495)
- `setButtonType:` (page 511)
- `setImage:` (page 589) (`NSCell`)

Declared In

`NSButtonCell.h`

setAlternateMnemonicLocation:

Sets the character in the alternate title that should be the "keyboard mnemonic."

```
- (void)setAlternateMnemonicLocation:(NSUInteger)location
```

Parameters

location

An unsigned integer indicating the character in the alternate title that should be marked as the "keyboard mnemonic." If you don't want the alternate title to have a keyboard mnemonic, specify a location of `NSNotFound`.

Discussion

Mnemonics are not supported in Mac OS X.

The `setAlternateMnemonicLocation:` method doesn't cause the button cell to be redisplayed.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `alternateMnemonicLocation` (page 496)
- `setAlternateTitleWithMnemonic:` (page 508)

Declared In

`NSButtonCell.h`

setAlternateTitle:

Sets the title the button displays when it's in its alternate state.

```
- (void)setAlternateTitle:(NSString *)aString
```

Parameters

aString

The string to set as the button's title when it's in its alternate state.

Discussion

Note that some button types don't display an alternate title.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `alternateTitle` (page 497)
- `setAlternateMnemonicLocation:` (page 507)
- `setAlternateTitleWithMnemonic:` (page 508)
- `setTitle:` (page 518)
- `setButtonType:` (page 511)
- `setFont:` (page 511)

Declared In

`NSButtonCell.h`

setAlternateTitleWithMnemonic:

Sets the title the button displays when it's in its alternate state to the given string with an embedded mnemonic.

```
- (void)setAlternateTitleWithMnemonic:(NSString *)aString
```

Parameters

aString

The string to set as the button's alternate title, taking into account the fact that an embedded "&" character is not a literal but instead marks the alternate state's "keyboard mnemonic."

Discussion

Mnemonics are not supported in Mac OS X.

If necessary, `setAlternateTitleWithMnemonic:` redraws the button cell. Note that some button types don't display an alternate title.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `setAlternateMnemonicLocation:` (page 507)
- `setTitleWithMnemonic:` (page 519)

Declared In

`NSButtonCell.h`

setAttributedAlternateTitle:

Sets the string the button displays when it's in its alternate state to the given attributed string.

```
- (void)setAttributedAlternateTitle:(NSAttributedString *)aString
```

Parameters

aString

The attributed string to set as the button's alternate title.

Discussion

Note that some button types don't display an alternate title.

Graphics attributes that are set on the cell (`backgroundColor`, `alignment`, `font`, etc.) are overriden when corresponding properties are set for the attributed string.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `attributedAlternateTitle` (page 497)
- `setAlternateMnemonicLocation:` (page 507)
- `setAlternateTitleWithMnemonic:` (page 508)
- `setAttributedTitle:` (page 509)
- `setButtonType:` (page 511)
- `setFont:` (page 511)

Declared In

`NSButtonCell.h`

setAttributedTitle:

Sets the string the button displays when it's in its normal state to the given attributed string and redraws the button.

```
- (void)setAttributedTitle:(NSAttributedString *)aString
```

Parameters

aString

The attributed string to set as the button's title.

Discussion

The title is always shown on buttons that don't use their alternate contents when highlighting or displaying their alternate state.

Graphics attributes configured for the cell (`backgroundColor`, `alignment`, `font`, etc.) are overriden when corresponding properties are set for the attributed string.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `attributedTitle` (page 498)
- `setAttributedAlternateTitle:` (page 508)
- `setButtonType:` (page 511)
- `setFont:` (page 511)
- `setMnemonicLocation:` (page 592) (`NSCell`)

Declared In
NSButtonCell.h

setBackgroundColor:

Sets the background color of the receiver.

```
- (void)setBackgroundColor:(NSColor *)color
```

Parameters

color

The color to use for the receiver's background.

Discussion
The background color is used only when drawing borderless buttons.

Availability
Available in Mac OS X v10.4 and later.

See Also
- backgroundColor (page 498)

Declared In
NSButtonCell.h

setBezelStyle:

Sets the appearance of the border, if the receiver has one.

```
- (void)setBezelStyle:(NSBezelStyle)bezelStyle
```

Parameters

bezelStyle

A constant specifying the bezel style to use for the button. This must be one of the values specified in "Bezel Styles" (page 522).

If the receiver is not bordered, the bezel style is ignored.

Discussion
A button uses shading to look like it's sticking out or pushed in. You can set the shading with setGradientType: (page 512).

Availability
Available in Mac OS X v10.0 and later.

See Also
- bezelStyle (page 499)

Related Sample Code
Sketch+Accessibility

Declared In
NSButtonCell.h

setButtonType:

Sets how the receiver highlights while pressed and how it shows its state.

```
- (void)setButtonType:(NSButtonType)aType
```

Parameters

aType

A constant specifying the type of button. This can be one of the constants defined in "Button Types" (page 524).

Discussion

`setButtonType:` redisplays the receiver before returning.

The types available are for the most common button types, which are also accessible in Interface Builder; you can configure different behavior with the `setHighlightsBy:` (page 512) and `setShowsStateBy:` (page 517) methods.

Note that there is no `-buttonType` method. The set method sets various button properties that together establish the behavior of the type.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `setAlternateImage:` (page 506)
- `setImage:` (page 589) (`NSCell`)

Related Sample Code

ButtonMadness

Declared In

`NSButtonCell.h`

setFont:

Sets the font used to display the button's title and alternate title.

```
- (void)setFont:(NSFont *)fontObj
```

Parameters

fontObj

The font object specifying the font to use.

Discussion

This method does nothing if the receiver has no title or alternate title.

If the button cell has a key equivalent, its font is not changed, but the key equivalent's font size is changed to match the new title font.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `setKeyEquivalentFont:` (page 515)

- setKeyEquivalentFont:size: (page 515)
- font (page 558) (NSCell)

Related Sample Code
QTAudioContextInsert
QTAudioExtractionPanel
Quartz Composer WWDC 2005 TextEdit

Declared In
NSButtonCell.h

setGradientType:

Sets the type of gradient to use for the receiver.

```
- (void)setGradientType:(NSGradientType)gradientType
```

Parameters

gradientType

A constant specifying the gradient to use for the button's border. This can be one of the constants defined in "Gradient Types" (page 526).

Discussion
If the receiver has no border, this method has no effect on its appearance. A concave gradient is darkest in the top-left corner; a convex gradient is darkest in the bottom-right corner. Weak versus strong is how much contrast exists between the colors used in opposite corners.

Note: This method is currently unused by the Application Kit and has no effect.

Availability
Available in Mac OS X v10.0 and later.

See Also
- gradientType (page 501)

Related Sample Code
FunHouse

Declared In
NSButtonCell.h

setHighlightsBy:

Sets the way the receiver highlights itself while pressed.

```
- (void)setHighlightsBy:(NSInteger)aType
```

Parameters

aType

The logical OR of one or more of the cell masks described in the "Constants" (page 613) section of NSCell (page 533).

Discussion
If both `NSChangeGrayCellMask` and `NSChangeBackgroundCellMask` are specified, both are recorded, but which behavior is used depends on the button cell's image. If the button has no image, or if the image has no alpha (transparency) data, `NSChangeGrayCellMask` is used. If the image does have alpha data, `NSChangeBackgroundCellMask` is used; this arrangement allows the color swap of the background to show through the image's transparent pixels.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `highlightsBy` (page 501)
- `setShowsStateBy:` (page 517)

Related Sample Code
MyMediaPlayer

Declared In
`NSButtonCell.h`

setImageDimsWhenDisabled:

Sets whether the receiver's image appears "dim" when the button cell is disabled.

```
- (void)setImageDimsWhenDisabled:(BOOL)flag
```

Parameters

flag

`YES` to indicate that the button's image should dim when the button is disabled.

Discussion
By default, all button types except `NSSwitchButton` and `NSRadioButton` do dim when disabled. When `NSSwitchButton`s and `NSRadioButton`s are disabled, only the associated text dims. The default setting for this condition is reasserted whenever you invoke `setButtonType:` (page 511), so be sure to specify the button cell's type before you invoke `setImageDimsWhenDisabled:`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `imageDimsWhenDisabled` (page 502)

Declared In
`NSButtonCell.h`

setImagePosition:

Sets the position of the receiver's image relative to its title.

```
- (void)setImagePosition:(NSCellImagePosition)aPosition
```

Parameters

aPosition

A constant specifying the position of the button's image. See the "Constants" (page 613) section of NSCell (page 533) for a listing of possible values.

Availability
Available in Mac OS X v10.0 and later.

See Also
- imagePosition (page 502)

Related Sample Code
FunkyOverlayWindow

Declared In
NSButtonCell.h

setImageScaling:

Sets the scale factor for the receiver's image.

```
- (void)setImageScaling:(NSImageScaling)scaling
```

Parameters

scaling

The scale factor for the receiver's image.

Availability
Available in Mac OS X v10.5 and later.

Declared In
NSButtonCell.h

setKeyEquivalent:

Sets the key equivalent character of the receiver.

```
- (void)setKeyEquivalent:(NSString *)aKeyEquivalent
```

Parameters

aKeyEquivalent

The key equivalent character.

Discussion
This method redraws the receiver's inside if it displays a key equivalent instead of an image. The key equivalent isn't displayed if the image position is set to NSNoImage, NSImageOnly, or NSImageOverlaps; that is, the button must display both its title and its "image" (the key equivalent in this case), and they must not overlap.

To display a key equivalent on a button, set the image and alternate image to nil, then set the key equivalent, then set the image position.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `keyEquivalent` (page 504)
- `setAlternateImage:` (page 506)
- `setImagePosition:` (page 513)
- `setKeyEquivalentFont:` (page 515)
- `setImage:` (page 589) (NSCell)

Declared In
`NSButtonCell.h`

setKeyEquivalentFont:

Sets the font used to draw the key equivalent and redisplays the receiver if necessary.

```
- (void)setKeyEquivalentFont:(NSFont *)fontObj
```

Parameters

fontObj
The font object specifying the font to use for the receiver's key equivalent.

Discussion
This method does nothing if the receiver doesn't have a key equivalent associated with it.

The default font is the same as that used to draw the title.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `keyEquivalentFont` (page 504)
- `setFont:` (page 511)

Declared In
`NSButtonCell.h`

setKeyEquivalentFont:size:

Sets by name and size of the font used to draw the key equivalent.

```
- (void)setKeyEquivalentFont:(NSString *)fontName size:(CGFloat)fontSize
```

Parameters

fontName
The name of the font to use to draw the key equivalent.

fontSize
The font size to use to draw the key equivalent.

Discussion
This method redisplays the receiver if necessary. It does nothing if the receiver doesn't have a key equivalent associated with it. The default font is the same as that used to draw the title.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `keyEquivalentFont` (page 504)
- `setFont:` (page 511)

Declared In
`NSButtonCell.h`

setKeyEquivalentModifierMask:

Sets the mask identifying the modifier keys to use with the button's key equivalent.

```
- (void)setKeyEquivalentModifierMask:(NSUInteger)mask
```

Parameters

mask

The mask indicating the modifier keys to be applied to the receiver's key equivalent.

Mask bits are defined in `NSEvent.h`. The only mask bits relevant in button key-equivalent modifier masks are `NSControlKeyMask`, `NSAlternateKeyMask`, and `NSCommandKeyMask`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `keyEquivalentModifierMask` (page 505)
- `setKeyEquivalent:` (page 514)

Declared In
`NSButtonCell.h`

setPeriodicDelay:interval:

Sets the message delay and interval for the receiver.

```
- (void)setPeriodicDelay:(float)delay interval:(float)interval
```

Parameters

delay

The amount of time (in seconds) that a continuous button will pause before starting to periodically send action messages to the target object.

The maximum value is 60.0 seconds; if a larger value is supplied, it's ignored, and 60.0 seconds is used.

interval

The amount of time (in seconds) between each action message.

The maximum value is 60.0 seconds; if a larger value is supplied, it's ignored, and 60.0 seconds is used.

Discussion
These values are used if the receiver is configured (by a `setContinuous:` (page 582) message) to continuously send the action message to the target object while tracking the mouse.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setContinuous:` (page 582) (NSCell)

Declared In
`NSButtonCell.h`

setShowsBorderOnlyWhileMouseInside:

Sets whether the receiver's border is displayed only when the cursor is over the button.

```
- (void)setShowsBorderOnlyWhileMouseInside:(BOOL)show
```

Parameters

show

`YES` to display the button's border only when the cursor is within the receiver's border and the button is active. `NO` to continue to display the border when the cursor is outside button's bounds.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `showsBorderOnlyWhileMouseInside` (page 520)

Declared In
`NSButtonCell.h`

setShowsStateBy:

Sets the way the receiver indicates its alternate state.

```
- (void)setShowsStateBy:(NSInteger)aType
```

Parameters

aType

The logical `OR` of one or more of the cell masks described in the "Constants" (page 613) section of NSCell (page 533).

Discussion
If both `NSChangeGrayCellMask` and `NSChangeBackgroundCellMask` are specified, both are recorded, but the actual behavior depends on the button cell's image. If the button has no image, or if the image has no alpha (transparency) data, `NSChangeGrayCellMask` is used. If the image exists and has alpha data, `NSChangeBackgroundCellMask` is used; this arrangement allows the color swap of the background to show through the image's transparent pixels.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setHighlightsBy:` (page 512)
- `showsStateBy` (page 520)

Declared In
NSButtonCell.h

setSound:

Sets the sound that's played when the user presses the receiver.

```
- (void)setSound:(NSSound *)aSound
```

Parameters

aSound

The sound to play when the button is pressed.

Discussion
The sound is played during a mouse-down event, such as `NSLeftMouseDown`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `sound` (page 520)

Declared In
NSButtonCell.h

setTitle:

Sets the title the button displays when in its normal state and, if necessary, redraws the receiver's contents.

```
- (void)setTitle:(NSString *)aString
```

Parameters

aString

The string to set as the button's title.

Discussion
The title is always shown on buttons that don't use their alternate contents when highlighting or displaying their alternate state.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `title` (page 521)
- `setAlternateTitle:` (page 507)
- `setButtonType:` (page 511)
- `setFont:` (page 511)
- `setTitleWithMnemonic:` (page 519)

Related Sample Code
ButtonMadness

Declared In
NSButtonCell.h

setTitleWithMnemonic:

Sets the title the button displays when it's in its normal state to the given string with an embedded mnemonic.

```
- (void)setTitleWithMnemonic:(NSString *)aString
```

Parameters

aString

The string to set as the button's title, taking into account the fact that an embedded "&" character is not a literal but instead marks the alternate state's "keyboard mnemonic." This title is always shown on buttons that don't use their alternate contents when highlighting or displaying their alternate state.

Discussion
If necessary, `setTitleWithMnemonic:` redraws the button cell. Mnemonics are not supported in Mac OS X.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setAlternateTitleWithMnemonic:` (page 508)
- `setTitleWithMnemonic:` (page 599) (`NSCell`)
- `setMnemonicLocation:` (page 592) (`NSCell`)

Declared In
NSButtonCell.h

setTransparent:

Sets whether the receiver is transparent.

```
- (void)setTransparent:(BOOL)flag
```

Parameters

flag

`YES` to make the button cell transparent.

Discussion
This method redraws the receiver if necessary. A transparent button tracks the mouse and sends its action, but doesn't draw. A transparent button is useful for sensitizing an area on the screen so that an action gets sent to a target when the area receives a mouse click.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `isTransparent` (page 504)
- `isOpaque` (page 503)

Declared In
NSButtonCell.h

showsBorderOnlyWhileMouseInside

Returns a Boolean value indicating whether the button displays its border only when the cursor is over it.

```
- (BOOL)showsBorderOnlyWhileMouseInside
```

Return Value
YES if the receiver's border is displayed only when the cursor is over the button and the button is active.

Discussion
By default, this method returns NO.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setShowsBorderOnlyWhileMouseInside: (page 517)

Declared In
NSButtonCell.h

showsStateBy

Returns the flags indicating how the button cell shows its alternate state.

```
- (NSInteger)showsStateBy
```

Return Value
The logical OR of flags that indicate the way the receiver shows its alternate state. See the "Constants" (page 613) section of NSCell (page 533) for the list of flags.

Availability
Available in Mac OS X v10.0 and later.

See Also
- highlightsBy (page 501)
- setShowsStateBy: (page 517)

Declared In
NSButtonCell.h

sound

Returns the sound that's played when the user presses the receiver.

```
- (NSSound *)sound
```

Return Value
The sound played when the receiver is pressed.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setSound:` (page 518)

Declared In
`NSButtonCell.h`

title

Returns the title displayed on the receiver when it's in its normal state.

```
- (NSString *)title
```

Return Value
The title displayed by the button in its normal state, or the empty string if the button doesn't display a title.

Discussion
This title is always displayed if the button doesn't use its alternate contents for highlighting or displaying the alternate state. By default, a button's title is "Button."

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setTitle:` (page 518)
- `alternateTitle` (page 497)
- `setButtonType:` (page 511)
- `mnemonic` (page 571) (`NSCell`)
- `mnemonicLocation` (page 571) (`NSCell`)

Declared In
`NSButtonCell.h`

Constants

NSBezelStyle

Type to define bezel styles.

```
typedef NSUInteger NSBezelStyle;
```

Discussion
For possible values, see "Bezel Styles" (page 522).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSButtonCell.h`

Bezel Styles

Define the bezel styles used by `bezelStyle` (page 499) and `setBezelStyle:` (page 510).

```
enum {
    NSRoundedBezelStyle          = 1,
    NSRegularSquareBezelStyle    = 2,
    NSThickSquareBezelStyle      = 3,
    NSThickerSquareBezelStyle    = 4,
    NSDisclosureBezelStyle       = 5,
    NSShadowlessSquareBezelStyle = 6,
    NSCircularBezelStyle         = 7,
    NSTexturedSquareBezelStyle   = 8,
    NSHelpButtonBezelStyle       = 9,
    NSSmallSquareBezelStyle      = 10,
    NSTexturedRoundedBezelStyle  = 11,
    NSRoundRectBezelStyle        = 12,
    NSRecessedBezelStyle         = 13,
    NSRoundedDisclosureBezelStyle = 14,
}
```

Constants

`NSRoundedBezelStyle`

A rounded rectangle button, designed for text.

Available in Mac OS X v10.0 and later.

Declared in `NSButtonCell.h`.

`NSRegularSquareBezelStyle`

A rectangular button with a 2 point border, designed for icons.

Available in Mac OS X v10.0 and later.

Declared in `NSButtonCell.h`.

`NSThickSquareBezelStyle`

A rectangular button with a 3 point border, designed for icons.

Available in Mac OS X v10.0 and later.

Declared in `NSButtonCell.h`.

`NSThickerSquareBezelStyle`

A rectangular button with a 4 point border, designed for icons.

Available in Mac OS X v10.0 and later.

Declared in `NSButtonCell.h`.

`NSDisclosureBezelStyle`

A bezel style for use with a disclosure triangle.

To create the disclosure triangle, set the button bezel style to `NSDisclosureBezelStyle` and the button type to `NSOnOffButton`.

Available in Mac OS X v10.3 and later.

Declared in `NSButtonCell.h`.

`NSShadowlessSquareBezelStyle`
Similar to `NSRegularSquareBezelStyle`, but has no shadow so you can abut the cells without overlapping shadows.

This style would be used in a tool palette, for example.

Available in Mac OS X v10.0 and later.

Declared in `NSButtonCell.h`.

`NSCircularBezelStyle`
A round button with room for a small icon or a single character.

This style has both regular and small variants, but the large variant is available only in gray at this time.

Available in Mac OS X v10.0 and later.

Declared in `NSButtonCell.h`.

`NSTexturedSquareBezelStyle`
A bezel style appropriate for use with textured (metal) windows.

Available in Mac OS X v10.3 and later.

Declared in `NSButtonCell.h`.

`NSHelpButtonBezelStyle`
A round button with a question mark providing the standard help button look.

Available in Mac OS X v10.3 and later.

Declared in `NSButtonCell.h`.

`NSSmallSquareBezelStyle`
A simple square bezel style. Buttons using this style can be scaled to any size.

Available in Mac OS X v10.4 and later.

Declared in `NSButtonCell.h`.

`NSTexturedRoundedBezelStyle`
A textured (metal) bezel style similar in appearance to the Finder's action (gear) button.

The height of this button is fixed.

Available in Mac OS X v10.4 and later.

Declared in `NSButtonCell.h`.

`NSRoundRectBezelStyle`
A bezel style that matches the search buttons in Finder and Mail.

Available in Mac OS X v10.4 and later.

Declared in `NSButtonCell.h`.

`NSRecessedBezelStyle`
A bezel style that matches the recessed buttons in Mail, Finder and Safari.

Available in Mac OS X v10.4 and later.

Declared in `NSButtonCell.h`.

`NSRoundedDisclosureBezelStyle`
A bezel style that matches the disclosure style used in the standard Save panel.

Available in Mac OS X v10.4 and later.

Declared in `NSButtonCell.h`.

Discussion
For examples of how these styles are displayed, see *Button Programming Topics*.

Declared In
NSButtonCell.h

NSButtonType

Type to define button types.

```
typedef NSUInteger NSButtonType;
```

Discussion
For possible values, see "Button Types" (page 524).

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSButtonCell.h

Button Types

Represent the button types that can be specified using `setButtonType:` (page 511).

```
enum {
    NSMomentaryLightButton   = 0,
    NSPushOnPushOffButton    = 1,
    NSToggleButton           = 2,
    NSSwitchButton           = 3,
    NSRadioButton            = 4,
    NSMomentaryChangeButton  = 5,
    NSOnOffButton            = 6,
    NSMomentaryPushInButton  = 7,
    NSMomentaryPushButton    = 0,
    NSMomentaryLight         = 7
};
```

Constants

`NSMomentaryLightButton`

While the button is held down it's shown as "lit," and also "pushed in" to the screen if the button is bordered.

This type of button is best for simply triggering actions, as it doesn't show its state; it always displays its normal image or title. This option is called "Momentary Light" in Interface Builder's Button Inspector.

Available in Mac OS X v10.0 and later.

Declared in `NSButtonCell.h`.

`NSPushOnPushOffButton`

The first click both highlights and causes the button to be "pushed in" if the button is bordered; a second click returns it to its normal state.

This option is called "Push On Push Off" in Interface Builder's Button Inspector.

Available in Mac OS X v10.0 and later.

Declared in `NSButtonCell.h`.

`NSToggleButton`

After the first click, the button displays its alternate image or title; a second click returns the button to its normal state.

This option is called “Toggle” in Interface Builder’s Button Inspector.

Available in Mac OS X v10.0 and later.

Declared in `NSButtonCell.h`.

`NSSwitchButton`

This style is a variant of `NSToggleButton` that has no border and is used to represent a checkbox.

This type of button is available as a separate Library item in Interface Builder.

Available in Mac OS X v10.0 and later.

Declared in `NSButtonCell.h`.

`NSRadioButton`

This style is similar to `NSSwitchButton`, but it used to constrain a selection to a single element from several.

You typically use this type of button in a group formed by an instance of `NSMatrix`. In Interface Builder, a matrix of this type of button is available as a separate Library item.

Available in Mac OS X v10.0 and later.

Declared in `NSButtonCell.h`.

`NSMomentaryChangeButton`

While the button is held down, the alternate image and alternate title are displayed.

The normal image and title are displayed when the button isn’t pressed. This option is called “Momentary Change” in Interface Builder’s Button Inspector.

Available in Mac OS X v10.0 and later.

Declared in `NSButtonCell.h`.

`NSOnOffButton`

The first click highlights the button; a second click returns it to the normal (unhighlighted) state.

This option is called “On Off” in Interface Builder’s Button Inspector.

Available in Mac OS X v10.0 and later.

Declared in `NSButtonCell.h`.

`NSMomentaryPushInButton`

While the button is held down it’s shown as “lit.”

This type of button is best for simply triggering actions, as it doesn’t show its state; it always displays its normal image or title. This option is called “Momentary Push In” in Interface Builder’s Button Inspector.

This button type is the default.

Available in Mac OS X v10.0 and later.

Declared in `NSButtonCell.h`.

`NSMomentaryPushButton`

While the button is held down it’s shown as “lit,” and also “pushed in” to the screen if the button is bordered. (Deprecated. Use `NSMomentaryLightButton` instead.)

Available in Mac OS X v10.0 and later.

Declared in `NSButtonCell.h`.

`NSMomentaryLight`

While the button is held down it's shown as "lit." (Deprecated. Use `NSMomentaryPushInButton` instead.)

Available in Mac OS X v10.0 and later.

Declared in `NSButtonCell.h`.

Discussion
For examples of how these types behave, see *Button Programming Topics*.

Declared In
`NSButtonCell.h`

NSGradientType

Type to define gradient types.

```
typedef NSUInteger NSGradientType;
```

Discussion
For possible values, see "Gradient Types" (page 526).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSButtonCell.h`

Gradient Types

Specify the gradients used by `gradientType` (page 501) and `setGradientType:` (page 512).

```
typedef enum _NSGradientType {
    NSGradientNone          = 0,
    NSGradientConcaveWeak   = 1,
    NSGradientConcaveStrong = 2,
    NSGradientConvexWeak    = 3,
    NSGradientConvexStrong  = 4
} NSGradientType;
```

Constants
`NSGradientNone`

There is no gradient, so the button looks flat.

Available in Mac OS X v10.0 and later.

Declared in `NSButtonCell.h`.

`NSGradientConcaveWeak`

The top-left corner is light gray, and the bottom-right corner is dark gray, so the button appears to be pushed in.

Available in Mac OS X v10.0 and later.

Declared in `NSButtonCell.h`.

`NSGradientConcaveStrong`
: As with `NSGradientConcaveWeak`, the top-left corner is light gray, and the bottom-right corner is dark gray, but the difference between the grays is greater, so the appearance of being pushed in is stronger.

  Available in Mac OS X v10.0 and later.

  Declared in `NSButtonCell.h`.

`NSGradientConvexWeak`
: The top-left corner is dark gray, and the bottom-right corner is light gray, so the button appears to be sticking out.

  Available in Mac OS X v10.0 and later.

  Declared in `NSButtonCell.h`.

`NSGradientConvexStrong`
: As with `NSGradientConvexWeak`, the top-left corner is dark gray, and the bottom-right corner is light gray, but the difference between the grays is greater, so the appearance of sticking out is stronger.

  Available in Mac OS X v10.0 and later.

  Declared in `NSButtonCell.h`.

Declared In
`NSButtonCell.h`

NSCachedImageRep Class Reference

Inherits from	NSImageRep : NSObject
Conforms to	NSCoding (NSImageRep) NSCopying (NSImageRep) NSObject (NSObject)
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.0 and later.
Declared in	AppKit/NSCachedImageRep.h
Companion guide	Cocoa Drawing Guide

Overview

An `NSCachedImageRep` object store image data in a form that can be readily transferred to the screen. An `NSCachedImageRep` object differs from other image representation objects in that it simply stores the already rendered image, whereas other image representation objects generally have knowledge about how to render the image from source data.

You typically do not use this class directly. Instead, `NSImage` and its other image representation objects create instances of `NSCachedImageRep` as needed to cache versions of the rendered image. This caching speeds up screen-based drawing for existing images during subsequent rendering operations. Cached image representations are also used to capture drawing commands for images created programmatically by locking focus on an image.

Tasks

Initializing an NSCachedImageRep

`- initWithSize:depth:separate:alpha:` (page 530)
Returns an `NSCachedImageRep` object initialized with the specified image characteristics.

`- initWithWindow:rect:` (page 531)
Returns an `NSCachedImageRep` object initialized for drawing in the specified window.

Getting the Representation

- `rect` (page 531)
  Returns the rectangle where the receiver is cached.
- `window` (page 531)
  Returns the window where the receiver is cached.

Instance Methods

initWithSize:depth:separate:alpha:

Returns an `NSCachedImageRep` object initialized with the specified image characteristics. (Deprecated in Mac OS X v10.6.)

```
- (id)initWithSize:(NSSize)size depth:(NSWindowDepth)depth separate:(BOOL)flag
    alpha:(BOOL)alpha
```

Parameters

size
  The size of the image, measured in points.

depth
  The bit depth of the image. Specify 0 if you want the image to be the same depth as the deepest screen on the current system.

flag
  `YES` if the receiver should use a separate offscreen window to store the image; otherwise, `NO` if the receiver should use a shared window.

alpha
  `YES` if the image includes transparency information; otherwise, `NO`.

Return Value
The initialized `NSCachedImageRep` object or `nil` if the object could not be initialized.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.6.

See Also
- `setAlpha:` (page 1420) (NSImageRep)
- `setBitsPerSample:` (page 1421) (NSImageRep)
- `setCacheDepthMatchesImageDepth:` (page 1364) (NSImage)
- `setCachedSeparately:` (page 1365) (NSImage)

Declared In
`NSCachedImageRep.h`

initWithWindow:rect:

Returns an `NSCachedImageRep` object initialized for drawing in the specified window. (Deprecated in Mac OS X v10.6.)

```
- (id)initWithWindow:(NSWindow *)aWindow rect:(NSRect)aRect
```

Parameters

aWindow

The window (typically offscreen) in which the image is to be rendered. The window is retained by the receiver.

aRect

The position and size of the image in the specified window. This rectangle should be specified in the base coordinate system of the window.

Discussion

You must draw the image yourself in the designated part of the window. There are no `NSCachedImageRep` methods for this purpose.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.6.

See Also

`- size` (page 1424) (NSImageRep)

Declared In

`NSCachedImageRep.h`

rect

Returns the rectangle where the receiver is cached. (Deprecated in Mac OS X v10.6.)

```
- (NSRect)rect
```

Return Value

The rectangle in the associated offscreen window where the receiver's image is located.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.6.

See Also

`- size` (page 1424) (NSImageRep)

Declared In

`NSCachedImageRep.h`

window

Returns the window where the receiver is cached. (Deprecated in Mac OS X v10.6.)

```
- (NSWindow *)window
```

Return Value
The window (typically offscreen) used to store the image.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.6.

Declared In
`NSCachedImageRep.h`

NSCell Class Reference

Inherits from	NSObject
Conforms to	NSCoding NSCopying NSObject (NSObject)
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.0 and later.
Declared in	AppKit/NSCell.h
Companion guide	Control and Cell Programming Topics for Cocoa
Related sample code	AnimatedTableView FunHouse PhotoSearch Quartz Composer WWDC 2005 TextEdit VertexPerformanceTest

Overview

The `NSCell` class provides a mechanism for displaying text or images in an `NSView` object without the overhead of a full `NSView` subclass. It's used heavily by most of the `NSControl` classes to implement their internal workings.

Designated Initializers

When subclassing `NSCell` you must implement all of the designated initializers. Those methods are: init, `initWithCoder:`, `initTextCell:` (page 564), and `initImageCell:` (page 563).

Tasks

Initializing a Cell

`- initImageCell:` (page 563)
Returns an `NSCell` object initialized with the specified image and set to have the cell's default menu.

- `initTextCell:` (page 564)
  Returns an NSCell object initialized with the specified string and set to have the cell's default menu.

Managing Cell Values

- `setObjectValue:` (page 592)
  Sets the receiver's object value.
- `objectValue` (page 572)
  Returns the receiver's value as an Objective-C object
- `hasValidObjectValue` (page 560)
  Returns a Boolean value that indicates whether the receiver has a valid object value.
- `setIntValue:` (page 590)
  Sets the value of the receiver using an integer.
- `intValue` (page 565)
  Returns the receiver's value as an integer.
- `setIntegerValue:` (page 590)
  Sets the value of the receiver using an `NSInteger`.
- `integerValue` (page 564)
  Returns the receiver's value as an `NSInteger`.
- `setStringValue:` (page 596)
  Sets the value of the receiver's cell using an `NSString` object.
- `stringValue` (page 605)
  Returns the value of the receiver's cell as an `NSString` object.
- `setDoubleValue:` (page 584)
  Sets the value of the receiver's cell using a double-precision floating-point number.
- `setFloatValue:` (page 587)
  Sets the value of the receiver's cell using a single-precision floating-point number.
- `floatValue` (page 557)
  Returns the value of the receiver's cell as a single-precision floating-point number.
- `doubleValue` (page 552) Available in Mac OS X v10.0 through Mac OS X v10.5
  Returns the value of the receiver's cell as a double-precision floating-point number.

Managing Cell Attributes

- `setCellAttribute:to:` (page 581)
  Sets the value for the specified cell attribute.
- `cellAttribute:` (page 548)
  Returns the value for the specified cell attribute.
- `setType:` (page 599)
  Sets the type of the cell, changing it to a text cell, image cell, or null cell.
- `type` (page 611)
  Returns the type of the receiver

- `setEnabled:` (page 585)
  Sets whether the receiver is enabled or disabled.
- `isEnabled` (page 567)
  Returns a Boolean value that indicates whether the receiver is enabled or disabled.
- `allowsUndo` (page 546)
  Returns a Boolean value that indicates whether the receiver assumes responsibility for undo operations.
- `setAllowsUndo:` (page 579)
  Sets whether the receiver assumes responsibility for undo operations within the cell.

Managing Display Attributes

- `setBezeled:` (page 581)
  Sets whether the receiver draws itself with a bezeled border.
- `isBezeled` (page 566)
  Returns a Boolean value that indicates whether the receiver has a bezeled border.
- `setBordered:` (page 581)
  Sets whether the receiver draws itself outlined with a plain border.
- `isBordered` (page 566)
  Returns a Boolean value that indicates whether the receiver has a plain border.
- `isOpaque` (page 568)
  Returns a Boolean value that indicates whether the receiver is opaque (nontransparent).
- `setControlTint:` (page 583)
  Sets the receiver's control tint.
- `controlTint` (page 551)
  Returns the receiver's control tint.
- `setBackgroundStyle:` (page 580)
  Sets the background style for the receiver.
- `backgroundStyle` (page 547)
  Returns the background style for the receiver.
- `interiorBackgroundStyle` (page 565)
  Returns the interior background style for the receiver.

Managing Cell State

- `allowsMixedState` (page 545)
  Returns a Boolean value that indicates whether the receiver supports three states.
- `nextState` (page 572)
  Returns the receiver's next state.
- `setAllowsMixedState:` (page 578)
  Sets whether the receiver supports three states or just two.
- `setNextState` (page 592)
  Changes the state of the receiver to its next state.

- `setState:` (page 596)
  Sets the receiver's state to the specified value.
- `state` (page 603)
  Returns the receiver's state.

Modifying Textual Attributes

- `setEditable:` (page 584)
  Sets whether the user can edit the receiver's text.
- `isEditable` (page 567)
  Returns a Boolean value that indicates whether the receiver is editable.
- `setSelectable:` (page 594)
  Sets whether text in the receiver can be selected.
- `isSelectable` (page 569)
  Returns a Boolean value that indicates whether the text of the receiver can be selected.
- `setScrollable:` (page 594)
  Sets whether excess text in the receiver is scrolled past the cell's bounds.
- `isScrollable` (page 569)
  Returns a Boolean value that indicates whether the receiver scrolls excess text past the cell's bounds.
- `setAlignment:` (page 577)
  Sets the alignment of text in the receiver.
- `alignment` (page 545)
  Returns the alignment of text in the receiver.
- `setFont:` (page 587)
  Sets the font to use when the receiver displays text.
- `font` (page 558)
  Returns the font used to display text in the receiver
- `lineBreakMode` (page 570)
  Returns the line break mode currently used when drawing text.
- `setLineBreakMode:` (page 591)
  Sets the line break mode to use when drawing text
- `truncatesLastVisibleLine` (page 610)
  Returns a Boolean value indicating whether the receiver truncates and adds the ellipsis character to the last visible line if the text doesn't fit into the cell bounds.
- `setTruncatesLastVisibleLine:` (page 599)
  Sets whether the receiver truncates and adds the ellipsis character to the last visible line if the text doesn't fit into the cell bounds.
- `setWraps:` (page 601)
  Sets whether text in the receiver wraps when its length exceeds the frame of the cell.
- `wraps` (page 612)
  Returns a Boolean value that indicates whether the receiver wraps its text when the text exceeds the borders of the cell.
- `baseWritingDirection` (page 547)
  Returns the initial writing direction used to determine the actual writing direction for text.

- `setBaseWritingDirection:` (page 580)
  Sets the initial writing direction used to determine the actual writing direction for text .
- `setAttributedStringValue:` (page 579)
  Sets the value of the receiver's cell using an attributed string.
- `attributedStringValue` (page 546)
  Returns the value of the receiver's cell as an attributed string using the receiver's formatter object (if one exists).
- `setAllowsEditingTextAttributes:` (page 578)
  Sets whether the receiver allows the user to edit textual attributes of its contents.
- `allowsEditingTextAttributes` (page 545)
  Returns a Boolean value that indicates whether the receiver allows user editing of textual attributes.
- `setImportsGraphics:` (page 589)
  Sets whether the receiver can import images into its text.
- `importsGraphics` (page 563)
  Returns a Boolean value that indicates whether the text of the receiver can contain imported graphics.
- `setUpFieldEditorAttributes:` (page 600)
  Configures the textual and background attributes of the receiver's field editor.
- `title` (page 609)
  Returns the receiver's title.
- `setTitle:` (page 598)
  Sets the title of the receiver.

Managing the Target and Action

- `setAction:` (page 577)
  Sets the cell's action method to the specified selector.
- `action` (page 544)
  Returns the default action-message selector associated with the cell.
- `setTarget:` (page 598)
  Sets the target object to receive action messages.
- `target` (page 608)
  Returns the target object of the receiver.
- `setContinuous:` (page 582)
  Sets whether the receiver's cell sends its action message continuously to its target during mouse tracking.
- `isContinuous` (page 566)
  Returns a Boolean value that indicates whether the receiver's cell sends its action message continuously to its target during mouse tracking.
- `sendActionOn:` (page 576)
  Sets the conditions on which the receiver sends action messages to its target.

Managing the Image

- `setImage:` (page 589)
  Sets the image to be displayed by the receiver.
- `image` (page 562)
  Returns the image displayed by the receiver (if any).

Managing the Tag

- `setTag:` (page 597)
  Sets the tag of the receiver.
- `tag` (page 605)
  Returns the tag identifying the receiver.

Formatting and Validating Data

- `setFormatter:` (page 588)
  Sets the receiver's formatter object.
- `formatter` (page 559)
  Returns the receiver's formatter object.
- `entryType` (page 556) Deprecated in Mac OS X v10.0 and later
  Returns the type of data the user can type into the receiver. (Deprecated. Use a formatter instead—see `setFormatter:` (page 588).)
- `setEntryType:` (page 585) Deprecated in Mac OS X v10.0 and later
  Sets how numeric data is formatted in the receiver and places restrictions on acceptable input. (Deprecated. Use a formatter instead—see `setFormatter:` (page 588).)
- `isEntryAcceptable:` (page 568) Deprecated in Mac OS X v 10.0 and later
  Returns whether a string representing a numeric or date value is formatted in a suitable way for the cell's entry type. (Deprecated. Use `NSFormatter` instead.)
- `setFloatingPointFormat:left:right:` (page 586) Deprecated in Mac OS X v10.0
  Sets the auto-ranging and floating point number format of the receiver's cell. (Deprecated. Use a formatter instead. See `setFormatter:` (page 588))

Managing Menus

+ `defaultMenu` (page 543)
  Returns the default menu for instances of the receiver.
- `setMenu:` (page 591)
  Sets the contextual menu for the cell.
- `menu` (page 570)
  Returns the receiver's contextual menu.
- `menuForEvent:inRect:ofView:` (page 570)
  Returns the menu associated with the receiver and related to the specified event and frame.

Comparing Cells

- `compare:` (page 550)
  Compares the string values of the receiver another cell, disregarding case.

Respond to Keyboard Events

- `acceptsFirstResponder` (page 544)
  Returns a Boolean value that indicates whether the receiver accepts first responder status.
- `setShowsFirstResponder:` (page 595)
  Sets whether the receiver draws some indication of its first responder status.
- `showsFirstResponder` (page 602)
  Returns a Boolean value that indicates whether the receiver should draw some indication of its first responder status.
- `setTitleWithMnemonic:` (page 599)
  Sets the title of the receiver with one character in the string denoted as an access key.
- `mnemonic` (page 571)
  Returns the character in the receiver's title that appears underlined for use as a mnemonic.
- `refusesFirstResponder` (page 573)
  Returns a Boolean value that indicates whether the receiver should not become the first responder.
- `setMnemonicLocation:` (page 592)
  Sets the character of the receiver's title to be used as a mnemonic character.
- `setRefusesFirstResponder:` (page 593)
  Sets whether the receiver should not become the first responder.
- `mnemonicLocation` (page 571)
  Returns the position of the underlined mnemonic character in the receiver's title.
- `performClick:` (page 573)
  Simulates a single mouse click on the receiver.

Deriving Values

- `takeObjectValueFrom:` (page 607)
  Sets the value of the receiver's cell to the object value obtained from the specified object.
- `takeIntegerValueFrom:` (page 606)
  Sets the value of the receiver's cell to an integer value obtained from the specified object.
- `takeIntValueFrom:` (page 607)
  Sets the value of the receiver's cell to an integer value obtained from the specified object.
- `takeStringValueFrom:` (page 608)
  Sets the value of the receiver's cell to the string value obtained from the specified object.
- `takeDoubleValueFrom:` (page 606)
  Sets the value of the receiver's cell to a double-precision floating-point value obtained from the specified object.

- takeFloatValueFrom: (page 606)
  Sets the value of the receiver's cell to a single-precision floating-point value obtained from the specified object.

Representing an Object

- setRepresentedObject: (page 593)
  Sets the object represented by the receiver.
- representedObject (page 574)
  Returns the object the receiver represents.

Tracking the Mouse

- trackMouse:inRect:ofView:untilMouseUp: (page 610)
  Initiates the mouse tracking behavior in a cell.
- startTrackingAt:inView: (page 603)
  Begins tracking mouse events within the receiver.
- continueTracking:at:inView: (page 550)
  Returns a Boolean value that indicates whether mouse tracking should continue in the receiving cell.
- stopTracking:at:inView:mouseIsUp: (page 604)
  Stops tracking mouse events within the receiver.
- mouseDownFlags (page 572)
  Returns the modifier flags for the last (left) mouse-down event.
+ prefersTrackingUntilMouseUp (page 543)
  Returns a Boolean value that indicates whether tracking stops when the cursor leaves the cell.
- getPeriodicDelay:interval: (page 559)
  Returns the initial delay and repeat values for continuous sending of action messages to target objects.

Hit Testing

- hitTestForEvent:inRect:ofView: (page 561)
  Returns hit testing information for the receiver.

Managing the Cursor

- resetCursorRect:inView: (page 574)
  Sets the receiver to show the I-beam cursor while it tracks the mouse.

Handling Keyboard Alternatives

- keyEquivalent (page 569)
  Returns the key equivalent to clicking the cell.

Managing Focus Rings

+ `defaultFocusRingType` (page 543)
  Returns the default type of focus ring for the receiver.
- `setFocusRingType:` (page 587)
  Sets the type of focus ring to be used.
- `focusRingType` (page 558)
  Returns the type of focus ring currently set for the receiver.

Determining Cell Size

- `calcDrawInfo:` (page 548)
  Recalculates the cell geometry.
- `cellSize` (page 549)
  Returns the minimum size needed to display the receiver.
- `cellSizeForBounds:` (page 549)
  Returns the minimum size needed to display the receiver, constraining it to the specified rectangle.
- `drawingRectForBounds:` (page 552)
  Returns the rectangle within which the receiver draws itself
- `imageRectForBounds:` (page 563)
  Returns the rectangle in which the receiver draws its image.
- `titleRectForBounds:` (page 609)
  Returns the rectangle in which the receiver draws its title text.
- `controlSize` (page 551)
  Returns the size of the receiver.
- `setControlSize:` (page 582)
  Sets the size of the receiver.

Drawing and Highlighting

- `drawWithFrame:inView:` (page 554)
  Draws the receiver's border and then draws the interior of the cell.
- `highlightColorWithFrame:inView:` (page 561)
  Returns the color the receiver uses when drawing the selection highlight.
- `drawInteriorWithFrame:inView:` (page 553)
  Draws the interior portion of the receiver, which includes the image or text portion but does not include the border.
- `controlView` (page 552)
  Returns the receiver's control.
- `setControlView:` (page 583)
  Sets the receiver's control view.
- `highlight:withFrame:inView:` (page 560)
  Redraws the receiver with the specified highlight setting.

- `setHighlighted:` (page 588)
  Sets whether the receiver has a highlighted appearance.
- `isHighlighted` (page 568)
  Returns a Boolean value that indicates whether the receiver is highlighted.

Editing and Selecting Text

- `editWithFrame:inView:editor:delegate:event:` (page 555)
  Begins editing of the receiver's text using the specified field editor.
- `selectWithFrame:inView:editor:delegate:start:length:` (page 575)
  Selects the specified text range in the cell's field editor.
- `sendsActionOnEndEditing` (page 576)
  Returns a Boolean value that indicates whether the receiver's `NSControl` object sends its action message whenever the user finishes editing the cell's text.
- `setSendsActionOnEndEditing:` (page 595)
  Sets whether the receiver's NSControl object sends its action message whenever the user finishes editing the cell's text.
- `endEditing:` (page 555)
  Ends the editing of text in the receiver using the specified field editor.
- `wantsNotificationForMarkedText` (page 612)
  Returns a Boolean value that indicates whether the field editor initiated by the receiver should post text change notifications.
- `fieldEditorForView:` (page 557)
  Returns a custom field editor for editing in the view.
- `usesSingleLineMode` (page 612)
  Returns whether the text cell restricts layout and rendering of its content to a single line.
- `setUsesSingleLineMode:` (page 601)
  Sets whether the text cell restricts layout and rendering of its content to a single line.

Managing Expansion Frames

- `expansionFrameWithFrame:inView:` (page 556)
  Returns the expansion cell frame for the receiver.
- `drawWithExpansionFrame:inView:` (page 554)
  Instructs the receiver to draw in an expansion frame.

User Interface Layout Direction

- `setUserInterfaceLayoutDirection:` (page 600)
  Sets the layout direction of the user interface.
- `userInterfaceLayoutDirection` (page 611)
  Returns the layout direction of the user interface.

Class Methods

defaultFocusRingType

Returns the default type of focus ring for the receiver.

```
+ (NSFocusRingType)defaultFocusRingType
```

Return Value
The default type of focus ring for the receiver (one of the values listed in `NSFocusRingType` (page 4009)).

Availability
Available in Mac OS X v10.3 and later.

Declared In
`NSCell.h`

defaultMenu

Returns the default menu for instances of the receiver.

```
+ (NSMenu *)defaultMenu
```

Return Value
The default menu. The `NSCell` implementation of this method returns `nil`.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- menu` (page 570)
`- setMenu:` (page 591)

Declared In
`NSCell.h`

prefersTrackingUntilMouseUp

Returns a Boolean value that indicates whether tracking stops when the cursor leaves the cell.

```
+ (BOOL)prefersTrackingUntilMouseUp
```

Return Value
`YES` if tracking stops when the cursor leaves the cell, otherwise `NO`.

Discussion
The default implementation returns `NO`. Subclasses may override this method to return a different value.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `trackMouse:inRect:ofView:untilMouseUp:` (page 610)

Related Sample Code
AnimatedTableView
Cocoa Tips and Tricks
PhotoSearch

Declared In
`NSCell.h`

Instance Methods

acceptsFirstResponder

Returns a Boolean value that indicates whether the receiver accepts first responder status.

```
- (BOOL)acceptsFirstResponder
```

Return Value
`YES` if the receiver can become the first responder, otherwise `NO`.

Discussion
The default value is `YES` if the receiver is enabled. Subclasses may override this method to return a different value.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `performClick:` (page 573)
- `setShowsFirstResponder:` (page 595)
- `setTitleWithMnemonic:` (page 599)

Declared In
`NSCell.h`

action

Returns the default action-message selector associated with the cell.

```
- (SEL)action
```

Return Value
The selector associated with the cell. The `NSCell` implementation of this method returns `NULL` by default.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setAction:` (page 577)
- `setTarget:` (page 598)
- `target` (page 608)

Declared In
`NSCell.h`

alignment

Returns the alignment of text in the receiver.

```
- (NSTextAlignment)alignment
```

Return Value
The alignment of text in the receiver (one of the following constants: `NSLeftTextAlignment`, `NSRightTextAlignment`,`NSCenterTextAlignment`, `NSJustifiedTextAlignment`, `NSNaturalTextAlignment`).

Discussion
The default value is `NSNaturalTextAlignment`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setAlignment:` (page 577)

Declared In
`NSCell.h`

allowsEditingTextAttributes

Returns a Boolean value that indicates whether the receiver allows user editing of textual attributes.

```
- (BOOL)allowsEditingTextAttributes
```

Return Value
`YES` if the receiver allows the user to edit textual attributes of the cell's text, otherwise `NO`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setAllowsEditingTextAttributes:` (page 578)

Declared In
`NSCell.h`

allowsMixedState

Returns a Boolean value that indicates whether the receiver supports three states.

```
- (BOOL)allowsMixedState
```

Return Value
`YES` if the receiver supports all three states (on, off, and mixed), otherwise `NO` (the receiver supports only the on and off states).

Availability
Available in Mac OS X v10.0 and later.

See Also
- `nextState` (page 572)
- `setAllowsMixedState:` (page 578)
- `setNextState` (page 592)

Declared In
`NSCell.h`

allowsUndo

Returns a Boolean value that indicates whether the receiver assumes responsibility for undo operations.

```
- (BOOL)allowsUndo
```

Return Value
`YES` if the receiver handles undo operations, otherwise `NO`.

Discussion
By default, the `NSTextFieldCell` class uses this feature to handle undo operations for edited text. Other controls set a value that is appropriate for their implementation.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `setAllowsUndo:` (page 579)

Declared In
`NSCell.h`

attributedStringValue

Returns the value of the receiver's cell as an attributed string using the receiver's formatter object (if one exists).

```
- (NSAttributedString *)attributedStringValue
```

Return Value
The value of the cell interpreted as an attributed string.

Discussion
The textual attributes are the default paragraph style, the receiver's font and alignment, and whether the receiver is enabled and scrollable.

For Mac OS X v10.3 and later: If you use a class that responds to the selector `attributedStringValue` for the object value of a cell, then the cell will use that method to fetch the string to draw rather than using `stringValue` (page 605).

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setAttributedStringValue:` (page 579)

Related Sample Code
SourceView

Declared In
`NSCell.h`

backgroundStyle

Returns the background style for the receiver.

```
- (NSBackgroundStyle)backgroundStyle
```

Return Value
The background style for the receiver.

Discussion
The background describes the surface the cell is drawn onto in `drawWithFrame:inView:` (page 554). A control typically sets this before it asks the cell to draw. A cell may draw differently based on background characteristics. For example, a tableview drawing a cell in a selected row might call `[cell setBackgroundStyle:NSBackgroundStyleDark]`. A text cell might decide to render its text white as a result. A rating-style level indicator might draw its stars white instead of gray.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSCell.h`

baseWritingDirection

Returns the initial writing direction used to determine the actual writing direction for text.

```
- (NSWritingDirection)baseWritingDirection
```

Return Value
The initial writing direction the receiver uses to determine the actual writing direction for text. See `NSWritingDirection` (page 2748) for possible values.

Discussion
The default value is `NSWritingDirectionNatural` (page 2748).

The Text system uses this value as a hint for calculating the actual direction for displaying Unicode characters. You should not need to call this method directly.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `setBaseWritingDirection:` (page 580)

Declared In
`NSCell.h`

calcDrawInfo:

Recalculates the cell geometry.

```
- (void)calcDrawInfo:(NSRect)aRect
```

Parameters

aRect

The reference rectangle to use when calculating the cell information.

Discussion
Objects (such as controls) that manage `NSCell` objects generally maintain a flag that informs them if any of their cells have been modified in such a way that the location or size of the cell should be recomputed. If so, `calcSize` (page 816) method of `NSControl` is automatically invoked prior to the display of the cell, and that method invokes the `calcDrawInfo:` method of the cell.

The default implementation of this method does nothing.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `cellSize` (page 549)
- `drawingRectForBounds:` (page 552)

Declared In
`NSCell.h`

cellAttribute:

Returns the value for the specified cell attribute.

```
- (NSInteger)cellAttribute:(NSCellAttribute)aParameter
```

Parameters

aParameter

The cell attribute whose value you want to get. Attributes include the receiver's current state and whether it is disabled, editable, or highlighted.

Return Value
The value for the cell attribute specified by *aParameter*.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setCellAttribute:to:` (page 581)

Declared In
`NSCell.h`

cellSize

Returns the minimum size needed to display the receiver.

```
- (NSSize)cellSize
```

Return Value
The size of the cell, or the size (10000, 10000) if the receiver is not a text or image cell. If the cell is an image cell but no image has been set, returns `NSZeroSize`.

Discussion
This method takes into account of the size of the image or text within a certain offset determined by the border type of the cell.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `drawingRectForBounds:` (page 552)

Declared In
`NSCell.h`

cellSizeForBounds:

Returns the minimum size needed to display the receiver, constraining it to the specified rectangle.

```
- (NSSize)cellSizeForBounds:(NSRect)aRect
```

Parameters
aRect
The size of the cell, or the size of the `aRect` parameter if the cell is not a text or image cell. If the cell is an image cell but no image has been set, returns `NSZeroSize`.

Discussion
This method takes into account of the size of the image or text within a certain offset determined by the border type of the cell. If the receiver is of text type, the text is resized to fit within *aRect* (as much as *aRect* is within the bounds of the cell).

Availability
Available in Mac OS X v10.0 and later.

See Also
`- drawingRectForBounds:` (page 552)

Cocoa Tips and Tricks

Declared In
`NSCell.h`

compare:

Compares the string values of the receiver another cell, disregarding case.

```
- (NSComparisonResult)compare:(id)otherCell
```

Parameters

otherCell

The cell to compare against the receiver. This parameter must be of type `NSCell`; if it is not, this method raises `NSBadComparisonException`.

This value must not be `nil`. If the value is `nil`, the behavior is undefined and may change in future versions of Mac OS X.

Return Value
`NSOrderedAscending` if the string value of the receiver precedes the string value of *otherCell* in lexical ordering, `NSOrderedSame` if the string values are equivalent in lexical value, and `NSOrderedDescending` string value of the receiver follows the string value of *otherCell* in lexical ordering.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSCell.h`

continueTracking:at:inView:

Returns a Boolean value that indicates whether mouse tracking should continue in the receiving cell.

```
- (BOOL)continueTracking:(NSPoint)lastPoint at:(NSPoint)currentPoint inView:(NSView
    *)controlView
```

Parameters

lastPoint

Contains either the initial location of the cursor when tracking began or the previous current point.

currentPoint

The current location of the cursor.

controlView

The `NSControl` object managing the receiver.

Return Value
`YES` if mouse tracking should continue, otherwise `NO`.

Discussion
This method is invoked in `trackMouse:inRect:ofView:untilMouseUp:` (page 610). The default implementation returns `YES` if the cell is set to continuously send action messages to its target when the mouse button is down or the mouse is being dragged. Subclasses can override this method to provide more sophisticated tracking behavior.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `startTrackingAt:inView:` (page 603)
- `stopTracking:at:inView:mouseIsUp:` (page 604)

Declared In
`NSCell.h`

controlSize

Returns the size of the receiver.

```
- (NSControlSize)controlSize
```

Return Value
A value that specifies the size of the receiver (for possible values, see "`NSControlSize`" (page 620)).

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setControlSize:` (page 582)

Declared In
`NSCell.h`

controlTint

Returns the receiver's control tint.

```
- (NSControlTint)controlTint
```

Return Value
An `NSControlTint` (page 533) value that specifies the tint of the receiver.).

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setControlTint:` (page 583)

Declared In
NSCell.h

controlView

Returns the receiver's control.

```
- (NSView *)controlView
```

Return Value
The view (normally an NSControl object) associated with this cell. The default implementation returns nil.

Availability
Available in Mac OS X v10.0 and later.

See Also
- drawWithFrame:inView: (page 554)
- setControlView: (page 583)

doubleValue

Returns the value of the receiver's cell as a double-precision floating-point number.

```
- (double)doubleValue
```

Return Value
The value of the cell interpreted as a double-precision floating-point number. If the receiver is not a text-type cell or the cell value is not scannable, returns 0.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setDoubleValue: (page 584)

Declared In
NSCell.h

drawingRectForBounds:

Returns the rectangle within which the receiver draws itself

```
- (NSRect)drawingRectForBounds:(NSRect)theRect
```

Parameters

theRect

The bounding rectangle of the receiver.

Return Value

The rectangle in which the receiver draws itself. This rectangle is slightly inset from the one in `theRect`.

Availability

Available in Mac OS X v10.0 and later.

See Also

`- calcSize` (page 816) (`NSControl`)

FunHouse

Declared In

`NSCell.h`

drawInteriorWithFrame:inView:

Draws the interior portion of the receiver, which includes the image or text portion but does not include the border.

```
- (void)drawInteriorWithFrame:(NSRect)cellFrame inView:(NSView *)controlView
```

Parameters

cellFrame

The bounding rectangle of the receiver, or a portion of the bounding rectangle.

controlView

The control that manages the cell.

Discussion

Text-type `NSCell` objects display their contents in a rectangle slightly inset from *cellFrame* using a global `NSText` object. Image-type `NSCell` objects display their contents centered within *cellFrame*. If the proper attributes are set, this method also displays the dotted-line rectangle to indicate if the control is the first responder and highlights the cell. This method is invoked from the `drawCellInside:` (page 818) method of `NSControl` to visually update what the cell displays when its contents change. The drawing done by the `NSCell` implementation is minimal and becomes more complex in objects such as `NSButtonCell` and `NSSliderCell`.

This method draws the cell in the currently focused view, which can be different from the *controlView* passed in. Taking advantage of this is not recommended.

Subclasses often override this method to provide more sophisticated drawing of cell contents. Because `drawWithFrame:inView:` (page 554) invokes `drawInteriorWithFrame:inView:` after it draws the cell's border, do not invoke `drawWithFrame:inView:` (page 554) in your override implementation.

Availability

Available in Mac OS X v10.0 and later.

See Also

`- isHighlighted` (page 568)

`- setShowsFirstResponder:` (page 595)

Declared In
NSCell.h

drawWithExpansionFrame:inView:

Instructs the receiver to draw in an expansion frame.

```
- (void)drawWithExpansionFrame:(NSRect)cellFrame inView:(NSView *)view
```

Parameters

cellFrame
The frame in which to draw.

view
The view in which to draw. This view may be different from the original view that the cell appeared in.

Discussion
This method allows the cell to perform custom expansion tool tip drawing. By default, NSCell simply calls drawWithFrame:inView: (page 554).

Availability
Available in Mac OS X v10.5 and later.

See Also
- expansionFrameWithFrame:inView: (page 556)

Declared In
NSCell.h

drawWithFrame:inView:

Draws the receiver's border and then draws the interior of the cell.

```
- (void)drawWithFrame:(NSRect)cellFrame inView:(NSView *)controlView
```

Parameters

cellFrame
The bounding rectangle of the receiver.

controlView
The control that manages the cell.

Discussion
This method draws the cell in the currently focused view, which can be different from the *controlView* passed in. Taking advantage of this behavior is not recommended, however.

Availability
Available in Mac OS X v10.0 and later.

See Also
- drawInteriorWithFrame:inView: (page 553)

Declared In
NSCell.h

editWithFrame:inView:editor:delegate:event:

Begins editing of the receiver's text using the specified field editor.

```
- (void)editWithFrame:(NSRect)aRect inView:(NSView *)controlView editor:(NSText
    *)textObj delegate:(id)anObject event:(NSEvent *)theEvent
```

Parameters

aRect
The bounding rectangle of the cell.

controlView
The control that manages the cell.

textObj
The field editor to use for editing the cell.

anObject
The object to use as a delegate for the field editor (`textObj` parameter). This delegate object receives various `NSText` delegation and notification methods during the course of editing the cell's contents.

theEvent
The `NSLeftMouseDown` event that initiated the editing behavior.

Discussion
If the receiver isn't a text-type `NSCell` object, no editing is performed. Otherwise, the field editor (*textObj*) is sized to *aRect* and its superview is set to *controlView*, so it exactly covers the receiver. The field editor is then activated and editing begins. It's the responsibility of the delegate to end editing when responding to `textShouldEndEditing:`. Upon ending the editing session, the delegate should remove any data from the field editor.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `endEditing:` (page 555)
- `selectWithFrame:inView:editor:delegate:start:length:` (page 575)

Declared In
NSCell.h

endEditing:

Ends the editing of text in the receiver using the specified field editor.

```
- (void)endEditing:(NSText *)textObj
```

Parameters

textObj

The field editor currently handling the editing of the cell's content.

Discussion

Ends any editing of text that began with a call to `editWithFrame:inView:editor:delegate:event:` (page 555) or `selectWithFrame:inView:editor:delegate:start:length:` (page 575).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSCell.h`

entryType

Returns the type of data the user can type into the receiver. (Deprecated in Mac OS X v10.0 and later. Use a formatter instead—see `setFormatter:` (page 588).)

```
- (NSInteger)entryType
```

Return Value

One of the types listed for this method in "`Data Entry Types`" (page 622). If the receiver is not a text-type cell, or if no type has been set, `NSAnyType` is returned.

Availability

Deprecated in Mac OS X v10.0 and later.

See Also

`- setFormatter:` (page 588)

Declared In

`NSCell.h`

expansionFrameWithFrame:inView:

Returns the expansion cell frame for the receiver.

```
- (NSRect)expansionFrameWithFrame:(NSRect)cellFrame inView:(NSView *)view
```

Parameters

cellFrame

The frame for the receiver.

view

The view in which the receiver will be drawn.

Return Value

The expansion cell frame for the receiver. If the frame is not too small, return an empty rect (`NSZeroRect`), and no expansion tool tip view will be shown.

Discussion
This method allows the cell to return an expansion cell frame if *cellFrame* is too small for the entire contents in the view. When the mouse is hovered over the cell in certain controls, the full cell contents are shown in a special floating tool tip view. By default, `NSCell` returns `NSZeroRect`, while some subclasses (such as `NSTextFieldCell`) will return the proper frame when required.

Availability
Available in Mac OS X v10.5 and later.

See Also
`- drawWithExpansionFrame:inView:` (page 554)

Declared In
`NSCell.h`

fieldEditorForView:

Returns a custom field editor for editing in the view.

```
- (NSTextView *)fieldEditorForView:(NSView *)aControlView
```

Parameters
aControlView
The view containing cells that require a custom field editor.

Return Value
A custom field editor. The field editor must have `isFieldEditor` (page 2902) set to `YES`.

Discussion
This is an override point for `NSCell` subclasses designed to use their own custom field editors. This message is sent to the selected cell of *aControlView* using the `NSWindow` method in `fieldEditor:forObject:` (page 3325).

Returning non-`nil` from this method indicates skipping the standard field editor querying processes including `windowWillReturnFieldEditor:toObject:` (page 3940) delegation.

The default implementation returns `nil`.

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSCell.h`

floatValue

Returns the value of the receiver's cell as a single-precision floating-point number.

```
- (float)floatValue
```

Return Value
The value of the cell interpreted as a single-precision floating-point number. If the receiver is not a text-type cell or the cell value is not scannable, returns `0`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSCell.h

focusRingType

Returns the type of focus ring currently set for the receiver.

```
- (NSFocusRingType)focusRingType
```

Return Value
The type of focus ring currently set for the receiver (one of the values listed in `NSFocusRingType` (page 4009)).

Discussion
You can disable a view's focus ring drawing by overriding this method so it always returns `NSFocusRingTypeNone`, or by calling `setFocusRingType:` (page 587) with `NSFocusRingTypeNone`. You should only disable a view from drawing its focus ring if you want to draw your own focus ring, or if there isn't sufficient space to display a focus ring in the default location.

Availability
Available in Mac OS X v10.3 and later.

See Also
- `setFocusRingType:` (page 587)
+ `defaultFocusRingType` (page 543)

Declared In
NSCell.h

font

Returns the font used to display text in the receiver

```
- (NSFont *)font
```

Return Value
The receiver's current font, or `nil` if the receiver is not a text-type cell.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setFont:` (page 587)

Declared In
NSCell.h

formatter

Returns the receiver's formatter object.

```
- (id)formatter
```

Return Value
An object of type NSFormatter used to format the receiver's content.

Discussion
The returned object handles translation of the receiver's contents between its onscreen representation and its object value.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setFormatter: (page 588)

Related Sample Code
Sketch+Accessibility

Declared In
NSCell.h

getPeriodicDelay:interval:

Returns the initial delay and repeat values for continuous sending of action messages to target objects.

```
- (void)getPeriodicDelay:(float *)delay interval:(float *)interval
```

Parameters

delay

On input, a pointer to a floating-point variable. On output, the variable contains the current delay (measured in seconds) before messages are sent. This parameter must not be NULL.

interval

On input, a pointer to a floating point variable. On output, the variable contains the interval (measured in seconds) at which messages are sent. This parameter must not be NULL.

Discussion
The default implementation returns a delay of 0.2 and an interval of 0.025 seconds. Subclasses can override this method to supply their own delay and interval values.

Availability
Available in Mac OS X v10.0 and later.

See Also
- isContinuous (page 566)
- setContinuous: (page 582)

Declared In
NSCell.h

hasValidObjectValue

Returns a Boolean value that indicates whether the receiver has a valid object value.

```
- (BOOL)hasValidObjectValue
```

Return Value
YES if the cell has a valid object value, otherwise NO.

Discussion
A valid object value is one that the receiver's formatter can "understand." Objects are always assumed to be valid unless they are rejected by the formatter. Invalid objects can still be accepted by the delegate of the receiver's NSControl object (using the control:didFailToFormatString:errorDescription: delegate method).

Availability
Available in Mac OS X v10.0 and later.

See Also
- objectValue (page 572)
- setObjectValue: (page 592)

Declared In
NSCell.h

highlight:withFrame:inView:

Redraws the receiver with the specified highlight setting.

```
- (void)highlight:(BOOL)flag withFrame:(NSRect)cellFrame inView:(NSView *)controlView
```

Parameters

flag
If YES, the cell is redrawn with a highlight; otherwise, if NO, the highlight is removed.

cellFrame
The bounding rectangle of the receiver.

controlView
The control that manages the cell.

Discussion
Note that the NSCell highlighting does not appear when highlighted cells are printed (although instances of NSTextFieldCell, NSButtonCell, and others can print themselves highlighted). Generally, you cannot depend on highlighting being printed because implementations of this method may choose (or not choose) to use transparency.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `drawWithFrame:inView:` (page 554)
- `isHighlighted` (page 568)

Declared In
`NSCell.h`

highlightColorWithFrame:inView:

Returns the color the receiver uses when drawing the selection highlight.

```
- (NSColor *)highlightColorWithFrame:(NSRect)cellFrame inView:(NSView *)controlView
```

Parameters

cellFrame
The bounding rectangle of the receiver.

controlView
The control that manages the cell.

Return Value
The color the receiver uses when drawing the selection highlight.

Discussion
You should not assume that a cell would necessarily want to draw itself with the value returned from `selectedControlColor` (page 688). A cell may wish to draw with different a selection highlight color depending on such things as the key state of its *controlView*.

Availability
Available in Mac OS X v10.1 and later.

Declared In
`NSCell.h`

hitTestForEvent:inRect:ofView:

Returns hit testing information for the receiver.

```
- (NSUInteger)hitTestForEvent:(NSEvent *)event inRect:(NSRect)cellFrame
    ofView:(NSView *)controlView
```

Parameters

event
The current event.

cellFrame
The cell's frame.

controlView
The control object in which the cell is located.

Return Value
A constant that specifies the type of area in which the event occurred—see "Hit Testing" (page 620) for values.

Discussion
You can use a bit-wise mask to look for a specific value when calling this method—see "Hit Testing" (page 620) for values.

Generally, this method should be overridden by custom `NSCell` subclasses to return the correct result. Currently, it is called by some multi-cell views, such as `NSTableView`.

By default, `NSCell` looks at the cell type and does the following:

- `NSImageCellType`: If the image exists and the event point is in the image returns `NSCellHitContentArea`, otherwise `NSCellHitNone`.
- `NSTextCellType` (also applies to `NSTextFieldCell`):

  If there is text: If the event point hits in the text, return `NSCellHitContentArea`. Additionally, if the cell is enabled return `NSCellHitContentArea | NSCellHitEditableTextArea`.

  If there is not text: return `NSCellHitNone`.
- `NSNullCellType` (this is the default that applies to non text or image cells who don't override `hitTestForEvent:inRect:ofView:`):

  Return `NSCellHitContentArea` by default;

  If the cell not disabled, and it would track, return `NSCellHitContentArea | NSCellHitTrackableArea`.

Availability
Available in Mac OS X v10.5 and later.

importsGraphics

Returns a Boolean value that indicates whether the text of the receiver can contain imported graphics.

```
- (BOOL)importsGraphics
```

Return Value
`YES` if the receiver's text is in the RTFD format and supports imported graphics, otherwise `NO`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setImportsGraphics:` (page 589)

Declared In
NSCell.h

initImageCell:

Returns an `NSCell` object initialized with the specified image and set to have the cell's default menu.

```
- (id)initImageCell:(NSImage *)anImage
```

Parameters

anImage

The image to use for the cell. If this parameter is `nil`, no image is set.

Return Value

An initialized `NSCell` object, or `nil` if the cell could not be initialized.

Discussion

This is one of four designated initializers you must implement when subclassing. See "Designated Initializers" (page 533) for the complete list.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSCell.h`

initTextCell:

Returns an NSCell object initialized with the specified string and set to have the cell's default menu.

```
- (id)initTextCell:(NSString *)aString
```

Parameters

aString

The initial string to use for the cell.

Return Value

An initialized `NSCell` object, or `nil` if the cell could not be initialized.

Discussion

If no field editor (a shared `NSText` object) has been created for all `NSCell` objects, one is created.

This is one of four designated initializers you must implement when subclassing. See "Designated Initializers" (page 533) for the complete list.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSCell.h`

integerValue

Returns the receiver's value as an `NSInteger`.

```
- (NSInteger)integerValue
```

Return Value

The value of the cell interpreted as an `NSInteger`. If the receiver is not a text-type cell or the cell value is not scannable, returns `0`.

Availability

Available in Mac OS X v10.5 and later.

See Also
- `setIntegerValue:` (page 590)
- `intValue` (page 565)

Declared In
`NSCell.h`

interiorBackgroundStyle

Returns the interior background style for the receiver.

```
- (NSBackgroundStyle)interiorBackgroundStyle
```

Return Value
Returns the interior background style for the receiver.

Discussion
The interior background style describes the surface drawn onto in `drawInteriorWithFrame:inView:` (page 553). This is often the same as the `backgroundStyle` (page 547), but a button that draws a bezel would have a different `interiorBackgroundStyle`.

This is both an override point and a useful method to call. In a custom button with a custom bezel you can override this method to describe that surface. A cell that has custom interior drawing might query this method to help pick an image that looks good on the cell. Calling this method gives you some independence from changes in framework art style.

Availability
Available in Mac OS X v10.5 and later.

Related Sample Code
PhotoSearch

Declared In
`NSCell.h`

intValue

Returns the receiver's value as an integer.

```
- (int)intValue
```

Return Value
The value of the cell interpreted as an integer. If the receiver is not a text-type cell or the cell value is not scannable, returns `0`.

Discussion
On Mac OS X v10.5 and later, you should use `integerValue` (page 564) instead.

Availability
Available in Mac OS X v10.0 and later.

Available in Mac OS X v10.0 and later.

Declared In

`NSCell.h`

isOpaque

Returns a Boolean value that indicates whether the receiver is opaque (nontransparent).

```
- (BOOL)isOpaque
```

Return Value

`YES` if the receiver is opaque, otherwise `NO` to indicate the receiver might have some transparency.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSCell.h`

isScrollable

Returns a Boolean value that indicates whether the receiver scrolls excess text past the cell's bounds.

```
- (BOOL)isScrollable
```

Return Value
`YES` if excess text scrolls past the cell's bounds, otherwise `NO` (text wrapping is enabled).

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setScrollable:` (page 594)

Declared In
`NSCell.h`

isSelectable

Returns a Boolean value that indicates whether the text of the receiver can be selected.

```
- (BOOL)isSelectable
```

Return Value
`YES` if the receiver's text can be selected, otherwise `NO`.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setSelectable:` (page 594)

Declared In
`NSCell.h`

keyEquivalent

Returns the key equivalent to clicking the cell.

```
- (NSString *)keyEquivalent
```

Return Value
An empty string object.

Discussion
Subclasses can override this method to return a string with a valid character for the key equivalent.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSCell.h`

lineBreakMode

Returns the line break mode currently used when drawing text.

```
- (NSLineBreakMode)lineBreakMode
```

Return Value
The line break mode the receiver currently uses when drawing text. See `NSLineBreakMode` (page 1878) for supported values.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `setLineBreakMode:` (page 591)
- `truncatesLastVisibleLine` (page 610)

Declared In
`NSCell.h`

menu

Returns the receiver's contextual menu.

```
- (NSMenu *)menu
```

Return Value
The receiver's contextual menu, or `nil` if no menu is assigned.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setMenu:` (page 591)

Related Sample Code
ClockControl

Declared In
`NSCell.h`

menuForEvent:inRect:ofView:

Returns the menu associated with the receiver and related to the specified event and frame.

```
- (NSMenu *)menuForEvent:(NSEvent *)anEvent inRect:(NSRect)cellFrame ofView:(NSView
    *)aView
```

Parameters
anEvent
The event used to find the menu.

cellFrame
The cell's rectangle. This rectangle indicates the region containing the cursor.

aView
The view that manages the receiver. This is usually the control object that owns the cell.

Return Value
The menu associated with the cell and event parameters, or `nil` if no menu is set.

Discussion
This method is usually invoked by the `NSControl` object (*aView*) managing the receiver. The default implementation simply invokes `menu` (page 570) and returns `nil` if no menu has been set. Subclasses can override to customize the returned menu according to the event received and the area in which the mouse event occurs.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSCell.h`

mnemonic

Returns the character in the receiver's title that appears underlined for use as a mnemonic.

```
- (NSString *)mnemonic
```

Return Value
A string containing the mnemonic character, or an empty string if no mnemonic character is set.

Discussion
Mnemonics are not supported in Mac OS X

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setTitleWithMnemonic:` (page 599)

Declared In
`NSCell.h`

mnemonicLocation

Returns the position of the underlined mnemonic character in the receiver's title.

```
- (NSUInteger)mnemonicLocation
```

Return Value
A zero-based index into the receiver's title string indicating the position of the character. If there is no mnemonic character, this method returns `NSNotFound`.

Discussion
Mnemonics are not supported in Mac OS X.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setMnemonicLocation:` (page 592)

Declared In
`NSCell.h`

mouseDownFlags

Returns the modifier flags for the last (left) mouse-down event.

```
- (NSInteger)mouseDownFlags
```

Return Value
The modifier flags, or `0` if tracking has not yet occurred or no modifier keys accompanied the mouse-down event.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `modifierFlags` (page 1082) (`NSEvent`)

Declared In
`NSCell.h`

nextState

Returns the receiver's next state.

```
- (NSInteger)nextState
```

Return Value
The receiver's next state (for possible values, see "`NSCellStateValue`" (page 618)).

Discussion
If the receiver has three states, it cycles through them in this order: on, off, mixed, on, and so forth. If the receiver has two states, it toggles between them.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `allowsMixedState` (page 545)
- `setAllowsMixedState:` (page 578)
- `setNextState` (page 592)

Declared In
`NSCell.h`

objectValue

Returns the receiver's value as an Objective-C object

```
- (id)objectValue
```

Return Value
The receiver's object value, or `nil` if a valid object has not been associated with the receiver.

Discussion
To be valid object value, the receiver must have a formatter capable of converting the object to and from its textual representation.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setObjectValue:` (page 592)

Related Sample Code
ClockControl
PhotoSearch

Declared In
`NSCell.h`

performClick:

Simulates a single mouse click on the receiver.

```
- (void)performClick:(id)sender
```

Parameters

sender

The object to use as the sender of the event (if the receiver's control view is not valid). This object must be a subclass of `NSView`.

Discussion
This method performs the receiver's action on its target. The receiver must be enabled to perform the action. If the receiver's control view is valid, that view is used as the sender; otherwise, the value in *sender* is used.

The receiver of this message must be a cell of type `NSActionCell`. This method raises an exception if the action message cannot be successfully sent.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- controlView` (page 552)

Declared In
`NSCell.h`

refusesFirstResponder

Returns a Boolean value that indicates whether the receiver should not become the first responder.

```
- (BOOL)refusesFirstResponder
```

Return Value
`YES` if the receiver should never become the first responder, otherwise `NO` if the receiver can become the first responder.

Discussion
To find out whether the receiver can become first responder at this time, use the method `acceptsFirstResponder` (page 544).

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setRefusesFirstResponder:` (page 593)

Declared In
`NSCell.h`

representedObject

Returns the object the receiver represents.

```
- (id)representedObject
```

Return Value
The object represented by the receiver.

Discussion
Represented objects let you link a cell to an appropriate object. For example, you could have a pop-up list of color names, and the represented objects could be the appropriate `NSColor` objects.

Special Considerations

Note that if you copy an `NSCell` instance, the represented object in the copy is set to `nil`.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setRepresentedObject:` (page 593)

Related Sample Code
NewsReader

Declared In
`NSCell.h`

resetCursorRect:inView:

Sets the receiver to show the I-beam cursor while it tracks the mouse.

```
- (void)resetCursorRect:(NSRect)cellFrame inView:(NSView *)controlView
```

Parameters

cellFrame

The rectangle in which to display the I-beam cursor.

controlView

The control that manages the cell.

Discussion

The receiver must be an enabled and selectable (or editable) text-type cell.

This method is invoked by `resetCursorRects` (page 3206) and in general you do not need to call this method unless you have a custom `NSView` that uses a cell.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSCell.h`

selectWithFrame:inView:editor:delegate:start:length:

Selects the specified text range in the cell's field editor.

```
- (void)selectWithFrame:(NSRect)aRect inView:(NSView *)controlView editor:(NSText
    *)textObj delegate:(id)anObject start:(NSInteger)selStart
  length:(NSInteger)selLength
```

Parameters

aRect

The bounding rectangle of the cell.

controlView

The control that manages the cell.

textObj

The field editor to use for editing the cell.

anObject

The object to use as a delegate for the field editor (`textObj` parameter). This delegate object receives various `NSText` delegation and notification methods during the course of editing the cell's contents.

selStart

The start of the text selection.

selLength

The length of the text range.

Discussion

This method is similar to `editWithFrame:inView:editor:delegate:event:` (page 555), except that it can be invoked in any situation, not only on a mouse-down event. This method returns without doing anything if *controlView*, *textObj*, or the receiver is `nil`, or if the receiver has no font set for it.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSCell.h`

sendActionOn:

Sets the conditions on which the receiver sends action messages to its target.

```
- (NSInteger)sendActionOn:(NSInteger)mask
```

Parameters

mask

A bit mask containing the conditions for sending the action. The only conditions that are actually checked are associated with the `NSLeftMouseDownMask` (page 1097), `NSLeftMouseUpMask` (page 1097), `NSLeftMouseDraggedMask` (page 1098), and `NSPeriodicMask` (page 1099) bits.

Return Value
A bit mask containing the previous settings. This bit mask uses the same values as specified in the *mask* parameter.

Discussion
You use this method during mouse tracking when the mouse button changes state, the mouse moves, or if the cell is marked to send its action continuously while tracking. Because of this, the only bits checked in *mask* are `NSLeftMouseDownMask` (page 1097), `NSLeftMouseUpMask` (page 1097), `NSLeftMouseDraggedMask` (page 1098), and `NSPeriodicMask` (page 1099), which are declared in the `NSEvent` class reference.

You can use the `setContinuous:` (page 582) method to turn on the flag corresponding to `NSPeriodicMask` (page 1099) or `NSLeftMouseDraggedMask` (page 1098), whichever is appropriate to the given subclass of `NSCell`.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- action` (page 544)

Declared In
`NSCell.h`

sendsActionOnEndEditing

Returns a Boolean value that indicates whether the receiver's `NSControl` object sends its action message whenever the user finishes editing the cell's text.

```
- (BOOL)sendsActionOnEndEditing
```

Return Value
`YES` if the receiver's control sends its action message when editing is complete, otherwise `NO`.

Discussion
If this method returns `YES`, the receiver's `NSControl` object sends its action message when the user does one of the following:

- Presses the Return key
- Presses the Tab key to move out of the field
- Clicks another text field

If it returns NO, the cell's NSControl object sends its action message only when the user presses the Return key.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setSendsActionOnEndEditing: (page 595)

Declared In
NSCell.h

setAction:

Sets the cell's action method to the specified selector.

```
- (void)setAction:(SEL)aSelector
```

Parameters

aSelector

The new action-message selector to associate with the receiver's cell. Specify NULL to prevent action messages from being sent to the receiver's target.

Discussion
The NSCell implementation of this method raises NSInternalInconsistencyException. Subclasses (such as NSActionCell) override this method to set the action method as part of the target/action implementation.

Availability
Available in Mac OS X v10.0 and later.

See Also
- action (page 544)
- setTarget: (page 598)
- target (page 608)

Declared In
NSCell.h

setAlignment:

Sets the alignment of text in the receiver.

```
- (void)setAlignment:(NSTextAlignment)mode
```

Parameters

mode

This value can be one of the following constants: NSLeftTextAlignment, NSRightTextAlignment,NSCenterTextAlignment, NSJustifiedTextAlignment, orNSNaturalTextAlignment.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `alignment` (page 545)
- `setWraps:` (page 601)

Related Sample Code
FunHouse

Declared In
`NSCell.h`

setAllowsEditingTextAttributes:

Sets whether the receiver allows the user to edit textual attributes of its contents.

```
- (void)setAllowsEditingTextAttributes:(BOOL)flag
```

Parameters

flag

If `YES`, the user can modify the font and other textual attributes of the cell's text. If `NO`, the user cannot edit the text or import graphics, which effectively means the cell cannot support RTFD text.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `allowsEditingTextAttributes` (page 545)
- `setImportsGraphics:` (page 589)

Declared In
`NSCell.h`

setAllowsMixedState:

Sets whether the receiver supports three states or just two.

```
- (void)setAllowsMixedState:(BOOL)flag
```

Parameters

flag

If `YES`, the receiver supports three states (on, off, and mixed); otherwise, if `NO`, the receiver supports only two states (on and off).

Availability
Available in Mac OS X v10.0 and later.

See Also
- `allowsMixedState` (page 545)
- `nextState` (page 572)
- `setNextState` (page 592)

Declared In
`NSCell.h`

setAllowsUndo:

Sets whether the receiver assumes responsibility for undo operations within the cell.

```
- (void)setAllowsUndo:(BOOL)allowsUndo
```

Parameters

allowsUndo

If YES, the receiver handles undo operations; otherwise, if NO, the application's custom undo manager handles undo operations.

Discussion

Subclasses invoke this method to indicate their preference for handling undo operations; otherwise, you should not need to call this method directly.

Availability

Available in Mac OS X v10.4 and later.

See Also

- allowsUndo (page 546)

Declared In

NSCell.h

setAttributedStringValue:

Sets the value of the receiver's cell using an attributed string.

```
- (void)setAttributedStringValue:(NSAttributedString *)attribStr
```

Parameters

attribStr

The value of the cell interpreted as an attributed string.

Discussion

If a formatter is set for the receiver, but the formatter does not understand the attributed string, it marks *attribStr* as an invalid object. If the receiver is not a text-type cell, it is converted to one before the value is set.

For Mac OS X v10.3 and later: If you use a class that responds to the selector attributedStringValue (page 546) for the object value of a cell, then the cell uses that method to fetch the string to draw rather than using stringValue (page 605).

The following example sets the text in a cell to 14 points, red, in the system font.

```
NSColor *txtColor = [NSColor redColor];
NSFont *txtFont = [NSFont boldSystemFontOfSize:14];
NSDictionary *txtDict = [NSDictionary dictionaryWithObjectsAndKeys:
        txtFont, NSFontAttributeName, txtColor, NSForegroundColorAttributeName,
 nil];
NSAttributedString *attrStr = [[[NSAttributedString alloc]
         initWithString:@"Hello!" attributes:txtDict] autorelease];
[[attrStrTextField cell] setAttributedStringValue:attrStr];
[attrStrTextField updateCell:[attrStrTextField cell]];
```

Availability
Available in Mac OS X v10.0 and later.

See Also
- attributedStringValue (page 546)

Declared In
NSCell.h

setBackgroundStyle:

Sets the background style for the receiver.

```
- (void)setBackgroundStyle:(NSBackgroundStyle)style
```

Parameters

style
The background style for the receiver.

Availability
Available in Mac OS X v10.5 and later.

Related Sample Code
TrackBall

Declared In
NSCell.h

setBaseWritingDirection:

Sets the initial writing direction used to determine the actual writing direction for text .

```
- (void)setBaseWritingDirection:(NSWritingDirection)writingDirection
```

Parameters

writingDirection
The initial writing direction the receiver uses to determine the actual writing direction for text. See NSWritingDirection (page 2748) for possible values.

Discussion
If you know the base writing direction of the text you are rendering, you can use this method to specify that direction to the text system.

Availability
Available in Mac OS X v10.4 and later.

See Also
- baseWritingDirection (page 547)

Declared In
NSCell.h

setBezeled:

Sets whether the receiver draws itself with a bezeled border.

```
- (void)setBezeled:(BOOL)flag
```

Parameters

flag

If YES, the receiver uses a bezeled border.

Discussion

The setBezeled: and setBordered: (page 581) methods are mutually exclusive (that is, a border can be only plain or bezeled). Invoking this method automatically removes any border that had already been set, regardless of the value in the flag parameter.

Availability

Available in Mac OS X v10.0 and later.

See Also

- isBezeled (page 566)

Related Sample Code

QTKitMovieShuffler

Declared In

NSCell.h

setBordered:

Sets whether the receiver draws itself outlined with a plain border.

```
- (void)setBordered:(BOOL)flag
```

Parameters

flag

If YES, the receiver uses a plain border.

Discussion

The setBezeled: (page 581) and setBordered: methods are mutually exclusive (that is, a border can be only plain or bezeled). Invoking this method automatically removes any bezel that had already been set, regardless of the value in the flag parameter.

Availability

Available in Mac OS X v10.0 and later.

See Also

- isBordered (page 566)

Declared In

NSCell.h

setCellAttribute:to:

Sets the value for the specified cell attribute.

```
- (void)setCellAttribute:(NSCellAttribute)aParameter to:(NSInteger)value
```

Parameters

aParameter

The cell attribute whose value you want to set. Attributes include the receiver's current state and whether it is disabled, editable, or highlighted.

value

The new value for the attribute.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `cellAttribute:` (page 548)

Declared In
`NSCell.h`

setContinuous:

Sets whether the receiver's cell sends its action message continuously to its target during mouse tracking.

```
- (void)setContinuous:(BOOL)flag
```

Parameters

flag

If `YES`, the action message should be sent continuously.

Discussion
In practice, the continuous setting of action messages has meaning only for `NSActionCell` and its subclasses, which implement the target/action mechanism. Some `NSControl` subclasses, notably `NSMatrix`, send a default action to a default target when a cell doesn't provide a target or action.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `isContinuous` (page 566)
- `sendActionOn:` (page 576)

Declared In
`NSCell.h`

setControlSize:

Sets the size of the receiver.

```
- (void)setControlSize:(NSControlSize)size
```

Parameters

size

A value that specifies the size of the receiver (for possible values, see "`NSControlSize`" (page 620)).

Discussion
Changing the cell's control size does not change the font of the cell. Use the `systemFontSizeForControlSize:` (page 1159) class method of `NSFont` to obtain the system font based on the new control size and set it.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- controlSize` (page 551)

QTAudioExtractionPanel
Quartz Composer WWDC 2005 TextEdit

Declared In
`NSCell.h`

setControlTint:

Sets the receiver's control tint.

```
- (void)setControlTint:(NSControlTint)controlTint
```

Parameters
controlTint
An `NSControlTint` (page 533) value that specifies the tint of the receiver.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- controlTint` (page 551)

Declared In
`NSCell.h`

setControlView:

Sets the receiver's control view.

```
- (void)setControlView:(NSView *)view
```

Parameters
view
The view (normally an `NSControl` object) to associate with the cell.

Discussion
The control view represents the control currently being rendered by the cell.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `controlView` (page 552)

Related Sample Code
PhotoSearch

Declared In
`NSCell.h`

setDoubleValue:

Sets the value of the receiver's cell using a double-precision floating-point number.

```
- (void)setDoubleValue:(double)aDouble
```

Parameters

aDouble

The value of the cell interpreted as a double-precision floating-point number.

Discussion
In its implementation, this method invokes the `setObjectValue:` (page 592) method to set the actual value. This method does nothing if the receiver is not a text-type cell.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `doubleValue` (page 552)

Declared In
`NSCell.h`

setEditable:

Sets whether the user can edit the receiver's text.

```
- (void)setEditable:(BOOL)flag
```

Parameters

flag

If `YES`, the user is allowed to edit the receiver's text. If this value is `YES`, the text is also made selectable. If it is `NO`, the selectable attribute is restored to the value it was before the cell was last made editable.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `isEditable` (page 567)
- `setSelectable:` (page 594)

Declared In
NSCell.h

setEnabled:

Sets whether the receiver is enabled or disabled.

```
- (void)setEnabled:(BOOL)flag
```

Parameters

flag

If YES the receiver is enabled; otherwise, if NO, the receiver is disabled.

Discussion
The text of disabled cells is changed to gray. If a cell is disabled, it cannot be highlighted, does not support mouse tracking (and thus cannot participate in target/action functionality), and cannot be edited. However, you can still alter many attributes of a disabled cell programmatically. (The setState: (page 596) method, for instance, still works.)

Availability
Available in Mac OS X v10.0 and later.

See Also
- isEnabled (page 567)

Declared In
NSCell.h

setEntryType:

Sets how numeric data is formatted in the receiver and places restrictions on acceptable input. (Deprecated in Mac OS X v10.0 and later. Use a formatter instead—see setFormatter: (page 588).)

```
- (void)setEntryType:(NSInteger)aType
```

Parameters

aType

One of the types listed for this method in "Data Entry Types" (page 622).

Availability
Deprecated in Mac OS X v10.0 and later.

See Also
- `setFormatter:` (page 588)

Declared In
`NSCell.h`

setFloatingPointFormat:left:right:

Sets the auto-ranging and floating point number format of the receiver's cell. (Deprecated in Mac OS X v10.0. Use a formatter instead. See `setFormatter:` (page 588))

```
- (void)setFloatingPointFormat:(BOOL)autoRange left:(NSUInteger)leftDigits
    right:(NSUInteger)rightDigits
```

Parameters

autoRange

If `YES`, auto-ranging is enabled, otherwise it is disabled.

leftDigits

The number of digits to display to the left of the decimal point.

rightDigits

The number of digits to display to the right of the decimal point.

Discussion

Sets whether floating-point numbers are auto-ranged in the receiver and sets the sizes of the fields to the left and right of the decimal point. If *autoRange* is `NO`, *leftDigits* specifies the maximum number of digits to the left of the decimal point, and *rightDigits* specifies the number of digits to the right (the fractional digit places will be padded with zeros to fill this width). However, if a number is too large to fit its integer part in *leftDigits* digits, as many places as are needed on the left are effectively removed from *rightDigits* when the number is displayed.

If *autoRange* is `YES`, *leftDigits* and *rightDigits* are simply added to form a maximum total field width for the receiver (plus 1 for the decimal point). The fractional part will be padded with zeros on the right to fill this width, or truncated as much as possible (up to removing the decimal point and displaying the number as an integer). The integer portion of a number is never truncated—that is, it is displayed in full no matter what the field width limit is.

The following example sets a cell used to display dollar amounts up to 99,999.99:

```
[[currencyDollarsField cell] setEntryType:NSFloatType];
[[currencyDollarsField cell] setFloatingPointFormat:NO left:5  right:2];
```

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.0.

See Also
- `setFormatter:` (page 588)

Declared In
`NSCell.h`

setFloatValue:

Sets the value of the receiver's cell using a single-precision floating-point number.

```
- (void)setFloatValue:(float)aFloat
```

Parameters

aFloat

The value of the cell interpreted as a single-precision floating-point number.

Discussion

In its implementation, this method invokes the `setObjectValue:` (page 592) method to set the actual value. This method does nothing if the receiver is not a text-type cell.

Availability

Available in Mac OS X v10.0 and later.

See Also

`- floatValue` (page 557)

Declared In

`NSCell.h`

setFocusRingType:

Sets the type of focus ring to be used.

```
- (void)setFocusRingType:(NSFocusRingType)focusRingType
```

Parameters

focusRingType

Possible values are listed in `NSFocusRingType` (page 4009). To disable a view's focus ring, specify `NSFocusRingTypeNone`.

Discussion

You should only disable a view from drawing its focus ring if you want to draw your own focus ring, or if there is not sufficient space to display a focus ring in the default location.

Availability

Available in Mac OS X v10.3 and later.

See Also

`- focusRingType` (page 558)

`+ defaultFocusRingType` (page 543)

Declared In

`NSCell.h`

setFont:

Sets the font to use when the receiver displays text.

```
- (void)setFont:(NSFont *)fontObj
```

Parameters

fontObj

The font to use.

Discussion

If the receiver is not a text-type cell, the method converts it to that type before setting the font.

Availability

Available in Mac OS X v10.0 and later.

See Also

- font (page 558)

Related Sample Code

FunHouse

Mountains

Declared In

NSCell.h

setFormatter:

Sets the receiver's formatter object.

```
- (void)setFormatter:(NSFormatter *)newFormatter
```

Parameters

newFormatter

The formatter to use with the cell, or nil if you do not want the cell to use a formatter.

Discussion

Cells use a formatter object to format the textual representation of their object value and to validate cell input and convert that input to an object value. If the new formatter cannot interpret the receiver's current object value, that value is converted to a string object.

Availability

Available in Mac OS X v10.0 and later.

See Also

- formatter (page 559)

Declared In

NSCell.h

setHighlighted:

Sets whether the receiver has a highlighted appearance.

```
- (void)setHighlighted:(BOOL)flag
```

Parameters

flag

If YES, the receiver has a highlight.

Discussion
By default, this method does nothing. The `NSButtonCell` class overrides this method to draw the button with the appearance specified by `NSCellLightsByBackground`, `NSCellLightsByContents`, or `NSCellLightsByGray`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSCell.h`

setImage:

Sets the image to be displayed by the receiver.

```
- (void)setImage:(NSImage *)image
```

Parameters

image
The image to display in the cell.

Discussion
If the receiver is not an image-type cell, the method converts it to that type of cell.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSCell.h`

setImportsGraphics:

Sets whether the receiver can import images into its text.

```
- (void)setImportsGraphics:(BOOL)flag
```

Parameters

flag
If `YES`, the receiver can import images into its text and support RTFD text. If `NO`, RTFD text is not supported.

Discussion
If *flag* is YES, the receiver is also set to allow editing of text attributes.

Availability
Available in Mac OS X v10.0 and later.

See Also
- importsGraphics (page 563)
- setAllowsEditingTextAttributes: (page 578)

Declared In
NSCell.h

setIntegerValue:

Sets the value of the receiver using an NSInteger.

```
- (void)setIntegerValue:(NSInteger)anInteger
```

Parameters
anInteger
The value of the cell interpreted as an NSInteger.

Discussion
In its implementation, this method invokes the setObjectValue: (page 592) method to set the actual value. This method does nothing if the receiver is not a text-type cell.

Availability
Available in Mac OS X v10.5 and later.

See Also
- integerValue (page 564)
- setIntValue: (page 590)

Declared In
NSCell.h

setIntValue:

Sets the value of the receiver using an integer.

```
- (void)setIntValue:(int)anInt
```

Parameters
anInt
The value of the cell interpreted as an integer.

Discussion
In its implementation, this method invokes the setObjectValue: (page 592) method to set the actual value. This method does nothing if the receiver is not a text-type cell.

On Mac OS X v10.5 and later, you should use setIntegerValue: (page 590) instead.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `intValue` (page 565)
- `setIntegerValue:` (page 590)

Declared In
`NSCell.h`

setLineBreakMode:

Sets the line break mode to use when drawing text

```
- (void)setLineBreakMode:(NSLineBreakMode)mode
```

Parameters

mode

The line break mode the receiver currently uses when drawing text. See `NSLineBreakMode` (page 1878) for supported values.

Discussion
The line break mode can also be modified by calling the `setWraps:` (page 601) method.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `lineBreakMode` (page 570)
- `setWraps:` (page 601)

Declared In
`NSCell.h`

setMenu:

Sets the contextual menu for the cell.

```
- (void)setMenu:(NSMenu *)aMenu
```

Parameters

aMenu

A menu that has commands contextually related to the receiver. Specify `nil` to clear the previous menu.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `menu` (page 570)

Related Sample Code
DragNDropOutlineView

Declared In
NSCell.h

setMnemonicLocation:

Sets the character of the receiver's title to be used as a mnemonic character.

```
- (void)setMnemonicLocation:(NSUInteger)location
```

Parameters

location

The zero-based index into the cell's title string specifying the location of the mnemonic character. The specified character is underlined when the title is drawn.

Discussion
Mnemonics are not supported in Mac OS X.

Availability
Available in Mac OS X v10.0 and later.

See Also
- mnemonicLocation (page 571)

Declared In
NSCell.h

setNextState

Changes the state of the receiver to its next state.

```
- (void)setNextState
```

Discussion
If the receiver has three states, it cycles through them in this order: on, off, mixed, on, and so forth. If the receiver has two states, it toggles between them.

Availability
Available in Mac OS X v10.0 and later.

See Also
- allowsMixedState (page 545)
- nextState (page 572)
- setAllowsMixedState: (page 578)

Declared In
NSCell.h

setObjectValue:

Sets the receiver's object value.

```
- (void)setObjectValue:(id < NSCopying >)object
```

Parameters

object

The new object value for the cell.

Discussion

To be valid object value, the receiver must have a formatter capable of converting the object to and from its textual representation.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `objectValue` (page 572)
- `setRepresentedObject:` (page 593)

Related Sample Code

STUCAuthoringDeviceCocoaSample

Declared In

`NSCell.h`

setRefusesFirstResponder:

Sets whether the receiver should not become the first responder.

```
- (void)setRefusesFirstResponder:(BOOL)flag
```

Parameters

flag

If `YES`, the receiver should never become the first responder; otherwise, it may become the first responder.

Discussion

If `refusesFirstResponder` (page 573) returns `NO` and the cell is enabled, the method `acceptsFirstResponder` (page 544) returns `YES`, allowing the cell to become first responder.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSCell.h`

setRepresentedObject:

Sets the object represented by the receiver.

```
- (void)setRepresentedObject:(id)anObject
```

Parameters

anObject

The object to associate with the receiver.

Discussion
You can use this method to link two objects together. For example, if the receiver's title was "Blue", you could associate an `NSColor` object whose color was set to blue.

Special Considerations

Note that if you copy an `NSCell` instance, the represented object in the copy is set to `nil`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setObjectValue:` (page 592)
- `representedObject` (page 574)

Related Sample Code
NewsReader

Declared In
`NSCell.h`

setScrollable:

Sets whether excess text in the receiver is scrolled past the cell's bounds.

```
- (void)setScrollable:(BOOL)flag
```

Parameters

flag

If `YES`, text can be scrolled past the cell's bounds; otherwise, if `NO`, the text wrapping is enabled.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `isScrollable` (page 569)

Declared In
`NSCell.h`

setSelectable:

Sets whether text in the receiver can be selected.

```
- (void)setSelectable:(BOOL)flag
```

Parameters

flag

If `YES`, the receiver's text can be selected. If this value is `NO`, editability is also disabled; if it is `YES`, editability is not affected.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `isSelectable` (page 569)
- `setEditable:` (page 584)

Declared In
`NSCell.h`

setSendsActionOnEndEditing:

Sets whether the receiver's NSControl object sends its action message whenever the user finishes editing the cell's text.

```
- (void)setSendsActionOnEndEditing:(BOOL)flag
```

Parameters

flag

If `YES`, the receiver's control sends its action message when editing is complete; otherwise, if `NO`, it sends the action message only when the user presses the Return key.

Discussion
If *flag* is `YES`, the receiver's `NSControl` object sends its action message when the user does one of the following:

- Presses the Return key
- Presses the Tab key to move out of the field
- Clicks another text field

Availability
Available in Mac OS X v10.0 and later.

See Also
- `sendsActionOnEndEditing` (page 576)

Related Sample Code
Quartz Composer QCTV

Declared In
`NSCell.h`

setShowsFirstResponder:

Sets whether the receiver draws some indication of its first responder status.

```
- (void)setShowsFirstResponder:(BOOL)flag
```

Parameters

flag

If `YES`, the receiver draws an indication of its first responder status, otherwise it does not.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `showsFirstResponder` (page 602)

Declared In
`NSCell.h`

setState:

Sets the receiver's state to the specified value.

```
- (void)setState:(NSInteger)value
```

Parameters

value

The possible state values are `NSOnState`, `NSOffState`, and `NSMixedState`. If the cell supports only two states and you specify `NSMixedState`, this method sets the state to `NSOnState`.

Discussion
The `NSOffState` state indicates the normal or unpressed state. The `NSOnState` state indicates the alternate or pressed state. The NSMixedState state indicates that the feature represented by the control is in effect somewhere.

Although using the enumerated constants is preferred, *value* can also be an integer. If the cell has two states, 0 is treated as `NSOffState`, and a nonzero value is treated as `NSOnState`. If the cell has three states, 0 is treated as `NSOffState`; a negative value, as `NSMixedState`; and a positive value, as `NSOnState`.

Note that the value `state` (page 603) returns may not be the same value you passed into the `value` parameter.

To check whether the cell has three states (and uses the mixed state), invoke the `allowsMixedState` (page 545) method.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `state` (page 603)
- `setAllowsMixedState:` (page 578)

Related Sample Code
EnhancedDataBurn

Declared In
`NSCell.h`

setStringValue:

Sets the value of the receiver's cell using an `NSString` object.

```
- (void)setStringValue:(NSString *)aString
```

Parameters

aString

The string value of the cell.

Discussion
In its implementation, this method invokes the `setObjectValue:` (page 592) method to set the actual value. If no formatter is assigned to the receiver or if the formatter cannot "translate" *aString* to an underlying object, the receiver is flagged as having an invalid object. If the receiver is not a text-type cell, this method converts it to one before setting the object value.

For Mac OS X v10.3 and later: If you use a class that responds to the selector `attributedStringValue` (page 546) for the object value of a cell, the cell uses that method to fetch the string to draw rather than the `stringValue` (page 605) method.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `stringValue` (page 605)

NewsReader
QTKitMovieShuffler
SimpleComboBox

Declared In
`NSCell.h`

setTag:

Sets the tag of the receiver.

```
- (void)setTag:(NSInteger)anInteger
```

Parameters
anInteger
The new tag for the cell.

Discussion
The `NSCell` implementation of this method raises `NSInternalInconsistencyException`. The `NSActionCell` implementation sets the receiver's tag integer to *anInteger*.

Tags allow you to identify particular cells. Tag values are not used internally; they are only changed by external invocations of `setTag:`. You typically set tag values in Interface Builder and use them at runtime in your application. When you set the tag of a control with a single cell in Interface Builder, it sets the tags of both the control and the cell to the same value as a convenience.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `tag` (page 605)

Related Sample Code
Quartz Composer WWDC 2005 TextEdit

Declared In
NSCell.h

setTarget:

Sets the target object to receive action messages.

```
- (void)setTarget:(id)anObject
```

Parameters

anObject
The new target object to associate with the receiver's cell, or `nil` to remove the current target.

Discussion
The `NSCell` implementation of this method raises `NSInternalInconsistencyException`. Subclasses (such as `NSActionCell`) override this method to set the target object as part of the target/action implementation.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- target` (page 608)

Declared In
NSCell.h

setTitle:

Sets the title of the receiver.

```
- (void)setTitle:(NSString *)aString
```

Parameters

aString
The new string value for the cell.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- title` (page 609)

Related Sample Code
ButtonMadness
ObjectPath
Quartz Composer WWDC 2005 TextEdit

TextLinks

Declared In
NSCell.h

setTitleWithMnemonic:

Sets the title of the receiver with one character in the string denoted as an access key.

```
- (void)setTitleWithMnemonic:(NSString *)aString
```

Parameters

aString

The new title of the cell. One character in the string should be preceded by an ampersand (&) character. The character that follows becomes the mnemonic character for the title.

Discussion

Mnemonics are not supported in Mac OS X.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `mnemonic` (page 571)
- `setMnemonicLocation:` (page 592)

Declared In

`NSCell.h`

setTruncatesLastVisibleLine:

Sets whether the receiver truncates and adds the ellipsis character to the last visible line if the text doesn't fit into the cell bounds.

```
- (void)setTruncatesLastVisibleLine:(BOOL)flag
```

Parameters

flag

If `YES`, the receiver truncates the last line; if `NO`, it does not truncate.

Discussion

The line break mode must be either `NSLineBreakByWordWrapping` or `NSLineBreakByCharWrapping`. Otherwise, this setting is ignored.

Availability

Available in Mac OS X v10.5 and later.

See Also

- `truncatesLastVisibleLine` (page 610)
- `setLineBreakMode:` (page 591)

Declared In

`NSCell.h`

setType:

Sets the type of the cell, changing it to a text cell, image cell, or null cell.

```
- (void)setType:(NSCellType)aType
```

Parameters

aType

The new type of the cell (see "NSCellType" (page 613) for possible values).

Discussion

If the cell is already the same type as the one specified in the *aType* parameter, this method does nothing.

If *aType* is NSTextCellType, this method converts the receiver to a cell of that type, giving it a default title and setting the font to the system font at the default size. If *aType* is NSImageCellType, the cell type is not changed until you set a new non-nil image.

Availability

Available in Mac OS X v10.0 and later.

See Also

- type (page 611)
- setImage: (page 589)

Declared In

NSCell.h

setUpFieldEditorAttributes:

Configures the textual and background attributes of the receiver's field editor.

```
- (NSText *)setUpFieldEditorAttributes:(NSText *)textObj
```

Parameters

textObj

The field editor to configure. .

Return Value

The configured field editor.

Discussion

If the receiver is disabled, this method sets the text color to dark gray; otherwise the method sets it to the default color. If the receiver has a bezeled border, this method sets the background to the default color for text backgrounds; otherwise, the method sets it to the color of the receiver's NSControl object.

You should not use this method to substitute a new field editor. setUpFieldEditorAttributes: (page 600) is intended to modify the attributes of the text object (that is, the field editor) passed into it and return that text object. If you want to substitute your own field editor, use the fieldEditor:forObject: (page 3325) method or the windowWillReturnFieldEditor:toObject: delegate method of NSWindow.

Availability

Available in Mac OS X v10.0 and later.

Declared In

NSCell.h

setUserInterfaceLayoutDirection:

Sets the layout direction of the user interface.

```
- (void)setUserInterfaceLayoutDirection:(NSUserInterfaceLayoutDirection)layoutDirection
```

Parameters

layoutDirection

The direction of the user interface layout. See `NSUserInterfaceLayoutDirection` (page 184) for possible values.

Discussion

This method specifies the general user interface layout flow directions. For `NSCell` subclasses that have multiple visual components in a single cell instance, this property should specify the directionality or flow of components. It affects, for example, the layout of an `NSForm` object's title and value fields, the position of a disclosure triangle, and so on.

Availability

Available in Mac OS X v10.6 and later.

See Also

`- userInterfaceLayoutDirection` (page 611)

Declared In

`NSCell.h`

setUsesSingleLineMode:

Sets whether the text cell restricts layout and rendering of its content to a single line.

```
- (void)setUsesSingleLineMode:(BOOL)flag
```

Parameters

flag

`YES` if layout and rendering should be restricted to a single line, otherwise `NO`.

Discussion

If YES, the cell ignores the return value from `wraps` (page 612), interprets `NSLineBreakByWordWrapping` and `NSLineBreakByCharWrapping` returned by `lineBreakMode` (page 570) as `NSLineBreakByClipping`, and configures the field editor to ignore key binding commands that insert paragraph and line separators.

The field editor bound to a single line cell filters paragraph and line separator insertion from user actions. Cells in the single line mode use the fixed baseline layout. The text baseline position is determined solely by the control size regardless of content font style or size.

Availability

Available in Mac OS X v10.6 and later.

See Also

`- usesSingleLineMode` (page 612)

Declared In

`NSCell.h`

setWraps:

Sets whether text in the receiver wraps when its length exceeds the frame of the cell.

```
- (void)setWraps:(BOOL)flag
```

Parameters

flag

If YES, the receiver wraps text and also makes the receiver non-scrollable; otherwise, if NO, text is not wrapped.

Discussion

If the text of the receiver is an attributed string value you must explicitly set the paragraph style line break mode. Calling this method with the value YES is equivalent to calling the setLineBreakMode: method with the value NSLineBreakByWordWrapping.

Availability

Available in Mac OS X v10.0 and later.

See Also

- setLineBreakMode: (page 591)
- wraps (page 612)

Related Sample Code

Quartz Composer QCTV

Declared In

NSCell.h

showsFirstResponder

Returns a Boolean value that indicates whether the receiver should draw some indication of its first responder status.

```
- (BOOL)showsFirstResponder
```

Return Value

YES if the receiver should draw an indication of its first responder status, otherwise NO.

Discussion

The NSCell class itself does not draw a first-responder indicator. Subclasses may use the returned value to determine whether or not they should draw one, however.

Availability

Available in Mac OS X v10.0 and later.

See Also

- setShowsFirstResponder: (page 595)

Related Sample Code

ClockControl

Declared In

NSCell.h

startTrackingAt:inView:

Begins tracking mouse events within the receiver.

```
- (BOOL)startTrackingAt:(NSPoint)startPoint inView:(NSView *)controlView
```

Parameters

startPoint

The initial location of the cursor.

controlView

The `NSControl` object managing the receiver.

Return Value

`YES` if the receiver is set to respond continuously or set to respond when the mouse is dragged, otherwise `NO`.

Discussion

The `NSCell` implementation of `trackMouse:inRect:ofView:untilMouseUp:` (page 610) invokes this method when tracking begins. Subclasses can override this method to implement special mouse-tracking behavior at the beginning of mouse tracking—for example, displaying a special cursor.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `continueTracking:at:inView:` (page 550)
- `stopTracking:at:inView:mouseIsUp:` (page 604)

Related Sample Code

QTKitMovieShuffler

Declared In

`NSCell.h`

state

Returns the receiver's state.

```
- (NSInteger)state
```

Return Value

The receiver's state (for possible values, see "`NSCellStateValue`" (page 618)).

Discussion

Cells can have two or three states. If the receiver has two states, it returns either `NSOffState` (the normal or unpressed state) or `NSOnState` (the alternate or pressed state). If it has three, it may also return `NSMixedState`, indicating the feature is in effect somewhere.

To check whether the receiver uses the mixed state, use the method `allowsMixedState` (page 545).

Note that the value `state` (page 603) returns may not be the same value you passed into `setState:` (page 596).

Availability

Available in Mac OS X v10.0 and later.

See Also
- `setState:` (page 596)
- `setAllowsMixedState:` (page 578)

Declared In
`NSCell.h`

stopTracking:at:inView:mouseIsUp:

Stops tracking mouse events within the receiver.

```
- (void)stopTracking:(NSPoint)lastPoint at:(NSPoint)stopPoint inView:(NSView
    *)controlView mouseIsUp:(BOOL)flag
```

Parameters

lastPoint
Contains the previous position of the cursor.

stopPoint
The current location of the cursor.

controlView
The `NSControl` object managing the receiver.

flag
If `YES`, this method was invoked because the user released the mouse button; otherwise, if `NO`, the cursor left the designated tracking rectangle.

Discussion
The default `NSCell` implementation of `trackMouse:inRect:ofView:untilMouseUp:` (page 610) invokes this method when the cursor has left the bounds of the receiver or the mouse button goes up. The default `NSCell` implementation of this method does nothing. Subclasses often override this method to provide customized tracking behavior. The following example increments the state of a tristate cell when the mouse button is clicked:

```
- (void)stopTracking:(NSPoint)lastPoint at:(NSPoint)stopPoint
    inView:(NSView *)controlView mouseIsUp:(BOOL)flag
{
    if (flag == YES) {
        [self setTriState:([self triState]+1)];
    }
}
```

Availability
Available in Mac OS X v10.0 and later.

See Also
- `startTrackingAt:inView:` (page 603)
- `continueTracking:at:inView:` (page 550)

Related Sample Code
QTKitMovieShuffler

Declared In
`NSCell.h`

stringValue

Returns the value of the receiver's cell as an `NSString` object.

```
- (NSString *)stringValue
```

Return Value
The string value of the cell. This value may be an interpreted version of the cell's actual value. Interpretations are performed by the cell's formatter.

Discussion
If no formatter exists and the cell's value is an `NSString` object, this method returns the value as a plain, attributed, or localized formatted string. If the value is not an `NSString` object or cannot be converted to one, this method returns an empty string.

For Mac OS X v10.3 and later: If you use a class that responds to the selector `attributedStringValue` (page 546) for the object value of a cell, the cell uses that method to fetch the string to draw rather than the `stringValue` method.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setStringValue:` (page 596)

Related Sample Code
QTKitMovieShuffler
SimpleComboBox

Declared In
`NSCell.h`

tag

Returns the tag identifying the receiver.

```
- (NSInteger)tag
```

Return Value
The tag value. The `NSCell` implementation of this method returns `-1`.

Discussion
Tags allow you to identify particular cells. Tag values are not used internally; they are only changed by external invocations of `setTag:`. You typically set tag values in Interface Builder and use them at runtime in your application. When you set the tag of a control with a single cell in Interface Builder, it sets the tags of both the control and the cell to the same value as a convenience.

Availability
Available in Mac OS X v10.0 and later.

takeStringValueFrom:

Sets the value of the receiver's cell to the string value obtained from the specified object.

```
- (void)takeStringValueFrom:(id)sender
```

Parameters

sender

The object from which to take the value. This object must respond to the `stringValue` (page 605) message.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setStringValue:` (page 596)

Declared In
`NSCell.h`

target

Returns the target object of the receiver.

```
- (id)target
```

Return Value
The target object that receives action messages from the cell. The `NSCell` implementation of this method returns `nil`.

Discussion
Subclasses (such as `NSActionCell`) override this method to return the target object as part of the target/action implementation.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setTarget:` (page 598)

Declared In
`NSCell.h`

title

Returns the receiver's title.

```
- (NSString *)title
```

Return Value
The cell's string value.

Discussion
Subclasses (such as `NSButtonCell`) may override this method to return a different value.

Availability
Available in Mac OS X v10.0 and later.

SourceView

Declared In
`NSCell.h`

titleRectForBounds:

Returns the rectangle in which the receiver draws its title text.

```
- (NSRect)titleRectForBounds:(NSRect)theRect
```

Parameters
theRect
The bounding rectangle of the receiver.

Return Value
The rectangle in which the receiver draws its title text.

Discussion
If the receiver is a text-type cell, this method resizes the drawing rectangle for the title (*theRect*) inward by a small offset to accommodate the cell border. If the receiver is not a text-type cell, the method does nothing.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- imageRectForBounds:` (page 563)

Related Sample Code
PhotoSearch

Declared In
`NSCell.h`

trackMouse:inRect:ofView:untilMouseUp:

Initiates the mouse tracking behavior in a cell.

```
- (BOOL)trackMouse:(NSEvent *)theEvent inRect:(NSRect)cellFrame ofView:(NSView
    *)controlView untilMouseUp:(BOOL)untilMouseUp
```

Parameters

theEvent
The event that caused the mouse tracking to occur.

cellFrame
The receiver's frame rectangle.

controlView
The view containing the receiver. This is usually an `NSControl` object.

untilMouseUp
If `YES`, mouse tracking continues until the user releases the mouse button. If `NO`, tracking continues until the cursor leaves the tracking rectangle, specified by the *cellFrame* parameter, regardless of the mouse button state. See the discussion for more information.

Return Value
`YES` if the mouse tracking conditions are met, otherwise `NO`.

Discussion
This method is generally not overridden because the default implementation invokes other `NSCell` methods that can be overridden to handle specific events in a dragging session. This method's return value depends on the *untilMouseUp* flag. If *untilMouseUp* is set to `YES`, this method returns `YES` if the mouse button goes up while the cursor is anywhere; `NO`, otherwise. If *untilMouseUp* is set to `NO`, this method returns `YES` if the mouse button goes up while the cursor is within *cellFrame*; `NO`, otherwise.

This method first invokes `startTrackingAt:inView:` (page 603). If that method returns `YES`, then as mouse-dragged events are intercepted, `continueTracking:at:inView:` (page 550) is invoked until either the method returns `NO` or the mouse is released. Finally, `stopTracking:at:inView:mouseIsUp:` (page 604) is invoked if the mouse is released. If *untilMouseUp* is `YES`, it's invoked when the mouse button goes up while the cursor is anywhere. If *untilMouseUp* is `NO`, it's invoked when the mouse button goes up while the cursor is within *cellFrame*. You usually override one or more of these methods to respond to specific mouse events.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSCell.h`

truncatesLastVisibleLine

Returns a Boolean value indicating whether the receiver truncates and adds the ellipsis character to the last visible line if the text doesn't fit into the cell bounds.

```
- (BOOL)truncatesLastVisibleLine
```

Return Value
`YES` if the receiver truncates the last line; otherwise `NO`.

Discussion
The line break mode must be either `NSLineBreakByWordWrapping` or `NSLineBreakByCharWrapping`. Otherwise, this setting is ignored.

Availability
Available in Mac OS X v10.5 and later.

See Also
- `setTruncatesLastVisibleLine:` (page 599)
- `lineBreakMode` (page 570)

Declared In
`NSCell.h`

type

Returns the type of the receiver

```
- (NSCellType)type
```

Return Value
The type of the cell (see "`NSCellType`" (page 613) for possible values).

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setType:` (page 599)

Related Sample Code
ClockControl
PhotoSearch

Declared In
`NSCell.h`

userInterfaceLayoutDirection

Returns the layout direction of the user interface.

```
- (NSUserInterfaceLayoutDirection)userInterfaceLayoutDirection
```

Return Value
The direction of the user interface layout. See `NSUserInterfaceLayoutDirection` (page 184) for possible values.

Availability
Available in Mac OS X v10.6 and later.

See Also
- `setUserInterfaceLayoutDirection:` (page 600)

Declared In
NSCell.h

usesSingleLineMode

Returns whether the text cell restricts layout and rendering of its content to a single line.

```
- (BOOL)usesSingleLineMode
```

Return Value
YES if layout and rendering is restricted to a single line, otherwise NO.

Availability
Available in Mac OS X v10.6 and later.

See Also
- setUsesSingleLineMode: (page 601)

Declared In
NSCell.h

wantsNotificationForMarkedText

Returns a Boolean value that indicates whether the field editor initiated by the receiver should post text change notifications.

```
- (BOOL)wantsNotificationForMarkedText
```

Return Value
YES if the field editor initiated by the receiver should post text change notifications (NSTextDidChangeNotification (page 2752)) while editing marked text; otherwise, they are delayed until the marked text confirmation.

Discussion
NSCell's implementation returns NO.

Availability
Available in Mac OS X v10.5 and later.

Declared In
NSCell.h

wraps

Returns a Boolean value that indicates whether the receiver wraps its text when the text exceeds the borders of the cell.

```
- (BOOL)wraps
```

Return Value
YES if the receiver wraps text, otherwise NO.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setWraps:` (page 601)

Declared In
`NSCell.h`

Constants

NSCellType

These constants specify how a cell represents its data (as text or as an image). These constants are used by `setType:` (page 599) and `type` (page 611).

```
enum {
    NSNullCellType  = 0,
    NSTextCellType  = 1,
    NSImageCellType = 2
};
typedef NSUInteger NSCellType;
```

Constants

`NSNullCellType`
Cell displays nothing.
Available in Mac OS X v10.0 and later.
Declared in `NSCell.h`.

`NSTextCellType`
Cell displays text.
Available in Mac OS X v10.0 and later.
Declared in `NSCell.h`.

`NSImageCellType`
Cell displays images.
Available in Mac OS X v10.0 and later.
Declared in `NSCell.h`.

NSCellAttribute

These constants specify how a button behaves when pressed and how it displays its state. These constants are used by the `NSButton` and `NSButtonCell` classes

```
enum {
    NSCellDisabled               = 0,
    NSCellState                  = 1,
    NSPushInCell                 = 2,
    NSCellEditable               = 3,
    NSChangeGrayCell             = 4,
    NSCellHighlighted            = 5,
    NSCellLightsByContents       = 6,
    NSCellLightsByGray           = 7,
    NSChangeBackgroundCell       = 8,
    NSCellLightsByBackground     = 9,
    NSCellIsBordered             = 10,
    NSCellHasOverlappingImage    = 11,
    NSCellHasImageHorizontal     = 12,
    NSCellHasImageOnLeftOrBottom = 13,
    NSCellChangesContents        = 14,
    NSCellIsInsetButton          = 15,
    NSCellAllowsMixedState       = 16
};
typedef NSUInteger NSCellAttribute;
```

Constants

`NSCellAllowsMixedState`

Lets the cell's state be `NSMixedState`, as well as `NSOffState` and `NSOnState`.

Available in Mac OS X v10.0 and later.

Declared in `NSCell.h`.

`NSChangeBackgroundCell`

If the cell's state is `NSMixedState` or `NSOnState`, changes the cell's background color from gray to white.

Available in Mac OS X v10.0 and later.

Declared in `NSCell.h`.

`NSCellChangesContents`

If the cell's state is `NSMixedState` or `NSOnState`, displays the cell's alternate image.

Available in Mac OS X v10.0 and later.

Declared in `NSCell.h`.

`NSChangeGrayCell`

If the cell's state is `NSMixedState` or `NSOnState`, displays the cell's image as darkened.

Available in Mac OS X v10.0 and later.

Declared in `NSCell.h`.

`NSCellDisabled`

Does not let the user manipulate the cell.

Available in Mac OS X v10.0 and later.

Declared in `NSCell.h`.

`NSCellEditable`

Lets the user edit the cell's contents.

Available in Mac OS X v10.0 and later.

Declared in `NSCell.h`.

`NSCellHasImageHorizontal`
Controls the position of the cell's image: places the image on the right of any text in the cell.

Together, `NSCellHasImageOnLeftOrBottom`, `NSCellHasImageHorizontal`, and `NSCellHasOverlappingImage` control the position of the cell's image and text. To place the image above, set none of them. To place the image below, set `NSCellHasImageOnLeftOrBottom`. To place the image to the right, set `NSCellHasImageHorizontal`. To place the image to the left, set `NSCellHasImageHorizontal` and `NSCellHasImageOnLeftOrBottom`. To place the image directly over, set `NSCellHasOverlappingImage`.

Available in Mac OS X v10.0 and later.

Declared in `NSCell.h`.

`NSCellHasImageOnLeftOrBottom`
Controls the position of the cell's image: places the image on the left of or below any text in the cell.

See `NSCellHasImageHorizontal` (page 615) for more details.

Available in Mac OS X v10.0 and later.

Declared in `NSCell.h`.

`NSCellHasOverlappingImage`
Controls the position of the cell's image: places the image over any text in the cell.

See `NSCellHasImageHorizontal` (page 615) for more details.

Available in Mac OS X v10.0 and later.

Declared in `NSCell.h`.

`NSCellHighlighted`

Draws the cell with a highlighted appearance. (Deprecated. Use `setHighlighted:` (page 588) instead.)

Available in Mac OS X v10.0 and later.

Declared in `NSCell.h`.

`NSCellIsBordered`
Draws a border around the cell.

Available in Mac OS X v10.0 and later.

Declared in `NSCell.h`.

`NSCellIsInsetButton`
Insets the cell's contents from the border.

By default, the cell's contents are inset by 2 points. This constant is ignored if the cell is unbordered.

Available in Mac OS X v10.0 and later.

Declared in `NSCell.h`.

`NSCellLightsByBackground`
If the cell is pushed in, changes the cell's background color from gray to white.

Available in Mac OS X v10.0 and later.

Declared in `NSCell.h`.

`NSCellLightsByContents`
If the cell is pushed in, displays the cell's alternate image.

Available in Mac OS X v10.0 and later.

Declared in `NSCell.h`.

`NSCellLightsByGray`
If the cell is pushed in, displays the cell's image as darkened.

Available in Mac OS X v10.0 and later.

Declared in `NSCell.h`.

`NSPushInCell`
Determines whether the cell's image and text appear to be shifted down and to the right.

Available in Mac OS X v10.0 and later.

Declared in `NSCell.h`.

`NSCellState`
The cell's state.

The cell's state can be `NSMixedState` (page 618), `NSOffState` (page 618), or `NSOnState` (page 618).

Available in Mac OS X v10.0 and later.

Declared in `NSCell.h`.

NSCellImagePosition

These constants specify the position of a button's image relative to its title. These constants are used by the `setImagePosition:` (page 483) and `imagePosition` (page 476) methods of `NSButton` and `NSButtonCell`.

```
enum {
    NSNoImage       = 0,
    NSImageOnly     = 1,
    NSImageLeft     = 2,
    NSImageRight    = 3,
    NSImageBelow    = 4,
    NSImageAbove    = 5,
    NSImageOverlaps = 6
};
typedef NSUInteger NSCellImagePosition;
```

Constants

`NSNoImage`
The cell doesn't display an image.

Available in Mac OS X v10.0 and later.

Declared in `NSCell.h`.

`NSImageOnly`
The cell displays an image, but not a title.

Available in Mac OS X v10.0 and later.

Declared in `NSCell.h`.

`NSImageLeft`
The image is to the left of the title.

Available in Mac OS X v10.0 and later.

Declared in `NSCell.h`.

`NSImageRight`
The image is to the right of the title.

Available in Mac OS X v10.0 and later.

Declared in `NSCell.h`.

`NSImageBelow`
The image is below the title.

Available in Mac OS X v10.0 and later.

Declared in `NSCell.h`.

`NSImageAbove`
The image is above the title.

Available in Mac OS X v10.0 and later.

Declared in `NSCell.h`.

`NSImageOverlaps`
The image overlaps the title.

Available in Mac OS X v10.0 and later.

Declared in `NSCell.h`.

NSImageScaling

These constants specify a cell's image scaling behavior.

```
enum {
    NSImageScaleProportionallyDown = 0,
    NSImageScaleAxesIndependently,
    NSImageScaleNone,
    NSImageScaleProportionallyUpOrDown
};
typedef NSUInteger NSImageScaling;
```

Constants

`NSImageScaleProportionallyDown`
If it is too large for the destination, scale the image down while preserving the aspect ratio.

Available in Mac OS X v10.5 and later.

Declared in `NSCell.h`.

`NSImageScaleAxesIndependently`
Scale each dimension to exactly fit destination.

This setting does not preserve the aspect ratio of the image.

Available in Mac OS X v10.5 and later.

Declared in `NSCell.h`.

`NSImageScaleNone`
Do not scale the image.

Available in Mac OS X v10.5 and later.

Declared in `NSCell.h`.

`NSImageScaleProportionallyUpOrDown`
Scale the image to its maximum possible dimensions while both staying within the destination area and preserving its aspect ratio.

Available in Mac OS X v10.5 and later.

Declared in `NSCell.h`.

NSCellStateValue

These constants specify a cell's state and are used mostly for buttons. These constants are described in Cell States of *Control and Cell Programming Topics for Cocoa*.

```
enum {
    NSMixedState = -1,
    NSOffState   = 0,
    NSOnState    = 1
};
typedef NSUInteger NSCellStateValue;
```

Constants

`NSMixedState`

The corresponding feature is in effect somewhere.

Available in Mac OS X v10.0 and later.

Declared in `NSCell.h`.

`NSOffState`

The corresponding feature is in effect nowhere.

Available in Mac OS X v10.0 and later.

Declared in `NSCell.h`.

`NSOnState`

The corresponding feature is in effect everywhere.

Available in Mac OS X v10.0 and later.

Declared in `NSCell.h`.

State Masks

These constants specify what happens when a button is pressed or is displaying its alternate state. These contents are used by the `highlightsBy` (page 501) and `showsStateBy` (page 520) methods of `NSButtonCell`.

```
enum {
   NSNoCellMask               = 0,
   NSContentsCellMask         = 1,
   NSPushInCellMask           = 2,
   NSChangeGrayCellMask       = 4,
   NSChangeBackgroundCellMask = 8
};
```

Constants

`NSNoCellMask`

The button cell doesn't change.

Available in Mac OS X v10.0 and later.

Declared in `NSCell.h`.

`NSPushInCellMask`

The button cell "pushes in" if it has a border.

Available in Mac OS X v10.0 and later.

Declared in `NSCell.h`.

`NSContentsCellMask`
The button cell displays its alternate icon and/or title.

Available in Mac OS X v10.0 and later.

Declared in `NSCell.h`.

`NSChangeGrayCellMask`
The button cell swaps the "control color" (the `controlColor` (page 678) method of `NSColor`) and white pixels on its background and icon.

Available in Mac OS X v10.0 and later.

Declared in `NSCell.h`.

`NSChangeBackgroundCellMask`
Same as `NSChangeGrayCellMask`, but only background pixels are changed.

Available in Mac OS X v10.0 and later.

Declared in `NSCell.h`.

NSControlTint

These constants specify a cell's tint. These constants are used by `controlTint` (page 551) and `setControlTint:` (page 583).

```
enum {
    NSDefaultControlTint  = 0,
    NSBlueControlTint     = 1,
    NSGraphiteControlTint = 6,
    NSClearControlTint    = 7
};
typedef NSUInteger NSControlTint;
```

Constants

`NSDefaultControlTint`
The current default tint setting

Available in Mac OS X v10.0 and later.

Declared in `NSCell.h`.

`NSClearControlTint`
Clear control tint

Available in Mac OS X v10.0 and later.

Declared in `NSCell.h`.

`NSBlueControlTint`
Aqua control tint

Available in Mac OS X v10.3 and later.

Declared in `NSCell.h`.

`NSGraphiteControlTint`
Graphite control tint

Available in Mac OS X v10.3 and later.

Declared in `NSCell.h`.

NSControlSize

These constants specify a cell's size. These constants are used by `controlSize` (page 551) and `setControlSize:` (page 582).

```
enum {
    NSRegularControlSize,
    NSSmallControlSize,
    NSMiniControlSize
};
typedef NSUInteger NSControlSize;
```

Constants

`NSRegularControlSize`
The control is sized as regular.

Available in Mac OS X v10.0 and later.

Declared in `NSCell.h`.

`NSSmallControlSize`
The control has a smaller size.

This constant is for controls that cannot be resized in one direction, such as push buttons, radio buttons, checkboxes, sliders, scroll bars, pop-up buttons, tabs, and progress indicators. You should use a small system font with a small control.

Available in Mac OS X v10.0 and later.

Declared in `NSCell.h`.

`NSMiniControlSize`
The control has a smaller size than `NSSmallControlSize`.

Available in Mac OS X v10.3 and later.

Declared in `NSCell.h`.

Hit Testing

These constants are used by `hitTestForEvent:inRect:ofView:` (page 561) to determine the effect of an event.

```
enum {
    NSCellHitNone = 0,
    NSCellHitContentArea = 1 << 0,
    NSCellHitEditableTextArea = 1 << 1,
    NSCellHitTrackableArea = 1 << 2,
};
```

Constants

`NSCellHitNone`
An empty area, or did not hit in the cell.

Available in Mac OS X v10.5 and later.

Declared in `NSCell.h`.

`NSCellHitContentArea`
A content area in the cell.

Available in Mac OS X v10.5 and later.

Declared in `NSCell.h`.

`NSCellHitEditableTextArea`
An editable text area of the cell.

Available in Mac OS X v10.5 and later.

Declared in `NSCell.h`.

`NSCellHitTrackableArea`
A trackable area in the cell.

Available in Mac OS X v10.5 and later.

Declared in `NSCell.h`.

Declared In
`NSCell.h`

NSBackgroundStyle

Background styles used with `backgroundStyle` (page 547), `setBackgroundStyle:` (page 580), and `interiorBackgroundStyle` (page 565).

```
enum {
    NSBackgroundStyleLight = 0,
    NSBackgroundStyleDark,
    NSBackgroundStyleRaised,
    NSBackgroundStyleLowered
};
typedef NSUInteger NSBackgroundStyle;
```

Constants
`NSBackgroundStyleLight`
The background is a light color.

Dark content contrasts well with this background.

Available in Mac OS X v10.5 and later.

Declared in `NSCell.h`.

`NSBackgroundStyleDark`
The background is a dark color.

Light content contrasts well with this background.

Available in Mac OS X v10.5 and later.

Declared in `NSCell.h`.

`NSBackgroundStyleRaised`
The background is intended to appear higher than the content drawn on it.

Content might need to be inset.

Available in Mac OS X v10.5 and later.

Declared in `NSCell.h`.

`NSBackgroundStyleLowered`
The background is intended to appear lower than the content drawn on it.

Content might need to be embossed.

Available in Mac OS X v10.5 and later.

Declared in `NSCell.h`.

Deprecated Scaling Constants

These are deprecated scaling constants. (Deprecated. Use "NSImageScaling" (page 617) constants instead.)

```
enum {
    NSScaleProportionally = 0,
    NSScaleToFit,
    NSScaleNone
};
```

Constants

`NSScaleProportionally`
Use `NSImageScaleProportionallyDown` (page 617).

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.6.

Declared in `NSCell.h`.

`NSScaleToFit`
Use `NSImageScaleAxesIndependently` (page 617).

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.6.

Declared in `NSCell.h`.

`NSScaleNone`
Use `NSImageScaleNone` (page 617).

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.6.

Declared in `NSCell.h`.

Data Entry Types

These constants specify how a cell formats numeric data.

```
enum {
   NSAnyType            = 0,
   NSIntType            = 1,
   NSPositiveIntType    = 2,
   NSFloatType          = 3,
   NSPositiveFloatType  = 4,
   NSDoubleType         = 6,
   NSPositiveDoubleType = 7
};
```

Constants

`NSIntType`
Must be between `INT_MIN` and `INT_MAX`.
Deprecated in Mac OS X v10.4 and later.
Declared in `NSCell.h`.

`NSPositiveIntType`
Must be between 1 and `INT_MAX`.
Deprecated in Mac OS X v10.4 and later.
Declared in `NSCell.h`.

`NSFloatType`
Must be between `-FLT_MAX` and `FLT_MAX`.
Deprecated in Mac OS X v10.4 and later.
Declared in `NSCell.h`.

`NSPositiveFloatType`
Must be between `FLT_MIN` and `FLT_MAX`.
Deprecated in Mac OS X v10.4 and later.
Declared in `NSCell.h`.

`NSDoubleType`
Must be between `-FLT_MAX` and `FLT_MAX`.
Deprecated in Mac OS X v10.4 and later.
Declared in `NSCell.h`.

`NSPositiveDoubleType`
Must be between `FLT_MIN` and `FLT_MAX`.
Deprecated in Mac OS X v10.4 and later.
Declared in `NSCell.h`.

`NSAnyType`
Any value is allowed.
Deprecated in Mac OS X v10.4 and later.
Declared in `NSCell.h`.

Discussion

These constants are used by `setEntryType:` (page 585) and `entryType` (page 556).

Declared In

`NSCell.h`

Notifications

NSControlTintDidChangeNotification

Sent after the user changes control tint preference. The notification object is `NSApp`. This notification does not contain a *`userInfo`* dictionary.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSCell.h`

NSCIImageRep Class Reference

Inherits from	NSImageRep : NSObject
Conforms to	NSCoding (NSImageRep) NSCopying (NSImageRep) NSObject (NSObject)
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.4 and later.
Declared in	AppKit/NSCIImageRep.h
Companion guide	Cocoa Drawing Guide
Related sample code	FunHouse Reducer StillMotion

Overview

An `NSCIImageRep` object can render an image from a Core Image `CIImage` instance. For more information about the `CIImage` class and Core Image, see *Core Image Programming Guide*.

Tasks

Initialization

`+ imageRepWithCIImage:` (page 626)
Creates and returns an `NSCIImageRep` object initialized to the specified `CIImage` instance.

`- initWithCIImage:` (page 626)
Returns an `NSCIImageRep` object initialized to the specified `CIImage` instance.

Returning an Image

`- CIImage` (page 626)
Returns the receiver's `CIImage` instance.

Class Methods

imageRepWithCIImage:

Creates and returns an `NSCIImageRep` object initialized to the specified `CIImage` instance.

```
+ (id)imageRepWithCIImage:(CIImage *)image
```

Parameters

image

The `CIImage` instance.

Return Value

An initialized `NSCIImageRep` object, or `nil` if the object could not be initialized.

Availability

Available in Mac OS X v10.4 and later.

Related Sample Code

FunHouse

Reducer

StillMotion

Declared In

`NSCIImageRep.h`

Instance Methods

CIImage

Returns the receiver's `CIImage` instance.

```
- (CIImage *)CIImage
```

Return Value

The `CIImage` instance.

Availability

Available in Mac OS X v10.4 and later.

Declared In

`NSCIImageRep.h`

initWithCIImage:

Returns an `NSCIImageRep` object initialized to the specified `CIImage` instance.

```
- (id)initWithCIImage:(CIImage *)image
```

Parameters

image

The `CIImage` instance.

Return Value

An initialized `NSCIImageRep` object, or `nil` if the object could not be initialized.

Availability

Available in Mac OS X v10.4 and later.

Declared In

`NSCIImageRep.h`

NSClipView Class Objective-C Reference

Inherits from	NSView : NSResponder : NSObject
Conforms to	NSAnimatablePropertyContainer (NSView) NSCoding (NSResponder) NSObject (NSObject)
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.0 and later.
Declared in	AppKit/NSClipView.h
Companion guide	Cocoa Drawing Guide
Related sample code	Quartz Composer WWDC 2005 TextEdit TextSizingExample

Class at a Glance

An NSClipView contains and scrolls the document view displayed by an NSScrollView. You normally don't need to program with NSClipViews, as NSScrollView handles most of the details of their operation.

Principal Attributes

- Efficient scrolling by copying drawn portions of the document view
- Monitoring of document view for automatic update

Interface Builder

`- initWithFrame:`
: Initializes the NSClipView.

Commonly Used Methods

`setDocumentView:` (page 636)
: Sets the view scrolled within the NSClipView.

`setCopiesOnScroll:` (page 636)
: Sets whether the NSClipView copies drawn portions of the document view during scrolling.

Overview

An NSClipView holds the document view of an NSScrollView, clipping the document view to its frame, handling the details of scrolling in an efficient manner, and updating the NSScrollView when the document view's size or position changes. You don't normally use the NSClipView class directly; it's provided primarily as the scrolling machinery for the NSScrollView class. However, you might use the NSClipView class to implement a class similar to NSScrollView.

Interaction With NSScrollView

When using an NSClipView within an NSScrollView (the usual configuration), you should issue messages that control background drawing state to the NSScrollView, rather than messaging the NSClipView directly. This recommendation applies to the following methods:

- `-setBackgroundColor:`
- `-backgroundColor`
- `-setDrawsBackground:`
- `-drawsBackground`

The NSClipView methods are intended for when the NSClipView is used independently of a containing NSScrollView. In the usual case, NSScrollView should be allowed to manage the background-drawing properties of its associated NSClipView.

There is only one background-drawing state per NSScrollView/NSClipView pair. The two objects do not maintain independent and distinct `drawsBackground` and `backgroundColor` properties; rather, NSScrollView's accessors for these properties largely defer to the associated NSClipView and allow the NSClipView to maintain the state. In Mac OS X v10.2 and earlier system versions, NSScrollView maintained a cache of the last state it set for its NSClipView. If the NSClipView was sent a `setDrawsBackground:` message directly, the cache might not reflect the state accurately. This caching of state has been removed in Mac OS X v10.3.

It is also important to note that sending a `setDrawsBackground:` message with a parameter of NO to an NSScrollView has the added effect of sending the NSClipView a `setCopiesOnScroll:` message with a parameter of NO. The side effect of sending the `setDrawsBackground:` message directly to the NSClipView is the appearance of "trails" (vestiges of previous drawing) in the document view as it is scrolled.

Tasks

Setting the Document View

`- setDocumentView:` (page 636)
Sets the receiver's document view to *`aView`*, removing any previous document view, and sets the origin of the receiver's bounds rectangle to the origin of *`aView`*'s frame rectangle.

`- documentView` (page 634)
Returns the receiver's document view.

Scrolling

- `scrollToPoint:` (page 635)
  Changes the origin of the receiver's bounds rectangle to *`newOrigin`*.
- `autoscroll:` (page 632)
  Scrolls the receiver proportionally to *`theEvent`*'s distance outside of it.
- `constrainScrollPoint:` (page 633)
  Returns a scroll point adjusted from *`proposedNewOrigin`*, if necessary, to guarantee the receiver will still lie within its document view.

Determining Scrolling Efficiency

- `setCopiesOnScroll:` (page 636)
  Controls whether the receiver copies rendered images while scrolling.
- `copiesOnScroll` (page 633)
  Returns `YES` if the receiver copies its existing rendered image while scrolling (only drawing exposed portions of its document view), `NO` if it forces its contents to be redrawn each time.

Getting the Visible Portion

- `documentRect` (page 634)
  Returns the rectangle defining the document view's frame, adjusted to the size of the receiver if the document view is smaller.
- `documentVisibleRect` (page 634)
  Returns the exposed rectangle of the receiver's document view, in the document view's own coordinate system.

Setting the Document Cursor

- `setDocumentCursor:` (page 636)
  Sets the cursor object used over the receiver to *`aCursor`*.
- `documentCursor` (page 633)
  Returns the cursor object used when the cursor lies over the receiver.

Working with Background Color

- `drawsBackground` (page 635)
  Returns `YES` if the receiver draws its background color.
- `setDrawsBackground:` (page 637)
  Sets whether the receiver draws its background color, depending on the Boolean value *`flag`*.
- `setBackgroundColor:` (page 635)
  Sets the receiver's background color to *`aColor`*.

- `backgroundColor` (page 632)
  Returns the color of the receiver's background.

Overriding NSView Methods

- `viewBoundsChanged:` (page 637)
  Handles an `NSViewBoundsDidChangeNotification` (page 3256), passed in the *`aNotification`* argument, by updating a containing NSScrollView based on the new bounds.
- `viewFrameChanged:` (page 638)
  Handles an `NSViewFrameDidChangeNotification` (page 3257), passed in the *`aNotification`* argument, by updating a containing NSScrollView based on the new frame.

Instance Methods

autoscroll:

Scrolls the receiver proportionally to *`theEvent`*'s distance outside of it.

```
- (BOOL)autoscroll:(NSEvent *)theEvent
```

Discussion
`theEvent`'s location should be expressed in the window's base coordinate system (which it normally is), not the receiving NSClipView's. Returns `YES` if any scrolling is performed; otherwise returns `NO`.

Never invoke this method directly; instead, the NSClipView's document view should repeatedly send itself `autoscroll:` (page 3148) messages when the cursor is dragged outside the NSClipView's frame during a modal event loop initiated by a mouse-down event. The NSView class implements `autoscroll:` (page 3148) to forward the message to the receiver's superview; thus the message is ultimately forwarded to the NSClipView.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSClipView.h`

backgroundColor

Returns the color of the receiver's background.

```
- (NSColor *)backgroundColor
```

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setBackgroundColor:` (page 635)

Declared In
NSClipView.h

constrainScrollPoint:

Returns a scroll point adjusted from *proposedNewOrigin*, if necessary, to guarantee the receiver will still lie within its document view.

```
- (NSPoint)constrainScrollPoint:(NSPoint)proposedNewOrigin
```

Discussion
For example, if *proposedNewOrigin*'s y coordinate lies to the left of the document view's origin, then the y coordinate returned is set to that of the document view's origin.

Availability
Available in Mac OS X v10.0 and later.

See Also
- scrollToPoint: (page 635)

Declared In
NSClipView.h

copiesOnScroll

Returns YES if the receiver copies its existing rendered image while scrolling (only drawing exposed portions of its document view), NO if it forces its contents to be redrawn each time.

```
- (BOOL)copiesOnScroll
```

Availability
Available in Mac OS X v10.0 and later.

See Also
- setCopiesOnScroll: (page 636)

Declared In
NSClipView.h

documentCursor

Returns the cursor object used when the cursor lies over the receiver.

```
- (NSCursor *)documentCursor
```

Availability
Available in Mac OS X v10.0 and later.

See Also
- setDocumentCursor: (page 636)

Declared In
NSClipView.h

documentRect

Returns the rectangle defining the document view's frame, adjusted to the size of the receiver if the document view is smaller.

```
- (NSRect)documentRect
```

Discussion
In other words, this rectangle is always at least as large as the receiver itself.

The document rectangle is used in conjunction with an NSClipView's bounds rectangle to determine values for the indicators of relative position and size between the NSClipView and its document view. For example, NSScrollView uses these rectangles to set the size and position of the knobs in its scrollers. When the document view is much larger than the NSClipView, the knob is small; when the document view is near the same size, the knob is large; and when the document view is the same size or smaller, there is no knob.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `reflectScrolledClipView:` (page 2351) (NSScrollView)
- `documentVisibleRect` (page 634)

Declared In
NSClipView.h

documentView

Returns the receiver's document view.

```
- (id)documentView
```

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setDocumentView:` (page 636)

Declared In
NSClipView.h

documentVisibleRect

Returns the exposed rectangle of the receiver's document view, in the document view's own coordinate system.

```
- (NSRect)documentVisibleRect
```

Discussion
Note that this rectangle doesn't reflect the effects of any clipping that may occur above the NSClipView itself. To get the portion of the document view that's guaranteed to be visible, send it a `visibleRect` message.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- documentRect` (page 634)

Declared In
`NSClipView.h`

drawsBackground

Returns `YES` if the receiver draws its background color.

```
- (BOOL)drawsBackground
```

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setDrawsBackground:` (page 637)

Declared In
`NSClipView.h`

scrollToPoint:

Changes the origin of the receiver's bounds rectangle to *newOrigin*.

```
- (void)scrollToPoint:(NSPoint)newOrigin
```

Availability
Available in Mac OS X v10.0 and later.

See Also
`- constrainScrollPoint:` (page 633)

Related Sample Code
WhackedTV

Declared In
`NSClipView.h`

setBackgroundColor:

Sets the receiver's background color to *aColor*.

```
- (void)setBackgroundColor:(NSColor *)aColor
```

Availability
Available in Mac OS X v10.0 and later.

See Also
- `backgroundColor` (page 632)

Declared In
`NSClipView.h`

setCopiesOnScroll:

Controls whether the receiver copies rendered images while scrolling.

```
- (void)setCopiesOnScroll:(BOOL)flag
```

Discussion
If *flag* is `YES`, the receiver copies the existing rendered image to its new location while scrolling and only draws exposed portions of its document view. If *flag* is `NO`, the receiver always forces its document view to draw itself on scrolling.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `copiesOnScroll` (page 633)

Declared In
`NSClipView.h`

setDocumentCursor:

Sets the cursor object used over the receiver to *aCursor*.

```
- (void)setDocumentCursor:(NSCursor *)aCursor
```

Availability
Available in Mac OS X v10.0 and later.

See Also
- `documentCursor` (page 633)

Declared In
`NSClipView.h`

setDocumentView:

Sets the receiver's document view to *aView*, removing any previous document view, and sets the origin of the receiver's bounds rectangle to the origin of *aView*'s frame rectangle.

```
- (void)setDocumentView:(NSView *)aView
```

Discussion
If the receiver is contained in an NSScrollView, you should send the NSScrollView a `setDocumentView:` (page 2355) message instead, so it can perform whatever updating it needs.

In the process of setting the document view, this method registers the receiver for the notifications `NSViewFrameDidChangeNotification` (page 3257) and `NSViewBoundsDidChangeNotification` (page 3256), adjusts the key view loop to include the new document view, and updates a parent NSScrollView's display if needed using `reflectScrolledClipView:` (page 2351).

Availability
Available in Mac OS X v10.0 and later.

See Also
- `documentView` (page 634)

Related Sample Code
TextSizingExample

Declared In
`NSClipView.h`

setDrawsBackground:

Sets whether the receiver draws its background color, depending on the Boolean value *flag*.

```
- (void)setDrawsBackground:(BOOL)flag
```

Discussion
If your NSClipView is enclosed in an NSScrollView, you should send the `setDrawsBackground:` message to the NSScrollView. Sending a `setDrawsBackground:` message with a parameter of NO to an NSScrollView has the added effect of sending the NSClipView a `setCopiesOnScroll:` message with a parameter of NO. The side effect of sending the `setDrawsBackground:` message directly to the NSClipView is the appearance of "trails" (vestiges of previous drawing) in the document view as it is scrolled.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `drawsBackground` (page 635)

Declared In
`NSClipView.h`

viewBoundsChanged:

Handles an `NSViewBoundsDidChangeNotification` (page 3256), passed in the *aNotification* argument, by updating a containing NSScrollView based on the new bounds.

```
- (void)viewBoundsChanged:(NSNotification *)aNotification
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSClipView.h

viewFrameChanged:

Handles an NSViewFrameDidChangeNotification (page 3257), passed in the *aNotification* argument, by updating a containing NSScrollView based on the new frame.

```
- (void)viewFrameChanged:(NSNotification *)aNotification
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSClipView.h

NSCoder Application Kit Additions Reference

Inherits from	NSObject
Framework	/System/Library/Frameworks/AppKit.framework
Declared in	AppKit/NSColor.h
Companion guide	Archives and Serializations Programming Guide

Overview

This category adds a single method to the Foundation framework's NSCoder class. This method, `decodeNXColor` (page 639), is used to convert archived `NXColor` structures into `NSColor` objects.

`NXColor`, a type that dates from pre-OpenStep versions of NEXTSTEP, was a `struct`. Its replacement, `NSColor`, is a class. The difficulties of converting from a `struct` to a class require a special method like `decodeNXColor` (page 639).

The `decodeNXColor` (page 639) method becomes part of the `NSCoder` class only for applications that use the Application Kit.

Tasks

Decoding NXColor Structures

- `decodeNXColor` (page 639)
  Decodes a color structure from NEXTSTEP Release 3 or earlier and returns an `NSColor` object.

Instance Methods

decodeNXColor

Decodes a color structure from NEXTSTEP Release 3 or earlier and returns an `NSColor` object.

```
- (NSColor *)decodeNXColor
```

Return Value
An autoreleased `NSColor` object. Returns `nil` if the archived color is invalid.

Discussion
This method does not have a matching method for encoding an `NXColor` structure. Encode an `NSColor` object instead.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSColor.h`

NSCollectionView Class Reference

Inherits from	NSView : NSResponder : NSObject
Conforms to	NSAnimatablePropertyContainer (NSView) NSCoding (NSResponder) NSObject (NSObject)
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.5 and later.
Declared in	AppKit/NSCollectionView.h
Companion guide	Collection View Programming Guide
Related sample code	IconCollection Reviews

Overview

`NSCollectionView` class displays an array of content as a grid of views. The views are specified using the `NSCollectionViewItem` class which makes loadings nibs containing the view easy, and supports bindings.

Tasks

Modifying the Collection View Item

`- setItemPrototype:` (page 651)
Sets the receiver's item prototype to the specified collection view item.

`- itemPrototype` (page 647)
Returns the receiver's collection view item prototype.

`- newItemForRepresentedObject:` (page 648)
Returns the collection view item that is used for the specified object.

Working with the Responder Chain

- `isFirstResponder` (page 646)
  Returns whether the receiver is the first responder.

Setting the Content

- `setContent:` (page 650)
  Sets the receiver's content array.
- `content` (page 644)
  Returns the receiver's content object.

Setting the Selection Mode

- `setSelectable:` (page 653)
  Controls whether the receiver allows the user to select items.
- `isSelectable` (page 646)
  Returns a Boolean value that indicates whether the receiver allows the user to select items, `NO` if it doesn't.
- `setAllowsMultipleSelection:` (page 649)
  Controls whether the user can select multiple items at a time.
- `allowsMultipleSelection` (page 643)
  Returns a Boolean value that indicates whether the receiver allows the user to select more than one item at a time.
- `setSelectionIndexes:` (page 653)
  Sets the receiver's selection using the specified indexes.
- `selectionIndexes` (page 649)
  Returns an index set containing the indexes of the receiver's currently selected objects in the content array.

Laying out the Collection View

- `setMaxNumberOfRows:` (page 652)
  Sets the maximum number of rows the receiver will display.
- `maxNumberOfRows` (page 648)
  Returns the maximum number of rows the receiver will display.
- `setMaxNumberOfColumns:` (page 652)
  Sets the maximum number of columns the receiver will display
- `maxNumberOfColumns` (page 647)
  Returns the maximum number of columns the receiver will display.
- `setMinItemSize:` (page 653)
  Sets the minimum size used to display individual layout items in the grid.
- `minItemSize` (page 648)
  Returns the minimum size used to display individual collection view items in the grid.

- `setMaxItemSize:` (page 651)
  Sets the maximum size used to display individual collection view items in the grid.
- `maxItemSize` (page 647)
  Returns the maximum size used to display individual collection view items in the grid

Modifying the Background

- `setBackgroundColors:` (page 649)
  Sets the receiver's background colors to the specified array of colors.
- `backgroundColors` (page 644)
  Return the receiver's background colors.

Getting and Setting the Delegate

- `delegate` (page 644)
  Returns the receiver's delegate.
- `setDelegate:` (page 650)
  Sets the receiver's delegate.

Drag and Drop Support

- `draggingImageForItemsAtIndexes:withEvent:offset:` (page 645)
  This method computes and returns an image to use for dragging.
- `setDraggingSourceOperationMask:forLocal:` (page 651)
  Configures the default value returned from `draggingSourceOperationMaskForLocal:` (page 3670).

Getting a Collection Item and Its Frame

- `itemAtIndex:` (page 646)
  Returns the collection view item for the represented object at the specified index.
- `frameForItemAtIndex:` (page 645)
  Returns the frame of the collection view item at the specified index.

Instance Methods

allowsMultipleSelection

Returns a Boolean value that indicates whether the receiver allows the user to select more than one item at a time.

```
- (BOOL)allowsMultipleSelection
```

Return Value
`YES` if the receiver allows the user to select more than one column or row at a time, otherwise `NO`.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSCollectionView.h`

backgroundColors

Return the receiver's background colors.

```
- (NSArray *)backgroundColors
```

Return Value
Returns an array containing the receiver's background colors.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSCollectionView.h`

content

Returns the receiver's content object.

```
- (NSArray *)content
```

Return Value
An array containing the receiver's content.

Discussion
This property is observable using key-value observing.

Availability
Available in Mac OS X v10.5 and later.

Related Sample Code
IconCollection

Declared In
`NSCollectionView.h`

delegate

Returns the receiver's delegate.

```
- (id < NSCollectionViewDelegate >)delegate
```

Return Value
The receiver's delegate object.

Availability
Available in Mac OS X v10.6 and later.

Declared In
NSCollectionView.h

draggingImageForItemsAtIndexes:withEvent:offset:

This method computes and returns an image to use for dragging.

```
- (NSImage *)draggingImageForItemsAtIndexes:(NSIndexSet *)indexes withEvent:(NSEvent
    *)event offset:(NSPointPointer)dragImageOffset
```

Parameters

indexes
The index set of the items to be dragged.

event
Mouse drag event.

dragImageOffset
An in/out parameter that will initially be set to NSZeroPoint. it can be modified to reposition the returned image. A *dragImageOffset* of NSZeroPoint will cause the image to be centered under the mouse.

Return Value
An image containing a rendering of the visible portions of the views for each item.

Discussion
You can override the default image by subclassing NSCollectionView and overriding this method, or by implementing the collectionView:draggingImageForItemsAtIndexes:withEvent:offset: (page 3609) delegate method, it will be preferred over this method.

Availability
Available in Mac OS X v10.6 and later.

Declared In
NSCollectionView.h

frameForItemAtIndex:

Returns the frame of the collection view item at the specified index.

```
- (NSRect)frameForItemAtIndex:(NSUInteger)index
```

Parameters

index
The index of the collection view item.

Return Value
Returns the frame calculated by the receiver where it intends to place the subview for the NSCollectionViewItem at the given index. The rectangle is returned in the receiver's coordinate system.

Discussion
You can use this method in the `collectionView:draggingImageForItemsAtIndexes:withEvent:offset:` (page 3609) method to determine which views are in the visible portion of the enclosing scroll view.

Overriding this method will have no effect on the receiver's subview layout.

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSCollectionView.h`

isFirstResponder

Returns whether the receiver is the first responder.

```
- (BOOL)isFirstResponder
```

Return Value
`YES` if the receiver is the first responder, otherwise `NO`.

Special Considerations
This method is fully key-value observing compliant.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSCollectionView.h`

isSelectable

Returns a Boolean value that indicates whether the receiver allows the user to select items, `NO` if it doesn't.

```
- (BOOL)isSelectable
```

Return Value
`YES` if the receiver allows the user to select items, otherwise `NO`.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSCollectionView.h`

itemAtIndex:

Returns the collection view item for the represented object at the specified index.

```
- (NSCollectionViewItem *)itemAtIndex:(NSUInteger)index
```

Parameters

index

The index of the collection view item.

Return Value
An instance of `NSCollectionViewItem`.

Discussion
Rather than using the `NSCollectionViewItem` instance returned by this method to determine the frame of the collection item's view you should use `frameForItemAtIndex:` (page 645), it is significantly more efficient.

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSCollectionView.h`

itemPrototype

Returns the receiver's collection view item prototype.

```
- (NSCollectionViewItem *)itemPrototype
```

Return Value
The receiver's collection view item prototype.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSCollectionView.h`

maxItemSize

Returns the maximum size used to display individual collection view items in the grid

```
- (NSSize)maxItemSize
```

Return Value
The maximum size, measured in points, used to display individual collection view items.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSCollectionView.h`

maxNumberOfColumns

Returns the maximum number of columns the receiver will display.

```
- (NSUInteger)maxNumberOfColumns
```

Return Value
The maximum number of columns the receiver will display.

Availability
Available in Mac OS X v10.5 and later.

Declared In
NSCollectionView.h

maxNumberOfRows

Returns the maximum number of rows the receiver will display.

```
- (NSUInteger)maxNumberOfRows
```

Return Value
The maximum number of rows the receiver will display.

Availability
Available in Mac OS X v10.5 and later.

Declared In
NSCollectionView.h

minItemSize

Returns the minimum size used to display individual collection view items in the grid.

```
- (NSSize)minItemSize
```

Return Value
The minimum size, measured in points, used to display individual collection view items.

Availability
Available in Mac OS X v10.5 and later.

Declared In
NSCollectionView.h

newItemForRepresentedObject:

Returns the collection view item that is used for the specified object.

```
- (NSCollectionViewItem *)newItemForRepresentedObject:(id)object
```

Parameters
object
The content object that the collection view item will represent.

Return Value
An initialized collection view item with the specified object and the appropriate view set. The collection view item should not be autoreleased.

Discussion
Subclasses can override this method if the collection view items are not generated from a prototype or if the prototype view needs to be modified. The subclass is responsible for setting the `view` and `representedObject` (page 657) of the new collection view item.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSCollectionView.h`

selectionIndexes

Returns an index set containing the indexes of the receiver's currently selected objects in the content array.

```
- (NSIndexSet *)selectionIndexes
```

Return Value
An index set containing the indexes of the receiver's currently selected objects in the content array.

Discussion
This property is observable using key-value observing.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSCollectionView.h`

setAllowsMultipleSelection:

Controls whether the user can select multiple items at a time.

```
- (void)setAllowsMultipleSelection:(BOOL)flag
```

Parameters
flag
`YES` to allow the user to select multiple items, otherwise `NO`.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSCollectionView.h`

setBackgroundColors:

Sets the receiver's background colors to the specified array of colors.

```
- (void)setBackgroundColors:(NSArray *)colors
```

Parameters

colors

An array containing the background colors for the receiver.

Discussion

Passing an empty array or `nil` resets the background colors to their default values provided by `controlAlternatingRowBackgroundColors` (page 677).

Availability

Available in Mac OS X v10.5 and later.

Declared In

`NSCollectionView.h`

setContent:

Sets the receiver's content array.

```
- (void)setContent:(NSArray *)content
```

Parameters

content

An array containing the receiver's content.

Discussion

The content array can also be provided by creating a binding between the receiver's `NSContentBinding` (page 3709) and an array controller's `arrangedObjects` (page 205) method.

Availability

Available in Mac OS X v10.5 and later.

Declared In

`NSCollectionView.h`

setDelegate:

Sets the receiver's delegate.

```
- (void)setDelegate:(id < NSCollectionViewDelegate >)aDelegate
```

Parameters

aDelegate

The delegate object for the receiver. The delegate must conform to the `NSCollectionViewDelegate Protocol` protocol.

Availability

Available in Mac OS X v10.6 and later.

Declared In

`NSCollectionView.h`

setDraggingSourceOperationMask:forLocal:

Configures the default value returned from `draggingSourceOperationMaskForLocal:` (page 3670).

```
- (void)setDraggingSourceOperationMask:(NSDragOperation)dragOperationMask
    forLocal:(BOOL)localDestination
```

Parameters

dragOperationMask

The types of drag operations allowed.

localDestination

If `YES`, mask applies when the drag destination object is in the same application as the receiver; if `NO`, mask applies when the destination object is outside the receiver's application.

Discussion

By default, this method returns `NSDragOperationEvery` (page 3665) when *localDestination* is `YES` and `NSDragOperationNone` (page 3666) when *localDestination* is `NO`. `NSCollectionView` will save the values you set for each *localDestination* value.

You typically will invoke this method, and not override it.

Availability

Available in Mac OS X v10.6 and later.

Declared In

`NSCollectionView.h`

setItemPrototype:

Sets the receiver's item prototype to the specified collection view item.

```
- (void)setItemPrototype:(NSCollectionViewItem *)prototype
```

Parameters

prototype

The collection view item used as the prototype by the receiver.

Availability

Available in Mac OS X v10.5 and later.

Declared In

`NSCollectionView.h`

setMaxItemSize:

Sets the maximum size used to display individual collection view items in the grid.

```
- (void)setMaxItemSize:(NSSize)size
```

Parameters

size

The new maximum size, measured in points, with which to display individual collection view items.

Discussion
Setting the size to (0,0) specifies no maximum grid size. The default is (0.0). If the view in the receiver's collection view item prototype is resizable you should set this to the maximum size that the view should be displayed using.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSCollectionView.h`

setMaxNumberOfColumns:

Sets the maximum number of columns the receiver will display

```
- (void)setMaxNumberOfColumns:(NSUInteger)number
```

Parameters

number
The maximum number of columns the receiver will display.

Discussion
Setting to 0 specifies no maximum number of columns. Defaults to 0.

It is possible for a `NSCollectionView` instance to specify both the maximum number of rows and a maximum number of columns. If the number of content objects exceeds the number of displayable items (*n*=`maxNumberOfRows` * `maxNumberOfColumns`) only the first *n* items of the content array are displayed.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSCollectionView.h`

setMaxNumberOfRows:

Sets the maximum number of rows the receiver will display.

```
- (void)setMaxNumberOfRows:(NSUInteger)number
```

Parameters

number
The maximum number of rows the receiver can display.

Discussion
Setting to 0 specifies no maximum number of rows. Defaults to 0.

It is possible for a `NSCollectionView` instance to specify both the maximum number of rows and a maximum number of columns. If the number of content objects exceeds the number of displayable items (*n*=`maxNumberOfRows` * `maxNumberOfColumns`) only the first *n* items of the content array are displayed.

Availability
Available in Mac OS X v10.5 and later.

Declared In
NSCollectionView.h

setMinItemSize:

Sets the minimum size used to display individual layout items in the grid.

```
- (void)setMinItemSize:(NSSize)size
```

Parameters

size

The new minimum size, measured in points, with which to display individual layout items.

Discussion
The default is (0.0). If the view in the receiver's collection view item prototype is resizable you should set this to the minimum size that the view should be displayed using.

Availability
Available in Mac OS X v10.5 and later.

Declared In
NSCollectionView.h

setSelectable:

Controls whether the receiver allows the user to select items.

```
- (void)setSelectable:(BOOL)flag
```

Parameters

flag

If flag is YES, the receiver allows the user to select items; if flag is NO, it doesn't.

Discussion
You can set selections programmatically regardless of this setting.

Availability
Available in Mac OS X v10.5 and later.

Declared In
NSCollectionView.h

setSelectionIndexes:

Sets the receiver's selection using the specified indexes.

```
- (void)setSelectionIndexes:(NSIndexSet *)indexes
```

Parameters

indexes

The set of selection indexes for the receiver.

Discussion
To select all the receiver's objects, indexes should be an index set with indexes [0...count -1]. To deselect all indexes, pass an empty index set.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSCollectionView.h`

Constants

NSCollectionViewDropOperation

These constants specify if acceptance of a drop should be at the item it is dropped on or before the item. These constants are used by the `collectionView:acceptDrop:index:dropOperation:` (page 3608) and `collectionView:validateDrop:proposedIndex:dropOperation:` (page 3610) methods in `NSCollectionViewDelegate Protocol`

```
enum {     NSCollectionViewDropOn = 0,     NSCollectionViewDropBefore = 1, };
typedef NSInteger NSCollectionViewDropOperation;
```

Constants

`NSCollectionViewDropOn`

The drop occurs at the collection view item to which the item was dragged.

Available in Mac OS X v10.6 and later.

Declared in `NSCollectionView.h`.

`NSCollectionViewDropBefore`

The drop occurs above the collection view item to which the item was dragged..

Available in Mac OS X v10.6 and later.

Declared in `NSCollectionView.h`.

NSCollectionViewItem Class Reference

Inherits from	NSViewController : NSResponder : NSObject
Conforms to	NSCopying NSCoding (NSViewController) NSCoding (NSResponder) NSObject (NSObject) NSEditor (Informal Protocol) (NSViewController) NSEditorRegistration (Informal Protocol) (NSViewController)
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.5 and later.
Declared in	AppKit/NSCollectionViewItem.h

Overview

`NSCollectionViewItem` class is a controller that manages the relationship between a compound view and the model object that provides its content. Instances of this class are replicated in a `NSCollectionView`.

Important: In Mac OS X v10.5, the superclass of the NSCollectionViewItem class was NSObject. In Mac OS X v10.6 and later, NSCollectionViewItem is now a subclass of NSViewController. This change was made to improve how the view is replicated within the NSCollectionView. NSCollectionViewItem remains binary compatible with the previous implementation and unarchiving is correctly handled.

Tasks

Setting the Represented Object

`- setRepresentedObject:` (page 657)
Sets the receiver's represented object to the specified model object.

`- representedObject` (page 657)
Returns the receiver's represented object.

Modifying the View

- `setView:` (page 658)
  Sets the view the receiver uses to display its represented object.
- `view` (page 658)
  Returns the view the receiver uses to display its represented object.

Managing the Selection

- `setSelected:` (page 657)
  Sets the selection state of the receiver.
- `isSelected` (page 656)
  Returns the selection state of the receiver.

Parent Collection View

- `collectionView` (page 656)
  Returns the receiver's collection view.

Instance Methods

collectionView

Returns the receiver's collection view.

```
- (NSCollectionView *)collectionView
```

Return Value
The receiver's collection view.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSCollectionView.h`

isSelected

Returns the selection state of the receiver.

```
- (BOOL)isSelected
```

Return Value
`YES` if the receiver is selected, otherwise `NO`.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSCollectionView.h`

representedObject

Returns the receiver's represented object. (Available in Mac OS X v10.5 through Mac OS X v10.5.)

```
- (id)representedObject
```

Return Value
The receiver's represented object.

Availability
Available in Mac OS X v10.5 through Mac OS X v10.5.

Declared In
`NSCollectionView.h`

setRepresentedObject:

Sets the receiver's represented object to the specified model object. (Available in Mac OS X v10.5 through Mac OS X v10.5.)

```
- (void)setRepresentedObject:(id)object
```

Parameters
object
The receiver's model object.

Availability
Available in Mac OS X v10.5 through Mac OS X v10.5.

Declared In
`NSCollectionView.h`

setSelected:

Sets the selection state of the receiver.

```
- (void)setSelected:(BOOL)flag
```

Parameters
flag
`YES` if the receiver is selected, otherwise `NO`.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSCollectionView.h`

setView:

Sets the view the receiver uses to display its represented object. (Available in Mac OS X v10.5 through Mac OS X v10.5.)

```
- (void)setView:(NSView *)view
```

Parameters

view

The view that is used to display the receiver's represented object.

Availability
Available in Mac OS X v10.5 through Mac OS X v10.5.

Declared In
NSCollectionView.h

view

Returns the view the receiver uses to display its represented object. (Available in Mac OS X v10.5 through Mac OS X v10.5.)

```
- (NSView *)view
```

Return Value
The view the receiver uses to display its represented object.

Availability
Available in Mac OS X v10.5 through Mac OS X v10.5.

Declared In
NSCollectionView.h

Class at a Glance

An `NSColor` object represents a color, which is defined in a color space, each point of which has a set of components (such as red, green, and blue) that uniquely define a color.

Principal Attributes

- Color space
- Color components

  Various `colorWith...` and `colorUsing...` methods.
  Preset colors: `blackColor` (page 667), `blueColor` (page 668), and so on.

Commonly Used Methods

`colorUsingColorSpaceName:` (page 700)
Creates an `NSColor` instance in the specified color space.

`set` (page 711)
Sets the drawing color.

Overview

An `NSColor` object represents color and sometimes opacity (alpha). By sending a `set` (page 711) message to an `NSColor` instance, you set the color for the current drawing context. Setting the color causes subsequently drawn graphics to have the color represented by the `NSColor` instance.

It is invalid to use an accessor method related to components of a particular color space on an `NSColor` object that is not in that color space. For example, methods such as `redComponent` (page 710) and `getRed:green:blue:alpha:` (page 705) work on color objects in the calibrated and device RGB color spaces. If you send such a message to an `NSColor` object in the CMYK color space, an exception is raised. Further, the methods `getComponents:` (page 703) and `numberOfComponents` (page 709) work in color spaces that have individual components. Thus they return the components of `NSColor` objects as individual floating-point values regardless of whether they're based on `NSColorSpace` objects or named color spaces. However, older component-fetching methods such as `redComponent` and `getRed:green:blue:alpha:` are only effective on `NSColor` objects based on named color spaces.

If you have an `NSColor` object in an unknown color space and you want to extract its components, you should first convert the color object to a known color space before using the component accessor methods of that color space.

Adopted Protocols

NSCoding
`encodeWithCoder:`
`initWithCoder:`

NSCopying
`copyWithZone:`

Tasks

Creating an NSColor Object from Component Values

`+ colorWithCalibratedHue:saturation:brightness:alpha:` (page 670)
Creates and returns an `NSColor` object using the given opacity and HSB color space components.

+ colorWithCalibratedRed:green:blue:alpha: (page 670)
Creates and returns an NSColor object using the given opacity and RGB components.

+ colorWithCalibratedWhite:alpha: (page 671)
Creates and returns an NSColor object using the given opacity and grayscale value.

+ colorWithCatalogName:colorName: (page 672)
Creates and returns an NSColor object by finding the color with the specified name in the given catalog.

+ colorWithDeviceCyan:magenta:yellow:black:alpha: (page 674)
Creates and returns an NSColor object using the given opacity value and CMYK components.

+ colorWithDeviceHue:saturation:brightness:alpha: (page 674)
Creates and returns an NSColor object using the given opacity value and HSB color space components.

+ colorWithDeviceRed:green:blue:alpha: (page 675)
Creates and returns an NSColor object using the given opacity value and RGB components.

+ colorWithDeviceWhite:alpha: (page 676)
Creates and returns an NSColor object using the given opacity and grayscale values.

+ colorWithCIColor: (page 672)
Converts a Core Image color object to its NSColor equivalent.

+ colorWithColorSpace:components:count: (page 673)
Returns an NSColor object created from the specified components of the given color space.

Creating an NSColor with Preset Components

+ blackColor (page 667)
Returns an NSColor object whose grayscale value is 0.0 and whose alpha value is 1.0.

+ blueColor (page 668)
Returns an NSColor object whose RGB value is 0.0, 0.0, 1.0 and whose alpha value is 1.0.

+ brownColor (page 668)
Returns an NSColor object whose RGB value is 0.6, 0.4, 0.2 and whose alpha value is 1.0.

+ clearColor (page 668)
Returns an NSColor object whose grayscale and alpha values are both 0.0.

+ cyanColor (page 681)
Returns an NSColor object whose RGB value is 0.0, 1.0, 1.0 and whose alpha value is 1.0.

+ darkGrayColor (page 681)
Returns an NSColor object whose grayscale value is 1/3 and whose alpha value is 1.0.

+ grayColor (page 682)
Returns an NSColor object whose grayscale value is 0.5 and whose alpha value is 1.0.

+ greenColor (page 682)
Returns an NSColor object whose RGB value is 0.0, 1.0, 0.0 and whose alpha value is 1.0.

+ lightGrayColor (page 686)
Returns an NSColor object whose grayscale value is 2/3 and whose alpha value is 1.0.

+ magentaColor (page 686)
Returns an NSColor object whose RGB value is 1.0, 0.0, 1.0 and whose alpha value is 1.0.

+ orangeColor (page 686)
Returns an NSColor object whose RGB value is 1.0, 0.5, 0.0 and whose alpha value is 1.0.

+ purpleColor (page 687)
    Returns an NSColor object whose RGB value is 0.5, 0.0, 0.5 and whose alpha value is 1.0.
+ redColor (page 687)
    Returns an NSColor object whose RGB value is 1.0, 0.0, 0.0 and whose alpha value is 1.0.
+ whiteColor (page 693)
    Returns an NSColor object whose grayscale and alpha values are both 1.0.
+ yellowColor (page 695)
    Returns an NSColor object whose RGB value is 1.0, 1.0, 0.0 and whose alpha value is 1.0.

Working with Pattern Images

+ colorWithPatternImage: (page 677)
    Creates and returns an NSColor object that uses the specified image pattern.
- patternImage (page 709)
    Returns the image that the receiver is using as a pattern.

Creating a System Color—an NSColor Whose Value Is Specified by User Preferences

+ alternateSelectedControlColor (page 666)
    Returns the system color used for the face of a selected control.
+ alternateSelectedControlTextColor (page 667)
    Returns the system color used for text in a selected control.
+ colorForControlTint: (page 669)
    Returns the NSColor object specified by the given control tint.
+ controlBackgroundColor (page 677)
    Returns the system color used for the background of large controls.
+ controlColor (page 678)
    Returns the system color used for the flat surfaces of a control.
+ controlAlternatingRowBackgroundColors (page 677)
    Returns an array containing the system specified background colors for alternating rows in tables and lists.
+ controlHighlightColor (page 679)
    Returns the system color used for the highlighted bezels of controls.
+ controlLightHighlightColor (page 679)
    Returns the system color used for light highlights in controls.
+ controlShadowColor (page 679)
    Returns the system color used for the shadows dropped from controls.
+ controlDarkShadowColor (page 678)
    Returns the system color used for the dark edge of the shadow dropped from controls.
+ controlTextColor (page 680)
    Returns the system color used for text on controls that aren't disabled.

+ currentControlTint (page 680)
  Returns the current system control tint.
+ disabledControlTextColor (page 681)
  Returns the system color used for text on disabled controls.
+ gridColor (page 683)
  Returns the system color used for the optional gridlines in, for example, a table view.
+ headerColor (page 683)
  Returns the system color used as the background color for header cells in table views and outline views.
+ headerTextColor (page 684)
  Returns the system color used for text in header cells in table views and outline views.
+ highlightColor (page 684)
  Returns the system color that represents the virtual light source on the screen.
+ keyboardFocusIndicatorColor (page 685)
  Returns the system color that represents the keyboard focus ring around controls.
+ knobColor (page 685)
  Returns the system color used for the flat surface of a slider knob that hasn't been selected.
+ scrollBarColor (page 688)
  Returns the system color used for scroll "bars"—that is, for the groove in which a scroller's knob moves
+ secondarySelectedControlColor (page 688)
  Returns the system color used in non-key views.
+ selectedControlColor (page 688)
  Returns the system color used for the face of a selected control.
+ selectedControlTextColor (page 689)
  Returns the system color used for text in a selected control—a control being clicked or dragged.
+ selectedMenuItemColor (page 690)
  Returns the system color used for the face of selected menu items.
+ selectedMenuItemTextColor (page 690)
  Returns the system color used for the text in menu items.
+ selectedTextBackgroundColor (page 690)
  Returns the system color used for the background of selected text.
+ selectedTextColor (page 691)
  Returns the system color used for selected text.
+ selectedKnobColor (page 689)
  Returns the system color used for the slider knob when it is selected.
+ shadowColor (page 692)
  Returns the system color that represents the virtual shadows cast by raised objects on the screen.
+ textBackgroundColor (page 692)
  Returns the system color used for the text background.
+ textColor (page 693)
  Returns the system color used for text.
+ windowBackgroundColor (page 694)
  Returns a pattern color that will draw the ruled lines for the window background.

+ windowFrameColor (page 694)
Returns the system color used for window frames, except for their text.

+ windowFrameTextColor (page 694)
Returns the system color used for the text in window frames.

Ignoring Alpha Components

+ ignoresAlpha (page 684)
Returns a Boolean value indicating whether the application supports alpha.

+ setIgnoresAlpha: (page 691)
Specifies whether an application supports alpha.

Copying and Pasting

+ colorFromPasteboard: (page 669)
Returns the NSColor currently on the given pasteboard.

- writeToPasteboard: (page 713)
Writes the receiver's data to the specified pasteboard.

Retrieving a Set of Components

- getCyan:magenta:yellow:black:alpha: (page 703)
Returns the receiver's CMYK and opacity values.

- getHue:saturation:brightness:alpha: (page 704)
Returns the receiver's HSB component and opacity values in the respective arguments.

- getRed:green:blue:alpha: (page 705)
Returns the receiver's RGB component and opacity values in the respective arguments.

- getWhite:alpha: (page 706)
Returns the receiver's grayscale value and alpha values.

- getComponents: (page 703)
Returns the components of the receiver as an array.

- numberOfComponents (page 709)
Returns the number of components in the receiver.

Retrieving Individual Components

- alphaComponent (page 695)
Returns the receiver's alpha (opacity) component.

- blackComponent (page 696)
Returns the receiver's black component.

- blueComponent (page 697)
Returns the receiver's blue component.

- `brightnessComponent` (page 697)
  Returns the brightness component of the HSB color equivalent to the receiver.
- `catalogNameComponent` (page 698)
  Returns the name of the catalog containing the receiver's name.
- `colorNameComponent` (page 698)
  Returns the receiver's name.
- `cyanComponent` (page 702)
  Returns the receiver's cyan component.
- `greenComponent` (page 706)
  Returns the receiver's green component.
- `hueComponent` (page 707)
  Returns the hue component of the HSB color equivalent to the receiver.
- `localizedCatalogNameComponent` (page 708)
  Returns the name of the catalog containing the receiver's name as a localized string.
- `localizedColorNameComponent` (page 708)
  Returns the name of the receiver as a localized string.
- `magentaComponent` (page 708)
  Returns the receiver's magenta component.
- `redComponent` (page 710)
  Returns the receiver's red component.
- `saturationComponent` (page 710)
  Returns the saturation component of the HSB color equivalent to the receiver.
- `whiteComponent` (page 712)
  Returns the receiver's white component.
- `yellowComponent` (page 713)
  Returns the receiver's yellow component.

Working with the Color Space

- `colorSpaceName` (page 699)
  Returns the name of the receiver's color space.
- `colorUsingColorSpaceName:` (page 700)
  Creates and returns an `NSColor` whose color is the same as the receiver's, except that the new `NSColor` is in the specified color space.
- `colorUsingColorSpaceName:device:` (page 701)
  Creates and returns an `NSColor` object whose color is the same as the receiver's, except that the new NSColor is in the given color space and is specific to the given device.
- `colorSpace` (page 699)
  Returns an object representing the color space of the receiver.
- `colorUsingColorSpace:` (page 700)
  Returns a new color object representing the color of the receiver in the specified color space.

Changing the Color

- `blendedColorWithFraction:ofColor:` (page 696)
  Creates and returns an `NSColor` object whose component values are a weighted sum of the receiver's and the specified color object's.
- `colorWithAlphaComponent:` (page 701)
  Creates and returns an `NSColor` object that has the same color space and component values as the receiver, but the specified alpha component.
- `highlightWithLevel:` (page 707)
  Returns an `NSColor` object that represents a blend between the receiver and the highlight color returned by `highlightColor` (page 684).
- `shadowWithLevel:` (page 712)
  Returns an `NSColor` object that represents a blend between the receiver and the shadow color returned by `shadowColor` (page 692).

Drawing

- `drawSwatchInRect:` (page 702)
  Draws the current color in the given rectangle.
- `set` (page 711)
  Sets the color of subsequent drawing to the color that the receiver represents.
- `setFill` (page 711)
  Sets the fill color of subsequent drawing to the receiver's color.
- `setStroke` (page 711)
  Sets the stroke color of subsequent drawing to the receiver's color.

Class Methods

alternateSelectedControlColor

Returns the system color used for the face of a selected control.

```
+ (NSColor *)alternateSelectedControlColor
```

Return Value
The system color used for the face of a selected control—a control being clicked or dragged. This color can be used where iApp-like highlighting is desired. For general information about system colors, see Accessing System Colors.

Availability
Available in Mac OS X v10.2 and later.

See Also
`+ alternateSelectedControlTextColor` (page 667)
`+ selectedControlColor` (page 688)

Declared In
NSColor.h

alternateSelectedControlTextColor

Returns the system color used for text in a selected control.

```
+ (NSColor *)alternateSelectedControlTextColor
```

Return Value
The system color used for text in a selected control—a control being clicked or dragged. This color can be used where iApp-like highlighting is desired. For general information about system colors, see Accessing System Colors.

Availability
Available in Mac OS X v10.2 and later.

See Also
+ alternateSelectedControlColor (page 666)
+ selectedControlTextColor (page 689)

colorForControlTint:

Returns the NSColor object specified by the given control tint.

```
+ (NSColor *)colorForControlTint:(NSControlTint)controlTint
```

Parameters
controlTint
The control tint for which to return an NSColor object. This is one of the tint settings. For more on control tints, see Using the System Control Tint.

Return Value
The NSColor object.

Availability
Available in Mac OS X v10.0 and later.

See Also
+ currentControlTint (page 680)

Declared In
NSColor.h

colorFromPasteboard:

Returns the NSColor currently on the given pasteboard.

```
+ (NSColor *)colorFromPasteboard:(NSPasteboard *)pasteBoard
```

Parameters
pasteBoard
The pasteboard from which to return the color.

Return Value
The color currently on the pasteboard or nil if *pasteBoard* doesn't contain color data. The returned color's alpha component is set to 1.0 if ignoresAlpha (page 684) returns YES.

Availability
Available in Mac OS X v10.0 and later.

colorWithCalibratedHue:saturation:brightness:alpha:

Creates and returns an NSColor object using the given opacity and HSB color space components.

```
+ (NSColor *)colorWithCalibratedHue:(CGFloat)hue saturation:(CGFloat)saturation
    brightness:(CGFloat)brightness alpha:(CGFloat)alpha
```

Parameters

hue
The hue component of the color object in the HSB color space.

saturation
The saturation component of the color object in the HSB color space.

brightness
The brightness (or value) component of the color object in the HSB color space.

alpha
The opacity value of the color object,

Return Value
The color object.

Discussion
Values below 0.0 are interpreted as 0.0, and values above 1.0 are interpreted as 1.0.

Availability
Available in Mac OS X v10.0 and later.

colorWithCalibratedRed:green:blue:alpha:

Creates and returns an NSColor object using the given opacity and RGB components.

```
+ (NSColor *)colorWithCalibratedRed:(CGFloat)red green:(CGFloat)green
    blue:(CGFloat)blue alpha:(CGFloat)alpha
```

Parameters

red

The red component of the color object.

green

The green component of the color object.

blue

The blue component of the color object.

alpha

The opacity value of the color object.

Return Value
The color object.

Discussion
Values below 0.0 are interpreted as 0.0, and values above 1.0 are interpreted as 1.0.

Availability
Available in Mac OS X v10.0 and later.

colorWithCalibratedWhite:alpha:

Creates and returns an `NSColor` object using the given opacity and grayscale value.

```
+ (NSColor *)colorWithCalibratedWhite:(CGFloat)white alpha:(CGFloat)alpha
```

Parameters

white

The grayscale value of the color object.

alpha

The opacity value of the color object.

Return Value
The color object.

Discussion
Values below 0.0 are interpreted as 0.0, and values above 1.0 are interpreted as 1.0.

Availability
Available in Mac OS X v10.0 and later.

colorWithCatalogName:colorName:

Creates and returns an `NSColor` object by finding the color with the specified name in the given catalog.

```
+ (NSColor *)colorWithCatalogName:(NSString *)listName colorName:(NSString
    *)colorName
```

Parameters

`listName`
The name of the catalog in which to find the specified color; this may be a standard catalog.

`colorName`
The name of the color. Note that the color must be defined in the named color space to retrieve it with this method.

Return Value
The color object.

Availability
Available in Mac OS X v10.0 and later.

colorWithCIColor:

Converts a Core Image color object to its `NSColor` equivalent.

```
+ (NSColor *)colorWithCIColor:(CIColor *)color
```

Parameters

color

The Core Image color to convert.

Return Value

The `NSColor` object corresponding to the specified Core Image color.

Discussion

The method raises if the color space and components associated with *color* are `nil` or invalid.

Availability

Available in Mac OS X v10.4 and later.

Related Sample Code

CIColorTracking

FunHouse

Declared In

`NSColor.h`

colorWithColorSpace:components:count:

Returns an `NSColor` object created from the specified components of the given color space.

```
+ (NSColor *)colorWithColorSpace:(NSColorSpace *)space components:(const CGFloat
    *)components count:(NSInteger)numberOfComponents
```

Parameters

space

An `NSColorSpace` object representing a color space. The method raises if this is `nil`.

components

An array of the components in the specified color space to use to create the `NSColor` object. The order of these components is determined by the color-space profile, with the alpha component always last. (If you want the created color to be opaque, specify 1.0 for the alpha component.)

numberOfComponents

The number of components in the `components` array. This should match the number dictated by the specified color space plus one for alpha. This method raises an exception if they do not match.

Return Value

The color object. If *space* represents a color space that cannot cannot be used with `NSColor` objects—for example, a "pattern" color space—the method returns `nil`.

Availability

Available in Mac OS X v10.4 and later.

See Also

`- colorUsingColorSpace:` (page 700)

Related Sample Code

AnimatedTableView

Declared In
NSColor.h

colorWithDeviceCyan:magenta:yellow:black:alpha:

Creates and returns an NSColor object using the given opacity value and CMYK components.

```
+ (NSColor *)colorWithDeviceCyan:(CGFloat)cyan magenta:(CGFloat)magenta
    yellow:(CGFloat)yellow black:(CGFloat)black alpha:(CGFloat)alpha
```

Parameters

cyan
The cyan component of the color object.

magenta
The magenta component of the color object.

yellow
The yellow component of the color object.

black
The black component of the color object.

alpha
The opacity value of the color object.

Return Value
The color object.

Discussion
Values below 0.0 are interpreted as 0.0, and values above 1.0 are interpreted as 1.0. In PostScript, this color space corresponds directly to the device-dependent operator setcmykcolor.

Availability
Available in Mac OS X v10.0 and later.

NSColor.h

colorWithDeviceHue:saturation:brightness:alpha:

Creates and returns an NSColor object using the given opacity value and HSB color space components.

```
+ (NSColor *)colorWithDeviceHue:(CGFloat)hue saturation:(CGFloat)saturation
    brightness:(CGFloat)brightness alpha:(CGFloat)alpha
```

Parameters

hue
The hue component of the color object.

saturation
The saturation component of the color object.

brightness
The brightness component of the color object.

alpha
The opacity value of the color object.

Return Value
The color object.

Discussion
Values below 0.0 are interpreted as 0.0, and values above 1.0 are interpreted as 1.0. In PostScript, this color space corresponds directly to the device-dependent operator `setrgbcolor`.

Availability
Available in Mac OS X v10.0 and later.

See Also
`+ colorWithCalibratedHue:saturation:brightness:alpha:` (page 670)

Declared In
`NSColor.h`

colorWithDeviceRed:green:blue:alpha:

Creates and returns an `NSColor` object using the given opacity value and RGB components.

```
+ (NSColor *)colorWithDeviceRed:(CGFloat)red green:(CGFloat)green blue:(CGFloat)blue
     alpha:(CGFloat)alpha
```

Parameters

red
The red component of the color object.

green
The green component of the color object.

blue
The blue component of the color object.

alpha
The opacity value of the color object.

Return Value
The color object.

Discussion
Values below 0.0 are interpreted as 0.0, and values above 1.0 are interpreted as 1.0. In PostScript, this color space corresponds directly to the device-dependent operator `setrgbcolor`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSColor.h`

colorWithDeviceWhite:alpha:

Creates and returns an `NSColor` object using the given opacity and grayscale values.

```
+ (NSColor *)colorWithDeviceWhite:(CGFloat)white alpha:(CGFloat)alpha
```

Parameters

white
The grayscale value of the color object.

alpha
The opacity value of the color object.

Return Value
The color object.

Discussion
Values below 0.0 are interpreted as 0.0, and values above 1.0 are interpreted as 1.0. In PostScript, this color space corresponds directly to the device-dependent operator `setgray`.

Availability
Available in Mac OS X v10.0 and later.

`NSColor.h`

colorWithPatternImage:

Creates and returns an `NSColor` object that uses the specified image pattern.

```
+ (NSColor *)colorWithPatternImage:(NSImage *)image
```

Parameters

image

The image to use as the pattern for the color object. The image is tiled starting at the bottom of the window. The image is not scaled.

Return Value
The `NSColor` object. This color object is autoreleased.

Availability
Available in Mac OS X v10.0 and later.

Worm

Declared In
`NSColor.h`

controlAlternatingRowBackgroundColors

Returns an array containing the system specified background colors for alternating rows in tables and lists.

```
+ (NSArray *)controlAlternatingRowBackgroundColors
```

Return Value
An array of `NSColor` objects specifying the system colors used for rows in tables and lists. You should not assume the array will contain only two colors. For general information on system colors, see Accessing System Colors.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`NSColor.h`

controlBackgroundColor

Returns the system color used for the background of large controls.

```
+ (NSColor *)controlBackgroundColor
```

Return Value
The system color used for the background of large controls such as browsers, table views, and clip views. For general information on system colors, see Accessing System Colors.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSColor.h

controlColor

Returns the system color used for the flat surfaces of a control.

```
+ (NSColor *)controlColor
```

Return Value
The system color used for the flat surfaces of a control. By default, the control color is a pattern color that will draw the ruled lines for the window background, which is the same as returned by `windowBackgroundColor` (page 694).

If you use `controlColor` assuming that it is a solid, you may have an incorrect appearance. You should use `lightGrayColor` (page 686) in its place.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
Quartz Composer WWDC 2005 TextEdit

Declared In

Available in Mac OS X v10.0 and later.

Declared In
NSColor.h

highlightColor

Returns the system color that represents the virtual light source on the screen.

```
+ (NSColor *)highlightColor
```

Return Value
The system color for the virtual light source on the screen.

Discussion
This method is invoked by the `highlightWithLevel:` (page 707) method. For general information about system colors, see Accessing System Colors.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- highlightWithLevel:` (page 707)

Declared In
NSColor.h

ignoresAlpha

Returns a Boolean value indicating whether the application supports alpha.

```
+ (BOOL)ignoresAlpha
```

Return Value
`YES` if the application doesn't support alpha; otherwise `NO`. This value is consulted when an application imports alpha (through color dragging, for instance). The value determines whether the color panel has an opacity slider.

This value is `YES` by default, indicating that the opacity components of imported colors will be set to 1.0. If an application wants alpha, it can invoke the `setIgnoresAlpha:` (page 691) method with a parameter of `NO`.

Availability
Available in Mac OS X v10.0 and later.

See Also
`+ setIgnoresAlpha:` (page 691)

`NSColor.h`

keyboardFocusIndicatorColor

Returns the system color that represents the keyboard focus ring around controls.

```
+ (NSColor *)keyboardFocusIndicatorColor
```

Return Value
The system color representing the focus ring.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSColor.h`

knobColor

Returns the system color used for the flat surface of a slider knob that hasn't been selected.

```
+ (NSColor *)knobColor
```

Return Value
The system color used for an unselected slider knob.

Discussion
The knob's beveled edges, which set it in relief, are drawn in highlighted and shadowed versions of the face color. When a knob is selected, its color changes to `selectedKnobColor` (page 689). For general information about system colors, see Accessing System Colors.

Declared In
`NSColor.h`

setIgnoresAlpha:

Specifies whether an application supports alpha.

```
+ (void)setIgnoresAlpha:(BOOL)flag
```

Parameters

flag

`YES` to indicate that the application won't support alpha. By default, applications ignore alpha.

Discussion
If the application doesn't support alpha, no opacity slider is displayed in the color panel, and colors dragged in or pasted have their alpha values set to 1.0. Applications that need to import alpha can invoke this method with *flag* set to `NO` and explicitly make colors opaque in cases where it matters to them. Note that calling this with a value of `YES` overrides any value set with the `NSColorPanel` method `setShowsAlpha:` (page 735).

Availability
Available in Mac OS X v10.0 and later.

blackComponent

Returns the receiver's black component.

```
- (CGFloat)blackComponent
```

Return Value
The color object's black component.

Discussion
This method works only with objects representing colors in the `NSDeviceCMYKColorSpace` color space. Sending it to other objects raises an exception.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- getCyan:magenta:yellow:black:alpha:` (page 703)

Declared In
NSColor.h

blendedColorWithFraction:ofColor:

Creates and returns an `NSColor` object whose component values are a weighted sum of the receiver's and the specified color object's.

```
- (NSColor *)blendedColorWithFraction:(CGFloat)fraction ofColor:(NSColor *)color
```

Parameters

fraction
The amount of the color to blend with the receiver's color. The method converts *color* and a copy of the receiver to RGB, and then sets each component of the returned color to *fraction* of *color*'s value plus 1 – *fraction* of the receiver's.

color
The color to blend with the receiver's color.

Return Value
The resulting color object or `nil` if the colors can't be converted.

Availability
Available in Mac OS X v10.0 and later.

colorSpace

Returns an object representing the color space of the receiver.

```
- (NSColorSpace *)colorSpace
```

Return Value
An object representing a color space. The returned `NSColorSpace` object may represent a custom color space.

Discussion
Calling this method raises an exception if the receiver is not based on a color space represented by an `NSColorSpace` object—specifically, colors designated by `NSNamedColorSpace` and `NSPatternColorSpace`. If you are unsure about a color object, convert it to an equivalent `NSColorSpace`-based object before calling this method. Color objects created with color-space names `NSCalibratedWhiteColorSpace`, `NSCalibratedBlackColorSpace`, `NSCalibratedRGBColorSpace`, `NSDeviceWhiteColorSpace`, `NSDeviceBlackColorSpace`, `NSDeviceRGBColorSpace`, `NSDeviceCMYKColorSpace`, or `NSCustomColorSpace`—or with the `NSColorSpace` class methods corresponding to these names—are safe to use with this method. See “About Color Spaces" in *Color Programming Topics* for a list of these corresponding methods.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `getComponents:` (page 703)
- `numberOfComponents` (page 709)

Declared In
`NSColor.h`

colorSpaceName

Returns the name of the receiver’s color space.

```
- (NSString *)colorSpaceName
```

Return Value
The name of the color space.

Discussion
This method should be implemented in subclasses of `NSColor`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `colorUsingColorSpaceName:` (page 700)
- `colorUsingColorSpaceName:device:` (page 701)

Related Sample Code
MyCustomColorPicker

Declared In
NSColor.h

colorUsingColorSpace:

Returns a new color object representing the color of the receiver in the specified color space.

```
- (NSColor *)colorUsingColorSpace:(NSColorSpace *)space
```

Parameters

space

The color space of the new NSColor object.

Return Value
The new NSColor object. This method converts the receiver's color to an equivalent one in the new color space. Although the new color might have different component values, it looks the same as the original. Returns nil if conversion is not possible.

If the receiver's color space is the same as that specified in space, this method returns the same NSColor object.

Availability
Available in Mac OS X v10.4 and later.

See Also
+ colorWithColorSpace:components:count: (page 673)

Related Sample Code
Quartz 2D Shadings
Quartz Composer QCTV

Declared In
NSColor.h

colorUsingColorSpaceName:

Creates and returns an NSColor whose color is the same as the receiver's, except that the new NSColor is in the specified color space.

```
- (NSColor *)colorUsingColorSpaceName:(NSString *)colorSpace
```

Parameters

colorSpace

The name of the color space containing the new NSColor object. If *colorSpace* is nil, the most appropriate color space is used.

Return Value
The new NSColor object or nil if the specified conversion cannot be done.

Availability
Available in Mac OS X v10.0 and later.

See Also
- colorSpaceName (page 699)

Related Sample Code

Reminders

Declared In
NSColor.h

colorUsingColorSpaceName:device:

Creates and returns an NSColor object whose color is the same as the receiver's, except that the new NSColor is in the given color space and is specific to the given device.

```
- (NSColor *)colorUsingColorSpaceName:(NSString *)colorSpace device:(NSDictionary
    *)deviceDescription
```

Parameters

colorSpace

The name of the color space containing the new NSColor object. If *colorSpace* is nil, the most appropriate color space is used.

deviceDescription

The device description. Device descriptions can be obtained from windows, screens, and printers with the deviceDescription method.

If *deviceDescription* is nil, the current device (as obtained from the currently lockFocus'ed view's window or, if printing, the current printer) is used.

Return Value
The new NSColor object or nil if the specified conversion cannot be done.

Availability
Available in Mac OS X v10.0 and later.

See Also
- colorSpaceName (page 699)
- colorUsingColorSpaceName: (page 700)

Declared In
NSColor.h

colorWithAlphaComponent:

Creates and returns an NSColor object that has the same color space and component values as the receiver, but the specified alpha component.

```
- (NSColor *)colorWithAlphaComponent:(CGFloat)alpha
```

Parameters

alpha

The opacity value of the new NSColor object.

Return Value
The new `NSColor` object. If the receiver's color space doesn't include an alpha component, the receiver is returned.

Discussion
A subclass with explicit opacity components should override this method to return a color with the specified alpha.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `alphaComponent` (page 695)

Declared In
`NSColor.h`

cyanComponent

Returns the receiver's cyan component.

```
- (CGFloat)cyanComponent
```

Return Value
The color object's cyan component.

Discussion
This method works only with objects representing colors in the `NSDeviceCMYKColorSpace` color space. Sending it to other objects raises an exception.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `getCyan:magenta:yellow:black:alpha:` (page 703)

Declared In
`NSColor.h`

drawSwatchInRect:

Draws the current color in the given rectangle.

```
- (void)drawSwatchInRect:(NSRect)rect
```

Parameters

rect

The rectangle in which to draw the color.

Discussion

Subclasses adorn the rectangle in some manner to indicate the type of color. This method is invoked by color wells, swatches, and other user interface objects that need to display colors.

Availability

Available in Mac OS X v10.0 and later.

Declared In

NSColor.h

getComponents:

Returns the components of the receiver as an array.

```
- (void)getComponents:(CGFloat *)components
```

Parameters

components

An array containing the components of the color object as `float` values.

Discussion

You can invoke this method on `NSColor` objects created from custom color spaces to get the individual floating point components, including alpha. Raises an exception if the receiver doesn't have floating-point components. To find out how many components are in the *components* array, send the receiver a `numberOfComponents` (page 709) message.

Availability

Available in Mac OS X v10.4 and later.

getCyan:magenta:yellow:black:alpha:

Returns the receiver's CMYK and opacity values.

```
- (void)getCyan:(CGFloat *)cyan magenta:(CGFloat *)magenta yellow:(CGFloat *)yellow
    black:(CGFloat *)black alpha:(CGFloat *)alpha
```

Parameters

cyan

Upon return, contains the cyan component of the color object.

magenta

Upon return, contains the magenta component of the color object.

yellow

Upon return, contains the yellow component of the color object.

black

Upon return, contains the black component of the color object.

alpha

Upon return, contains opacity value of the color object.

Discussion

If `NULL` is passed in as an argument, the method doesn't set that value. This method works only with objects representing colors in the `NSDeviceCMYKColorSpace`. Sending it to other objects raises an exception.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSColor.h`

getHue:saturation:brightness:alpha:

Returns the receiver's HSB component and opacity values in the respective arguments.

```
- (void)getHue:(CGFloat *)hue saturation:(CGFloat *)saturation brightness:(CGFloat
    *)brightness alpha:(CGFloat *)alpha
```

Parameters

hue

Upon return, contains the hue component of the color object.

saturation

Upon return, contains the saturation component of the color object.

brightness

Upon return, contains the brightness component of the color object.

alpha

Upon return, contains the opacity value of the color object.

Discussion

If `NULL` is passed in as an argument, the method doesn't set that value. This method works only with objects representing colors in the `NSCalibratedRGBColorSpace` or `NSDeviceRGBColorSpace` color space. Sending it to other objects raises an exception.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSColor.h`

getRed:green:blue:alpha:

Returns the receiver's RGB component and opacity values in the respective arguments.

```
- (void)getRed:(CGFloat *)red green:(CGFloat *)green blue:(CGFloat *)blue
    alpha:(CGFloat *)alpha
```

Parameters

red
Upon return, contains the red component of the color object.

green
Upon return, contains the green component of the color object.

blue
Upon return, contains the blue component of the color object.

alpha
Upon return, contains the opacity value of the color object.

Discussion
If `NULL` is passed in as an argument, the method doesn't set that value. This method works only with objects representing colors in the `NSCalibratedRGBColorSpace` or `NSDeviceRGBColorSpace` color space. Sending it to other objects raises an exception.

Availability
Available in Mac OS X v10.0 and later.

Reminders

Declared In
NSColor.h

getWhite:alpha:

Returns the receiver's grayscale value and alpha values.

```
- (void)getWhite:(CGFloat *)white alpha:(CGFloat *)alpha
```

Parameters

white

Upon return, contains the grayscale value of the color object.

alpha

Upon return, contains the opacity value of the color object.

Discussion
If NULL is passed in as an argument, the method doesn't set that value. This method works only with objects representing colors in the NSCalibratedWhiteColorSpace, NSCalibratedBlackColorSpace, NSDeviceBlackColorSpace, or NSDeviceWhiteColorSpace color space. Sending it to other objects raises an exception.

Availability
Available in Mac OS X v10.0 and later.

`NSColor.h`

highlightWithLevel:

Returns an `NSColor` object that represents a blend between the receiver and the highlight color returned by `highlightColor` (page 684).

```
- (NSColor *)highlightWithLevel:(CGFloat)highlightLevel
```

Parameters

highlightLevel

The amount of the highlight color that is blended with the receiver's color. This should be a number from 0.0 through 1.0. A *highlightLevel* below 0.0 is interpreted as 0.0; a *highlightLevel* above 1.0 is interpreted as 1.0.

Return Value
The new `NSColor` object. Returns `nil` if the colors can't be converted.

Discussion
Invoke this method when you want to brighten the receiving `NSColor` for use in highlights.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- shadowWithLevel:` (page 712)

Declared In
`NSColor.h`

hueComponent

Returns the hue component of the HSB color equivalent to the receiver.

```
- (CGFloat)hueComponent
```

Return Value
The color object's hue component.

Discussion
This method works only with objects representing colors in the `NSCalibratedRGBColorSpace` or `NSDeviceRGBColorSpace` color space. Sending it to other objects raises an exception.

Availability
Available in Mac OS X v10.0 and later.

shadowWithLevel:

Returns an `NSColor` object that represents a blend between the receiver and the shadow color returned by `shadowColor` (page 692).

```
- (NSColor *)shadowWithLevel:(CGFloat)shadowLevel
```

Parameters

shadowLevel
The amount of the shadow color used for the blend. This should be a number from 0.0 through 1.0. A *shadowLevel* below 0.0 is interpreted as 0.0; a *shadowLevel* above 1.0 is interpreted as 1.0.

Return Value
The new `NSColor` object. Returns `nil` if the colors can't be converted.

Discussion
Invoke this method when you want to darken the receiving NSColor for use in shadows.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `highlightWithLevel:` (page 707)

Declared In
`NSColor.h`

whiteComponent

Returns the receiver's white component.

```
- (CGFloat)whiteComponent
```

Return Value
The color object's white component.

Discussion
This method works only with objects representing colors in the `NSCalibratedWhiteColorSpace`, `NSCalibratedBlackColorSpace`, `NSDeviceBlackColorSpace`, or `NSDeviceWhiteColorSpace` color space. Sending it to other objects raises an exception.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `getWhite:alpha:` (page 706)

Declared In
`NSColor.h`

writeToPasteboard:

Writes the receiver's data to the specified pasteboard.

```
- (void)writeToPasteboard:(NSPasteboard *)pasteBoard
```

Parameters

pasteBoard
The pasteboard to which to write the receiver's color data. If this pasteboard doesn't support color data, the method does nothing.

Availability
Available in Mac OS X v10.0 and later.

See Also
+ `colorFromPasteboard:` (page 669)

Declared In
`NSColor.h`

yellowComponent

Returns the receiver's yellow component.

```
- (CGFloat)yellowComponent
```

Return Value
The color object's yellow component.

Discussion
This method works only with objects representing colors in the `NSDeviceCMYKColorSpace` color space. Sending it to other objects raises an exception.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `getCyan:magenta:yellow:black:alpha:` (page 703)

Declared In

Overview

An `NSColorList` object is an ordered list of `NSColor` objects, identified by keys. Instances of `NSColorList`, or more simply color lists, are used to manage named lists of `NSColor` instances. The `NSColorPanel` list mode color picker uses instances of `NSColorList` to represent any lists of colors that come with the system, as well as any lists created by the user. An application can use `NSColorList` to manage document-specific color lists.

Adopted Protocols

NSCoding

- `encodeWithCoder:`
- `initWithCoder:`

Tasks

Initializing an NSColorList Object

`- initWithName:` (page 718)
Initializes and returns the receiver, registering it under the given name if it isn't in use already.

- `initWithName:fromFile:` (page 719)
  Initializes and returns the receiver, registering it under the given name if it isn't in use already.

Getting Color Lists

+ `availableColorLists` (page 717)
  Returns an array of all color lists found in the standard color list directories.

+ `colorListNamed:` (page 717)
  Searches the array that's returned by `availableColorLists` (page 717) and returns the color list with the given name.

Getting Color List Properties

- `name` (page 720)
  Returns the name of the receiver.

- `isEditable` (page 720)
  Returns a Boolean value indicating whether the receiver can be modified.

Managing Colors By Key

- `allKeys` (page 718)
  Returns an array of the keys by which the `NSColor` objects are stored in the receiver.

- `colorWithKey:` (page 718)
  Returns the `NSColor` object associated with the given key.

- `insertColor:key:atIndex:` (page 719)
  Inserts the specified color at the specified location in the receiver.

- `removeColorWithKey:` (page 721)
  Removes the color associated with the specified key from the receiver.

- `setColor:forKey:` (page 721)
  Associates the specified `NSColor` object with the specified key.

Writing and Removing Color-List Files

- `removeFile` (page 721)
  Removes the file from which the list was created, if the file is in a standard search path and owned by the user.

- `writeToFile:` (page 722)
  Saves the receiver to a file at the specified path.

Class Methods

availableColorLists

Returns an array of all color lists found in the standard color list directories.

```
+ (NSArray *)availableColorLists
```

Return Value
An array of `NSColorList` objects representing all of the color lists found in the standard color list directories, including color catalogs (lists of colors identified only by name). Color lists created at runtime aren't included in this list unless they're saved into one of the standard color list directories.

Availability
Available in Mac OS X v10.0 and later.

See Also
`+ colorListNamed:` (page 717)

Declared In
`NSColorList.h`

colorListNamed:

Searches the array that's returned by `availableColorLists` (page 717) and returns the color list with the given name.

```
+ (NSColorList *)colorListNamed:(NSString *)name
```

Parameters

name

The name of the color list to retrieve. This name must not include the "`.clr`" suffix.

Return Value
The color list with the specified name or `nil` if no such color list exists.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- name` (page 720)

Related Sample Code
AnimatedTableView

Declared In
`NSColorList.h`

Instance Methods

allKeys

Returns an array of the keys by which the `NSColor` objects are stored in the receiver.

```
- (NSArray *)allKeys
```

Return Value
An array of `NSString` objects containing all the keys by which the `NSColor` objects are stored in the receiver.

The length of this array equals the number of colors, and its contents are arranged according to the ordering specified when the colors were inserted.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
AnimatedTableView

Declared In
`NSColorList.h`

colorWithKey:

Returns the `NSColor` object associated with the given key.

```
- (NSColor *)colorWithKey:(NSString *)key
```

Parameters

key
The key for which to retrieve the color.

Return Value
The color associated with the given key or `nil` if there is none.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
AnimatedTableView

Declared In
`NSColorList.h`

initWithName:

Initializes and returns the receiver, registering it under the given name if it isn't in use already.

```
- (id)initWithName:(NSString *)name
```

Parameters

name

The name under which to register the color list. Specify @"" if you don't want a name.

Return Value
The initialized color list.

Discussion
This method invokes `initWithName:fromFile:` (page 719) with a `fromFile:` argument of `nil`, indicating that the color list doesn't need to be initialized from a file. Note that this method does not add the color list to `availableColorLists` (page 717) until the color list is saved into the user's path with `writeToFile:` (page 722) with a value of `nil`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSColorList.h`

initWithName:fromFile:

Initializes and returns the receiver, registering it under the given name if it isn't in use already.

```
- (id)initWithName:(NSString *)name fromFile:(NSString *)path
```

Parameters

name

The name of the file for the color list (minus the ".clr" extension). Specify @"" if you don't want a name.

path

The full path to the file for the color list. A `nil` path indicates the color list should be initialized with no colors.

Discussion
Note that this method does not add the color list to `availableColorLists` (page 717) until the color list is saved into the user's path with `writeToFile:` (page 722) with a value of `nil`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSColorList.h`

insertColor:key:atIndex:

Inserts the specified color at the specified location in the receiver.

```
- (void)insertColor:(NSColor *)color key:(NSString *)key atIndex:(NSUInteger)location
```

Parameters

color

The color to add to the color list.

key
The key with which to associate the color.

location
The location in the color list at which to place the specified color. Locations are numbered starting with 0.

Discussion
If the list already contains a color with the same key at a different location, it's removed from the old location. This method posts `NSColorListDidChangeNotification` (page 722) to the default notification center. It raises `NSColorListNotEditableException` if the color list isn't editable.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `colorWithKey:` (page 718)
- `removeColorWithKey:` (page 721)
- `setColor:forKey:` (page 721)

Declared In
`NSColorList.h`

isEditable

Returns a Boolean value indicating whether the receiver can be modified.

```
- (BOOL)isEditable
```

Return Value
`YES` if the color list can be modified; otherwise `NO`. This result depends on the source of the list: If it came from a write-protected file, this method returns `NO`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSColorList.h`

name

Returns the name of the receiver.

```
- (NSString *)name
```

Return Value
The name of the receiver.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSColorList.h`

removeColorWithKey:

Removes the color associated with the specified key from the receiver.

```
- (void)removeColorWithKey:(NSString *)key
```

Parameters

key

The key for which to remove the color.

Discussion

This method does nothing if the receiver doesn't contain the key. This method posts `NSColorListDidChangeNotification` (page 722) to the default notification center. It raises `NSColorListNotEditableException` if the receiver is not editable.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `insertColor:key:atIndex:` (page 719)
- `setColor:forKey:` (page 721)

Declared In

`NSColorList.h`

removeFile

Removes the file from which the list was created, if the file is in a standard search path and owned by the user.

```
- (void)removeFile
```

Discussion

The receiver is removed from the list of available color lists returned by `availableColorLists` (page 717). If there are no outstanding references to the color list, this method might deallocate the object as well.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSColorList.h`

setColor:forKey:

Associates the specified `NSColor` object with the specified key.

```
- (void)setColor:(NSColor *)color forKey:(NSString *)key
```

Parameters

color

The color to associate with the given key.

key

The key.

Discussion
If the list already contains *key*, this method sets the corresponding color to *color*; otherwise, it inserts *color* at the end of the list by invoking `insertColor:key:atIndex:` (page 719).

Availability
Available in Mac OS X v10.0 and later.

See Also
- `colorWithKey:` (page 718)
- `insertColor:key:atIndex:` (page 719)
- `removeColorWithKey:` (page 721)

Declared In
`NSColorList.h`

writeToFile:

Saves the receiver to a file at the specified path.

```
- (BOOL)writeToFile:(NSString *)path
```

Parameters
path

The path at which to save the color list. If *path* is a directory, the receiver is saved in a file named *listname*`.clr` in that directory (where *listname* is the name with which the receiver was initialized).

If *path* includes a filename, this method saves the file under that name. If *path* is `nil`, the file is saved as *listname*`.clr` in the user's private colorlists directory.

Return Value
`YES` upon success and `NO` if the method fails to write the file.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `removeFile` (page 721)

Declared In
`NSColorList.h`

Notifications

NSColorListDidChangeNotification

Posted whenever a color list changes. The notification object is the `NSColorList` object that changed. This notification does not contain a *userInfo* dictionary.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSColorList.h`

NSColorPanel Class Reference

Inherits from	NSPanel : NSWindow : NSResponder : NSObject
Conforms to	NSUserInterfaceValidations (NSWindow) NSAnimatablePropertyContainer (NSWindow) NSCoding (NSResponder) NSObject (NSObject)
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.0 and later.
Declared in	AppKit/NSColorPanel.h
Companion guide	Color Programming Topics
Related sample code	CWCocoaComponent QTAudioContextInsert QTAudioExtractionPanel QTCoreVideo301 QTKitPlayer

Overview

The `NSColorPanel` class provides a standard user interface for selecting color in an application. It provides a number of standard color selection modes and, with the `NSColorPickingDefault` and `NSColorPickingCustom` protocols, allows an application to add its own color selection modes. It allows the user to save swatches containing frequently used colors.

Tasks

Obtaining the Shared Color-Panel Object

`+ sharedColorPanel` (page 729)
Returns the shared `NSColorPanel` instance, creating it if necessary.

`+ sharedColorPanelExists` (page 729)
Returns a Boolean value indicating whether the `NSColorPanel` has been created already.

Configuring the Color Panel

- `accessoryView` (page 729)
  Returns the accessory view.
- `isContinuous` (page 731)
  Returns a Boolean value indicating whether the receiver continuously sends the action message to the target.
- `mode` (page 732)
  Returns the color picker mode of the receiver.
- `setAccessoryView:` (page 732)
  Sets the accessory view displayed in the receiver.
- `setAction:` (page 733)
  Sets the color panel's action message.
- `setContinuous:` (page 734)
  Sets the receiver to send the action message to its target continuously as the user sets the color.
- `setMode:` (page 734)
  Sets the mode of the receiver the mode is one of the modes allowed by the color mask.
- `setShowsAlpha:` (page 735)
  Tells the receiver whether or not to show alpha values and an opacity slider.
- `setTarget:` (page 735)
  Sets the target of the receiver.
- `showsAlpha` (page 736)
  Returns a Boolean value indicating whether or not the receiver shows alpha values and an opacity slider.

Managing Color Lists

- `attachColorList:` (page 730)
  Adds the list of `NSColor` objects specified to all the color pickers in the receiver that display color lists by invoking `attachColorList:` (page 730) on all color pickers in the application.
- `detachColorList:` (page 731)
  Removes the list of colors from all the color pickers in the receiver that display color lists by invoking `detachColorList:` on all color pickers in the application.

Setting Color Picker Modes

+ `setPickerMask:` (page 728)
  Determines which color selection modes are available in an application's `NSColorPanel`.
+ `setPickerMode:` (page 728)
  Specifies the color panel's initial picker.

Setting Color

`+ dragColor:withEvent:fromView:` (page 727)
Drags a color into a destination view from the specified source view.

`- setColor:` (page 733)
Sets the color of the receiver.

Getting Color Information

`- alpha` (page 730)
Returns the receiver's current alpha value based on its opacity slider.

`- color` (page 731)
Returns the currently selected color in the receiver.

Responding to a Color Change

`- changeColor:` (page 736) *delegate method*
Sent to the first responder when the user selects a color in an `NSColorPanel` object.

Class Methods

dragColor:withEvent:fromView:

Drags a color into a destination view from the specified source view.

```
+ (BOOL)dragColor:(NSColor *)color withEvent:(NSEvent *)anEvent fromView:(NSView
    *)sourceView
```

Parameters

color
The color to drag.

anEvent
The drag event.

sourceView
The view from which the color was dragged.

Return Value
`YES`

Discussion
This method is usually invoked by the `mouseDown:` method of *sourceView*. The dragging mechanism handles all subsequent events.

Because it is a class method, `dragColor:withEvent:fromView:` can be invoked whether or not the instance of `NSColorPanel` exists.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSColorPanel.h`

setPickerMask:

Determines which color selection modes are available in an application's `NSColorPanel`.

```
+ (void)setPickerMask:(NSUInteger)mask
```

Parameters

mask

One or more logically ORed color mode masks described in Color Panel Mode Masks (page 737).

Discussion
This method has an effect only before an `NSColorPanel` object is instantiated.

If you create a class that implements the color-picking protocols (`NSColorPickingDefault` and `NSColorPickingCustom`), you may want to give it a unique mask—one different from those defined for the standard color pickers. To display your color picker, your application will need to logically OR that unique mask with the standard color mask constants when invoking this method.

Availability
Available in Mac OS X v10.0 and later.

See Also
`+ setPickerMode:` (page 728)

Declared In
`NSColorPanel.h`

setPickerMode:

Specifies the color panel's initial picker.

```
+ (void)setPickerMode:(NSColorPanelMode)mode
```

Parameters

mode

A constant specifying which color picker mode is initially visible. This is one of the symbolic constants described in Color Panel Modes (page 738).

Discussion
This method may be called at any time, whether or not an application's `NSColorPanel` has been instantiated.

Availability
Available in Mac OS X v10.0 and later.

See Also
`+ setPickerMask:` (page 728)
`- setMode:` (page 734)

Declared In
NSColorPanel.h

sharedColorPanel

Returns the shared NSColorPanel instance, creating it if necessary.

```
+ (NSColorPanel *)sharedColorPanel
```

Return Value
The shared NSColorPanel instance.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
AnimatingViews
CWCocoaComponent
FunHouse
QTAudioExtractionPanel
QTCoreVideo301

Declared In
NSColorPanel.h

sharedColorPanelExists

Returns a Boolean value indicating whether the NSColorPanel has been created already.

```
+ (BOOL)sharedColorPanelExists
```

Return Value
YES if the NSColorPanel has been created already; otherwise NO.

Availability
Available in Mac OS X v10.0 and later.

See Also
+ sharedColorPanel (page 729)

Declared In
NSColorPanel.h

Instance Methods

accessoryView

Returns the accessory view.

```
- (NSView *)accessoryView
```

Return Value
The accessory view or `nil` if there is none.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setAccessoryView:` (page 732)

Declared In
`NSColorPanel.h`

alpha

Returns the receiver's current alpha value based on its opacity slider.

```
- (CGFloat)alpha
```

Return Value
The alpha value of the `NSColorPanel`. This is 1.0 (opaque) if the panel has no opacity slider.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setShowsAlpha:` (page 735)
- `showsAlpha` (page 736)

Declared In
`NSColorPanel.h`

attachColorList:

Adds the list of `NSColor` objects specified to all the color pickers in the receiver that display color lists by invoking `attachColorList:` (page 730) on all color pickers in the application.

```
- (void)attachColorList:(NSColorList *)colorList
```

Parameters
colorList
The list of colors to add to the color pickers in the receiver.

Discussion
An application should use this method to add an `NSColorList` saved with a document in its file package or in a directory other than `NSColorList`'s standard search directories.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `detachColorList:` (page 731)

Declared In
NSColorPanel.h

color

Returns the currently selected color in the receiver.

```
- (NSColor *)color
```

Return Value
The currently selected color.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setColor: (page 733)

Declared In
NSColorPanel.h

detachColorList:

Removes the list of colors from all the color pickers in the receiver that display color lists by invoking detachColorList: on all color pickers in the application.

```
- (void)detachColorList:(NSColorList *)colorList
```

Parameters
colorList
The list of NSColor objects to remove from the color pickers in the color panel.

Discussion
Your application should use this method to remove an NSColorList saved with a document in its file package or in a directory other than NSColorList's standard search directories.

Availability
Available in Mac OS X v10.0 and later.

See Also
- attachColorList: (page 730)

Declared In
NSColorPanel.h

isContinuous

Returns a Boolean value indicating whether the receiver continuously sends the action message to the target.

```
- (BOOL)isContinuous
```

Return Value
`YES` if the receiver continuously sends the action message to the target as the user manipulates the color picker; otherwise `NO`.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setContinuous:` (page 734)

Declared In
`NSColorPanel.h`

mode

Returns the color picker mode of the receiver.

```
- (NSColorPanelMode)mode
```

Return Value
A constant indicating the current color picker mode. See Color Panel Modes (page 738).

Availability
Available in Mac OS X v10.0 and later.

See Also
`+ setPickerMode:` (page 728)
`- setMode:` (page 734)

Declared In
`NSColorPanel.h`

setAccessoryView:

Sets the accessory view displayed in the receiver.

```
- (void)setAccessoryView:(NSView *)aView
```

Parameters
aView
The accessory view displayed in the receiver. The accessory view can be any custom view you want to display with `NSColorPanel`, such as a view offering color blends in a drawing program. The accessory view is displayed below the color picker and above the color swatches in the `NSColorPanel`. The `NSColorPanel` automatically resizes to accommodate the accessory view.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- accessoryView` (page 729)

Related Sample Code
QTCoreVideo301

Declared In
NSColorPanel.h

setAction:

Sets the color panel's action message.

```
- (void)setAction:(SEL)action
```

Return Value
The action message. When you select a color in the color panel `NSColorPanel` sends its action to its target, provided that neither the action nor the target is `nil`. The action is `NULL` by default.

Discussion
See *Action Messages* for additional information on action messages.

Availability
Available in Mac OS X v10.0 and later.

setColor:

Sets the color of the receiver.

```
- (void)setColor:(NSColor *)color
```

Parameters
color
The color of the `NSColorPanel`.

Discussion
This method posts an `NSColorPanelColorDidChangeNotification` (page 740) with the receiver to the default notification center.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- color` (page 731)

Declared In
NSColorPanel.h

setContinuous:

Sets the receiver to send the action message to its target continuously as the user sets the color.

```
- (void)setContinuous:(BOOL)flag
```

Parameters

flag

YES to have the receiver send its action message to its target continuously as the color of the NSColorPanel is set by the user; otherwise NO. Set this to YES if, for example, you want to continuously update the color of the target.

Availability
Available in Mac OS X v10.0 and later.

See Also
- isContinuous (page 731)

Declared In
NSColorPanel.h

setMode:

Sets the mode of the receiver the mode is one of the modes allowed by the color mask.

```
- (void)setMode:(NSColorPanelMode)mode
```

Parameters

mode

A constant specifying the mode of the color panel. These constants are described in Color Picker Modes (page 738). The color mask is set when you first create the shared instance of NSColorPanel for an application.

Availability
Available in Mac OS X v10.0 and later.

See Also
+ setPickerMode: (page 728)
- mode (page 732)

Declared In
NSColorPanel.h

setShowsAlpha:

Tells the receiver whether or not to show alpha values and an opacity slider.

```
- (void)setShowsAlpha:(BOOL)flag
```

Parameters

flag

YES to have the color panel show alpha values and an opacity slider; otherwise NO.

Discussion

Note that calling the NSColor method setIgnoresAlpha: (page 691) with a value of YES overrides any value set with this method.

Availability

Available in Mac OS X v10.0 and later.

NSColorPanel.h

setTarget:

Sets the target of the receiver.

```
- (void)setTarget:(id)target
```

Parameters

target

The target of the receiver. When you select a color in the color panel NSColorPanel sends its action to its target, provided that neither the action nor the target is nil. The target is nil by default.

Availability

Available in Mac OS X v10.0 and later.

See Also

Declared In
NSColorPanel.h

showsAlpha

Returns a Boolean value indicating whether or not the receiver shows alpha values and an opacity slider.

```
- (BOOL)showsAlpha
```

Return Value
YES if the color picker shows alpha values and an opacity slider; otherwise NO.

Discussion
Note that calling the NSColor method setIgnoresAlpha: (page 691) with a value of YES overrides any value set with setShowsAlpha: (page 735).

Availability
Available in Mac OS X v10.0 and later.

See Also
- alpha (page 730)
- setShowsAlpha: (page 735)

Declared In
NSColorPanel.h

Delegate Methods

changeColor:

Sent to the first responder when the user selects a color in an NSColorPanel object.

```
- (void)changeColor:(id)sender
```

Parameters
sender
The NSColorPanel sending the message.

Discussion
When the user selects a color in an NSColorPanel object, the panel sends a changeColor: action message to the first responder. You can override this method in any responder that needs to respond to a color change.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSColorPanel.h

Constants

Color Picker Mode Masks

Used to specify in the `setPickerMask:` (page 728) class method which of the color modes the `NSColorPanel` can use.

```
enum {
    NSColorPanelGrayModeMask            = 0x00000001,
    NSColorPanelRGBModeMask             = 0x00000002,
    NSColorPanelCMYKModeMask            = 0x00000004,
    NSColorPanelHSBModeMask             = 0x00000008,
    NSColorPanelCustomPaletteModeMask   = 0x00000010,
    NSColorPanelColorListModeMask       = 0x00000020,
    NSColorPanelWheelModeMask           = 0x00000040,
    NSColorPanelCrayonModeMask          = 0x00000080,
    NSColorPanelAllModesMask            = 0x0000ffff
};
```

Constants

`NSColorPanelGrayModeMask`

Grayscale-alpha.

Available in Mac OS X v10.0 and later.

Declared in `NSColorPanel.h`.

`NSColorPanelRGBModeMask`

Red-green-blue.

Available in Mac OS X v10.0 and later.

Declared in `NSColorPanel.h`.

`NSColorPanelCMYKModeMask`

Cyan-yellow-magenta-black.

Available in Mac OS X v10.0 and later.

Declared in `NSColorPanel.h`.

`NSColorPanelHSBModeMask`

Hue-saturation-brightness.

Available in Mac OS X v10.0 and later.

Declared in `NSColorPanel.h`.

`NSColorPanelCustomPaletteModeMask`

Custom palette.

Available in Mac OS X v10.0 and later.

Declared in `NSColorPanel.h`.

`NSColorPanelColorListModeMask`

Custom color list.

Available in Mac OS X v10.0 and later.

Declared in `NSColorPanel.h`.

`NSColorPanelWheelModeMask`
: Color wheel.

  Available in Mac OS X v10.0 and later.

  Declared in `NSColorPanel.h`.

`NSColorPanelCrayonModeMask`
: Crayons.

  Declared in `NSColorPanel.h`.

  Available in Mac OS X v10.2 and later.

`NSColorPanelAllModesMask`
: All of the above.

  Available in Mac OS X v10.0 and later.

  Declared in `NSColorPanel.h`.

Discussion
For more information, see "Choosing the Color Pickers in a Color Panel".

Declared In
`NSColorPanel.h`

NSColorPanelMode

A type defined for the `enum` constants specifying color panel modes.

```
typedef NSInteger NSColorPanelMode;
```

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSColorPanel.h`

Color Panel Modes

Specify the active color mode used when an application's instance of `NSColorPanel` is masked for more than one color mode.

```
enum {
    NSNoModeColorPanel              = -1,
    NSGrayModeColorPanel             = 0,
    NSRGBModeColorPanel              = 1,
    NSCMYKModeColorPanel             = 2,
    NSHSBModeColorPanel              = 3,
    NSCustomPaletteModeColorPanel    = 4,
    NSColorListModeColorPanel        = 5,
    NSWheelModeColorPanel            = 6,
    NSCrayonModeColorPanel           = 7
};
```

Constants

`NSNoModeColorPanel`
Indicates no color panel mode.
Available in Mac OS X version 10.5 and later.
Declared in `NSColorPanel.h`.

`NSGrayModeColorPanel`
Grayscale-alpha
Available in Mac OS X v10.0 and later.
Declared in `NSColorPanel.h`.

`NSRGBModeColorPanel`
Red-green-blue
Available in Mac OS X v10.0 and later.
Declared in `NSColorPanel.h`.

`NSCMYKModeColorPanel`
Cyan-yellow-magenta-black
Available in Mac OS X v10.0 and later.
Declared in `NSColorPanel.h`.

`NSHSBModeColorPanel`
Hue-saturation-brightness
Available in Mac OS X v10.0 and later.
Declared in `NSColorPanel.h`.

`NSCustomPaletteModeColorPanel`
Custom palette
Available in Mac OS X v10.0 and later.
Declared in `NSColorPanel.h`.

`NSColorListModeColorPanel`
Custom color list
Available in Mac OS X v10.0 and later.
Declared in `NSColorPanel.h`.

`NSWheelModeColorPanel`
Color wheel
Available in Mac OS X v10.0 and later.
Declared in `NSColorPanel.h`.

`NSCrayonModeColorPanel`
: Crayons.

  Declared in `NSColorPanel.h`.

  Available in Mac OS X v10.2 and later.

Discussion
These enum constants are specified or returned in the instance methods `mode` (page 732) and `setMode:` (page 734), and in the `setPickerMode:` (page 728)class method. For more information, see "Choosing the Color Pickers in a Color Panel".

Declared In
`NSColorPanel.h`

Notifications

NSColorPanelColorDidChangeNotification

Posted when the color of the `NSColorPanel` is set, as when `setColor:` (page 733) is invoked.

The notification object is the notifying `NSColorPanel`. This notification does not contain a *`userInfo`* dictionary.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSColorPanel.h`

NSColorPicker Class Reference

Inherits from	NSObject
Conforms to	NSColorPickingDefault NSObject (NSObject)
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.0 and later.
Declared in	AppKit/NSColorPicker.h

Overview

The `NSColorPicker` class is an abstract superclass that implements the `NSColorPickingDefault` protocol. The `NSColorPickingDefault` and `NSColorPickingCustom` protocols define a way to add color pickers (custom user interfaces for color selection) to the `NSColorPanel`.

Adopted Protocols

NSColorPickingDefault

- `- alphaControlAddedOrRemoved:` (page 3618)
- `- attachColorList:` (page 3618)
- `- detachColorList:` (page 744)
- `- initWithPickerMask:colorPanel:` (page 3620)
- `- insertNewButtonImage:in:` (page 3621)
- `- provideNewButtonImage` (page 3621)
- `- setMode:` (page 3622)
- `- viewSizeChanged:` (page 746)

Tasks

Initializing an NSColorPicker Object

- `initWithPickerMask:colorPanel:` (page 744)
  Initializes the color picker with the specified color panel and color picker mode mask.

Getting the Color Panel

- `colorPanel` (page 743)
  Returns the NSColorPanel that owns the receiver.

Adding Button Images

- `insertNewButtonImage:in:` (page 745)
  Sets the image used for the specified button cell.
- `provideNewButtonImage` (page 746)
  Returns the button image for the receiver.

Setting the Mode

- `setMode:` (page 746)
  Does nothing. Override to set the color picker's mode.

Mananging Color Lists

- `attachColorList:` (page 743)
  Does nothing. Override to attach a color list to a color picker.
- `detachColorList:` (page 744)
  Does nothing. Override to detach a color list from a color picker.

Responding to View Changes

- `viewSizeChanged:` (page 746)
  Does nothing. Override to respond to a size change.

Customizing the Color Picker

- `buttonToolTip` (page 743)
  Returns the tool tip to be shown when the mouse cursor is over the receiver's button image.

- minContentSize (page 745)
  Returns the minimum content size for the receiver.

Instance Methods

attachColorList:

Does nothing. Override to attach a color list to a color picker.

```
- (void)attachColorList:(NSColorList *)colorList
```

Parameters

colorList
The color list to attach to the color picker.

Availability
Available in Mac OS X v10.0 and later.

See Also
- detachColorList: (page 744)

Declared In
NSColorPicker.h

buttonToolTip

Returns the tool tip to be shown when the mouse cursor is over the receiver's button image.

```
- (NSString *)buttonToolTip
```

Return Value
A string representing the tool tip.

Discussion
Override this method to provide a custom tool tip. The default implementation of this method returns the name of the receiver's class. If you want the color picker to have no tool tip, return an empty string.

Availability
Available in Mac OS X v10.5 and later.

Related Sample Code
RadiantColorPicker

Declared In
NSColorPicker.h

colorPanel

Returns the NSColorPanel that owns the receiver.

```
- (NSColorPanel *)colorPanel
```

Return Value
The owning color panel.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSColorPicker.h

detachColorList:

Does nothing. Override to detach a color list from a color picker.

```
- (void)detachColorList:(NSColorList *)colorList
```

Parameters

colorList
The color list to detach.

Availability
Available in Mac OS X v10.0 and later.

See Also
- attachColorList: (page 743)

Declared In
NSColorPicker.h

initWithPickerMask:colorPanel:

Initializes the color picker with the specified color panel and color picker mode mask.

```
- (id)initWithPickerMask:(NSUInteger)mask colorPanel:(NSColorPanel *)owningColorPanel
```

Parameters

mask
The color picker mask.

owningColorPanel
The NSColorPanel that owns the color picker. This value is cached so it can be returned later by the colorPanel (page 743) method.

Return Value
An initialized color picker object.

Discussion
Override this method to respond to the values in *mask* or do other custom initialization. If you override this method in a subclass, you should forward the message to super as part of the implementation.

Availability
Available in Mac OS X v10.0 and later.

See Also
- colorPanel (page 743)

Declared In
NSColorPicker.h

insertNewButtonImage:in:

Sets the image used for the specified button cell.

```
- (void)insertNewButtonImage:(NSImage *)newButtonImage in:(NSButtonCell *)buttonCell
```

Parameters

newButtonImage
The image used for the specified button cell.

buttonCell
The button cell for which to set the image.

Discussion
Called by the color panel to insert a new image into the specified cell by invoking NSButtonCell's setImage: (page 69) method. Override this method to customize *newButtonImage* before insertion in *buttonCell*.

Availability
Available in Mac OS X v10.0 and later.

See Also
- provideNewButtonImage (page 746)

Declared In
NSColorPicker.h

minContentSize

Returns the minimum content size for the receiver.

```
- (NSSize)minContentSize
```

Return Value
The minimum size of the receiver, an NSColorPicker object. The NSColorPanel object does not allow the color picker to be made smaller than this size.

Discussion
Override this method to return a minimum size for the color picker's content area. The default implementation of this method obtains the minimum content size from the view-autoresizing behavior specified for the receiver and returns that. You should not have to override this method if you properly set up the color picker's auto-sizing attributes in Interface Builder.

Availability
Available in Mac OS X v10.5 and later.

Declared In
NSColorPicker.h

provideNewButtonImage

Returns the button image for the receiver.

```
- (NSImage *)provideNewButtonImage
```

Return Value
The image placed on the mode button the user uses to select this color picker. This is the same image the color panel uses as an argument when sending the `insertNewButtonImage:in:` (page 745) message.) The default implementation looks in the color picker's bundle for a TIFF file named after the color picker's class, with the extension "`.tiff`".

Availability
Available in Mac OS X v10.0 and later.

See Also
`- insertNewButtonImage:in:` (page 745)

Related Sample Code
MyCustomColorPicker

Declared In
`NSColorPicker.h`

setMode:

Does nothing. Override to set the color picker's mode.

```
- (void)setMode:(NSColorPanelMode)mode
```

Parameters

mode

A constant specifying the color picking mode. These constants are defined in `AppKit/NSColorPanel.h`.

Discussion
In grayscale-alpha, red-green-blue, cyan-magenta-yellow-black, and hue-saturation-brightness modes, the user adjusts colors by manipulating sliders. In the custom palette mode, the user can load an `NSImage` file (TIFF or EPS) into the `NSColorPanel`, then select colors from the image. In custom color list mode, the user can create and load lists of named colors. The two custom modes provide `NSPopUpLists` for loading and saving files. Finally, color wheel mode provides a simplified control for selecting colors.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSColorPicker.h`

viewSizeChanged:

Does nothing. Override to respond to a size change.

```
- (void)viewSizeChanged:(id)sender
```

Availability
Available in Mac OS X v10.0 and later.

Overview

The `NSColorSpace` class enables the creation of objects representing custom color spaces. You can make custom color spaces from ColorSync profiles or from ICC profiles. `NSColorSpace` also has factory methods that return objects representing the system color spaces.

You can use the `colorWithColorSpace:components:count:` (page 673) method of the `NSColor` class to create color objects using custom `NSColorSpace` objects. You can also send the `colorUsingColorSpace:` (page 700) message to an `NSColor` object to convert it between two color spaces, either of which may be a custom color space.

Tasks

Getting a Named NSColorSpace Object

`+ deviceRGBColorSpace` (page 752)
Returns an `NSColorSpace` object representing a calibrated or device-dependent RGB color space.

`+ genericRGBColorSpace` (page 754)
Returns an `NSColorSpace` object representing a device-independent RGB color space.

`+ deviceCMYKColorSpace` (page 751)
Returns an `NSColorSpace` object representing a calibrated or device-dependent CMYK color space.

+ genericCMYKColorSpace (page 753)
Returns an NSColorSpace object representing a device-independent CMYK color space.

+ deviceGrayColorSpace (page 752)
Returns an NSColorSpace object representing a calibrated or device-dependent gray color space.

+ genericGrayColorSpace (page 753)
Returns an NSColorSpace object representing a device-independent gray color space.

+ sRGBColorSpace (page 754)
Returns an NSColorSpace object representing an sRGB color space.

+ genericGamma22GrayColorSpace (page 753)
Returns an NSColorSpace object representing a gray color space with a gamma value of 2.2.

+ adobeRGB1998ColorSpace (page 751)
Returns an NSColorSpace object representing an Adobe RGB (1998) color space.

Getting the Color Spaces Available On the System

+ availableColorSpacesWithModel: (page 751)
Returns the list of color spaces available on the system that are displayed in the color panel, in the order they are displayed in the color panel.

Initializing a Custom NSColorSpace Object

- initWithCGColorSpace: (page 756)
Initializes and returns an NSColorSpace object initialized from a Core Graphics color-space object.

- initWithColorSyncProfile: (page 757)
Initializes and returns an NSColorSpace object given a ColorSync profile.

- initWithICCProfileData: (page 757)
Initializes and returns an NSColorSpace object given an ICC profile.

Accessing Color-Space Data and Attributes

- CGColorSpace (page 755)
Returns a Core Graphics color-space object that represents a color space equivalent to the receiver's.

- colorSpaceModel (page 755)
Returns the model on which the color space of the receiver is based.

- colorSyncProfile (page 755)
Returns the ColorSync profile from which the receiver was created.

- ICCProfileData (page 756)
Returns the ICC profile data from which the receiver was created.

- localizedName (page 758)
Returns the localized name of the receiver.

- numberOfColorComponents (page 758)
Returns the number of components supported by the receiver.

Class Methods

adobeRGB1998ColorSpace

Returns an `NSColorSpace` object representing an Adobe RGB (1998) color space.

```
+ (NSColorSpace *)adobeRGB1998ColorSpace
```

Return Value
The `NSColorSpace` object. This color-additive color space has red, green, blue, and alpha components.

Discussion
The Adobe RGB (1998) color space was designed to encompass most of the colors achievable on CMYK color printers, but by using RGB primary colors on a device such as the computer display. For more information on this color space, go to http://www.adobe.com/digitalimag/adobergb.html.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSColorSpace.h`

availableColorSpacesWithModel:

Returns the list of color spaces available on the system that are displayed in the color panel, in the order they are displayed in the color panel.

```
+ (NSArray *)availableColorSpacesWithModel:(NSColorSpaceModel)model
```

Parameters

model

The model to return the color spaces for.

Return Value
The list of color spaces, or an empty array if no color spaces are available for the specified model.

Discussion
This method doesn't return color spaces created on the fly or spaces without user-displayable names. Pass `NSUnknownColorSpaceModel` as *model* to get all available color spaces.

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSColorSpace.h`

deviceCMYKColorSpace

Returns an `NSColorSpace` object representing a calibrated or device-dependent CMYK color space.

```
+ (NSColorSpace *)deviceCMYKColorSpace
```

Return Value
The `NSColorSpace` object. This color space has cyan, magenta, yellow, black, and alpha components. Typical devices that use the color-subtractive CMYK color space are color printers. This object corresponds to the Cocoa color space name `NSDeviceCMYKColorSpace`.

Availability
Available in Mac OS X v10.4 and later.

See Also
`+ genericCMYKColorSpace` (page 753)

Declared In
`NSColorSpace.h`

deviceGrayColorSpace

Returns an `NSColorSpace` object representing a calibrated or device-dependent gray color space.

```
+ (NSColorSpace *)deviceGrayColorSpace
```

Return Value
The `NSColorSpace` object. The color space also includes an alpha component. Typical devices that use this color space are grayscale printers and displays. This object corresponds to the Cocoa color space name `NSDeviceWhiteColorSpace`.

Availability
Available in Mac OS X v10.4 and later.

See Also
`+ genericGrayColorSpace` (page 753)
`+ genericGamma22GrayColorSpace` (page 753)

Declared In
`NSColorSpace.h`

deviceRGBColorSpace

Returns an `NSColorSpace` object representing a calibrated or device-dependent RGB color space.

```
+ (NSColorSpace *)deviceRGBColorSpace
```

Return Value
The `NSColorSpace` object. This color space has red, green, blue, and alpha components. Typical devices that use the color-additive RGB color space are displays and scanners. This object corresponds to the Cocoa color space name `NSDeviceRGBColorSpace`.

Availability
Available in Mac OS X v10.4 and later.

See Also
`+ genericRGBColorSpace` (page 754)

Declared In
NSColorSpace.h

genericCMYKColorSpace

Returns an NSColorSpace object representing a device-independent CMYK color space.

```
+ (NSColorSpace *)genericCMYKColorSpace
```

Return Value
The NSColorSpace object. This color space has cyan, magenta, yellow, black and alpha component.

Availability
Available in Mac OS X v10.4 and later.

See Also
+ deviceCMYKColorSpace (page 751)

Declared In
NSColorSpace.h

genericGamma22GrayColorSpace

Returns an NSColorSpace object representing a gray color space with a gamma value of 2.2.

```
+ (NSColorSpace *)genericGamma22GrayColorSpace
```

Return Value
The NSColorSpace object.

Availability
Available in Mac OS X v10.6 and later.

See Also
+ deviceGrayColorSpace (page 752)
+ genericGrayColorSpace (page 753)

Declared In
NSColorSpace.h

genericGrayColorSpace

Returns an NSColorSpace object representing a device-independent gray color space.

```
+ (NSColorSpace *)genericGrayColorSpace
```

Return Value
The NSColorSpace object. The color space also includes an alpha component. This object corresponds to the Cocoa color space name NSCalibratedWhiteColorSpace.

Availability
Available in Mac OS X v10.4 and later.

See Also
+ deviceGrayColorSpace (page 752)
+ genericGamma22GrayColorSpace (page 753)

Declared In
NSColorSpace.h

genericRGBColorSpace

Returns an NSColorSpace object representing a device-independent RGB color space.

```
+ (NSColorSpace *)genericRGBColorSpace
```

Return Value
The NSColorSpace object. This color-additive color space has red, green, blue, and alpha components. This object corresponds to the Cocoa color space name NSCalibratedRGBColorSpace.

Availability
Available in Mac OS X v10.4 and later.

See Also
+ deviceRGBColorSpace (page 752)

Related Sample Code
Quartz 2D Shadings
Quartz Composer QCTV

Declared In
NSColorSpace.h

sRGBColorSpace

Returns an NSColorSpace object representing an sRGB color space.

```
+ (NSColorSpace *)sRGBColorSpace
```

Return Value
The NSColorSpace object. This color-additive color space has red, green, blue, and alpha components.

Discussion
The sRGB color space is a standard color space for use on monitors, printers, and the Internet. For further information on sRGB, see http://www.color.org/srgb.html.

Availability
Available in Mac OS X v10.5 and later.

Declared In
NSColorSpace.h

Instance Methods

CGColorSpace

Returns a Core Graphics color-space object that represents a color space equivalent to the receiver's.

```
- (CGColorSpaceRef)CGColorSpace
```

Return Value
A reference to an Core Graphics color-space object (`CGColorSpaceRef`) or `NULL` if the type of color space represented by the receiver cannot be represented by a `CGColorSpace` object.

Availability
Available in Mac OS X v10.5 and later.

See Also
`- initWithCGColorSpace:` (page 756)

Declared In
`NSColorSpace.h`

colorSpaceModel

Returns the model on which the color space of the receiver is based.

```
- (NSColorSpaceModel)colorSpaceModel
```

Return Value
A constant specifying the color space model of the receiver. See Color Space Models (page 758) for a list of valid `NSColorSpaceModel` constants.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`NSColorSpace.h`

colorSyncProfile

Returns the ColorSync profile from which the receiver was created.

```
- (void *)colorSyncProfile
```

Return Value
The ColorSync profile on which the receiver is based. You need to cast this value to an object of opaque type `CMProfileRef`. Returns `NULL` if the receiver was created from a ICC-profile data instead. See *ColorSync Manager Reference* for further information on `CMProfileRef`.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `initWithColorSyncProfile:` (page 757)

Declared In
`NSColorSpace.h`

ICCProfileData

Returns the ICC profile data from which the receiver was created.

```
- (NSData *)ICCProfileData
```

Return Value
The ICC profile from which the receiver was created. This method attempts to compute the profile data from a `CMProfileRef` object and returns `nil` if it is unable to.

For information on ICC profiles, see the latest ICC specification at the International Color Consortium website.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `initWithICCProfileData:` (page 757)

Declared In
`NSColorSpace.h`

initWithCGColorSpace:

Initializes and returns an `NSColorSpace` object initialized from a Core Graphics color-space object.

```
- (id)initWithCGColorSpace:(CGColorSpaceRef)cgColorSpace
```

Parameters
cgColorSpace
A reference to a Core Graphics color-space object (`CGColorSpaceRef`).

Return Value
The initialized `NSColorSpace` object or `nil` if initialization was not successful, which might happen if the color space represented by the `CGColorSpace` object is not supported by `NSColorSpace`.

Discussion
Because `NSColorSpace` might retain or copy the `CGColorSpace` object depending on circumstances, you should not assume pointer equality of the provided object with that returned by `CGColorSpace` (page 755). And even if the pointer equality is preserved during runtime, it may not be after the `NSColorSpace` object is archived and unarchived.

Availability
Available in Mac OS X v10.5 and later.

Related Sample Code
AnimatedTableView

Declared In
NSColorSpace.h

initWithColorSyncProfile:

Initializes and returns an NSColorSpace object given a ColorSync profile.

```
- (id)initWithColorSyncProfile:(void *)prof
```

Parameters

prof

The ColorSync profile to use when initializing the NSColorSpace object. This should be an object of opaque type CMProfileRef. See *ColorSync Manager Reference* for further information on CMProfileRef.

Return Value
The initialized NSColorSpace object or nil if initialization was not successful.

Availability
Available in Mac OS X v10.4 and later.

See Also
- colorSyncProfile (page 755)

Declared In
NSColorSpace.h

initWithICCProfileData:

Initializes and returns an NSColorSpace object given an ICC profile.

```
- (id)initWithICCProfileData:(NSData *)iccData
```

Parameters

iccData

The ICC profile to use when initializing the NSColorSpace object. For information on ICC profiles, see the latest ICC specification at the International Color Consortium website.

Return Value
The initialized NSColorSpace object or nil if initialization was not successful.

Availability
Available in Mac OS X v10.4 and later.

See Also
- ICCProfileData (page 756)

Declared In
NSColorSpace.h

localizedName

Returns the localized name of the receiver.

```
- (NSString *)localizedName
```

Return Value
The name of the color space as a localized string or `nil` if no localized name exists.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`NSColorSpace.h`

numberOfColorComponents

Returns the number of components supported by the receiver.

```
- (NSInteger)numberOfColorComponents
```

Return Value
The number of components (excluding alpha) the receiver supports or zero if the receiver is not based on `float` components.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`NSColorSpace.h`

Constants

NSColorSpaceModel

The type of the color-space mode constants listed in "Color Space Models" (page 758).

```
typedef NSInteger NSColorSpaceModel;
```

Availability
Available in Mac OS X v10.4 and later.

Declared In
`NSColorSpace.h`

Color Space Models

Identify the abstract model on which an `NSColorSpace` object is based.

```
typedef enum {
    NSUnknownColorSpaceModel = -1,
    NSGrayColorSpaceModel,
    NSRGBColorSpaceModel,
    NSCMYKColorSpaceModel,
    NSLABColorSpaceModel,
    NSDeviceNColorSpaceModel,
    NSIndexedColorSpaceModel,
    NSPatternColorSpaceModel
};
```

Constants

`NSUnknownColorSpaceModel`
This model is not known to `NSColorSpace`.

Available in Mac OS X v10.4 and later.

Declared in `NSColorSpace.h`.

`NSGrayColorSpaceModel`
The grayscale color-space model. Can refer to both device-dependent and generic color space variants.

Available in Mac OS X v10.4 and later.

Declared in `NSColorSpace.h`.

`NSRGBColorSpaceModel`
The RGB (red green blue) color-space model. Can refer to both device-dependent and generic color space variants.

Available in Mac OS X v10.4 and later.

Declared in `NSColorSpace.h`.

`NSCMYKColorSpaceModel`
The CYMK (cyan, yellow, magenta, black) color-space model. Can refer to both device-dependent and generic color space variants.

Available in Mac OS X v10.4 and later.

Declared in `NSColorSpace.h`.

`NSLABColorSpaceModel`
The L*a*b* device-independent color-space model, which represents colors relative to a reference white point.

Available in Mac OS X v10.4 and later.

Declared in `NSColorSpace.h`.

`NSDeviceNColorSpaceModel`
DeviceN is a color-space model from Adobe Systems, Inc. used in PostScript and PDF color specification.

Available in Mac OS X v10.4 and later.

Declared in `NSColorSpace.h`.

`NSIndexedColorSpaceModel`
An indexed color space, which identifies specified discrete colors in a color list by index number. An indexed color value (a color specification in indexed color space) consists of an index value that refers to a color in a color list.

Available in Mac OS X v10.5 and later.

Declared in `NSColorSpace.h`.

`NSPatternColorSpaceModel`

Identifies a pattern color space, which is simply an image that is repeated over and over again in a tiled pattern.

Available in Mac OS X v10.5 and later.

Declared in `NSColorSpace.h`.

Discussion

These constants are returned from `colorSpaceModel` (page 755) and are derived from the profile data encapsulated by the object.

Overview

An `NSColorWell` object is an `NSControl` for selecting and displaying a single color value. An example of an `NSColorWell` object (or simply color well) is found in an `NSColorPanel`, which uses a color well to display the current color selection. A color well is available from the Palettes panel of Interface Builder.

Tasks

Managing Color From Color Wells

`- color` (page 763)
Returns the color of the receiver.

`- setColor:` (page 765)
Sets the color of the receiver and redraws the receiver.

`- takeColorFrom:` (page 765)
Changes the color of the receiver to that of the specified object.

Activating and Deactivating Color Wells

- `activate:` (page 762)
  Activates the receiver, displays the color panel, and makes the current color the same as its own.
- `deactivate` (page 763)
  Deactivates the receiver and redraws it.
- `isActive` (page 764)
  Returns a Boolean value indicating whether the receiver is active.

Managing Borders of Color Wells

- `isBordered` (page 764)
  Returns a Boolean value indicating whether the receiver has a border.
- `setBordered:` (page 764)
  Places or removes a border on the receiver and redraws the receiver.

Drawing a Color Well

- `drawWellInside:` (page 763)
  Draws the colored area inside the receiver at the specified location without drawing borders.

Instance Methods

activate:

Activates the receiver, displays the color panel, and makes the current color the same as its own.

```
- (void)activate:(BOOL)exclusive
```

Parameters

exclusive
`YES` to deactivate any other color wells; `NO` to keep them active. If a color panel is active with *exclusive* set to `YES` and another is subsequently activated with *exclusive* set to `NO`, the exclusive setting of the first panel is ignored.

Discussion
This method redraws the receiver. An active color well will have its color updated when the current color of the `NSColorPanel` changes. Any color well that shows its border highlights the border when it's active.

Availability
Available in Mac OS X v10.0 and later.

drawWellInside:

Draws the colored area inside the receiver at the specified location without drawing borders.

```
- (void)drawWellInside:(NSRect)insideRect
```

Parameters

insideRect

The rectangle specifying the area within which to draw.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSColorWell.h

isActive

Returns a Boolean value indicating whether the receiver is active.

```
- (BOOL)isActive
```

Return Value
YES if the receiver is active, NO otherwise.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSColorWell.h

isBordered

Returns a Boolean value indicating whether the receiver has a border.

```
- (BOOL)isBordered
```

Return Value
YES if the receiver is bordered, NO otherwise.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setBordered: (page 764)

Declared In
NSColorWell.h

setBordered:

Places or removes a border on the receiver and redraws the receiver.

```
- (void)setBordered:(BOOL)bordered
```

Parameters

bordered

YES to place a border on the receiver, NO to remove it.

Availability
Available in Mac OS X v10.0 and later.

NSComboBox Class Reference

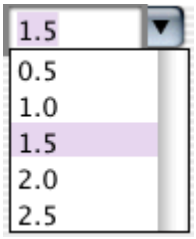
Inherits from	NSTextField : NSControl : NSView : NSResponder : NSObject
Conforms to	NSUserInterfaceValidations (NSTextField) NSAnimatablePropertyContainer (NSView) NSCoding (NSResponder) NSObject (NSObject)
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.0 and later.
Declared in	AppKit/NSComboBox.h
Companion guide	Combo Box Programming Topics
Related sample code	DemoAssistant QTAudioExtractionPanel QTKitPlayer SimpleComboBox URL CacheInfo

Overview

An `NSComboBox` is a kind of `NSControl` that allows you to either enter text directly (as you would with an `NSTextField`) or click the attached arrow at the right of the combo box and select from a displayed ("pop-up") list of items.

Normally an instance of `NSComboBox` looks like this:

When you click the downward-pointing arrow at the right side of the text field, the pop-up list appears, like this:



The `NSComboBox` class uses `NSComboBoxCell` to implement its user interface.

Also see the `NSComboBoxDataSource` informal protocol, which declares the methods that an `NSComboBox` uses to access the contents of its data source object.

Tasks

Setting Display Attributes

- `hasVerticalScroller` (page 773)
  Returns a Boolean value indicating whether the receiver will display a vertical scroller.
- `intercellSpacing` (page 775)
  Returns the horizontal and vertical spacing between cells in the receiver's pop-up list.
- `isButtonBordered` (page 775)
  Returns whether the combo box button is set to display a border.
- `itemHeight` (page 775)
  Returns the height of each item in the receiver's pop-up list.
- `numberOfVisibleItems` (page 777)
  Returns the maximum number of items visible in the pop-up list.
- `setButtonBordered:` (page 782)
  Determines whether the button in the combo box is displayed with a border.
- `setHasVerticalScroller:` (page 783)
  Determines whether the receiver displays a vertical scroller.
- `setIntercellSpacing:` (page 784)
  Sets the spacing between pop-up list items.
- `setItemHeight:` (page 784)
  Sets the height for items.
- `setNumberOfVisibleItems:` (page 785)
  Sets the maximum number of items that are visible in the receiver's pop-up list.

Setting a Data Source

- `dataSource` (page 772)
  Returns the object that provides the data displayed in the receiver's pop-up list.

- `setDataSource:` (page 783)
  Sets the receiver's data source to *aSource*.
- `setUsesDataSource:` (page 785)
  Sets whether the receiver uses an external data source to populate the receiver's pop-up list.
- `usesDataSource` (page 786)
  Returns a Boolean value indicating whether the receiver uses an external data source to populate its pop-up list.

Working with an Internal List

- `addItemsWithObjectValues:` (page 770)
  Adds multiple objects to the end of the receiver's internal item list.
- `addItemWithObjectValue:` (page 771)
  Adds an object to the end of the receiver's internal item list.
- `insertItemWithObjectValue:atIndex:` (page 774)
  Inserts an object at the specified location in the receiver's internal item list.
- `objectValues` (page 778)
  Returns as an array the receiver's internal item list.
- `removeAllItems` (page 779)
  Removes all items from the receiver's internal item list.
- `removeItemAtIndex:` (page 779)
  Removes the object at the specified location from the receiver's internal item list.
- `removeItemWithObjectValue:` (page 779)
  Removes all occurrences of the given object from the receiver's internal item list.
- `numberOfItems` (page 777)
  Returns the total number of items in the pop-up list.

Manipulating the Displayed List

- `indexOfItemWithObjectValue:` (page 773)
  Searches the receiver's internal item list for the specified object and returns the lowest matching index.
- `itemObjectValueAtIndex:` (page 776)
  Returns the object located at the given index within the receiver's internal item list.
- `noteNumberOfItemsChanged` (page 776)
  Informs the receiver that the number of items in its data source has changed.
- `reloadData` (page 778)
  Marks the receiver as needing redisplay, so that it will reload the data for visible pop-up items and draw the new values.
- `scrollItemAtIndexToTop:` (page 780)
  Scrolls the receiver's pop-up list vertically so that the item at the specified index is as close to the top as possible.
- `scrollItemAtIndexToVisible:` (page 780)
  Scrolls the receiver's pop-up list vertically so that the item at the specified index is visible.

Manipulating the Selection

- `deselectItemAtIndex:` (page 772)
  Deselects the pop-up list item at the specified index if it's selected.
- `indexOfSelectedItem` (page 774)
  Returns the index of the last item selected from the pop-up list.
- `objectValueOfSelectedItem` (page 777)
  Returns the object corresponding to the last item selected from the pop-up list.
- `selectItemAtIndex:` (page 781)
  Selects the pop-up list row at the given index.
- `selectItemWithObjectValue:` (page 781)
  Selects the first pop-up list item that corresponds to the given object.

Completing the Text Field

- `completes` (page 771)
  Returns a Boolean value indicating whether the receiver tries to complete what the user types in the text field.
- `setCompletes:` (page 782)
  Sets whether the receiver tries to complete what the user types in the text field.

New Methods

- `delegate` (page 772)
  Returns the receiver's delegate.
- `setDelegate:` (page 783)
  Sets the receiver's delegate.

Instance Methods

addItemsWithObjectValues:

Adds multiple objects to the end of the receiver's internal item list.

```
- (void)addItemsWithObjectValues:(NSArray *)objects
```

Parameters

objects
  An array of the objects to add to the internal item list.

Discussion
This method logs a warning if `usesDataSource` (page 786) returns `YES`.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
LSMSmartCategorizer

Declared In
NSComboBox.h

addItemWithObjectValue:

Adds an object to the end of the receiver's internal item list.

```
- (void)addItemWithObjectValue:(id)anObject
```

Parameters

anObject
The object to add to the internal item list.

Discussion
This method logs a warning if `usesDataSource` (page 786) returns `YES`.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
QTAudioExtractionPanel
QTKitPlayer

Declared In
NSComboBox.h

completes

Returns a Boolean value indicating whether the receiver tries to complete what the user types in the text field.

```
- (BOOL)completes
```

Return Value
`YES` if the receiver tries to complete what the user types in the text field; otherwise `NO`.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setCompletes:` (page 782)

Declared In
NSComboBox.h

dataSource

Returns the object that provides the data displayed in the receiver's pop-up list.

```
- (id < NSComboBoxDataSource >)dataSource
```

Return Value
The data source for the combo box's pop-up list.

Discussion
This method logs a warning if `usesDataSource` (page 786) returns `NO`. See the class description and the `NSComboBoxDataSource` informal protocol specification for more information on combo box data source objects.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSComboBox.h`

delegate

Returns the receiver's delegate.

```
- (id < NSComboBoxDelegate >)delegate
```

Return Value
The receiver's delegate.

Availability
Available in Mac OS X v10.6 and later.

See Also
`- setDelegate:` (page 783)

Declared In
`NSComboBox.h`

deselectItemAtIndex:

Deselects the pop-up list item at the specified index if it's selected.

```
- (void)deselectItemAtIndex:(NSInteger)index
```

Parameters
index
The index of the item to deselect.

Discussion
If the selection does in fact change, this method posts an `NSComboBoxSelectionDidChangeNotification` (page 786) to the default notification center.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `indexOfSelectedItem` (page 774)
- `numberOfItems` (page 777)
- `selectItemAtIndex:` (page 781)

Declared In
`NSComboBox.h`

hasVerticalScroller

Returns a Boolean value indicating whether the receiver will display a vertical scroller.

```
- (BOOL)hasVerticalScroller
```

Return Value
`YES` if the receiver will display a vertical scroller; otherwise `NO`.

Discussion
Note that the scroller will be displayed even if the pop-up list contains fewer items than will fit in the area specified for display.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `numberOfItems` (page 777)
- `numberOfVisibleItems` (page 777)

Declared In
`NSComboBox.h`

indexOfItemWithObjectValue:

Searches the receiver's internal item list for the specified object and returns the lowest matching index.

```
- (NSInteger)indexOfItemWithObjectValue:(id)anObject
```

Parameters
anObject
The object for which to return the index.

Return Value
The lowest index in the internal item list whose corresponding value is equal to that of the specified object. Objects are considered equal if they have the same `id` or if `isEqual:` returns `YES`.

If none of the objects in the receiver's internal item list are equal to *anObject*, `indexOfItemWithObjectValue:` returns `NSNotFound`.

Discussion
This method logs a warning if `usesDataSource` (page 786) returns `YES`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `selectItemWithObjectValue:` (page 781)

Declared In
`NSComboBox.h`

indexOfSelectedItem

Returns the index of the last item selected from the pop-up list.

```
- (NSInteger)indexOfSelectedItem
```

Return Value
The index of the last item selected from the receiver's pop-up list or -1 if no item is selected.

Discussion
Note that nothing is initially selected in a newly initialized combo box.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `objectValueOfSelectedItem` (page 777)

Related Sample Code
ClipboardViewer

Declared In
`NSComboBox.h`

insertItemWithObjectValue:atIndex:

Inserts an object at the specified location in the receiver's internal item list.

```
- (void)insertItemWithObjectValue:(id)anObject atIndex:(NSInteger)index
```

Parameters

anObject
The object to add to the internal item list.

index
The index in the list at which to add the new object. The previous item at *index*—along with all following items—is shifted down one slot to make room

Discussion
This method logs a warning if `usesDataSource` (page 786) returns `YES`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `addItemWithObjectValue:` (page 771)
- `numberOfItems` (page 777)

Related Sample Code
DemoAssistant

Declared In
`NSComboBox.h`

intercellSpacing

Returns the horizontal and vertical spacing between cells in the receiver's pop-up list.

```
- (NSSize)intercellSpacing
```

Return Value
The space between cells in the pop-up list. The default spacing is (3.0, 2.0).

Availability
Available in Mac OS X v10.0 and later.

See Also
- `itemHeight` (page 775)
- `numberOfVisibleItems` (page 777)

Declared In
`NSComboBox.h`

isButtonBordered

Returns whether the combo box button is set to display a border.

```
- (BOOL)isButtonBordered
```

Return Value
`YES` if the button has a border; otherwise `NO`.

Availability
Available in Mac OS X v10.3 and later.

See Also
- `setButtonBordered:` (page 782)

Declared In
`NSComboBox.h`

itemHeight

Returns the height of each item in the receiver's pop-up list.

```
- (CGFloat)itemHeight
```

Return Value
The height of items in the pop-up list. The default item height is 16.0.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `intercellSpacing` (page 775)
- `numberOfVisibleItems` (page 777)

Declared In
`NSComboBox.h`

itemObjectValueAtIndex:

Returns the object located at the given index within the receiver's internal item list.

```
- (id)itemObjectValueAtIndex:(NSInteger)index
```

Parameters

index

The index of the object to retrieve. If *index* is beyond the end of the list, an `NSRangeException` is raised.

Return Value
The object located at the specified index in the internal item list.

Discussion
This method logs a warning if `usesDataSource` (page 786) returns `YES`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `objectValueOfSelectedItem` (page 777)

Declared In
`NSComboBox.h`

noteNumberOfItemsChanged

Informs the receiver that the number of items in its data source has changed.

```
- (void)noteNumberOfItemsChanged
```

Discussion
This method allows the receiver to update the scrollers in its displayed pop-up list without actually reloading data into the receiver. It is particularly useful for a data source that continually receives data in the background over a period of time, in which case the `NSComboBox` can remain responsive to the user while the data is received.

See the `NSComboBoxDataSource` informal protocol specification for information on the messages an `NSComboBox` sends to its data source.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `reloadData` (page 778)

Declared In
`NSComboBox.h`

numberOfItems

Returns the total number of items in the pop-up list.

```
- (NSInteger)numberOfItems
```

Return Value
The number of items in the list.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `numberOfVisibleItems` (page 777)
- `numberOfItemsInComboBox:` (`NSComboBoxDataSource` protocol)

Related Sample Code
DemoAssistant

Declared In
`NSComboBox.h`

numberOfVisibleItems

Returns the maximum number of items visible in the pop-up list.

```
- (NSInteger)numberOfVisibleItems
```

Return Value
The maximum number of items visible at any one time in the pop-up list.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `numberOfItems` (page 777)

Declared In
`NSComboBox.h`

objectValueOfSelectedItem

Returns the object corresponding to the last item selected from the pop-up list.

```
- (id)objectValueOfSelectedItem
```

Return Value
The object in the receiver's internal item list corresponding to the last item selected from the pop-up list, or `nil` if no item is selected.

Discussion
Note that nothing is initially selected in a newly initialized combo box. This method logs a warning if `usesDataSource` (page 786) returns `YES`.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- indexOfSelectedItem` (page 774)

Declared In
`NSComboBox.h`

objectValues

Returns as an array the receiver's internal item list.

```
- (NSArray *)objectValues
```

Return Value
The array containing the objects in the receiver's internal item list.

Discussion
This method logs a warning if `usesDataSource` (page 786) returns `YES`.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
DemoAssistant

Declared In
`NSComboBox.h`

reloadData

Marks the receiver as needing redisplay, so that it will reload the data for visible pop-up items and draw the new values.

```
- (void)reloadData
```

Availability
Available in Mac OS X v10.0 and later.

See Also
- noteNumberOfItemsChanged (page 776)

Declared In
NSComboBox.h

removeAllItems

Removes all items from the receiver's internal item list.

```
- (void)removeAllItems
```

Discussion
This method logs a warning if usesDataSource (page 786) returns YES.

Availability
Available in Mac OS X v10.0 and later.

See Also
- objectValues (page 778)

Declared In
NSComboBox.h

removeItemAtIndex:

Removes the object at the specified location from the receiver's internal item list.

```
- (void)removeItemAtIndex:(NSInteger)index
```

Parameters
index
The index of the object to remove. All items beyond *index* are moved up one slot to fill the gap.

Discussion
The removed object receives a release message. This method raises an NSRangeException if *index* is beyond the end of the list and logs a warning if usesDataSource (page 786) returns YES.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
DemoAssistant

Declared In

`NSComboBox.h`

scrollItemAtIndexToTop:

Scrolls the receiver's pop-up list vertically so that the item at the specified index is as close to the top as possible.

```
- (void)scrollItemAtIndexToTop:(NSInteger)index
```

Parameters

index

The index of the item to scroll to the top.

Discussion

The pop-up list need not be displayed at the time this method is invoked.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSComboBox.h`

scrollItemAtIndexToVisible:

Scrolls the receiver's pop-up list vertically so that the item at the specified index is visible.

```
- (void)scrollItemAtIndexToVisible:(NSInteger)index
```

Parameters

index

The index of the item to make visible.

Discussion
The pop-up list need not be displayed at the time this method is invoked.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSComboBox.h

selectItemAtIndex:

Selects the pop-up list row at the given index.

```
- (void)selectItemAtIndex:(NSInteger)index
```

Parameters

index
The index of the item to select in the pop-up list.

Discussion
Posts an NSComboBoxSelectionDidChangeNotification (page 786) to the default notification center if the selection does in fact change. Note that this method does not alter the contents of the combo box's text field—see Setting the Combo Box's Value for more information.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setObjectValue: (page 836) (NSControl)

Declared In
NSComboBox.h

selectItemWithObjectValue:

Selects the first pop-up list item that corresponds to the given object.

```
- (void)selectItemWithObjectValue:(id)anObject
```

Parameters

anObject
The object to select in the pop-up list. Objects are considered equal if they have the same id or if isEqual: returns YES.

Discussion
This method logs a warning if usesDataSource (page 786) returns YES. Posts an NSComboBoxSelectionDidChangeNotification (page 786) to the default notification center if the selection does in fact change. Note that this method doesn't alter the contents of the combo box's text field—see Setting the Combo Box's Value for more information.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setObjectValue:` (page 836) (NSControl)

Declared In
`NSComboBox.h`

setButtonBordered:

Determines whether the button in the combo box is displayed with a border.

```
- (void)setButtonBordered:(BOOL)flag
```

Parameters

flag

`YES` to display a border; `NO` to display the button without a border. For example, it is often useful when using a combo box in an `NSTableView` to display the button without the border.

Availability
Available in Mac OS X v10.3 and later.

See Also
- `isButtonBordered` (page 775)

Declared In
`NSComboBox.h`

setCompletes:

Sets whether the receiver tries to complete what the user types in the text field.

```
- (void)setCompletes:(BOOL)completes
```

Parameters

completes

`YES` to indicate that the receiver should try to complete test entered by the user. If *completes* is `YES`, every time the user adds characters to the end of the text field, the combo box calls the `NSComboBoxCell` method `completedString:` (page 792).

Discussion
If `completedString:` (page 792) returns a string that's longer than the existing string, the combo box replaces the existing string with the returned string and selects the additional characters. If the user is deleting characters or adds characters somewhere besides the end of the string, the combo box does not try to complete it.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `completes` (page 771)

Declared In
`NSComboBox.h`

setDataSource:

Sets the receiver's data source to *aSource*.

```
- (void)setDataSource:(id < NSComboBoxDataSource >)aSource
```

Parameters

aSource

The new data source for the receiver. The data source should implement the appropriate methods of the `NSComboBoxDataSource` informal protocol.

This method logs a warning if *aSource* doesn't respond to either `numberOfItemsInComboBox:` or `comboBox:objectValueForItemAtIndex:`.

Discussion

This method doesn't automatically set `usesDataSource` (page 786) to `NO` and in fact logs a warning if `usesDataSource` (page 786) returns `NO`.

Availability

Available in Mac OS X v10.0 and later.

See Also

`- setUsesDataSource:` (page 785)

Declared In

`NSComboBox.h`

setDelegate:

Sets the receiver's delegate.

```
- (void)setDelegate:(id < NSComboBoxDelegate >)anObject
```

Parameters

anObject

The delegate for the receiver. The delegate must conform to the `NSComboBoxDelegate Protocol` protocol.

Availability

Available in Mac OS X v10.6 and later.

See Also

`- delegate` (page 772)

Declared In

`NSComboBox.h`

setHasVerticalScroller:

Determines whether the receiver displays a vertical scroller.

```
- (void)setHasVerticalScroller:(BOOL)flag
```

Parameters

flag

YES to display a vertical scroller; NO otherwise. By default, *flag* is YES.

Discussion

If *flag* is NO and the combo box has more list items (either in its internal item list or from its data source) than are allowed by numberOfVisibleItems (page 777), only a subset are displayed. The NSComboBox class' scroll... methods can be used to position this subset within the pop-up list.

Note that if flag is YES, a scroller will be displayed even if the combo box has fewer list items than are allowed by numberOfVisibleItems (page 777).

Availability

Available in Mac OS X v10.0 and later.

See Also

- scrollItemAtIndexToTop: (page 780)
- scrollItemAtIndexToVisible: (page 780)

Declared In

NSComboBox.h

setIntercellSpacing:

Sets the spacing between pop-up list items.

```
- (void)setIntercellSpacing:(NSSize)aSize
```

Parameters

aSize

The new width and height between pop-up list items. The default intercell spacing is (3.0, 2.0).

Availability

Available in Mac OS X v10.0 and later.

See Also

- setItemHeight: (page 784)
- setNumberOfVisibleItems: (page 785)

Declared In

NSComboBox.h

setItemHeight:

Sets the height for items.

```
- (void)setItemHeight:(CGFloat)itemHeight
```

Parameters

itemHeight

The new height for items in the pop-up list.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setIntercellSpacing:` (page 784)
- `setNumberOfVisibleItems:` (page 785)

Declared In
`NSComboBox.h`

setNumberOfVisibleItems:

Sets the maximum number of items that are visible in the receiver's pop-up list.

```
- (void)setNumberOfVisibleItems:(NSInteger)visibleItems
```

Parameters

visibleItems
The maximum number of items that are visible at one time in the pop-up list.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `numberOfItems` (page 777)
- `setItemHeight:` (page 784)
- `setIntercellSpacing:` (page 784)

Declared In
`NSComboBox.h`

setUsesDataSource:

Sets whether the receiver uses an external data source to populate the receiver's pop-up list.

```
- (void)setUsesDataSource:(BOOL)flag
```

Parameters

flag
`YES` if the receiver uses an external data source (specified by `setDataSource:` (page 783)); otherwise `NO`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSComboBox.h`

usesDataSource

Returns a Boolean value indicating whether the receiver uses an external data source to populate its pop-up list.

```
- (BOOL)usesDataSource
```

Return Value
`YES` if the receiver uses an external data source to populate the receiver's pop-up list, `NO` if it uses an internal item list.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- dataSource` (page 772)

`NSComboBox.h`

Notifications

NSComboBoxSelectionDidChangeNotification

Posted after the pop-up list selection of the `NSComboBox` changes.

The notification object is the `NSComboBox` whose selection changed. This notification does not contain a *`userInfo`* dictionary.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSComboBox.h`

NSComboBoxSelectionIsChangingNotification

Posted whenever the pop-up list selection of the `NSComboBox` is changing.

The notification object is the `NSComboBox` whose selection is changing. This notification does not contain a *`userInfo`* dictionary.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSComboBox.h`

NSComboBoxWillDismissNotification

Posted whenever the pop-up list of the `NSComboBox` is about to be dismissed.

The notification object is the `NSComboBox` whose pop-up list will be dismissed. This notification does not contain a *`userInfo`* dictionary.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSComboBox.h`

NSComboBoxWillPopUpNotification

Posted whenever the pop-up list of the `NSComboBox` is going to be displayed.

The notification object is the `NSComboBox` whose pop-up window will be displayed. This notification does not contain a *`userInfo`* dictionary.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSComboBox.h`

Related sample code	SimpleComboBox

Overview

`NSComboBoxCell` is a subclass of `NSTextFieldCell` used to implement the user interface of "combo boxes" (see `NSComboBox` for information on how combo boxes look and work). The `NSComboBox` subclass of `NSTextField` uses a single `NSComboBoxCell`, and essentially all of the `NSComboBox` class' methods simply invoke the corresponding `NSComboBoxCell` method.

Also see the `NSComboBoxCellDataSource` protocol, which declares the methods that an `NSComboBoxCell` object uses to access the contents of its data source object.

Tasks

Setting Display Attributes

- `hasVerticalScroller` (page 794)
  Returns a Boolean value indicating whether the receiver will display a vertical scroller.
- `isButtonBordered` (page 796)
  Returns a Boolean value indicating whether the combo box button is set to display a border.
- `intercellSpacing` (page 796)
  Returns the spacing between cells in the receiver's pop-up list.
- `itemHeight` (page 797)
  Returns the height of each item in the receiver's pop-up list.

- `numberOfVisibleItems` (page 798)
  Returns the maximum number of items visible in the pop-up list.
- `setButtonBordered:` (page 803)
  Determines whether the button in the combo box is displayed with a border.
- `setHasVerticalScroller:` (page 804)
  Determines whether the receiver displays a vertical scroller.
- `setIntercellSpacing:` (page 805)
  Sets the spacing between pop-up list items.
- `setItemHeight:` (page 805)
  Sets the height for items.
- `setNumberOfVisibleItems:` (page 805)
  Sets the maximum number of items that are visible in the pop-up list.

Setting a Data Source

- `dataSource` (page 793)
  Returns the object that provides the data displayed in the receiver's pop-up list.
- `setDataSource:` (page 804)
  Sets the receiver's data source.
- `setUsesDataSource:` (page 806)
  Sets whether the receiver uses an external data source to populate its pop-up list.
- `usesDataSource` (page 806)
  Returns a Boolean value indicating whether the receiver uses an external data source.

Working with an Internal List

- `addItemsWithObjectValues:` (page 792)
  Adds multiple objects to the internal item list.
- `addItemWithObjectValue:` (page 792)
  Adds the specified object to the internal item list.
- `insertItemWithObjectValue:atIndex:` (page 795)
  Inserts an object at the specified location in the internal item list.
- `objectValues` (page 799)
  Returns the receiver's internal item list.
- `removeAllItems` (page 800)
  Removes all items from the receiver's internal item list.
- `removeItemAtIndex:` (page 800)
  Removes the object at the specified location from the receiver's internal item list.
- `removeItemWithObjectValue:` (page 801)
  Removes all occurrences of the specified object from the receiver's internal item list.
- `numberOfItems` (page 798)
  Returns the total number of items in the pop-up list.

Manipulating the Displayed List

- `indexOfItemWithObjectValue:` (page 795)
  Searches the receiver's internal item list for the given object and returns the matching index number.
- `itemObjectValueAtIndex:` (page 797)
  Returns the object located at the specified location in the internal item list.
- `noteNumberOfItemsChanged` (page 798)
  Informs the receiver that the number of items in its data source has changed.
- `reloadData` (page 799)
  Marks the receiver as needing redisplay, so that it will reload the data for visible pop-up items and draw the new values.
- `scrollItemAtIndexToTop:` (page 801)
  Scrolls the receiver's pop-up list vertically so that the item at the given index is as close to the top as possible.
- `scrollItemAtIndexToVisible:` (page 801)
  Scrolls the receiver's pop-up list vertically so that the item at the given index is visible.

Manipulating the Selection

- `deselectItemAtIndex:` (page 794)
  Deselects the pop-up list item at the given index if it's selected.
- `indexOfSelectedItem` (page 795)
  Returns the index of the last item selected from the pop-up list.
- `objectValueOfSelectedItem` (page 799)
  Returns the object corresponding to the last item selected from the pop-up list.
- `selectItemAtIndex:` (page 802)
  Selects the pop-up list row at the given index.
- `selectItemWithObjectValue:` (page 802)
  Selects the first pop-up list item that corresponds to the specified object.

Completing the Text Field

- `completedString:` (page 792)
  Returns a string from the receiver's pop-up list that starts with the given substring.
- `completes` (page 793)
  Returns a Boolean value indicating whether the receiver tries to complete text entered by the user.
- `setCompletes:` (page 803)
  Sets whether the receiver tries to complete what the user types in the text field.

Instance Methods

addItemsWithObjectValues:

Adds multiple objects to the internal item list.

```
- (void)addItemsWithObjectValues:(NSArray *)objects
```

Parameters

objects

The object to add to the end of the receiver's internal item list.

Discussion

This method logs a warning if `usesDataSource` (page 806) returns `YES`.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSComboBoxCell.h`

addItemWithObjectValue:

Adds the specified object to the internal item list.

```
- (void)addItemWithObjectValue:(id)anObject
```

Parameters

anObject

The object to add to the end of the receiver's internal item list.

Discussion

This method logs a warning if `usesDataSource` (page 806) returns `YES`.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSComboBoxCell.h`

completedString:

Returns a string from the receiver's pop-up list that starts with the given substring.

```
- (NSString *)completedString:(NSString *)substring
```

Parameters

substring

The substring to search for. This is what the user entered in the combo box's text field.

Return Value
The string from the receiver's pop-up list that starts with the specified substring or `nil` if there is no such string.

Discussion
The default implementation of this method first checks whether the combo box uses a data source and whether the data source responds to `comboBox:completedString:` or `comboBoxCell:completedString:`. If so, the combo box cell returns that method's return value. Otherwise, this method goes through the combo box's items one by one and returns an item that starts with *`substring`*.

Override this method only if your subclass completes strings differently. The overriding method does not need to call the superclass's method. Generally, you do not need to call this method directly.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSComboBoxCell.h`

completes

Returns a Boolean value indicating whether the receiver tries to complete text entered by the user.

```
- (BOOL)completes
```

Return Value
`YES` if the receiver tries to complete what the user types in the text field; `NO` otherwise.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setCompletes:` (page 803)

Declared In
`NSComboBoxCell.h`

dataSource

Returns the object that provides the data displayed in the receiver's pop-up list.

```
- (id < NSComboBoxCellDataSource >)dataSource
```

Return Value
The data source for the receiver's pop-up list.

Discussion
This method logs a warning if `usesDataSource` (page 806) returns `NO`. See the class description and the `NSComboBoxCellDataSource` informal protocol specification for more information on combo box cell data source objects.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSComboBoxCell.h

deselectItemAtIndex:

Deselects the pop-up list item at the given index if it's selected.

```
- (void)deselectItemAtIndex:(NSInteger)index
```

Parameters

index
The index of the item to deselect.

Discussion
If the selection does in fact change, this method posts an `NSComboBoxSelectionDidChangeNotification` (page 786) to the default notification center.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `indexOfSelectedItem` (page 795)
- `numberOfItems` (page 798)
- `selectItemAtIndex:` (page 802)

Declared In
NSComboBoxCell.h

hasVerticalScroller

Returns a Boolean value indicating whether the receiver will display a vertical scroller.

```
- (BOOL)hasVerticalScroller
```

Return Value
`YES` if the receiver displays a vertical scroller; otherwise `NO`.

Discussion
Note that the scroller will be displayed even if the pop-up list contains fewer items than will fit in the area specified for display.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `numberOfItems` (page 798)
- `numberOfVisibleItems` (page 798)

Declared In
NSComboBoxCell.h

indexOfItemWithObjectValue:

Searches the receiver's internal item list for the given object and returns the matching index number.

```
- (NSInteger)indexOfItemWithObjectValue:(id)anObject
```

Parameters

anObject

The object for which to return the index.

Return Value

The lowest index whose corresponding value is equal to *anObject*. Objects are considered equal if they have the same `id` or if `isEqual:` returns `YES`. If none of the objects in the receiver's internal item list is equal to *anObject*, `indexOfItemWithObjectValue:` returns `NSNotFound`.

Discussion

This method logs a warning if `usesDataSource` (page 806) returns `YES`.

Availability

Available in Mac OS X v10.0 and later.

See Also

`- selectItemWithObjectValue:` (page 802)

Declared In

`NSComboBoxCell.h`

indexOfSelectedItem

Returns the index of the last item selected from the pop-up list.

```
- (NSInteger)indexOfSelectedItem
```

Return Value

The index of the last item selected from the receiver's pop-up list or –1 if no item is selected.

Discussion

Note that nothing is initially selected in a newly initialized combo box cell.

Availability

Available in Mac OS X v10.0 and later.

See Also

`- objectValueOfSelectedItem` (page 799)

Declared In

`NSComboBoxCell.h`

insertItemWithObjectValue:atIndex:

Inserts an object at the specified location in the internal item list.

```
- (void)insertItemWithObjectValue:(id)anObject atIndex:(NSInteger)index
```

Parameters

anObject

The object to add to the receiver's internal item list.

index

The index at which to add the specified object. The previous item at *index*—along with all following items—is shifted down one slot to make room.

Discussion

This method logs a warning if `usesDataSource` (page 806) returns `YES`.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `addItemWithObjectValue:` (page 792)
- `numberOfItems` (page 798)

Declared In

`NSComboBoxCell.h`

intercellSpacing

Returns the spacing between cells in the receiver's pop-up list.

```
- (NSSize)intercellSpacing
```

Return Value

The horizontal and vertical spacing between cells in the receiver's pop-up list. The default spacing is (3.0, 2.0).

Availability

Available in Mac OS X v10.0 and later.

See Also

- `itemHeight` (page 797)
- `numberOfVisibleItems` (page 798)

Declared In

`NSComboBoxCell.h`

isButtonBordered

Returns a Boolean value indicating whether the combo box button is set to display a border.

```
- (BOOL)isButtonBordered
```

Return Value

`YES` if the button has a border; otherwise `NO`.

Availability

Available in Mac OS X v10.3 and later.

See Also
- `setButtonBordered:` (page 803)

Declared In
`NSComboBoxCell.h`

itemHeight

Returns the height of each item in the receiver's pop-up list.

```
- (CGFloat)itemHeight
```

Return Value
The height of each item in the pop-up list. The default item height is 16.0.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `intercellSpacing` (page 796)
- `numberOfVisibleItems` (page 798)

Declared In
`NSComboBoxCell.h`

itemObjectValueAtIndex:

Returns the object located at the specified location in the internal item list.

```
- (id)itemObjectValueAtIndex:(NSInteger)index
```

Parameters
index
The index of the object to return. If *index* is beyond the end of the list, an `NSRangeException` is raised.

Return Value
The object at the given location in the receiver's internal item list.

Discussion
This method logs a warning if `usesDataSource` (page 806) returns `YES`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `objectValueOfSelectedItem` (page 799)

Declared In
`NSComboBoxCell.h`

noteNumberOfItemsChanged

Informs the receiver that the number of items in its data source has changed.

```
- (void)noteNumberOfItemsChanged
```

Discussion
This method allows the receiver to update the scrollers in its displayed pop-up list without actually reloading data into the receiver. It is particularly useful for a data source that continually receives data in the background over a period of time, in which case the `NSComboBoxCell` can remain responsive to the user while the data is received.

See the `NSComboBoxCellDataSource` informal protocol specification for information on the messages an `NSComboBoxCell` sends to its data source.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `reloadData` (page 799)

Declared In
`NSComboBoxCell.h`

numberOfItems

Returns the total number of items in the pop-up list.

```
- (NSInteger)numberOfItems
```

Return Value
The number of items in the pop-up list.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `numberOfVisibleItems` (page 798)
- `numberOfItemsInComboBoxCell:` (NSComboBoxCellDataSource protocol)

Declared In
`NSComboBoxCell.h`

numberOfVisibleItems

Returns the maximum number of items visible in the pop-up list.

```
- (NSInteger)numberOfVisibleItems
```

Return Value
The maximum number of items that are visible in the receiver's pop-up list at any one time.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `numberOfItems` (page 798)

Declared In
`NSComboBoxCell.h`

objectValueOfSelectedItem

Returns the object corresponding to the last item selected from the pop-up list.

```
- (id)objectValueOfSelectedItem
```

Return Value
The object from the receiver's internal item list corresponding to the last item selected from the pop-up list, or `nil` if no item is selected.

Discussion
Note that nothing is initially selected in a newly initialized combo box cell. This method logs a warning if `usesDataSource` (page 806) returns `YES`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `indexOfSelectedItem` (page 795)
- `comboBoxCell:objectValueForItemAtIndex:` (`NSComboBoxCellDataSource` protocol)

Declared In
`NSComboBoxCell.h`

objectValues

Returns the receiver's internal item list.

```
- (NSArray *)objectValues
```

Return Value
An array containing the objects in the receiver's internal item list.

Discussion
This method logs a warning if `usesDataSource` (page 806) returns `YES`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSComboBoxCell.h`

reloadData

Marks the receiver as needing redisplay, so that it will reload the data for visible pop-up items and draw the new values.

```
- (void)reloadData
```

Availability
Available in Mac OS X v10.0 and later.

See Also
- noteNumberOfItemsChanged (page 798)

Declared In
NSComboBoxCell.h

removeAllItems

Removes all items from the receiver's internal item list.

```
- (void)removeAllItems
```

Discussion
This method logs a warning if usesDataSource (page 806) returns YES.

Availability
Available in Mac OS X v10.0 and later.

See Also
- objectValues (page 799)

Declared In
NSComboBoxCell.h

removeItemAtIndex:

Removes the object at the specified location from the receiver's internal item list.

```
- (void)removeItemAtIndex:(NSInteger)index
```

Parameters
index
The index of the object to remove from the receiver's internal item list. All items beyond *index* are moved up one slot to fill the gap.

Discussion
The removed object receives a release message. This method raises an NSRangeException if *index* is beyond the end of the list and logs a warning if usesDataSource (page 806) returns YES.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSComboBoxCell.h

removeItemWithObjectValue:

Removes all occurrences of the specified object from the receiver's internal item list.

```
- (void)removeItemWithObjectValue:(id)anObject
```

Parameters

anObject

The object to remove from the receiver's internal item list. Objects are considered equal if they have the same `id` or if `isEqual:` returns `YES`.

Discussion

This method logs a warning if `usesDataSource` (page 806) returns `YES`.

Availability

Available in Mac OS X v10.0 and later.

See Also

`- indexOfItemWithObjectValue:` (page 795)

Declared In

`NSComboBoxCell.h`

scrollItemAtIndexToTop:

Scrolls the receiver's pop-up list vertically so that the item at the given index is as close to the top as possible.

```
- (void)scrollItemAtIndexToTop:(NSInteger)index
```

Parameters

index

The index of the item to scroll to the top.

Discussion

The pop-up list need not be displayed at the time this method is invoked.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSComboBoxCell.h`

scrollItemAtIndexToVisible:

Scrolls the receiver's pop-up list vertically so that the item at the given index is visible.

```
- (void)scrollItemAtIndexToVisible:(NSInteger)index
```

Parameters

index

The index of the item to make visible.

Discussion

The pop-up list need not be displayed at the time this method is invoked.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSComboBoxCell.h

selectItemAtIndex:

Selects the pop-up list row at the given index.

```
- (void)selectItemAtIndex:(NSInteger)index
```

Parameters

index

The index of the row to select.

Discussion
Posts an NSComboBoxSelectionDidChangeNotification (page 786) to the default notification center if the selection does in fact change. Note that this method does not alter the contents of the combo box cell's text field—see Setting the Combo Box's Value for more information.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setObjectValue: (page 836) (NSControl)

Declared In
NSComboBoxCell.h

selectItemWithObjectValue:

Selects the first pop-up list item that corresponds to the specified object.

```
- (void)selectItemWithObjectValue:(id)anObject
```

Parameters

anObject

The object for which to select the corresponding pop-up list item. Objects are considered equal if they have the same id or if isEqual: returns YES.

Discussion
This method logs a warning if usesDataSource (page 806) returns YES. Posts an NSComboBoxSelectionDidChangeNotification (page 786) to the default notification center if the selection does in fact change. Note that this method doesn't alter the contents of the combo box cell's text field—see Setting the Combo Box's Value for more information.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setObjectValue: (page 836) (NSControl)

Declared In
NSComboBoxCell.h

setButtonBordered:

Determines whether the button in the combo box is displayed with a border.

```
- (void)setButtonBordered:(BOOL)flag
```

Parameters

flag

YES to display a border. For example, it is often useful when using a combo box in an NSTableView to display the button without the border.

Availability
Available in Mac OS X v10.3 and later.

See Also
- isButtonBordered (page 796)

Declared In
NSComboBoxCell.h

setCompletes:

Sets whether the receiver tries to complete what the user types in the text field.

```
- (void)setCompletes:(BOOL)completes
```

Parameters

completes

YES to indicate that the receiver should try to complete text typed by the user. If *completes* is YES, every time the user adds characters to the end of the text field, the combo box calls the NSComboBoxCell method completedString: (page 792).

Discussion
If completedString: (page 792) returns a string that's longer than the existing string, the combo box replaces the existing string with the returned string and selects the additional characters. If the user is deleting characters or adds characters somewhere besides the end of the string, the combo box does not try to complete it.

Availability
Available in Mac OS X v10.0 and later.

See Also
- completes (page 793)

Declared In
NSComboBoxCell.h

setDataSource:

Sets the receiver's data source.

```
- (void)setDataSource:(id < NSComboBoxCellDataSource >)aSource
```

Parameters

aSource

The data source for the receiver. *aSource* should implement the appropriate methods of the NSComboBoxCellDataSource informal protocol.

This method logs a warning if *aSource* doesn't respond to either numberOfItemsInComboBoxCell: or comboBoxCell:objectValueForItemAtIndex:.

Discussion

This method doesn't automatically set usesDataSource (page 806) to NO and in fact logs a warning if usesDataSource returns NO.

Availability

Available in Mac OS X v10.0 and later.

See Also

- setUsesDataSource: (page 806)

Declared In

NSComboBoxCell.h

setHasVerticalScroller:

Determines whether the receiver displays a vertical scroller.

```
- (void)setHasVerticalScroller:(BOOL)flag
```

Parameters

flag

YES to have the receiver display a vertical scroller. By default, *flag* is YES.

Discussion

If *flag* is NO and the combo box cell has more list items (either in its internal item list or from its data source) than are allowed by numberOfVisibleItems (page 798), only a subset will be displayed. NSComboBoxCell's scroll... methods can be used to position this subset within the pop-up list.

Note that if *flag* is YES, a scroller will be displayed even if the combo box cell has fewer list items than are allowed by numberOfVisibleItems.

Availability

Available in Mac OS X v10.0 and later.

See Also

- numberOfItems (page 798)
- scrollItemAtIndexToTop: (page 801)
- scrollItemAtIndexToVisible: (page 801)

Declared In

NSComboBoxCell.h

setIntercellSpacing:

Sets the spacing between pop-up list items.

```
- (void)setIntercellSpacing:(NSSize)aSize
```

Parameters

aSize

The width and height between pop-up list items. The default intercell spacing is (3.0, 2.0).

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setItemHeight:` (page 805)
- `setNumberOfVisibleItems:` (page 805)

Declared In
`NSComboBoxCell.h`

setItemHeight:

Sets the height for items.

```
- (void)setItemHeight:(CGFloat)itemHeight
```

Parameters

itemHeight

The height of pop-up list items.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setIntercellSpacing:` (page 805)
- `setNumberOfVisibleItems:` (page 805)

Declared In
`NSComboBoxCell.h`

setNumberOfVisibleItems:

Sets the maximum number of items that are visible in the pop-up list.

```
- (void)setNumberOfVisibleItems:(NSInteger)visibleItems
```

Parameters

visibleItems

The maximum number of items that should be visible at one time in the receiver's pop-up list.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `numberOfItems` (page 798)
- `numberOfVisibleItems` (page 798)
- `setIntercellSpacing:` (page 805)
- `setItemHeight:` (page 805)

Declared In
`NSComboBoxCell.h`

setUsesDataSource:

Sets whether the receiver uses an external data source to populate its pop-up list.

```
- (void)setUsesDataSource:(BOOL)flag
```

Parameters

flag

`YES` to indicate that the receiver uses an external data source (specified by `setDataSource:` (page 804)) to populate the receiver's pop-up list.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSComboBoxCell.h`

usesDataSource

Returns a Boolean value indicating whether the receiver uses an external data source.

```
- (BOOL)usesDataSource
```

Return Value
`YES` if the receiver uses an external data source to populate the receiver's pop-up list, `NO` if it uses an internal item list.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `dataSource` (page 793)

Overview

`NSControl` is an abstract superclass that provides three fundamental features for implementing user interface devices: drawing devices on the screen, responding to user events, and sending action messages. It works closely with the `NSCell` class.

About Delegate Methods

The `NSControl` class provides several delegate methods for its subclasses that allow text editing, such as `NSTextField` and `NSMatrix`. These include: `controlTextDidBeginEditing:` (page 846), `controlTextDidChange:` (page 846), and `controlTextDidEndEditing:` (page 847).

Note that although `NSControl` defines delegate methods, it does not itself have a delegate. Any subclass that uses these methods must have a delegate and the methods to get and set it. In addition, a formal delegate protocol `NSControlTextEditingDelegate` also defines delegate methods used by control delegates.

Tasks

Initializing an NSControl

- `initWithFrame:` (page 820)
  Returns an NSControl object initialized with the specified frame rectangle.

Setting the Control's Cell

+ `cellClass` (page 812)
  Returns the type of cell used by the receiver.
+ `setCellClass:` (page 813)
  Sets the type of cell used by the receiver.
- `cell` (page 816)
  Returns the receiver's cell object.
- `setCell:` (page 830)
  Sets the receiver's cell

Enabling and Disabling the Control

- `isEnabled` (page 823)
  Returns whether the receiver reacts to mouse events.
- `setEnabled:` (page 831)
  Sets whether the receiver (and its cell) reacts to mouse events.

Identifying the Selected Cell

- `selectedCell` (page 825)
  Returns the receiver's selected cell.
- `selectedTag` (page 826)
  Returns the tag of the receiver's selected cell.

Setting the Control's Value

- `doubleValue` (page 817)
  Returns the value of the receiver's cell as a double-precision floating-point number.
- `setDoubleValue:` (page 831)
  Sets the value of the receiver's cell using a double-precision floating-point number.
- `floatValue` (page 819)
  Returns the value of the receiver's cell as a single-precision floating-point number.

- `setFloatValue:` (page 832)
  Sets the value of the receiver's cell using a single-precision floating-point number.
- `intValue` (page 821)
  Returns the value of the receiver's cell as an integer.
- `setIntValue:` (page 835)
  Sets the value of the receiver's cell using an integer.
- `integerValue` (page 821)
  Returns the value of the receiver's cell as an `NSInteger` value.
- `setIntegerValue:` (page 834)
  Sets the value of the receiver's cell using an `NSInteger` value.
- `objectValue` (page 824)
  Returns the value of the receiver's cell as an Objective-C object.
- `setObjectValue:` (page 836)
  Sets the value of the receiver's cell using an Objective-C object.
- `stringValue` (page 840)
  Returns the value of the receiver's cell as an `NSString` object.
- `setStringValue:` (page 837)
  Sets the value of the receiver's cell using an `NSString` object.
- `setNeedsDisplay` (page 836)
  Marks the receiver as needing redisplay (assuming automatic display is enabled).
- `attributedStringValue` (page 815)
  Returns the value of the receiver's cell as an attributed string.
- `setAttributedStringValue:` (page 829)
  Sets the value of the receiver's cell using an attributed string.

Interacting with Other Controls

- `takeDoubleValueFrom:` (page 841)
  Sets the value of the receiver's cell to a double-precision floating-point value obtained from the specified object.
- `takeFloatValueFrom:` (page 841)
  Sets the value of the receiver's cell to a single-precision floating-point value obtained from the specified object.
- `takeIntValueFrom:` (page 842)
  Sets the value of the receiver's cell to an integer value obtained from the specified object.
- `takeIntegerValueFrom:` (page 842)
  Sets the value of the receiver's cell to an `NSInteger` value obtained from the specified object.
- `takeObjectValueFrom:` (page 843)
  Sets the value of the receiver's cell to the object value obtained from the specified object.
- `takeStringValueFrom:` (page 843)
  Sets the value of the receiver's cell to the string value obtained from the specified object.

Formatting Text

- `alignment` (page 814)
  Returns the alignment mode of the text in the receiver's cell.
- `setAlignment:` (page 828)
  Sets the alignment of text in the receiver's cell.
- `font` (page 819)
  Returns the font used to draw text in the receiver's cell.
- `setFont:` (page 833)
  Sets the font used to draw text in the receiver's cell.
- `formatter` (page 820)
  Returns the receiver's formatter.
- `setFormatter:` (page 834)
  Sets the receiver's formatter
- `baseWritingDirection` (page 815)
  Returns the initial writing direction used to determine the actual writing direction for text.
- `setBaseWritingDirection:` (page 829)
  Sets the initial writing direction used to determine the actual writing direction for text .
- `setFloatingPointFormat:left:right:` (page 832) Deprecated in Mac OS X v10.0 Available in Mac OS X v10.0 through Mac OS X v10.5
  Sets the auto-ranging and floating point number format of the receiver's cell.

Managing the Field Editor

- `abortEditing` (page 813)
  Terminates the current editing operation and discards any edited text.
- `currentEditor` (page 817)
  Returns the current field editor for the control.
- `validateEditing` (page 845)
  Validates changes to any user-typed text.

Resizing the Control

- `calcSize` (page 816)
  Recomputes any internal sizing information for the receiver, if necessary.
- `sizeToFit` (page 839)
  Resizes the receiver's frame so that it is the minimum size needed to contain its cell.

Displaying a Cell

- `selectCell:` (page 825)
  Selects the specified cell and redraws the control as needed.

- `drawCell:` (page 818)
  Draws the specified cell, as long as it belongs to the receiver.
- `drawCellInside:` (page 818)
  Draws the inside of the receiver's cell (the area within the bezel or border)
- `updateCell:` (page 844)
  Marks the specified cell as in need of redrawing.
- `updateCellInside:` (page 845)
  Marks the inside of the specified cell as in need of redrawing.

Implementing the Target/action Mechanism

- `action` (page 814)
  Returns the default action-message selector associated with the control.
- `setAction:` (page 828)
  Sets the receiver's action method to the specified selector.
- `target` (page 844)
  Returns the target object of the receiver's cell.
- `setTarget:` (page 838)
  Sets the target object to receive action messages from the receiver's cell.
- `isContinuous` (page 822)
  Returns a Boolean value indicating whether the receiver's cell sends its action message continuously to its target during mouse tracking.
- `setContinuous:` (page 830)
  Sets whether the receiver's cell sends its action message continuously to its target during mouse tracking.
- `sendAction:to:` (page 826)
  Causes the specified action to be sent the target.
- `sendActionOn:` (page 827)
  Sets the conditions on which the receiver sends action messages to its target.

Getting and Setting Tags

- `tag` (page 840)
  Returns the tag identifying the receiver (not the tag of the receiver's cell).
- `setTag:` (page 838)
  Sets the tag of the receiver.

Activating from the Keyboard

- `performClick:` (page 824)
  Simulates a single mouse click on the receiver.
- `refusesFirstResponder` (page 825)
  Returns a Boolean value indicating whether the receiver refuses the first responder role.

- `setRefusesFirstResponder:` (page 837)
  Sets whether the receiver refuses first responder role.

Tracking the Mouse

- `mouseDown:` (page 823)
  Informs the receiver that the user has pressed the left mouse button.
- `ignoresMultiClick` (page 820)
  Returns a Boolean value indicating whether the receiver ignores multiple clicks made in rapid succession.
- `setIgnoresMultiClick:` (page 834)
  Sets whether the receiver ignores multiple clicks made in rapid succession.

Control Editing Notifications

- `controlTextDidBeginEditing:` (page 846) *delegate method*
  Sent when a control with editable text begins an editing session.
- `controlTextDidChange:` (page 846) *delegate method*
  Sent when the text in the receiving control changes.
- `controlTextDidEndEditing:` (page 847) *delegate method*
  Sent when a control with editable text ends an editing session.

Class Methods

cellClass

Returns the type of cell used by the receiver.

```
+ (Class)cellClass
```

Return Value
The class of the cell used to manage the receiver's contents, or `nil` if no cell class has been set for the receiver or its superclasses (up to NSControl).

Availability
Available in Mac OS X v10.0 and later.

See Also
- `cell` (page 816)
- `setCell:` (page 830)
- `setCellClass:` (page 813)

Related Sample Code
ClockControl
TrackBall

Declared In
NSControl.h

setCellClass:

Sets the type of cell used by the receiver.

```
+ (void)setCellClass:(Class)class
```

Parameters

class

The class of the cell to use with this control.

Discussion
If you have a custom cell subclass that you would like to substitute for the class of a cell object in a nib file, you should set the cell class in the awakeFromNib (page 3731) method (NSNibAwaking protocol). You cannot change the class programmatically after the cell object has been unarchived from the nib and instantiated, which occurs immediately after awakeFromNib (page 3731) returns. If you are going to be using your custom cell frequently, consider creating your own Interface Builder palette containing the cell.

Availability
Available in Mac OS X v10.0 and later.

See Also
- cell (page 816)
- setCell: (page 830)
+ cellClass (page 812)

Declared In
NSControl.h

Instance Methods

abortEditing

Terminates the current editing operation and discards any edited text.

```
- (BOOL)abortEditing
```

Return Value
YES if there was a field editor associated with the control; otherwise, NO.

Discussion
If there was a field editor, this method removes the field editor's delegate.

Availability
Available in Mac OS X v10.0 and later.

See Also
- currentEditor (page 817)
- validateEditing (page 845)

Related Sample Code
QTMetadataEditor

Declared In
`NSControl.h`

action

Returns the default action-message selector associated with the control.

```
- (SEL)action
```

Return Value
The selector associated with the receiver's cell.

Discussion
The `NSControl` implementation of this method returns the action message selector of the receiver's cell. Controls that support multiple cells (such as `NSMatrix` and `NSForm`) must override this method to return the appropriate action-message selector.

If you want the action-message selector for a control that has multiple cells, it is better to use the get the selector directly from the cell's own `action` method, as shown in the following example:

```
SEL someAction = [[theControl selectedCell] action];
```

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setAction:` (page 828)
- `setTarget:` (page 838)
- `target` (page 844)

Related Sample Code
SimpleToolbar

Declared In
`NSControl.h`

alignment

Returns the alignment mode of the text in the receiver's cell.

```
- (NSTextAlignment)alignment
```

Return Value
One of the following constants: `NSLeftTextAlignment`, `NSRightTextAlignment`,`NSCenterTextAlignment`, `NSJustifiedTextAlignment`, or `NSNaturalTextAlignment`. The default value is `NSNaturalTextAlignment`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setAlignment:` (page 828)

Declared In
`NSControl.h`

attributedStringValue

Returns the value of the receiver's cell as an attributed string.

```
- (NSAttributedString *)attributedStringValue
```

Return Value
The value of the cell interpreted as an attributed string, or an empty attributed string if the receiver has no cell.

Discussion
If the control contains many cells (for example, `NSMatrix`), then the value of the currently selected cell is returned. If the control is in the process of editing the affected cell, then it invokes the `validateEditing` (page 845) method before extracting and returning the value.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setAttributedStringValue:` (page 829)

Declared In
`NSControl.h`

baseWritingDirection

Returns the initial writing direction used to determine the actual writing direction for text.

```
- (NSWritingDirection)baseWritingDirection
```

Return Value
One of the following values: `NSWritingDirectionNatural`, `NSWritingDirectionLeftToRight`, or `NSWritingDirectionRightToLeft`. The default value is `NSWritingDirectionNatural`.

Discussion
The Text system uses this value as a hint for calculating the actual direction for displaying Unicode characters. You should not need to call this method directly.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `setBaseWritingDirection:` (page 829)

Declared In
`NSControl.h`

calcSize

Recomputes any internal sizing information for the receiver, if necessary.

```
- (void)calcSize
```

Discussion
This method uses the `calcDrawInfo:` (page 548) method of its cell to perform the calculations. Most controls maintain a flag that informs them if any of their cells have been modified in such a way that the location or size of the cell should be recomputed. If such a modification happens, this method is automatically invoked before the control is displayed. You should never need to invoke it yourself.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- sizeToFit` (page 839)

Declared In
`NSControl.h`

cell

Returns the receiver's cell object.

```
- (id)cell
```

Return Value
The cell object of the receiver.

Discussion
For controls with multiple cells (such as `NSMatrix` or `NSForm`), use the `selectedCell` (page 825) method or a similar method to retrieve a specific cell.

Availability
Available in Mac OS X v10.0 and later.

See Also
`+ cellClass` (page 812)
`+ setCellClass:` (page 813)
`- setCell:` (page 830)

Related Sample Code
ButtonMadness
ClockControl
DatePicker
FunHouse
Quartz Composer QCTV

Declared In
`NSControl.h`

currentEditor

Returns the current field editor for the control.

```
- (NSText *)currentEditor
```

Return Value
The field editor for the current control, or `nil` if the receiver does not have a field editor.

Discussion
When the receiver is a control displaying editable text (for example, a text field) and it is the first responder, it has a field editor, which is returned by this method. The field editor is a single `NSTextView` object that is shared among all the controls in a window for light text-editing needs. It is automatically instantiated when needed.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `abortEditing` (page 813)
- `validateEditing` (page 845)

Declared In
`NSControl.h`

doubleValue

Returns the value of the receiver's cell as a double-precision floating-point number.

```
- (double)doubleValue
```

Return Value
The value of the cell interpreted as a double-precision floating-point number.

Discussion
If the control contains many cells (for example, `NSMatrix`), then the value of the currently selected cell is returned. If the control is in the process of editing the affected cell, then it invokes the `validateEditing` (page 845) method before extracting and returning the value.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `floatValue` (page 819)
- `intValue` (page 821)
- `integerValue` (page 821)

CocoaSpeechSynthesisExample

FunHouse

Declared In
NSControl.h

drawCell:

Draws the specified cell, as long as it belongs to the receiver.

```
- (void)drawCell:(NSCell *)aCell
```

Parameters

aCell

The cell to draw. If the cell does not belong to the receiver, this method does nothing.

Discussion
This method is provided primarily to support a consistent set of methods between NSControl objects with single and multiple cells, because a control with multiple cells needs to be able to draw individual cells.

Availability
Available in Mac OS X v10.0 and later.

See Also
- selectCell: (page 825)
- updateCell: (page 844)
- updateCellInside: (page 845)

Declared In
NSControl.h

drawCellInside:

Draws the inside of the receiver's cell (the area within the bezel or border)

```
- (void)drawCellInside:(NSCell *)aCell
```

Parameters

aCell

The cell to draw. If the cell does not belong to the receiver, this method does nothing.

Discussion
If the receiver is transparent, the method causes the superview to draw itself. This method invokes the drawInteriorWithFrame:inView: (page 553) method of NSCell. This method has no effect on controls (such as NSMatrix and NSForm) that have multiple cells.

Availability
Available in Mac OS X v10.0 and later.

See Also
- selectCell: (page 825)
- updateCell: (page 844)
- updateCellInside: (page 845)

Declared In
NSControl.h

floatValue

Returns the value of the receiver's cell as a single-precision floating-point number.

```
- (float)floatValue
```

Return Value
The value of the cell interpreted as a single-precision floating-point number.

Discussion
If the control contains many cells (for example, NSMatrix), then the value of the currently selected cell is returned. If the control is in the process of editing the affected cell, then it invokes the validateEditing (page 845) method before extracting and returning the value.

Availability
Available in Mac OS X v10.0 and later.

See Also
- doubleValue (page 817)
- intValue (page 821)
- integerValue (page 821)
- objectValue (page 824)
- stringValue (page 840)
- setFloatValue: (page 832)

Declared In
NSControl.h

font

Returns the font used to draw text in the receiver's cell.

```
- (NSFont *)font
```

Return Value
The font object used for drawing text.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setFont:` (page 833)

Declared In
`NSControl.h`

formatter

Returns the receiver's formatter.

```
- (id)formatter
```

Return Value
The formatter object.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setFormatter:` (page 834)

Related Sample Code
TrackBall

Declared In
`NSControl.h`

ignoresMultiClick

Returns a Boolean value indicating whether the receiver ignores multiple clicks made in rapid succession.

```
- (BOOL)ignoresMultiClick
```

Return Value
`YES` if the receiver ignores multiple clicks; otherwise, `NO`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setIgnoresMultiClick:` (page 834)

Declared In
`NSControl.h`

initWithFrame:

Returns an NSControl object initialized with the specified frame rectangle.

```
- (id)initWithFrame:(NSRect)frameRect
```

Parameters

frameRect

The rectangle of the control, specified in points in the coordinate space of the enclosing view.

Return Value

An initialized control object, or `nil` if the object could not be initialized.

Discussion

If a cell has been specified for controls of this type, this method also creates an instance of the cell. Because `NSControl` is an abstract class, invocations of this method should appear only in the designated initializers of subclasses; that is, there should always be a more specific designated initializer for the subclass, as this method is the designated initializer for `NSControl`.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSControl.h`

integerValue

Returns the value of the receiver's cell as an `NSInteger` value.

```
- (NSInteger)integerValue
```

Return Value

The value of the cell interpreted as an `NSInteger` value.

Discussion

If the control contains many cells (for example, `NSMatrix`), then the value of the currently selected cell is returned. If the control is in the process of editing the affected cell, then it invokes the `validateEditing` (page 845) method before extracting and returning the value.

Availability

Available in Mac OS X v10.5 and later.

See Also

- `doubleValue` (page 817)
- `floatValue` (page 819)
- `intValue` (page 821)
- `objectValue` (page 824)
- `stringValue` (page 840)
- `setIntegerValue:` (page 834)

Declared In

`NSControl.h`

intValue

Returns the value of the receiver's cell as an integer.

```
- (int)intValue
```

Return Value
The value of the cell interpreted as an integer.

Discussion
If the control contains many cells (for example, `NSMatrix`), then the value of the currently selected cell is returned. If the control is in the process of editing the affected cell, then it invokes the `validateEditing` (page 845) method before extracting and returning the value.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `doubleValue` (page 817)
- `floatValue` (page 819)

Declared In
`NSControl.h`

isEnabled

Returns whether the receiver reacts to mouse events.

```
- (BOOL)isEnabled
```

Return Value
`YES` if the receiver responds to mouse events; otherwise, `NO`.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setEnabled:` (page 831)

Related Sample Code
EnhancedDataBurn
TrackBall

Declared In
`NSControl.h`

mouseDown:

Informs the receiver that the user has pressed the left mouse button.

```
- (void)mouseDown:(NSEvent *)theEvent
```

Parameters
theEvent
The event resulting from the user action.

Discussion
Invoked when the mouse button is pressed while the cursor is within the bounds of the receiver, generating *theEvent*. This method highlights the receiver's cell and sends it a `trackMouse:inRect:ofView:untilMouseUp:` (page 610) message. Whenever the cell finishes tracking the mouse (for example, because the cursor has left the cell's bounds), the cell is unhighlighted. If the mouse button is still down and the cursor reenters the bounds, the cell is again highlighted and a new `trackMouse:inRect:ofView:untilMouseUp:` (page 610) message is sent. This behavior repeats until the mouse button goes up. If it goes up with the cursor in the control, the state of the control is changed, and the action message is sent to the target. If the mouse button goes up when the cursor is outside the control, no action message is sent.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- ignoresMultiClick` (page 820)
`- trackMouse:inRect:ofView:untilMouseUp:` (page 610) (`NSCell`)

Declared In
`NSControl.h`

objectValue

Returns the value of the receiver's cell as an Objective-C object.

```
- (id)objectValue
```

Return Value
The value of the cell interpreted as an Objective-C object.

Discussion
If the control contains many cells (for example, `NSMatrix`), then the value of the currently selected cell is returned. If the control is in the process of editing the affected cell, then it invokes the `validateEditing` (page 845) method before extracting and returning the value.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `doubleValue` (page 817)

TrackBall

Declared In
`NSControl.h`

performClick:

Simulates a single mouse click on the receiver.

```
- (void)performClick:(id)sender
```

Parameters
sender
The object requesting the action. This parameter is ignored.

Discussion
This method calls the `performClick:` (page 573) method of the receiver's cell with the sender being the control itself. This method raises an exception if the action message cannot be successfully sent.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSControl.h`

refusesFirstResponder

Returns a Boolean value indicating whether the receiver refuses the first responder role.

```
- (BOOL)refusesFirstResponder
```

Return Value
`YES` if the receiver refuses the first responder role; otherwise, `NO`.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setRefusesFirstResponder:` (page 837)

Declared In
`NSControl.h`

selectCell:

Selects the specified cell and redraws the control as needed.

```
- (void)selectCell:(NSCell *)aCell
```

Parameters
aCell
The cell to select. The cell must belong to the receiver.

Discussion
If the cell is already selected (or does not belong to the receiver), this method does nothing. If the cell belongs to the receiver and is not selected, this method changes its state to `NSOnState` and redraws the cell.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- selectedCell` (page 825)

Declared In
`NSControl.h`

selectedCell

Returns the receiver's selected cell.

```
- (id)selectedCell
```

Return Value
The selected cell object.

Discussion
The default implementation of this method simply returns the control's associated cell (or `nil` if no cell has been set). Subclasses of `NSControl` that manage multiple cells (such as `NSMatrix` and `NSForm`) must override this method to return the cell selected by the user.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `cell` (page 816)
- `setCell:` (page 830)

Related Sample Code
Cropped Image

Declared In
`NSControl.h`

selectedTag

Returns the tag of the receiver's selected cell.

```
- (NSInteger)selectedTag
```

Return Value
The tag of the selected cell, or `-1` if no cell is selected.

Discussion
When you set the tag of a control with a single cell in Interface Builder, it sets the tags of both the control and the cell with the same value as a convenience.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setTag:` (page 838)
- `tag` (page 840)

Related Sample Code
CalendarItems
WhackedTV

Declared In
`NSControl.h`

sendAction:to:

Causes the specified action to be sent the target.

```
- (BOOL)sendAction:(SEL)theAction to:(id)theTarget
```

Parameters
theAction
The selector to invoke on the target. If the selector is `NULL`, no message is sent.

theTarget

The target object to receive the message. If the object is `nil`, the application searches the responder chain for an object capable of handling the message. For more information on dispatching actions, see the class description for `NSActionCell`.

Return Value
`YES` if the message was successfully sent; otherwise, `NO`.

Discussion
This method uses the `sendAction:to:from:` (page 166) method of `NSApplication` to invoke the specified method on an object. The receiver is passed as the parameter to the action message. This method is invoked primarily by the `trackMouse:inRect:ofView:untilMouseUp:` (page 610) method of `NSCell`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `action` (page 814)
- `target` (page 844)

Declared In
`NSControl.h`

sendActionOn:

Sets the conditions on which the receiver sends action messages to its target.

```
- (NSInteger)sendActionOn:(NSInteger)mask
```

Parameters

mask

A bit mask containing the conditions for sending the action. The only conditions that are actually checked are associated with the `NSLeftMouseDownMask`, `NSLeftMouseUpMask`, `NSLeftMouseDraggedMask`, and `NSPeriodicMask` bits.

Return Value
A bit mask containing the previous settings. This bit mask uses the same values as specified in the *mask* parameter.

Discussion
You use this method during mouse tracking when the mouse button changes state, the mouse moves, or if the cell is marked to send its action continuously while tracking. Because of this, the only bits checked in *mask* are `NSLeftMouseDownMask`, `NSLeftMouseUpMask`, `NSLeftMouseDraggedMask`, and `NSPeriodicMask`, which are declared in the `NSEvent` class reference.

The default implementation of this method simply invokes the `sendActionOn:` (page 576) method of its associated cell.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `sendAction:to:` (page 826)
- `sendActionOn:` (page 576) (`NSCell`)

Declared In
NSControl.h

setAction:

Sets the receiver's action method to the specified selector.

```
- (void)setAction:(SEL)aSelector
```

Parameters

aSelector

The new action-message selector to associate with the receiver's cell. Specify NULL to prevent action messages from being sent to the receiver's target.

Discussion
See *Action Messages* for additional information on action messages.

Availability
Available in Mac OS X v10.0 and later.

See Also
- action (page 814)
- setTarget: (page 838)
- target (page 844)

setAlignment:

Sets the alignment of text in the receiver's cell.

```
- (void)setAlignment:(NSTextAlignment)mode
```

Parameters

mode

One of the following constants: NSLeftTextAlignment, NSRightTextAlignment,NSCenterTextAlignment, NSJustifiedTextAlignment, or NSNaturalTextAlignment.

Discussion
If the cell is currently being edited, this method aborts the edits to change the alignment.

Availability
Available in Mac OS X v10.0 and later.

See Also
- alignment (page 814)

Related Sample Code
Quartz Composer QCTV

Declared In
NSControl.h

setAttributedStringValue:

Sets the value of the receiver's cell using an attributed string.

```
- (void)setAttributedStringValue:(NSAttributedString *)object
```

Parameters

object

The value of the cell interpreted as an attributed string.

Discussion
If the cell is being edited, this method aborts all editing before setting the value. If the cell does not inherit from NSActionCell, the method marks the cell's interior as needing to be redisplayed; NSActionCell performs its own updating of cells.

Availability
Available in Mac OS X v10.0 and later.

See Also
- attributedStringValue (page 815)

Declared In
NSControl.h

setBaseWritingDirection:

Sets the initial writing direction used to determine the actual writing direction for text .

```
- (void)setBaseWritingDirection:(NSWritingDirection)writingDirection
```

Parameters

writingDirection

One of the following values: NSWritingDirectionNatural, NSWritingDirectionLeftToRight, or NSWritingDirectionRightToLeft.

Discussion
If you know the base writing direction of the text you are rendering, you can use this method to specify that direction to the text system.

Availability
Available in Mac OS X v10.4 and later.

See Also
- baseWritingDirection (page 815)

Declared In
NSControl.h

setCell:

Sets the receiver's cell

```
- (void)setCell:(NSCell *)aCell
```

Parameters

aCell

The new cell for the receiver.

Discussion
Use this method with great care as it can irrevocably damage the affected control; specifically, you should only use this method in initializers for subclasses of `NSControl`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `cell` (page 816)
- `selectedCell` (page 825)

Declared In
NSControl.h

setContinuous:

Sets whether the receiver's cell sends its action message continuously to its target during mouse tracking.

```
- (void)setContinuous:(BOOL)flag
```

Parameters

flag

`YES` if the action message should be sent continuously; otherwise, `NO`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `isContinuous` (page 822)

Declared In

`NSControl.h`

setEnabled:

Sets whether the receiver (and its cell) reacts to mouse events.

```
- (void)setEnabled:(BOOL)flag
```

Parameters

flag

`YES` if you want the receiver to react to mouse events; otherwise, `NO`.

Discussion

If *flag* is `NO`, any editing is aborted. This method redraws the entire control if it is marked as needing redisplay. Subclasses may want to override this method to redraw only a portion of the control when the enabled state changes; `NSButton` and `NSSlider` do this.

Availability

Available in Mac OS X v10.0 and later.

See Also
- `isEnabled` (page 823)

Declared In
`NSControl.h`

setFloatingPointFormat:left:right:

Sets the auto-ranging and floating point number format of the receiver's cell. (Deprecated in Mac OS X v10.0.)

```
- (void)setFloatingPointFormat:(BOOL)autoRange left:(NSUInteger)leftDigits
    right:(NSUInteger)rightDigits
```

Parameters

autoRange
`YES` to enable auto-ranging; otherwise, `NO`.

leftDigits
The number of digits to display to the left of the decimal point.

rightDigits
The number of digits to display to the right of the decimal point.

Discussion
For more information about auto-ranging and how it works, see the description of this method in the `NSCell` class specification. If the cell is being edited, the current edits are discarded and the cell's interior is redrawn.

Note: This method is being deprecated in favor of a new class of formatter objects. For more information, see `NSFormatter`. This documentation is provided only for developers who need to modify older applications.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.0.

See Also
- `setFloatingPointFormat:left:right:` (page 586) (`NSCell`)

Declared In
`NSControl.h`

setFloatValue:

Sets the value of the receiver's cell using a single-precision floating-point number.

```
- (void)setFloatValue:(float)aFloat
```

Parameters

aFloat

The value of the cell interpreted as a single-precision floating-point number.

Discussion

If the cell is being edited, this method aborts all editing before setting the value. If the cell does not inherit from `NSActionCell`, the method marks the cell's interior as needing to be redisplayed; `NSActionCell` performs its own updating of cells.

Availability

Available in Mac OS X v10.0 and later.

Declared In
NSControl.h

setFormatter:

Sets the receiver's formatter

```
- (void)setFormatter:(NSFormatter *)newFormatter
```

Parameters

newFormatter
The new formatter object to use with the control.

Availability
Available in Mac OS X v10.0 and later.

See Also
- formatter (page 820)

Declared In
NSControl.h

setIgnoresMultiClick:

Sets whether the receiver ignores multiple clicks made in rapid succession.

```
- (void)setIgnoresMultiClick:(BOOL)flag
```

Parameters

flag
YES if the receiver should ignore multiple clicks; otherwise, NO.

Discussion
By default, controls treat double clicks as two distinct clicks, triple clicks as three distinct clicks, and so on. However, if you pass YES to this method, additional clicks (within a predetermined interval after the first) occurring after the first click are not processed by the receiver, and are instead passed on to super.

Availability
Available in Mac OS X v10.0 and later.

See Also
- ignoresMultiClick (page 820)

Declared In
NSControl.h

setIntegerValue:

Sets the value of the receiver's cell using an NSInteger value.

```
- (void)setIntegerValue:(NSInteger)anInteger
```

Parameters

anInteger

The value of the cell interpreted as an `NSInteger` value.

Discussion

If the cell is being edited, this method aborts all editing before setting the value. If the cell does not inherit from `NSActionCell`, the method marks the cell's interior as needing to be redisplayed; `NSActionCell` performs its own updating of cells.

Availability

Available in Mac OS X v10.5 and later.

setIntValue:

Sets the value of the receiver's cell using an integer.

```
- (void)setIntValue:(int)anInt
```

Parameters

anInt

The value of the cell interpreted as an integer.

Discussion

If the cell is being edited, this method aborts all editing before setting the value. If the cell does not inherit from `NSActionCell`, the method marks the cell's interior as needing to be redisplayed; `NSActionCell` performs its own updating of cells.

Availability

Available in Mac OS X v10.0 and later.

From A View to A Picture
ObjectPath

Declared In
NSControl.h

setNeedsDisplay

Marks the receiver as needing redisplay (assuming automatic display is enabled).

```
- (void)setNeedsDisplay
```

Discussion
This method also recalculates the dimensions of the control as needed.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setNeedsDisplay: (page 3225) (NSView)

Declared In
NSControl.h

setObjectValue:

Sets the value of the receiver's cell using an Objective-C object.

```
- (void)setObjectValue:(id < NSCopying >)object
```

Parameters
object
The value of the cell interpreted as an Objective-C object.

Discussion
If the cell is being edited, this method aborts all editing before setting the value. If the cell does not inherit from NSActionCell, the method marks the cell's interior as needing to be redisplayed; NSActionCell performs its own updating of cells.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSControl.h

setRefusesFirstResponder:

Sets whether the receiver refuses first responder role.

```
- (void)setRefusesFirstResponder:(BOOL)flag
```

Parameters

flag

YES if the receiver should refuse the first responder role; otherwise, NO.

Discussion
By default, the user can advance the focus of keyboard events between controls by pressing the Tab key; when this focus—or first responder status—is indicated for a control (by the insertion point or, for nontext controls, a faint rectangle), the user can activate the control by pressing the Space bar.

Availability
Available in Mac OS X v10.0 and later.

See Also
- refusesFirstResponder (page 825)
- objectValue (page 824)
- setDoubleValue: (page 831)
- setFloatValue: (page 832)

Declared In
NSControl.h

setStringValue:

Sets the value of the receiver's cell using an NSString object.

```
- (void)setStringValue:(NSString *)aString
```

Parameters

aString

The value of the cell interpreted as an NSString object.

Discussion
If the cell is being edited, this method aborts all editing before setting the value. If the cell does not inherit from NSActionCell, the method marks the cell's interior as needing to be redisplayed; NSActionCell performs its own updating of cells.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSControl.h`

setTag:

Sets the tag of the receiver.

```
- (void)setTag:(NSInteger)anInt
```

Parameters
anInt
The new tag.

Discussion
This method does not affect the tag of the receiver's cell. Tags allow you to identify particular cells. Tag values are not used internally; they are only changed by external invocations of `setTag:` (page 838). You typically set tag values in Interface Builder and use them at runtime in your application. When you set the tag of a control with a single cell in Interface Builder, it sets the tags of both the control and the cell to the same value as a convenience.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `tag` (page 840)
- `selectedTag` (page 826)

Related Sample Code
FunHouse
Quartz Composer QCTV

Declared In
`NSControl.h`

setTarget:

Sets the target object to receive action messages from the receiver's cell.

```
- (void)setTarget:(id)anObject
```

Parameters

anObject

The new target object to associate with the receiver's cell, or `nil` to remove the current target.

Discussion

If *anObject* is `nil` but the control still has a valid action message assigned, the application follows the responder chain looking for an object that can respond to the message. See the description of the `NSActionCell` class for details.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `action` (page 814)
- `setAction:` (page 828)

Declared In

`NSControl.h`

sizeToFit

Resizes the receiver's frame so that it is the minimum size needed to contain its cell.

```
- (void)sizeToFit
```

Discussion

If you want a multiple-cell custom subclass of `NSControl` to size itself to fit its cells, you must override this method. This method neither redisplays the receiver nor marks it as needing display. You must do this yourself with either the`display` (page 3163) or `setNeedsDisplay` (page 836) method.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `calcSize` (page 816)

Related Sample Code

Quartz Composer QCTV

Declared In

`NSControl.h`

stringValue

Returns the value of the receiver's cell as an `NSString` object.

```
- (NSString *)stringValue
```

Return Value
The value of the cell interpreted as an `NSString` object.

Discussion
If the control contains many cells (for example, `NSMatrix`), then the value of the currently selected cell is returned. If the control is in the process of editing the affected cell, then it invokes the `validateEditing` (page 845) method before extracting and returning the value.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSControl.h`

takeDoubleValueFrom:

Sets the value of the receiver's cell to a double-precision floating-point value obtained from the specified object.

```
- (void)takeDoubleValueFrom:(id)sender
```

Parameters

sender

The object from which to take the value. This object must respond to the `doubleValue` (page 817) message.

Discussion
You can use this method to link action messages between controls. It permits one control or cell (*sender*) to affect the value of another control (the receiver) by invoking this method in an action message to the receiver. For example, a text field can be made the target of a slider. Whenever the slider is moved, it sends this message to the text field. The text field then obtains the slider's value, turns it into a text string, and displays it.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSControl.h`

takeFloatValueFrom:

Sets the value of the receiver's cell to a single-precision floating-point value obtained from the specified object.

```
- (void)takeFloatValueFrom:(id)sender
```

Parameters

sender

The object from which to take the value. This object must respond to the `floatValue` (page 819) message.

Discussion
You can use this method to link action messages between controls. It permits one control or cell (*sender*) to affect the value of another control (the receiver) by invoking this method in an action message to the receiver. For example, a text field can be made the target of a slider. Whenever the slider is moved, it sends this message to the text field. The text field then obtains the slider's value, turns it into a text string, and displays it.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSControl.h

takeIntegerValueFrom:

Sets the value of the receiver's cell to an NSInteger value obtained from the specified object.

```
- (void)takeIntegerValueFrom:(id)sender
```

Parameters

sender

The object from which to take the value. This object must respond to the integerValue (page 821) message.

Discussion
You can use this method to link action messages between controls. It permits one control or cell (*sender*) to affect the value of another control (the receiver) by invoking this method in an action message to the receiver. For example, a text field can be made the target of a slider. Whenever the slider is moved, it sends this message to the text field. The text field then obtains the slider's value, turns it into a text string, and displays it.

Availability
Available in Mac OS X v10.5 and later.

Declared In
NSControl.h

takeIntValueFrom:

Sets the value of the receiver's cell to an integer value obtained from the specified object.

```
- (void)takeIntValueFrom:(id)sender
```

Parameters

sender

The object from which to take the value. This object must respond to the intValue (page 821) message.

Discussion
You can use this method to link action messages between controls. It permits one control or cell (*sender*) to affect the value of another control (the receiver) by invoking this method in an action message to the receiver. For example, a text field can be made the target of a slider. Whenever the slider is moved, it sends this message to the text field. The text field then obtains the slider's value, turns it into a text string, and displays it.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSControl.h

takeObjectValueFrom:

Sets the value of the receiver's cell to the object value obtained from the specified object.

```
- (void)takeObjectValueFrom:(id)sender
```

Parameters

sender

The object from which to take the value. This object must respond to the `objectValue` (page 824) message.

Discussion
You can use this method to link action messages between controls. It permits one control or cell (*sender*) to affect the value of another control (the receiver) by invoking this method in an action message to the receiver. For example, a text field can be made the target of a slider. Whenever the slider is moved, it sends this message to the text field. The text field then obtains the slider's value, turns it into a text string, and displays it.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSControl.h

takeStringValueFrom:

Sets the value of the receiver's cell to the string value obtained from the specified object.

```
- (void)takeStringValueFrom:(id)sender
```

Parameters

sender

The object from which to take the value. This object must respond to the `stringValue` (page 840) message.

Discussion
You can use this method to link action messages between controls. It permits one control or cell (*sender*) to affect the value of another control (the receiver) by invoking this method in an action message to the receiver. For example, a text field can be made the target of a slider. Whenever the slider is moved, it sends this message to the text field. The text field then obtains the slider's value, turns it into a text string, and displays it.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSControl.h

target

Returns the target object of the receiver's cell.

```
- (id)target
```

Return Value
The target object that receives action messages from the cell.

Availability
Available in Mac OS X v10.0 and later.

See Also
- action (page 814)
- setAction: (page 828)
- setTarget: (page 838)

Declared In
NSControl.h

updateCell:

Marks the specified cell as in need of redrawing.

```
- (void)updateCell:(NSCell *)aCell
```

Parameters
aCell
The cell to redraw.

Discussion
If the cell currently has the focus, this method updates the cell's focus ring; otherwise, the entire cell is marked as needing redisplay. The cell is redrawn during the next update cycle.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSControl.h

updateCellInside:

Marks the inside of the specified cell as in need of redrawing.

```
- (void)updateCellInside:(NSCell *)aCell
```

Parameters

aCell

The cell to redraw.

Availability
Available in Mac OS X v10.0 and later.

See Also
- updateCell: (page 844)

Declared In
NSControl.h

validateEditing

Validates changes to any user-typed text.

```
- (void)validateEditing
```

Discussion
Validation sets the object value of the cell to the current contents of the cell's editor (the NSText object used for editing), storing it as a simple NSString or an attributed string object based on the attributes of the editor.

Availability
Available in Mac OS X v10.0 and later.

See Also
- abortEditing (page 813)
- currentEditor (page 817)

Declared In
NSControl.h

Delegate Methods

controlTextDidBeginEditing:

Sent when a control with editable text begins an editing session.

```
- (void)controlTextDidBeginEditing:(NSNotification *)aNotification
```

Parameters

aNotification

The notification object. The name of the notification is always `NSControlTextDidBeginEditingNotification` (page 847).

Discussion

This method is invoked when the user begins editing text in a control such as a text field or a form field. The control posts a `NSControlTextDidBeginEditingNotification` (page 847) notification, and if the control's delegate implements this method, it is automatically registered to receive the notification. Use the key `@"NSFieldEditor"` to obtain the field editor from the `userInfo` dictionary of the notification object.

See `controlTextDidEndEditing:` (page 847) for an explanation of why you may not always get one invocation of `controlTextDidBeginEditing:` (page 846) for each invocation of `controlTextDidEndEditing:` (page 847).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSControl.h`

controlTextDidChange:

Sent when the text in the receiving control changes.

```
- (void)controlTextDidChange:(NSNotification *)aNotification
```

Parameters

aNotification

The notification object. The name of the notification is always `NSControlTextDidChangeNotification` (page 848).

Discussion

This method is invoked when text in a control such as a text field or form changes. The control posts a `NSControlTextDidChangeNotification` (page 848) notification, and if the control's delegate implements this method, it is automatically registered to receive the notification. Use the key `@"NSFieldEditor"` to obtain the field editor from the `userInfo` dictionary of the notification object.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSControl.h`

controlTextDidEndEditing:

Sent when a control with editable text ends an editing session.

```
- (void)controlTextDidEndEditing:(NSNotification *)aNotification
```

Parameters

aNotification

The notification object. The name of the notification is always `NSControlTextDidEndEditingNotification` (page 848).

Discussion

This method is invoked when the user stops editing text in a control such as a text field or form. The control posts a `NSControlTextDidEndEditingNotification` (page 848) notification, and if the control's delegate implements this method, it is automatically registered to receive the notification. Use the key `@"NSFieldEditor"` to obtain the field editor from the `userInfo` dictionary of the notification object.

Warning: In some cases, such as when editing within an instance of `NSOutlineView`, this method may be invoked without a previous invocation of `controlTextDidBeginEditing:` (page 846). You will only get the `controlTextDidBeginEditing:` notification if the user actually types something, but you can get the `controlTextDidEndEditing:` notification if the user just double-clicks the field and then clicks outside the field, without typing.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSControl.h`

Notifications

An `NSControl` object posts the following notifications to interested observers and its delegate. Note that although the `NSControl` class defines delegate methods, it does not itself have a delegate. Any subclass that uses these methods must have a delegate and the methods to get and set it.

NSControlTextDidBeginEditingNotification

Sent when a control with editable cells begins an edit session.

The field editor of the edited cell originally sends an `NSTextDidBeginEditingNotification` (page 2752) to the control, which passes it on in this form to its delegate. The notification object is the `NSControl` object posting the notification. The *userInfo* dictionary contains the following information:

Key	Value
`@"NSFieldEditor"`	The edited cell's field editor

See the `controlTextDidEndEditing:` (page 847) method for details.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSControl.h`

NSControlTextDidChangeNotification

Sent when the text in the receiving control changes.

The field editor of the edited cell originally sends an `NSTextDidChangeNotification` (page 2752) to the control, which passes it on in this form to its delegate. The notification object is the `NSControl` object posting the notification. The *`userInfo`* dictionary contains the following information:

Key	Value
`@"NSFieldEditor"`	The edited cell's field editor

See the `controlTextDidChange:` (page 846) method for details.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSControl.h`

NSControlTextDidEndEditingNotification

Sent when a control with editable cells ends an editing session.

The field editor of the edited cell originally sends an `NSControlTextDidEndEditingNotification` (page 848) to the control, which passes it on in this form to its delegate. The notification object is the `NSControl` object posting the notification. The *`userInfo`* dictionary contains the following information:

Key	Value
`@"NSFieldEditor"`	The edited cell's field editor

See the `controlTextDidEndEditing:` (page 847) method for details.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSControl.h`

NSController Class Reference

Inherits from	NSObject
Conforms to	NSCoding NSObject (NSObject)
Framework	/System/Library/Frameworks/AppKit.framework
Declared in	AppKit/NSController.h
Availability	Available in Mac OS X v10.3 and later.
Companion guide	Cocoa Bindings Programming Topics
Related sample code	CIRAWFilterSample

Overview

NSController is an abstract class that implements the NSEditor and NSEditorRegistration informal protocols required for controller classes.

Adopted Protocols

NSCoding
- `encodeWithCoder:`
- `initWithCoder:`

Tasks

Managing Editing

`- objectDidBeginEditing:` (page 852)
Invoked to inform the receiver that *`editor`* has uncommitted changes that can affect the receiver.

`- objectDidEndEditing:` (page 852)
Invoked to inform the receiver that *`editor`* has committed or discarded its changes.

- `commitEditing` (page 850)
  Causes the receiver to attempt to commit any pending edits, returning `YES` if successful or no edits were pending.
- `commitEditingWithDelegate:didCommitSelector:contextInfo:` (page 850)
  Attempts to commit any pending changes in known editors of the receiver.
- `discardEditing` (page 851)
  Discards any pending changes by registered editors.
- `isEditing` (page 852)
  Returns `YES` if there are any editors currently registered with the receiver, `NO` otherwise.

Instance Methods

commitEditing

Causes the receiver to attempt to commit any pending edits, returning `YES` if successful or no edits were pending.

```
- (BOOL)commitEditing
```

Discussion
The receiver invokes `commitEditing` (page 3678) on any current editors, returning their response. A commit is denied if the receiver fails to apply the changes to the model object, perhaps due to a validation error.

Availability
Available in Mac OS X v10.3 and later.

See Also
- `discardEditing` (page 851)

Declared In
`NSController.h`

commitEditingWithDelegate:didCommitSelector:contextInfo:

Attempts to commit any pending changes in known editors of the receiver.

```
-(void)commitEditingWithDelegate:(id)delegate
    didCommitSelector:(SEL)didCommitSelector contextInfo:(void *)contextInfo
```

Parameters

delegate
An object that can serve as the receiver's delegate. It should implement the method specified by *didCommitSelector*.

didCommitSelector
A selector that is invoked on delegate. The method specified by the selector must have the same signature as the following method:

```
- (void)editor:(id)editor didCommit:(BOOL)didCommit contextInfo:(void
*)contextInfo
```

contextInfo

Contextual information that is sent as the `contextInfo` argument to delegate when *didCommitSelector* is invoked.

Discussion
Provides support for the `NSEditor` informal protocol. This method attempts to commit pending changes in known editors. Known editors are either instances of a subclass of `NSController` or (more rarely) user interface controls that may contain pending edits—such as text fields—that registered with the context using `objectDidBeginEditing:` and have not yet unregistered using a subsequent invocation of `objectDidEndEditing:`.

The receiver iterates through the array of its known editors and invokes `commitEditing` on each. The receiver then sends the message specified by the *didCommitSelector* selector to the specified delegate.

The `didCommit` argument is the value returned by the editor specified by `editor` from the `commitEditing` message. The `contextInfo` argument is the same value specified as the *contextInfo* parameter—you may use this value however you wish.

If an error occurs while attempting to commit, for example if key-value coding validation fails, your implementation of this method should typically send the view in which editing is being performed a `presentError:modalForWindow:delegate:didRecoverSelector:contextInfo:` message, specifying the view's containing window.

You may find this method useful in some situations (typically if you are using Cocoa Bindings) when you want to ensure that pending changes are applied before a change in user interface state. For example, you may need to ensure that changes pending in a text field are applied before a window is closed. See also `commitEditing` (page 850) which performs a similar function but which allows you to handle any errors directly, although it provides no information beyond simple success/failure.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `commitEditing` (page 850)
- `discardEditing` (page 851)
- `objectDidBeginEditing:` (page 852)
- `objectDidEndEditing:` (page 852)

Declared In
`NSController.h`

discardEditing

Discards any pending changes by registered editors.

```
- (void)discardEditing
```

Discussion
The receiver invokes `discardEditing` (page 3679) on any current editors.

Availability
Available in Mac OS X v10.3 and later.

See Also
- `commitEditing` (page 850)

Declared In
`NSController.h`

isEditing

Returns `YES` if there are any editors currently registered with the receiver, `NO` otherwise.

```
- (BOOL)isEditing
```

Availability
Available in Mac OS X v10.3 and later.

Declared In
`NSController.h`

objectDidBeginEditing:

Invoked to inform the receiver that *editor* has uncommitted changes that can affect the receiver.

```
- (void)objectDidBeginEditing:(id)editor
```

Availability
Available in Mac OS X v10.3 and later.

See Also
- `objectDidEndEditing:` (page 852)

Declared In
`NSController.h`

objectDidEndEditing:

Invoked to inform the receiver that *editor* has committed or discarded its changes.

```
- (void)objectDidEndEditing:(id)editor
```

Availability
Available in Mac OS X v10.3 and later.

See Also
- `objectDidBeginEditing:` (page 852)

Declared In
`NSController.h`

NSCursor Class Reference

Inherits from	NSObject
Conforms to	NSCoding NSObject (NSObject)
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.0 and later.
Declared in	AppKit/NSCursor.h
Companion guide	Cursor Management
Related sample code	DragItemAround GLUT Sketch+Accessibility Sketch-112 TextLinks

Overview

Instances of the `NSCursor` class manage the appearance of the cursor.

The following table shows and describes the system cursors, and indicates the class method for obtaining them:

Cursor	Description
	The arrow cursor (`arrowCursor` (page 857))
	The I-beam cursor for indicating insertion points (`IBeamCursor` (page 860))
	The cross-hair cursor (`crosshairCursor` (page 858))
	The closed-hand cursor (`closedHandCursor` (page 857))

Cursor	Description
	The open-hand cursor (`openHandCursor` (page 861))
	The pointing-hand cursor (`pointingHandCursor` (page 862))
	The resize-left cursor (`resizeLeftCursor` (page 863))
	The resize-right cursor (`resizeRightCursor` (page 863))
	The resize-left-and-right cursor (`resizeLeftRightCursor` (page 863))
	The resize-up cursor (`resizeUpCursor` (page 864))
	The resize-down cursor (`resizeDownCursor` (page 862))
	The resize-up-and-down cursor (`resizeUpDownCursor` (page 864))
	The disappearing item cursor (`disappearingItemCursor` (page 859))

In Mac OS X version 10.3 and later, cursor size is no longer limited to 16 by 16 pixels.

Cursor Rectangles

In Cocoa, you can change the currently displayed cursor based on the position of the mouse over one of your views. You might use this technique to provide visual feedback about what actions the user can take with the mouse. For example, you might display one of the resize cursors whenever the mouse moves over a portion of your view that acts as a custom resizing handle. To set this up, you associate a cursor object with one or more cursor rectangles in the view.

Cursor rectangles are a specialized type of tracking rectangles, which are used to monitor the mouse location in a view. Views implement cursor rectangles using tracking rectangles but provide methods for setting and refreshing cursor rectangles that are distinct from the generic tracking rectangle interface. For information on how to set up cursor rectangles, see Mouse-Tracking and Cursor-Update Events.

Tasks

Initializing a New Cursor

- `initWithImage:hotSpot:` (page 867)
  Initializes a cursor with the given image and hot spot.
- `initWithImage:foregroundColorHint:backgroundColorHint:hotSpot:` (page 866)
  Initializes the cursor with the specified image and hot spot.

Setting Cursor Attributes

- `image` (page 866)
  Returns the receiver's image.
- `hotSpot` (page 865)
  Returns the position of the cursor's hot spot.
+ `hide` (page 860)
  Makes the current cursor invisible.
+ `unhide` (page 865)
  Negates an earlier call to `hide` (page 860) by showing the current cursor.
+ `setHiddenUntilMouseMoves:` (page 864)
  Sets whether the cursor is hidden until the mouse moves.

Controlling Which Cursor Is Current

+ `pop` (page 862)
  Pops the current cursor off the top of the stack.
- `pop` (page 869)
  Sends a `pop` (page 862) message to the receiver's class.
- `push` (page 870)
  Puts the receiver on top of the cursor stack and makes it the current cursor.
- `set` (page 870)
  Makes the receiver the current cursor.
- `mouseEntered:` (page 868)
  Automatically sent to the receiver when the cursor enters a cursor rectangle owned by the receiver.
- `setOnMouseEntered:` (page 871)
  Specifies whether the receiver accepts mouseEntered: (page 868) events.
- `isSetOnMouseEntered` (page 867)
  Returns a Boolean value indicating whether the receiver becomes current on receiving a `mouseEntered:` (page 868) message.
- `mouseExited:` (page 869)
  Automatically sent to the receiver when the cursor exits a cursor rectangle owned by the receiver.

- `setOnMouseExited:` (page 871)
  Sets whether the receiver accepts `mouseExited:` (page 869) events.
- `isSetOnMouseExited` (page 868)
  Returns a Boolean value indicating whether the receiver becomes current when it receives a `mouseExited:` (page 869) message.

Retrieving Cursor Instances

+ `currentCursor` (page 858)
  Returns the application's current cursor.
+ `currentSystemCursor` (page 859)
  Returns the current system cursor.
+ `arrowCursor` (page 857)
  Returns the default cursor, the arrow cursor.
+ `contextualMenuCursor` (page 858)
  Returns the contextual menu system cursor.
+ `closedHandCursor` (page 857)
  Returns the closed-hand system cursor.
+ `crosshairCursor` (page 858)
  Returns the cross-hair system cursor.
+ `disappearingItemCursor` (page 859)
  Returns a cursor indicating that the current operation will result in a disappearing item.
+ `dragCopyCursor` (page 859)
  Returns a cursor indicating that the current operation will result in a copy action.
+ `dragLinkCursor` (page 860)
  Returns a cursor indicating that the current operation will result in a link action.
+ `IBeamCursor` (page 860)
  Returns a cursor that looks like a capital I with a tiny crossbeam at its middle.
+ `openHandCursor` (page 861)
  Returns the open-hand system cursor.
+ `operationNotAllowedCursor` (page 861)
  Returns the operation not allowed cursor.
+ `pointingHandCursor` (page 862)
  Returns the pointing-hand system cursor.
+ `resizeDownCursor` (page 862)
  Returns the resize-down system cursor.
+ `resizeLeftCursor` (page 863)
  Returns the resize-left system cursor.
+ `resizeLeftRightCursor` (page 863)
  Returns the resize-left-and-right system cursor.
+ `resizeRightCursor` (page 863)
  Returns the resize-right system cursor.
+ `resizeUpCursor` (page 864)
  Returns the resize-up system cursor.

`+ resizeUpDownCursor` (page 864)
Returns the resize-up-and-down system cursor.

Class Methods

arrowCursor

Returns the default cursor, the arrow cursor.

```
+ (NSCursor *)arrowCursor
```

Return Value
The default cursor, a slanted arrow with its hot spot at the tip. The arrow cursor is the one you're used to seeing over buttons, scrollers, and many other objects in the window system.

Availability
Available in Mac OS X v10.0 and later.

See Also
`+ IBeamCursor` (page 860)
`+ currentCursor` (page 858)
`- hotSpot` (page 865)

Sketch-112
TextLinks

Declared In
`NSCursor.h`

closedHandCursor

Returns the closed-hand system cursor.

```
+ (NSCursor *)closedHandCursor
```

Return Value
The closed-hand cursor.

Availability
Available in Mac OS X v10.3 and later.

Related Sample Code
DragItemAround
GeekGameBoard

Declared In
NSCursor.h

contextualMenuCursor

Returns the contextual menu system cursor.

```
+ (NSCursor *)contextualMenuCursor
```

Return Value
The contextual menu cursor

Availability
Available in Mac OS X v10.6 and later.

Declared In
NSCursor.h

crosshairCursor

Returns the cross-hair system cursor.

```
+ (NSCursor *)crosshairCursor
```

Return Value
The cross-hair cursor. This cursor is used for situations when precise location is required (where the lines cross is the hot spot).

Availability
Available in Mac OS X v10.3 and later.

Related Sample Code
TrackIt

Declared In
NSCursor.h

currentCursor

Returns the application's current cursor.

```
+ (NSCursor *)currentCursor
```

Return Value
The top cursor on the application's cursor stack. This cursor may not be the visible cursor on the screen if a different application is currently active.

Discussion
The method only returns the cursor set by your application using `NSCursor` methods. It does return not cursors set by other applications or cursors set by your application using Carbon API.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `set` (page 870)
- `push` (page 870)
- `pop` (page 869)
- `mouseEntered:` (page 868)
- `mouseExited:` (page 869)

Declared In
`NSCursor.h`

currentSystemCursor

Returns the current system cursor.

```
+ (NSCursor *)currentSystemCursor
```

Return Value
A cursor whose image and hot spot match those of the currently-displayed cursor on the system

Discussion
This method returns the current system cursor regardless of which application set the cursor, and whether Cocoa or Carbon APIs were used to set it.

This method replaces the now deprecated `QDGetCursorData` function.

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSCursor.h`

disappearingItemCursor

Returns a cursor indicating that the current operation will result in a disappearing item.

```
+ (NSCursor *)disappearingItemCursor
```

Return Value
The system cursor that indicates that the current operation will result in a disappearing item (for example, when dragging an item from the dock or a toolbar).

Availability
Available in Mac OS X v10.3 and later.

Declared In
`NSCursor.h`

dragCopyCursor

Returns a cursor indicating that the current operation will result in a copy action.

```
+ (NSCursor *)dragCopyCursor
```

Return Value
The drag copy cursor.

Availability
Available in Mac OS X v10.6 and later.

Declared In
NSCursor.h

dragLinkCursor

Returns a cursor indicating that the current operation will result in a link action.

```
+ (NSCursor *)dragLinkCursor
```

Return Value
The drag link cursor.

Availability
Available in Mac OS X v10.6 and later.

Declared In
NSCursor.h

hide

Makes the current cursor invisible.

```
+ (void)hide
```

Discussion
If another cursor becomes current, that cursor will be invisible, too. It will remain invisible until you invoke the `unhide` (page 865) method.

`hide` (page 860) overrides `setHiddenUntilMouseMoves:` (page 864).

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
CoreAnimationKioskStyleMenu
iChatTheater
LightTable

Declared In
NSCursor.h

IBeamCursor

Returns a cursor that looks like a capital I with a tiny crossbeam at its middle.

```
+ (NSCursor *)IBeamCursor
```

Return Value
The I-beam cursor. This is the cursor that you're used to seeing over editable or selectable text. The I-beam cursor's default hot spot is where the crossbeam intersects the I.

Availability
Available in Mac OS X v10.0 and later.

See Also
`+ arrowCursor` (page 857)

Related Sample Code
GLUT

Declared In
`NSCursor.h`

openHandCursor

Returns the open-hand system cursor.

```
+ (NSCursor *)openHandCursor
```

Return Value
The open-hand cursor.

Availability
Available in Mac OS X v10.3 and later.

Related Sample Code
DragItemAround
GeekGameBoard

Declared In
`NSCursor.h`

operationNotAllowedCursor

Returns the operation not allowed cursor.

```
+ (NSCursor *)operationNotAllowedCursor
```

Return Value
The operation not allowed cursor.

Discussion
This cursor indicates that the operation that is being attempted, perhaps dragging to an item that can't accept the drag type, is being denied.

Availability
Available in Mac OS X v10.6 and later.

Declared In
NSCursor.h

pointingHandCursor

Returns the pointing-hand system cursor.

```
+ (NSCursor *)pointingHandCursor
```

Return Value
The pointing-hand cursor. The tip of the pointing finger is the hot spot.

Availability
Available in Mac OS X v10.3 and later.

Related Sample Code
CocoaDVDPlayer

Declared In
NSCursor.h

pop

Pops the current cursor off the top of the stack.

```
+ (void)pop
```

Discussion
The new object on the top of the stack becomes the current cursor. If the current cursor is the only cursor on the stack, this method does nothing.

Availability
Available in Mac OS X v10.0 and later.

See Also
- push (page 870)

DragItemAround
GeekGameBoard

Declared In
NSCursor.h

resizeDownCursor

Returns the resize-down system cursor.

```
+ (NSCursor *)resizeDownCursor
```

Return Value
The resize-down cursor. This cursor is used when moving or resizing an object to indicate that the user can move only in the indicated direction.

Availability
Available in Mac OS X v10.3 and later.

Declared In
NSCursor.h

resizeLeftCursor

Returns the resize-left system cursor.

```
+ (NSCursor *)resizeLeftCursor
```

Return Value
The resize-left cursor. This cursor is used when moving or resizing an object to indicate that the user can move only in the indicated direction.

Availability
Available in Mac OS X v10.3 and later.

Declared In
NSCursor.h

resizeLeftRightCursor

Returns the resize-left-and-right system cursor.

```
+ (NSCursor *)resizeLeftRightCursor
```

Return Value
The resize-left-and-right cursor. This cursor is used when moving or resizing an object and the object can be moved left or right.

Availability
Available in Mac OS X v10.3 and later.

Declared In
NSCursor.h

resizeRightCursor

Returns the resize-right system cursor.

```
+ (NSCursor *)resizeRightCursor
```

Return Value
The resize-right cursor. This cursor is used when moving or resizing an object to indicate that the user can move only in the indicated direction.

Availability
Available in Mac OS X v10.3 and later.

Declared In
NSCursor.h

resizeUpCursor

Returns the resize-up system cursor.

```
+ (NSCursor *)resizeUpCursor
```

Return Value
The resize-up cursor. This cursor is used when moving or resizing an object to indicate that the user can move only in the indicated direction.

Availability
Available in Mac OS X v10.3 and later.

Declared In
NSCursor.h

resizeUpDownCursor

Returns the resize-up-and-down system cursor.

```
+ (NSCursor *)resizeUpDownCursor
```

Return Value
The resize-up-and-down cursor. This cursor is used when moving or resizing an object and the object can be moved up or down.

Availability
Available in Mac OS X v10.3 and later.

Declared In
NSCursor.h

setHiddenUntilMouseMoves:

Sets whether the cursor is hidden until the mouse moves.

```
+ (void)setHiddenUntilMouseMoves:(BOOL)flag
```

Parameters
flag

YES to hide the cursor until one of the following occurs:

- The mouse moves.
- You invoke the method again, with *flag* set to NO.

Discussion
Do not try to counter this method by invoking `unhide` (page 865). The results are undefined.

Availability
Available in Mac OS X v10.0 and later.

See Also
`+ hide` (page 860)

Related Sample Code
LightTable
PhotoSearch

Declared In
`NSCursor.h`

unhide

Negates an earlier call to `hide` (page 860) by showing the current cursor.

```
+ (void)unhide
```

Availability
Available in Mac OS X v10.0 and later.

See Also
`+ setHiddenUntilMouseMoves:` (page 864)
`+ hide` (page 860)

Related Sample Code
iChatTheater
LightTable

Declared In
`NSCursor.h`

Instance Methods

hotSpot

Returns the position of the cursor's hot spot.

```
- (NSPoint)hotSpot
```

Return Value
The point describing the position of the hot spot, specified according to the cursor's flipped coordinate system.

Discussion
For a more complete explanation, see the class description.

Note that an `NSCursor` object is immutable: you cannot change its hot spot after it's created. Instead, use `initWithImage:hotSpot:` (page 867) to create a new cursor with the new settings.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- initWithImage:hotSpot:` (page 867)

Declared In
`NSCursor.h`

image

Returns the receiver's image.

```
- (NSImage *)image
```

Return Value
The cursor image or `nil` if none exists

Discussion
Note that an `NSCursor` object is immutable: you cannot change its image after it's created. Instead, use `initWithImage:hotSpot:` (page 867) to create a new cursor with the new settings.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- initWithImage:hotSpot:` (page 867)

Declared In
`NSCursor.h`

initWithImage:foregroundColorHint:backgroundColorHint:hotSpot:

Initializes the cursor with the specified image and hot spot.

```
- (id)initWithImage:(NSImage *)newImage foregroundColorHint:(NSColor *)fg
    backgroundColorHint:(NSColor *)bg hotSpot:(NSPoint)hotSpot
```

Parameters

newImage
The image to assign to the cursor.

fg
The foreground color. This is currently ignored.

bg
The background color. This is currently ignored.

hotSpot
The point to assign as the cursor's hot spot.

Return Value
The initialized cursor object.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `initWithImage:hotSpot:` (page 867)

Declared In
`NSCursor.h`

initWithImage:hotSpot:

Initializes a cursor with the given image and hot spot.

```
- (id)initWithImage:(NSImage *)newImage hotSpot:(NSPoint)aPoint
```

Parameters

newImage
The image to assign to the cursor.

aPoint
The point to set as the cursor's hot spot.

Return Value
An initialized cursor object.

Discussion
This method is the designated initializer for the class.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `hotSpot` (page 865)

Declared In
`NSCursor.h`

isSetOnMouseEntered

Returns a Boolean value indicating whether the receiver becomes current on receiving a `mouseEntered:` (page 868) message.

```
- (BOOL)isSetOnMouseEntered
```

Return Value
`YES` if the receiver will become current when it receives a `mouseEntered:` (page 868) message; otherwise, `NO`.

Discussion
To receive such a message, the receiver must first be assigned a cursor rectangle. This assignment can be made using the `NSView` method `addCursorRect:cursor:` (page 3139). For a more complete explanation, see the class description.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setOnMouseEntered:` (page 871)
- `isSetOnMouseExited` (page 868)

Declared In
`NSCursor.h`

isSetOnMouseExited

Returns a Boolean value indicating whether the receiver becomes current when it receives a `mouseExited:` (page 869) message.

```
- (BOOL)isSetOnMouseExited
```

Return Value
`YES` if the receiver becomes current when it receives a `mouseExited:` (page 869) message; otherwise, `NO`.

Discussion
To receive such a message, the receiver must first be assigned a cursor rectangle. This assignment can be made using the `NSView` method `addCursorRect:cursor:` (page 3139). For a more complete explanation, see the class description.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setOnMouseExited:` (page 871)

Declared In
`NSCursor.h`

mouseEntered:

Automatically sent to the receiver when the cursor enters a cursor rectangle owned by the receiver.

```
- (void)mouseEntered:(NSEvent *)anEvent
```

Parameters

anEvent

The event generated when the cursor enters the cursor rectangle.

Discussion

If used after `setOnMouseEntered:` (page 871) has been called with an argument of `YES`, `mouseEntered:` can make the receiver the current cursor.

In your programs, you won't invoke `mouseEntered:` explicitly. It's only included in the class interface so you can override it.

For a more complete explanation, see Mouse-Tracking and Cursor-Update Events and the `NSView` method `addTrackingRect:owner:userData:assumeInside:` (page 3142).

Availability

Available in Mac OS X v10.0 and later.

See Also

- `isSetOnMouseEntered` (page 867)
- `mouseExited:` (page 869)

Declared In

`NSCursor.h`

mouseExited:

Automatically sent to the receiver when the cursor exits a cursor rectangle owned by the receiver.

```
- (void)mouseExited:(NSEvent *)anEvent
```

Parameters

anEvent

The event generated when the cursor exits the cursor rectangle.

Discussion

Like `mouseEntered:` (page 868), this message is part of the class interface only so you can override it.

For a more complete explanation, see Mouse-Tracking and Cursor-Update Events and the NSView method `addTrackingRect:owner:userData:assumeInside:` (page 3142).

Availability

Available in Mac OS X v10.0 and later.

See Also

- `setOnMouseExited:` (page 871)
- `isSetOnMouseExited` (page 868)

Declared In

`NSCursor.h`

pop

Sends a `pop` (page 862) message to the receiver's class.

```
- (void)pop
```

Availability
Available in Mac OS X v10.0 and later.

See Also
- push (page 870)
- pop (page 869)

Declared In
NSCursor.h

push

Puts the receiver on top of the cursor stack and makes it the current cursor.

```
- (void)push
```

Availability
Available in Mac OS X v10.0 and later.

See Also
- pop (page 869)
- pop (page 869)

Related Sample Code
DragItemAround
GeekGameBoard

Declared In
NSCursor.h

set

Makes the receiver the current cursor.

```
- (void)set
```

Availability
Available in Mac OS X v10.0 and later.

See Also
+ currentCursor (page 858)

Related Sample Code
CocoaDVDPlayer
PDFKitLinker2
TrackIt

Declared In
NSCursor.h

setOnMouseEntered:

Specifies whether the receiver accepts mouseEntered: (page 868) events.

```
- (void)setOnMouseEntered:(BOOL)flag
```

Parameters

flag

YES if the receiver accepts future mouseEntered: (page 868) event messages; otherwise it ignores them.

Discussion

Accepting mouseEntered: (page 868) event messages allows the cursor to be made the current cursor when the cursor enters a view's cursor rectangle.

Availability

Available in Mac OS X v10.0 and later.

See Also

- mouseEntered: (page 868)

Declared In

NSCursor.h

setOnMouseExited:

Sets whether the receiver accepts mouseExited: (page 869) events.

```
- (void)setOnMouseExited:(BOOL)flag
```

Parameters

flag

YES if the receiver accepts future mouseExited: (page 869) event messages; otherwise it ignores them.

Discussion

Accepting mouseExited: (page 869) event messages allows the cursor to be made the current cursor when the cursor exits a view's cursor rectangle.

Availability

Available in Mac OS X v10.0 and later.

Declared In

NSCursor.h

Constants

AppKit Versions for NSCursor Bug Fixes

The version of the AppKit framework containing a specific bug fix.

```
#define NSAppKitVersionNumberWithCursorSizeSupport 682.0
```

Constants

`NSAppKitVersionNumberWithCursorSizeSupport`

The specific version of the AppKit framework that introduced support for cursors larger than 16 x 16 pixels in size. Developers should not need to use this constant unless they are writing applications for Mac OS X v10.2 and earlier.

Available in Mac OS X v10.3 and later.

Declared in `NSCursor.h`.

NSCustomImageRep Class Reference

Inherits from	NSImageRep : NSObject
Conforms to	NSCoding (NSImageRep) NSCopying (NSImageRep) NSObject (NSObject)
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.0 and later.
Declared in	AppKit/NSCustomImageRep.h
Companion guide	Cocoa Drawing Guide
Related sample code	CompositeLab

Overview

An `NSCustomImageRep` object uses a delegate object to render an image. When called upon to produce an image, it sends a message to its delegate to do the actual drawing. You can use this class to support custom image formats without going to the trouble of subclassing `NSImageRep` directly.

Tasks

Initializing a New NSCustomImageRep

`- initWithDrawSelector:delegate:` (page 874)
Returns an `NSCustomImageRep` object initialized with the specified delegate information.

Identifying the Object

`- delegate` (page 874)
Returns the delegate object that renders the image for the receiver.

`- drawSelector` (page 874)
Returns the selector for the delegate's drawing method.

Instance Methods

delegate

Returns the delegate object that renders the image for the receiver.

```
- (id)delegate
```

Return Value
The delegate object.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSCustomImageRep.h`

drawSelector

Returns the selector for the delegate's drawing method.

```
- (SEL)drawSelector
```

Return Value
The selector for the delegate's drawing method.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSCustomImageRep.h`

initWithDrawSelector:delegate:

Returns an `NSCustomImageRep` object initialized with the specified delegate information.

```
- (id)initWithDrawSelector:(SEL)aMethod delegate:(id)anObject
```

Parameters

aMethod

The selector to call when it is time to draw the image. The method should take a single parameter of type `id` that represents the `NSCustomImageRep` object that initiated drawing. The method must draw the image starting at the point (0, 0) in the current coordinate system.

anObject

The delegate object that responds to the selector in *aMethod*.

Return Value
An initialized `NSCustomImageRep` object, or `nil` if the object could not be initialized.

Discussion
When the receiver is asked to draw the image, it sends the specified message to the selector, passing itself as a parameter to the delegate method. The delegate's drawing method should have the following form:

```
- (void)myCustomDrawMethod:(id)anNSCustomImageRep;
```

Availability
Available in Mac OS X v10.0 and later.

See Also
- `draw` (page 1415) (NSImageRep)

CompositeLab

Declared In
`NSCustomImageRep.h`

NSDatePicker Class Reference

Inherits from	NSControl : NSView : NSResponder : NSObject
Conforms to	NSAnimatablePropertyContainer (NSView) NSCoding (NSResponder) NSObject (NSObject)
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.4 and later.
Declared in	AppKit/NSDatePicker.h
Related sample code	DatePicker Mountains ScriptingBridgeiCal

Overview

`NSDatePicker` is a subclass of `NSControl` that provides a user interface for displaying and editing an `NSDate` object.

`NSDatePicker` uses an `NSDatePickerCell` to implement much of the control's functionality. `NSDatePicker` provides cover methods for most of `NSDatePickerCell` methods, which invoke the corresponding cell method.

Tasks

Configuring Date Pickers

`- isBezeled` (page 882)
Returns whether the receiver has a bezeled border.

`- setBezeled:` (page 884)
Specifies whether the receiver draws a bezeled border.

`- isBordered` (page 883)
Returns whether the receiver has a plain border.

`- setBordered:` (page 885)
Specifies whether the receiver draws a plain border.

- `backgroundColor` (page 879)
  Returns the background color of the receiver.
- `setBackgroundColor:` (page 884)
  Sets the receiver's background color.
- `drawsBackground` (page 882)
  Returns whether the receiver draws the background.
- `setDrawsBackground:` (page 888)
  Specifies whether the receiver draws the background.
- `textColor` (page 891)
  Returns the text color of the receiver.
- `setTextColor:` (page 889)
  Sets the text color of the receiver.
- `datePickerStyle` (page 881)
  Returns the receiver's date picker style.
- `setDatePickerStyle:` (page 886)
  Sets the receiver's date picker style.
- `delegate` (page 881)
  Returns the delegate of the receiver's date picker cell.
- `setDelegate:` (page 887)
  Sets the delegate of the receiver's date picker cell.
- `datePickerElements` (page 880)
  Returns a bitmask that indicates which visual elements of the date picker are currently shown, and which won't be usable because they are hidden.
- `setDatePickerElements:` (page 886)
  Sets a bitmask that indicates which visual elements of the date picker are currently shown, and which won't be usable because they are hidden.

Controlling Date Picker Range and Mode

- `calendar` (page 880)
  Returns the calendar used by the receiver.
- `setCalendar:` (page 885)
  Sets the receiver's calendar.
- `locale` (page 883)
  Returns the receiver's locale.
- `setLocale:` (page 888)
  Sets the receiver's locale.
- `datePickerMode` (page 880)
  Returns the receiver's date picker mode.
- `setDatePickerMode:` (page 886)
  Sets the receiver's date picker mode.
- `timeZone` (page 891)
  Returns the receiver's time zone.

- `setTimeZone:` (page 890)
  Sets the receiver's time zone.

Accessing Object Values

- `dateValue` (page 881)
  Returns the receiver's date.
- `setDateValue:` (page 887)
  Sets the receiver's date to a new starting value.
- `timeInterval` (page 891)
  Returns the time interval that represents the date range.
- `setTimeInterval:` (page 890)
  Sets the time interval of the date range.

Constraining the Displayable/Selectable Range

- `minDate` (page 884)
  Returns the minimum date value the receiver allows as input.
- `setMinDate:` (page 889)
  Sets the minimum date allowed as input by the receiver.
- `maxDate` (page 883)
  Returns the maximum date value the receiver allows as input.
- `setMaxDate:` (page 889)
  Sets the maximum date allowed as input by the receiver.

Instance Methods

backgroundColor

Returns the background color of the receiver.

```
- (NSColor *)backgroundColor
```

Return Value
The background color of the receiver.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `setBackgroundColor:` (page 884)

Declared In
`NSDatePicker.h`

calendar

Returns the calendar used by the receiver.

```
- (NSCalendar *)calendar
```

Return Value
The calendar used by the receiver.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- setCalendar:` (page 885)

Declared In
`NSDatePicker.h`

datePickerElements

Returns a bitmask that indicates which visual elements of the date picker are currently shown, and which won't be usable because they are hidden.

```
- (NSDatePickerElementFlags)datePickerElements
```

Return Value
A bitmask that specifies the date picker elements displayed by the receiver. See “Constants” in `NSDatePickerCell` for a description of the possible values.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- setDatePickerElements:` (page 886)

Related Sample Code
DatePicker

Declared In
`NSDatePicker.h`

datePickerMode

Returns the receiver’s date picker mode.

```
- (NSDatePickerMode)datePickerMode
```

Return Value
The receiver’s date picker mode.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `setDatePickerMode:` (page 886)

Declared In
`NSDatePicker.h`

datePickerStyle

Returns the receiver's date picker style.

```
- (NSDatePickerStyle)datePickerStyle
```

Return Value
The receiver's date picker style.

Declared In
`NSDatePicker.h`

delegate

Returns the delegate of the receiver's date picker cell.

```
- (id)delegate
```

Return Value
The delegate of the receiver's date picker cell.

Discussion
The date picker's `NSDatePickerCell` instance handles all delegate methods.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- setDelegate:` (page 887)

Declared In
`NSDatePicker.h`

drawsBackground

Returns whether the receiver draws the background.

```
- (BOOL)drawsBackground
```

Return Value
`TRUE` if the receiver draws the background, `FALSE` otherwise.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- setDrawsBackground:` (page 888)

Declared In
`NSDatePicker.h`

isBezeled

Returns whether the receiver has a bezeled border.

```
- (BOOL)isBezeled
```

Return Value
`TRUE` if the receiver has a bezeled border, `FALSE` otherwise.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- setBezeled:` (page 884)

Declared In
`NSDatePicker.h`

isBordered

Returns whether the receiver has a plain border.

```
- (BOOL)isBordered
```

Return Value
`TRUE` if the receiver has a plain border, `FALSE` otherwise.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- setBordered:` (page 885)

Declared In
`NSDatePicker.h`

locale

Returns the receiver's locale.

```
- (NSLocale *)locale
```

Return Value
The receiver's locale.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- setLocale:` (page 888)

Declared In
`NSDatePicker.h`

maxDate

Returns the maximum date value the receiver allows as input.

```
- (NSDate *)maxDate
```

Return Value
The maximum date value the receiver allows as input. `nil` indicates no maximum date.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- setMaxDate:` (page 889)

Declared In
`NSDatePicker.h`

minDate

Returns the minimum date value the receiver allows as input.

```
- (NSDate *)minDate
```

Return Value
The minimum date value the receiver allows as input. `nil` indicates no minimum date.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- setMinDate:` (page 889)

Declared In
`NSDatePicker.h`

setBackgroundColor:

Sets the receiver's background color.

```
- (void)setBackgroundColor:(NSColor *)color
```

Parameters
color
The new background color.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- backgroundColor` (page 879)

Related Sample Code
DatePicker

Declared In
`NSDatePicker.h`

setBezeled:

Specifies whether the receiver draws a bezeled border.

```
- (void)setBezeled:(BOOL)flag
```

Parameters
flag
`TRUE` if the receiver has a bezeled border, `FALSE` otherwise.

Availability
Available in Mac OS X v10.4 and later.

See Also
- isBezeled (page 882)

Related Sample Code
DatePicker

Declared In
NSDatePicker.h

setBordered:

Specifies whether the receiver draws a plain border.

```
- (void)setBordered:(BOOL)flag
```

Parameters

flag

TRUE if the receiver has a plain border, FALSE otherwise.

Availability
Available in Mac OS X v10.4 and later.

See Also
- isBordered (page 883)

Related Sample Code
DatePicker

Declared In
NSDatePicker.h

setCalendar:

Sets the receiver's calendar.

```
- (void)setCalendar:(NSCalendar *)newCalendar
```

Parameters

newCalendar

The new calendar.

Availability
Available in Mac OS X v10.4 and later.

See Also
- calendar (page 880)

Declared In
NSDatePicker.h

setDatePickerElements:

Sets a bitmask that indicates which visual elements of the date picker are currently shown, and which won't be usable because they are hidden.

```
- (void)setDatePickerElements:(NSDatePickerElementFlags)elementFlags
```

Parameters

elementFlags

A bitmask that specifies the date picker elements displayed by the receiver. See "Constants" in `NSDatePickerCell` for a description of the possible values.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- datePickerElements` (page 880)

Related Sample Code
DatePicker

Declared In
`NSDatePicker.h`

setDatePickerMode:

Sets the receiver's date picker mode.

```
- (void)setDatePickerMode:(NSDatePickerMode)newMode
```

Parameters

newMode

The new date picker mode.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- datePickerMode` (page 880)

Related Sample Code
DatePicker

Declared In
`NSDatePicker.h`

setDatePickerStyle:

Sets the receiver's date picker style.

```
- (void)setDatePickerStyle:(NSDatePickerStyle)newStyle
```

Parameters

newStyle

The new date picker style.

Availability

Available in Mac OS X v10.4 and later.

See Also

- datePickerStyle (page 881)

Related Sample Code

DatePicker

Declared In

NSDatePicker.h

setDateValue:

Sets the receiver's date to a new starting value.

```
- (void)setDateValue:(NSDate *)newStartDate
```

Parameters

newStartDate

The new starting date.

Availability

Available in Mac OS X v10.4 and later.

See Also

- dateValue (page 881)

Related Sample Code

DatePicker

Declared In

NSDatePicker.h

setDelegate:

Sets the delegate of the receiver's date picker cell.

```
- (void)setDelegate:(id)anObject
```

Parameters

anObject

The new delegate.

Discussion

The date picker's NSDatePickerCell instance handles all delegate methods.

Availability

Available in Mac OS X v10.4 and later.

See Also
- delegate (page 881)

Related Sample Code
DatePicker

Declared In
NSDatePicker.h

setDrawsBackground:

Specifies whether the receiver draws the background.

```
- (void)setDrawsBackground:(BOOL)flag
```

Parameters

flag

TRUE if the receiver draws the background, FALSE otherwise.

Availability
Available in Mac OS X v10.4 and later.

See Also
- drawsBackground (page 882)

Related Sample Code
DatePicker

Declared In
NSDatePicker.h

setLocale:

Sets the receiver's locale.

```
- (void)setLocale:(NSLocale *)newLocale
```

Parameters

newLocale

The new locale.

Availability
Available in Mac OS X v10.4 and later.

See Also
- locale (page 883)

Declared In
NSDatePicker.h

setMaxDate:

Sets the maximum date allowed as input by the receiver.

```
- (void)setMaxDate:(NSDate *)date
```

Parameters

date

The maximum date allowed as input by the receiver. `nil` indicates no maximum date.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- maxDate` (page 883)

Related Sample Code
DatePicker

Declared In
`NSDatePicker.h`

setMinDate:

Sets the minimum date allowed as input by the receiver.

```
- (void)setMinDate:(NSDate *)date
```

Parameters

date

The minimum date allowed as input by the receiver. `nil` indicates no minimum date.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- minDate` (page 884)

Related Sample Code
DatePicker

Declared In
`NSDatePicker.h`

setTextColor:

Sets the text color of the receiver.

```
- (void)setTextColor:(NSColor *)color
```

Parameters

color

The new text color.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `textColor` (page 891)

Related Sample Code
DatePicker

Declared In
`NSDatePicker.h`

setTimeInterval:

Sets the time interval of the date range.

```
- (void)setTimeInterval:(NSTimeInterval)newTimeInterval
```

Parameters

newTimeInterval
The new time interval.

Discussion
The time interval only applies when the receiver is in the `NSRangeDateMode` mode.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `timeInterval` (page 891)

Declared In
`NSDatePicker.h`

setTimeZone:

Sets the receiver's time zone.

```
- (void)setTimeZone:(NSTimeZone *)newTimeZone
```

Parameters

newTimeZone
The new time zone.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `timeZone` (page 891)

Declared In
`NSDatePicker.h`

textColor

Returns the text color of the receiver.

```
- (NSColor *)textColor
```

Return Value
The text color of the receiver.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `setTextColor:` (page 889)

Declared In
`NSDatePicker.h`

timeInterval

Returns the time interval that represents the date range.

```
- (NSTimeInterval)timeInterval
```

Return Value
The time interval that represents the receiver's date range. The date range begins at the date returned by `dateValue` (page 881). This method returns 0 when the receiver is not in the `NSRangeDateMode` mode.

Special Considerations

Prior to Mac OS X v 10.5, this method always returned 0.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `setTimeInterval:` (page 890)

Declared In
`NSDatePicker.h`

timeZone

Returns the receiver's time zone.

```
- (NSTimeZone *)timeZone
```

Return Value
The receiver's time zone.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `setTimeZone:` (page 890)

Declared In
`NSDatePicker.h`

NSDatePickerCell Class Reference

Inherits from	NSActionCell : NSCell : NSObject
Conforms to	NSCoding (NSCell) NSCopying (NSCell) NSObject (NSObject)
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.4 and later.
Declared in	AppKit/NSDatePickerCell.h
Related sample code	DatePicker

Overview

An `NSDatePickerCell` instance controls the behavior of an `NSDatePicker` control, or of a single date picker cell in a matrix.

Tasks

Configuring Appearance

- `backgroundColor` (page 895)
  Returns the receiver's background color.
- `setBackgroundColor:` (page 899)
  Sets the receiver's background color
- `drawsBackground` (page 897)
  Returns whether the receiver draws the background.
- `setDrawsBackground:` (page 901)
  Sets whether the receiver draws the background.
- `textColor` (page 904)
  Returns the receiver's text color.
- `setTextColor:` (page 903)
  Sets the receiver's text color.

- `datePickerStyle` (page 896)
  Returns the receiver's date picker style.
- `setDatePickerStyle:` (page 900)
  Sets the receiver's date picker style.
- `datePickerElements` (page 896)
  Returns a bitmask that indicates which visual elements of the date picker are currently shown, and which won't be usable because they are hidden.
- `setDatePickerElements:` (page 900)
  Sets a bitmask that indicates which visual elements of the date picker are currently shown, and which won't be usable because they are hidden.

Range Mode

- `datePickerMode` (page 896)
  Returns the receiver's date picker mode.
- `setDatePickerMode:` (page 900)
  Sets the receiver's date picker mode.

Object Values

- `dateValue` (page 897)
  Returns the receiver's date.
- `setDateValue:` (page 901)
  Sets the receiver's date to a new starting value.
- `timeInterval` (page 904)
  Returns the time interval that represents the date range.
- `setTimeInterval:` (page 903)
  Sets the time interval of the date range.
- `calendar` (page 895)
  Returns the calendar used by the receiver.
- `setCalendar:` (page 899)
  Sets the receiver's calendar.
- `locale` (page 898)
  Returns the receiver's locale.
- `setLocale:` (page 902)
  Sets the receiver's locale.
- `timeZone` (page 905)
  Returns the receiver's time zone.
- `setTimeZone:` (page 904)
  Sets the receiver's time zone.

Date Range Constraints

- `minDate` (page 899)
  Returns the minimum date value that the receiver allows as input.
- `setMinDate:` (page 903)
  Sets the minimum date allowed as input by the receiver to the given date.
- `maxDate` (page 898)
  Returns the maximum date value that the receiver allows as input.
- `setMaxDate:` (page 902)
  Sets the maximum date allowed as input by the receiver to the given date.

Getting and Setting the Delegate

- `delegate` (page 897)
  Returns the receiver's delegate.
- `setDelegate:` (page 901)
  Sets the receiver's delegate.

Instance Methods

backgroundColor

Returns the receiver's background color.

```
- (NSColor *)backgroundColor
```

Return Value
The receiver's background color.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `setBackgroundColor:` (page 899)

Declared In
`NSDatePickerCell.h`

calendar

Returns the calendar used by the receiver.

```
- (NSCalendar *)calendar
```

Return Value
The calendar used by the receiver.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `setCalendar:` (page 899)

Declared In
`NSDatePickerCell.h`

datePickerElements

Returns a bitmask that indicates which visual elements of the date picker are currently shown, and which won't be usable because they are hidden.

```
- (NSDatePickerElementFlags)datePickerElements
```

Return Value
A bitmask that specifies the date picker elements displayed by the receiver. See "Constants" (page 905) for a description of the possible values.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `setDatePickerElements:` (page 900)

Declared In
`NSDatePickerCell.h`

datePickerMode

Returns the receiver's date picker mode.

```
- (NSDatePickerMode)datePickerMode
```

Return Value
The receiver's date picker mode.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `setDatePickerMode:` (page 900)

Declared In
`NSDatePickerCell.h`

datePickerStyle

Returns the receiver's date picker style.

```
- (NSDatePickerStyle)datePickerStyle
```

Return Value
The receiver's date picker style.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `setDatePickerStyle:` (page 900)

Declared In
`NSDatePickerCell.h`

dateValue

Returns the receiver's date.

```
- (NSDate *)dateValue
```

Return Value
The receiver's date.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `setDateValue:` (page 901)

Declared In
`NSDatePickerCell.h`

delegate

Returns the receiver's delegate.

```
- (id < NSDatePickerCellDelegate >)delegate
```

Return Value
The receiver's delegate.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `setDelegate:` (page 901)

Declared In
`NSDatePickerCell.h`

drawsBackground

Returns whether the receiver draws the background.

```
- (BOOL)drawsBackground
```

Return Value
`YES` if the receiver draws the background, otherwise `NO`.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- setDrawsBackground:` (page 901)

Declared In
`NSDatePickerCell.h`

locale

Returns the receiver's locale.

```
- (NSLocale *)locale
```

Return Value
The receiver's locale.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- setLocale:` (page 902)

Declared In
`NSDatePickerCell.h`

maxDate

Returns the maximum date value that the receiver allows as input.

```
- (NSDate *)maxDate
```

Return Value
The maximum date value that the receiver allows as input.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- setMaxDate:` (page 902)

Declared In
`NSDatePickerCell.h`

minDate

Returns the minimum date value that the receiver allows as input.

```
- (NSDate *)minDate
```

Return Value
The minimum date value that the receiver allows as input.

Availability
Available in Mac OS X v10.4 and later.

See Also
- setMinDate: (page 903)

Declared In
NSDatePickerCell.h

setBackgroundColor:

Sets the receiver's background color

```
- (void)setBackgroundColor:(NSColor *)color
```

Parameters
color
The new background color.

Availability
Available in Mac OS X v10.4 and later.

See Also
- backgroundColor (page 895)

Declared In
NSDatePickerCell.h

setCalendar:

Sets the receiver's calendar.

```
- (void)setCalendar:(NSCalendar *)newCalendar
```

Parameters
newCalendar
The calendar used by the receiver.

Availability
Available in Mac OS X v10.4 and later.

See Also
- backgroundColor (page 895)

Declared In
NSDatePickerCell.h

setDatePickerElements:

Sets a bitmask that indicates which visual elements of the date picker are currently shown, and which won't be usable because they are hidden.

```
- (void)setDatePickerElements:(NSDatePickerElementFlags)elementFlags
```

Parameters

elementFlags

A bitmask that specifies the date picker elements displayed by the receiver. See "Constants" (page 905) for a description of the possible values.

Availability
Available in Mac OS X v10.4 and later.

See Also
- datePickerElements (page 896)

Declared In
NSDatePickerCell.h

setDatePickerMode:

Sets the receiver's date picker mode.

```
- (void)setDatePickerMode:(NSDatePickerMode)newMode
```

Parameters

newMode

The new date picker mode.

Availability
Available in Mac OS X v10.4 and later.

See Also
- datePickerMode (page 896)

Declared In
NSDatePickerCell.h

setDatePickerStyle:

Sets the receiver's date picker style.

```
- (void)setDatePickerStyle:(NSDatePickerStyle)newStyle
```

Parameters

newStyle

The new date picker style.

Availability
Available in Mac OS X v10.4 and later.

See Also
- datePickerStyle (page 896)

Declared In
NSDatePickerCell.h

setDateValue:

Sets the receiver's date to a new starting value.

```
- (void)setDateValue:(NSDate *)newStartDate
```

Parameters

newStartDate
The new starting date.

Availability
Available in Mac OS X v10.4 and later.

See Also
- dateValue (page 897)

Declared In
NSDatePickerCell.h

setDelegate:

Sets the receiver's delegate.

```
- (void)setDelegate:(id < NSDatePickerCellDelegate >)anObject
```

Parameters

anObject
The receiver's delegate.

Availability
Available in Mac OS X v10.4 and later.

See Also
- delegate (page 897)

Declared In
NSDatePickerCell.h

setDrawsBackground:

Sets whether the receiver draws the background.

```
- (void)setDrawsBackground:(BOOL)flag
```

Parameters

flag

YES if the receiver draws the background, otherwise NO.

Availability
Available in Mac OS X v10.4 and later.

See Also
- drawsBackground (page 897)

Declared In
NSDatePickerCell.h

setLocale:

Sets the receiver's locale.

```
- (void)setLocale:(NSLocale *)newLocale
```

Parameters

newLocale

The receiver's locale.

Availability
Available in Mac OS X v10.4 and later.

See Also
- locale (page 898)

Declared In
NSDatePickerCell.h

setMaxDate:

Sets the maximum date allowed as input by the receiver to the given date.

```
- (void)setMaxDate:(NSDate *)date
```

Parameters

date

The maximum date the receiver allows as input. Pass nil to allow any date as the maximum value.

Availability
Available in Mac OS X v10.4 and later.

See Also
- maxDate (page 898)

Declared In
NSDatePickerCell.h

setMinDate:

Sets the minimum date allowed as input by the receiver to the given date.

```
- (void)setMinDate:(NSDate *)date
```

Parameters

date

The minimum date the receiver allows as input. Pass `nil` to allow any date as the minimum value.

Discussion

Passing `nil` for *date* allows any date as the minimum value.

Availability

Available in Mac OS X v10.4 and later.

See Also

- `minDate` (page 899)

Declared In

`NSDatePickerCell.h`

setTextColor:

Sets the receiver's text color.

```
- (void)setTextColor:(NSColor *)color
```

Parameters

color

The new text color.

Availability

Available in Mac OS X v10.4 and later.

See Also

- `textColor` (page 904)

Declared In

`NSDatePickerCell.h`

setTimeInterval:

Sets the time interval of the date range.

```
- (void)setTimeInterval:(NSTimeInterval)newTimeInterval
```

Parameters

newTimeInterval

The time interval of the date range.

Discussion

The time interval only applies when the receiver is in the `NSRangeDateMode` (page 907) mode.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `timeInterval` (page 904)

Declared In
`NSDatePickerCell.h`

setTimeZone:

Sets the receiver's time zone.

```
- (void)setTimeZone:(NSTimeZone *)newTimeZone
```

Parameters

newTimeZone
The receiver's time zone.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `timeZone` (page 905)

Declared In
`NSDatePickerCell.h`

textColor

Returns the receiver's text color.

```
- (NSColor *)textColor
```

Return Value
The receiver's text color.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `setTextColor:` (page 903)

Declared In
`NSDatePickerCell.h`

timeInterval

Returns the time interval that represents the date range.

```
- (NSTimeInterval)timeInterval
```

Return Value
The time interval that represents the date range.

Discussion
The date range begins at the date returned by `dateValue` (page 897). This method returns `0` when the receiver is not in the `NSRangeDateMode` (page 907) mode.

Special Considerations

Prior to Mac OS X v 10.5 this method always returned `0`.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- setTimeInterval:` (page 903)

Declared In
`NSDatePickerCell.h`

timeZone

Returns the receiver's time zone.

```
- (NSTimeZone *)timeZone
```

Return Value
The receiver's time zone.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- setTimeZone:` (page 904)

Declared In
`NSDatePickerCell.h`

Constants

NSDatePickerStyle

Specifies a type for constants that define the visual appearance of the `NSDatePickerCell`.

```
typedef NSUInteger NSDatePickerStyle;
```

Discussion
For a discussion of possible values, see "Date Picker Style" (page 906).

Availability
Available in Mac OS X v10.4 and later.

Declared In
NSDatePickerCell.h

Date Picker Style

The NSDatePickerStyle constants define the visual appearance of the NSDatePickerCell. These values are used by datePickerStyle (page 896) and setDatePickerStyle: (page 900).

```
enum {
    NSTextFieldAndStepperDatePickerStyle    = 0,
    NSClockAndCalendarDatePickerStyle       = 1,
    NSTextFieldDatePickerStyle              = 2
};
typedef NSUInteger NSDatePickerStyle;
```

Constants

NSTextFieldAndStepperDatePickerStyle
Provide a text field and stepper style interface.
Available in Mac OS X v10.4 and later.
Declared in NSDatePickerCell.h.

NSClockAndCalendarDatePickerStyle
Provide a visual clock and calendar style interface.
Available in Mac OS X v10.4 and later.
Declared in NSDatePickerCell.h.

NSTextFieldDatePickerStyle
Provide a text field interface.
Available in Mac OS X v10.5 and later.
Declared in NSDatePickerCell.h.

Declared In
NSDatePickerCell.h

NSDatePickerMode

Specifies a type for constants that define whether the control provides a single date, or a range of dates.

```
typedef NSUInteger NSDatePickerMode;
```

Discussion
For a discussion of possible values, see "Date Picker Mode" (page 907).

Availability
Available in Mac OS X v10.4 and later.

Declared In
NSDatePickerCell.h

Date Picker Mode

The `NSDatePickerMode` constants define whether the control provides a single date, or a range of dates. These values are used by `datePickerMode` (page 896) and `setDatePickerMode:` (page 900).

```
enum {
    NSSingleDateMode = 0,
    NSRangeDateMode = 1
};
typedef NSUInteger NSDatePickerMode;
```

Constants

`NSSingleDateMode`

Allow selection of a single date.

Available in Mac OS X v10.4 and later.

Declared in `NSDatePickerCell.h`.

`NSRangeDateMode`

Allow selection of a range of dates. (First implemented in Mac OS X v 10.5.)

Available in Mac OS X v10.4 and later.

Declared in `NSDatePickerCell.h`.

Special Considerations

Prior to Mac OS X v 10.5 only `NSSingleDateMode` was implemented.

Declared In

`NSDatePickerCell.h`

NSDatePickerElementFlags

Specifies a type for constants that allow you to specify the date and time elements that the `NSDatePickerCell` can edit.

```
typedef NSUInteger NSDatePickerElementFlags;
```

Discussion

For a discussion of possible values, see "Date Picker Elements" (page 907).

Availability

Available in Mac OS X v10.4 and later.

Declared In

`NSDatePickerCell.h`

Date Picker Elements

The `NSDatePickerElementFlag` constants allow you to specify the date and time elements that the `NSDatePickerCell` can edit by combining these constants using the C bitwise `OR` operator. These values are used by `datePickerElements` (page 896) and `setDatePickerElements:` (page 900):

```
enum {
    NSHourMinuteDatePickerElementFlag       = 0x000c,
    NSHourMinuteSecondDatePickerElementFlag = 0x000e,
    NSTimeZoneDatePickerElementFlag         = 0x0010,
    NSYearMonthDatePickerElementFlag        = 0x00c0,
    NSYearMonthDayDatePickerElementFlag     = 0x00e0,
    NSEraDatePickerElementFlag              = 0x0100,
};
typedef NSUInteger NSDatePickerElementFlags;
```

Constants

`NSHourMinuteDatePickerElementFlag`

Display and allow editing of the hour and minute elements of the date.

Available in Mac OS X v10.4 and later.

Declared in `NSDatePickerCell.h`.

`NSHourMinuteSecondDatePickerElementFlag`

Display and allow editing of the hour, minute and second elements of the date.

Available in Mac OS X v10.4 and later.

Declared in `NSDatePickerCell.h`.

`NSTimeZoneDatePickerElementFlag`

Display and allow editing of the time zone.

This flag has been declared for possible future use, and does not yet have any effect.

Available in Mac OS X v10.4 and later.

Declared in `NSDatePickerCell.h`.

`NSYearMonthDatePickerElementFlag`

Display and allow editing of the year and month elements of the date.

Available in Mac OS X v10.4 and later.

Declared in `NSDatePickerCell.h`.

`NSYearMonthDayDatePickerElementFlag`

Display and allow editing of the year, month and day elements of the date.

Available in Mac OS X v10.4 and later.

Declared in `NSDatePickerCell.h`.

`NSEraDatePickerElementFlag`

Display and allow editing of the era of the date, if applicable.

This flag has been declared for possible future use, and does not yet have any effect.

Available in Mac OS X v10.4 and later.

Declared in `NSDatePickerCell.h`.

Declared In

`NSDatePickerCell.h`

Related sample code	DictionaryController

Overview

`NSDictionaryController` is a bindings compatible class that manages display and editing of the contents of an `NSDictionary` object. `NSDictionaryController` transforms the contents of a dictionary into an array of key-value pairs that can be bound to user interface items such as the columns of an `NSTableView`.

The content of an `NSDictionaryController` instance is specified using the inherited method `setContent:` (page 1756) or by binding an `NSDictionary` instance to the `contentDictionary` binding. New key/value pairs inserted into the dictionary are created using the newObject method. The initial key name is set to the string returned by `initialKey` (page 912) (specified using `setInitialKey:` (page 915) or the `initialKey` binding). The initial value object is set to the object returned by `initialValue` (page 912) (specified using `setInitialValue:` (page 915) or the `initialValue` binding). The initial key name is copied to the newly inserted object, while the object returned by `initialValue` (page 912) is simply retained. As new items are inserted the controller enumerates the initial key name, resulting in key names such as "key", "key1", "key2", and so on. This behavior can be customized by overriding `newObject` (page 914).

An `NSDictionaryController` instance can be configured to exclude specified keys in a dictionary from being returned by `arrangedObjects` (page 911) using the `setExcludedKeys:` (page 914) method or by binding an array of key names to the `excludedKeys` binding. Similarly, you can specify an array of key names that are always included in the arranged objects, even if they are not present in the content dictionary, using the `setIncludedKeys:` (page 914) method or the `includedKeys` binding.

`NSDictionaryController` supports providing localized key names for the keys in the dictionary, allowing a user-friendly representation of the key name to be displayed. The localized key names are specified by a dictionary (using `setLocalizedKeyDictionary:` (page 915) or the `localizedKeyDictionary` binding) or by providing a strings table (using `setLocalizedKeyTable:` (page 916)).

The `arrangedObjects` (page 911) method returns an array of objects that implement the `NSDictionaryControllerKeyValuePair` informal protocol. User interface controls are bound to the arranged objects array using key paths such as: `arrangedObjects.key` (displays the key name), `arrangedObjects.value` (displays the value for the key), or `arrangedObjects.localizedKey` (displays the localized key name). See *NSDictionaryControllerKeyValuePair Protocol Reference* for more information.

Note: You must enable the "Validates Immediately" option for the value binding of all controls that edit the key names or values returned by `arrangedObjects` (page 911).

Adopted Protocols

NSCoding
- `encodeWithCoder:`
- `initWithCoder:`

Tasks

Arranging Objects

- `arrangedObjects` (page 911)
  Returns an array containing the objects that represent the receiver's content.

Creating New Entries

- `newObject` (page 914)
  Creates and returns a new key-value pair to represent an entry in the content dictionary.

Localizing Key Names

- `setLocalizedKeyDictionary:` (page 915)
  Sets the localized key names that are displayed by the receiver in place of the key names.
- `localizedKeyDictionary` (page 913)
  Returns the receiver's localization dictionary.
- `localizedKeyTable` (page 913)
  Returns the strings file used to localize key names.
- `setLocalizedKeyTable:` (page 916)
  Specifies the strings file used to localize key names.

Keys to Display

- `setIncludedKeys:` (page 914)
  Sets the key names that are represented by a key-value pair, even if they are not present in the receiver's content dictionary.
- `includedKeys` (page 912)
  Returns an array containing the key names that are represented by a key-value pair, even if they are not present in the receiver's content dictionary.
- `setExcludedKeys:` (page 914)
  Sets the key names that are never displayed in the user interface items bound to the receiver.
- `excludedKeys` (page 911)
  Returns an array containing the key names that are never displayed in the user interface items bound to the receiver.

Setting Initial Key and Values

- `setInitialKey:` (page 915)
  Sets the string used as the initial key name for a newly inserted item.
- `initialKey` (page 912)
  Returns the string used as the initial key name for a newly inserted item.
- `setInitialValue:` (page 915)
  Sets the string used as the initial value for a newly inserted item.
- `initialValue` (page 912)
  Returns the string used as the initial value for a newly inserted item.

Instance Methods

arrangedObjects

Returns an array containing the objects that represent the receiver's content.

```
- (id)arrangedObjects
```

Return Value
An array of objects that implement the `NSDictionaryControllerKeyValuePair` informal protocol. See *NSDictionaryControllerKeyValuePair Protocol Reference* for more information.

excludedKeys

Returns an array containing the key names that are never displayed in the user interface items bound to the receiver.

```
- (NSArray *)excludedKeys
```

Return Value
An array containing the key names.

Availability
Available in Mac OS X v10.5 and later.

See Also
`- setExcludedKeys:` (page 914)

Declared In
`NSDictionaryController.h`

includedKeys

Returns an array containing the key names that are represented by a key-value pair, even if they are not present in the receiver's content dictionary.

```
- (NSArray *)includedKeys
```

Return Value
An array containing the key names.

Availability
Available in Mac OS X v10.5 and later.

See Also
`- setIncludedKeys:` (page 914)

Declared In
`NSDictionaryController.h`

initialKey

Returns the string used as the initial key name for a newly inserted item.

```
- (NSString *)initialKey
```

Return Value
The key name.

Availability
Available in Mac OS X v10.5 and later.

See Also
`- setInitialKey:` (page 915)

Declared In
`NSDictionaryController.h`

initialValue

Returns the string used as the initial value for a newly inserted item.

```
- (id)initialValue
```

Return Value
The value.

Availability
Available in Mac OS X v10.5 and later.

See Also
- `setInitialValue:` (page 915)

Declared In
`NSDictionaryController.h`

localizedKeyDictionary

Returns the receiver's localization dictionary.

```
- (NSDictionary *)localizedKeyDictionary
```

Return Value
A dictionary containing localized string values for the key names.

Availability
Available in Mac OS X v10.5 and later.

See Also
- `setLocalizedKeyDictionary:` (page 915)

Declared In
`NSDictionaryController.h`

localizedKeyTable

Returns the strings file used to localize key names.

```
- (NSString *)localizedKeyTable
```

Return Value
A string that specifies the string table to use when localizing key names.

Availability
Available in Mac OS X v10.5 and later.

See Also
- `setLocalizedKeyTable:` (page 916)

Declared In
`NSDictionaryController.h`

newObject

Creates and returns a new key-value pair to represent an entry in the content dictionary.

```
- (id)newObject
```

Return Value
An object that represents the key-value pair. The object must not be autoreleased, and must implement the NSDictionaryControllerKeyValuePair informal protocol

Discussion
This method is invoked for insertions of new key-value pairs, as well as transforming existing dictionary entries into key-value pairs for display. Objects returned by this method must implement the NSDictionaryControllerKeyValuePair informal protocol.

Special Considerations

Subclass implementations must ensure that the object returned by `newObject` is not autoreleased.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSDictionaryController.h`

setExcludedKeys:

Sets the key names that are never displayed in the user interface items bound to the receiver.

```
- (void)setExcludedKeys:(NSArray *)keys
```

Parameters
keys
An array containing the key names.

Availability
Available in Mac OS X v10.5 and later.

See Also
`- excludedKeys` (page 911)

Declared In
`NSDictionaryController.h`

setIncludedKeys:

Sets the key names that are represented by a key-value pair, even if they are not present in the receiver's content dictionary.

```
- (void)setIncludedKeys:(NSArray *)keys
```

Parameters
keys
An array containing the key names.

Availability
Available in Mac OS X v10.5 and later.

See Also
- `includedKeys` (page 912)

Declared In
`NSDictionaryController.h`

setInitialKey:

Sets the string used as the initial key name for a newly inserted item.

```
- (void)setInitialKey:(NSString *)key
```

Parameters

key
The key name. The string is copied by the receiver.

Availability
Available in Mac OS X v10.5 and later.

See Also
- `initialKey` (page 912)

Declared In
`NSDictionaryController.h`

setInitialValue:

Sets the string used as the initial value for a newly inserted item.

```
- (void)setInitialValue:(id)value
```

Parameters

value
The initial value.

Availability
Available in Mac OS X v10.5 and later.

See Also
- `initialValue` (page 912)

Declared In
`NSDictionaryController.h`

setLocalizedKeyDictionary:

Sets the localized key names that are displayed by the receiver in place of the key names.

```
- (void)setLocalizedKeyDictionary:(NSDictionary *)dictionary
```

Parameters

dictionary

A dictionary containing the localized key name strings.

Discussion

The dictionary contains the key names as the keys, and the localized key names as the corresponding values.

Availability

Available in Mac OS X v10.5 and later.

See Also

- localizedKeyDictionary (page 913)

Declared In

NSDictionaryController.h

setLocalizedKeyTable:

Specifies the strings file used to localize key names.

```
- (void)setLocalizedKeyTable:(NSString *)stringsFile
```

Parameters

stringsFile

Specifies the string table to use when localizing key names.

Discussion

The string table must reside within the application's resource . See Strings Files in Introduction to Internationalization Programming Topics.

Availability

Available in Mac OS X v10.5 and later.

Constants

Exposed Bindings

The following constants are used to specify a binding to bind:toObject:withKeyPath:options: (page 3699), infoForBinding: (page 3700), unbind: (page 3701), and valueClassForBinding: (page 3701). See the *Cocoa Bindings Reference* for more information.

```
NSString *NSContentDictionaryBinding;
NSString *NSIncludedKeysBinding;
NSString *NSExcludedKeysBinding;
NSString *NSLocalizedKeyDictionaryBinding;
NSString *NSInitialKeyBinding;
NSString *NSInitialValueBinding;
```

Constants

`NSContentDictionaryBinding`

A dictionary used as the content dictionary.

Available in Mac OS X v10.5 and later.

Declared in `NSKeyValueBinding.h`.

`NSIncludedKeysBinding`

An array containing the key-value pairs always represented by the receiver.

Available in Mac OS X v10.5 and later.

Declared in `NSKeyValueBinding.h`.

`NSExcludedKeysBinding`

An array containing the key names that are never displayed in the user interface items bound to the receiver.

Available in Mac OS X v10.5 and later.

Declared in `NSKeyValueBinding.h`.

`NSLocalizedKeyDictionaryBinding`

A dictionary containing the localized key names that are displayed by the receiver in place of the key names.

Available in Mac OS X v10.5 and later.

Declared in `NSKeyValueBinding.h`.

`NSInitialKeyBinding`

A string used as the initial key name for newly inserted items.

Available in Mac OS X v10.5 and later.

Declared in `NSKeyValueBinding.h`.

`NSInitialValueBinding`

A string used as the initial value for newly inserted items.

Available in Mac OS X v10.5 and later.

Declared in `NSKeyValueBinding.h`.

Overview

The `NSDockTile` class lets you customize the visual representation for your application's miniaturized windows and application icon as they appear in the Dock. You do not create Dock tile objects explicitly in your application. Instead, you retrieve the Dock tile for an existing window or for the application by calling that object's `dockTile` method.

Typically, you do not subclass the `NSDockTile` class. Instead, you use the methods of the class to make the following customizations:

- Badge the tile with a custom string.
- Remove or show the application icon badge.
- Draw the tile content yourself.

If you decide to draw the tile content yourself, you must provide a custom content view to handle the drawing.

Application Dock Tiles

An application Dock tile defaults to display the application's `applicationIconImage` (page 138).

The application Dock tile never shows a smaller application icon badge.

Whether using the default or custom view, the application Dock tile may be badged with a short custom string.

Window Dock Tiles

A window Dock tile defaults to display a miniaturized version of the windows contents with a badge derived from the application Dock icon, including any customized application Dock icon. The default window Dock tile image may not be badged with a custom string.

A window Dock tile can use a custom view to draw the Dock icon. If a custom view is used, no application badge will be added, but the text label will be overlaid on top of the icon.

Tasks

Drawing the Tile's Content

- `setContentView:` (page 923)
  Sets the view to use for drawing the dock tile contents.
- `contentView` (page 921)
  Returns the view used to draw the dock tile contents.

Getting the Tile Information

- `size` (page 924)
  Returns the size of the tile.
- `owner` (page 922)
  Returns the object represented by the dock tile.

Applying Badge Icons to the Tile

- `setShowsApplicationBadge:` (page 923)
  Sets whether the tile should be badged with the application's icon.
- `showsApplicationBadge` (page 924)
  Returns a Boolean value indicating whether the tile is badged with the application's icon.
- `setBadgeLabel:` (page 922)
  Sets the string to be displayed in the tile's badging area.
- `badgeLabel` (page 921)
  Returns the tile's current badge label.

Updating the Dock Tile

- `display` (page 921)
  Redraws the dock tile's content.

Instance Methods

badgeLabel

Returns the tile's current badge label.

```
- (NSString *)badgeLabel
```

Return Value
The localized string to be displayed in the tile's badging area. This string may be empty or `nil`.

Availability
Available in Mac OS X v10.5 and later.

See Also
`- setBadgeLabel:` (page 922)

Declared In
`NSDockTile.h`

contentView

Returns the view used to draw the dock tile contents.

```
- (NSView *)contentView
```

Return Value
The view used to draw the tile.

Availability
Available in Mac OS X v10.5 and later.

See Also
`- setContentView:` (page 923)

Declared In
`NSDockTile.h`

display

Redraws the dock tile's content.

```
- (void)display
```

Discussion
If a custom content view is provided, Cocoa calls the `drawRect:` method of that view (and its subviews) to draw the tile's content.

You can call this method to force the redrawing of the dock tile contents. You might do this if the contents of the underlying application or window change in a way that would require a refreshing of the tile. Some types of system activity, such as resizing the dock, may trigger automatic redraws of the tile. In most cases, however, your application is responsible for triggering redraws.

Cocoa does not automatically redraw the contents of your dock tile. Instead, your application must explicitly send `display` messages to the dock tile object whenever the contents of your view change and need to be redrawn.

Availability
Available in Mac OS X v10.5 and later.

Related Sample Code
DockTile

Declared In
`NSDockTile.h`

owner

Returns the object represented by the dock tile.

```
- (id)owner
```

Return Value
The object represented by the dock tile. This is either the `NSApplication` object or one of your application's `NSWindow` objects.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSDockTile.h`

setBadgeLabel:

Sets the string to be displayed in the tile's badging area.

```
- (void)setBadgeLabel:(NSString *)string
```

Parameters

string

The localized string to display. This string can contain a count value or other badging information. To clear the badge string, specify an empty string (`@""`) or `nil`.

Discussion
The appearance of the badge area is system defined.

Window dock tiles only display a badge label when there is a custom view associated with the dock tile.

Availability
Available in Mac OS X v10.5 and later.

See Also
- `badgeLabel` (page 921)
- `showsApplicationBadge` (page 924)

Declared In
`NSDockTile.h`

setContentView:

Sets the view to use for drawing the dock tile contents.

```
- (void)setContentView:(NSView *)view
```

Parameters

view

The view to use for drawing the tile. This view may contain additional subviews.

Discussion
The view you specify should be height and width resizable.

Cocoa does not automatically redraw the contents of your dock tile. Instead, your application must explicitly send display messages to the dock tile object whenever the contents of your view change and need to be redrawn. Your dock tile view is responsible for drawing the entire contents of the dock tile. Your view does not need to draw the application or custom string badges.

Availability
Available in Mac OS X v10.5 and later.

See Also
- `contentView` (page 921)
- `display` (page 921)

Related Sample Code
DockTile

Declared In
`NSDockTile.h`

setShowsApplicationBadge:

Sets whether the tile should be badged with the application's icon.

```
- (void)setShowsApplicationBadge:(BOOL)flag
```

Parameters

flag

`YES` to show the application icon; otherwise, `NO` to hide it.

Discussion
Miniaturized windows include the application badge by default to convey the associated application to the user. In Mac OS X v10.5 and later, application tiles do not support the application badge. A miniaturized window with a custom view does not draw the application badge.

The application icon is positioned automatically in the tile by the `NSDockTile` object.

Availability
Available in Mac OS X v10.5 and later.

See Also
`- showsApplicationBadge` (page 924)

Declared In
`NSDockTile.h`

showsApplicationBadge

Returns a Boolean value indicating whether the tile is badged with the application's icon.

```
- (BOOL)showsApplicationBadge
```

Return Value
`YES` if the tile is badged; otherwise, `NO`. Returns `YES` by default.

Availability
Available in Mac OS X v10.5 and later.

See Also
`- setShowsApplicationBadge:` (page 923)

Declared In
`NSDockTile.h`

size

Returns the size of the tile.

```
- (NSSize)size
```

Return Value
The size of the tile, measured in screen coordinates.

Discussion
The size returned by this method corresponds to the size of the backing store in the dock, which may be bigger than the actual tile displayed on the screen.

Availability
Available in Mac OS X v10.5 and later.

Class at a Glance

`NSDocument` is an abstract class that defines the interface for documents, objects that can internally represent data displayed in windows and that can read data from and write data to files. Documents create and manage one or more window controllers and are in turn managed by a document controller. Documents respond to first-responder action messages to save, revert, and print their data.

Principal Attributes

- Window controllers
- Filenames
- Document types
- Print information

`init` (page 954)
Designated initializer for new documents

`initWithContentsOfURL:ofType:error:` (page 957)
For existing documents

Commonly Used Methods

`dataOfType:error:` (page 944)
Returns the document's data in a specified type.

`readFromData:ofType:error:` (page 967)
Sets the contents of this document by reading from data of a specified type.

`writeToURL:ofType:error:` (page 996)
Writes the document's data to a URL.

`readFromURL:ofType:error:` (page 970)
Reads the document's data from a file.

`windowNibName` (page 992)
Returns the name of the document's sole nib file (resulting in the creation of a window controller for the window in that file).

`makeWindowControllers` (page 961)
Creates and returns the window controllers used to manage document windows.

Overview

`NSDocument` is an abstract class that defines the interface for documents.

Conceptually, a document is a container for a body of information identified by a name under which it is stored in a disk file. In this sense, however, the document is not the same as the file but is an object in memory that owns and manages the document data. In the context of the Application Kit, a document is an instance of a custom `NSDocument` subclass that knows how to represent internally, in one or more formats, persistent data that is displayed in windows.

A document can read that data from a file and write it to a file. It is also the first-responder target for many menu commands related to documents, such as Save, Revert, and Print. A document manages its window's edited status and is set up to perform undo and redo operations. When a window is closing, the document is asked before the window delegate to approve the closing.

`NSDocument` is one of the triad of Application Kit classes that establish an architectural basis for document-based applications (the others being `NSDocumentController` and `NSWindowController`).

Subclassing NSDocument

`NSDocument` is designed to be subclassed. That is, `NSDocument` is an abstract class, and your application must create at least one `NSDocument` subclass to use the document architecture. To create a useful `NSDocument` subclass, you must override some methods, and you can optionally override others.

The `NSDocument` class itself knows how to handle document data as undifferentiated lumps; although it understands that these lumps are typed, it knows nothing about particular types. In their overrides of the data-based reading and writing methods, subclasses must add the knowledge of particular types and how data of the document's native type is structured internally. Subclasses are also responsible for the creation of the window controllers that manage document windows and for the implementation of undo and redo. The `NSDocument` class takes care of much of the rest, including generally managing the state of the document.

See "Creating a Subclass of NSDocument" in *Document-Based Applications Overview* for more information about creating subclasses of `NSDocument`, particularly the list of primitive methods that subclasses must override and those that you can optionally override.

Writing of HFS Creator and File Type Codes

The `fileAttributesToWriteToFile:ofType:saveOperation:` (page 946) method can be overridden to specify that a creator code or file type code (or both) should be written to a file as it is being saved. See `NSFileManager` for descriptions of the `NSFileHFSCreatorCode` and `NSFileHFSTypeCode` file attributes. The `NSDocument` implementation of `fileAttributesToWriteToFile:ofType:saveOperation:` returns zeroed-out creator and file type codes, effectively excluding creator code and file type code from the attribute preservation described in `fileAttributesToWriteToFile:ofType:saveOperation:`.

NSDocument Saving Behavior

`NSDocument` implements document saving in a way that preserves, when possible, various attributes of each document, including:

- Creation date
- Permissions/privileges
- Location of the document's icon in its parent folder's Icon View Finder window
- Value of the document's Show Extension setting

Care is also taken to save documents in a way that does not break any user-created aliases that may point to documents. As a result, some methods in any class of `NSDocument` may be invoked with parameters that do not have the same meaning as they did in early releases of Mac OS X. It is important that overrides of `writeToURL:ofType:error:` (page 996) and `writeToURL:ofType:forSaveOperation:originalContentsURL:error:` (page 997) make no assumptions about the file paths passed as parameters, including:

- The location to which the file is being written. This location might be a hidden temporary directory.
- The name of the file being written. It is possible that this file has no obvious relation to the document name.
- The relation of any file being passed, including the original file, to the return value of `fileName` (page 948).

When updating your application to link against Mac OS X v10.5, keep in mind that it's usually more appropriate to invoke in your application code one of the `NSDocument save...` methods than one of the `write...` methods. The `write...` methods are there primarily for you to override. The `saveToURL:ofType:forSaveOperation:error:` (page 980) method that's meant always to be invoked during document saving, invokes `setFileModificationDate:` (page 981) with the file's new modification date after it has been written (for `NSSaveOperation` (page 999) and `NSSaveAsOperation` (page 999) only).

Likewise, it's usually more appropriate to invoke in your application code one of the `NSDocument` `revert...` methods than one of the `read...` methods. The `read...` methods are there primarily for you to override. The `revertToContentsOfURL:ofType:error:` (page 971) method that's meant always to be invoked during rereading of an open document, invokes `setFileModificationDate:` (page 981) with the file's modification date after it has been read.

Multicore Considerations

In Mac OS X v10.6 and later, `NSDocument` supports the ability to open multiple documents concurrently. However, this support requires the cooperation of the document object. If your document subclass is able to read specific document types independently of other similar documents, you should override the `canConcurrentlyReadDocumentsOfType:` (page 938) class method and return `YES` for the appropriate document types. If specific document types rely on shared state information, however, you should return `NO` for those types.

Tasks

Initializing

- `init` (page 954)
  Initializes and returns an empty `NSDocument` object.
- `initWithContentsOfURL:ofType:error:` (page 957)
  Initializes a document located by a URL of a specified type.
- `initForURL:withContentsOfURL:ofType:error:` (page 955)
  Initializes a document located by a URL of a specified type, but by reading the contents for the document from a different URL.
- `initWithType:error:` (page 957)
  Initializes a document of a specified type.

Loading Document Data

- `dataOfType:error:` (page 944)
  Creates and returns a data object that contains the contents of the document, formatted to a specified type.
- `fileWrapperOfType:error:` (page 951)
  Creates and returns a file wrapper that contains the contents of the document, formatted to the specified type.
- `readFromData:ofType:error:` (page 967)
  Sets the contents of this document by reading from data of a specified type and returns `YES` if successful.

Creating and Managing Window Controllers

- `makeWindowControllers` (page 961)
  Subclasses may override this method to create the initial window controller(s) for the document.
- `windowNibName` (page 992)
  Overridden by subclasses to return the name of the document's sole nib file.
- `windowControllerDidLoadNib:` (page 990)
  Sent after the specified window controller loads a nib file if the receiver is the nib file's owner.
- `windowControllerWillLoadNib:` (page 991)
  Sent before the specified window controller loads a nib file if the receiver is the nib file's owner.
- `windowControllers` (page 991)
  Returns the receiver's current window controllers.
- `addWindowController:` (page 940)
  Adds the specified window controller to the array of window controllers associated with the receiver.
- `removeWindowController:` (page 970)
  Removes the specified window controller from the receiver's array of window controllers.
- `shouldCloseWindowController:delegate:shouldCloseSelector:contextInfo:` (page 986)
  Invokes *`shouldCloseSelector`* with the result of `canCloseDocumentWithDelegate:shouldCloseSelector:contextInfo:` (page 943) if the the specified window controller that is closing is the last one or is marked as causing the document to close.

Managing Document Windows

- `showWindows` (page 987)
  Displays all of the document's windows, bringing them to the front and making them main or key as necessary.
- `displayName` (page 945)
  Returns the name of the receiver as displayed in the title bars of the document's windows and in alert dialogs related to the document.
- `setWindow:` (page 985)
  Sets the `window` Interface Builder outlet of this class.
- `windowForSheet` (page 992)
  Returns the most appropriate window, of the windows associated with the receiver, to use as the parent window of a document-modal sheet.

Reading From and Writing to Files

- `readFromFileWrapper:ofType:error:` (page 969)
  Sets the contents of this document by reading from a file wrapper of a specified type.
- `fileModificationDate` (page 948)
  Returns the last known modification date of the document's on-disk representation.
- `setFileModificationDate:` (page 981)
  Sets the last known modification date of the document's on-disk representation to the given modification date.

- `runModalSavePanelForSaveOperation:delegate:didSaveSelector:contextInfo:` (page 975)
  Presents a modal Save panel to the user, then tries to save the document if the user approves the panel.
- `shouldRunSavePanelWithAccessoryView` (page 987)
  Returns `YES` by default; as a result, when `NSDocument` displays the Save panel, it includes an accessory view containing a pop-up menu of supported writable document types.
- `keepBackupFile` (page 958)
  Returns a Boolean value indicating whether the receiver should keep the backup files created before document data is written to a file (`NO` by default).

Reading From and Writing to URLs

- `readFromURL:ofType:error:` (page 970)
  Sets the contents of this document by reading from a file or file package, of a specified type, located by a URL.
- `writeToURL:ofType:error:` (page 996)
  Writes the contents of the document to a file or file package located by a URL, formatted to a specified type.
- `writeSafelyToURL:ofType:forSaveOperation:error:` (page 994)
  Writes the contents of the document to a file or file package located by a URL.
- `writeToURL:ofType:forSaveOperation:originalContentsURL:error:` (page 997)
  Writes the contents of the document to a file or file package located by a URL.
- `setFileURL:` (page 982)
  Sets the location of the document's on-disk representation.
- `fileURL` (page 951)
  Returns the location of the document's on-disk representation.
- `fileAttributesToWriteToURL:ofType:forSaveOperation:originalContentsURL:error:` (page 946)
  As a file is being saved, returns the attributes that should be written to a file or file package located by a URL, formatted to a specified type, for a particular kind of save operation.
- `saveToURL:ofType:forSaveOperation:delegate:didSaveSelector:contextInfo:` (page 979)
  Saves the contents of the document to a file or file package located by a URL, formatted to a specified type, for a particular kind of save operation.
- `saveToURL:ofType:forSaveOperation:error:` (page 980)
  Saves the contents of the document to a file or file package located by a URL, formatted to a specified type, for a particular kind of save operation, and returns `YES` if successful.

Autosaving

- `hasUnautosavedChanges` (page 954)
  Return `YES` if the document has changes that have not been autosaved, as determined by the history of previous invocations of `updateChangeCount:` (page 988).
- `autosaveDocumentWithDelegate:didAutosaveSelector:contextInfo:` (page 941)
  Autosaves the document's contents at an appropriate location.

- `autosavingFileType` (page 942)
  Returns the document type that should be used for an autosave operation.
- `setAutosavedContentsFileURL:` (page 980)
  Sets the location of the most recently autosaved document contents.
- `autosavedContentsFileURL` (page 941)
  Returns the location of the most recently autosaved document contents.

Managing Document Status

- `isDocumentEdited` (page 958)
  Returns `YES` if the receiver has changes that have not been saved, `NO` otherwise.
- `updateChangeCount:` (page 988)
  Updates the receiver's change count according to the given change type.
- `fileNameExtensionWasHiddenInLastRunSavePanel` (page 949)
  Returns `YES` if a Save panel was presented by this document and the user chose to hide the name extension of the file that was selected in that Save panel.

Handling User Actions

- `prepareSavePanel:` (page 962)
  Invoked by `runModalSavePanelForSaveOperation:delegate:didSaveSelector:contextInfo:` (page 975) to do any customization of the given Save panel.
- `printDocument:` (page 964)
  Prints the receiver in response to the user choosing the Print menu command.
- `runPageLayout:` (page 975)
  The action method invoked in the receiver as first responder when the user chooses the Page Setup menu command.
- `revertDocumentToSaved:` (page 971)
  The action of the File menu item Revert in a document-based application.
- `saveDocument:` (page 976)
  The action method invoked in the receiver as first responder when the user chooses the Save menu command.
- `saveDocumentAs:` (page 977)
  The action method invoked in the receiver as first responder when the user chooses the Save As menu command.
- `saveDocumentTo:` (page 977)
  The action method invoked in the receiver as first responder when the user chooses the Save To menu command.
- `saveDocumentWithDelegate:didSaveSelector:contextInfo:` (page 978)
  Saves the document.

Closing Documents

- `canCloseDocumentWithDelegate:shouldCloseSelector:contextInfo:` (page 943)
  If the receiver is not dirty, this method immediately calls the *`shouldCloseSelector`* callback on the specified delegate with `YES`.
- `close` (page 943)
  Closes all windows owned by the receiver and removes the receiver from the list of documents maintained by the document controller, which consequently releases it.

Reverting Documents

- `revertToContentsOfURL:ofType:error:` (page 971)
  Discards all unsaved document modifications and replaces the document's contents by reading a file or file package located by a URL of a specified type.

Printing Documents

- `printInfo` (page 966)
  Returns the receiver's customized `NSPrintInfo` object or the default `NSPrintInfo` instance.
- `setPrintInfo:` (page 984)
  Sets the receiver's `NSPrintInfo` object.
- `preparePageLayout:` (page 962)
  Invoked by `runModalPageLayoutWithPrintInfo:` (page 973) and `runModalPageLayoutWithPrintInfo:delegate:didRunSelector:contextInfo:` (page 973) to do any customization of the Page Layout panel *`pageLayout`*, such as adding an accessory view.
- `runModalPageLayoutWithPrintInfo:delegate:didRunSelector:contextInfo:` (page 973)
  Runs the modal page layout panel with the receiver's printing information object
- `runModalPrintOperation:delegate:didRunSelector:contextInfo:` (page 974)
  Runs the specified print operation modally.
- `shouldChangePrintInfo:` (page 985)
  Returns a Boolean value indicating whether the receiver should allow changes to the default `NSPrintInfo` object used in printing the document.
- `printDocumentWithSettings:showPrintPanel:delegate:didPrintSelector:contextInfo:` (page 965)
  Prints the document.
- `printOperationWithSettings:error:` (page 966)
  Creates a print operation and returns it if successful.

Handling Errors

- `presentError:modalForWindow:delegate:didPresentSelector:contextInfo:` (page 963)
  Presents an error alert to the user as a modal panel.
- `presentError:` (page 962)
  Presents an error alert to the user as a modal panel.

- `willPresentError:` (page 989)
  Called when the receiver is about to present an error.

Working with Undo Manager

- `hasUndoManager` (page 954)
  Returns a Boolean value indicating whether the receiver owns or should own an `NSUndoManager` object.
- `setHasUndoManager:` (page 983)
  Sets whether the receiver has its own `NSUndoManager` object.
- `setUndoManager:` (page 984)
  Sets the undo manager owned by the receiver to the specified undo manager and releases any undo manager currently owned by the receiver.
- `undoManager` (page 988)
  Returns the receiver's undo manager.

Managing File Types

- `setFileType:` (page 982)
  Sets the document type under which the file is saved.
- `fileType` (page 950)
  Returns the document type under which the receiver is saved.
- `fileTypeFromLastRunSavePanel` (page 950)
  Returns the file type that was last selected in the Save panel.
+ `isNativeType:` (page 939)
  Returns a Boolean value indicating whether document data of the specified type is a native type—one the receiver can both read and write.
+ `readableTypes` (page 939)
  Returns the types of data the receiver can read natively and any types filterable to that native type.
+ `canConcurrentlyReadDocumentsOfType:` (page 938)
  Returns a Boolean value indicating whether the receiver reads multiple documents of the given type concurrently.
+ `writableTypes` (page 940)
  Returns the types of data the receiver can write natively and any types filterable to that native type.
- `writableTypesForSaveOperation:` (page 993)
  Returns the names of the types to which this document can be saved for a specified kind of save operation.
- `fileNameExtensionForType:saveOperation:` (page 949)
  Returns a filename extension that can be appended to a base filename, for a specified file type and kind of save operation.

Validating User Interface Items

- `validateUserInterfaceItem:` (page 989)
  Validates the specified user interface item that the receiver manages.

Scripting

- `handleCloseScriptCommand:` (page 952)
  Handles the Close AppleScript command by attempting to close the document.
- `handlePrintScriptCommand:` (page 953)
  Handles the Print AppleScript command by attempting to print the document.
- `handleSaveScriptCommand:` (page 953)
  Handles the Save AppleScript command by attempting to save the document.
- `objectSpecifier` (page 961)
  Returns an object specifier for the document.
- `lastComponentOfFileName` (page 959)
  Returns the document name in terms of the scripting name property (the name a script writer would use to specify the document in a script).
- `setLastComponentOfFileName:` (page 983)
  Sets the document name to the given string in terms of the scripting name property (the name a script writer would use to specify the document in a script).

Deprecated Methods

- `canCloseDocument` (page 942) Available in Mac OS X v10.0 through Mac OS X v10.3
  This method is no longer supported. (Deprecated. Use `canCloseDocumentWithDelegate:shouldCloseSelector:contextInfo:` (page 943) instead.)
- `fileNameFromRunningSavePanelForSaveOperation:` (page 950) Available in Mac OS X v10.0 through Mac OS X v10.3
  Returns the filename entered into the Save panel. (Deprecated. Use `saveDocumentWithDelegate:didSaveSelector:contextInfo:` (page 978) instead.)
- `shouldCloseWindowController:` (page 986) Available in Mac OS X v10.0 through Mac OS X v10.3
  Gives the user an opportunity to save the document. (Deprecated. Use `shouldCloseWindowController:delegate:shouldCloseSelector:contextInfo:` (page 986) instead.)
- `validateMenuItem:` (page 989) Available in Mac OS X v10.0 through Mac OS X v10.3
  Validates the Revert menu item and items selected from the Save panel's pop-up list of writable document types items. (Deprecated. Use `validateUserInterfaceItem:` (page 989) instead.)
- `dataRepresentationOfType:` (page 945) Deprecated in Mac OS X v10.4
  A primitive method overridden by subclasses to return a data object that represents the data of the receiver in a given type. (Deprecated. Use `dataOfType:error:` (page 944) instead.)
- `fileAttributesToWriteToFile:ofType:saveOperation:` (page 946) Deprecated in Mac OS X v10.4
  Returns the file attributes that should be written to the named document file of the specified type. (Deprecated. Use

`fileAttributesToWriteToURL:ofType:forSaveOperation:originalContentsURL:error:` (page 946) instead.)

- `fileName` (page 948) Deprecated in Mac OS X v10.4
  Returns the filename (as a fully qualified path) under which the receiver has been saved. (Deprecated. Use `fileURL` (page 951) instead.)
- `fileWrapperRepresentationOfType:` (page 952) Deprecated in Mac OS X v10.4
  Returns an NSFileWrapper object that represents the data of the receiver in a given type. (Deprecated. Use `fileWrapperOfType:error:` (page 951) instead.)
- `initWithContentsOfFile:ofType:` (page 956) Deprecated in Mac OS X v10.4
  Initializes and returns an `NSDocument` object. (Deprecated. Use `initWithContentsOfURL:ofType:error:` (page 957) instead.)
- `initWithContentsOfURL:ofType:` (page 956) Deprecated in Mac OS X v10.4
  Initializes and returns an NSDocument object of a given document type. (Deprecated. Use `initWithContentsOfURL:ofType:error:` (page 957) instead.)
- `loadDataRepresentation:ofType:` (page 959) Deprecated in Mac OS X v10.4
  Overridden by subclasses to load document data. (Deprecated. Use `readFromData:ofType:error:` (page 967) instead.)
- `loadFileWrapperRepresentation:ofType:` (page 960) Deprecated in Mac OS X v10.4
  Loads document data from a given file wrapper. (Deprecated. Use `readFromFileWrapper:ofType:error:` (page 969) instead.)
- `printShowingPrintPanel:` (page 967) Deprecated in Mac OS X v10.4
  Overridden by subclasses to print the current document's (the receiver's) data. (Deprecated. Use `printDocumentWithSettings:showPrintPanel:delegate:didPrintSelector:contextInfo:` (page 965) instead.)
- `readFromFile:ofType:` (page 968) Deprecated in Mac OS X v10.4
  Reads and loads document data of the given type from the given file. (Deprecated. Use `readFromURL:ofType:error:` (page 970) instead.)
- `readFromURL:ofType:` (page 969) Deprecated in Mac OS X v10.4
  Reads and loads document data. (Deprecated. Use `readFromURL:ofType:error:` (page 970) instead.)
- `revertToSavedFromFile:ofType:` (page 972) Deprecated in Mac OS X v10.4
  Reverts the receiver to the data stored in the file system. (Deprecated. Use `revertToContentsOfURL:ofType:error:` (page 971) instead.)
- `revertToSavedFromURL:ofType:` (page 972) Deprecated in Mac OS X v10.4
  Reverts the receiver. (Deprecated. Use `revertToContentsOfURL:ofType:error:` (page 971) instead.)
- `runModalPageLayoutWithPrintInfo:` (page 973) Deprecated in Mac OS X v10.4
  Runs the page layout modal panel with the receiver's printing information object. (Deprecated. Use `runModalPageLayoutWithPrintInfo:delegate:didRunSelector:contextInfo:` (page 973) instead.)
- `saveToFile:saveOperation:delegate:didSaveSelector:contextInfo:` (page 978) Deprecated in Mac OS X v10.4
  Called after the user has been given the opportunity to select a destination through the modal Save panel. (Deprecated. Use `saveToURL:ofType:forSaveOperation:delegate:didSaveSelector:contextInfo:` (page 979) instead.)

- `setFileName:` (page 981) Deprecated in Mac OS X v10.4
  Sets the file (filename and directory path) under which document data is saved. (Deprecated. Use `setFileURL:` (page 982) instead.)
- `writeToFile:ofType:` (page 995) Deprecated in Mac OS X v10.4
  Writes document data to a file. (Deprecated. Use `writeToURL:ofType:error:` (page 996) instead.)
- `writeToFile:ofType:originalFile:saveOperation:` (page 995) Deprecated in Mac OS X v10.4
  Writes the receiver document's contents to a file. (Deprecated. Use `writeToURL:ofType:forSaveOperation:originalContentsURL:error:` (page 997) instead.)
- `writeToURL:ofType:` (page 996) Deprecated in Mac OS X v10.4
  Writes document data to a URL. (Deprecated. Use `writeToURL:ofType:error:` (page 996) instead.)
- `writeWithBackupToFile:ofType:saveOperation:` (page 998) Deprecated in Mac OS X v10.4
  This method is called by action methods to save document contents to a file. (Deprecated. Use `writeSafelyToURL:ofType:forSaveOperation:error:` (page 994) instead.)

Class Methods

canConcurrentlyReadDocumentsOfType:

Returns a Boolean value indicating whether the receiver reads multiple documents of the given type concurrently.

```
+ (BOOL)canConcurrentlyReadDocumentsOfType:(NSString *)typeName
```

Parameters

typeName
The string that identifies the document type.

Return Value

`NO` by default; subclasses can override to return `YES`, thereby causing documents of the specified type to be read concurrently.

Discussion

Your `NSDocument` subclass can implement this method to return `YES` to enable loading of documents concurrently, using background threads. When this facility is enabled in this way, `initWithContentsOfURL:ofType:error:` (page 957) executes on a background thread when opening files via the Open panel or from the Finder. This allows concurrent reading of multiple documents and also allows the application to be responsive while reading a large document.

The default implementation of this method returns `NO`. A subclass override should return `YES` only for document types whose reading is thread-safe, as described in "Multicore Considerations" (page 930). You should disable undo registration during document reading, which is a good idea even in the absence of concurrency.

If you are checking the current Apple Event for a search string, you should not enable concurrent document opening, because code handling a document opening triggered by an Apple Event cannot get the current Apple Event. This happens because the event is suspended until all documents are read to enable correct reporting of success or error.

Availability

Available in Mac OS X v10.6 and later.

See Also
+ readableTypes (page 939)

Declared In
NSDocument.h

isNativeType:

Returns a Boolean value indicating whether document data of the specified type is a native type—one the receiver can both read and write.

```
+ (BOOL)isNativeType:(NSString *)aType
```

Parameters

aType
The string that identifies the document type to test.

Return Value
YES if the document type is a native type; otherwise, NO.

Availability
Available in Mac OS X v10.0 and later.

See Also
+ readableTypes (page 939)
+ writableTypes (page 940)

Declared In
NSDocument.h

readableTypes

Returns the types of data the receiver can read natively and any types filterable to that native type.

```
+ (NSArray *)readableTypes
```

Return Value
An array of NSString objects representing the readable document types.

Availability
Available in Mac OS X v10.0 and later.

See Also
+ isNativeType: (page 939)
+ writableTypes (page 940)
+ canConcurrentlyReadDocumentsOfType: (page 938)

Related Sample Code

iSpend

Declared In
NSDocument.h

writableTypes

Returns the types of data the receiver can write natively and any types filterable to that native type.

```
+ (NSArray *)writableTypes
```

Return Value
An array of `NSString` objects representing the writable document types.

Availability
Available in Mac OS X v10.0 and later.

See Also
`+ isNativeType:` (page 939)
`+ readableTypes` (page 939)

Related Sample Code

ImageApp
iSpend

Declared In
`NSDocument.h`

Instance Methods

addWindowController:

Adds the specified window controller to the array of window controllers associated with the receiver.

```
- (void)addWindowController:(NSWindowController *)aController
```

Parameters
aController
The window controller that is added.

Discussion
An `NSDocument` object uses this list when it displays all document windows, sets window edited status upon an undo or redo operation, and modifies window titles. The method also sets the document outlet of the window controller to `self` if it is not already set. If you create window controllers by overriding `windowNibName` (page 992), this method is invoked automatically. If you create window controllers in `makeWindowControllers` (page 961) or in any other context, such as in response to a user event, you should invoke this method for each created window controller. To remove a window controller from the list of active controllers, send it the `NSWindowController` message `close` (page 3432).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSDocument.h`

autosavedContentsFileURL

Returns the location of the most recently autosaved document contents.

```
- (NSURL *)autosavedContentsFileURL
```

Return Value
The location of the most recently autosaved document contents.

Discussion
The default implementation of this method just returns whatever was stored by a previous invocation of the default implementation of `setAutosavedContentsFileURL:` (page 980).

Availability
Available in Mac OS X v10.4 and later.

See Also
`- setAutosavedContentsFileURL:` (page 980)

Declared In
`NSDocument.h`

autosaveDocumentWithDelegate:didAutosaveSelector:contextInfo:

Autosaves the document's contents at an appropriate location.

```
- (void)autosaveDocumentWithDelegate:(id)delegate
    didAutosaveSelector:(SEL)didAutosaveSelector contextInfo:(void *)contextInfo
```

Parameters

delegate
The delegate to which the selector message is sent.

didAutosaveSelector
The selector of the message sent to the delegate.

contextInfo
Object passed with the callback to provide any additional context information.

Discussion
After autosaving, sends the message selected by *didAutosaveSelector* to the delegate, with *contextInfo* as the last argument. The method selected by *didAutosaveSelector* must have the same signature as:

```
- (void)document:(NSDocument *)document didAutosave:(BOOL)didAutosaveSuccessfully
  contextInfo:(void *)contextInfo
```

If an error occurs while autosaving, the method reports it to the user before sending the delegate a `succeeded:NO` message.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `autosavedContentsFileURL` (page 941)

Declared In
`NSDocument.h`

autosavingFileType

Returns the document type that should be used for an autosave operation.

```
- (NSString *)autosavingFileType
```

Return Value
The string that identifies the document type.

Discussion
The default implementation just returns `[self fileType]`. You can override this method and return `nil` in your override to completely disable autosaving of individual documents (because `NSDocumentController` does not send `autosaveDocumentWithDelegate:didAutosaveSelector:contextInfo:` to a document that has no autosaving file type). You can also override it if your application defines a document type that is specifically designed for autosaving, for example, one that efficiently represents document content changes instead of complete document contents.

Overriding `autosavingFileType` can result in incorrect behavior during reopening of autosaved documents. The `NSDocument` method `initForURL:withContentsOfURL:ofType:error:` (page 955), which is invoked during reopening of autosaved documents after a crash, takes two URLs, but only the type name of the autosaved contents file. The default implementation invokes `[self setFileType:]` with that type name, but that may not be the right thing to do if `autosavingFileType` returned something other than `fileType` (page 950) during document autosaving. If you override `autosavingFileType`, you probably need to override `initForURL:withContentsOfURL:ofType:error:` (page 955) too, and make the override invoke `setFileType:` (page 982) with the type of the actual document file, after invoking `super`. See TextEdit's `Document` class for an example of how to do this.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`NSDocument.h`

canCloseDocument

This method is no longer supported. (Available in Mac OS X v10.0 through Mac OS X v10.3. Use `canCloseDocumentWithDelegate:shouldCloseSelector:contextInfo:` (page 943) instead.)

```
- (BOOL)canCloseDocument
```

Availability
Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared In
NSDocument.h

canCloseDocumentWithDelegate:shouldCloseSelector:contextInfo:

If the receiver is not dirty, this method immediately calls the *shouldCloseSelector* callback on the specified delegate with YES.

```
- (void)canCloseDocumentWithDelegate:(id)delegate
    shouldCloseSelector:(SEL)shouldCloseSelector contextInfo:(void *)contextInfo
```

Parameters

delegate
The delegate to which the selector message is sent.

shouldCloseSelector
The selector of the message sent to the delegate.

contextInfo
Object passed with the callback to provide any additional context information.

Discussion
If the receiver is dirty, an alert is presented giving the user a chance to save, not save, or cancel. If the user chooses to save, this method saves the document. If the save completes successfully, this method calls the callback with YES. If the save is canceled or otherwise unsuccessful, this method calls the callback with NO. This method may be called by `shouldCloseWindowController:delegate:shouldCloseSelector:contextInfo:` (page 986). It is also called by the NSDocumentController method `closeAllDocuments`. You should call it before you call `close` (page 943) if you are closing the document and want to give the user a chance to save any edits. Pass the *contextInfo* object with the callback.

The *shouldCloseSelector* callback method should have the following signature:

```
- (void)document:(NSDocument *)doc shouldClose:(BOOL)shouldClose
contextInfo:(void  *)contextInfo
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSDocument.h

close

Closes all windows owned by the receiver and removes the receiver from the list of documents maintained by the document controller, which consequently releases it.

```
- (void)close
```

Discussion
This method closes the document immediately, without asking users if they want to save the document.

This method may not always be called. Additional information on application termination can be found in Graceful Application Termination.

Availability
Available in Mac OS X v10.0 and later.

ZipBrowser

Declared In
`NSDocument.h`

dataOfType:error:

Creates and returns a data object that contains the contents of the document, formatted to a specified type.

```
- (NSData *)dataOfType:(NSString *)typeName error:(NSError **)outError
```

Parameters

typeName
The string that identifies the document type.

outError
On return, If the data object could not be created, a pointer to an error object that encapsulates the reason it could not be created.

Return Value
A data object containing the document contents, or, if the data object could not be created, `nil`.

Discussion
The default implementation of this method throws an exception because at least one of the writing methods (this method, `writeToURL:ofType:error:` (page 996), `fileWrapperOfType:error:` (page 951), or `writeToURL:ofType:forSaveOperation:originalContentsURL:error:` (page 997)) must be overridden.

For backward binary compatibility with Mac OS X v10.3 and earlier, the default implementation of this method instead invokes `dataRepresentationOfType:`*typeName* on `self` if `dataRepresentationOfType:` is overridden.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `writeToURL:ofType:error:` (page 996)

- fileWrapperOfType:error: (page 951)

Declared In
NSDocument.h

dataRepresentationOfType:

A primitive method overridden by subclasses to return a data object that represents the data of the receiver in a given type. (Deprecated in Mac OS X v10.4. Use dataOfType:error: (page 944) instead.)

```
- (NSData *)dataRepresentationOfType:(NSString *)aType
```

Discussion
A primitive method overridden by subclasses to return a data object that represents the data of the receiver in a given type (*aType*). The default implementation raises an NSInternalInconsistencyException. This method is invoked by the default implementation of fileWrapperRepresentationOfType:.

aType is the type name corresponding to the value of the CFBundleTypeName entry in the document type's Info.plist dictionary.

Here is a typical implementation:

```
//Document type name
NSString *MyDocumentType = @"Rich Text Format (RTF) document";

...

- (NSData *)dataRepresentationOfType:(NSString *)aType {
    NSAssert([aType isEqualToString:MyDocumentType], @"Unknown  type");
    return [textView RTFFromRange:NSMakeRange(0, [[textView textStorage]
length])];
}
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

See Also
- loadDataRepresentation:ofType: (page 959)

Related Sample Code
FinalCutPro_AppleEvents

Declared In
NSDocument.h

displayName

Returns the name of the receiver as displayed in the title bars of the document's windows and in alert dialogs related to the document.

```
- (NSString *)displayName
```

Return Value
The display name of the receiver.

Discussion
If the document has been saved, the display name is the last component of the directory location of the saved file (for example, "`MyDocument`" if the path is "`/tmp/MyDocument.rtf`"). If the document is new, `NSDocument` makes the display name "Untitled *n*," where *n* is a number in a sequence of new and unsaved documents. The displayable name also takes into account whether the document's filename extension should be hidden. Subclasses of `NSWindowController` can override `windowTitleForDocumentDisplayName:` (page 3444) to modify the display name as it appears in window titles.

Availability
Available in Mac OS X v10.0 and later.

`NSDocument.h`

fileAttributesToWriteToFile:ofType:saveOperation:

Returns the file attributes that should be written to the named document file of the specified type. (Deprecated in Mac OS X v10.4. Use `fileAttributesToWriteToURL:ofType:forSaveOperation:originalContentsURL:error:` (page 946) instead.)

```
- (NSDictionary *)fileAttributesToWriteToFile:(NSString *)fullDocumentPath
    ofType:(NSString *)docType saveOperation:(NSSaveOperationType)saveOperationType
```

Discussion
Returns the file attributes that should be written to the named document file of the specified type *docType*, as part of a particular *saveOperationType*. The set of valid file attributes is a subset of those understood by the `NSFileManager` class.

Availability
Available in Mac OS X v10.1 and later.
Deprecated in Mac OS X v10.4.

Declared In
`NSDocument.h`

fileAttributesToWriteToURL:ofType:forSaveOperation:originalContentsURL:error:

As a file is being saved, returns the attributes that should be written to a file or file package located by a URL, formatted to a specified type, for a particular kind of save operation.

```
- (NSDictionary *)fileAttributesToWriteToURL:(NSURL *)absoluteURL ofType:(NSString
    *)typeName forSaveOperation:(NSSaveOperationType)saveOperation
   originalContentsURL:(NSURL *)absoluteOriginalContentsURL error:(NSError
   **)outError
```

Parameters

absoluteURL

The location to which the document is being written.

typeName

The string that identifies the document type.

saveOperation

The type of save operation.

absoluteOriginalContentsURL

The location of the previously saved copy of the document (if not `nil`).

outError

On return, If the attributes could not be returned, a pointer to an error object that encapsulates the reason they could not be returned.

Return Value

A dictionary containing the attributes to be written, or `nil` if unsuccessful.

Discussion

The set of valid file attributes is a subset of those understood by the `NSFileManager` class. The default implementation of this method returns a dictionary with `NSFileHFSCreatorCode` and `NSFileHFSTypeCode` entries that have a value of 0 for `NSSaveOperation`, or a dictionary with an appropriate `NSFileExtensionHidden` entry for `NSSaveAsOperation` and `NSSaveToOperation`. You can override this method to customize the attributes that are written to document files.

This method is meant to be used just for attributes that need to be written for the first time, for `NSSaveAsOperation` and `NSSaveToOperation`.

Invokers of this method should silently ignore invalid attributes. Of particular interest is the `NSFileExtensionHidden` attribute, which is documented in `NSFileManager`.

Your subclass of `NSDocument` can override this method to control the attributes that are set during a save operation. An override of this method should return a copy of the dictionary returned by its superclass's version of this method, with appropriate alterations.

The dictionary returned by the default implementation of this method contains an `NSFileExtensionHidden` entry when that is appropriate. For Save As or Export commands (`NSSaveAsOperation` or `NSSaveToOperation`) the attributes dictionary contains an `NSFileExtensionHidden` entry whose value is the result of `[self fileNameExtensionWasHiddenInLastRunSavePanel]`. For autosaving (`NSAutosaveOperation`) the contents of documents that have already been saved (that is, not untitled documents), there's an `NSFileExtensionHidden` entry whose value is the same as that in the file attributes dictionary for the document itself, so the autosaved file has the same name extension hiding as the real document.

An override of `writeSafelyToURL:ofType:forSaveOperation:error:` (page 994) should invoke this method and set the returned attributes on the written document file, possibly using the `NSFileManager` method `changeFileAttributes:atPath:`.

Implementers of overrides of this method should not assume that:

- The file pointed to by *absoluteURL* at the moment the method is invoked, if there is one, is related to the document itself. It may be an unrelated file that is about to be overwritten.
- The `fileURL` (page 951) or `fileType` (page 950) method will return anything useful at the moment.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`NSDocument.h`

fileModificationDate

Returns the last known modification date of the document's on-disk representation.

```
- (NSDate *)fileModificationDate
```

Return Value
The file modification date.

Discussion
The `NSDocument` default file saving machinery uses this information to warn the user when the on-disk representation of an open document has been modified by something other than the current application.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- setFileModificationDate:` (page 981)

Declared In
`NSDocument.h`

fileName

Returns the filename (as a fully qualified path) under which the receiver has been saved. (Deprecated in Mac OS X v10.4. Use `fileURL` (page 951) instead.)

```
- (NSString *)fileName
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

See Also
`- setFileName:` (page 981)

Related Sample Code
QTAudioExtractionPanel
QTKitPlayer

Declared In
`NSDocument.h`

fileNameExtensionForType:saveOperation:

Returns a filename extension that can be appended to a base filename, for a specified file type and kind of save operation.

```
- (NSString *)fileNameExtensionForType:(NSString *)typeName
    saveOperation:(NSSaveOperationType)saveOperation
```

Parameters

typeName
The file type.

saveOperation
The kind of save operation.

Return Value
The filename extension.

Discussion
The default implementation of this method invokes `preferredFileNameExtensionForType:` on the shared workspace object if the type is a UTI or, if it is not, for backward binary compatibility with Mac OS X v10.4 and earlier, invokes `fileExtensionsFromType:` (page 1015) on the shared document controller and chooses the first filename extension in the returned array.

You can override this method to customize the appending of extensions to filenames by `NSDocument`. In Mac OS X v10.5, it's only invoked from two places in the Application Kit:

1. The `autosaveDocumentWithDelegate:didAutosaveSelector:contextInfo:` (page 941) method uses this method when creating a new filename for the autosaved contents.

2. The `handleSaveScriptCommand:` (page 953) method uses this method when adding an extension to the filename specified by a script.

In all other cases, the name of any file being saved will have been fully specified by the user with the Save panel (whether they know it or not).

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSDocument.h`

fileNameExtensionWasHiddenInLastRunSavePanel

Returns `YES` if a Save panel was presented by this document and the user chose to hide the name extension of the file that was selected in that Save panel.

```
- (BOOL)fileNameExtensionWasHiddenInLastRunSavePanel
```

Return Value
`YES` if a Save panel was presented and the user chose to hide the extension; otherwise, `NO`.

Availability
Available in Mac OS X v10.1 and later.

Declared In
NSDocument.h

fileNameFromRunningSavePanelForSaveOperation:

Returns the filename entered into the Save panel. (Available in Mac OS X v10.0 through Mac OS X v10.3. Use `saveDocumentWithDelegate:didSaveSelector:contextInfo:` (page 978) instead.)

```
- (NSString
    *)fileNameFromRunningSavePanelForSaveOperation:(NSSaveOperationType)saveOperation
```

Availability
Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared In
NSDocument.h

fileType

Returns the document type under which the receiver is saved.

```
- (NSString *)fileType
```

Return Value
The string that identifies the document type.

Discussion
When a document is saved, the type is determined by the entries in the application's information property list (specified in `Info.plist`).

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setFileType:` (page 982)

Related Sample Code
ImageApp
ThreadsExporter
ThreadsImporter
ThreadsImportMovie

Declared In
NSDocument.h

fileTypeFromLastRunSavePanel

Returns the file type that was last selected in the Save panel.

```
- (NSString *)fileTypeFromLastRunSavePanel
```

Return Value
The string that identifies the document type.

Discussion
This type is primarily used by the `saveDocument:` (page 976), `saveDocumentAs:` (page 977), and `saveDocumentTo:` (page 977) methods to determine the type the user chose after the Save panel has been run.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
ImageApp

Declared In
`NSDocument.h`

fileURL

Returns the location of the document's on-disk representation.

```
- (NSURL *)fileURL
```

Return Value
The document's location.

Discussion
The default implementation of this method returns whatever was stored by a previous invocation of the default implementation of `setFileURL:` (page 982). For backward binary compatibility with Mac OS X v10.3 and earlier, if `fileName` (page 948) is overridden, the default implementation of this method instead invokes `[self fileName]` and returns the result as a URL.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- setFileURL:` (page 982)

Declared In
`NSDocument.h`

fileWrapperOfType:error:

Creates and returns a file wrapper that contains the contents of the document, formatted to the specified type.

```
- (NSFileWrapper *)fileWrapperOfType:(NSString *)typeName error:(NSError **)outError
```

Parameters

typeName

The string that identifies the document type.

outError

On return, If the file wrapper could not be created, a pointer to an error object that encapsulates the reason it could not be created.

Return Value

A file wrapper containing the document contents, or, if the file wrapper could not be created, `nil`.

Discussion

For backward binary compatibility with Mac OS X v10.3 and earlier, if `fileWrapperRepresentationOfType:` (page 952) is overridden, the default implementation of this method instead invokes `[self fileWrapperRepresentationOfType:typeName]`.

Availability

Available in Mac OS X v10.4 and later.

See Also

`- dataOfType:error:` (page 944)

Declared In

`NSDocument.h`

fileWrapperRepresentationOfType:

Returns an NSFileWrapper object that represents the data of the receiver in a given type. (Deprecated in Mac OS X v10.4. Use `fileWrapperOfType:error:` (page 951) instead.)

```
- (NSFileWrapper *)fileWrapperRepresentationOfType:(NSString *)aType
```

Discussion

Returns an `NSFileWrapper` object that represents the data of the receiver in a given type (*aType*). This method invokes `dataRepresentationOfType:` to get the data object from which to create a plain-file file wrapper. Subclasses can override this method if `dataRepresentationOfType:` is not adequate for their needs. This method is invoked by the default implementation of `writeToFile:ofType:` (page 995).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

See Also

`- loadFileWrapperRepresentation:ofType:` (page 960)

Declared In

`NSDocument.h`

handleCloseScriptCommand:

Handles the Close AppleScript command by attempting to close the document.

```
- (id)handleCloseScriptCommand:(NSCloseCommand *)command
```

Parameters

command

A Close AppleScript command object.

Discussion

Extracts Close command arguments from the *command* object and uses them to determine how to close the document—specifically, whether to ignore unsaved changes, save changes automatically, or ask the user and to identify the file in which to save the document (by default, the file that was opened or previously saved to). A Close AppleScript command may specify more than one document to close. If so, a message is sent to each document object.

Availability

Available in Mac OS X v10.0 and later.

Declared In

NSDocumentScripting.h

handlePrintScriptCommand:

Handles the Print AppleScript command by attempting to print the document.

```
- (id)handlePrintScriptCommand:(NSScriptCommand *)command
```

Parameters

command

An AppleScript command object.

Discussion

Extracts Print command arguments from the *command* object and uses them to determine how to print the document—specifically, any print settings and whether to show the Print dialog. A Print AppleScript command may specify more than one document to print. If so, a message is sent to each document.

Availability

Available in Mac OS X v10.0 and later.

Declared In

NSDocumentScripting.h

handleSaveScriptCommand:

Handles the Save AppleScript command by attempting to save the document.

```
- (id)handleSaveScriptCommand:(NSScriptCommand *)command
```

Parameters

command

An AppleScript command object.

Discussion

Extracts Save command arguments from the *command* object and uses them to determine the file in which to save the document and the file type.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSDocumentScripting.h

hasUnautosavedChanges

Return YES if the document has changes that have not been autosaved, as determined by the history of previous invocations of updateChangeCount: (page 988).

```
- (BOOL)hasUnautosavedChanges
```

Return Value
YES if the document has changes that have not been autosaved; otherwise, NO.

Availability
Available in Mac OS X v10.4 and later.

Declared In
NSDocument.h

hasUndoManager

Returns a Boolean value indicating whether the receiver owns or should own an NSUndoManager object.

```
- (BOOL)hasUndoManager
```

Return Value
YES if the receiver has its own undo manager; otherwise, NO.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setHasUndoManager: (page 983)

Declared In
NSDocument.h

init

Initializes and returns an empty NSDocument object.

```
- (id)init
```

Return Value
An initialized NSDocument object.

Discussion
This initializer (the designated initializer) is invoked by each of the other NSDocument initialization methods.

You can override this method to perform initialization that must be done both when creating new empty documents and when opening existing documents. Your override must invoke `super` to initialize private `NSDocument` instance variables. It must never return `nil`. If an error can occur during object initialization, check for the error in an override of `initWithType:error:` (page 957), `initWithContentsOfURL:ofType:error:` (page 957), or `initForURL:withContentsOfURL:ofType:error:` (page 955), because those methods can return `NSError` objects.

Availability
Available in Mac OS X v10.0 and later.

QTMetadataEditor
Simple Bindings Adoption
Sketch-112
ZipBrowser

Declared In
`NSDocument.h`

initForURL:withContentsOfURL:ofType:error:

Initializes a document located by a URL of a specified type, but by reading the contents for the document from a different URL.

```
- (id)initForURL:(NSURL *)absoluteDocumentURL withContentsOfURL:(NSURL
    *)absoluteDocumentContentsURL ofType:(NSString *)typeName error:(NSError
    **)outError
```

Parameters

absoluteDocumentURL
The URL where the document is located.

absoluteDocumentContentsURL
The URL from which the contents of the document are obtained.

typeName
The string that identifies the document type.

outError
On return, If initialization is unsuccessful, a pointer to an error object that encapsulates the reason the document could not be created.

Return Value
The initialized `NSDocument` object, or, if the document could not be created, `nil`.

Discussion
The *absoluteDocumentURL* argument is `nil` if the initializing is part of the reopening of an autosaved document when the autosaved document was never explicitly saved.

During reopening of autosaved documents, this method uses the following `NSDocumentChangeType` constant to indicate that an autosaved document is being reopened:

```
NSChangeReadOtherContents
```

Availability
Available in Mac OS X v10.4 and later.

Declared In
NSDocument.h

initWithContentsOfFile:ofType:

Initializes and returns an NSDocument object. (Deprecated in Mac OS X v10.4. Use initWithContentsOfURL:ofType:error: (page 957) instead.)

```
- (id)initWithContentsOfFile:(NSString *)fileName ofType:(NSString *)docType
```

Discussion
Initializes and returns an NSDocument object of document type *docType* containing data stored in the file *fileName*. In opening the file, invokes the readFromFile:ofType: (page 968) method. If the document successfully opens the file, it calls setFileName: and setFileType: (page 982) with *fileName* and *docType*, respectively, as arguments. If the file cannot be opened, or the document is unable to load the contents of the file, this method returns nil. This initializer is typically invoked by the NSDocumentController method makeDocumentWithContentsOfFile:ofType: (page 1017).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Related Sample Code
QTAudioContextInsert
QTAudioExtractionPanel
QTKitAdvancedDocument
QTKitImport
QTKitPlayer

Declared In
NSDocument.h

initWithContentsOfURL:ofType:

Initializes and returns an NSDocument object of a given document type. (Deprecated in Mac OS X v10.4. Use initWithContentsOfURL:ofType:error: (page 957) instead.)

```
- (id)initWithContentsOfURL:(NSURL *)aURL ofType:(NSString *)docType
```

Discussion
Initializes and returns an NSDocument object of document type *docType* containing data stored at *aURL*. In opening the location, invokes the readFromURL:ofType: (page 969) method. If the document successfully opens the location, it calls setFileName: and setFileType: (page 982) with the location's path and *docType*, respectively, as arguments. If the location cannot be opened, or the document is unable to load the contents of the location, this method returns nil. This initializer is typically invoked by the NSDocumentController method makeDocumentWithContentsOfURL:ofType: (page 1018).

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In
NSDocument.h

initWithContentsOfURL:ofType:error:

Initializes a document located by a URL of a specified type.

```
- (id)initWithContentsOfURL:(NSURL *)absoluteURL ofType:(NSString *)typeName
    error:(NSError **)outError
```

Parameters

absoluteURL
The URL from which the contents of the document are obtained.

typeName
The string that identifies the document type.

outError
On return, If initialization is unsuccessful, a pointer to an error object that encapsulates the reason the document could not be created.

Return Value
The initialized NSDocument object, or, if the document could not be created, nil.

Discussion
You can override this method to customize the reopening of autosaved documents.

This method is invoked by the NSDocumentController method makeDocumentWithContentsOfURL:ofType:error: (page 1019). The default implementation of this method invokes init (page 954), readFromURL:ofType:error: (page 970), setFileURL: (page 982), setFileType: (page 982), and setFileModificationDate: (page 981).

For backward binary compatibility with Mac OS X v10.3 and earlier, the default implementation of this method instead invokes initWithContentsOfFile:ofType: (page 956) if it is overridden and the URL uses the file: scheme. It still invokes setFileModificationDate: in this situation.

Availability
Available in Mac OS X v10.4 and later.

Related Sample Code
QTKitCreateMovie
QTKitFrameStepper
QTMetadataEditor

Declared In
NSDocument.h

initWithType:error:

Initializes a document of a specified type.

```
- (id)initWithType:(NSString *)typeName error:(NSError **)outError
```

Parameters

typeName

The string that identifies the document type.

outError

On return, If initialization is unsuccessful, a pointer to an error object that encapsulates the reason the document could not be created.

Return Value
The initialized `NSDocument` object, or, if the document could not be created, `nil`.

Discussion
The default implementation of this method just invokes `[self init]` and `[self setFileType:typeName]`.

You can override this method to perform initialization that must be done when creating new documents but should not be done when opening existing documents. Your override should typically invoke `super`, or at least it must invoke `init` (page 954), the `NSDocument` designated initializer, to initialize the `NSDocument` private instance variables.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`NSDocument.h`

isDocumentEdited

Returns `YES` if the receiver has changes that have not been saved, `NO` otherwise.

```
- (BOOL)isDocumentEdited
```

Return Value
`YES` if the receiver has been edited; otherwise, `NO`.

Discussion
The edited status of each document window reflects the document's edited status.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- updateChangeCount:` (page 988)
`- setDocumentEdited:` (page 3379) (NSWindow)

Related Sample Code
FunHouse

Declared In
`NSDocument.h`

keepBackupFile

Returns a Boolean value indicating whether the receiver should keep the backup files created before document data is written to a file (`NO` by default).

```
- (BOOL)keepBackupFile
```

Return Value
NO by default; subclasses can override to return YES, thereby causing backup files to be kept.

Availability
Available in Mac OS X v10.0 and later.

See Also
- writeToFile:ofType: (page 995)

Declared In
NSDocument.h

lastComponentOfFileName

Returns the document name in terms of the scripting name property (the name a script writer would use to specify the document in a script).

```
- (NSString *)lastComponentOfFileName
```

Return Value
The scripting name of the document.

Discussion
Note that this name may be different than the name returned by fileName (page 948) or used in methods such as writeToFile:ofType: (page 995).

Availability
Available in Mac OS X v10.0 and later.

See Also
- displayName (page 945)

Declared In
NSDocumentScripting.h

loadDataRepresentation:ofType:

Overridden by subclasses to load document data. (Deprecated in Mac OS X v10.4. Use readFromData:ofType:error: (page 967) instead.)

```
- (BOOL)loadDataRepresentation:(NSData *)docData ofType:(NSString *)docType
```

Discussion
Overridden by subclasses to load document data (*docData*) of type *docType* into the receiver, display it in windows, and return whether the operation was successful. This method is typically invoked by loadFileWrapperRepresentation:ofType: (page 960) after an NSData object is created from the contents of the file wrapper (which can include directories). The default implementation raises an NSInternalInconsistencyException. Subclasses must override this method unless they override readFromFile:ofType: (page 968) or loadFileWrapperRepresentation:ofType: (page 960) to do specialized reading and loading of document data.

The *docType* argument is the type name corresponding to the value of the `CFBundleTypeName` entry in the document type's `Info.plist` dictionary.

Here is an example implementation:

```
//Document type name
NSString *MyDocumentType = @"Rich Text Format (RTF) document";

...

- (BOOL)loadDataRepresentation:(NSData *)data ofType:(NSString *)aType  {
    NSAssert([aType isEqualToString: MyDocumentType], @"Unknown  type");
    fileContents = [data copyWithZone:[self zone]];
    return YES;
}
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

See Also
`- dataRepresentationOfType:` (page 945)

Related Sample Code
FinalCutPro_AppleEvents

Declared In
`NSDocument.h`

loadFileWrapperRepresentation:ofType:

Loads document data from a given file wrapper. (Deprecated in Mac OS X v10.4. Use `readFromFileWrapper:ofType:error:` (page 969) instead.)

```
- (BOOL)loadFileWrapperRepresentation:(NSFileWrapper *)wrapper ofType:(NSString
    *)docType
```

Discussion
Loads document data in file wrapper *wrapper* of type *docType* into the receiver, displays it in windows, and returns whether the operation was successful. If *wrapper* is a simple file, it invokes `loadDataRepresentation:ofType:` (page 959) to load the data. If *wrapper* is a directory, it returns `NO` by default; subclasses can override to handle file wrappers that are directories. This method is typically invoked by `readFromFile:ofType:` (page 968) after it creates an NSData object from the contents of the file.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

See Also
`- fileWrapperRepresentationOfType:` (page 952)

Declared In
`NSDocument.h`

makeWindowControllers

Subclasses may override this method to create the initial window controller(s) for the document.

```
- (void)makeWindowControllers
```

Discussion
The base class implementation creates an `NSWindowController` object with `windowNibName` (page 992) and with the document as the file's owner if `windowNibName` (page 992) returns a name. If you override this method to create your own window controllers, be sure to use `addWindowController:` (page 940) to add them to the document after creating them.

This method is called by the `NSDocumentController` `open...` methods, but you might want to call it directly in some circumstances.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- windowControllers` (page 991)

Declared In
`NSDocument.h`

objectSpecifier

Returns an object specifier for the document.

```
- (NSScriptObjectSpecifier *)objectSpecifier
```

Return Value
The document object specifier.

Discussion
An object specifier represents an AppleScript reference form, which is a natural-language expression such as `words 10 through 20` or `front document`. During script processing, an object contained by a document (such as the `second paragraph` or the `third rectangle`) may need to specify its container (the document).

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
QuickLookSketch
Sketch+Accessibility

Declared In
`NSDocumentScripting.h`

preparePageLayout:

Invoked by `runModalPageLayoutWithPrintInfo:` (page 973) and `runModalPageLayoutWithPrintInfo:delegate:didRunSelector:contextInfo:` (page 973) to do any customization of the Page Layout panel *pageLayout*, such as adding an accessory view.

```
- (BOOL)preparePageLayout:(NSPageLayout *)pageLayout
```

Parameters

pageLayout

The page layout panel to prepare.

Return Value

`YES` if successfully prepared; otherwise, `NO`.

Discussion

The default implementation is empty and returns `YES`.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSDocument.h`

prepareSavePanel:

Invoked by `runModalSavePanelForSaveOperation:delegate:didSaveSelector:contextInfo:` (page 975) to do any customization of the given Save panel.

```
- (BOOL)prepareSavePanel:(NSSavePanel *)savePanel
```

Parameters

savePanel

The Save panel.

Return Value

`YES` if successfully prepared; otherwise, `NO`.

Discussion

The default implementation is empty and returns `YES`.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSDocument.h`

presentError:

Presents an error alert to the user as a modal panel.

```
- (BOOL)presentError:(NSError *)error
```

Parameters

error

The error object encapsulating the information to present to the user.

Return Value

`YES` if error recovery was done; otherwise, `NO`.

Discussion

This method does not return until the user dismisses the alert and, if the error has recovery options and a recovery delegate, the error's recovery delegate is sent an `attemptRecoveryFromError:optionIndex:` message.

The `NSDocument` default implementation of this method is equivalent to that of `NSResponder` and treats the shared `NSDocumentController` as the next responder and forwards these messages to it.

The default implementation of this method invokes `willPresentError:` (page 989) to give subclasses an opportunity to customize error presentation. You should not override this method but should instead override `willPresentError:` (page 989).

Availability

Available in Mac OS X v10.4 and later.

See Also

- `willPresentError:` (page 989)
- `presentError:modalForWindow:delegate:didPresentSelector:contextInfo:` (page 963)

Declared In

`NSDocument.h`

presentError:modalForWindow:delegate:didPresentSelector:contextInfo:

Presents an error alert to the user as a modal panel.

```
- (void)presentError:(NSError *)error modalForWindow:(NSWindow *)window
    delegate:(id)delegate didPresentSelector:(SEL)didPresentSelector
    contextInfo:(void *)contextInfo
```

Parameters

error

The error object encapsulating the information to present to the user.

window

The window to which the modal alert belongs.

delegate

The delegate to which the selector message is sent.

didPresentSelector

The selector of the message sent to the delegate.

contextInfo

Object passed with the callback to provide any additional context information.

Discussion

When the user dismisses the alert and any recovery possible for the error and chosen by the user has been attempted, sends the message *didPresentSelector* to the specified *delegate*.

The NSDocument default implementation of this method is equivalent to that of NSResponder and treats the shared NSDocumentController object as the next responder and forwards these messages to it. The default implementations of several NSDocument methods invoke this method.

The default implementation of this method invokes willPresentError: (page 989) to give subclasses an opportunity to customize error presentation. You should not override this method but should instead override willPresentError:.

The method selected by *didPresentSelector* must have the same signature as:

```
- (void)didPresentErrorWithRecovery:(BOOL)didRecover contextInfo:(void
*)contextInfo
```

Availability
Available in Mac OS X v10.4 and later.

printDocumentWithSettings:showPrintPanel:delegate:didPrintSelector:contextInfo:

Prints the document.

```
- (void)printDocumentWithSettings:(NSDictionary *)printSettings
    showPrintPanel:(BOOL)showPrintPanel delegate:(id)delegate
    didPrintSelector:(SEL)didPrintSelector contextInfo:(void *)contextInfo
```

Parameters

printSettings

The print settings dictionary to use.

showPrintPanel

A Boolean value indicating whether the print panel is shown.

delegate

The delegate to which the selector message is sent.

didPrintSelector

The selector of the message sent to the delegate.

contextInfo

Object passed with the callback to provide any additional context information.

Discussion

If showing of the print panel is specified by *showPrintPanel*, the method presents it first and prints only if the user approves the panel. The `NSPrintInfo` attributes in the passed-in *printSettings* dictionary are added to a copy of the document's print info, and the resulting print info settings are used for the operation. When printing is complete or canceled, the method sends the message selected by *didPrintSelector* to the *delegate*, with the *contextInfo* as the last argument. The method selected by *didPrintSelector* must have the same signature as:

```
- (void)document:(NSDocument *)document didPrint:(BOOL)didPrintSuccessfully
contextInfo: (void *)contextInfo
```

The default implementation of this method invokes `printOperationWithSettings:error:` (page 966). If `nil` is returned it presents the error to the user in a document-modal panel before messaging the delegate. Otherwise it invokes `[thePrintOperation setShowsPrintPanel:showPrintPanel]` then `[self runModalPrintOperation:thePrintOperation delegate:delegate didRunSelector:didPrintSelector contextInfo:contextInfo]`.

For backward binary compatibility with Mac OS X v10.3 and earlier, the default implementation of this method invokes `printShowingPrintPanel:` (page 967) if it is overridden. When doing this it uses private functionality to arrange for the print settings to take effect (despite the fact that the override of `printShowingPrintPanel:` can't possibly know about them) and to get notified when the print operation has been completed, so it can message the delegate at the correct time. Correct messaging of the delegate is necessary for correct handling of the Print Apple event.

Availability

Available in Mac OS X v10.4 and later.

See Also

- `printOperationWithSettings:error:` (page 966)

Declared In

`NSDocument.h`

printInfo

Returns the receiver's customized `NSPrintInfo` object or the default `NSPrintInfo` instance.

```
- (NSPrintInfo *)printInfo
```

Return Value
The receiver's `NSPrintInfo` object.

Discussion
The document's copy of the `NSPrintInfo` object can either be directly set or set as a result of running the Page Layout panel. A subclass can override this method to always return the shared `NSPrintInfo` instance if it does not want its own copy.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `runPageLayout:` (page 975)
- `setPrintInfo:` (page 984)
- `shouldChangePrintInfo:` (page 985)

Declared In
`NSDocument.h`

printOperationWithSettings:error:

Creates a print operation and returns it if successful.

```
- (NSPrintOperation *)printOperationWithSettings:(NSDictionary *)printSettings
    error:(NSError **)outError
```

Parameters
printSettings
The print settings dictionary to use.

outError
On return, If the print operation could not be created, a pointer to an error object that encapsulates the reason it could not be created.

Return Value
The print operation, or `nil` if unsuccessful.

Discussion
The print operation can be run to print the document's current contents. The `NSPrintInfo` attributes in the passed-in *`printSettings`* dictionary are added to a copy of the document's print info, and the resulting print info is used for the operation. The default implementation of this method does nothing. You must override it to enable printing in your application.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- printDocumentWithSettings:showPrintPanel:delegate:didPrintSelector:contextInfo:` (page 965)

Declared In
`NSDocument.h`

printShowingPrintPanel:

Overridden by subclasses to print the current document's (the receiver's) data. (Deprecated in Mac OS X v10.4. Use `printDocumentWithSettings:showPrintPanel:delegate:didPrintSelector:contextInfo:` (page 965) instead.)

```
- (void)printShowingPrintPanel:(BOOL)flag
```

Discussion
Overridden by subclasses to print the current document's (the receiver's) data; if *`flag`* is `YES`, the implementation should first display the Print panel. This method is typically invoked by `printDocument:` with an argument of `YES`. The default implementation does nothing. If there is any printing information other than that encoded in the receiver's `NSPrintInfo` object, subclasses should get it here.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

See Also
`- printInfo` (page 966)

Declared In
`NSDocument.h`

readFromData:ofType:error:

Sets the contents of this document by reading from data of a specified type and returns `YES` if successful.

```
- (BOOL)readFromData:(NSData *)data ofType:(NSString *)typeName error:(NSError
    **)outError
```

Parameters

`data`

The data object from which the document contents are read.

typeName
The string that identifies the document type.

outError
On return, If the document contents could not be read, a pointer to an error object that encapsulates the reason they could not be read.

Return Value
`YES` if the document contents could be read; otherwise, `NO`.

Discussion
The default implementation of this method throws an exception because at least one of the three reading methods (this method, `readFromURL:ofType:error:` (page 970), `readFromFileWrapper:ofType:error:` (page 969)), or every method that may invoke `readFromURL:ofType:error:` (page 970), must be overridden.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`NSDocument.h`

readFromFile:ofType:

Reads and loads document data of the given type from the given file. (Deprecated in Mac OS X v10.4. Use `readFromURL:ofType:error:` (page 970) instead.)

```
- (BOOL)readFromFile:(NSString *)fileName ofType:(NSString *)docType
```

Discussion
Reads and loads document data of type *docType* from the file *fileName*, returning whether the operation was successful. This method invokes `loadDataRepresentation:ofType:` and is invoked when the receiver is first created and initialized by `initWithContentsOfFile:ofType:`. It uses `NSData initWithContentsOfFile:` to get the document data.

This method is one of the location-based primitives. Subclasses can override this method instead of overriding `loadDataRepresentation:ofType:` to read and load document data. Subclasses that handle file packages such as RTFD or that treat locations of files as anything other than paths should override this method. Override implementations of this method can filter the document data using `NSPasteboard` or other filtering services.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

See Also
`- dataRepresentationOfType:` (page 945)
`- writeToFile:ofType:` (page 995)

Declared In
`NSDocument.h`

readFromFileWrapper:ofType:error:

Sets the contents of this document by reading from a file wrapper of a specified type.

```
- (BOOL)readFromFileWrapper:(NSFileWrapper *)fileWrapper ofType:(NSString *)typeName
    error:(NSError **)outError
```

Parameters

fileWrapper

The file wrapper from which the document contents are read.

typeName

The string that identifies the document type.

outError

On return, If the document contents could not be read, a pointer to an error object that encapsulates the reason they could not be read.

Return Value

`YES` if the document contents could be read; otherwise, `NO`.

Discussion

The default implementation of this method invokes `[self readFromData:[fileWrapper regularFileContents] ofType:typeName error:outError]`.

For backward binary compatibility with Mac OS X v10.3 and earlier, the default implementation of this method instead invokes `[self loadFileWrapperRepresentation:fileWrapper ofType:typeName]` if `loadFileWrapperRepresentation:ofType:` (page 960) is overridden.

Availability

Available in Mac OS X v10.4 and later.

See Also

- `readFromURL:ofType:error:` (page 970)
- `readFromData:ofType:error:` (page 967)

Declared In

`NSDocument.h`

readFromURL:ofType:

Reads and loads document data. (Deprecated in Mac OS X v10.4. Use `readFromURL:ofType:error:` (page 970) instead.)

```
- (BOOL)readFromURL:(NSURL *)aURL ofType:(NSString *)docType
```

Discussion

Reads and loads document data of type *docType* from the URL *aURL*, returning whether the operation was successful. This method only supports URLs of the `file:` scheme and calls `readFromFile:ofType:` (page 968).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In
NSDocument.h

readFromURL:ofType:error:

Sets the contents of this document by reading from a file or file package, of a specified type, located by a URL.

```
- (BOOL)readFromURL:(NSURL *)absoluteURL ofType:(NSString *)typeName error:(NSError **)outError
```

Parameters

absoluteURL
The location from which the document contents are read.

typeName
The string that identifies the document type.

outError
On return, If the document contents could not be read, a pointer to an error object that encapsulates the reason they could not be read.

Return Value
YES if the document contents could be read; otherwise, NO.

Discussion
The default implementation of this method just creates an NSFileWrapper and invokes `[self readFromFileWrapper:theFileWrapper ofType:typeName error:outError]`.

For backward binary compatibility with Mac OS X v10.3 and earlier, the default implementation of this method instead invokes `[self readFromFile:[absoluteURL path] ofType:typeName]` if `readFromFile:ofType:` (page 968) is overridden and the URL uses the `file:` scheme.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `readFromFileWrapper:ofType:error:` (page 969)
- `readFromData:ofType:error:` (page 967)

Declared In
NSDocument.h

removeWindowController:

Removes the specified window controller from the receiver's array of window controllers.

```
- (void)removeWindowController:(NSWindowController *)windowController
```

Parameters

windowController
The window controller that is removed.

Discussion
A document with no window controllers is not necessarily closed. However, a window controller can be set to close its associated document when the window is closed or the window controller is deallocated.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `shouldCloseDocument` (page 3440) (`NSWindowController`)

Declared In
`NSDocument.h`

revertDocumentToSaved:

The action of the File menu item Revert in a document-based application.

```
- (void)revertDocumentToSaved:(id)sender
```

Parameters

sender
The control sending the message.

Discussion
The default implementation of this method presents an alert dialog giving the user the opportunity to cancel the operation. If the user chooses to continue, the method ensures that any editor registered using the Cocoa Bindings `NSEditorRegistration` informal protocol has discarded its changes and then invokes `revertToContentsOfURL:ofType:error:` (page 971). If that returns `NO`, the method presents the error to the user in an document-modal alert dialog.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `updateChangeCount:` (page 988)

Declared In
`NSDocument.h`

revertToContentsOfURL:ofType:error:

Discards all unsaved document modifications and replaces the document's contents by reading a file or file package located by a URL of a specified type.

```
- (BOOL)revertToContentsOfURL:(NSURL *)absoluteURL ofType:(NSString *)typeName
    error:(NSError **)outError
```

Parameters

absoluteURL
The location from which the document contents are read.

typeName
The string that identifies the document type.

outError
On return, If the document could not be reverted, a pointer to an error object that encapsulates the reason it could not be reverted.

Return Value
YES if the document could be reverted; otherwise, NO.

Availability
Available in Mac OS X v10.4 and later.

Declared In
NSDocument.h

revertToSavedFromFile:ofType:

Reverts the receiver to the data stored in the file system. (Deprecated in Mac OS X v10.4. Use revertToContentsOfURL:ofType:error: (page 971) instead.)

```
- (BOOL)revertToSavedFromFile:(NSString *)fileName ofType:(NSString *)type
```

Discussion
Reverts the receiver to the data stored in the file system in file named *fileName* of file type *type*. Invokes readFromFile:ofType: (page 968) and returns whether that method successfully read the file and processed the document data.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

See Also
- revertDocumentToSaved: (page 971)

Declared In
NSDocument.h

revertToSavedFromURL:ofType:

Reverts the receiver. (Deprecated in Mac OS X v10.4. Use revertToContentsOfURL:ofType:error: (page 971) instead.)

```
- (BOOL)revertToSavedFromURL:(NSURL *)aURL ofType:(NSString *)type
```

Discussion
Reverts the receiver to the data stored at *aURL* of type *type*. Invokes readFromURL:ofType: (page 969) and returns whether that method successfully read the file and processed the document data.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

See Also
- revertDocumentToSaved: (page 971)

Declared In
NSDocument.h

runModalPageLayoutWithPrintInfo:

Runs the page layout modal panel with the receiver's printing information object. (Deprecated in Mac OS X v10.4. Use runModalPageLayoutWithPrintInfo:delegate:didRunSelector:contextInfo: (page 973) instead.)

```
- (NSInteger)runModalPageLayoutWithPrintInfo:(NSPrintInfo *)printInfo
```

Discussion
Runs the page layout modal panel with the receiver's printing information object (*printInfo*) as argument and returns the result constant (indicating the button pressed by the user). To run as sheet on the receiver's document window, use runModalPageLayoutWithPrintInfo:delegate:didRunSelector:contextInfo: (page 973) instead.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

See Also
- shouldChangePrintInfo: (page 985)
- runModalWithPrintInfo: (page 1857) (NSPageLayout)

Declared In
NSDocument.h

runModalPageLayoutWithPrintInfo:delegate:didRunSelector:contextInfo:

Runs the modal page layout panel with the receiver's printing information object

```
- (void)runModalPageLayoutWithPrintInfo:(NSPrintInfo *)printInfo
    delegate:(id)delegate didRunSelector:(SEL)didRunSelector contextInfo:(void
    *)contextInfo
```

Parameters
printInfo
The NSPrintInfo object for the page layout panel to use.
delegate
The delegate to which the selector message is sent.
didRunSelector
The selector of the message sent to the delegate.
contextInfo
Object passed with the callback to provide any additional context information.

Discussion
Invoked from the action method runPageLayout: (page 975). Presents the page layout panel application modally if there is no document window to which it can be presented document modally.

When the panel is dismissed, *delegate* is sent a *didRunSelector* message. The *didRunSelector* callback method should have the following signature:

```
- (void)documentDidRunModalPageLayout:(NSDocument *)document
accepted:(BOOL)accepted  contextInfo:(void *)contextInfo
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSDocument.h

runModalPrintOperation:delegate:didRunSelector:contextInfo:

Runs the specified print operation modally.

```
- (void)runModalPrintOperation:(NSPrintOperation *)printOperation
    delegate:(id)delegate didRunSelector:(SEL)didRunSelector contextInfo:(void
    *)contextInfo
```

Parameters

printOperation
The print operation to run.

delegate
The delegate to which the selector message is sent.

didRunSelector
The selector of the message sent to the delegate.

contextInfo
Object passed with the callback to provide any additional context information.

Discussion
Overrides of `printShowingPrintPanel:` (page 967) can invoke this method.

When the panel is dismissed, *delegate* is sent a *didRunSelector* message. Pass the *contextInfo* object with the callback. The *didRunSelector* callback method should have the following signature:

```
- (void)documentDidRunModalPrintOperation:(NSDocument *)document
success:(BOOL)success  contextInfo:(void *)contextInfo
```

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
QTAudioContextInsert
QTAudioExtractionPanel
QTKitImport
QTKitPlayer

Declared In
NSDocument.h

runModalSavePanelForSaveOperation:delegate:didSaveSelector:contextInfo:

Presents a modal Save panel to the user, then tries to save the document if the user approves the panel.

```
- (void)runModalSavePanelForSaveOperation:(NSSaveOperationType)saveOperation
    delegate:(id)delegate didSaveSelector:(SEL)didSaveSelector contextInfo:(void
    *)contextInfo
```

Parameters

saveOperation
The type of save operation.

delegate
The delegate to which the selector message is sent.

didSaveSelector
The selector of the message sent to the delegate.

contextInfo
Object passed with the callback to provide any additional context information.

Discussion
When saving is completed, regardless of success or failure, or has been canceled, sends the message selected by *didSaveSelector* to the *delegate*, with *contextInfo* as the last argument. The method selected by *didSaveSelector* must have the same signature as:

```
- (void)document:(NSDocument *)doc didSave:(BOOL)didSave contextInfo:(void
*)contextInfo
```

Invoked from `saveDocumentWithDelegate:didSaveSelector:contextInfo:` (page 978), and the action methods `saveDocumentAs:` (page 977) and `saveDocumentTo:` (page 977). The default implementation of this method first makes sure that any editor registered using the Cocoa Bindings `NSEditorRegistration` informal protocol has committed its changes, then creates a Save panel, adds a standard file format accessory view (if there is more than one file type for the user to choose from and `shouldRunSavePanelWithAccessoryView` (page 987) returns `YES`), sets various attributes of the panel, invokes `prepareSavePanel:` (page 962) to provide an opportunity for customization, then presents the panel. If the user approves the panel, the default implementation sends the message `saveToURL:ofType:forSaveOperation:delegate:didSaveSelector:contextInfo:` (page 979).

For backward binary compatibility with Mac OS 10.3 and earlier, the default implementation of this method instead invokes the deprecated `saveToFile:saveOperation:delegate:didSaveSelector:contextInfo:` (page 978) if it is overridden, even if the user cancels the panel.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSDocument.h`

runPageLayout:

The action method invoked in the receiver as first responder when the user chooses the Page Setup menu command.

```
- (void)runPageLayout:(id)sender
```

Parameters

sender

The control sending the message.

Discussion

The default implementation invokes `runModalPageLayoutWithPrintInfo:delegate:didRunSelector:contextInfo:` (page 973) with the document's current NSPrintInfo object as argument; if the user clicks the OK button and the document authorizes changes to its printing information (`shouldChangePrintInfo:` (page 985)), the method sets the document's new `NSPrintInfo` object and increments the document's change count.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `setPrintInfo:` (page 984)
- `updateChangeCount:` (page 988)

Declared In

`NSDocument.h`

saveDocument:

The action method invoked in the receiver as first responder when the user chooses the Save menu command.

```
- (void)saveDocument:(id)sender
```

Parameters

sender

The control sending the message.

Discussion

The default implementation saves the document in two different ways, depending on whether the document has a file path and a document type assigned. If path and type are assigned, it simply writes the document under its current file path and type after making a backup copy of the previous file. If the document is new (no file path and type), it runs the modal Save panel to get the file location under which to save the document. It writes the document to this file, sets the document's file location and document type (if a native type), and clears the document's edited status.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `saveDocumentWithDelegate:didSaveSelector:contextInfo:` (page 978)
- `setFileName:` (page 981)
- `setFileType:` (page 982)
- `updateChangeCount:` (page 988)

Declared In

`NSDocument.h`

saveDocumentAs:

The action method invoked in the receiver as first responder when the user chooses the Save As menu command.

```
- (void)saveDocumentAs:(id)sender
```

Parameters

sender

The control sending the message.

Discussion

The default implementation runs the modal Save panel to get the file location under which to save the document. It writes the document to this file, sets the document's file location and document type (if a native type), and clears the document's edited status.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `saveDocumentWithDelegate:didSaveSelector:contextInfo:` (page 978)
- `setFileName:` (page 981)
- `setFileType:` (page 982)
- `updateChangeCount:` (page 988)

Declared In

`NSDocument.h`

saveDocumentTo:

The action method invoked in the receiver as first responder when the user chooses the Save To menu command.

```
- (void)saveDocumentTo:(id)sender
```

Parameters

sender

The control sending the message.

Discussion

The default implementation is identical to `saveDocumentAs:` except that this method doesn't clear the document's edited status and doesn't reset file location and document type if the document is a native type.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `saveDocumentWithDelegate:didSaveSelector:contextInfo:` (page 978)

Declared In

`NSDocument.h`

saveDocumentWithDelegate:didSaveSelector:contextInfo:

Saves the document.

```
- (void)saveDocumentWithDelegate:(id)delegate didSaveSelector:(SEL)didSaveSelector
    contextInfo:(void *)contextInfo
```

Parameters

delegate

The delegate to which the selector message is sent.

didSaveSelector

The selector of the message sent to the delegate.

contextInfo

Object passed with the callback to provide any additional context information.

Discussion

If an `NSSaveOperation` can be performed without further user intervention (at the very least, neither `fileURL` (page 951) nor `fileType` (page 950) return `nil`), then the method immediately saves the document. Otherwise, it presents a Save panel to the user and saves the document if the user approves the panel. When saving has been completed or canceled, the method sends the message selected by *didSaveSelector* to the *delegate*, with the *contextInfo* as the last argument.

As of Mac OS X v10.5, this method checks to see if the document's file has been modified since the document was opened or most recently saved or reverted, in addition to the checking for file moving, renaming, and trashing that it has done since Mac OS X v10.1. When it senses file modification it presents an alert telling the user "This document's file has been changed by another application since you opened or saved it," giving them the choice of saving or not saving. For backward binary compatibility this is only done in applications linked against Mac OS X v10.5 or later.

The *didSaveSelector* callback method should have the following signature:

```
- (void)document:(NSDocument *)doc didSave:(BOOL)didSave contextInfo:(void
*)contextInfo
```

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSDocument.h`

saveToFile:saveOperation:delegate:didSaveSelector:contextInfo:

Called after the user has been given the opportunity to select a destination through the modal Save panel. (Deprecated in Mac OS X v10.4. Use `saveToURL:ofType:forSaveOperation:delegate:didSaveSelector:contextInfo:` (page 979) instead.)

```
- (void)saveToFile:(NSString *)fileName
    saveOperation:(NSSaveOperationType)saveOperation delegate:(id)delegate
    didSaveSelector:(SEL)didSaveSelector contextInfo:(void *)contextInfo
```

Discussion
Called after the user has been given the opportunity to select a destination through the modal Save panel presented by `runModalSavePanelForSaveOperation:delegate:didSaveSelector:contextInfo:` (page 975). The *`delegate`* is assigned to the Save panel. If *`fileName`* is non-`nil`, this method writes the document to *`fileName`*, sets the document's file location and document type (if a native type), and clears the document's edited status. *`didSaveSelector`* gets called with `YES` if the document is saved successfully, and `NO` otherwise. The *`saveOperation`* is one of the constants in "Constants" (page 999). Pass *`contextInfo`* with the callback.

The *`didSaveSelector`* callback method should have the following signature:

```
- (void)document:(NSDocument *)doc didSave:(BOOL)didSave contextInfo:(void
*)contextInfo
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`NSDocument.h`

saveToURL:ofType:forSaveOperation:delegate:didSaveSelector:contextInfo:

Saves the contents of the document to a file or file package located by a URL, formatted to a specified type, for a particular kind of save operation.

```
- (void)saveToURL:(NSURL *)absoluteURL ofType:(NSString *)typeName
    forSaveOperation:(NSSaveOperationType)saveOperation delegate:(id)delegate
    didSaveSelector:(SEL)didSaveSelector contextInfo:(void *)contextInfo
```

Parameters

`absoluteURL`
The location of the file or file package to which the document contents are saved.

`typeName`
The string that identifies the document type.

`saveOperation`
The type of save operation.

`delegate`
The delegate to which the selector message is sent.

`didSaveSelector`
The selector of the message sent to the delegate.

`contextInfo`
Object passed with the callback to provide any additional context information.

Discussion
When saving is completed, regardless of success or failure, the method sends the message selected by *`didSaveSelector`* to the *`delegate`*, with the *`contextInfo`* as the last argument. The method selected by *`didSaveSelector`* must have the same signature as:

```
- (void)document:(NSDocument *)document didSave:(BOOL)didSaveSuccessfully
contextInfo:(void  *)contextInfo;
```

The default implementation of this method invokes `[self saveToURL:absoluteURL ofType:typeName forSaveOperation:saveOperation error:&anError]` and, if `NO` is returned, presents the error to the user in a document-modal panel before messaging the delegate.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- saveToURL:ofType:forSaveOperation:error:` (page 980)

Declared In
`NSDocument.h`

saveToURL:ofType:forSaveOperation:error:

Saves the contents of the document to a file or file package located by a URL, formatted to a specified type, for a particular kind of save operation, and returns `YES` if successful.

```
- (BOOL)saveToURL:(NSURL *)absoluteURL ofType:(NSString *)typeName
    forSaveOperation:(NSSaveOperationType)saveOperation error:(NSError **)outError
```

Parameters

absoluteURL
The location of the file or file package to which the document contents are saved.

typeName
The string that identifies the document type.

saveOperation
The type of save operation.

outError
On return, If the document contents could not be saved, a pointer to an error object that encapsulates the reason they could not be saved.

Return Value
`YES` if the document contents were successfully saved; otherwise, `NO`.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- saveToURL:ofType:forSaveOperation:delegate:didSaveSelector:contextInfo:` (page 979)

Declared In
`NSDocument.h`

setAutosavedContentsFileURL:

Sets the location of the most recently autosaved document contents.

```
- (void)setAutosavedContentsFileURL:(NSURL *)absoluteURL
```

Parameters

absoluteURL

The location of the most recently autosaved document contents.

Discussion

The default implementation of this method records the URL and notifies the shared document controller that this document should be automatically reopened if the application quits or crashes before the document is saved.

Availability

Available in Mac OS X v10.4 and later.

See Also

- autosavedContentsFileURL (page 941)

Declared In

NSDocument.h

setFileModificationDate:

Sets the last known modification date of the document's on-disk representation to the given modification date.

```
- (void)setFileModificationDate:(NSDate *)modificationDate
```

Parameters

modificationDate

The date to which the file modification date is set.

Discussion

The NSDocument default file saving machinery uses this information to warn the user when the on-disk representation of an open document has been modified by something other than the current application.

Availability

Available in Mac OS X v10.4 and later.

See Also

- fileModificationDate (page 948)

Declared In

NSDocument.h

setFileName:

Sets the file (filename and directory path) under which document data is saved. (Deprecated in Mac OS X v10.4. Use setFileURL: (page 982) instead.)

```
- (void)setFileName:(NSString *)fileName
```

Discussion

Sets the file (filename and directory path) under which document data is saved to *fileName*. As a side effect, synchronizes the titles of the document's windows with the new name or location. A document's filename is automatically set when it is saved as a new document (Save) and when an existing document is saved

under a different filename or path (Save As). The Finder also keeps track of open documents and their associated files. When a user moves or renames a file in the Finder that corresponds to an open document, the Finder calls `setFileName:` with the new filename.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

See Also
`- fileName` (page 948)

Declared In
`NSDocument.h`

setFileType:

Sets the document type under which the file is saved.

```
- (void)setFileType:(NSString *)docType
```

Parameters
docType
The string that identifies the document type.

Discussion
The document type affects how the data is filtered when it is written to or read from a file. This method isn't for changing the document's format; it's just for initially recording the document's format during opening or saving.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSDocument.h`

setFileURL:

Sets the location of the document's on-disk representation.

```
- (void)setFileURL:(NSURL *)absoluteURL
```

Parameters
absoluteURL
The document's location.

Discussion
This method doesn't actually rename the document; it's just for recording the document's location during initial opening or saving. The default implementation of this method just records the URL so that the default implementation of `fileURL` (page 951) can return it.

For backward binary compatibility with Mac OS X v10.3 and earlier, if `setFileName:` (page 981) is overridden and the URL is `nil` or uses the `file:` scheme, the default implementation of this method instead invokes `[self setFileName:[absoluteURL path]]`.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `fileURL` (page 951)

QTMetadataEditor

Declared In
`NSDocument.h`

setHasUndoManager:

Sets whether the receiver has its own `NSUndoManager` object.

```
- (void)setHasUndoManager:(BOOL)flag
```

Parameters
flag
A Boolean value setting whether the receiver should own an `NSUndoManager` object.

Discussion
If *flag* is `NO` and the receiver currently owns an `NSUndoManager` object, the `NSUndoManager` object is released after being removed as an observer of undo-related notifications.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `hasUndoManager` (page 954)

Declared In
`NSDocument.h`

setLastComponentOfFileName:

Sets the document name to the given string in terms of the scripting name property (the name a script writer would use to specify the document in a script).

```
- (void)setLastComponentOfFileName:(NSString *)str
```

Parameters

str

The scripting name of the document.

Discussion

Note that this name may be different than the name used in `setFileName:` (page 981).

Availability

Available in Mac OS X v10.0 and later.

See Also

`- displayName` (page 945)

Declared In

`NSDocumentScripting.h`

setPrintInfo:

Sets the receiver's `NSPrintInfo` object.

```
- (void)setPrintInfo:(NSPrintInfo *)printInfo
```

Parameters

printInfo

The `NSPrintInfo` object for the receiver to use.

Discussion

This `NSPrintInfo` object is used in laying out the document for printing.

Availability

Available in Mac OS X v10.0 and later.

See Also

`- printInfo` (page 966)

Declared In

`NSDocument.h`

setUndoManager:

Sets the undo manager owned by the receiver to the specified undo manager and releases any undo manager currently owned by the receiver.

```
- (void)setUndoManager:(NSUndoManager *)undoManager
```

Parameters

undoManager

The undo manager to be owned by the receiver; may be `nil`.

Discussion

If *undoManager* is `nil`, it turns off the `hasUndoManager` flag. If *undoManager* is non-`nil`, it adds the receiver as an observer of `NSUndoManagerDidUndoChangeNotification`, `NSUndoManagerDidRedoChangeNotification`, and `NSUndoManagerWillCloseUndoGroupNotification`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- undoManager (page 988)

Declared In
NSDocument.h

setWindow:

Sets the window Interface Builder outlet of this class.

```
- (void)setWindow:(NSWindow *)aWindow
```

Parameters

aWindow

The window to which the receiver's window outlet points.

Discussion
This method is invoked automatically during the loading of any nib for which this document is the file's owner, if the file's owner window outlet is connected in the nib. You should not invoke this method directly, and typically you would not override it either.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSDocument.h

shouldChangePrintInfo:

Returns a Boolean value indicating whether the receiver should allow changes to the default NSPrintInfo object used in printing the document.

```
- (BOOL)shouldChangePrintInfo:(NSPrintInfo *)newPrintInfo
```

Parameters

newPrintInfo

The NSPrintInfo object that is the result of the user approving the page layout panel presented by runPageLayout: (page 975).

Return Value
YES by default; subclasses can override this method to return NO.

Discussion
This method is invoked by the runPageLayout: (page 975) method, which sets a new NSPrintInfoobject for the document only if this method returns YES.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSDocument.h

shouldCloseWindowController:

Gives the user an opportunity to save the document. (Available in Mac OS X v10.0 through Mac OS X v10.3. Use `shouldCloseWindowController:delegate:shouldCloseSelector:contextInfo:` (page 986) instead.)

```
- (BOOL)shouldCloseWindowController:(NSWindowController *)windowController
```

Discussion

If closing the *windowController* would cause the receiver to be closed, invokes `canCloseDocumentWithDelegate:shouldCloseSelector:contextInfo:` (page 943) to display a Save panel and give the user an opportunity to save the document. Returns the return value of `canCloseDocumentWithDelegate:shouldCloseSelector:contextInfo:`. Note that the receiver doesn't close until its window controller closes.

Availability

Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared In

`NSDocument.h`

shouldCloseWindowController:delegate:shouldCloseSelector:contextInfo:

Invokes *shouldCloseSelector* with the result of `canCloseDocumentWithDelegate:shouldCloseSelector:contextInfo:` (page 943) if the the specified window controller that is closing is the last one or is marked as causing the document to close.

```
- (void)shouldCloseWindowController:(NSWindowController *)windowController
    delegate:(id)delegate shouldCloseSelector:(SEL)shouldCloseSelector
    contextInfo:(void *)contextInfo
```

Parameters

windowController
: The window controller that is closed.

delegate
: The delegate to which the selector message is sent.

shouldCloseSelector
: The selector of the message sent to the delegate.

contextInfo
: Object passed with the callback to provide any additional context information.

Discussion

Otherwise it invokes *shouldCloseSelector* with `YES`. This method is called automatically by `NSWindow` for any window that has a window controller and a document associated with it. `NSWindow` calls this method prior to sending its *delegate* the `windowShouldClose:` message. Pass the *contextInfo* object with the callback.

The *shouldCloseSelector* callback method should have the following signature:

```
- (void)document:(NSDocument *)document shouldClose:(BOOL)shouldClose
contextInfo:(void  *)contextInfo
```

Availability

Available in Mac OS X v10.0 and later.

Declared In
NSDocument.h

shouldRunSavePanelWithAccessoryView

Returns YES by default; as a result, when NSDocument displays the Save panel, it includes an accessory view containing a pop-up menu of supported writable document types.

```
- (BOOL)shouldRunSavePanelWithAccessoryView
```

Return Value
YES by default; subclasses can override to return NO, thereby excluding the accessory view from the Save panel.

Discussion
Here is an example implementation:

```
- (BOOL)shouldRunSavePanelWithAccessoryView {
    return [self fileName] == nil;
}
```

Availability
Available in Mac OS X v10.0 and later.

See Also
- runModalSavePanelForSaveOperation:delegate:didSaveSelector:contextInfo: (page 975)

Declared In
NSDocument.h

showWindows

Displays all of the document's windows, bringing them to the front and making them main or key as necessary.

```
- (void)showWindows
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSDocument.h

undoManager

Returns the receiver's undo manager.

```
- (NSUndoManager *)undoManager
```

Return Value
The `NSUndoManager` object used by the receiver or `nil` if the receiver should not own one.

Discussion
If the undo manager doesn't exist and `hasUndoManager` returns `YES`, the method creates one and invokes `setUndoManager:` with the `NSUndoManager` as argument.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSDocument.h`

updateChangeCount:

Updates the receiver's change count according to the given change type.

```
- (void)updateChangeCount:(NSDocumentChangeType)changeType
```

Parameters
changeType
The type of change made to the document.

Discussion
The change count indicates the document's edited status; if the change count is 0, the document has no changes to save, and if the change count is greater than 0, the document has been edited and is unsaved. The *changeType* is described in "Constants" (page 999). If you are implementing undo and redo in an application, you should increment the change count every time you create an undo group and decrement the change count when an undo or redo operation is performed.

Note that if you are using the `NSDocument` default undo/redo features, setting the document's edited status by updating the change count happens automatically. You only need to invoke this method when you are not using these features.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
QTAudioExtractionPanel
QTKitImport
QTKitPlayer

StillMotion

Declared In
NSDocument.h

validateMenuItem:

Validates the Revert menu item and items selected from the Save panel's pop-up list of writable document types items. (Available in Mac OS X v10.0 through Mac OS X v10.3. Use `validateUserInterfaceItem:` (page 989) instead.)

```
- (BOOL)validateMenuItem:(NSMenuItem *)anItem
```

Discussion
Returns `YES` if *anItem* should be enabled, `NO` otherwise. Returns `YES` for Revert if the document has been edited and a file exists for the document. Returns `YES` for an item representing a writable type if, during a Save or Save As operation, it is a native type for the document. Subclasses can override this method to perform additional validations.

Availability
Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared In
NSDocument.h

validateUserInterfaceItem:

Validates the specified user interface item that the receiver manages.

```
- (BOOL)validateUserInterfaceItem:(id < NSValidatedUserInterfaceItem >)anItem
```

Parameters
anItem
The user interface item to validate.

Return Value
`YES` if the item is valid; otherwise, `NO`.

Discussion
These items currently include only Revert (which is enabled only if the document has a `fileName` (page 948)) and Save. You can override this method to add more selectors validated by your document subclass.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSDocument.h

willPresentError:

Called when the receiver is about to present an error.

```
- (NSError *)willPresentError:(NSError *)error
```

Parameters

error

The error object that is about to be presented to the user.

Return Value

The error that should actually be presented.

Discussion

The default implementation of this method merely returns the passed-in error. The returned error may simply be forwarded to the document controller.

You can override this method to customize the presentation of errors by examining the passed-in error and, for example, returning more specific information. When you override this method always check the `NSError` object's domain and code to discriminate between errors whose presentation you want to customize and those you don't. For errors you don't want to customize, call the superclass implementation, passing the original error.

Availability

Available in Mac OS X v10.4 and later.

See Also

- `presentError:` (page 962)
- `presentError:modalForWindow:delegate:didPresentSelector:contextInfo:` (page 963)

Declared In

`NSDocument.h`

windowControllerDidLoadNib:

Sent after the specified window controller loads a nib file if the receiver is the nib file's owner.

```
- (void)windowControllerDidLoadNib:(NSWindowController *)windowController
```

Parameters

windowController

The window controller that loads the nib file.

Discussion

See the class description for NSWindowController for additional information about nib files and the file's owner object.

Typically an `NSDocument` subclass overrides `windowNibName` (page 992) or `makeWindowControllers` (page 961), but not both. If `windowNibName` is overridden, the default implementation of `makeWindowControllers` will load the named nib file, making the `NSDocument` object the nib file's owner. In that case, you can override `windowControllerDidLoadNib:` and do custom processing after the nib file is loaded.

The default implementation of this method does nothing.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `windowControllerWillLoadNib:` (page 991)

- windowControllers (page 991)

QTRecorder
Sketch-112

Declared In
NSDocument.h

windowControllerWillLoadNib:

Sent before the specified window controller loads a nib file if the receiver is the nib file's owner.

```
- (void)windowControllerWillLoadNib:(NSWindowController *)windowController
```

Parameters
windowController
The window controller that loads the nib file.

Discussion
See the class description for NSWindowController for additional information about nib files and the file's owner object.

Typically an `NSDocument` subclass overrides `windowNibName` (page 992) or `makeWindowControllers` (page 961), but not both. If `windowNibName` is overridden, the default implementation of `makeWindowControllers` will load the named nib file, making the NSDocument the nib file's owner. In that case, you can override `windowControllerWillLoadNib:` and do custom processing before the nib file is loaded.

The default implementation of this method does nothing.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `windowControllerDidLoadNib:` (page 990)
- `windowControllers` (page 991)

Declared In
`NSDocument.h`

windowForSheet

Returns the most appropriate window, of the windows associated with the receiver, to use as the parent window of a document-modal sheet.

```
- (NSWindow *)windowForSheet
```

Return Value
The window to use as the parent window of the sheet.

Discussion
May return `nil`, in which case the sender should present an application-modal panel. The `NSDocument` implementation of this method returns the window of the first window controller, or `[NSApp mainWindow]` if there are no window controllers or if the first window controller has no window.

Availability
Available in Mac OS X v10.3 and later.

Related Sample Code
MovieAssembler
MyMediaPlayer

Declared In
`NSDocument.h`

windowNibName

Overridden by subclasses to return the name of the document's sole nib file.

```
- (NSString *)windowNibName
```

Return Value
The name of the document nib file.

Discussion
Using this name, `NSDocument` creates and instantiates a default instance of `NSWindowController` to manage the window. If your document has multiple nib files, each with its own single window, or if the default `NSWindowController` instance is not adequate for your purposes, you should override `makeWindowControllers`.

The default implementation returns `nil`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSDocument.h`

writableTypesForSaveOperation:

Returns the names of the types to which this document can be saved for a specified kind of save operation.

```
- (NSArray *)writableTypesForSaveOperation:(NSSaveOperationType)saveOperation
```

Parameters

saveOperation
The kind of save operation.

Return Value
An array of `NSString` objects representing the writable document types.

Discussion
The save operation type is represented by *saveOperation*. For every kind of save operation except `NSSaveToOperation`, the returned array must only include types for which the the application can play the Editor role. For `NSSaveToOperation` the returned array may include types for which the application can only play the Viewer role, and other types that the application can merely export. The default implementation of this method returns `[[self class] writableTypes]` with, except during `NSSaveToOperation`, types for which `isNativeType:` (page 939) returns `NO` filtered out.

You can override this method to limit the set of writable types when the document currently contains data that is not representable in all types. For example, you can disallow saving to RTF files when the document contains an attachment and can only be saved properly to RTFD files.

You can invoke this method when creating a custom save panel accessory view to present easily the same set of types as `NSDocument` does in its standard file format popup menu.

Availability
Available in Mac OS X v10.4 and later.

Declared In
NSDocument.h

writeSafelyToURL:ofType:forSaveOperation:error:

Writes the contents of the document to a file or file package located by a URL.

```
- (BOOL)writeSafelyToURL:(NSURL *)absoluteURL ofType:(NSString *)typeName
    forSaveOperation:(NSSaveOperationType)saveOperation error:(NSError **)outError
```

Parameters

absoluteURL
The location to which the document contents are written.

typeName
The string that identifies the document type.

saveOperation
The type of save operation.

outError
On return, If the document contents could not be written, a pointer to an error object that encapsulates the reason they could not be written.

Return Value
YES if the document contents could be written; otherwise, NO.

Discussion
The default implementation of this method invokes writeToURL:ofType:forSaveOperation:originalContentsURL:error: (page 997). It also invokes fileAttributesToWriteToURL:ofType:forSaveOperation:originalContentsURL:error: (page 946) and writes the returned attributes, if any, to the file. It may copy some attributes from the old on-disk revision of the document at the same time, if applicable.

This method is responsible for doing document writing in a way that minimizes the danger of leaving the disk to which writing is being done in an inconsistent state in the event of an application crash, system crash, hardware failure, power outage, and so on. If you override this method, be sure to invoke the superclass implementation.

For NSSaveOperation, the default implementation of this method invokes keepBackupFile (page 958) to determine whether or not the old on-disk revision of the document, if there was one, should be preserved after being renamed.

For backward binary compatibility with Mac OS X v10.3 and earlier, the default implementation of this method instead invokes writeWithBackupToFile:ofType:saveOperation: (page 998) if that method is is overridden and the URL uses the file: scheme. The save operation in this case is never NSAutosaveOperation; NSSaveToOperation is used instead.

Availability
Available in Mac OS X v10.4 and later.

See Also
- writeToURL:ofType:forSaveOperation:originalContentsURL:error: (page 997)

- fileAttributesToWriteToURL:ofType:forSaveOperation:originalContentsURL:error: (page 946)

QTMetadataEditor

Declared In
NSDocument.h

writeToFile:ofType:

Writes document data to a file. (Deprecated in Mac OS X v10.4. Use writeToURL:ofType:error: (page 996) instead.)

```
- (BOOL)writeToFile:(NSString *)fileName ofType:(NSString *)docType
```

Discussion
Writes document data of type *docType* to the file *fileName*, returning whether the operation was successful. This method invokes dataRepresentationOfType: (page 945) and is indirectly invoked whenever the document file is saved. It uses the NSData method writeToFile:atomically: to write to the file.

This method is one of the location-based primitives. Subclasses can override this method instead of overriding dataRepresentationOfType: to write document data to the file system as an NSData object after creating that object from internal data structures. Subclasses that handle file packages such as RTFD or that treat locations of files as anything other than paths should override this method. Override implementations of this method should ensure that they filter document data appropriately using NSPasteboard filtering services.

See "NSDocument Saving Behavior" (page 929) for additional information about saving documents.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

See Also
- loadDataRepresentation:ofType: (page 959)
- readFromFile:ofType: (page 968)
- writeToFile:ofType:originalFile:saveOperation: (page 995)

Declared In
NSDocument.h

writeToFile:ofType:originalFile:saveOperation:

Writes the receiver document's contents to a file. (Deprecated in Mac OS X v10.4. Use writeToURL:ofType:forSaveOperation:originalContentsURL:error: (page 997) instead.)

```
- (BOOL)writeToFile:(NSString *)fullDocumentPath ofType:(NSString *)docType
    originalFile:(NSString *)fullOriginalDocumentPath
    saveOperation:(NSSaveOperationType)saveOperationType
```

Discussion
This method is called from `writeWithBackupToFile:ofType:saveOperation:` (page 998) to actually write the file of type *docType* to *fullDocumentPath*. *fullOriginalDocumentPath* is the path to the original file if there is one and `nil` otherwise. The default implementation simply calls `writeToFile:ofType:` (page 995). You should not need to call this method directly, but subclasses that need access to the previously saved copy of their document while saving the new one can override this method. The *saveOperationType* argument is one of the constants listed in "Constants" (page 999).

See "NSDocument Saving Behavior" (page 929) for additional information about saving documents.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`NSDocument.h`

writeToURL:ofType:

Writes document data to a URL. (Deprecated in Mac OS X v10.4. Use `writeToURL:ofType:error:` (page 996) instead.)

```
- (BOOL)writeToURL:(NSURL *)aURL ofType:(NSString *)docType
```

Discussion
Writes document data of type *docType* to the URL *aURL*, returning whether the operation was successful. This method only supports URLs of the `file:` scheme and calls `writeToFile:ofType:` (page 995).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`NSDocument.h`

writeToURL:ofType:error:

Writes the contents of the document to a file or file package located by a URL, formatted to a specified type.

```
- (BOOL)writeToURL:(NSURL *)absoluteURL ofType:(NSString *)typeName error:(NSError
    **)outError
```

Parameters

absoluteURL
The location to which the document contents are written.

typeName
The string that identifies the document type.

outError
On return, If the document contents could not be written, a pointer to an error object that encapsulates the reason they could not be written.

Return Value
`YES` if the document contents could be written; otherwise, `NO`.

Discussion
The default implementation of this method just invokes `[self fileWrapperOfType:typeName error:outError]` and writes the returned file wrapper to disk.

For backward binary compatibility with Mac OS X v10.3 and earlier, the default implementation of this method instead invokes `[self writeToFile:[absoluteURL path] ofType:typeName]` if `writeToFile:ofType:` (page 995) is overridden and the URL uses the `file:` scheme.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `fileWrapperOfType:error:` (page 951)
- `dataOfType:error:` (page 944)

Declared In
`NSDocument.h`

writeToURL:ofType:forSaveOperation:originalContentsURL:error:

Writes the contents of the document to a file or file package located by a URL.

```
- (BOOL)writeToURL:(NSURL *)absoluteURL ofType:(NSString *)typeName
    forSaveOperation:(NSSaveOperationType)saveOperation originalContentsURL:(NSURL
     *)absoluteOriginalContentsURL error:(NSError **)outError
```

Parameters

absoluteURL
The location to which the document contents are written.

typeName
The string that identifies the document type.

saveOperation
The type of save operation.

absoluteOriginalContentsURL
The location of the previously saved copy of the document (if not `nil`).

outError
On return, If the document contents could not be written, a pointer to an error object that encapsulates the reason they could not be written.

Return Value
`YES` if the document contents could be written; otherwise, `NO`.

Discussion
The default implementation of this method merely invokes `[self writeToURL:absoluteURL ofType:typeName error:outError]`. You can override this method instead of one of the three simple writing methods (`writeToURL:ofType:error:` (page 996), `fileWrapperOfType:error:` (page 951), and `dataOfType:error:` (page 944)) if your document writing machinery needs access to the on-disk representation of the document revision that is about to be overwritten. The value of *absoluteURL* is often not the same as `[self fileURL]`. Other times it is not the same as the URL for the final save destination.

Likewise, *absoluteOriginalContentsURL* is often not the same value as `[self fileURL]`. If *absoluteOriginalContentsURL* is `nil`, either the document has never been saved or the user deleted the document file since it was opened.

For backward binary compatibility with Mac OS X v10.3 and earlier, if `writeToFile:ofType:originalFile:saveOperation:` (page 995) is overridden and both URLs use the `file:` scheme, the default implementation of this method instead invokes:

```
[self writeToFile:[absoluteURL path]
      ofType:typeName
      originalFile:[absoluteOriginalContentsURL path]
      saveOperation:aSaveOperation];
```

The save operation used in this case is never `NSAutosaveOperation`; `NSSaveToOperation` is used instead.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`NSDocument.h`

writeWithBackupToFile:ofType:saveOperation:

This method is called by action methods to save document contents to a file. (Deprecated in Mac OS X v10.4. Use `writeSafelyToURL:ofType:forSaveOperation:error:` (page 994) instead.)

```
- (BOOL)writeWithBackupToFile:(NSString *)fullDocumentPath ofType:(NSString *)docType
    saveOperation:(NSSaveOperationType)saveOperationType
```

Discussion
This method is called by action methods like `saveDocument:` (page 976), `saveDocumentAs:` (page 977), and `saveDocumentTo:` (page 977). It is responsible for handling backup of the existing file, if any, and removal of that backup if `keepBackupFile` (page 958) returns `NO`. In between those two things, it calls `writeToFile:ofType:originalFile:saveOperation:` (page 995) to write the document of type *docType* to *fullDocumentPath*. You should never need to call `writeWithBackupToFile:ofType:saveOperation:`, but subclasses that want to change the way the backup works can override it. The *saveOperationType* argument is one of the constants listed in "Constants" (page 999).

If you override this method, you should invoke `fileAttributesToWriteToFile:ofType:saveOperation:` (page 946) and set the variables returned from this method when writing *fullDocumentPath*. `NSFileManager changeFileAttributes:atPath:` can be used to do this.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

NSDocument.h

Constants

NSSaveOperationType

The following constants specify types of save operations. These values are used with method parameters of type NSSaveOperationType. Depending on the method, those parameters can affect the title of the Save panel, as well as the files displayed.

```
enum {
    NSSaveOperation   = 0,
    NSSaveAsOperation = 1,
    NSSaveToOperation = 2
    NSAutosaveOperation = 3
};
typedef NSUInteger NSSaveOperationType;
```

Constants

NSSaveOperation
: Specifies a Save operation, the overwriting of a document's file or file package with the document's current contents.

  Available in Mac OS X v10.0 and later.

  Declared in NSDocument.h.

NSSaveAsOperation
: Specifies a Save As operation, the writing of a document's current contents to a new file or file package, and then making the just-written file or file package the document's current one.

  Available in Mac OS X v10.0 and later.

  Declared in NSDocument.h.

NSSaveToOperation
: Specifies a Save To operation, the writing of a document's current contents to a new file or file package without changing the document's current one.

  Available in Mac OS X v10.0 and later.

  Declared in NSDocument.h.

NSAutosaveOperation
: Specifies an autosave operation, writing a document’s contents to a file or file package separate from the document's current one, without changing the document's current one.

  Available in Mac OS X v10.4 and later.

  Declared in NSDocument.h.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSDocument.h

NSDocumentChangeType

Change counts indicate a document's edit status. These constants indicate how a document should operate on its change count and are passed to `updateChangeCount:` (page 988).

```
enum {
    NSChangeDone = 0,
    NSChangeUndone = 1,
    NSChangeCleared = 2,
    NSChangeReadOtherContents = 3,
    NSChangeAutosaved = 4,
    NSChangeRedone = 5
};
typedef NSUInteger NSDocumentChangeType;
```

Constants

`NSChangeDone`

Increment change count. The value to pass to `updateChangeCount:` (page 988) to indicate that a single change has been done. For example, the built-in undo support of `NSDocument` passes this value whenever a document receives an `NSUndoManagerWillCloseUndoGroupNotification` from its own undo manager.

Available in Mac OS X v10.0 and later.

Declared in `NSDocument.h`.

`NSChangeUndone`

Decrement change count. A single change has been undone. For example, the built-in undo support of `NSDocument` passes this value whenever a document receives an `NSUndoManagerDidUndoChangeNotification` from its own undo manager.

Available in Mac OS X v10.0 and later.

Declared in `NSDocument.h`.

`NSChangeCleared`

Set change count to 0. The document has been synchronized with its file or file package. For example, `saveToURL:ofType:forSaveOperation:error:` (page 980) passes this value for a successful `NSSaveOperation` (page 999) or `NSSaveAsOperation` (page 999). The `revertDocumentToSaved:` (page 971) method does too.

Available in Mac OS X v10.0 and later.

Declared in `NSDocument.h`.

`NSChangeReadOtherContents`

The document has been initialized with the contents of a file or file package other than the one whose location would be returned by `fileURL` (page 951), and therefore can't possibly be synchronized with its persistent representation. For example, `initForURL:withContentsOfURL:ofType:error:` (page 955) passes this value when the two passed-in URLs are not equal to indicate that an autosaved document is being reopened.

Available in Mac OS X v10.4 and later.

Declared in `NSDocument.h`.

`NSChangeAutosaved`

The document's contents have been autosaved. For example, `saveToURL:ofType:forSaveOperation:error:` (page 980) passes this value for a successful `NSAutosaveOperation` (page 999).

Available in Mac OS X v10.4 and later.

Declared in `NSDocument.h`.

`NSChangeRedone`

A single change has been redone. For example, the built-in undo support of `NSDocument` passes this value whenever a document receives an `NSUndoManagerDidRedoChangeNotification` from its own undo manager.

Available in Mac OS X v10.5 and later.

Declared in `NSDocument.h`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSDocument.h`

NSDocumentController Class Reference

Overview

An `NSDocumentController` object manages an application's documents. As the first-responder target of New and Open menu commands, it creates and opens documents and tracks them throughout a session of the application. When opening documents, an `NSDocumentController` runs and manages the modal Open panel. `NSDocumentController` objects also maintain and manage the mappings of document types, extensions, and `NSDocument` subclasses as specified in the `CFBundleDocumentTypes` property loaded from the information property list (`Info.plist`).

You can use various `NSDocumentController` methods to get a list of the current documents; get the current document (which is the document whose window is currently key); get documents based on a given filename or window; and find out about a document's extension, type, display name, and document class.

In some situations, it is worthwhile to subclass `NSDocumentController` in non-`NSDocument`-based applications to get some of its features. For example, the `NSDocumentController` management of the Open Recent menu is useful in applications that don't use subclasses of `NSDocument`.

Adopted Protocols

NSCoding

`encodeWithCoder:`
`initWithCoder:`

Tasks

Obtaining the Shared Document Controller

`+ sharedDocumentController` (page 1008)
Returns the shared `NSDocumentController` instance.

Initializing a New NSDocumentController

`- init` (page 1017)
This method is the designated initializer for `NSDocumentController`.

Creating and Opening Documents

`- documentForURL:` (page 1014)
Returns, for a given URL, the open document whose file or file package is located by the URL, or `nil` if there is no such open document.

`- openUntitledDocumentAndDisplay:error:` (page 1024)
Creates a new untitled document, presents its user interface if *`displayDocument`* is `YES`, and returns the document if successful.

`- makeUntitledDocumentOfType:error:` (page 1020)
Instantiates a new untitled document of the specified type and returns it if successful.

`- openDocumentWithContentsOfURL:display:error:` (page 1023)
Opens a document located by the given URL presents its user interface if requested, and returns the document if successful.

`- makeDocumentWithContentsOfURL:ofType:error:` (page 1019)
Instantiates a document located by a URL, of a specified type, and returns it if successful.

`- reopenDocumentForURL:withContentsOfURL:error:` (page 1027)
Reopens an autosaved document located by a URL, by reading the contents for the document from another URL, presents its user interface, and returns `YES` if successful.

`- makeDocumentForURL:withContentsOfURL:ofType:error:` (page 1017)
Instantiates a document located by a URL, of a specified type, but by reading the contents for the document from another URL, and returns it if successful.

Managing Documents

`- documents` (page 1015)
Returns the `NSDocument` objects managed by the receiver.

- `addDocument:` (page 1009)
  Adds the given document to the list of open documents.
- `currentDocument` (page 1011)
  Returns the `NSDocument` object associated with the main window.
- `documentForWindow:` (page 1014)
  Returns the document object whose window controller owns a specified window.
- `hasEditedDocuments` (page 1016)
  Returns a Boolean value that indicates whether the receiver has any documents with unsaved changes.
- `removeDocument:` (page 1026)
  Removes the given document from the list of open documents.

Managing Document Types

- `documentClassNames` (page 1013)
  Returns the names of `NSDocument` subclasses supported by this application.
- `defaultType` (page 1011)
  Returns the name of the document type that should be used when creating new documents.
- `documentClassForType:` (page 1012)
  Returns the `NSDocument` subclass associated with a given document type.
- `displayNameForType:` (page 1012)
  Returns the descriptive name for the specified document type, which is used in the File Format pop-up menu of the Save As dialog.
- `typeForContentsOfURL:error:` (page 1030)
  Returns, for a specified URL, the name of the document type that should be used when opening the document at that location, if successful.
- `fileExtensionsFromType:` (page 1015) Deprecated in Mac OS X v10.5
  Returns the allowable file extensions for the given document type. (Deprecated. Use the `NSDocument` method `fileNameExtensionForType:saveOperation:` (page 949) instead.)
- `typeFromFileExtension:` (page 1030) Deprecated in Mac OS X v10.5
  Returns the document type associated with files having extension *`fileExtensionOrHFSFileType`*. (Deprecated. Use `typeForContentsOfURL:error:` (page 1030) instead.)

Autosaving

- `autosavingDelay` (page 1009)
  Returns the time interval in seconds for periodic autosaving.
- `setAutosavingDelay:` (page 1028)
  Sets the time interval in seconds for periodic autosaving.

Closing Documents

- `closeAllDocumentsWithDelegate:didCloseAllSelector:contextInfo:` (page 1010)
  Iterates through all the open documents and tries to close them one by one using the specified delegate.

- reviewUnsavedDocumentsWithAlertTitle:cancellable:delegate:didReviewAllSelector:contextInfo: (page 1027)

  Displays an alert dialog asking if the user wants to review unsaved documents (only if there are two or more unsaved documents), quit regardless of unsaved documents, or (if the choice is allowed) cancel the impending save operation.

Responding to Action Messages

- newDocument: (page 1020)

  An action method invoked by the New menu command, this method creates a new NSDocument object and adds it to the list of such objects managed by the document controller.

- openDocument: (page 1021)

  An action method invoked by the Open menu command, it runs the modal Open panel and, based on the selected filenames, creates one or more NSDocument objects from the contents of the files.

- saveAllDocuments: (page 1028)

  As the action method invoked by the Save All command, saves all open documents of the application that need to be saved.

Managing the Open Panel

- runModalOpenPanel:forTypes: (page 1028)

  Invokes the NSOpenPanel runModalForTypes: (page 1821) method, passing the *openPanel* object and the file *extensions* associated with a document type.

- currentDirectory (page 1010)

  Returns the directory path to be used as the starting point in the Open panel.

- URLsFromRunningOpenPanel (page 1031)

  Creates an NSOpenPanel instance and initializes it appropriately.

Managing the Open Recent Menu

- maximumRecentDocumentCount (page 1020)

  Returns the maximum number of items that may be presented in the standard Open Recent menu.

- clearRecentDocuments: (page 1009)

  Empties the recent documents list for the application.

- noteNewRecentDocumentURL: (page 1021)

  This method should be called by applications not based on NSDocument when they open or save documents identified by the given URL.

- noteNewRecentDocument: (page 1021)

  This method is called by NSDocument objects at appropriate times for managing the recent-documents list.

- recentDocumentURLs (page 1026)

  Returns the list of recent-document URLs.

Validating User Interface Items

- `validateUserInterfaceItem:` (page 1031)
  Returns a Boolean value that indicates whether a given user interface item should be enabled.

Handling Errors

- `presentError:` (page 1025)
  Presents an error alert to the user as a modal panel.
- `presentError:modalForWindow:delegate:didPresentSelector:contextInfo:` (page 1026)
  Presents an error alert to the user as a modal panel.
- `willPresentError:` (page 1031)
  Called when the receiver is about to present an error, returns the error that should actually be presented.

Deprecated Methods

- `documentForFileName:` (page 1013) Deprecated in Mac OS X v10.4
  Returns the document object for the file in which the document data is stored. (Deprecated. Use `documentForURL:` (page 1014) instead.)
- `fileNamesFromRunningOpenPanel` (page 1016) Deprecated in Mac OS X v10.4
  Returns a selection of files chosen by the user in the Open panel. (Deprecated. Use `URLsFromRunningOpenPanel` (page 1031) instead.)
- `makeDocumentWithContentsOfFile:ofType:` (page 1017) Deprecated in Mac OS X v10.4
  Creates and returns a document object of a given document type from the contents of a file. (Deprecated. Use `makeDocumentWithContentsOfURL:ofType:error:` (page 1019) instead.)
- `makeDocumentWithContentsOfURL:ofType:` (page 1018) Deprecated in Mac OS X v10.4
  Creates and returns a ocument object for the given document type from the contents of a given URL. (Deprecated. Use `makeDocumentWithContentsOfURL:ofType:error:` (page 1019) instead.)
- `makeUntitledDocumentOfType:` (page 1019) Deprecated in Mac OS X v10.4
  Creates and returns a document object for document type. (Deprecated. Use `makeUntitledDocumentOfType:error:` (page 1020) instead.)
- `openDocumentWithContentsOfFile:display:` (page 1022) Deprecated in Mac OS X v10.4
  Returns a document object created from the contents of a given file and optionally displays it. (Deprecated. Use `openDocumentWithContentsOfURL:display:error:` (page 1023) instead.)
- `openDocumentWithContentsOfURL:display:` (page 1023) Deprecated in Mac OS X v10.4
  Returns a document object created from the contents of a given URL and optionally displays it. (Deprecated. Use `openDocumentWithContentsOfURL:display:error:` (page 1023) instead.)
- `openUntitledDocumentOfType:display:` (page 1024) Deprecated in Mac OS X v10.4
  Returns a document object instantiated from the subclass of the given document type and optionally displays it. (Deprecated. Use `openUntitledDocumentAndDisplay:error:` (page 1024) with `defaultType` (page 1011) instead.)

- `setShouldCreateUI:` (page 1029) Deprecated in Mac OS X v10.4
  Sets whether the window controllers of a document should be created when the document is created. (Deprecated. Use the display parameter of `openUntitledDocumentAndDisplay:error:` (page 1024) or `openDocumentWithContentsOfURL:display:error:` (page 1023) instead.)
- `shouldCreateUI` (page 1029) Deprecated in Mac OS X v10.4
  Returns a Boolean value that indicates whether the window controllers of a document should be created when the document is created. (Deprecated. Use the *display* parameter of `openUntitledDocumentAndDisplay:error:` (page 1024) or `openDocumentWithContentsOfURL:display:error:` (page 1023) instead.)

Class Methods

sharedDocumentController

Returns the shared `NSDocumentController` instance.

```
+ (id)sharedDocumentController
```

Return Value
The shared `NSDocumentController` instance.

Discussion
If an `NSDocumentController` instance doesn't exist yet, it is created.

Initialization reads in the document types from the `CFBundleDocumentTypes` property list (in `Info.plist`), registers the instance for `NSWorkspaceWillPowerOffNotification` (page 3495)s, and turns on the flag indicating that document user interfaces should be visible. You should always obtain your application's `NSDocumentController` using this method.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setShouldCreateUI:` (page 1029)

Related Sample Code
FunHouse
QTAudioContextInsert
QTAudioExtractionPanel
QTKitPlayer
Quartz Composer WWDC 2005 TextEdit

Declared In
`NSDocumentController.h`

Instance Methods

addDocument:

Adds the given document to the list of open documents.

```
- (void)addDocument:(NSDocument *)document
```

Discussion
The `open...` methods automatically call `addDocument:`. This method is mostly provided for subclasses that want to know when documents arrive.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
QTAudioContextInsert
QTAudioExtractionPanel
QTKitImport
QTKitPlayer
QTMetadataEditor

Declared In
`NSDocumentController.h`

autosavingDelay

Returns the time interval in seconds for periodic autosaving.

```
- (NSTimeInterval)autosavingDelay
```

Discussion
A value of 0 indicates that periodic autosaving should not be done at all. `NSDocumentController` uses this number as the amount of time to wait between detecting that a document has unautosaved changes and sending the document an `autosaveDocumentWithDelegate:didAutosaveSelector:contextInfo:` (page 941) message. The default value is 0.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- setAutosavingDelay:` (page 1028)

Declared In
`NSDocumentController.h`

clearRecentDocuments:

Empties the recent documents list for the application.

```
- (IBAction)clearRecentDocuments:(id)sender
```

Discussion
This is the action for the Clear menu command, but it can be invoked directly if necessary.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSDocumentController.h`

closeAllDocumentsWithDelegate:didCloseAllSelector:contextInfo:

Iterates through all the open documents and tries to close them one by one using the specified delegate.

```
- (void)closeAllDocumentsWithDelegate:(id)delegate
    didCloseAllSelector:(SEL)didCloseAllSelector contextInfo:(void *)contextInfo
```

Discussion
Each `NSDocument` object is sent `canCloseDocumentWithDelegate:shouldCloseSelector:contextInfo:` (page 943), which, if the document is dirty, gives it a chance to refuse to close or to save itself first. This method may ask whether to save or to perform a save.

The *`didCloseAllSelector`* callback method is invoked with `YES` if all documents are closed, and `NO` otherwise. Pass the *`contextInfo`* object with the callback. The *`didCloseAllSelector`* callback method should have the following signature:

```
- (void)documentController:(NSDocumentController *)docController  didCloseAll:
 (BOOL)didCloseAll contextInfo:(void *)contextInfo
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSDocumentController.h`

currentDirectory

Returns the directory path to be used as the starting point in the Open panel.

```
- (NSString *)currentDirectory
```

Discussion
The first valid directory from the following list is returned:

- The directory location where the current document was last saved
- The last directory visited in the Open panel
- The user's home directory

Availability
Available in Mac OS X v10.0 and later.

See Also
- `documentForFileName:` (page 1013)

Declared In
`NSDocumentController.h`

currentDocument

Returns the `NSDocument` object associated with the main window.

```
- (id)currentDocument
```

Discussion
This method returns `nil` if it is called when its application is not active. This can occur during processing of a drag-and-drop operation, for example, in an implementation of `readSelectionFromPasteboard:`. In such a case, send the following message instead from an `NSView` subclass associated with the document:

```
[[[self window] windowController] document];
```

Availability
Available in Mac OS X v10.0 and later.

See Also
- `documentForFileName:` (page 1013)
- `documentForWindow:` (page 1014)
- `documents` (page 1015)

QTAudioExtractionPanel
QTKitPlayer

Declared In
`NSDocumentController.h`

defaultType

Returns the name of the document type that should be used when creating new documents.

```
- (NSString *)defaultType
```

Discussion
The default implementation of this method returns the first Editor type declared by the `CFBundleDocumentTypes` array in the application's `Info.plist`, or returns `nil` if no Editor type is declared. You can override it to customize the type of document that is created when, for instance, the user chooses New in the File menu.

Availability
Available in Mac OS X v10.4 and later.

Related Sample Code
CIRAWFilterSample
ImageApp

Declared In
NSDocumentController.h

displayNameForType:

Returns the descriptive name for the specified document type, which is used in the File Format pop-up menu of the Save As dialog.

```
- (NSString *)displayNameForType:(NSString *)documentTypeName
```

Parameters

documentTypeName

The name of a document type, specified by `CFBundleTypeName` in the application's `Info.plist` file.

Return Value
The descriptive name for the document type specified by *documentTypeName*. If there is no descriptive name, returns *documentTypeName*.

Discussion
For a document-based application, supported document types are specified in the `Info.plist` file by the `CFBundleDocumentTypes` array. Each document type is specified by a dictionary in this array, and is named by the `CFBundleTypeName` attribute. You can provide a descriptive, localized, representation of this name by providing a corresponding entry in the `InfoPlist.strings` file(s). For example, given an `Info.plist` file that contains the following fragment:

```
<dict>
    <key>CFBundleDocumentTypes</key>
    <array>
        <dict>
            <key>CFBundleTypeName</key>
            <string>BinaryFile</string>
            <key>CFBundleTypeExtensions</key>
            <array>
                <string>binary</string>
            </array>
```

you could provide a descriptive name by adding an entry in the `InfoPlist.strings` file:

```
BinaryFile = "Binary file format";
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSDocumentController.h

documentClassForType:

Returns the `NSDocument` subclass associated with a given document type.

```
- (Class)documentClassForType:(NSString *)documentTypeName
```

Parameters

documentTypeName

The name of a document type, specified by `CFBundleTypeName` in the application's `Info.plist` file.

The document type must be one the receiver can read.

Return Value
Returns the `NSDocument` subclass associated with *documentTypeName*. If the class cannot be found, returns `nil`.

Discussion
Para

Availability
Available in Mac OS X v10.0 and later.

See Also
`- displayNameForType:` (page 1012)

Declared In
`NSDocumentController.h`

documentClassNames

Returns the names of `NSDocument` subclasses supported by this application.

```
- (NSArray *)documentClassNames
```

Return Value
The names of `NSDocument` subclasses supported by this application.

Discussion
The default implementation of this method returns information derived from the application's `Info.plist` property list file. You can override it to return the names of document classes that are dynamically loaded from plugins.

Availability
Available in Mac OS X v10.4 and later.

Related Sample Code
ImageApp

Declared In
`NSDocumentController.h`

documentForFileName:

Returns the document object for the file in which the document data is stored. (Deprecated in Mac OS X v10.4. Use `documentForURL:` (page 1014) instead.)

```
- (id)documentForFileName:(NSString *)fileName
```

Discussion
The *fileName* argument is a fully qualified path in the file system. Returns `nil` if no document can be found.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

See Also
- `documentForWindow:` (page 1014)
- `documents` (page 1015)

Related Sample Code
QTAudioContextInsert
QTAudioExtractionPanel
QTKitAdvancedDocument
QTKitImport
QTKitPlayer

Declared In
`NSDocumentController.h`

documentForURL:

Returns, for a given URL, the open document whose file or file package is located by the URL, or `nil` if there is no such open document.

```
- (id)documentForURL:(NSURL *)absoluteURL
```

Discussion
The default implementation of this method queries each open document to find one whose URL matches, and returns the first one whose URL does match.

For backward binary compatibility with Mac OS X v10.3 and earlier, the default implementation of this method instead invokes `documentForFileName:` (page 1013) if it is overridden and the URL uses the `file:` scheme.

Availability
Available in Mac OS X v10.4 and later.

Related Sample Code
QTKitCreateMovie
QTKitFrameStepper
QTMetadataEditor

Declared In
`NSDocumentController.h`

documentForWindow:

Returns the document object whose window controller owns a specified window.

```
- (id)documentForWindow:(NSWindow *)window
```

Return Value
The document object whose window controller owns *window*. Returns `nil` if *window* is `nil`, if *window* has no window controller, or if the window controller does not have an association with an instance of `NSDocument`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `currentDocument` (page 1011)
- `documentForFileName:` (page 1013)
- `documents` (page 1015)

Related Sample Code
ImageApp

Declared In
`NSDocumentController.h`

documents

Returns the `NSDocument` objects managed by the receiver.

```
- (NSArray *)documents
```

Return Value
The `NSDocument` objects managed by the receiver. If there are currently no documents, returns an empty `NSArray` object.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `currentDocument` (page 1011)
- `documentForFileName:` (page 1013)
- `documentForWindow:` (page 1014)

QTAudioExtractionPanel

Declared In
`NSDocumentController.h`

fileExtensionsFromType:

Returns the allowable file extensions for the given document type. (Deprecated in Mac OS X v10.5. Use the `NSDocument` method `fileNameExtensionForType:saveOperation:` (page 949) instead.)

```
- (NSArray *)fileExtensionsFromType:(NSString *)documentTypeName
```

Parameters

documentTypeName

The name of a document type, specified by `CFBundleTypeName` in the application's `Info.plist` file.

Return Value

The allowable file extensions (as `NSString` objects) for *documentTypeName*.

Discussion

Type extensions are specified by the `CFBundleTypeExtensions` array for the given type in the `Info.plist` file.

The first string in the returned array is typically the most common extension. The array may also contain encoded HFS file types as will as filename extensions.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

See Also

`- displayNameForType:` (page 1012)

Declared In

`NSDocumentController.h`

fileNamesFromRunningOpenPanel

Returns a selection of files chosen by the user in the Open panel. (Deprecated in Mac OS X v10.4. Use `URLsFromRunningOpenPanel` (page 1031) instead.)

```
- (NSArray *)fileNamesFromRunningOpenPanel
```

Discussion

Each file in the returned `NSArray` is a fully qualified path to the file's location in the file system. This method is invoked by `openDocument:` (page 1021), and it invokes `runModalOpenPanel:forTypes:` (page 1028) after initializing the Open panel (which includes getting the starting directory with `currentDirectory` (page 1010)). Returns `nil` if the user cancels the Open panel or makes no selection.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`NSDocumentController.h`

hasEditedDocuments

Returns a Boolean value that indicates whether the receiver has any documents with unsaved changes.

```
- (BOOL)hasEditedDocuments
```

Return Value

`YES` if the receiver has any documents with unsaved changes, otherwise `NO`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `documents` (page 1015)

Declared In
`NSDocumentController.h`

init

This method is the designated initializer for `NSDocumentController`.

```
- (id)init
```

Discussion
The first instance of `NSDocumentController` or any of its subclasses that is created becomes the shared instance.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSDocumentController.h`

makeDocumentForURL:withContentsOfURL:ofType:error:

Instantiates a document located by a URL, of a specified type, but by reading the contents for the document from another URL, and returns it if successful.

```
- (id)makeDocumentForURL:(NSURL *)absoluteDocumentURL withContentsOfURL:(NSURL
    *)absoluteDocumentContentsURL ofType:(NSString *)typeName error:(NSError
    **)outError
```

Discussion
The URL is specified by *absoluteDocumentURL*, the type by *typeName*, and the other URL providing the contents by *absoluteDocumentContentsURL*. If not successful, the method returns `nil` after setting *outError* to point to an `NSError` object that encapsulates the reason why the document could not be instantiated. The default implementation of this method invokes `documentClassForType:` (page 1012) to find out the class of document to instantiate, allocates a document object, and initializes it by sending it an `initForURL:withContentsOfURL:ofType:error:` (page 955) message.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`NSDocumentController.h`

makeDocumentWithContentsOfFile:ofType:

Creates and returns a document object of a given document type from the contents of a file. (Deprecated in Mac OS X v10.4. Use `makeDocumentWithContentsOfURL:ofType:error:` (page 1019) instead.)

```
- (id)makeDocumentWithContentsOfFile:(NSString *)fileName ofType:(NSString *)docType
```

Discussion
Creates and returns an `NSDocument` object for document type *docType* from the contents of the file *fileName*, which must be a fully qualified path. The returned object is not retained. Returns `nil` if the `NSDocument` subclass for *docType* couldn't be determined or if the object couldn't be created. This method invokes the `NSDocument` method `initWithContentsOfFile:ofType:` (page 956) and is invoked by `openDocumentWithContentsOfFile:display:` (page 1022).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

See Also
- `makeUntitledDocumentOfType:` (page 1019)
- `openDocument:` (page 1021)

Related Sample Code
QTKitImport

Declared In
`NSDocumentController.h`

makeDocumentWithContentsOfURL:ofType:

Creates and returns a ocument object for the given document type from the contents of a given URL. (Deprecated in Mac OS X v10.4. Use `makeDocumentWithContentsOfURL:ofType:error:` (page 1019) instead.)

```
- (id)makeDocumentWithContentsOfURL:(NSURL *)aURL ofType:(NSString *)docType
```

Discussion
Creates and returns an `NSDocument` object for document type *docType* from the contents of *aURL*. The returned object is not retained. Returns `nil` if the `NSDocument` subclass for *docType* couldn't be determined or if the object couldn't be created. This method invokes the `NSDocument` method `initWithContentsOfURL:ofType:` (page 956) and is invoked by `openDocumentWithContentsOfURL:display:` (page 1023).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

See Also

Declared In
`NSDocumentController.h`

makeDocumentWithContentsOfURL:ofType:error:

Instantiates a document located by a URL, of a specified type, and returns it if successful.

```
- (id)makeDocumentWithContentsOfURL:(NSURL *)absoluteURL ofType:(NSString *)typeName
    error:(NSError **)outError
```

Discussion
The URL is specified by *absoluteURL* and the document type by *typeName*. If not successful, the method returns `nil` after setting *outError* to point to an NSError that encapsulates the reason why the document could not be instantiated. The default implementation of this method invokes `documentClassForType:` (page 1012) to find out the class of document to instantiate, allocates a document object, and initializes it by sending it an `initWithContentsOfURL:ofType:error:` (page 957) message.

For backward binary compatibility with Mac OS X v10.3 and earlier, the default implementation of this method instead invokes `makeDocumentWithContentsOfFile:ofType:` (page 1017) if it is overridden and the URL uses the `file:` scheme.

Availability
Available in Mac OS X v10.4 and later.

Related Sample Code
QTKitPlayer

Declared In
`NSDocumentController.h`

makeUntitledDocumentOfType:

Creates and returns a document object for document type. (Deprecated in Mac OS X v10.4. Use `makeUntitledDocumentOfType:error:` (page 1020) instead.)

```
- (id)makeUntitledDocumentOfType:(NSString *)type
```

Discussion
Creates and returns an `NSDocument` object for document type *type*. The returned object is not retained. Returns `nil` if the `NSDocument` subclass for *type* couldn't be determined or if the object couldn't be created. This method invokes the `NSDocument` `init` (page 954) method and is invoked by `openUntitledDocumentOfType:display:` (page 1024).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

See Also
- `makeDocumentWithContentsOfFile:ofType:` (page 1017)
- `newDocument:` (page 1020)

Declared In
`NSDocumentController.h`

makeUntitledDocumentOfType:error:

Instantiates a new untitled document of the specified type and returns it if successful.

```
- (id)makeUntitledDocumentOfType:(NSString *)typeName error:(NSError **)outError
```

Discussion
The document type is specified by *typeName*. If not successful, the method returns `nil` after setting *outError* to point to an `NSError` object that encapsulates the reason why a new untitled document could not be instantiated. The default implementation of this method invokes `documentClassForType:` (page 1012) to find out the class of document to instantiate, then allocates and initializes a document by sending it `initWithType:error:` (page 957).

For backward binary compatibility with Mac OS X v10.3 and earlier, the default implementation of this method instead invokes `makeUntitledDocumentOfType:` (page 1019) if it is overridden.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`NSDocumentController.h`

maximumRecentDocumentCount

Returns the maximum number of items that may be presented in the standard Open Recent menu.

```
- (NSUInteger)maximumRecentDocumentCount
```

Discussion
A value of 0 indicates that `NSDocumentController` will not attempt to add an Open Recent menu to your application's File menu, although `NSDocumentController` will not attempt to remove any preexisting Open Recent menu item. The default implementation returns a value that is subject to change and may or may not be derived from a setting made by the user in System Preferences.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`NSDocumentController.h`

newDocument:

An action method invoked by the New menu command, this method creates a new `NSDocument` object and adds it to the list of such objects managed by the document controller.

```
- (IBAction)newDocument:(id)sender
```

Discussion
This method invokes `openUntitledDocumentAndDisplay:error:` (page 1024), as described in "Message Flow in the Document Architecture".

Availability
Available in Mac OS X v10.0 and later.

See Also
- openDocument: (page 1021)

Declared In
NSDocumentController.h

noteNewRecentDocument:

This method is called by NSDocument objects at appropriate times for managing the recent-documents list.

```
- (void)noteNewRecentDocument:(NSDocument *)aDocument
```

Discussion
This method constructs a URL and calls noteNewRecentDocumentURL: (page 1021). Subclasses might override this method to prevent certain documents or kinds of documents from getting into the list.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSDocumentController.h

noteNewRecentDocumentURL:

This method should be called by applications not based on NSDocument when they open or save documents identified by the given URL.

```
- (void)noteNewRecentDocumentURL:(NSURL *)aURL
```

Discussion
NSDocument automatically calls this method when appropriate for NSDocument-based applications. Applications not based on NSDocument must also implement the application:openFile: method in the application delegate to handle requests from the Open Recent menu command. You can override this method in an NSDocument-based application to prevent certain kinds of documents from getting into the list (but you have to identify them by URL).

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
Quartz Composer WWDC 2005 TextEdit

Declared In
NSDocumentController.h

openDocument:

An action method invoked by the Open menu command, it runs the modal Open panel and, based on the selected filenames, creates one or more NSDocument objects from the contents of the files.

```
- (IBAction)openDocument:(id)sender
```

Discussion
The method adds the newly created objects to the list of `NSDocument` objects managed by the document controller. This method invokes `openDocumentWithContentsOfURL:display:error:` (page 1023), which actually creates the `NSDocument` objects.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `fileNamesFromRunningOpenPanel` (page 1016)
- `newDocument:` (page 1020)

CIRAWFilterSample

Declared In
`NSDocumentController.h`

openDocumentWithContentsOfFile:display:

Returns a document object created from the contents of a given file and optionally displays it. (Deprecated in Mac OS X v10.4. Use `openDocumentWithContentsOfURL:display:error:` (page 1023) instead.)

```
- (id)openDocumentWithContentsOfFile:(NSString *)fileName display:(BOOL)flag
```

Discussion
Returns an `NSDocument` object created from the contents of the file *`fileName`* (an absolute path) and displays it if *`flag`* is `YES`. The returned object is not retained, but is added to the receiver's list of managed documents. Returns `nil` if the object could not be created, typically because *`fileName`* does not point to a valid file or because there is no `NSDocument` subclass for the document type (as indicated by the file extension or HFS file type). Even if *`flag`* is `YES`, the document is not displayed if `shouldCreateUI` (page 1029) returns `NO`. This method invokes `makeDocumentWithContentsOfFile:ofType:` (page 1017) to obtain the created NSDocument object. If you override this method, your implementation should be prepared to handle either `YES` or `NO`.

To handle an Open Documents Apple event, the Application Kit's built-in Apple event handling automatically invokes this method with the path to the file to open and a display argument.

Invoked with a display argument of `YES` instead of `NO` when a Print Documents Apple event is handled. This may have been handled differently in versions of Mac OS X prior to version 10.3.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
NSDocumentController.h

openDocumentWithContentsOfURL:display:

Returns a document object created from the contents of a given URL and optionally displays it. (Deprecated in Mac OS X v10.4. Use openDocumentWithContentsOfURL:display:error: (page 1023) instead.)

```
- (id)openDocumentWithContentsOfURL:(NSURL *)aURL display:(BOOL)flag
```

Discussion
Returns an NSDocument object created from the contents of *aURL* and displays it if *flag* is YES. The returned object is not retained, but is added to the receiver's list of managed documents. Returns nil if the object could not be created, typically because *aURL* does not point to a valid location or because there is no NSDocument subclass for the document type. Even if *flag* is YES, the document is not displayed if shouldCreateUI (page 1029) returns NO. This method invokes makeDocumentWithContentsOfURL:ofType: (page 1018) to obtain the created NSDocument object.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

See Also
- openDocument: (page 1021)
- openUntitledDocumentOfType:display: (page 1024)
- setShouldCreateUI: (page 1029)

Declared In
NSDocumentController.h

openDocumentWithContentsOfURL:display:error:

Opens a document located by the given URL presents its user interface if requested, and returns the document if successful.

```
- (id)openDocumentWithContentsOfURL:(NSURL *)absoluteURL
    display:(BOOL)displayDocument error:(NSError **)outError
```

Discussion
If not successful, the method returns nil after setting *outError* to point to an NSError object that encapsulates the reason why the document could not be opened.

The default implementation of this method checks to see if the document is already open according to documentForURL: (page 1014), and if it is not open determines the type of the document, invokes makeDocumentWithContentsOfURL:ofType:error: (page 1019) to instantiate it, then invokes addDocument: (page 1009) to record its opening, and sends the document makeWindowControllers (page 961) and showWindows (page 987) messages if *displayDocument* is YES. If the document is already open it is just sent a showWindows (page 987) message if *displayDocument* is YES.

For backward binary compatibility with Mac OS X v10.3 and earlier, the default implementation of this method instead invokes `openDocumentWithContentsOfFile:display:` (page 1022), if it is overridden and the URL uses the `file:` scheme.

Availability
Available in Mac OS X v10.4 and later.

Related Sample Code
Reviews

Declared In
`NSDocumentController.h`

openUntitledDocumentAndDisplay:error:

Creates a new untitled document, presents its user interface if *`displayDocument`* is `YES`, and returns the document if successful.

```
- (id)openUntitledDocumentAndDisplay:(BOOL)displayDocument error:(NSError **)outError
```

Discussion
If not successful, the method returns `nil` after setting *`outError`* to point to an NSError that encapsulates the reason why a new untitled document could not be created.

The default implementation of this method invokes `defaultType` (page 1011) to determine the type of new document to create, invokes `makeUntitledDocumentOfType:error:` (page 1020) to create it, then invokes `addDocument:` (page 1009) to record its opening. If *`displayDocument`* is `YES`, it then sends the new document `makeWindowControllers` (page 961) and `showWindows` (page 987) messages.

For backward binary compatibility with Mac OS X v10.3 and earlier, the default implementation of this method instead invokes `openUntitledDocumentOfType:display:` (page 1024) if it is overridden.

Availability
Available in Mac OS X v10.4 and later.

iSpend

Declared In
`NSDocumentController.h`

openUntitledDocumentOfType:display:

Returns a document object instantiated from the subclass of the given document type and optionally displays it. (Deprecated in Mac OS X v10.4. Use `openUntitledDocumentAndDisplay:error:` (page 1024) with `defaultType` (page 1011) instead.)

```
- (id)openUntitledDocumentOfType:(NSString *)docType display:(BOOL)display
```

Discussion
Returns an `NSDocument` object instantiated from the `NSDocument` subclass required by document type *`docType`* and displays it if *`flag`* is `YES`. The returned object is not retained, but is added to the receiver's list of managed documents. Returns `nil` if the object could not be created, typically because no `NSDocument` subclass could be found for *`docType`*. Even if *`flag`* is `YES`, the document is not displayed if `shouldCreateUI` (page 1029) returns `NO`. This method invokes `makeUntitledDocumentOfType:` (page 1019) to obtain the created `NSDocument` object.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`NSDocumentController.h`

presentError:

Presents an error alert to the user as a modal panel.

```
- (BOOL)presentError:(NSError *)error
```

Discussion
Returns `YES` if error recovery was done, `NO` otherwise. This method does not return until the user dismisses the alert and, if the error has recovery options and a recovery delegate, the error's recovery delegate is sent an `attemptRecoveryFromError:optionIndex:` message.

The default `NSDocumentController` implementation of this method is equivalent to that of `NSResponder` while treating the application object as the next responder and forwarding error presentation messages to it. (The default `NSDocument` implementation of this method treats the shared `NSDocumentController` instance as the next responder and forwards these messages to it.) The default implementations of several `NSDocumentController` methods invoke this method.

The default implementation of this method invokes `willPresentError:` (page 1031) to give subclasses an opportunity to customize error presentation. You should not override this method but should instead override `willPresentError:` (page 1031).

Availability
Available in Mac OS X v10.4 and later.

See Also
- `willPresentError:` (page 1031)
- `presentError:modalForWindow:delegate:didPresentSelector:contextInfo:` (page 1026)

Declared In
`NSDocumentController.h`

presentError:modalForWindow:delegate:didPresentSelector:contextInfo:

Presents an error alert to the user as a modal panel.

```
- (void)presentError:(NSError *)error modalForWindow:(NSWindow *)window
    delegate:(id)delegate didPresentSelector:(SEL)didPresentSelector
    contextInfo:(void *)contextInfo
```

Discussion
When the user dismisses the alert and any recovery possible for the error and chosen by the user has been attempted, sends the message *didPresentSelector* to the specified *delegate*. The method selected by *didPresentSelector* must have the same signature as:

```
- (void)didPresentErrorWithRecovery:(BOOL)didRecover contextInfo:(void
*)contextInfo;
```

The default `NSDocumentController` implementation of this method is equivalent to that of `NSResponder` while treating the application object as the next responder and forwarding error presentation messages to it. (The default `NSDocument` implementation of this method treats the shared `NSDocumentController` instance as the next responder and forwards these messages to it.)

The default implementation of this method invokes `willPresentError:` (page 1031) to give subclasses an opportunity to customize error presentation. You should not override this method but should instead override `willPresentError:` (page 1031).

Availability
Available in Mac OS X v10.4 and later.

See Also
- `willPresentError:` (page 1031)
- `presentError:` (page 1025)

Declared In
`NSDocumentController.h`

recentDocumentURLs

Returns the list of recent-document URLs.

```
- (NSArray *)recentDocumentURLs
```

Discussion
This method is not a good one to override since the internals of `NSDocumentController` do not generally use it.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSDocumentController.h`

removeDocument:

Removes the given document from the list of open documents.

```
- (void)removeDocument:(NSDocument *)document
```

Discussion
A document will automatically call `removeDocument:` (page 1026) when it closes. This method is mostly provided for subclasses that want to know when documents close.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
iSpend

Declared In
`NSDocumentController.h`

reopenDocumentForURL:withContentsOfURL:error:

Reopens an autosaved document located by a URL, by reading the contents for the document from another URL, presents its user interface, and returns `YES` if successful.

```
- (BOOL)reopenDocumentForURL:(NSURL *)absoluteDocumentURL withContentsOfURL:(NSURL
    *)absoluteDocumentContentsURL error:(NSError **)outError
```

Discussion
The document is located by *absoluteDocumentURL* and the contents are read from *absoluteDocumentContentsURL*. If not successful, the method returns `NO` after setting *outError* to point to an `NSError` object that encapsulates the reason why the document could not be reopened.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`NSDocumentController.h`

reviewUnsavedDocumentsWithAlertTitle:cancellable:delegate:didReviewAllSelector:contextInfo:

Displays an alert dialog asking if the user wants to review unsaved documents (only if there are two or more unsaved documents), quit regardless of unsaved documents, or (if the choice is allowed) cancel the impending save operation.

```
- (void)reviewUnsavedDocumentsWithAlertTitle:(NSString *)title
    cancellable:(BOOL)cancellable delegate:(id)delegate
    didReviewAllSelector:(SEL)didReviewAllSelector contextInfo:(void *)contextInfo
```

Discussion
Assigns *delegate* to the panel. Invokes *didReviewAllSelector* with `YES` if quit without saving is chosen or if there are no dirty documents, and `NO` otherwise. If the user selects the "Review Unsaved" option, `closeAllDocumentsWithDelegate:didCloseAllSelector:contextInfo:` (page 1010) is invoked. This method is invoked when the user chooses the Quit menu command, and also when the computer power is being turned off. Note that *title* is ignored. Pass the *contextInfo* object with the callback.

The *didReviewAllSelector* callback method should have the following signature:

```
- (void)documentController:(NSDocumentController *)docController  didReviewAll:
 (BOOL)didReviewAll contextInfo:(void *)contextInfo
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSDocumentController.h

runModalOpenPanel:forTypes:

Invokes the `NSOpenPanel` `runModalForTypes:` (page 1821) method, passing the *openPanel* object and the file *extensions* associated with a document type.

```
- (NSInteger)runModalOpenPanel:(NSOpenPanel *)openPanel forTypes:(NSArray
    *)extensions
```

Discussion
This method is invoked by the `URLsFromRunningOpenPanel` (page 1031) method. The *extensions* parameter may also contain encoded HFS file types as well as filename extensions.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSDocumentController.h

saveAllDocuments:

As the action method invoked by the Save All command, saves all open documents of the application that need to be saved.

```
- (IBAction)saveAllDocuments:(id)sender
```

Availability
Available in Mac OS X v10.0 and later.

See Also
- `saveDocument:` (page 976) (`NSDocument`)

Declared In
NSDocumentController.h

setAutosavingDelay:

Sets the time interval in seconds for periodic autosaving.

```
- (void)setAutosavingDelay:(NSTimeInterval)autosavingDelay
```

Discussion
A value of 0 indicates that periodic autosaving should not be done at all. `NSDocumentController` uses this number as the amount of time to wait between detecting that a document has unautosaved changes and sending the document an `autosaveDocumentWithDelegate:didAutosaveSelector:contextInfo:` (page 941) message. The default value is 0.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- autosavingDelay` (page 1009)

Related Sample Code
Sketch+Accessibility

Declared In
`NSDocumentController.h`

setShouldCreateUI:

Sets whether the window controllers of a document should be created when the document is created. (Deprecated in Mac OS X v10.4. Use the display parameter of `openUntitledDocumentAndDisplay:error:` (page 1024) or `openDocumentWithContentsOfURL:display:error:` (page 1023) instead.)

```
- (void)setShouldCreateUI:(BOOL)flag
```

Discussion
Sets whether the window controllers (`NSWindowController` instances) of a document should be created when the document is created. When a window controller is created, it loads the nib file containing the window it manages. Often *`flag`* is set to `NO` for scripting or searching operations involving the document's data.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

See Also
`- shouldCreateUI` (page 1029)

Declared In
`NSDocumentController.h`

shouldCreateUI

Returns a Boolean value that indicates whether the window controllers of a document should be created when the document is created. (Deprecated in Mac OS X v10.4. Use the *`display`* parameter of `openUntitledDocumentAndDisplay:error:` (page 1024) or `openDocumentWithContentsOfURL:display:error:` (page 1023) instead.)

```
- (BOOL)shouldCreateUI
```

Return Value
A Boolean value that indicates whether the window controllers (`NSWindowController` instances) of a document should be created when the document is created.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

See Also
`- setShouldCreateUI:` (page 1029)

Declared In
`NSDocumentController.h`

typeForContentsOfURL:error:

Returns, for a specified URL, the name of the document type that should be used when opening the document at that location, if successful.

```
- (NSString *)typeForContentsOfURL:(NSURL *)inAbsoluteURL error:(NSError **)outError
```

Discussion
The URL is represented by *absoluteURL*. If not successful, the method returns `nil` after setting *outError* to point to an `NSError` object that encapsulates the reason why the document type could not be determined, or the fact that the document type is unrecognized.

You can override this method to customize type determination for documents being opened.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`NSDocumentController.h`

typeFromFileExtension:

Returns the document type associated with files having extension *fileExtensionOrHFSFileType*. (Deprecated in Mac OS X v10.5. Use `typeForContentsOfURL:error:` (page 1030) instead.)

```
- (NSString *)typeFromFileExtension:(NSString *)fileExtensionOrHFSFileType
```

Discussion
The *fileExtensionOrHFSFileType* parameter may also be an encoded HFS file type, as well as a filename extension.

This method only works when passed a file name extension used in a `CFBundleDocumentTypes` entry that does not have an `LSItemContentTypes` subentry.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

See Also
- `displayNameForType:` (page 1012)

Declared In
`NSDocumentController.h`

URLsFromRunningOpenPanel

Creates an `NSOpenPanel` instance and initializes it appropriately.

```
- (NSArray *)URLsFromRunningOpenPanel
```

Discussion
This method uses `runModalOpenPanel:forTypes:` (page 1028) to run the open panel. Returns the chosen files as an array of URLs. Returns `nil` if the user cancels the Open panel or makes no selection.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSDocumentController.h`

validateUserInterfaceItem:

Returns a Boolean value that indicates whether a given user interface item should be enabled.

```
- (BOOL)validateUserInterfaceItem:(id < NSValidatedUserInterfaceItem >)anItem
```

Parameters

anItem

The user interface item to validate. You can send *anItem* the `action` (page 3925) and `tag` (page 3926) messages.

Return Value
`YES` if *anItem* should be enabled, otherwise `NO`.

Discussion
Subclasses can override this method to perform additional validations. Subclasses should call `super` in their implementation for items they don't handle themselves.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSDocumentController.h`

willPresentError:

Called when the receiver is about to present an error, returns the error that should actually be presented.

```
- (NSError *)willPresentError:(NSError *)error
```

Discussion
The default implementation of this method merely returns the passed-in error. The returned error may simply be forwarded to the application object.

You can override this method to customize the presentation of errors by examining the passed-in error and, for example, returning more specific information. When you override this method always check the `NSError` object's domain and code to discriminate between errors whose presentation you want to customize and those you don't. For errors you don't want to customize, call the superclass implementation, passing the original error.

Availability
Available in Mac OS X v10.4 and later.

Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.0 and later.
Declared in	AppKit/NSDrawer.h
Companion guide	Drawers
Related sample code	CocoaAUHost DrawerMadness PDFKitLinker2 QTAudioExtractionPanel

Overview

An `NSDrawer` object is a user interface element that contains and displays view objects including `NSTextView`, `NSScrollView`, `NSBrowser`, and other classes that inherit from `NSView`. A drawer is associated with a window, called its parent, and can appear only while its parent is visible onscreen. A drawer cannot be moved or ordered independently of a window, but is instead attached to one edge of its parent and moves along with it.

Tasks

Creating Drawers

`- initWithContentSize:preferredEdge:` (page 1037)
Creates a new drawer with the given size on the specified edge of the parent window.

`- delegate` (page 1037)
Returns the receiver's delegate.

`- setDelegate:` (page 1042)
Sets the receiver's delegate.

Opening and Closing Drawers

- `close` (page 1035)
  If the receiver is open, this method closes it.
- `close:` (page 1036)
  An action method to close the receiver.
- `open` (page 1039)
  If the receiver is closed, this method opens it.
- `open:` (page 1039)
  An action method to open the drawer.
- `openOnEdge:` (page 1040)
  Causes the receiver to open on the specified edge of the parent window.
- `toggle:` (page 1045)
  Toggles the drawer open or closed.
- `state` (page 1044)
  Returns the state of the receiver.

Managing Drawer Size

- `contentSize` (page 1036)
  Returns the size of the receiver's content area.
- `leadingOffset` (page 1038)
  Returns the receiver's leading offset.
- `maxContentSize` (page 1038)
  Returns the maximum allowed size of the receiver's content area.
- `minContentSize` (page 1039)
  Returns the minimum allowed size of the receiver's content area.
- `setContentSize:` (page 1041)
  Sets the size of the receiver's content area.
- `setLeadingOffset:` (page 1042)
  Sets the receiver's leading offset.
- `setMaxContentSize:` (page 1042)
  Specifies the maximum size of the receiver's content area.
- `setMinContentSize:` (page 1043)
  Specifies the minimum size of the receiver's content area.
- `setTrailingOffset:` (page 1044)
  Sets the receiver's trailing offset.
- `trailingOffset` (page 1045)
  Returns the receiver's trailing offset.

Managing Drawer Edges

- `edge` (page 1037)
  Returns the edge of the window that the receiver is connected to.
- `preferredEdge` (page 1040)
  Returns the receiver's preferred, or default, edge.
- `setPreferredEdge:` (page 1044)
  Sets the receiver's preferred, or default, edge.

Managing Drawer Views

- `contentView` (page 1036)
  Returns the receiver's content view.
- `parentWindow` (page 1040)
  Returns the receiver's parent window.
- `setContentView:` (page 1041)
  Sets the receiver's content view.
- `setParentWindow:` (page 1043)
  Sets the receiver's parent window.

Instance Methods

close

If the receiver is open, this method closes it.

```
- (void)close
```

Discussion
Calling *close* on a closed drawer does nothing. You can get the state of a drawer by sending it `state` (page 1044).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSDrawer.h`

close:

An action method to close the receiver.

```
- (void)close:(id)sender
```

Parameters

sender

A user interface element, such as a button or menu item, that invokes the action method.

Discussion

This method is an action method and likely would not be invoked programatically. Rather, it is an action that is commonly connected in Interface Builder.

Availability

Available in Mac OS X v10.0 and later.

See Also

- open: (page 1039)

Declared In

NSDrawer.h

contentSize

Returns the size of the receiver's content area.

```
- (NSSize)contentSize
```

Return Value

The size of the receiver's content area.

Availability

Available in Mac OS X v10.0 and later.

See Also

- setContentSize: (page 1041)
- setMaxContentSize: (page 1042)
- setMinContentSize: (page 1043)

Declared In

NSDrawer.h

contentView

Returns the receiver's content view.

```
- (NSView *)contentView
```

Return Value

The receiver's content view.

Availability

Available in Mac OS X v10.0 and later.

See Also
- setContentView: (page 1041)

Declared In
NSDrawer.h

delegate

Returns the receiver's delegate.

```
- (id < NSDrawerDelegate >)delegate
```

Return Value
The receiver's delegate.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setDelegate: (page 1042)

Declared In
NSDrawer.h

edge

Returns the edge of the window that the receiver is connected to.

```
- (NSRectEdge)edge
```

Return Value
The edge of the parent window at which the drawer is attached. See "Constants" (page 1046) for a list of edge constants and locations.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSDrawer.h

initWithContentSize:preferredEdge:

Creates a new drawer with the given size on the specified edge of the parent window.

```
- (id)initWithContentSize:(NSSize)contentSize preferredEdge:(NSRectEdge)edge
```

Parameters

contentSize
The size of the new drawer.

edge
The edge to which to attach the new drawer.

Discussion
You must specify the parent window and content view of the drawer using the methods in this class. When you create a drawer in Interface Builder, this constructor is invoked. The NSDrawer Inspector in Interface Builder allows you to set the edge, and you can specify the size by changing the content view in Interface Builder.

See Positioning and Sizing a Drawer for additional detail on content size and drawer positioning.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
DrawerMadness

Declared In
`NSDrawer.h`

leadingOffset

Returns the receiver's leading offset.

```
- (CGFloat)leadingOffset
```

Return Value
The receiver's leading offset. This is the distance from the top or left edge of the parent window to the drawer.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setLeadingOffset:` (page 1042)

Declared In
`NSDrawer.h`

maxContentSize

Returns the maximum allowed size of the receiver's content area.

```
- (NSSize)maxContentSize
```

Return Value
The maximum size of the receiver's content area. This is useful for determining if an opened drawer would fit onscreen given the current window position.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setMaxContentSize:` (page 1042)

Declared In
`NSDrawer.h`

minContentSize

Returns the minimum allowed size of the receiver's content area.

```
- (NSSize)minContentSize
```

Return Value
The minimum size of the receiver's content area.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setMinContentSize:` (page 1043)

Declared In
`NSDrawer.h`

open

If the receiver is closed, this method opens it.

```
- (void)open
```

Discussion
Calling *open* on an open drawer does nothing. You can get the state of a drawer by sending it `state` (page 1044). If an edge is not specified, an attempt will be made to choose an edge based on the space available to display the drawer onscreen. If you need to ensure that a drawer opens on a particular edge, use `openOnEdge:` (page 1040).

Availability
Available in Mac OS X v10.0 and later.

See Also
`- close` (page 1035)

Declared In
`NSDrawer.h`

open:

An action method to open the drawer.

```
- (void)open:(id)sender
```

Parameters
sender
A user interface element, such as a button or menu item, that invokes the action method.

Discussion
This method is an action method and likely would not be invoked programatically. Rather, it is an action that is commonly connected in Interface Builder.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `close:` (page 1036)

Declared In
`NSDrawer.h`

openOnEdge:

Causes the receiver to open on the specified edge of the parent window.

```
- (void)openOnEdge:(NSRectEdge)edge
```

Parameters

edge

The edge of the parent window on which to open the receiver. See "Constants" (page 1046) for a list of edge constants and locations.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
DrawerMadness

Declared In
`NSDrawer.h`

parentWindow

Returns the receiver's parent window.

```
- (NSWindow *)parentWindow
```

Return Value
The receiver's parent window. By definition, a drawer can appear onscreen only if it has a parent.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setParentWindow:` (page 1043)

Declared In
`NSDrawer.h`

preferredEdge

Returns the receiver's preferred, or default, edge.

```
- (NSRectEdge)preferredEdge
```

Return Value
The receiver's preferred edge. If a drawer is told to open and an edge is not specified at that time, it opens on its preferred edge. When you a create a drawer with Interface Builder, the preferred edge is set to the left by default.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setPreferredEdge:` (page 1044)

Declared In
`NSDrawer.h`

setContentSize:

Sets the size of the receiver's content area.

```
- (void)setContentSize:(NSSize)size
```

Parameters

size
The new size of the receiver's content area. See Positioning and Sizing a Drawer for additional detail.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `contentSize` (page 1036)
- `setMaxContentSize:` (page 1042)
- `setMinContentSize:` (page 1043)

Declared In
`NSDrawer.h`

setContentView:

Sets the receiver's content view.

```
- (void)setContentView:(NSView *)aView
```

Parameters

aView
The content view of the receiver. Rather than connect a drawer to its content view in Interface Builder, you can specify it programatically with this method.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `contentView` (page 1036)

Declared In
NSDrawer.h

setDelegate:

Sets the receiver's delegate.

```
- (void)setDelegate:(id < NSDrawerDelegate >)anObject
```

Parameters

anObject

The object to assign as the receiver's delegate. The object must conform to the *NSDrawerDelegate Protocol Reference*.

Discussion
You may find it useful to associate a delegate with a drawer, especially since drawers do not open and close instantly. A drawer's delegate can better regulate drawer behavior.

Availability
Available in Mac OS X v10.0 and later.

See Also
- delegate (page 1037)

Declared In
NSDrawer.h

setLeadingOffset:

Sets the receiver's leading offset.

```
- (void)setLeadingOffset:(CGFloat)offset
```

Parameters

offset

The leading offset of the receiver. This is the distance from the top or left edge of the parent window to the drawer. See Positioning and Sizing a Drawer for additional detail.

Availability
Available in Mac OS X v10.0 and later.

See Also
- leadingOffset (page 1038)
- setTrailingOffset: (page 1044)

Declared In
NSDrawer.h

setMaxContentSize:

Specifies the maximum size of the receiver's content area.

```
- (void)setMaxContentSize:(NSSize)size
```

Parameters

size

The new maximum size of the receiver's content area. See Positioning and Sizing a Drawer for additional detail.

Availability
Available in Mac OS X v10.0 and later.

See Also
- maxContentSize (page 1038)

Declared In
NSDrawer.h

setMinContentSize:

Specifies the minimum size of the receiver's content area.

```
- (void)setMinContentSize:(NSSize)size
```

Parameters

size

The new minimum size of the receiver's content area. See Positioning and Sizing a Drawer for additional detail.

Availability
Available in Mac OS X v10.0 and later.

See Also
- minContentSize (page 1039)

Declared In
NSDrawer.h

setParentWindow:

Sets the receiver's parent window.

```
- (void)setParentWindow:(NSWindow *)parent
```

Parameters

parent

The parent window of the receiver. Every drawer must be associated with a parent window for a drawer to appear onscreen. If this argument is nil, the drawer is removed from its parent.

Discussion
Changes in a drawer's parent window do not take place while the drawer is onscreen; they are delayed until the drawer next closes.

Availability
Available in Mac OS X v10.0 and later.

See Also
- parentWindow (page 1040)

Declared In
NSDrawer.h

setPreferredEdge:

Sets the receiver's preferred, or default, edge.

```
- (void)setPreferredEdge:(NSRectEdge)preferredEdge
```

Parameters

preferredEdge

The edge on which the receiver should open by default. A drawer can be told to open on a specific edge (page 1037); if an edge is not specified, however, it opens on the preferred edge.

Availability
Available in Mac OS X v10.0 and later.

See Also
- preferredEdge (page 1040)

Declared In
NSDrawer.h

setTrailingOffset:

Sets the receiver's trailing offset.

```
- (void)setTrailingOffset:(CGFloat)offset
```

Parameters

offset

The receiver's trailing offset. This is the distance to the right or bottom edge of the drawer from the right or bottom edge of the parent window. See Positioning and Sizing a Drawer for additional detail.

Availability
Available in Mac OS X v10.0 and later.

See Also
- leadingOffset (page 1038)

Declared In
NSDrawer.h

state

Returns the state of the receiver.

```
- (NSInteger)state
```

Return Value
The drawer's state. Refer to `NSDrawerState` (page 1046) for a list of possible values.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
DrawerMadness

Declared In
`NSDrawer.h`

toggle:

Toggles the drawer open or closed.

```
- (void)toggle:(id)sender
```

Parameters

sender
The sender of the message.

Discussion
If the receiver is closed, or in the process of either opening or closing, it is opened. Otherwise, the drawer is closed.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
QTAudioExtractionPanel

Declared In
`NSDrawer.h`

trailingOffset

Returns the receiver's trailing offset.

```
- (CGFloat)trailingOffset
```

Return Value
The receiver's trailing offset. This is the distance to the right or bottom edge of the drawer from the right or bottom edge of the parent window.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setTrailingOffset:` (page 1044)

Declared In
`NSDrawer.h`

Constants

NSDrawerState

These constants specify the possible states of a drawer.

```
typedef enum _NSDrawerState {
    NSDrawerClosedState  = 0,
    NSDrawerOpeningState = 1,
    NSDrawerOpenState    = 2,
    NSDrawerClosingState = 3
} NSDrawerState;
```

Constants

`NSDrawerClosedState`
The drawer is closed (not visible onscreen).
Available in Mac OS X v10.0 and later.
Declared in `NSDrawer.h`.

`NSDrawerOpeningState`
The drawer is in the process of opening.
Available in Mac OS X v10.0 and later.
Declared in `NSDrawer.h`.

`NSDrawerOpenState`
The drawer is open (visible onscreen).
Available in Mac OS X v10.0 and later.
Declared in `NSDrawer.h`.

`NSDrawerClosingState`
The drawer is in the process of closing.
Available in Mac OS X v10.0 and later.
Declared in `NSDrawer.h`.

Discussion
These constants are returned by `state` (page 1044).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSDrawer.h`

Notifications

NSDrawerDidCloseNotification

Posted whenever the drawer is closed.

The notification object is the `NSDrawer` object that closed. This notification does not contain a *`userInfo`* dictionary.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSDrawer.h`

NSDrawerDidOpenNotification

Posted whenever the drawer is opened.

The notification object is the `NSDrawer` object that opened. This notification does not contain a *`userInfo`* dictionary.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSDrawer.h`

NSDrawerWillCloseNotification

Posted whenever the drawer is about to close.

The notification object is the `NSDrawer`object about to close. This notification does not contain a *`userInfo`* dictionary.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSDrawer.h`

NSDrawerWillOpenNotification

Posted whenever the drawer is about to open.

The notification object is the `NSDrawer` object about to open. This notification does not contain a *`userInfo`* dictionary.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSDrawer.h`

NSEPSImageRep Class Reference

Inherits from	NSImageRep : NSObject
Conforms to	NSCoding (NSImageRep) NSCopying (NSImageRep) NSObject (NSObject)
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.0 and later.
Declared in	AppKit/NSEPSImageRep.h
Companion guide	Cocoa Drawing Guide

Overview

An `NSEPSImageRep` object can render an image from encapsulated PostScript (EPS) code.

Tasks

Creating an NSEPSImageRep

`+ imageRepWithData:` (page 1050)
Creates and returns an `NSEPSImageRep` object initialized with the specified EPS data.

`- initWithData:` (page 1051)
Returns an `NSEPSImageRep` object initialized with the specified EPS data.

Getting Image Data

`- boundingBox` (page 1050)
Returns the rectangle that bounds the receiver.

`- EPSRepresentation` (page 1051)
Returns the EPS representation of the receiver.

Drawing the Image

- prepareGState (page 1051)
  Implemented by subclasses to configure the graphics state prior to drawing.

Class Methods

imageRepWithData:

Creates and returns an NSEPSImageRep object initialized with the specified EPS data.

```
+ (id)imageRepWithData:(NSData *)epsData
```

Parameters

epsData
The EPS data representing the desired image.

Return Value
A new, initialized NSEPSImageRep object or nil if the object could not be initialized.

Discussion
The size of the receiver is set using the bounding box information specified in the EPS header comments.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSEPSImageRep.h

Instance Methods

boundingBox

Returns the rectangle that bounds the receiver.

```
- (NSRect)boundingBox
```

Return Value
The bounding box of the receiver. This rectangle is obtained from the "%%BoundingBox:" comment in the EPS header when the NSEPSImageRep object is initialized.

Availability
Available in Mac OS X v10.0 and later.

See Also
+ imageRepWithData: (page 1050)
- initWithData: (page 1051)

Declared In
NSEPSImageRep.h

EPSRepresentation

Returns the EPS representation of the receiver.

```
- (NSData *)EPSRepresentation
```

Return Value
A data object containing the EPS data for the image.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSEPSImageRep.h

initWithData:

Returns an `NSEPSImageRep` object initialized with the specified EPS data.

```
- (id)initWithData:(NSData *)epsData
```

Parameters
epsData
The EPS data representing the desired image.

Return Value
The initialized `NSEPSImageRep` object or `nil` if the object could not be initialized

Discussion
The size of the receiver is set using the bounding box information specified in the EPS header comments.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSEPSImageRep.h

prepareGState

Implemented by subclasses to configure the graphics state prior to drawing.

```
- (void)prepareGState
```

Discussion
The `draw` (page 1415) method of `NSEPSImageRep` sends this message to itself just before rendering the EPS code. The default implementation of this method does nothing. You can override it in your subclass to prepare the graphics state as needed.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSEPSImageRep.h`

NSEvent Class Reference

Inherits from	NSObject
Conforms to	NSCoding NSCopying NSObject (NSObject)
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.0 and later.
Declared in	AppKit/NSEvent.h
Companion guide	Cocoa Event-Handling Guide
Related sample code	Cocoa OpenGL DragItemAround GLUT LightTable Sketch-112

Overview

An `NSEvent` object, or simply an event, contains information about an input action such as a mouse click or a key down. The Application Kit associates each such user action with a window, reporting the event to the application that created the window. The `NSEvent` object contains pertinent information about each event, such as where the cursor was located or which character was typed. As the application receives events, it temporarily places them in a buffer called the event queue. When the application is ready to process an event, it takes one from the queue.

Beginning with Mac OS X version 10.4, `NSEvent` objects can represent tablet-pointing and tablet-proximity events. A tablet-proximity event is generated when a pointing device enters or leaves proximity of its tablet; such event objects have a type of `NSTypeProximity` or a mouse subtype of `NSTabletProximityEventSubtype`. A tablet-pointing event is generated when a pointing device changes state, such as location, pressure, or tilt; such event objects have a type of `NSTypePoint` or a mouse subtype of `NSTabletPointEventSubtype`. The Application Kit reports all pure tablet events to responder objects through the `NSResponder` methods `tabletPoint:` (page 2199) and `tabletProximity:` (page 2200). Mouse events can also contain tablet data (as event subtypes), so you can handle these events by overriding the `NSResponder` methods `mouseDown:` (page 2164), `mouseDragged:` (page 2164), and `mouseUp:` (page 2166).

Support for touch and gesture events masks have been added to `NSEvent` in Mac OS X v10.6. Magnify (pinch), swipe, and rotate masks are supported, as are more generic gesture masks. Using `touchesMatchingPhase:inView:` (page 1086) method a view can get all of the touch events associated with a gesture without overriding the individual touch responder methods defined in `NSResponder`.

Mac OS X v10.6 adds the ability to create application event monitors that call block object handlers for certain event types that are sent through the `NSApplication sendEvent:` (page 167) method. You can create a local monitor that will be informed of the events in your application and allow you to modify or cancel them. You can also create a global event monitor that allows you to monitor events in other applications, although you are unable to alter those events. See "Monitoring Application Events" (page 1058) for more information.

Tasks

Creating Events

`+ keyEventWithType:location:modifierFlags:timestamp:windowNumber:context:characters:charactersIgnoringModifiers:isARepeat:keyCode:` (page 1063)

Returns a new `NSEvent` object describing a key event.

`+ mouseEventWithType:location:modifierFlags:timestamp:windowNumber:context:eventNumber:clickCount:pressure:` (page 1066)

Returns a new NSEvent object describing a mouse-down, -up, -moved, or -dragged event.

`+ enterExitEventWithType:location:modifierFlags:timestamp:windowNumber:context:eventNumber:trackingNumber:userData:` (page 1061)

Returns a new `NSEvent` object describing a tracking-rectangle or cursor-update event.

`+ otherEventWithType:location:modifierFlags:timestamp:windowNumber:context:subtype:data1:data2:` (page 1067)

Returns a new NSEvent object describing a custom event.

`+ eventWithEventRef:` (page 1063)

Creates an event object that is based on a Carbon type of event.

`+ eventWithCGEvent:` (page 1062)

Creates and returns an event object that is based on a Core Graphics type of event.

Getting General Event Information

`- context` (page 1075)

Returns the display graphics context of the receiver.

`- locationInWindow` (page 1080)

Returns the receiver's location in the base coordinate system of the associated window.

`- modifierFlags` (page 1082)

Returns an integer bit field indicating the modifier keys in effect for the receiver.

`- timestamp` (page 1086)

Returns the time the receiver occurred in seconds since system startup.

`- type` (page 1088)

Returns the type of the receiving event.

- `window` (page 1090)
  Returns the window object associated with the receiver.
- `windowNumber` (page 1091)
  Returns the identifier for the window device associated with the receiver.
- `eventRef` (page 1079)
  Returns the Carbon type associated with the receiver for representing an event.
- `CGEvent` (page 1073)
  Returns a Core Graphics event object corresponding to the receiver.

Getting Key Event Information

+ `modifierFlags` (page 1065)
  Returns the currently pressed modifier flags.
+ `keyRepeatDelay` (page 1065)
  Returns the length of time a key must be held down in order to generate the first key repeat event.
+ `keyRepeatInterval` (page 1065)
  Returns the length between subsequent key repeat events being posted.
- `characters` (page 1074)
  Returns the characters associated with the receiving key-up or key-down event.
- `charactersIgnoringModifiers` (page 1074)
  Returns the characters generated by the receiving key event as if no modifier key (except for Shift) applies.
- `isARepeat` (page 1079)
  Returns `YES` if the receiving key event is a repeat caused by the user holding the key down, `NO` if the key event is new.
- `keyCode` (page 1080)
  Returns the virtual key code for the keyboard key associated with the receiving key event.

Getting Mouse Event Information

+ `pressedMouseButtons` (page 1068)
  Returns the indices of the currently depressed mouse buttons.
+ `doubleClickInterval` (page 1061)
  Returns the time, in seconds, in which a second mouse click must occur in order to be considered a double click.
+ `mouseLocation` (page 1067)
  Reports the current mouse position in screen coordinates.
- `buttonNumber` (page 1073)
  Returns the button number for the mouse button that generated an `NSOtherMouse...` event.
- `clickCount` (page 1075)
  Returns the number of mouse clicks associated with the receiver, which represents a mouse-down or mouse-up event.

- `pressure` (page 1083)
  Returns a value from 0.0 through 1.0 indicating the pressure applied to the input device (used for appropriate devices).
+ `setMouseCoalescingEnabled:` (page 1069)
  Controls whether mouse-movement event coalescing is enabled.
+ `isMouseCoalescingEnabled` (page 1063)
  Indicates whether mouse-movement event coalescing is enabled.

Getting Mouse-Tracking Event Information

- `eventNumber` (page 1078)
  Returns the counter value of the latest mouse or tracking-rectangle event object; every system-generated mouse and tracking-rectangle event increments this counter.
- `trackingNumber` (page 1087)
  Returns the identifier of a mouse-tracking event.
- `trackingArea` (page 1087)
  Returns the `NSTrackingArea` object that generated the event represented by the receiver.
- `userData` (page 1089)
  Returns data associated with a mouse-tracking event,

Getting Custom Event Information

- `data1` (page 1076)
  Returns additional data associated with the receiver.
- `data2` (page 1076)
  Returns additional data associated with the receiver.
- `subtype` (page 1084)
  Returns the subtype of the receiving event object.

Getting Scroll Wheel Event Information

- `deltaX` (page 1077)
  Returns the x-coordinate change for a scroll wheel, mouse-move, or mouse-drag event.
- `deltaY` (page 1077)
  Returns the y-coordinate change for a scroll wheel, mouse-move, or mouse-drag event.
- `deltaZ` (page 1077)
  Returns the z-coordinate change for a scroll wheel, mouse-move, or mouse-drag event.

Getting Tablet Proximity Information

- `capabilityMask` (page 1073)
  Returns a mask whose set bits indicate the capabilities of the tablet device that generated the event represented by the receiver.

- `deviceID` (page 1078)
  Returns a special identifier that is used to match tablet-pointer events with the tablet-proximity event represented by the receiver.
- `isEnteringProximity` (page 1080)
  Returns `YES` to indicate that a pointing device is entering the proximity of its tablet and `NO` when it is leaving it.
- `pointingDeviceID` (page 1082)
  Returns the index of the pointing device currently in proximity with the tablet.
- `pointingDeviceSerialNumber` (page 1082)
  Returns the vendor-assigned serial number of a pointing device of a certain type.
- `pointingDeviceType` (page 1083)
  Returns a `NSPointingDeviceType` constant indicating the kind of pointing device associated with the receiver.
- `systemTabletID` (page 1085)
  Returns the index of the tablet device connected to the system.
- `tabletID` (page 1085)
  Returns the USB model identifier of the tablet device associated with the receiver.
- `uniqueID` (page 1088)
  Returns the unique identifier of the pointing device that generated the event represented by the receiver.
- `vendorID` (page 1090)
  Returns the vendor identifier of the tablet associated with the receiver.
- `vendorPointingDeviceType` (page 1090)
  Returns a coded bit field whose set bits indicate the type of pointing device (within a vendor selection) associated with the receiver.

Getting Tablet Pointing Information

- `absoluteX` (page 1071)
  Reports the absolute x coordinate of a pointing device on its tablet at full tablet resolution.
- `absoluteY` (page 1071)
  Reports the absolute y coordinate of a pointing device on its tablet at full tablet resolution.
- `absoluteZ` (page 1072)
  Reports the absolute z coordinate of pointing device on its tablet at full tablet resolution.
- `buttonMask` (page 1072)
  Returns a bit mask identifying the buttons pressed when the tablet event represented by the receiver was generated.
- `rotation` (page 1084)
  Returns the rotation in degrees of the tablet pointing device associated with the receiver.
- `tangentialPressure` (page 1085)
  Reports the tangential pressure on the device that generated the event represented by the receiver.
- `tilt` (page 1086)
  Reports the scaled tilt values of the pointing device that generated the event represented by the receiver.

- `vendorDefined` (page 1089)
  Returns an array of three vendor-defined `NSNumber` objects associated with the pointing-type event represented by the receiver.

Requesting and Stopping Periodic Events

+ `startPeriodicEventsAfterDelay:withPeriod:` (page 1070)
  Begins generating periodic events for the current thread.

+ `stopPeriodicEvents` (page 1070)
  Stops generating periodic events for the current thread and discards any periodic events remaining in the queue.

Getting Touch and Gesture Information

- `magnification` (page 1081)
  Returns the change in magnification.

- `touchesMatchingPhase:inView:` (page 1086)
  Returns all the `NSTouch` objects associated with a specific phase.

Monitoring Application Events

+ `addGlobalMonitorForEventsMatchingMask:handler:` (page 1058)
  Installs an event monitor that receives copies of events posted to other applications.

+ `addLocalMonitorForEventsMatchingMask:handler:` (page 1060)
  Installs an event monitor that receives copies of events posted to this application before they are dispatched.

+ `removeMonitor:` (page 1069)
  Remove the specified event monitor.

Class Methods

addGlobalMonitorForEventsMatchingMask:handler:

Installs an event monitor that receives copies of events posted to other applications.

```
+ (id)addGlobalMonitorForEventsMatchingMask:(NSEventMask)mask handler:(void
    (^)(NSEvent*))block
```

Parameters

mask
  An event mask specifying which events you wish to monitor. See `Masks for event types` (page 1096) for possible values.

block

The event handler block object. It is passed the event to monitor. You are unable to change the event, merely observe it.

Return Value
An event handler object.

Discussion
Events are delivered asynchronously to your app and you can only observe the event; you cannot modify or otherwise prevent the event from being delivered to its original target application.

Key-related events may only be monitored if accessibility is enabled or if your application is trusted for accessibility access (see `AXIsProcessTrusted`).

Note that your handler will not be called for events that are sent to your own application.

Special Considerations

In Mac OS X v 10.6, event monitors are only able to monitor the following event types:

- `NSFlagsChanged` (page 1095)
- `NSLeftMouseDragged` (page 1094)
- `NSRightMouseDragged` (page 1094)
- `NSOtherMouseDragged` (page 1094)
- `NSLeftMouseUp` (page 1093)
- `NSRightMouseUp` (page 1093)
- `NSOtherMouseUp` (page 1094)
- `NSLeftMouseDown` (page 1093)
- `NSRightMouseDown` (page 1093)
- `NSOtherMouseDown` (page 1094)
- `NSMouseMoved` (page 1094)
- `NSFlagsChanged` (page 1095)
- `NSScrollWheel` (page 1095)
- `NSTabletPoint` (page 1095)
- `NSTabletProximity` (page 1095)
- `NSKeyDown` (page 1094) (Key repeats are determined by sending the event an `isARepeat` (page 1079) message.)

Availability
Available in Mac OS X v10.6 and later.

See Also
`+ addLocalMonitorForEventsMatchingMask:handler:` (page 1060)
`+ removeMonitor:` (page 1069)

Declared In
`NSEvent.h`

addLocalMonitorForEventsMatchingMask:handler:

Installs an event monitor that receives copies of events posted to this application before they are dispatched.

```
+ (id)addLocalMonitorForEventsMatchingMask:(NSEventMask)mask handler:(NSEvent*
    (^)(NSEvent*))block
```

Parameters

mask

An event mask specifying which events you wish to monitor. See `Masks for event types` (page 1096) for possible values.

block

The event handler block object. It is passed the event to monitor. You can return the event unmodified, create and return a new NSEvent object, or return nil to stop the dispatching of the event.

Return Value

An event handler object.

Discussion

Your handler will not be called for events that are consumed by nested event-tracking loops such as control tracking, menu tracking, or window dragging; only events that are dispatched through the applications `sendEvent:` (page 167) method will be passed to your handler.

Special Considerations

In Mac OS X v 10.6, event monitors are only able to monitor the following event types:

- `NSFlagsChanged` (page 1095)
- `NSLeftMouseDragged` (page 1094)
- `NSRightMouseDragged` (page 1094)
- `NSOtherMouseDragged` (page 1094)
- `NSLeftMouseUp` (page 1093)
- `NSRightMouseUp` (page 1093)
- `NSOtherMouseUp` (page 1094)
- `NSLeftMouseDown` (page 1093)
- `NSRightMouseDown` (page 1093)
- `NSOtherMouseDown` (page 1094)
- `NSMouseMoved` (page 1094)
- `NSFlagsChanged` (page 1095)
- `NSScrollWheel` (page 1095)
- `NSTabletPoint` (page 1095)
- `NSTabletProximity` (page 1095)
- `NSKeyDown` (page 1094) (Key repeats are determined by sending the event an `isARepeat` (page 1079) message.)

Availability

Available in Mac OS X v10.6 and later.

See Also
`+ addGlobalMonitorForEventsMatchingMask:handler:` (page 1058)

Declared In
`NSEvent.h`

doubleClickInterval

Returns the time, in seconds, in which a second mouse click must occur in order to be considered a double click.

```
+ (NSTimeInterval)doubleClickInterval
```

Return Value
The double-click time interval, in seconds.

Discussion
This is a system setting, overriding this method will have no effect.

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSEvent.h`

enterExitEventWithType:location:modifierFlags:timestamp:windowNumber:context:eventNumber:trackingNumber:userData:

Returns a new `NSEvent` object describing a tracking-rectangle or cursor-update event.

```
+ (NSEvent *)enterExitEventWithType:(NSEventType)type location:(NSPoint)location
    modifierFlags:(NSUInteger)flags timestamp:(NSTimeInterval)time
    windowNumber:(NSInteger)windowNumber context:(NSGraphicsContext *)context
    eventNumber:(NSInteger)eventNumber trackingNumber:(NSInteger)trackingNumber
    userData:(void *)userData
```

Parameters

type
One of the following event-type constants: `NSMouseEntered`, `NSMouseExited`, `NSCursorUpdate`. If the specified constant is not one of these, an `NSInternalInconsistencyException` is raised

location
The cursor location in the base coordinate system of the window specified by *windowNum*.

flags
An integer bit field containing any of the modifier key masks described in "Constants" (page 1091), combined using the C bitwise OR operator.

time
The time the event occurred in seconds since system startup.

windowNum
: An integer that identifies the window device associated with the event, which is associated with the `NSWindow` that will receive the event.

context
: The display graphics context of the event.

eventNumber
: An identifier for the new event. It's normally taken from a counter for mouse events, which continually increases as the application runs.

trackingNumber
: A number that identifies the tracking rectangle. This identifier is the same as that returned by the `NSView` method `addTrackingRect:owner:userData:assumeInside:` (page 3142).

userData
: Data arbitrarily associated with the tracking rectangle when it was set up using the `NSView` method `addTrackingRect:owner:userData:assumeInside:` (page 3142).

Return Value
The created `NSEvent` object or `nil` if the object could not be created.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `eventNumber` (page 1078)
- `trackingNumber` (page 1087)
- `userData` (page 1089)

Declared In
`NSEvent.h`

eventWithCGEvent:

Creates and returns an event object that is based on a Core Graphics type of event.

```
+ (NSEvent *)eventWithCGEvent:(CGEventRef)cgEvent
```

Parameters

cgEvent
: A `CGEventRef` opaque type that represents an event.

Return Value
An autoreleased `NSEvent` object that is equivalent to *cgEvent*.

Discussion
The returned object retains the `CGEventRef` object (`cgEvent`) until it (the Objective-C object) is freed—it then releases the `CGEventRef` object. If no Cocoa event corresponds to the `CGEventRef` object, this method returns `nil`.

Availability
Available in Mac OS X v10.5 and later.

See Also
- `CGEvent` (page 1073)

Declared In
NSEvent.h

eventWithEventRef:

Creates an event object that is based on a Carbon type of event.

```
+ (NSEvent *)eventWithEventRef:(const void *)eventRef
```

Parameters

eventRef

The EventRef opaque type to be associated with the created NSEvent object.

Return Value
An autoreleased NSEvent object corresponding to *eventRef* or nil if *eventRef* cannot be converted into an equivalent NSEvent object.

Discussion
This method is valid for all events. The created NSEvent object retains the EventRef object and is released when the NSEvent object is freed.

Availability
Available in Mac OS X v10.5 and later.

See Also
- eventRef (page 1079)

Declared In
NSEvent.h

isMouseCoalescingEnabled

Indicates whether mouse-movement event coalescing is enabled.

```
+ (BOOL)isMouseCoalescingEnabled
```

Return Value
YES if mouse-movement event coalescing is enabled, NO if it is disabled.

Availability
Available in Mac OS X v10.5 and later.

See Also
+ setMouseCoalescingEnabled: (page 1069)

Declared In
NSEvent.h

keyEventWithType:location:modifierFlags:timestamp:windowNumber:context:characters:charactersIgnoringModifiers:isARepeat:keyCode:

Returns a new NSEvent object describing a key event.

```
+ (NSEvent *)keyEventWithType:(NSEventType)type location:(NSPoint)location
    modifierFlags:(NSUInteger)flags timestamp:(NSTimeInterval)time
    windowNumber:(NSInteger)windowNum context:(NSGraphicsContext *)context
    characters:(NSString *)characters charactersIgnoringModifiers:(NSString
    *)unmodCharacters isARepeat:(BOOL)repeatKey keyCode:(unsigned short)code
```

Parameters

type

One of the following event-type constants: `NSKeyDown`, `NSKeyUp`, `NSFlagsChanged`. If anything else is specified, an `NSInternalInconsistencyException` is raised.

location

The cursor location in the base coordinate system of the window specified by *windowNum*.

flags

An integer bit field containing any of the modifier key masks described in "Constants" (page 1091), combined using the C bitwise OR operator.

time

The time the event occurred in seconds since system startup.

windowNum

An integer that identifies the window device associated with the event, which is associated with the `NSWindow` that will receive the event.

context

The display graphics context of the event.

characters

A string of characters associated with the key event. Though most key events contain only one character, it is possible for a single keypress to generate a series of characters.

unmodCharacters

The string of characters generated by the key event as if no modifier key had been pressed (except for Shift). This argument is useful for getting the "basic" key value in a hardware-independent manner.

repeatKey

`YES` if the key event is a repeat caused by the user holding the key down, `NO` if the key event is new.

code

A number that identifies the keyboard key associated with the key event. Its value is hardware-independent.

Return Value

The created `NSEvent` instance or `nil` if the instance could not be created.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `characters` (page 1074)
- `charactersIgnoringModifiers` (page 1074)
- `isARepeat` (page 1079)
- `keyCode` (page 1080)

Declared In

`NSEvent.h`

keyRepeatDelay

Returns the length of time a key must be held down in order to generate the first key repeat event.

```
+ (NSTimeInterval)keyRepeatDelay
```

Return Value
The delay interval, in seconds.

Discussion
This is a system setting, overriding this method will have no effect.

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSEvent.h`

keyRepeatInterval

Returns the length between subsequent key repeat events being posted.

```
+ (NSTimeInterval)keyRepeatInterval
```

Return Value
The repeat interval, in seconds.

Discussion
This is a system setting, overriding this method will have no effect.

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSEvent.h`

modifierFlags

Returns the currently pressed modifier flags.

```
+ (NSUInteger)modifierFlags
```

Return Value
A mask of the current modifiers using the values in "Modifier Flags" (page 1100).

Discussion
This returns the state of devices combined with synthesized events at the moment, independent of which events have been delivered via the event stream.

Availability
Available in Mac OS X v10.6 and later.

Declared In
NSEvent.h

mouseEventWithType:location:modifierFlags:timestamp:windowNumber:context:eventNumber:clickCount:pressure:

Returns a new NSEvent object describing a mouse-down, -up, -moved, or -dragged event.

```
+ (NSEvent *)mouseEventWithType:(NSEventType)type location:(NSPoint)location
    modifierFlags:(NSUInteger)flags timestamp:(NSTimeInterval)time
    windowNumber:(NSInteger)windowNum context:(NSGraphicsContext *)context
    eventNumber:(NSInteger)eventNumber clickCount:(NSInteger)clickNumber
    pressure:(float)pressure
```

Parameters

type
One of the modifier key masks described in "Constants" (page 1091), or an NSInternalInconsistencyException is raised.

location
The cursor location in the base coordinate system of the window specified by *windowNum*.

flags
An integer bit field containing any of the modifier key masks described in "Constants" (page 1091), combined using the C bitwise OR operator.

time
The time the event occurred in seconds since system startup.

windowNum
An integer that identifies the window device associated with the event, which is associated with the NSWindow that will receive the event.

context
The display graphics context of the event.

eventNumber
An identifier for the new event. It's normally taken from a counter for mouse events, which continually increases as the application runs.

clickNumber
The number of mouse clicks associated with the mouse event.

pressure
A value from 0.0 to 1.0 indicating the pressure applied to the input device on a mouse event, used for an appropriate device such as a graphics tablet. For devices that aren't pressure-sensitive, the value should be either 0.0 or 1.0.

Return Value
The created NSEvent instance or nil if the instance could not be created.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `clickCount` (page 1075)
- `eventNumber` (page 1078)
- `pressure` (page 1083)

Declared In
`NSEvent.h`

mouseLocation

Reports the current mouse position in screen coordinates.

```
+ (NSPoint)mouseLocation
```

Return Value
The current mouse location in screen coordinates.

Discussion
This method is similar to the `NSWindow` method `mouseLocationOutsideOfEventStream` (page 3348). It returns the location regardless of the current event or pending events. The difference between these methods is that `mouseLocationOutsideOfEventStream` returns a point in the receiving window's coordinates and `mouseLocation` returns the same information in screen coordinates.

> **Note:** The `y` coordinate of the returned point will never be less than `1`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSEvent.h`

otherEventWithType:location:modifierFlags:timestamp:windowNumber:context:subtype:data1:data2:

Returns a new NSEvent object describing a custom event.

```
+ (NSEvent *)otherEventWithType:(NSEventType)type location:(NSPoint)location
    modifierFlags:(NSUInteger)flags timestamp:(NSTimeInterval)time
    windowNumber:(NSInteger)windowNum context:(NSGraphicsContext *)context
    subtype:(short)subtype data1:(NSInteger)data1 data2:(NSInteger)data2
```

Parameters

type

One of the following event-type constants:

`NSAppKitDefined`

`NSSystemDefined`

`NSApplicationDefined`

`NSPeriodic`

If *type* is anything else, an `NSInternalInconsistencyException` is raised. Your code should only create events of type `NSApplicationDefined`.

location

The cursor location in the base coordinate system of the window specified by *windowNum*.

flags

An integer bit field containing any of the modifier key masks described in "Constants" (page 1091), combined using the C bitwise OR operator.

time

The time the event occurred in seconds since system startup.

windowNum

An integer that identifies the window device associated with the event, which is associated with the `NSWindow` that will receive the event.

context

The display graphics context of the event.

subtype

A numeric identifier that further differentiates custom events of types `NSAppKitDefined`, `NSSystemDefined`, and `NSApplicationDefined`. `NSPeriodic` events don't use this attribute.

data1

Additional data associated with the event. `NSPeriodic` events don't use these attributes.

data2

Additional data associated with the event. `NSPeriodic` events don't use these attributes.

Return Value

The created `NSEvent` object or `nil` if the object couldn't be created.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `subtype` (page 1084)
- `data1` (page 1076)
- `data2` (page 1076)

Declared In

`NSEvent.h`

pressedMouseButtons

Returns the indices of the currently depressed mouse buttons.

```
+ (NSUInteger)pressedMouseButtons
```

Return Value
The indices of the currently depressed mouse buttons.

Discussion
A return value of `1 << 0` corresponds to left the mouse, `1 << 1` corresponds to the right mouse, `1<< n, n >=2` to other mouse buttons.

This returns the state of devices combined with synthesized events at the moment, independent of which events have been delivered via the event stream, so this method is not suitable for tracking.

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSEvent.h`

removeMonitor:

Remove the specified event monitor.

```
+ (void)removeMonitor:(id)eventMonitor
```

Parameters

eventMonitor
The event handler object to remove.

Discussion
You must ensure that *eventMonitor* is removed only once. Removing the same *eventMonitor* instance multiple times results in an over-release condition, even in a Garbage Collected environment

Availability
Available in Mac OS X v10.6 and later.

See Also
`+ addGlobalMonitorForEventsMatchingMask:handler:` (page 1058)

AnimatedTableView

Declared In
`NSEvent.h`

setMouseCoalescingEnabled:

Controls whether mouse-movement event coalescing is enabled.

```
+ (void)setMouseCoalescingEnabled:(BOOL)flag
```

Parameters

flag
`YES` to enable mouse-movement event coalescing, `NO` to disable it.

Discussion
This method affects mouse-moved, mouse-dragged, and tablet events. Mouse-movement event coalescing is enabled by default.

Availability
Available in Mac OS X v10.5 and later.

See Also
`+ isMouseCoalescingEnabled` (page 1063)

Declared In
`NSEvent.h`

startPeriodicEventsAfterDelay:withPeriod:

Begins generating periodic events for the current thread.

```
+ (void)startPeriodicEventsAfterDelay:(NSTimeInterval)delaySeconds
    withPeriod:(NSTimeInterval)periodSeconds
```

Parameters

delaySeconds
The number of seconds that `NSEvent` should wait before beginning to generate periodic events.

periodSeconds
The period in seconds between the generated events.

Discussion
Raises an `NSInternalInconsistencyException` if periodic events are already being generated for the current thread. This method is typically used in a modal loop while tracking mouse-dragged events.

Availability
Available in Mac OS X v10.0 and later.

See Also
`+ stopPeriodicEvents` (page 1070)

Related Sample Code
Rulers

Declared In
`NSEvent.h`

stopPeriodicEvents

Stops generating periodic events for the current thread and discards any periodic events remaining in the queue.

```
+ (void)stopPeriodicEvents
```

Discussion
This message is ignored if periodic events aren't currently being generated.

Availability
Available in Mac OS X v10.0 and later.

Rulers

Declared In
`NSEvent.h`

Instance Methods

absoluteX

Reports the absolute x coordinate of a pointing device on its tablet at full tablet resolution.

```
- (NSInteger)absoluteX
```

Discussion
For the coordinate to be valid, the receiver should represent an event generated by a tablet pointing device (otherwise 0 is returned). This method is valid only for mouse events with a subtype of `NSTabletPointEventSubtype` and for events of type `NSTabletPoint`. Use this value if you want to scale from tablet location to screen location yourself; otherwise use the class method `mouseLocation` (page 1067) or the instance method `locationInWindow` (page 1080).

Availability
Available in Mac OS X v10.4 and later.

See Also
`- absoluteY` (page 1071)
`- absoluteZ` (page 1072)

Declared In
`NSEvent.h`

absoluteY

Reports the absolute y coordinate of a pointing device on its tablet at full tablet resolution.

```
- (NSInteger)absoluteY
```

Discussion
For the coordinate to be valid, the receiver should represent an event generated by a tablet pointing device (otherwise 0 is returned). This method is valid only for mouse events with a subtype of `NSTabletPointEventSubtype` and for events of type `NSTabletPoint`. Use this value if you want to scale from tablet location to screen location yourself; otherwise use the class method `mouseLocation` (page 1067) or the instance method `locationInWindow` (page 1080).

Availability
Available in Mac OS X v10.4 and later.

See Also
- `absoluteX` (page 1071)
- `absoluteZ` (page 1072)

Declared In
`NSEvent.h`

absoluteZ

Reports the absolute z coordinate of pointing device on its tablet at full tablet resolution.

```
- (NSInteger)absoluteZ
```

Discussion
For the coordinate to be valid, the receiver should represent an event generated by a tablet pointing device (otherwise 0 is returned). The z coordinate does not represent pressure. It registers the depth coordinate returned by some tablet devices with wheels; if the device is something other than these, 0 is returned. This method is valid only for mouse events with a subtype of `NSTabletPointEventSubtype` and for events of type `NSTabletPoint`.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `absoluteX` (page 1071)
- `absoluteY` (page 1071)

Declared In
`NSEvent.h`

buttonMask

Returns a bit mask identifying the buttons pressed when the tablet event represented by the receiver was generated.

```
- (NSUInteger)buttonMask
```

Discussion
Use one or more of the button-mask constants described in "Constants" (page 1091) to determine which buttons of the pointing device are pressed. This method is valid only for mouse events with a subtype of `NSTabletPointEventSubtype` and for events of type `NSTabletPoint`.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`NSEvent.h`

buttonNumber

Returns the button number for the mouse button that generated an `NSOtherMouse...` event.

```
- (NSInteger)buttonNumber
```

Discussion
This method is intended for use with the `NSOtherMouseDown`, `NSOtherMouseUp`, and `NSOtherMouseDragged` events, but will return values for `NSLeftMouse...` and `NSRightMouse...` events also.

Availability
Available in Mac OS X v10.1 and later.

Declared In
`NSEvent.h`

capabilityMask

Returns a mask whose set bits indicate the capabilities of the tablet device that generated the event represented by the receiver.

```
- (NSUInteger)capabilityMask
```

Discussion
These bits are vendor-defined. This method is valid only for mouse events with a subtype of `NSTabletProximityEventSubtype` and for events of type `NSTabletProximity`.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`NSEvent.h`

CGEvent

Returns a Core Graphics event object corresponding to the receiver.

```
- (CGEventRef)CGEvent
```

Discussion
The returned `CGEventRef` opaque type is autoreleased. If no `CGEventRef` object corresponding to the `NSEvent` object can be created, this method returns `NULL`.

Availability
Available in Mac OS X v10.5 and later.

See Also
`+ eventWithCGEvent:` (page 1062)

Declared In
`NSEvent.h`

characters

Returns the characters associated with the receiving key-up or key-down event.

```
- (NSString *)characters
```

Discussion
These characters are derived from a keyboard mapping that associates various key combinations with Unicode characters. Raises an `NSInternalInconsistencyException` if sent to any other kind of event object.

This method returns an empty string for dead keys, such as Option-e. However, for a key combination such as Option-Shift-e this method returns the standard accent ("´").

For a list of constants corresponding to commonly-used Unicode characters, see *NSText Class Reference*.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- charactersIgnoringModifiers` (page 1074)

Related Sample Code
Cocoa OpenGL
CocoaDVDPlayer
FunHouse
GLUT
TrackBall

Declared In
`NSEvent.h`

charactersIgnoringModifiers

Returns the characters generated by the receiving key event as if no modifier key (except for Shift) applies.

```
- (NSString *)charactersIgnoringModifiers
```

Discussion
Raises an `NSInternalInconsistencyException` if sent to a nonkey event.

This method returns the non-modifier key character pressed for dead keys, such as Option-e. For example, Option-e (no shift key) returns an “e" for this method, whereas the `characters` (page 1074) method returns an empty string.

This method is useful for determining “basic” key values in a hardware-independent manner, enabling such features as keyboard equivalents defined in terms of modifier keys plus character keys. For example, to determine if the user typed Alt-S, you don’t have to know whether Alt-S generates a German double ess, an integral sign, or a section symbol. You simply examine the string returned by this method along with the event’s modifier flags, checking for “s” and `NSAlternateKeyMask`.

For a list of constants corresponding to commonly-used Unicode characters, see *NSText Class Reference*.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `characters` (page 1074)

OpenCL NBody Simulation Example
PDFKitLinker2

Declared In
`NSEvent.h`

clickCount

Returns the number of mouse clicks associated with the receiver, which represents a mouse-down or mouse-up event.

```
- (NSInteger)clickCount
```

Discussion
Raises an `NSInternalInconsistencyException` if sent to a nonmouse event.

Returns 0 for a mouse-up event if a time threshold has passed since the corresponding mouse-down event. This is because if this time threshold passes before the mouse button is released, it is no longer considered a mouse click, but a mouse-down event followed by a mouse-up event.

The return value of this method is meaningless for events other than mouse-down or mouse-up events.

Availability
Available in Mac OS X v10.0 and later.

See Also
+ mouseEventWithType:location:modifierFlags:timestamp:windowNumber:context:eventNumber:clickCount:pressure: (page 1066)

Declared In
`NSEvent.h`

context

Returns the display graphics context of the receiver.

```
- (NSGraphicsContext *)context
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSEvent.h

data1

Returns additional data associated with the receiver.

```
- (NSInteger)data1
```

Discussion
The value returned by this method is dependent on the event type, and is defined by the originator of the event. Raises an `NSInternalInconsistencyException` if sent to an event not of type `NSAppKitDefined`, `NSSystemDefined`, `NSApplicationDefined`, or `NSPeriodic`.

`NSPeriodic` events don't use this attribute.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `data2` (page 1076)
- `subtype` (page 1084)

Declared In
NSEvent.h

deltaX

Returns the x-coordinate change for a scroll wheel, mouse-move, or mouse-drag event.

```
- (CGFloat)deltaX
```

Availability
Available in Mac OS X v10.0 and later.

See Also
- deltaY (page 1077)
- deltaZ (page 1077)

Declared In
NSEvent.h

deltaY

Returns the y-coordinate change for a scroll wheel, mouse-move, or mouse-drag event.

```
- (CGFloat)deltaY
```

Discussion
The behavior of this method may seem counter-intuitive: as the mouse moves up the screen, the value is negative; and as it moves down the screen, the value is positive. The reason for this behavior is that NSEvent computes this delta value in device space, which is flipped, but both the screen and the window's base coordinate system are not flipped.

Availability
Available in Mac OS X v10.0 and later.

See Also
- deltaX (page 1077)
- deltaZ (page 1077)

Declared In
NSEvent.h

deltaZ

Returns the z-coordinate change for a scroll wheel, mouse-move, or mouse-drag event.

```
- (CGFloat)deltaZ
```

Discussion
This value is typically 0.0.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `deltaX` (page 1077)
- `deltaY` (page 1077)

Related Sample Code
Cocoa OpenGL
TrackBall

Declared In
`NSEvent.h`

deviceID

Returns a special identifier that is used to match tablet-pointer events with the tablet-proximity event represented by the receiver.

```
- (NSUInteger)deviceID
```

Discussion
All tablet-pointer events generated in the period between the device entering and leaving tablet proximity have the same device ID. This message is valid only for mouse events with subtype `NSTabletPointEventSubtype` or `NSTabletProximityEventSubtype`, and for `NSTabletPoint` and `NSTabletProximity` events.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `pointingDeviceID` (page 1082)
- `systemTabletID` (page 1085)
- `tabletID` (page 1085)

Declared In
`NSEvent.h`

eventNumber

Returns the counter value of the latest mouse or tracking-rectangle event object; every system-generated mouse and tracking-rectangle event increments this counter.

```
- (NSInteger)eventNumber
```

Discussion
Raises an `NSInternalInconsistencyException` if sent to any other type of event object.

Availability
Available in Mac OS X v10.0 and later.

See Also
`+enterExitEventWithType:location:modifierFlags:timestamp:windowNumber:context:eventNumber:trackingNumber:userData:` (page 1061)

+ mouseEventWithType:location:modifierFlags:timestamp:windowNumber:context:eventNumber:clickCount:pressure: (page 1066)

Declared In
NSEvent.h

eventRef

Returns the Carbon type associated with the receiver for representing an event.

```
- (const void *)eventRef
```

Return Value
Returns an EventRef opaque type corresponding to the receiver. User-input events typically are created with an associated EventRef. An NSEvent object created through other means creates an EventRef in this method if that is necessary and possible. If there is no equivalent NSEvent for the receiver, this method returns NULL.

Discussion
This method is valid for all types of events. The EventRef object is retained by the receiver, so it is valid as long as the NSEvent object is valid, and is released when the NSEvent object is freed. You can use RetainEvent to extend the lifetime of the EventRef object, with a corresponding ReleaseEvent when you are done with it.

Availability
Available in Mac OS X v10.5 and later.

See Also
+ eventWithEventRef: (page 1063)

Declared In
NSEvent.h

isARepeat

Returns YES if the receiving key event is a repeat caused by the user holding the key down, NO if the key event is new.

```
- (BOOL)isARepeat
```

Discussion
Raises an NSInternalInconsistencyException if sent to an NSFlagsChanged event or other nonkey event.

Availability
Available in Mac OS X v10.0 and later.

See Also
+ keyEventWithType:location:modifierFlags:timestamp:windowNumber:context:characters:charactersIgnoringModifiers:isARepeat:keyCode: (page 1063)

Declared In
NSEvent.h

isEnteringProximity

Returns `YES` to indicate that a pointing device is entering the proximity of its tablet and `NO` when it is leaving it.

```
- (BOOL)isEnteringProximity
```

Discussion
This method is valid for mouse events with subtype `NSTabletProximityEventSubtype` and for `NSTabletProximity` events.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`NSEvent.h`

keyCode

Returns the virtual key code for the keyboard key associated with the receiving key event.

```
- (unsigned short)keyCode
```

Return Value
The virtual key code. The returned value is hardware-independent. The value returned is the same as the value returned in the `kEventParamKeyCode` when using Carbon Events.

Discussion
Raises an `NSInternalInconsistencyException` if sent to a non-key event.

Availability
Available in Mac OS X v10.0 and later.

See Also
+ keyEventWithType:location:modifierFlags:timestamp:windowNumber:context:characters:charactersIgnoringModifiers:isARepeat:keyCode: (page 1063)

Related Sample Code

NURBSSurfaceVertexProg
SurfaceVertexProgram
Vertex Optimization

Declared In
`NSEvent.h`

locationInWindow

Returns the receiver's location in the base coordinate system of the associated window.

```
- (NSPoint)locationInWindow
```

Discussion
For non-mouse events the return value of this method is undefined.

With `NSMouseMoved` (page 1094) and possibly other events, the receiver can have a `nil` window (that is, `window` (page 1090) returns nil). In this case, `locationInWindow` returns the event location in screen coordinates.

In a method of a custom view that handles mouse events, you commonly use the `locationInWindow` method in conjunction with the NSView method `convertPoint:fromView:` (page 3155)to get the mouse location in the view's coordinate system. For example:

```
NSPoint event_location = [theEvent locationInWindow];
NSPoint local_point = [self convertPoint:event_location fromView:nil];
```

Note: The y coordinate in the returned point starts from a base of 1, not 0.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- window` (page 1090)

GLSL Showpiece Lite
LightTable
Sketch+Accessibility
Sketch-112

Declared In
`NSEvent.h`

magnification

Returns the change in magnification.

```
- (CGFloat)magnification
```

Return Value
The change in magnification that should be added to the current scaling of an item to achieve the new scale factor.

Discussion
This message is valid for events of type `NSEventTypeMagnify` (page 1096).

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSEvent.h`

modifierFlags

Returns an integer bit field indicating the modifier keys in effect for the receiver.

```
- (NSUInteger)modifierFlags
```

Discussion
You can examine individual flag settings using the C bitwise AND operator with the predefined key masks described in "Constants" (page 1091). The lower 16 bits of the modifier flags are reserved for device-dependent bits.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSEvent.h`

pointingDeviceID

Returns the index of the pointing device currently in proximity with the tablet.

```
- (NSUInteger)pointingDeviceID
```

Discussion
This index is significant for multimode (or Dual Tracking) tablets that support multiple concurrent pointing devices; the index is incremented for each pointing device that comes into proximity. Otherwise, zero is always returned. The receiver of this message should be a mouse event object with subtype `NSTabletProximityEventSubtype` or an event of type `NSTabletProximity`.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `pointingDeviceSerialNumber` (page 1082)
- `pointingDeviceType` (page 1083)
- `systemTabletID` (page 1085)

Declared In
`NSEvent.h`

pointingDeviceSerialNumber

Returns the vendor-assigned serial number of a pointing device of a certain type.

```
- (NSUInteger)pointingDeviceSerialNumber
```

Discussion
Devices of different types, such as a puck and a pen, may have the same serial number. The receiver of this message should be a mouse event object with subtype `NSTabletProximityEventSubtype` or an event of type `NSTabletProximity`.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `pointingDeviceID` (page 1082)
- `pointingDeviceType` (page 1083)

Declared In
`NSEvent.h`

pointingDeviceType

Returns a `NSPointingDeviceType` constant indicating the kind of pointing device associated with the receiver.

```
- (NSPointingDeviceType)pointingDeviceType
```

Discussion
For example, the device could be a pen, eraser, or cursor pointing device. This method is valid for mouse events with subtype `NSTabletProximityEventSubtype` and for `NSTabletProximity` events. See "Constants" (page 1091) for descriptions of valid `NSPointingDeviceType` constants.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `pointingDeviceSerialNumber` (page 1082)
- `pointingDeviceType` (page 1083)

Declared In
`NSEvent.h`

pressure

Returns a value from 0.0 through 1.0 indicating the pressure applied to the input device (used for appropriate devices).

```
- (float)pressure
```

Discussion
For devices that aren't pressure-sensitive, the value is either 0.0 or 1.0. Raises an `NSInternalInconsistencyException` if sent to a nonmouse event.

For tablet pointing devices that are in proximity, the pressure value is 0.0 if they are not actually touching the tablet. As the device is pressed into the tablet, the value is increased.

Availability
Available in Mac OS X v10.0 and later.

See Also
+ `mouseEventWithType:location:modifierFlags:timestamp:windowNumber:context:eventNumber:clickCount:pressure:` (page 1066)
- `rotation` (page 1084)

Declared In
NSEvent.h

rotation

Returns the rotation in degrees of the tablet pointing device associated with the receiver.

```
- (float)rotation
```

Discussion
Many devices do not support rotation, in which case the returned value is 0.0. This method is valid only for mouse events with subtype `NSTabletPointEventSubtype` and for `NSTabletPoint` events.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `pressure` (page 1083)
- `tilt` (page 1086)

Declared In
NSEvent.h

subtype

Returns the subtype of the receiving event object.

```
- (short)subtype
```

Discussion
Raises an `NSInternalInconsistencyException` if sent to an event not of type `NSAppKitDefined`, `NSSystemDefined`, `NSApplicationDefined`, or `NSPeriodic`.

`NSPeriodic` events don't use this attribute.

This method is also valid for mouse events on Mac OS X v10.4 and later. See "Constants" (page 1091) for the predefined mouse and tablet subtypes.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `data1` (page 1076)
- `data2` (page 1076)
- `+ otherEventWithType:location:modifierFlags:timestamp:windowNumber:context:subtype:data1:data2:` (page 1067)

Declared In
NSEvent.h

systemTabletID

Returns the index of the tablet device connected to the system.

```
- (NSUInteger)systemTabletID
```

Discussion
If multiple tablets are connected to the system, the system-tablet ID is incremented for each subsequent one. If there is only one tablet device, its system-tablet ID is zero. The receiver of this message should be a mouse event object with subtype `NSTabletProximityEventSubtype` or an event of type `NSTabletProximity`.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `pointingDeviceID` (page 1082)
- `tabletID` (page 1085)

Declared In
`NSEvent.h`

tabletID

Returns the USB model identifier of the tablet device associated with the receiver.

```
- (NSUInteger)tabletID
```

Discussion
This method is valid for mouse events with subtype `NSTabletProximityEventSubtype` and for `NSTabletProximity` events.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `pointingDeviceID` (page 1082)
- `systemTabletID` (page 1085)

Declared In
`NSEvent.h`

tangentialPressure

Reports the tangential pressure on the device that generated the event represented by the receiver.

```
- (float)tangentialPressure
```

Discussion
The value returned can range from -1.0 to 1.0. Tangential pressure is also known as barrel pressure. Only some pointing devices support tangential pressure. This method is valid for mouse events with subtype `NSTabletPointEventSubtype` and for `NSTabletPoint` events.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `pressure` (page 1083)

Declared In
`NSEvent.h`

tilt

Reports the scaled tilt values of the pointing device that generated the event represented by the receiver.

```
- (NSPoint)tilt
```

Discussion
The value returned can range from -1.0 to 1.0 for both axes. An x-coordinate value that is negative indicates a tilt to the left and a positive value indicates a tilt to the right; a y-coordinate value that is negative indicates a tilt to the top and a positive value indicates a tilt to the bottom. If the device is perfectly perpendicular to the table surface, the values are 0.0 for both axes. This method is valid for mouse events with subtype `NSTabletPointEventSubtype` and for `NSTabletPoint` events.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `pressure` (page 1083)
- `rotation` (page 1084)

Declared In
`NSEvent.h`

timestamp

Returns the time the receiver occurred in seconds since system startup.

```
- (NSTimeInterval)timestamp
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSEvent.h`

touchesMatchingPhase:inView:

Returns all the `NSTouch` objects associated with a specific phase.

```
- (NSSet *)touchesMatchingPhase:(NSTouchPhase)phase inView:(NSView *)view
```

Parameters

phase

The touch phase for which you want touches. See "Touch Phases" (page 1091) for the possible values.

view

The view for which touches are wanted. Touches that target this view, or any of the view's descendants will be returned. Passing `nil` as the view gets all touches regardless of their targeted view.

Return Value
A set of applicable `NSTouch` objects.

Discussion
This method is only valid for gesture events (gesture, magnify, swipe, rotate, etc.). Using this method a view can get all of the touches associated with a gesture without overriding the individual touch responder methods.

Availability
Available in Mac OS X v10.6 and later.

Related Sample Code
LightTable

Declared In
`NSEvent.h`

trackingArea

Returns the `NSTrackingArea` object that generated the event represented by the receiver.

```
- (NSTrackingArea *)trackingArea
```

Return Value
Returns the `NSTrackingArea` object that generated the event represented by the receiver. If the receiver is not a mouse-tracking event (that is, an event of type `NSMouseEntered` (page 1094), `NSMouseExited` (page 1094), or `NSCursorUpdate` (page 1094)), this method raises an `NSInternalInconsistencyException`. This method returns `nil` if the event was generated by a tracking rectangle (pre-Mac OS X version 10.5) instead of a `NSTrackingArea` object.

Discussion
If no `NSTrackingArea` object is associated with the event because the event corresponds to a tracking rectangle installed with the `NSView` method `addTrackingRect:owner:userData:assumeInside:` (page 3142), this method returns `nil`. Note that the `trackingNumber` (page 1087) method returns either an `NSTrackingArea` object or the `NSTrackingRectTag` (page 3251) constant depending on how the event was generated.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSEvent.h`

trackingNumber

Returns the identifier of a mouse-tracking event.

```
- (NSInteger)trackingNumber
```

Discussion
This method returns either an `NSTrackingArea` object or a `NSTrackingRectTag` (page 3251) constant depending on whether the event was generated from an `NSTrackingArea` object or a call to `addTrackingRect:owner:userData:assumeInside:` (page 3142). Valid mouse-tracking methods are of types `NSMouseEntered` (page 1094), `NSMouseExited` (page 1094), and `NSCursorUpdate` (page 1094). This method raises an `NSInternalInconsistencyException` if sent to any other type of event.

The `NSTrackingArea` class is new with Mac OS X version 10.5

Availability
Available in Mac OS X v10.0 and later.

See Also
`+ enterExitEventWithType:location:modifierFlags:timestamp:windowNumber:context:eventNumber:trackingNumber:userData:` (page 1061)
`- trackingArea` (page 1087)

Declared In
`NSEvent.h`

type

Returns the type of the receiving event.

```
- (NSEventType)type
```

Return Value
Returns the event type. The possible values are described in "Event Types" (page 1092).

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
People
VBL

Declared In
`NSEvent.h`

uniqueID

Returns the unique identifier of the pointing device that generated the event represented by the receiver.

```
- (unsigned long long)uniqueID
```

Discussion
Also known as tool ID, this is a unique number recorded in the chip inside every pointing device. The unique ID makes it possible to assign a specific pointing device to a specific tablet. You can also use it to "sign" documents or to restrict access to document layers to a specific pointing device. This method is valid for mouse events with subtype `NSTabletProximityEventSubtype` and for `NSTabletProximity` events.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `vendorDefined` (page 1089)
- `vendorID` (page 1090)

Declared In
`NSEvent.h`

userData

Returns data associated with a mouse-tracking event,

```
- (void *)userData
```

Discussion
The returned data was assigned to the mouse-tracking event when it was set up using the `NSView` method `addTrackingRect:owner:userData:assumeInside:` (page 3142). It is only valid to send this message if the receiver represents an `NSMouseEntered` (page 1094) or `NSMouseExited` (page 1094) event. Raises an `NSInternalInconsistencyException` if sent to any other type of event object.

Availability
Available in Mac OS X v10.0 and later.

See Also

TrackIt

Declared In
`NSEvent.h`

vendorDefined

Returns an array of three vendor-defined `NSNumber` objects associated with the pointing-type event represented by the receiver.

```
- (id)vendorDefined
```

Discussion
The `NSNumber` objects encapsulate `short` values that vendors may return for various reasons; see the vendor documentation for details.This method is valid for mouse events with subtype `NSTabletPointEventSubtype` and for `NSTabletPoint` events.

Availability
Available in Mac OS X v10.4 and later.

Declared In
NSEvent.h

vendorID

Returns the vendor identifier of the tablet associated with the receiver.

```
- (NSUInteger)vendorID
```

Discussion
The tablet is typically a USB device. This method is valid only for mouse events with subtype `NSTabletProximityEventSubtype` and for `NSTabletProximity` events.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `tabletID` (page 1085)
- `vendorPointingDeviceType` (page 1090)

Declared In
NSEvent.h

vendorPointingDeviceType

Returns a coded bit field whose set bits indicate the type of pointing device (within a vendor selection) associated with the receiver.

```
- (NSUInteger)vendorPointingDeviceType
```

Discussion
See the vendor documentation for an interpretation of significant bits. This method is valid only for mouse events with subtype `NSTabletProximityEventSubtype` and for `NSTabletProximity` events.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `vendorID` (page 1090)

Declared In
NSEvent.h

window

Returns the window object associated with the receiver.

```
- (NSWindow *)window
```

Discussion
A periodic event, however, has no window; in this case the return value is undefined.

Availability
Available in Mac OS X v10.0 and later.

See Also
- windowNumber (page 1091)

Declared In
NSEvent.h

windowNumber

Returns the identifier for the window device associated with the receiver.

```
- (NSInteger)windowNumber
```

Discussion
A periodic event, however, has no window; in this case the return value is undefined.

Availability
Available in Mac OS X v10.0 and later.

Constants

Touch Phases

These constants represent the possible phases during a touch gesture.

```
enum {
    NSTouchPhaseBegan           = 1 << 0,
    NSTouchPhaseMoved           = 1 << 1,
    NSTouchPhaseStationary      = 1 << 2,
    NSTouchPhaseEnded           = 1 << 3,
    NSTouchPhaseCancelled       = 1 << 4,
    NSTouchPhaseTouching = NSTouchPhaseBegan | NSTouchPhaseMoved |
NSTouchPhaseStationary,
    NSTouchPhaseAny             = NSUIntegerMax
};
typedef NSUInteger NSTouchPhase;
```

Constants
NSTouchPhaseBegan
A finger for a given event touched the screen.
Available in Mac OS X v10.6 and later.
Declared in NSTouch.h.

`NSTouchPhaseMoved`
A finger for a given event moved on the screen.
Available in Mac OS X v10.6 and later.
Declared in `NSTouch.h`.

`NSTouchPhaseStationary`
A finger is touching the surface but hasn't moved since the previous event.
Available in Mac OS X v10.6 and later.
Declared in `NSTouch.h`.

`NSTouchPhaseEnded`
A finger for a given event was lifted from the screen.
Available in Mac OS X v10.6 and later.
Declared in `NSTouch.h`.

`NSTouchPhaseCancelled`
The system cancelled tracking for the touch.
Available in Mac OS X v10.6 and later.
Declared in `NSTouch.h`.

`NSTouchPhaseTouching`
An NSTouchPhaseBegan, or NSTouchPhaseMoved, or NSTouchPhaseStationary phase is in progress.
Available in Mac OS X v10.6 and later.
Declared in `NSTouch.h`.

`NSTouchPhaseAny`
Any touch phase.
Available in Mac OS X v10.6 and later.
Declared in `NSTouch.h`.

Event Types

These constants represent various kinds of events. They are returned by `type` (page 1088) and are used as the first argument to the methods `enterExitEventWithType:location:modifierFlags:timestamp:windowNumber:context:eventNumber:trackingNumber:userData:` (page 1061), `keyEventWithType:location:modifierFlags:timestamp:windowNumber:context:characters:charactersIgnoringModifiers:isARepeat:keyCode:` (page 1063), `mouseEventWithType:location:modifierFlags:timestamp:windowNumber:context:eventNumber:clickCount:pressure:` (page 1066), and `otherEventWithType:location:modifierFlags:timestamp:windowNumber:context:subtype:data1:data2:` (page 1067).

```
enum {
    NSLeftMouseDown      = 1,

`NSScrollWheel`
See "Handling Mouse Events" in *Cocoa Event-Handling Guide*.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSTabletPoint`
An event representing the current state of a tablet pointing device, including its location, pressure, and tilt.
Available in Mac OS X v10.4 and later.
Declared in `NSEvent.h`.

`NSTabletProximity`
An event representing the proximity of a pointing device to its tablet.
Available in Mac OS X v10.4 and later.
Declared in `NSEvent.h`.

`NSEventTypeGesture`
An event that represents some type of gesture such as `NSEventTypeMagnify`, `NSEventTypeSwipe`, `NSEventTypeRotate`, `NSEventTypeBeginGesture`, or `NSEventTypeEndGesture`.
Available in Mac OS X v10.6 and later.
Declared in `NSEvent.h`.

`NSEventTypeMagnify`
: An event representing a pinch open or pinch close gesture.

: Available in Mac OS X v10.6 and later.

: Declared in `NSEvent.h`.

`NSEventTypeSwipe`
: An event representing a swipe gesture.

: Available in Mac OS X v10.6 and later.

: Declared in `NSEvent.h`.

`NSEventTypeRotate`
: An event representing a rotation gesture.

: Available in Mac OS X v10.6 and later.

: Declared in `NSEvent.h`.

`NSEventTypeBeginGesture`
: An event that represents a gesture beginning.

: Available in Mac OS X v10.6 and later.

: Declared in `NSEvent.h`.

`NSEventTypeEndGesture`
: An event that represents a gesture ending.

: Available in Mac OS X v10.6 and later.

: Declared in `NSEvent.h`.

Masks for event types

These constants are masks for the events defined in "Event Types" (page 1092). Pass them to the `NSCell` method `sendActionOn:` (page 576) to specify when an `NSCell` should send its action message.

```
enum {
   NSLeftMouseDownMask      = 1 << NSLeftMouseDown,
   NSLeftMouseUpMask        = 1 << NSLeftMouseUp,
   NSRightMouseDownMask     = 1 << NSRightMouseDown,
   NSRightMouseUpMask       = 1 << NSRightMouseUp,
   NSMouseMovedMask         = 1 << NSMouseMoved,
   NSLeftMouseDraggedMask   = 1 << NSLeftMouseDragged,
   NSRightMouseDraggedMask  = 1 << NSRightMouseDragged,
   NSMouseEnteredMask       = 1 << NSMouseEntered,
   NSMouseExitedMask        = 1 << NSMouseExited,
   NSKeyDownMask            = 1 << NSKeyDown,
   NSKeyUpMask              = 1 << NSKeyUp,
   NSFlagsChangedMask       = 1 << NSFlagsChanged,
   NSAppKitDefinedMask      = 1 << NSAppKitDefined,
   NSSystemDefinedMask      = 1 << NSSystemDefined,
   NSApplicationDefinedMask = 1 << NSApplicationDefined,
   NSPeriodicMask           = 1 << NSPeriodic,
   NSCursorUpdateMask       = 1 << NSCursorUpdate,
   NSScrollWheelMask        = 1 << NSScrollWheel,
   NSTabletPointMask           = 1 << NSTabletPoint,
   NSTabletProximityMask       = 1 << NSTabletProximity,
   NSOtherMouseDownMask     = 1 << NSOtherMouseDown,
   NSOtherMouseUpMask       = 1 << NSOtherMouseUp,
   NSOtherMouseDraggedMask  = 1 << NSOtherMouseDragged,
   NSEventMaskGesture          = 1 << NSEventTypeGesture,
   NSEventMaskMagnify          = 1 << NSEventTypeMagnify,
   NSEventMaskSwipe            = 1U << NSEventTypeSwipe,
   NSEventMaskRotate           = 1 << NSEventTypeRotate,
   NSEventMaskBeginGesture     = 1 << NSEventTypeBeginGesture,
   NSEventMaskEndGesture       = 1 << NSEventTypeEndGesture,
   NSAnyEventMask           = 0xffffffffU
};
NSUInteger NSEventMaskFromType(NSEventType type) { return (1 << type); };
```

Constants

`NSLeftMouseDownMask`

Corresponds to `NSLeftMouseDown`. See "Handling Mouse Events" in *Cocoa Event-Handling Guide*.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSLeftMouseUpMask`

Corresponds to `NSLeftMouseUp`. See "Handling Mouse Events" in *Cocoa Event-Handling Guide*.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSRightMouseDownMask`

Corresponds to `NSRightMouseDown`. See "Handling Mouse Events" in *Cocoa Event-Handling Guide*.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSRightMouseUpMask`

Corresponds to `NSRightMouseUp`. See "Handling Mouse Events" in *Cocoa Event-Handling Guide*.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSOtherMouseDownMask`
Corresponds to `NSOtherMouseDown`. See "Handling Mouse Events" in *Cocoa Event-Handling Guide*.

Available in Mac OS X v10.1 and later.

Declared in `NSEvent.h`.

`NSOtherMouseUpMask`
Corresponds to `NSOtherMouseUp`. See "Handling Mouse Events" in *Cocoa Event-Handling Guide*.

Available in Mac OS X v10.1 and later.

Declared in `NSEvent.h`.

`NSMouseMovedMask`
Corresponds to `NSMouseMoved`. See "Handling Mouse Events" in *Cocoa Event-Handling Guide*.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSLeftMouseDraggedMask`
Corresponds to `NSLeftMouseDragged`. See "Handling Mouse Events" in *Cocoa Event-Handling Guide*.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSRightMouseDraggedMask`
Corresponds to `NSRightMouseDragged`. See "Handling Mouse Events" in *Cocoa Event-Handling Guide*.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSOtherMouseDraggedMask`
Corresponds to `NSOtherMouseDragged`. See "Handling Mouse Events" in *Cocoa Event-Handling Guide*.

Available in Mac OS X v10.1 and later.

Declared in `NSEvent.h`.

`NSMouseEnteredMask`
Corresponds to `NSMouseEntered`. See See "Mouse-Tracking and Cursor-Update Events" in *Cocoa Event-Handling Guide*..

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSMouseExitedMask`
Corresponds to `NSMouseExited`. See See "Mouse-Tracking and Cursor-Update Events" in *Cocoa Event-Handling Guide*..

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSCursorUpdateMask`
Corresponds to `NSCursorUpdate`. See See "Mouse-Tracking and Cursor-Update Events" in *Cocoa Event-Handling Guide*..

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSKeyDownMask`
Corresponds to `NSKeyDown`. See "Handling Key Events" in *Cocoa Event-Handling Guide*.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSKeyUpMask`
Corresponds to `NSKeyUp`. See "Handling Key Events" in *Cocoa Event-Handling Guide*.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSFlagsChangedMask`
Corresponds to `NSFlagsChanged`. See "Handling Key Events" in *Cocoa Event-Handling Guide*.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSAppKitDefinedMask`
Corresponds to `NSAppKitDefined`. See "Event Objects and Types" in *Cocoa Event-Handling Guide*.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSSystemDefinedMask`
Corresponds to `NSSystemDefined`. See "Event Objects and Types" in *Cocoa Event-Handling Guide*.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSApplicationDefinedMask`
Corresponds to `NSApplicationDefined`. See "Event Objects and Types" in *Cocoa Event-Handling Guide*.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSPeriodicMask`
Corresponds to `NSPeriodic`. See "Event Objects and Types" in *Cocoa Event-Handling Guide*.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSScrollWheelMask`
Corresponds to `NSScrollWheel`. See "Handling Mouse Events" in *Cocoa Event-Handling Guide*..

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSTabletPointMask`
Corresponds to `NSTabletPoint`.

Available in Mac OS X v10.4 and later.

Declared in `NSEvent.h`.

`NSTabletProximityMask`
Corresponds to `NSTabletProximity`.

Available in Mac OS X v10.4 and later.

Declared in `NSEvent.h`.

`NSEventMaskGesture`
Corresponds to `NSEventTypeGesture`.

Available in Mac OS X v10.6 and later.

Declared in `NSEvent.h`.

`NSEventMaskMagnify`
Corresponds to `NSEventTypeMagnify`.
Available in Mac OS X v10.6 and later.
Declared in `NSEvent.h`.

`NSEventMaskSwipe`
Corresponds to `NSEventTypeSwipe`.
Available in Mac OS X v10.6 and later.
Declared in `NSEvent.h`.

`NSEventMaskRotate`
Corresponds to `NSEventTypeRotate`.
Available in Mac OS X v10.6 and later.
Declared in `NSEvent.h`.

`NSEventMaskBeginGesture`
Corresponds to `NSEventTypeBeginGesture`.
Available in Mac OS X v10.6 and later.
Declared in `NSEvent.h`.

`NSEventMaskEndGesture`
Corresponds to `NSEventTypeEndGesture`.
Available in Mac OS X v10.6 and later.
Declared in `NSEvent.h`.

`NSAnyEventMask`
Corresponds to any event mask.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

Modifier Flags

The following constants (except for `NSDeviceIndependentModifierFlagsMask`) represent device-independent bits found in event modifier flags:

```
enum {
    NSAlphaShiftKeyMask = 1 << 16,
    NSShiftKeyMask      = 1 << 17,
    NSControlKeyMask    = 1 << 18,
    NSAlternateKeyMask  = 1 << 19,
    NSCommandKeyMask    = 1 << 20,
    NSNumericPadKeyMask = 1 << 21,
    NSHelpKeyMask       = 1 << 22,
    NSFunctionKeyMask   = 1 << 23,
    NSDeviceIndependentModifierFlagsMask = 0xffff0000U
};
```

Constants

`NSAlphaShiftKeyMask`
Set if Caps Lock key is pressed.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSShiftKeyMask`
Set if Shift key is pressed.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSControlKeyMask`
Set if Control key is pressed.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSAlternateKeyMask`
Set if Option or Alternate key is pressed.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSCommandKeyMask`
Set if Command key is pressed.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSNumericPadKeyMask`
Set if any key in the numeric keypad is pressed. The numeric keypad is generally on the right side of the keyboard. This is also set if any of the arrow keys are pressed (`NSUpArrowFunctionKey` (page 1107), `NSDownArrowFunctionKey` (page 1107), `NSLeftArrowFunctionKey` (page 1107), and `NSRightArrowFunctionKey` (page 1107)).

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSHelpKeyMask`
Set if the Help key is pressed.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSFunctionKeyMask`
Set if any function key is pressed. The function keys include the F keys at the top of most keyboards (F1, F2, and so on) and the navigation keys in the center of most keyboards (Help, Forward Delete, Home, End, Page Up, Page Down, and the arrow keys).

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSDeviceIndependentModifierFlagsMask`
Used to retrieve only the device-independent modifier flags, allowing applications to mask off the device-dependent modifier flags, including event coalescing information.

Available in Mac OS X v10.4 and later.

Declared in `NSEvent.h`.

NSPointingDeviceType

The following constants represent pointing-device types for `NSTabletProximity` events or mouse events with subtype `NSTabletProximityEventSubtype`. The `pointingDeviceType` (page 1083) method returns one of these constants.

```
typedef enum {
    NSUnknownPointingDevice = NX_TABLET_POINTER_UNKNOWN,
    NSPenPointingDevice     = NX_TABLET_POINTER_PEN,
    NSCursorPointingDevice  = NX_TABLET_POINTER_CURSOR,
    NSEraserPointingDevice  = NX_TABLET_POINTER_ERASER
} NSPointingDeviceType;
```

Constants

`NSUnknownPointingDevice`
Represents an unknown type of pointing device.
Available in Mac OS X v10.4 and later.
Declared in `NSEvent.h`.

`NSPenPointingDevice`
Represents the tip end of a stylus-like pointing device.
Available in Mac OS X v10.4 and later.
Declared in `NSEvent.h`.

`NSCursorPointingDevice`
Represents a cursor (or puck-like) pointing device.
Available in Mac OS X v10.4 and later.
Declared in `NSEvent.h`.

`NSEraserPointingDevice`
Represents the eraser end of a stylus-like pointing device.
Available in Mac OS X v10.4 and later.
Declared in `NSEvent.h`.

Mouse-event subtypes

The following constants represent mouse-event subtypes for mouse and tablet events (accessed with the `subtype` (page 1084) method).

```
enum {
    NSMouseEventSubtype           = NX_SUBTYPE_DEFAULT,
    NSTabletPointEventSubtype     = NX_SUBTYPE_TABLET_POINT,
    NSTabletProximityEventSubtype = NX_SUBTYPE_TABLET_PROXIMITY
    NSTouchEventSubtype             = NX_SUBTYPE_MOUSE_TOUCH
};
```

Constants

`NSMouseEventSubtype`
Indicates a purely mouse event.
Available in Mac OS X v10.4 and later.
Declared in `NSEvent.h`.

`NSTabletPointEventSubtype`
Indicates a tablet-pointer event; see description of `NSTabletPoint`.
Available in Mac OS X v10.4 and later.
Declared in `NSEvent.h`.

`NSTabletProximityEventSubtype`
: Indicates a tablet-proximity event; see description of `NSTabletProximity`.

Available in Mac OS X v10.4 and later.

Declared in `NSEvent.h`.

`NSTouchEventSubtype`
: Indicates a touch event subtype.

Available in Mac OS X v10.6 and later.

Declared in `NSEvent.h`.

Tablet event masks

The following constants represent button masks for `NSTabletPoint` events or mouse events with subtype `NSTabletPointEventSubtype`. The `buttonMask` (page 1072) method returns a bit mask, which you test with one or more of these constants to determine the state of the buttons on a tablet pointing device.

```
enum {
    NSPenTipMask =       NX_TABLET_BUTTON_PENTIPMASK,
    NSPenLowerSideMask = NX_TABLET_BUTTON_PENLOWERSIDEMASK,
    NSPenUpperSideMask = NX_TABLET_BUTTON_PENUPPERSIDEMASK
};
```

Constants

`NSPenTipMask`
: The pen tip is activated.

Available in Mac OS X v10.4 and later.

Declared in `NSEvent.h`.

`NSPenLowerSideMask`
: The button on the lower side of the device is activated.

Available in Mac OS X v10.4 and later.

Declared in `NSEvent.h`.

`NSPenUpperSideMask`
: The button on the upper side of the device is activated.

Available in Mac OS X v10.4 and later.

Declared in `NSEvent.h`.

Types Defined by the Application Kit

These constants represent the types of events defined by the Application Kit.

```
enum {
   NSWindowExposedEventType = 0,
   NSApplicationActivatedEventType = 1,
   NSApplicationDeactivatedEventType = 2,
   NSWindowMovedEventType = 4,
   NSScreenChangedEventType = 8,
   NSAWTEventType = 16
};
```

Constants

`NSWindowExposedEventType`
A non-retained NSWindow has been exposed.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSApplicationActivatedEventType`
The application has been activated.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSApplicationDeactivatedEventType`
The application has been deactivated.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSWindowMovedEventType`
An NSWindow has moved.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSScreenChangedEventType`
An NSWindow has changed screens.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSAWTEventType`
An event type used to support Java applications.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

Power-off event

This constant denotes that the user is turning off the computer.

```
enum {
   NSPowerOffEventType = 1
};
```

Constants

`NSPowerOffEventType`

Specifies that the user is turning off the computer.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

Function-Key Unicodes

These constants represent Unicode characters (0xF700–0xF8FF) that are reserved for function keys on the keyboard. Combined in NSStrings, they are the return values of the NSEvent methods `characters` (page 1074) and `charactersIgnoringModifiers` (page 1074) and may be used in some parameters in the NSEvent method `keyEventWithType:location:modifierFlags:timestamp:windowNumber:context:characters:charactersIgnoringModifiers:isARepeat:keyCode:` (page 1063).

```
enum {
   NSUpArrowFunctionKey = 0xF700,
   NSDownArrowFunctionKey = 0xF701,
   NSLeftArrowFunctionKey = 0xF702,
   NSRightArrowFunctionKey = 0xF703,
   NSF1FunctionKey = 0xF704,
   NSF2FunctionKey = 0xF705,
   NSF3FunctionKey = 0xF706,
   NSF4FunctionKey = 0xF707,
   NSF5FunctionKey = 0xF708,
   NSF6FunctionKey = 0xF709,
   NSF7FunctionKey = 0xF70A,
   NSF8FunctionKey = 0xF70B,
   NSF9FunctionKey = 0xF70C,
   NSF10FunctionKey = 0xF70D,
   NSF11FunctionKey = 0xF70E,
   NSF12FunctionKey = 0xF70F,
   NSF13FunctionKey = 0xF710,
   NSF14FunctionKey = 0xF711,
   NSF15FunctionKey = 0xF712,
   NSF16FunctionKey = 0xF713,
   NSF17FunctionKey = 0xF714,
   NSF18FunctionKey = 0xF715,
   NSF19FunctionKey = 0xF716,
   NSF20FunctionKey = 0xF717,
   NSF21FunctionKey = 0xF718,
   NSF22FunctionKey = 0xF719,
   NSF23FunctionKey = 0xF71A,
   NSF24FunctionKey = 0xF71B,
   NSF25FunctionKey = 0xF71C,
   NSF26FunctionKey = 0xF71D,
   NSF27FunctionKey = 0xF71E,
   NSF28FunctionKey = 0xF71F,
   NSF29FunctionKey = 0xF720,
   NSF30FunctionKey = 0xF721,
   NSF31FunctionKey = 0xF722,
   NSF32FunctionKey = 0xF723,
   NSF33FunctionKey = 0xF724,
   NSF34FunctionKey = 0xF725,
   NSF35FunctionKey = 0xF726,
   NSInsertFunctionKey = 0xF727,
   NSDeleteFunctionKey = 0xF728,
   NSHomeFunctionKey = 0xF729,
   NSBeginFunctionKey = 0xF72A,
   NSEndFunctionKey = 0xF72B,
   NSPageUpFunctionKey = 0xF72C,
   NSPageDownFunctionKey = 0xF72D,
   NSPrintScreenFunctionKey = 0xF72E,
   NSScrollLockFunctionKey = 0xF72F,
   NSPauseFunctionKey = 0xF730,
   NSSysReqFunctionKey = 0xF731,
   NSBreakFunctionKey = 0xF732,
   NSResetFunctionKey = 0xF733,
   NSStopFunctionKey = 0xF734,
   NSMenuFunctionKey = 0xF735,
   NSUserFunctionKey = 0xF736,
   NSSystemFunctionKey = 0xF737,
   NSPrintFunctionKey = 0xF738,
```

```
    NSClearLineFunctionKey = 0xF739,
    NSClearDisplayFunctionKey = 0xF73A,
    NSInsertLineFunctionKey = 0xF73B,
    NSDeleteLineFunctionKey = 0xF73C,
    NSInsertCharFunctionKey = 0xF73D,
    NSDeleteCharFunctionKey = 0xF73E,
    NSPrevFunctionKey = 0xF73F,
    NSNextFunctionKey = 0xF740,
    NSSelectFunctionKey = 0xF741,
    NSExecuteFunctionKey = 0xF742,
    NSUndoFunctionKey = 0xF743,
    NSRedoFunctionKey = 0xF744,
    NSFindFunctionKey = 0xF745,
    NSHelpFunctionKey = 0xF746,
    NSModeSwitchFunctionKey = 0xF747
};
```

Constants

`NSUpArrowFunctionKey`

Up Arrow key.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSDownArrowFunctionKey`

Down Arrow key.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSLeftArrowFunctionKey`

Left Arrow key.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSRightArrowFunctionKey`

Right Arrow key.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSF1FunctionKey`

F1 key.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSF2FunctionKey`

F2 key.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSF3FunctionKey`

F3 key.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSF4FunctionKey`
F4 key.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSF5FunctionKey`
F5 key.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSF6FunctionKey`
F6 key.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSF7FunctionKey`
F7 key.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSF8FunctionKey`
F8 key.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSF9FunctionKey`
F9 key.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSF10FunctionKey`
F10 key.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSF11FunctionKey`
F11 key.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSF12FunctionKey`
F12 key.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSF13FunctionKey`
F13 key.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSF14FunctionKey`
F14 key.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSF15FunctionKey`
F15 key.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSF16FunctionKey`
F16 key.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSF17FunctionKey`
F17 key.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSF18FunctionKey`
F18 key.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSF19FunctionKey`
F19 key.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSF20FunctionKey`
F20 key. Not on most Macintosh keyboards.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSF21FunctionKey`
F21 keyc. Not on most Macintosh keyboards.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSF22FunctionKey`
F22 key. Not on most Macintosh keyboards.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSF23FunctionKey`
F23 key. Not on most Macintosh keyboards.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSF24FunctionKey`
F24 key. Not on most Macintosh keyboards.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSF25FunctionKey`
F25 key. Not on most Macintosh keyboards.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSF26FunctionKey`
F26 key. Not on most Macintosh keyboards.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSF27FunctionKey`
F27 key. Not on most Macintosh keyboards.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSF28FunctionKey`
F28 key. Not on most Macintosh keyboards.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSF29FunctionKey`
F29 key. Not on most Macintosh keyboards.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSF30FunctionKey`
F30 key. Not on most Macintosh keyboards.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSF31FunctionKey`
F31 key. Not on most Macintosh keyboards.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSF32FunctionKey`
F32 key. Not on most Macintosh keyboards.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSF33FunctionKey`
F33 key. Not on most Macintosh keyboards.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSF34FunctionKey`
F34 key. Not on most Macintosh keyboards.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSF35FunctionKey`
F35 key. Not on most Macintosh keyboards.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSInsertFunctionKey`
Insert key. Not on most Macintosh keyboards.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSDeleteFunctionKey`
Forward Delete key.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSHomeFunctionKey`
Home key.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSBeginFunctionKey`
Begin key. Not on most Macintosh keyboards.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSEndFunctionKey`
End key.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSPageUpFunctionKey`
Page Up key.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSPageDownFunctionKey`
Page Down key.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSPrintScreenFunctionKey`
Print Screen key. Not on most Macintosh keyboards.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSScrollLockFunctionKey`
Scroll Lock key. Not on most Macintosh keyboards.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSPauseFunctionKey`
Pause key. Not on most Macintosh keyboards.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSSysReqFunctionKey`
System Request key. Not on most Macintosh keyboards.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSBreakFunctionKey`
Break key. Not on most Macintosh keyboards.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSResetFunctionKey`
Reset key. Not on most Macintosh keyboards.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSStopFunctionKey`
Stop key. Not on most Macintosh keyboards.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSMenuFunctionKey`
Menu key. Not on most Macintosh keyboards.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSUserFunctionKey`
User key. Not on most Macintosh keyboards.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSSystemFunctionKey`
System key. Not on most Macintosh keyboards.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSPrintFunctionKey`
Print key. Not on most Macintosh keyboards.
Available in Mac OS X v10.0 and later.
Declared in `NSEvent.h`.

`NSClearLineFunctionKey`
Clear/Num Lock key.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSClearDisplayFunctionKey`
Clear Display key. Not on most Macintosh keyboards.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSInsertLineFunctionKey`
Insert Line key. Not on most Macintosh keyboards.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSDeleteLineFunctionKey`
Delete Line key. Not on most Macintosh keyboards.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSInsertCharFunctionKey`
Insert Character key. Not on most Macintosh keyboards.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSDeleteCharFunctionKey`
Delete Character key. Not on most Macintosh keyboards.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSPrevFunctionKey`
Previous key. Not on most Macintosh keyboards.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSNextFunctionKey`
Next key. Not on most Macintosh keyboards.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSSelectFunctionKey`
Select key. Not on most Macintosh keyboards.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSExecuteFunctionKey`
Execute key. Not on most Macintosh keyboards.

Available in Mac OS X v10.0 and later.

Declared in `NSEvent.h`.

`NSUndoFunctionKey`
: Undo key. Not on most Macintosh keyboards.

  Available in Mac OS X v10.0 and later.

  Declared in `NSEvent.h`.

`NSRedoFunctionKey`
: Redo key. Not on most Macintosh keyboards.

  Available in Mac OS X v10.0 and later.

  Declared in `NSEvent.h`.

`NSFindFunctionKey`
: Find key. Not on most Macintosh keyboards.

  Available in Mac OS X v10.0 and later.

  Declared in `NSEvent.h`.

`NSHelpFunctionKey`
: Help key.

  Available in Mac OS X v10.0 and later.

  Declared in `NSEvent.h`.

`NSModeSwitchFunctionKey`
: Mode Switch key. Not on most Macintosh keyboards.

  Available in Mac OS X v10.0 and later.

  Declared in `NSEvent.h`.

Discussion
Note that some function keys are handled at a lower level and are never seen by your application. They include the Volume Up key, Volume Down key, Volume Mute key, Eject key, and Function key found on many iBook and PowerBook computers.

NSFileWrapper Class Reference

Inherits from	NSObject
Conforms to	NSCoding NSObject (NSObject)
Framework	/System/Library/Frameworks/Foundation.framework
Availability	Available in Mac OS X v10.0 and later.
Declared in	Foundation/NSFileWrapper.h
Companion guide	Application File Management
Related sample code	File Wrappers with Core Data Documents FunHouse GLUT Quartz Composer WWDC 2005 TextEdit SimpleStickies

Overview

The `NSFileWrapper` class provides access to the attributes and contents of file-system nodes. A **file-system node** is a file, directory, or symbolic link. Instances of this class are known as **file wrappers**.

File wrappers represent a file-system node as an object that can be displayed as an image (and possibly edited in place), saved to the file system, or transmitted to another application.

There are three types of file wrappers:

- **Regular-file file wrapper:** Represents a regular file.
- **Directory file wrapper:** Represents a directory.
- **Symbolic-link file wrapper:** Represents a symbolic link.

A file wrapper has these attributes:

- **Filename.** Name of the file-system node the file wrapper represents.
- **file-system attributes.** See *NSFileManager Class Reference* for information on the contents of the `attributes` dictionary.
- **Regular-file contents.** Applicable only to regular-file file wrappers.
- **File wrappers.** Applicable only to directory file wrappers.

- **Destination node.** Applicable only to symbolic-link file wrappers.

Adopted Protocols

NSCoding
`encodeWithCoder:`
`initWithCoder:`

Tasks

Creating File Wrappers

This class has several designated initializers.

- `initWithURL:options:error:` (page 1127)
  Initializes a file wrapper instance whose kind is determined by the type of file-system node located by the URL.
- `initWithPath:` (page 1126)
  Initializes a file wrapper instance whose kind is determined by the type of file-system node located by the path. (Deprecated. Use `initWithURL:options:error:` (page 1127) instead.)
- `initDirectoryWithFileWrappers:` (page 1123)
  Initializes the receiver as a directory file wrapper, with a given file-wrapper list.
- `initRegularFileWithContents:` (page 1124)
  Initializes the receiver as a regular-file file wrapper.
- `initSymbolicLinkWithDestinationURL:` (page 1125)
  Initializes the receiver as a symbolic-link file wrapper that links to a specified file.
- `initWithSerializedRepresentation:` (page 1126)
  Initializes the receiver as a regular-file file wrapper from given serialized data.
- `initSymbolicLinkWithDestination:` (page 1124) Deprecated in Mac OS X v10.6
  Initializes the receiver as a symbolic-link file wrapper. (Deprecated. Use `initSymbolicLinkWithDestinationURL:` (page 1125) instead.)

Querying File Wrappers

- `isRegularFile` (page 1128)
  Indicates whether the receiver is a regular-file file wrapper.
- `isDirectory` (page 1128)
  Indicates whether the receiver is a directory file wrapper.
- `isSymbolicLink` (page 1128)
  Indicates whether the receiver is a symbolic-link file wrapper.

Accessing File-Wrapper Information

- `fileWrappers` (page 1122)
  Returns the file wrappers contained by a directory file wrapper.
- `addFileWrapper:` (page 1119)
  Adds a child file wrapper to the receiver, which must be a directory file wrapper.
- `removeFileWrapper:` (page 1133)
  Removes a child file wrapper from the receiver, which must be a directory file wrapper.
- `addRegularFileWithContents:preferredFilename:` (page 1120)
  Creates a regular-file file wrapper with the given contents and adds it to the receiver, which must be a directory file wrapper.
- `keyForFileWrapper:` (page 1129)
  Returns the dictionary key used by a directory to identify a given file wrapper.
- `symbolicLinkDestinationURL` (page 1136)
  Provides the URL referenced by the receiver, which must be a symbolic-link file wrapper.
- `addFileWithPath:` (page 1118) Deprecated in Mac OS X v10.6
  Creates a file wrapper from a given file-system node and adds it to the receiver, which must be a directory file wrapper. (Deprecated. Use `addFileWrapper:` (page 1119) instead.)
- `addSymbolicLinkWithDestination:preferredFilename:` (page 1121) Deprecated in Mac OS X v10.6
  Creates a symbolic-link file wrapper pointing to a given file-system node and adds it to the receiver, which must be a directory file wrapper. (Deprecated. Use `addFileWrapper:` (page 1119) instead.)
- `symbolicLinkDestination` (page 1136) Deprecated in Mac OS X v10.6
  Provides the pathname referenced by the receiver, which must be a symbolic-link file wrapper. (Deprecated. Use `symbolicLinkDestinationURL` (page 1136) instead.)

Updating File Wrappers

- `matchesContentsOfURL:` (page 1129)
  Indicates whether the contents of a file wrapper matches a directory, regular file, or symbolic link on disk.
- `readFromURL:options:error:` (page 1132)
  Recursively rereads the entire contents of a file wrapper from the specified location on disk.
- `needsToBeUpdatedFromPath:` (page 1130) Deprecated in Mac OS X v10.6
  Indicates whether the file wrapper needs to be updated to match a given file-system node. (Deprecated. Use `matchesContentsOfURL:` (page 1129) instead.)
- `updateFromPath:` (page 1137) Deprecated in Mac OS X v10.6
  Updates the file wrapper to match a given file-system node. (Deprecated. Use `readFromURL:options:error:` (page 1132) instead.)

Serializing

- `serializedRepresentation` (page 1133)
  Returns the contents of the file wrapper as an opaque collection of data.

Accessing Files

- `filename` (page 1122)
  Provides the filename of a file wrapper.
- `setFilename:` (page 1134)
  Specifies the filename of a file wrapper.
- `preferredFilename` (page 1131)
  Provides the preferred filename for a file wrapper.
- `setPreferredFilename:` (page 1135)
  Specifies the receiver's preferred filename.
- `fileAttributes` (page 1121)
  Returns a file wrapper's file attributes.
- `setFileAttributes:` (page 1134)
  Specifies a file wrapper's file attributes.
- `regularFileContents` (page 1132)
  Returns the contents of the file-system node associated with a regular-file file wrapper.

Writing Files

- `writeToURL:options:originalContentsURL:error:` (page 1138)
  Recursively writes the entire contents of a file wrapper to a given file-system URL.
- `writeToFile:atomically:updateFilenames:` (page 1137) Deprecated in Mac OS X v10.6
  Writes a file wrapper's contents to a given file-system node. (Deprecated. Use `writeToURL:options:originalContentsURL:error:` (page 1138) instead.)

Instance Methods

addFileWithPath:

Creates a file wrapper from a given file-system node and adds it to the receiver, which must be a directory file wrapper. (Deprecated in Mac OS X v10.6. Use `addFileWrapper:` (page 1119) instead.)

```
- (NSString *)addFileWithPath:(NSString *)node
```

Parameters

node

file-system node from which to create the file wrapper to add to the directory.

Return Value

Dictionary key used to store the new file wrapper in the directory's list of file wrappers. See "Working With Directory Wrappers" for more information.

Special Considerations

Beginning with Mac OS X v10.6, the preferred method of referring to files is with a `file://` URL. Instead of using this method, you can instantiate `NSFileWrapper` with one of the initializers, send it `setPreferredFilename:` (page 1135) if necessary, and pass the result to `addFileWrapper:` (page 1119).

This method raises `NSInternalInconsistencyException` if the receiver is not a directory file wrapper.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.6.

See Also
- `addRegularFileWithContents:preferredFilename:` (page 1120)
- `addSymbolicLinkWithDestination:preferredFilename:` (page 1121)
- `removeFileWrapper:` (page 1133)
- `fileWrappers` (page 1122)

Related Sample Code
File Wrappers with Core Data Documents

Declared In
`NSFileWrapper.h`

addFileWrapper:

Adds a child file wrapper to the receiver, which must be a directory file wrapper.

```
- (NSString *)addFileWrapper:(NSFileWrapper *)child
```

Parameters

child

File wrapper to add to the directory.

Return Value
Dictionary key used to store *fileWrapper* in the directory's list of file wrappers. The dictionary key is a unique filename, which is the same as the passed-in file wrapper's preferred filename unless that name is already in use as a key in the directory's dictionary of children. See "Working With Directory Wrappers" in *Application File Management* for more information about the file-wrapper list structure.

Discussion
Use this method to add an existing file wrapper as a child of a directory file wrapper. If the file wrapper does not have a preferred filename, use the `setPreferredFilename:` (page 1135) method to give it one before calling `addFileWrapper:`. To create a new file wrapper and add it to a directory, use the `addRegularFileWithContents:preferredFilename:` (page 1120) method.

Special Considerations

This method raises `NSInternalInconsistencyException` if the receiver is not a directory file wrapper.

This method raises `NSInvalidArgumentException` if the child file wrapper doesn't have a preferred name.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `addRegularFileWithContents:preferredFilename:` (page 1120)
- `removeFileWrapper:` (page 1133)
- `fileWrappers` (page 1122)
- `preferredFilename` (page 1131)

Related Sample Code
File Wrappers with Core Data Documents

Declared In
`NSFileWrapper.h`

addRegularFileWithContents:preferredFilename:

Creates a regular-file file wrapper with the given contents and adds it to the receiver, which must be a directory file wrapper.

```
- (NSString *)addRegularFileWithContents:(NSData *)data preferredFilename:(NSString
    *)filename
```

Parameters

data

Contents for the new regular-file file wrapper.

filename

Preferred filename for the new regular-file file wrapper.

Return Value
Dictionary key used to store the new file wrapper in the directory's list of file wrappers. The dictionary key is a unique filename, which is the same as the passed-in file wrapper's preferred filename unless that name is already in use as a key in the directory's dictionary of children. See "Working With Directory Wrappers" in *Application File Management* for more information about the file-wrapper list structure.

Discussion
This is a convenience method. The default implementation allocates a new file wrapper, initializes it with `initRegularFileWithContents:` (page 1124), sends it `setPreferredFilename:` (page 1135), adds it to the directory with `addFileWrapper:` (page 1119), and returns what `addFileWrapper:` returned.

Special Considerations

This method raises `NSInternalInconsistencyException` if the receiver is not a directory file wrapper.

This method raises `NSInvalidArgumentException` if you pass `nil` or an empty value for `filename`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `addFileWrapper:` (page 1119)
- `removeFileWrapper:` (page 1133)
- `fileWrappers` (page 1122)

Related Sample Code
FunHouse
SimpleStickies

Declared In
`NSFileWrapper.h`

addSymbolicLinkWithDestination:preferredFilename:

Creates a symbolic-link file wrapper pointing to a given file-system node and adds it to the receiver, which must be a directory file wrapper. (Deprecated in Mac OS X v10.6. Use `addFileWrapper:` (page 1119) instead.)

```
- (NSString *)addSymbolicLinkWithDestination:(NSString *)node
    preferredFilename:(NSString *)preferredFilename
```

Parameters

node

Pathname the new symbolic-link file wrapper is to reference.

preferredFilename

Preferred filename for the new symbolic-link file wrapper.

Return Value

Dictionary key used to store the new file wrapper in the directory's list of file wrappers. See "Working With Directory Wrappers" for more information.

Special Considerations

Beginning with Mac OS X v10.6, the preferred method of referring to files is with a `file://` URL. Instead of using this method, you can instantiate `NSFileWrapper` with one of the initializers, send it `setPreferredFilename:` (page 1135) if necessary, and pass the result to `addFileWrapper:` (page 1119).

This method raises `NSInternalInconsistencyException` if the receiver is not a directory file wrapper.

This method raises `NSInvalidArgumentException` if you pass `nil` or an empty value for `preferredFilename`.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.6.

See Also

- `addFileWrapper:` (page 1119)
- `addRegularFileWithContents:preferredFilename:` (page 1120)
- `removeFileWrapper:` (page 1133)
- `fileWrappers` (page 1122)

Declared In

`NSFileWrapper.h`

fileAttributes

Returns a file wrapper's file attributes.

```
- (NSDictionary *)fileAttributes
```

Return Value

File attributes, in a dictionary of the same sort as that returned by `attributesOfItemAtPath:error:` (`NSFileManager`).

Availability

Available in Mac OS X v10.0 and later.

See Also
- `setFileAttributes:` (page 1134)

Declared In
`NSFileWrapper.h`

filename

Provides the filename of a file wrapper.

```
- (NSString *)filename
```

Return Value
The file wrapper's filename; `nil` when the file wrapper has no corresponding file-system node.

Discussion
The filename is used for record-keeping purposes only and is set automatically when the file wrapper is created from the file system using `initWithURL:options:error:` (page 1127) and when it's saved to the file system using `writeToURL:options:originalContentsURL:error:` (page 1138) (although this method allows you to request that the filename not be updated).

The filename is usually the same as the preferred filename, but might instead be a name derived from the preferred filename. You can use this method to get the name of a child that's just been read. Don't use this method to get the name of a child that's about to be written, because the name might be about to change; send `keyForFileWrapper:` (page 1129) to the parent instead.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `preferredFilename` (page 1131)
- `setFilename:` (page 1134)

Related Sample Code
File Wrappers with Core Data Documents
Quartz Composer WWDC 2005 TextEdit

Declared In
`NSFileWrapper.h`

fileWrappers

Returns the file wrappers contained by a directory file wrapper.

```
- (NSDictionary *)fileWrappers
```

Return Value
A key-value dictionary of the file wrappers contained in the directory. The dictionary contains entries whose values are the file wrappers and whose keys are the unique filenames that have been assigned to each one. See "Working With Directory Wrappers" in *Application File Management* for more information about the file-wrapper list structure.

Discussion
Returns a dictionary whose values are the file wrapper's children and whose keys are the unique filenames that have been assigned to each one. This method may return `nil` if the user modifies the directory after you call `readFromURL:options:error:` (page 1132) or `initWithURL:options:error:` (page 1127) but before `NSFileWrapper` has read the contents of the directory. Use the `NSFileWrapperReadingImmediate` reading option to reduce the likelihood of that problem.

Special Considerations

This method raises `NSInternalInconsistencyException` if the receiver is not a directory file wrapper.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `filename` (page 1122)
- `addFileWrapper:` (page 1119)

Related Sample Code

FunHouse

Declared In
`NSFileWrapper.h`

initDirectoryWithFileWrappers:

Initializes the receiver as a directory file wrapper, with a given file-wrapper list.

```
- (id)initDirectoryWithFileWrappers:(NSDictionary *)childrenByPreferredName
```

Parameters

childrenByPreferredName

Key-value dictionary of file wrappers with which to initialize the receiver. The dictionary must contain entries whose values are the file wrappers that are to become children and whose keys are filenames. See "Working With Directory Wrappers" in *Application File Management* for more information about the file-wrapper list structure.

Return Value
Initialized file wrapper for *fileWrappers*.

Discussion
After initialization, the file wrapper is not associated with a file-system node until you save it using `writeToURL:options:originalContentsURL:error:` (page 1138).

The receiver is initialized with open permissions: anyone can read, write, or modify the directory on disk.

If any file wrapper in the directory doesn't have a preferred filename, its preferred name is automatically set to its corresponding key in the *childrenByPreferredName* dictionary.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setPreferredFilename:` (page 1135)

- `filename` (page 1122)
- `setFileAttributes:` (page 1134)

File Wrappers with Core Data Documents
FunHouse
SimpleStickies

Declared In
`NSFileWrapper.h`

initRegularFileWithContents:

Initializes the receiver as a regular-file file wrapper.

```
- (id)initRegularFileWithContents:(NSData *)contents
```

Parameters
contents
Contents of the file.

Return Value
Initialized regular-file file wrapper containing *contents*.

Discussion
After initialization, the file wrapper is not associated with a file-system node until you save it using `writeToURL:options:originalContentsURL:error:` (page 1138).

The file wrapper is initialized with open permissions: anyone can write to or read the file wrapper. .

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setPreferredFilename:` (page 1135)
- `filename` (page 1122)

Declared In
`NSFileWrapper.h`

initSymbolicLinkWithDestination:

Initializes the receiver as a symbolic-link file wrapper. (Deprecated in Mac OS X v10.6. Use `initSymbolicLinkWithDestinationURL:` (page 1125) instead.)

```
- (id)initSymbolicLinkWithDestination:(NSString *)node
```

Parameters

node

Pathname the receiver is to represent.

Return Value

Initialized symbolic-link file wrapper referencing *node*.

Discussion

The receiver is not associated to a file-system node until you save it using `writeToFile:atomically:updateFilenames:` (page 1137). It's also initialized with open permissions; anyone can read or write the disk representations it saves.

Special Considerations

Beginning with Mac OS X v10.6, the preferred method of referring to files is with a `file://` URL. Therefore, this method has been deprecated in favor of `initSymbolicLinkWithDestinationURL:` (page 1125).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.6.

See Also

- `setPreferredFilename:` (page 1135)
- `filename` (page 1122)
- `fileAttributes` (page 1121)

Declared In

`NSFileWrapper.h`

initSymbolicLinkWithDestinationURL:

Initializes the receiver as a symbolic-link file wrapper that links to a specified file.

```
- (id)initSymbolicLinkWithDestinationURL:(NSURL *)url
```

Parameters

url

URL of the file the file wrapper is to reference.

Return Value

Initialized symbolic-link file wrapper referencing *url*.

Discussion

The file wrapper is not associated with a file-system node until you save it using `writeToURL:options:originalContentsURL:error:` (page 1138).

The file wrapper is initialized with open permissions: anyone can modify or read the file reference. .

Availability

Available in Mac OS X v10.6 and later.

See Also

- `setPreferredFilename:` (page 1135)
- `filename` (page 1122)
- `fileAttributes` (page 1121)

Declared In
NSFileWrapper.h

initWithPath:

Initializes a file wrapper instance whose kind is determined by the type of file-system node located by the path. (Deprecated in Mac OS X v10.6. Use `initWithURL:options:error:` (page 1127) instead.)

```
- (id)initWithPath:(NSString *)node
```

Parameters

node

Pathname of the file-system node the file wrapper is to represent.

Return Value
File wrapper for *node*.

Discussion
If *node* is a directory, this method recursively creates file wrappers for each node within that directory.

Special Considerations

Beginning with Mac OS X v10.6, the preferred method of referring to files is with a `file://` URL. Therefore, this method has been deprecated in favor of `initWithURL:options:error:` (page 1127).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.6.

See Also
- `setPreferredFilename:` (page 1135)
- `filename` (page 1122)
- `fileAttributes` (page 1121)

Declared In
NSFileWrapper.h

initWithSerializedRepresentation:

Initializes the receiver as a regular-file file wrapper from given serialized data.

```
- (id)initWithSerializedRepresentation:(NSData *)serializedRepresentation
```

Parameters

serializedRepresentation

Serialized representation of a file wrapper in the format used for the `NSFileContentsPboardType` pasteboard type. Data of this format is returned by such methods as `serializedRepresentation` (page 1133) and `RTFDFromRange:documentAttributes:` (page 268) (`NSAttributedString`).

Return Value
Regular-file file wrapper initialized from *serializedRepresentation*.

Discussion
The file wrapper is not associated with a file-system node until you save it using `writeToURL:options:originalContentsURL:error:` (page 1138).

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setPreferredFilename:` (page 1135)
- `filename` (page 1122)
- `fileAttributes` (page 1121)

Declared In
`NSFileWrapper.h`

initWithURL:options:error:

Initializes a file wrapper instance whose kind is determined by the type of file-system node located by the URL.

```
- (id)initWithURL:(NSURL *)url options:(NSFileWrapperReadingOptions)options
    error:(NSError **)outError
```

Parameters

url

URL of the file-system node the file wrapper is to represent.

options

Option flags for reading the node located at `url`. See "File Wrapper Reading Options" (page 1139) for possible values.

outError

If an error occurs, upon return contains an `NSError` object that describes the problem. Pass `NULL` if you do not want error information.

Return Value
File wrapper for the file-system node at *url*. May be a directory, file, or symbolic link, depending on what is located at the URL. Returns `NO` (0) if reading is not successful.

Discussion
If *url* is a directory, this method recursively creates file wrappers for each node within that directory. Use the `fileWrappers` (page 1122) method to get the file wrappers of the nodes contained by the directory.

Availability
Available in Mac OS X v10.6 and later.

See Also
- `fileWrappers` (page 1122)

Declared In
NSFileWrapper.h

isDirectory

Indicates whether the receiver is a directory file wrapper.

```
- (BOOL)isDirectory
```

Return Value
YES when the receiver is a directory file wrapper, NO otherwise.

Discussion
Invocations of readFromURL:options:error: (page 1132) may change what is returned by subsequent invocations of this method if the type of the file on disk has changed.

Availability
Available in Mac OS X v10.0 and later.

See Also
- isRegularFile (page 1128)
- isSymbolicLink (page 1128)

Declared In
NSFileWrapper.h

isRegularFile

Indicates whether the receiver is a regular-file file wrapper.

```
- (BOOL)isRegularFile
```

Return Value
YES when the receiver is a regular-file wrapper, NO otherwise.

Discussion
Invocations of readFromURL:options:error: (page 1132) may change what is returned by subsequent invocations of this method if the type of the file on disk has changed.

Availability
Available in Mac OS X v10.0 and later.

See Also
- isDirectory (page 1128)
- isSymbolicLink (page 1128)

Declared In
NSFileWrapper.h

isSymbolicLink

Indicates whether the receiver is a symbolic-link file wrapper.

```
- (BOOL)isSymbolicLink
```

Return Value
`YES` when the receiver is a symbolic-link file wrapper, `NO` otherwise.

Discussion
Invocations of `readFromURL:options:error:` (page 1132) may change what is returned by subsequent invocations of this method if the type of the file on disk has changed.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `isDirectory` (page 1128)
- `isRegularFile` (page 1128)

Declared In
`NSFileWrapper.h`

keyForFileWrapper:

Returns the dictionary key used by a directory to identify a given file wrapper.

```
- (NSString *)keyForFileWrapper:(NSFileWrapper *)child
```

Parameters
child
The child file wrapper for which you want the key.

Return Value
Dictionary key used to store the file wrapper in the directory's list of file wrappers. The dictionary key is a unique filename, which may not be the same as the passed-in file wrapper's preferred filename if more than one file wrapper in the directory's dictionary of children has the same preferred filename. See "Working With Directory Wrappers" in *Application File Management* for more information about the file-wrapper list structure. Returns `nil` if the file wrapper specified in `child` is not a child of the directory.

Special Considerations
This method raises `NSInternalInconsistencyException` if the receiver is not a directory file wrapper.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `filename` (page 1122)

Declared In
`NSFileWrapper.h`

matchesContentsOfURL:

Indicates whether the contents of a file wrapper matches a directory, regular file, or symbolic link on disk.

```
- (BOOL)matchesContentsOfURL:(NSURL *)url
```

Parameters

url

URL of the file-system node with which to compare the file wrapper.

Return Value

YES when the contents of the file wrapper match the contents of *url*, NO otherwise.

Discussion

The contents of files are not compared; matching of regular files is based on file modification dates. For a directory, children are compared against the files in the directory, recursively.

Because children of directory file wrappers are not read immediately by the `initWithURL:options:error:` (page 1127) method unless the `NSFileWrapperReadingImmediate` reading option is used, even a newly-created directory file wrapper might not have the same contents as the directory on disk. You can use this method to determine whether the file wrapper's contents in memory need to be updated.

If the file wrapper needs updating, use the `readFromURL:options:error:` (page 1132) method with the `NSFileWrapperReadingImmediate` reading option.

This table describes which attributes of the file wrapper and file-system node are compared to determine whether the file wrapper matches the node on disk:

File-wrapper type	Comparison determinants
Regular file	Modification date and access permissions.
Directory	Children (recursive).
Symbolic link	Destination pathname.

Availability

Available in Mac OS X v10.6 and later.

See Also

- `readFromURL:options:error:` (page 1132)
- `fileAttributes` (page 1121)

Declared In

NSFileWrapper.h

needsToBeUpdatedFromPath:

Indicates whether the file wrapper needs to be updated to match a given file-system node. (Deprecated in Mac OS X v10.6. Use `matchesContentsOfURL:` (page 1129) instead.)

```
- (BOOL)needsToBeUpdatedFromPath:(NSString *)node
```

Parameters

node

file-system node with which to compare the file wrapper.

Return Value

YES when the file wrapper needs to be updated to match *node*, NO otherwise.

Discussion
This table describes which attributes of the file wrapper and *node* are compared to determine whether the file wrapper needs to be updated:

File-wrapper type	Comparison determinants
Regular file	Modification date and access permissions.
Directory	Member hierarchy (recursive).
Symbolic link	Destination pathname.

Special Considerations

Beginning with Mac OS X v10.6, the preferred method of referring to files is with a `file://` URL. Therefore, this method has been deprecated in favor of `matchesContentsOfURL:` (page 1129).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.6.

See Also
- `updateFromPath:` (page 1137)
- `fileAttributes` (page 1121)

Declared In
`NSFileWrapper.h`

preferredFilename

Provides the preferred filename for a file wrapper.

```
- (NSString *)preferredFilename
```

Return Value
The file wrapper's preferred filename.

Discussion
This name is normally used as the dictionary key when a child file wrapper is added to a directory file wrapper. However, if another file wrapper with the same preferred name already exists in the directory file wrapper when the receiver is added, the filename assigned as the dictionary key may differ from the preferred filename.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `filename` (page 1122)
- `setPreferredFilename:` (page 1135)

Declared In
`NSFileWrapper.h`

readFromURL:options:error:

Recursively rereads the entire contents of a file wrapper from the specified location on disk.

```
- (BOOL)readFromURL:(NSURL *)url options:(NSFileWrapperReadingOptions)options
    error:(NSError **)outError
```

Parameters

url

URL of the file-system node corresponding to the file wrapper.

options

Option flags for reading the node located at `url`. See "File Wrapper Reading Options" (page 1139) for possible values.

outError

If an error occurs, upon return contains an `NSError` object that describes the problem. Pass `NULL` if you do not want error information.

Return Value

`YES` if successful. If not successful, returns `NO` after setting `outError` to an `NSError` object that describes the reason why the file wrapper could not be reread.

Discussion

When reading a directory, children are added and removed as necessary to match the file system.

Availability

Available in Mac OS X v10.6 and later.

See Also

- `initWithURL:options:error:` (page 1127)
- `fileWrappers` (page 1122)
- `filename` (page 1122)
- `fileAttributes` (page 1121)
- `writeToURL:options:originalContentsURL:error:` (page 1138)

Declared In

`NSFileWrapper.h`

regularFileContents

Returns the contents of the file-system node associated with a regular-file file wrapper.

```
- (NSData *)regularFileContents
```

Return Value

Contents of the file-system node the file wrapper represents.

Discussion

This method may return `nil` if the user modifies the file after you call `readFromURL:options:error:` (page 1132) or `initWithURL:options:error:` (page 1127) but before `NSFileWrapper` has read the contents of the file. Use the `NSFileWrapperReadingImmediate` reading option to reduce the likelihood of that problem.

Special Considerations

This method raises `NSInternalInconsistencyException` if the receiver is not a regular-file file wrapper.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `initRegularFileWithContents:` (page 1124)
- `readFromURL:options:error:` (page 1132)

Declared In
`NSFileWrapper.h`

removeFileWrapper:

Removes a child file wrapper from the receiver, which must be a directory file wrapper.

```
- (void)removeFileWrapper:(NSFileWrapper *)child
```

Parameters
child
File wrapper to remove from the directory.

Special Considerations
This method raises `NSInternalInconsistencyException` if the receiver is not a directory file wrapper.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `addFileWrapper:` (page 1119)
- `addRegularFileWithContents:preferredFilename:` (page 1120)
- `fileWrappers` (page 1122)

Related Sample Code
File Wrappers with Core Data Documents

Declared In
`NSFileWrapper.h`

serializedRepresentation

Returns the contents of the file wrapper as an opaque collection of data.

```
- (NSData *)serializedRepresentation
```

Return Value
The file wrapper's contents in the format used for the pasteboard type `NSFileContentsPboardType`.

Discussion
Returns an `NSData` object suitable for passing to `initWithSerializedRepresentation:` (page 1126). This method may return `nil` if the user modifies the contents of the file-system node after you call `readFromURL:options:error:` (page 1132) or `initWithURL:options:error:` (page 1127) but before `NSFileWrapper` has read the contents of the file. Use the `NSFileWrapperReadingImmediate` reading option to reduce the likelihood of that problem.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- initWithSerializedRepresentation:` (page 1126)

Declared In
`NSFileWrapper.h`

setFileAttributes:

Specifies a file wrapper's file attributes.

```
- (void)setFileAttributes:(NSDictionary *)fileAttributes
```

Parameters
fileAttributes
File attributes for the file wrapper, in a dictionary of the same sort as that used by `setAttributes:ofItemAtPath:error:` (`NSFileManager`).

Availability
Available in Mac OS X v10.0 and later.

See Also
`- fileAttributes` (page 1121)
`- writeToURL:options:originalContentsURL:error:` (page 1138)

Declared In
`NSFileWrapper.h`

setFilename:

Specifies the filename of a file wrapper.

```
- (void)setFilename:(NSString *)filename
```

Parameters
filename
Filename of the file wrapper.

Discussion
The file name is a dictionary key used to store *fileWrapper* in a directory's list of child file wrappers. The dictionary key is a unique filename, which is the same as the child file wrapper's preferred filename unless that name is already in use as a key in the directory's dictionary of children. See "Working With Directory Wrappers" in *Application File Management* for more information about the file-wrapper list structure. In general, the filename is set for you by the `initWithURL:options:error:` (page 1127),

`initDirectoryWithFileWrappers:` (page 1123), or `writeToURL:options:originalContentsURL:error:` (page 1138) methods; you do not normally have to call this method directly.

Special Considerations

This method raises `NSInvalidArgumentException` if you pass `nil` or an empty value for `filename`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `filename` (page 1122)
- `setPreferredFilename:` (page 1135)
- `initWithURL:options:error:` (page 1127)
- `initDirectoryWithFileWrappers:` (page 1123)
- `writeToURL:options:originalContentsURL:error:` (page 1138)

Declared In
`NSFileWrapper.h`

setPreferredFilename:

Specifies the receiver's preferred filename.

```
- (void)setPreferredFilename:(NSString *)filename
```

Parameters

filename
Preferred filename for the receiver.

Discussion
When a file wrapper is added to a parent directory file wrapper, the parent attempts to use the child's preferred filename as the key in its dictionary of children. If that key is already in use, then the parent derives a unique filename from the preferred filename and uses that for the key.

When you change the preferred filename of a file wrapper, the default implementation of this method causes existing parent directory file wrappers to remove and re-add the child to accommodate the change. Preferred filenames of children are not preserved when you write a file wrapper to disk and then later instantiate another file wrapper by reading the file from disk. If you need to preserve the user-visible names of attachments, you have to store the names yourself.

Special Considerations

This method raises `NSInvalidArgumentException` if you pass `nil` or an empty value for `filename`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `preferredFilename` (page 1131)
- `setFilename:` (page 1134)
- `addFileWrapper:` (page 1119)
- `initWithURL:options:error:` (page 1127)

- initDirectoryWithFileWrappers: (page 1123)
- writeToURL:options:originalContentsURL:error: (page 1138)

Declared In
NSFileWrapper.h

symbolicLinkDestination

Provides the pathname referenced by the receiver, which must be a symbolic-link file wrapper. (Deprecated in Mac OS X v10.6. Use symbolicLinkDestinationURL (page 1136) instead.)

```
- (NSString *)symbolicLinkDestination
```

Return Value
Pathname the file wrapper references (the destination of the symbolic link the file wrapper represents).

Special Considerations
Beginning with Mac OS X v10.6, the preferred method of referring to files is with a file:// URL. Therefore, this method has been deprecated in favor of symbolicLinkDestinationURL (page 1136).

This method raises NSInternalInconsistencyException if the receiver is not a symbolic-link file wrapper.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.6.

Declared In
NSFileWrapper.h

symbolicLinkDestinationURL

Provides the URL referenced by the receiver, which must be a symbolic-link file wrapper.

```
- (NSURL *)symbolicLinkDestinationURL
```

Return Value
Pathname the file wrapper references (that is, the destination of the symbolic link the file wrapper represents).

Discussion
This method may return nil if the user modifies the symbolic link after you call readFromURL:options:error: (page 1132) or initWithURL:options:error: (page 1127) but before NSFileWrapper has read the contents of the link. Use the NSFileWrapperReadingImmediate reading option to reduce the likelihood of that problem.

Special Considerations
This method raises NSInternalInconsistencyException if the receiver is not a symbolic-link file wrapper.

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSFileWrapper.h`

updateFromPath:

Updates the file wrapper to match a given file-system node. (Deprecated in Mac OS X v10.6. Use `readFromURL:options:error:` (page 1132) instead.)

```
- (BOOL)updateFromPath:(NSString *)path
```

Return Value
`YES` if the update is carried out, `NO` if it isn't needed.

Discussion
For a directory file wrapper, the contained file wrappers are also sent `updateFromPath:` messages. If nodes in the corresponding directory on the file system have been added or removed, corresponding file wrappers are released or created as needed.

Special Considerations

Beginning with Mac OS X v10.6, the preferred method of referring to files is with a `file://` URL. Therefore, this method has been deprecated in favor of `readFromURL:options:error:` (page 1132).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.6.

See Also
`- needsToBeUpdatedFromPath:` (page 1130)
`updateAttachmentsFromPath:` (page 1714) (NSAttributedString)

Declared In
`NSFileWrapper.h`

writeToFile:atomically:updateFilenames:

Writes a file wrapper's contents to a given file-system node. (Deprecated in Mac OS X v10.6. Use `writeToURL:options:originalContentsURL:error:` (page 1138) instead.)

```
- (BOOL)writeToFile:(NSString *)node atomically:(BOOL)atomically
    updateFilenames:(BOOL)updateNames
```

Parameters
node
Pathname of the file-system node to which the receiver's contents are written.

atomically

YES to write the file safely so that:

- An existing file is not overwritten
- The method fails if the file cannot be written in its entirety

NO to overwrite an existing file and ignore incomplete writes.

updateNames

YES to update the receiver's filenames (its filename and—for directory file wrappers—the filenames of its sub–file wrappers) be changed to the filenames of the corresponding nodes in the file system, after a successful write operation. Use this in Save or Save As operations.

NO to specify that the receiver's filenames not be updated. Use this in Save To operations.

Return Value

YES when the write operation is successful, NO otherwise.

Special Considerations

Beginning with Mac OS X v10.6, the preferred method of referring to files is with a `file://` URL. Therefore, this method has been deprecated in favor of `writeToURL:options:originalContentsURL:error:` (page 1138).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.6.

Related Sample Code

File Wrappers with Core Data Documents

Quartz Composer WWDC 2005 TextEdit

Declared In

NSFileWrapper.h

writeToURL:options:originalContentsURL:error:

Recursively writes the entire contents of a file wrapper to a given file-system URL.

```
- (BOOL)writeToURL:(NSURL *)url options:(NSFileWrapperWritingOptions)options
    originalContentsURL:(NSURL *)originalContentsURL error:(NSError **)outError
```

Parameters

url

URL of the file-system node to which the file wrapper's contents are written.

options

Option flags for writing to the node located at `url`. See "File Wrapper Writing Options" (page 1140) for possible values.

originalContentsURL

The location of a previous revision of the contents being written. The default implementation of this method attempts to avoid unnecessary I/O by writing hard links to regular files instead of actually writing out their contents when the contents have not changed. The child file wrappers must return accurate values when sent the `filename` (page 1122) method for this to work. Use the `NSFileWrapperWritingWithNameUpdating` writing option to increase the likelihood of that.

Specify `nil` for this parameter if there is no earlier version of the contents or if you want to ensure that all the contents are written to files.

updateNames

`YES` to update the receiver's filenames (its filename and—for directory file wrappers—the filenames of its sub–file wrappers) be changed to the filenames of the corresponding nodes in the file system, after a successful write operation. Use this in Save or Save As operations.

`NO` to specify that the receiver's filenames not be updated. Use this in Save To operations.

outError

If an error occurs, upon return contains an `NSError` object that describes the problem. Pass `NULL` if you do not want error information.

Return Value

`YES` when the write operation is successful. If not successful, returns `NO` after setting `outError` to an `NSError` object that describes the reason why the file wrapper's contents could not be written.

Availability

Available in Mac OS X v10.6 and later.

See Also

- `filename` (page 1122)
- `readFromURL:options:error:` (page 1132)

Declared In

`NSFileWrapper.h`

Constants

File Wrapper Reading Options

Reading options that can be set by the `initWithURL:options:error:` (page 1127) and `readFromURL:options:error:` (page 1132) methods.

```
enum {
 NSFileWrapperReadingImmediate = 1 << 0,
 NSFileWrapperReadingWithoutMapping = 1 << 1
};
typedef NSUInteger NSFileWrapperReadingOptions;
```

Constants

`NSFileWrapperReadingImmediate`

If reading with this option succeeds, then subsequent invocations of `fileWrappers` (page 1122), `regularFileContents` (page 1132), `symbolicLinkDestinationURL` (page 1136), and `serializedRepresentation` (page 1133) sent to the file wrapper and all its child file wrappers will fail and return `nil` only if an actual error occurs (for example, the volume has disappeared or the file server is unreachable)—not as a result of the user moving or deleting files.

For performance reasons, `NSFileWrapper` may not read the contents of some file packages immediately even when this option is chosen. For example, because the contents of bundles (not all file packages are bundles) are immutable to the user, `NSFileWrapper` may read the children of such a directory lazily.

You can use this option to take a snapshot of a file or folder for writing later. For example, an application like TextEdit can use this option when creating new file wrappers to represent attachments that the user creates by copying and pasting or dragging and dropping from the Finder to a TextEdit document. Don't use this option when reading a document file package, because that would cause unnecessarily bad performance. For example, an application wouldn't use this option when creating file wrappers to represent attachments as it's opening a document stored in a file package.

Available in Mac OS X v10.6 and later.

Declared in `NSFileWrapper.h`.

`NSFileWrapperReadingWithoutMapping`

Whether file mapping for regular file wrappers is disallowed.

You can use this option to keep `NSFileWrapper` from memory-mapping files. This is useful if you want to make sure your application doesn't hold files open (mapped files are open files), therefore preventing the user from ejecting DVDs, unmounting disk partitions, or unmounting disk images. In Mac OS X v10.6 and later, `NSFileWrapper` memory-maps files that are on internal drives only. It never memory-maps files on external drives or network volumes, regardless of whether this option is used.

Available in Mac OS X v10.6 and later.

Declared in `NSFileWrapper.h`.

Discussion

You can use the `NSFileWrapperReadingImmediate` and `NSFileWrapperReadingWithoutMapping` reading options together to take an exact snapshot of a file-system hierarchy that is safe from all errors (including the ones mentioned above) once reading has succeeded. If reading with both options succeeds, then subsequent invocations of the methods listed in the comment for the `NSFileWrapperReadingImmediate` reading option to the receiver and all its descendant file wrappers will never fail. However, note that reading with both options together is expensive in terms of both I/O and memory for large files, or directories containing large files, or even directories containing many small files.

File Wrapper Writing Options

Writing options that can be set by the `writeToURL:options:originalContentsURL:error:` (page 1138) method.

```
enum {
 NSFileWrapperWritingAtomic = 1 << 0,
 NSFileWrapperWritingWithNameUpdating = 1 << 1
};
typedef NSUInteger NSFileWrapperWritingOptions;
```

Constants

`NSFileWrapperWritingAtomic`

Whether writing is done atomically.

You can use this option to ensure that, when overwriting a file package, the overwriting either completely succeeds or completely fails, with no possibility of leaving the file package in an inconsistent state. Because this option causes additional I/O, you shouldn't use it unnecessarily. For example, don't use this option in an override of `-[NSDocument writeToURL:ofType:error:]` (page 996), because `NSDocument` safe-saving is already done atomically.

Available in Mac OS X v10.6 and later.

Declared in `NSFileWrapper.h`.

`NSFileWrapperWritingWithNameUpdating`

Whether descendant file wrappers are sent the `setFilename:` (page 1134) method if the writing succeeds.

This option is necessary when your application passes a URL in the `originalContentsURL` parameter to the `writeToURL:options:originalContentsURL:error:` (page 1138) method. Without using this option (and reusing child file wrappers properly), subsequent invocations of `writeToURL:options:originalContentsURL:error:` (page 1138) would not be able to reliably create hard links in a new file package, because the record of names in the old file package would be out of date.

Available in Mac OS X v10.6 and later.

Declared in `NSFileWrapper.h`.

Overview

`NSFont` objects represent fonts to an application, providing access to characteristics of the font and assistance in laying out glyphs relative to one another. Font objects are also used to establish the current font for drawing text directly into a graphics context, using the `set` (page 1179) method.

You don't create `NSFont` objects using the `alloc` and `init` methods. Instead, you use either `fontWithDescriptor:size:` (page 1150) or `fontWithName:size:` (page 1152) to look up an available font and alter its size or matrix to your needs. These methods check for an existing font object with the specified characteristics, returning it if there is one. Otherwise, they look up the font data requested and create the appropriate object. `NSFont` also defines a number of methods for getting standard system fonts, such as `systemFontOfSize:` (page 1157), `userFontOfSize:` (page 1161), and `messageFontOfSize:` (page 1154). To request the default size for these standard fonts, pass a negative number or 0 as the font size.

Adopted Protocols

NSCoding

- `encodeWithCoder:`
- `initWithCoder:`

NSCopying
- copyWithZone:

Tasks

Creating Arbitrary Fonts

+ fontWithName:size: (page 1152)
Creates a font object for the specified font name and font size.

+ fontWithDescriptor:size: (page 1150)
Returns a font object for the specified font descriptor and font size.

+ fontWithDescriptor:textTransform: (page 1150)
Returns a font object for the specified font descriptor and text transform.

+ fontWithName:matrix: (page 1151)
Returns a font object for the specified font name and matrix.

Creating User Fonts

+ userFontOfSize: (page 1161)
Returns the font used by default for documents and other text under the user's control (that is, text whose font the user can normally change), in the specified size.

+ userFixedPitchFontOfSize: (page 1161)
Returns the font used by default for documents and other text under the user's control (that is, text whose font the user can normally change), when that font should be fixed-pitch, in the specified size.

Creating System Fonts

+ boldSystemFontOfSize: (page 1149)
Returns the Aqua system font used for standard interface items that are rendered in boldface type in the specified size.

+ controlContentFontOfSize: (page 1149)
Returns the font used for the content of controls in the specified size.

+ labelFontOfSize: (page 1152)
Returns the Aqua font used for standard interface labels in the specified size.

+ menuFontOfSize: (page 1154)
Returns the font used for menu items, in the specified size.

+ menuBarFontOfSize: (page 1153)
Returns the font used for menu bar items, in the specified size.

+ messageFontOfSize: (page 1154)
Returns the font used for standard interface items, such as button labels, menu items, and so on, in the specified size.

+ `paletteFontOfSize:` (page 1155)
  Returns the font used for palette window title bars, in the specified size.

+ `systemFontOfSize:` (page 1157)
  Returns the Aqua system font used for standard interface items, such as button labels, menu items, and so on, in the specified size.

+ `titleBarFontOfSize:` (page 1159)
  Returns the font used for window title bars, in the specified size.

+ `toolTipsFontOfSize:` (page 1160)
  Returns the font used for tool tips labels, in the specified size.

Using a Font to Draw

- `set` (page 1179)
  Sets this font as the font for the current graphics context.

- `setInContext:` (page 1180)
  Sets this font as the font for the specified graphics context.

Getting General Font Information

- `coveredCharacterSet` (page 1165)
  Returns an `NSCharacterSet` object containing all of the nominal characters renderable by the receiver, which is all of the entries mapped in the receiver's '`cmap`' table.

- `fontDescriptor` (page 1167)
  Returns the receiver's font descriptor.

- `isFixedPitch` (page 1171)
  Returns a Boolean value indicating whether all glyphs in the receiver have the same advancement.

- `mostCompatibleStringEncoding` (page 1173)
  Returns the string encoding that works best with the receiver, where there are the fewest possible unmatched characters in the string encoding and glyphs in the font.

- `renderingMode` (page 1178)
  Returns the rendering mode of the receiver.

Getting Information About Glyphs

- `glyphWithName:` (page 1170)
  Returns the named encoded glyph, or –1 if the receiver contains no such glyph.

Getting Metrics Information

+ `labelFontSize` (page 1153)
  Returns the size of the standard label font.

+ `smallSystemFontSize` (page 1157)
  Returns the size of the standard small system font.

+ `systemFontSize` (page 1158)
  Returns the size of the standard system font.

+ `systemFontSizeForControlSize:` (page 1159)
  Returns the font size used for the specified control size.

- `advancementForGlyph:` (page 1162)
  Returns the nominal spacing for the given glyph—the distance the current point moves after showing the glyph—accounting for the receiver's size.

- `ascender` (page 1163)
  Returns the top y-coordinate, offset from the baseline, of the receiver's longest ascender.

- `boundingRectForFont` (page 1163)
  Returns the receiver's bounding rectangle, scaled to the font's size.

- `boundingRectForGlyph:` (page 1164)
  Returns the bounding rectangle for the specified glyph, scaled to the receiver's size.

- `capHeight` (page 1164)
  Returns the receiver's cap height.

- `descender` (page 1166)
  Returns the bottom y coordinate, offset from the baseline, of the receiver's longest descender.

- `getAdvancements:forGlyphs:count:` (page 1168)
  Returns an array of the advancements for the specified glyphs rendered by the receiver.

- `getAdvancements:forPackedGlyphs:length:` (page 1168)
  Returns an array of the advancements for the specified packed glyphs and rendered by the receiver.

- `getBoundingRects:forGlyphs:count:` (page 1169)
  Returns an array of the bounding rectangles for the specified glyphs rendered by the receiver.

- `italicAngle` (page 1171)
  Returns the receiver's italic angle, the amount that the font is slanted in degrees counterclockwise from the vertical, as read from its AFM file. Because the slant is measured counterclockwise, English italic fonts typically return a negative value.

- `leading` (page 1172)
  Returns the receiver's leading.

- `matrix` (page 1172)
  Returns the receiver's font matrix, a standard six-element transformation matrix as used in the PostScript language, specifically with the `makefont` operator.

- `maximumAdvancement` (page 1172)
  Returns the greatest advancement of any of the receiver's glyphs.

- `numberOfGlyphs` (page 1173)
  Returns the number of glyphs in the receiver.

- `pointSize` (page 1174)
  Returns the receiver's point size, or the effective vertical point size for a font with a nonstandard matrix.

- `textTransform` (page 1180)
  Returns the current transformation matrix for the receiver.

- `underlinePosition` (page 1181)
  Returns the baseline offset that should be used when drawing underlines with the receiver, as determined by the font's AFM file.

- `underlineThickness` (page 1181)
  Returns the thickness that should be used when drawing underlines with the receiver, as determined by the font's AFM file.
- `xHeight` (page 1182)
  Returns the x-height of the receiver.

Getting Font Names

- `displayName` (page 1166)
  Returns the name, including family and face, used to represent the font in the user interface, typically localized for the user's language.
- `familyName` (page 1167)
  Returns the receiver's family name—for example, "Times" or "Helvetica."
- `fontName` (page 1167)
  Returns the receiver's full font name, as used in PostScript language code—for example, "Times-Roman" or "Helvetica-Oblique."

Setting User Fonts

+ `setUserFont:` (page 1157)
  Sets the font used by default for documents and other text under the user's control to the specified font.
+ `setUserFixedPitchFont:` (page 1156)
  Sets the font used by default for documents and other text under the user's control, when that font should be fixed-pitch, to the specified font.

Getting Corresponding Device Fonts

- `printerFont` (page 1178)
  Returns the scalable PostScript font corresponding to itself.
- `screenFont` (page 1178)
  Returns the bitmapped screen font corresponding to itself.
- `screenFontWithRenderingMode:` (page 1179)
  Returns a bitmapped screen font, when sent to a font object representing a scalable PostScript font, with the specified rendering mode, matching the receiver in typeface and matrix (or size), or `nil` if such a font can't be found.

Deprecated Methods

+ `preferredFontNames` (page 1155) Deprecated in Mac OS X v10.4
  Returns the names of fonts that the Application Kit tries first when a character has no font specified. (Deprecated. The `NSFontDescriptor` constant `NSFontCascadeListAttribute` offers more powerful font substitution management.)

`+ setPreferredFontNames:` (page 1156) Deprecated in Mac OS X v10.4

Sets the list of preferred font names. (Deprecated. The `NSFontDescriptor` constant `NSFontCascadeListAttribute` offers more powerful font substitution management.)

`+ useFont:` (page 1160) Deprecated in Mac OS X v10.4

Records the given font name as one used in the current print operation. (Deprecated. This is now automatically handled by Quartz.)

`- afmDictionary` (page 1163) Deprecated in Mac OS X v10.4

Returns the AFM font's dictionary. (Deprecated. Use accessor functions listed in "`Keys to the AFM Dictionary`" (page 1184) instead.)

`- defaultLineHeightForFont` (page 1165) Deprecated in Mac OS X v10.4

Returns the default line height for the receiver. (Deprecated. Use the `NSLayoutManager` method `defaultLineHeightForFont:` (page 1456) instead.)

`- encodingScheme` (page 1166) Deprecated in Mac OS X v10.4

Returns the name of the receiver's encoding scheme. (Deprecated. Use `mostCompatibleStringEncoding` (page 1173) instead.)

`- glyphIsEncoded:` (page 1169) Deprecated in Mac OS X v10.4

Returns a Boolean value indicating whether the receiver encodes the given glyph. (Deprecated. The value can be deduced by `aGlyph < [NSFont numberOfGlyphs]` since only `NSNativeShortGlyphPacking` is supported.)

`- glyphPacking` (page 1170) Deprecated in Mac OS X v10.4

Returns the best way to encode the receiver's glyphs into an array of bytes. (Deprecated. Only `NSNativeShortGlyphPacking` (page 1184) is supported.)

`- isBaseFont` (page 1170) Deprecated in Mac OS X v10.4

Returns a Boolean value indicating whether the receiver is a PostScript base font. (Deprecated. This information is not relevant to Mac OS X.)

`- positionOfGlyph:forCharacter:struckOverRect:` (page 1174) Deprecated in Mac OS X v10.4

Calculates and returns a suitable location for the given glyph to be drawn. (Deprecated. Context-sensitive interglyph spacing is now performed at the typesetting stage.)

`- positionOfGlyph:precededByGlyph:isNominal:` (page 1175) Deprecated in Mac OS X v10.4

Calculates and returns the location of a glyph. (Deprecated. Context-sensitive interglyph spacing is now performed at the typesetting stage.)

`- positionOfGlyph:struckOverGlyph:metricsExist:` (page 1175) Deprecated in Mac OS X v10.4

Calculates and returns a suitable location for the given glyph to be drawn. (Deprecated. Context-sensitive interglyph spacing is now performed at the typesetting stage.)

`- positionOfGlyph:struckOverRect:metricsExist:` (page 1176) Deprecated in Mac OS X v10.4

Overridden by subclasses to calculate and return a suitable location for a glyph to be drawn. (Deprecated. Context-sensitive interglyph spacing is now performed at the typesetting stage.)

`- positionOfGlyph:withRelation:toBaseGlyph:totalAdvancement:metricsExist:` (page 1176) Deprecated in Mac OS X v10.4

Calculates and returns a suitable location for a glyph to be drawn. (Deprecated. Context-sensitive interglyph spacing is now performed at the typesetting stage.)

`- positionsForCompositeSequence:numberOfGlyphs:pointArray:` (page 1177) Deprecated in Mac OS X v10.4

Calculates glyph locations. (Deprecated. Context-sensitive interglyph spacing is now performed at the typesetting stage.)

`- widthOfString:` (page 1181) Deprecated in Mac OS X v10.4
Returns the x-axis offset of the current point when the specified string is drawn with a `show` operator in the receiving font. (Deprecated. Use the Application Kit string-drawing methods, as described in NSString Additions (page 2581).)

Class Methods

boldSystemFontOfSize:

Returns the Aqua system font used for standard interface items that are rendered in boldface type in the specified size.

```
+ (NSFont *)boldSystemFontOfSize:(CGFloat)fontSize
```

Parameters

fontSize
The size in points to which the font is scaled.

Return Value
A font object of the specified size.

Discussion
If *fontSize* is 0 or negative, returns the boldface system font at the default size.

Availability
Available in Mac OS X v10.0 and later.

See Also
`+ fontWithName:size:` (page 1152)

Worm

Declared In
`NSFont.h`

controlContentFontOfSize:

Returns the font used for the content of controls in the specified size.

```
+ (NSFont *)controlContentFontOfSize:(CGFloat)fontSize
```

Parameters

fontSize
The size in points to which the font is scaled.

Return Value
A font object of the specified size.

Discussion
For example, in a table, the user's input uses the control content font, and the table's header uses another font. If *fontSize* is 0 or negative, returns the control content font at the default size.

Availability
Available in Mac OS X v10.0 and later.

See Also
+ fontWithName:size: (page 1152)

Declared In
NSFont.h

fontWithDescriptor:size:

Returns a font object for the specified font descriptor and font size.

```
+ (NSFont *)fontWithDescriptor:(NSFontDescriptor *)fontDescriptor
    size:(CGFloat)fontSize
```

Parameters

fontDescriptor
A font descriptor object.

fontSize
The size in points to which the font is scaled.

Return Value
A font object for the specified descriptor and size.

Discussion
In most cases, you can simply use fontWithName:size: (page 1152) to create standard scaled fonts.

Availability
Available in Mac OS X v10.4 and later.

See Also
+ fontWithName:size: (page 1152)

Declared In
NSFont.h

fontWithDescriptor:textTransform:

Returns a font object for the specified font descriptor and text transform.

```
+ (NSFont *)fontWithDescriptor:(NSFontDescriptor *)fontDescriptor
    textTransform:(NSAffineTransform *)textTransform
```

Parameters

fontDescriptor

The font descriptor object describing the font to return.

textTransform

An affine transformation applied to the font.

Return Value
A font object for the specified name and transform.

Discussion
In most cases, you can simply use `fontWithName:size:` (page 1152) to create standard scaled fonts. If *textTransform* is non-nil, it has precedence over `NSFontMatrixAttribute` in *fontDescriptor*.

Availability
Available in Mac OS X v10.4 and later.

See Also
`+ fontWithName:size:` (page 1152)

Declared In
`NSFont.h`

fontWithName:matrix:

Returns a font object for the specified font name and matrix.

```
+ (NSFont *)fontWithName:(NSString *)fontName matrix:(const CGFloat *)fontMatrix
```

Parameters

fontName

The fully specified family-face name of the font.

fontMatrix

A transformation matrix applied to the font.

Return Value
A font object for the specified name and transformation matrix.

Discussion
The *fontName* is a fully specified family-face name, such as Helvetica-BoldOblique or Times-Roman (not a name as shown in the Font Panel). The *fontMatrix* is a standard 6-element transformation matrix as used in the PostScript language, specifically with the `makefont` operator. In most cases, you can simply use `fontWithName:size:` (page 1152) to create standard scaled fonts.

You can use the defined value `NSFontIdentityMatrix` for [1 0 0 1 0 0]. Fonts created with a matrix other than `NSFontIdentityMatrix` don't automatically flip themselves in flipped views.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- isFlipped` (page 3181) (`NSView`)

Declared In
`NSFont.h`

fontWithName:size:

Creates a font object for the specified font name and font size.

```
+ (NSFont *)fontWithName:(NSString *)fontName size:(CGFloat)fontSize
```

Parameters

fontName

The fully specified family-face name of the font.

fontSize

The size in points to which the font is scaled.

Return Value
A font object for the specified name and size.

Discussion
The *fontName* is a fully specified family-face name, such as Helvetica-BoldOblique or Times-Roman. The *fontSize* is equivalent to using a font matrix of [*fontSize* 0 0 *fontSize* 0 0] with `fontWithDescriptor:size:` (page 1150). If you use a *fontSize* of 0.0, this method uses the default User Font size.

Fonts created with this method automatically flip themselves in flipped views. This method is the preferred means for creating fonts.

Availability
Available in Mac OS X v10.0 and later.

```

Return Value
The label font size in points.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSFont.h

menuBarFontOfSize:

Returns the font used for menu bar items, in the specified size.

```
+ (NSFont *)menuBarFontOfSize:(CGFloat)fontSize
```

Parameters
fontSize
The size in points to which the font is scaled.

Return Value
A font object of the specified size.

Discussion
If *fontSize* is 0 or negative, returns the menu bar font with the default size.

Availability
Available in Mac OS X v10.3 and later.

See Also
+ fontWithName:size: (page 1152)

Declared In
NSFont.h

menuFontOfSize:

Returns the font used for menu items, in the specified size.

```
+ (NSFont *)menuFontOfSize:(CGFloat)fontSize
```

Parameters

fontSize

The size in points to which the font is scaled.

Return Value

A font object of the specified size.

Discussion

If *fontSize* is 0 or negative, returns the menu items font with the default size.

Availability

Available in Mac OS X v10.0 and later.

+ titleBarFontOfSize: (page 1159)

Declared In
NSFont.h

preferredFontNames

Returns the names of fonts that the Application Kit tries first when a character has no font specified. (Deprecated in Mac OS X v10.4. The NSFontDescriptor constant NSFontCascadeListAttribute offers more powerful font substitution management.)

```
+ (NSArray *)preferredFontNames
```

Discussion
Returns the names of fonts that the Application Kit tries first when a character has no font specified or when the font specified doesn't have a glyph for that character. If none of these fonts provides a glyph, the remaining fonts on the system are searched for a glyph.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

See Also
+ setPreferredFontNames: (page 1156)

Declared In
NSFont.h

setPreferredFontNames:

Sets the list of preferred font names. (Deprecated in Mac OS X v10.4. The NSFontDescriptor constant NSFontCascadeListAttribute offers more powerful font substitution management.)

```
+ (void)setPreferredFontNames:(NSArray *)fontNames
```

Discussion
Sets the list of preferred font names to *fontNames* and records them in the user defaults database for all applications. The Application Kit tries these fonts first when a character has no font specified or when the font specified doesn't have a glyph for that character. If none of these fonts provides a glyph, the remaining fonts on the system are searched for a glyph.

This method is useful for optimizing glyph rendering for uncommon scripts, by guaranteeing that appropriate fonts are searched first. For example, suppose you have three hundred Latin alphabet fonts and one Cyrillic alphabet font. When you read a document in Russian, you want it to find the Cyrillic font quickly. Ordinarily, the Application Kit will search for the Cyrillic font among all 301 fonts. But if it is in the list of preferred fonts, the Cyrillic font will be one of the first searched.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

TipWrapper

Declared In

NSFont.h

useFont:

Records the given font name as one used in the current print operation. (Deprecated in Mac OS X v10.4. This is now automatically handled by Quartz.)

```
+ (void)useFont:(NSString *)fontName
```

Discussion

Records *fontName* as one used in the current print operation.

The NSFont class object keeps track of the fonts used in an NSView by recording each one that receives a set (page 1179) message. When the view is called upon to generate conforming PostScript language output (such as during printing), the NSFont class provides the list of fonts required for the %%DocumentFonts comment, as required by Adobe's document structuring conventions.

The useFont: argument augments this system by providing a way to register fonts that are included in the document but not set using NSFont's set (page 1179) method. For example, you might set a font by executing the setfont operator within a function created by the pswrap utility. In such a case, be sure to pair the use of the font with a useFont: message to register the font for listing in the document comments.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
NSFont.h

userFixedPitchFontOfSize:

Returns the font used by default for documents and other text under the user's control (that is, text whose font the user can normally change), when that font should be fixed-pitch, in the specified size.

```
+ (NSFont *)userFixedPitchFontOfSize:(CGFloat)fontSize
```

Parameters

fontSize
The size in points to which the font is scaled.

Return Value
A font object of the specified size.

Discussion
If *fontSize* is 0 or negative, returns the fixed-pitch font at the default size.

The system does not guarantee that all the glyphs in a fixed-pitch font are the same width. For example, certain Japanese fonts are dual-pitch, and other fonts may have nonspacing marks that can affect the display of other glyphs.

Availability
Available in Mac OS X v10.0 and later.

Instance Methods

advancementForGlyph:

Returns the nominal spacing for the given glyph—the distance the current point moves after showing the glyph—accounting for the receiver's size.

```
- (NSSize)advancementForGlyph:(NSGlyph)aGlyph
```

Parameters

aGlyph
The glyph whose advancement is returned.

Return Value
The advancement spacing in points.

Discussion
This spacing is given according to the glyph's movement direction, which is either strictly horizontal or strictly vertical.

Availability
Available in Mac OS X v10.0 and later.

See Also
- boundingRectForGlyph: (page 1164)
- maximumAdvancement (page 1172)

boundingRectForFont

Returns the receiver's bounding rectangle, scaled to the font's size.

```
- (NSRect)boundingRectForFont
```

Discussion
The bounding rectangle is the union of the bounding rectangles of every glyph in the font.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `boundingRectForGlyph:` (page 1164)

Related Sample Code
NSFontAttributeExplorer

Declared In
`NSFont.h`

boundingRectForGlyph:

Returns the bounding rectangle for the specified glyph, scaled to the receiver's size.

```
- (NSRect)boundingRectForGlyph:(NSGlyph)aGlyph
```

Discussion
Japanese fonts encoded with the scheme "EUC12-NJE-CFEncoding" do not have individual metrics or bounding boxes available for the glyphs above 127. For those glyphs, this method returns the bounding rectangle for the font instead.

Availability
Available in Mac OS X v10.0 and later.

See Also

Declared In
`NSFont.h`

capHeight

Returns the receiver's cap height.

```
- (CGFloat)capHeight
```

Availability
Available in Mac OS X v10.0 and later.

See Also
- `ascender` (page 1163)
- `descender` (page 1166)
- `xHeight` (page 1182)

Related Sample Code
NSFontAttributeExplorer

Declared In
NSFont.h

coveredCharacterSet

Returns an NSCharacterSet object containing all of the nominal characters renderable by the receiver, which is all of the entries mapped in the receiver's 'cmap' table.

```
- (NSCharacterSet *)coveredCharacterSet
```

Return Value
An NSCharacterSet object containing all of the nominal characters renderable by the receiver.

Discussion
The number of glyphs supported by a given font is often larger than the number of characters contained in the character set returned by this method.

Availability
Available in Mac OS X v10.2 and later.

Declared In
NSFont.h

defaultLineHeightForFont

Returns the default line height for the receiver. (Deprecated in Mac OS X v10.4. Use the NSLayoutManager method defaultLineHeightForFont: (page 1456) instead.)

```
- (CGFloat)defaultLineHeightForFont
```

Discussion
Equivalent to ascent plus descent plus linegap.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

See Also
- ascender (page 1163)
- descender (page 1166)

Related Sample Code
NSFontAttributeExplorer

Declared In
NSFont.h

descender

Returns the bottom y coordinate, offset from the baseline, of the receiver's longest descender.

```
- (CGFloat)descender
```

Discussion
Thus, if the longest descender extends 2 points below the baseline, `descender` will return –2.

Availability
Available in Mac OS X v10.0 and later.

encodingScheme

Returns the name of the receiver's encoding scheme. (Deprecated in Mac OS X v10.4. Use `mostCompatibleStringEncoding` (page 1173) instead.)

```
- (NSString *)encodingScheme
```

Discussion
Returns the name of the receiver's encoding scheme, such as "AdobeStandardEncoding," "ISOLatin1Encoding," "FontSpecific," and so on.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
NSFont.h

familyName

Returns the receiver's family name—for example, "Times" or "Helvetica."

```
- (NSString *)familyName
```

Discussion
This name is the one that `NSFontManager` uses and may differ slightly from the AFM name.

The value returned by this method is intended for an application's internal usage and not for display. Use `displayName` (page 1166) instead.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- fontName` (page 1167)

Declared In
NSFont.h

fontDescriptor

Returns the receiver's font descriptor.

```
- (NSFontDescriptor *)fontDescriptor
```

Return Value
A font descriptor object that describes the receiver.

Discussion
The font descriptor contains a mutable dictionary of optional attributes for creating an `NSFont` object. See documentation on NSFontDescriptor for more information.

Availability
Available in Mac OS X v10.3 and later.

Related Sample Code
CoreTextArcCocoa

Declared In
NSFont.h

fontName

Returns the receiver's full font name, as used in PostScript language code—for example, "Times-Roman" or "Helvetica-Oblique."

```
- (NSString *)fontName
```

Discussion
The value returned by this method is intended for an application's internal usage and not for display. Use `displayName` (page 1166) instead.

Availability
Available in Mac OS X v10.0 and later.

- `familyName` (page 1167)

Related Sample Code
FunHouse

Declared In
`NSFont.h`

getAdvancements:forGlyphs:count:

Returns an array of the advancements for the specified glyphs rendered by the receiver.

```
- (void)getAdvancements:(NSSizeArray)advancements forGlyphs:(const NSGlyph *)glyphs
    count:(NSUInteger)glyphCount
```

Discussion
Returns in *advancements* an array of the advancements for the glyphs specified by *glyphs* and rendered by the receiver. The *glyphCount* must specify the count of glyphs passed in *glyphs*.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `boundingRectForFont` (page 1163)
- `boundingRectForGlyph:` (page 1164)
- `getAdvancements:forPackedGlyphs:length:` (page 1168)
- `getBoundingRects:forGlyphs:count:` (page 1169)

Declared In
`NSFont.h`

getAdvancements:forPackedGlyphs:length:

Returns an array of the advancements for the specified packed glyphs and rendered by the receiver.

```
- (void)getAdvancements:(NSSizeArray)advancements forPackedGlyphs:(const void
  *)packedGlyphs length:(NSUInteger)length- (void)getAdvancements
```

Discussion
Returns in *advancements* an array of the advancements for the packed glyphs specified by *packedGlyphs* and rendered by the receiver. The *glyphCount* must specify the count of glyphs passed in *packedGlyphs*.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `boundingRectForFont` (page 1163)
- `boundingRectForGlyph:` (page 1164)
- `getBoundingRects:forGlyphs:count:` (page 1169)
- `getAdvancements:forGlyphs:count:` (page 1168)

Declared In
`NSFont.h`

getBoundingRects:forGlyphs:count:

Returns an array of the bounding rectangles for the specified glyphs rendered by the receiver.

```
- (void)getBoundingRects:(NSRectArray)bounds forGlyphs:(const NSGlyph *)glyphs
    count:(NSUInteger)glyphCount
```

Discussion
Returns in *bounds* an array of the bounding rectangles for the glyphs specified by *glyphs* and rendered by the receiver. The *glyphCount* must specify the count of glyphs passed in *glyphs*.

Availability
Available in Mac OS X v10.4 and later.

See Also

- `getAdvancements:forPackedGlyphs:length:` (page 1168)

Declared In
`NSFont.h`

glyphIsEncoded:

Returns a Boolean value indicating whether the receiver encodes the given glyph. (Deprecated in Mac OS X v10.4. The value can be deduced by `aGlyph < [NSFont numberOfGlyphs]` since only `NSNativeShortGlyphPacking` is supported.)

```
- (BOOL)glyphIsEncoded:(NSGlyph)aGlyph
```

Discussion
Returns `YES` if the receiver encodes *aGlyph*, `NO` if it doesn't contain it.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
NSFont.h

glyphPacking

Returns the best way to encode the receiver's glyphs into an array of bytes. (Deprecated in Mac OS X v10.4. Only `NSNativeShortGlyphPacking` (page 1184) is supported.)

```
- (NSMultibyteGlyphPacking)glyphPacking
```

Discussion
Returns the best way to encode the receiver's glyphs into an array of bytes. The return value is one of values described in "Constants" (page 1182).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
NSFont.h

glyphWithName:

Returns the named encoded glyph, or –1 if the receiver contains no such glyph.

```
- (NSGlyph)glyphWithName:(NSString *)glyphName
```

Parameters
glyphName
The name of the glyph.

Return Value
The named encoded glyph.

Discussion
Returns –1 if the glyph named *glyphName* isn't encoded.

Glyph names in fonts do not always accurately identify the glyph. If possible, look up the appropriate glyph on your own.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSFont.h

isBaseFont

Returns a Boolean value indicating whether the receiver is a PostScript base font. (Deprecated in Mac OS X v10.4. This information is not relevant to Mac OS X.)

```
- (BOOL)isBaseFont
```

Discussion
Returns `YES` if the receiver is a PostScript base font, `NO` if it's a PostScript composite font composed of other base fonts.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`NSFont.h`

isFixedPitch

Returns a Boolean value indicating whether all glyphs in the receiver have the same advancement.

```
- (BOOL)isFixedPitch
```

Return Value
`YES` if all glyphs in the receiver have the same advancement; `NO` if any advancements differ.

Discussion
Some Japanese fonts encoded with the scheme "EUC12-NJE-CFEncoding" return that they have the same advancement, but actually encode glyphs with one of two advancements, for historical compatibility. You may need to handle such fonts specially for some applications.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- advancementForGlyph:` (page 1162)

Related Sample Code
NSFontAttributeExplorer

Declared In
`NSFont.h`

italicAngle

Returns the receiver's italic angle, the amount that the font is slanted in degrees counterclockwise from the vertical, as read from its AFM file. Because the slant is measured counterclockwise, English italic fonts typically return a negative value.

```
- (CGFloat)italicAngle
```

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
NSFontAttributeExplorer

Declared In
NSFont.h

leading

Returns the receiver's leading.

```
- (CGFloat)leading
```

Availability
Available in Mac OS X v10.4 and later.

See Also
+ fontWithDescriptor:size: (page 1150)

NSFontAttributeExplorer

Declared In
NSFont.h

matrix

Returns the receiver's font matrix, a standard six-element transformation matrix as used in the PostScript language, specifically with the `makefont` operator.

```
- (const CGFloat *)matrix
```

Discussion
In most cases, with a font of `fontSize`, this matrix is [`fontSize` 0 0 `fontSize` 0 0].

Availability
Available in Mac OS X v10.0 and later.

See Also
+ fontWithDescriptor:size: (page 1150)

Declared In
NSFont.h

maximumAdvancement

Returns the greatest advancement of any of the receiver's glyphs.

```
- (NSSize)maximumAdvancement
```

Discussion
This advancement is always either strictly horizontal or strictly vertical.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `advancementForGlyph:` (page 1162)

Related Sample Code
NSFontAttributeExplorer
Quartz Composer WWDC 2005 TextEdit

Declared In
`NSFont.h`

mostCompatibleStringEncoding

Returns the string encoding that works best with the receiver, where there are the fewest possible unmatched characters in the string encoding and glyphs in the font.

```
- (NSStringEncoding)mostCompatibleStringEncoding
```

Return Value
The string encoding that works best with the receiver.

Discussion
You can use `NSString`'s `dataUsingEncoding:` or `dataUsingEncoding:allowLossyConversion:` method to convert the string to this encoding.

If this method returns `NSASCIIStringEncoding`, it could not determine the correct encoding and assumed that the font can render only ASCII characters.

This method works heuristically using well-known font encodings, so for nonstandard encodings it may not in fact return the optimal string encoding.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
NSFontAttributeExplorer

Declared In
`NSFont.h`

numberOfGlyphs

Returns the number of glyphs in the receiver.

```
- (NSUInteger)numberOfGlyphs
```

Discussion
Glyphs are numbered starting at 0.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
NSFontAttributeExplorer

Declared In
NSFont.h

pointSize

Returns the receiver's point size, or the effective vertical point size for a font with a nonstandard matrix.

```
- (CGFloat)pointSize
```

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
FunHouse
GeekGameBoard
Quartz Composer WWDC 2005 TextEdit

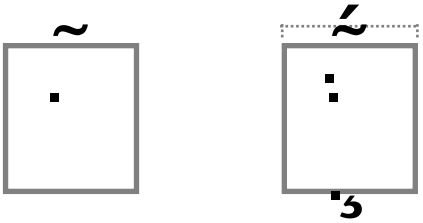
Declared In
NSFont.h

positionOfGlyph:forCharacter:struckOverRect:

Calculates and returns a suitable location for the given glyph to be drawn. (Deprecated in Mac OS X v10.4. Context-sensitive interglyph spacing is now performed at the typesetting stage.)

```
- (NSPoint)positionOfGlyph:(NSGlyph)aGlyph forCharacter:(unichar)aChar
    struckOverRect:(NSRect)aRect
```

Discussion
Calculates and returns a suitable location for *aGlyph* to be drawn as a diacritic or nonspacing mark relative to *aRect*, assuming that *aGlyph* represents *aChar*. Returns NSZeroPoint if the location can't be calculated. The nature of *aChar* as one appearing above or below its base character determines the location returned. For example, in the first figure below, the gray tilde and box represent *aGlyph* and *aRect*, and the black dot is the point returned (defined relative to the origin of the *aRect*).



To place multiple glyphs with respect to a rectangle, work from the innermost glyphs to the outermost. As you calculate the position of each glyph, enlarge the rectangle to include the bounding rectangle of the glyph in preparation for the next glyph. The second figure shows a tilde, acute accent, and cedilla all placed in their appropriate positions with respect to a rectangle, with the acute accent placed relative to the expanded bounding box of the base rectangle and the tilde.

This method is the last fallback mechanism for performing minimally legible typography when metrics aren't available. Use it when `positionOfGlyph:struckOverGlyph:metricsExist:` (page 1175) indicates that metrics don't exist for the base glyph specified, or when you are combining glyphs from different fonts (for example, the base glyph is in a different font than the accent). It can account for the layout and placement of most Latin, Greek, and Cyrillic nonspacing marks. You should draw the glyph at the returned location, even if it's `NSZeroRect`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`NSFont.h`

positionOfGlyph:precededByGlyph:isNominal:

Calculates and returns the location of a glyph. (Deprecated in Mac OS X v10.4. Context-sensitive interglyph spacing is now performed at the typesetting stage.)

```
- (NSPoint)positionOfGlyph:(NSGlyph)aGlyph precededByGlyph:(NSGlyph)prevGlyph
    isNominal:(BOOL *)flag
```

Discussion
Calculates and returns the location of *aGlyph* relative to *prevGlyph*, assuming that *prevGlyph* precedes it in the layout (not necessarily in the character stream). The point returned should be used relative to whatever location is used for *prevGlyph*. If *flag* is non-`nil`, it's filled with `NO` if kerning tables are available and were used in the calculation; it is filled with `YES` if the default spacing is used.

Returns `NSZeroPoint` if either *aGlyph* or *prevGlyph* is `NSControlGlyph` or is invalid. Returns the nominal advancement of *prevGlyph* if *aGlyph* is `NSNullGlyph`.

This method is useful for sequential glyph placement when glyphs aren't drawn with a single PostScript operation.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`NSFont.h`

positionOfGlyph:struckOverGlyph:metricsExist:

Calculates and returns a suitable location for the given glyph to be drawn. (Deprecated in Mac OS X v10.4. Context-sensitive interglyph spacing is now performed at the typesetting stage.)

```
- (NSPoint)positionOfGlyph:(NSGlyph)aGlyph struckOverGlyph:(NSGlyph)baseGlyph
    metricsExist:(BOOL *)flag
```

Discussion
Calculates and returns a suitable location for *aGlyph* to be drawn as a diacritic or nonspacing mark relative to *baseGlyph*. The point returned should be used relative to whatever location is used for *baseGlyph*. If *flag* is non-nil it's filled with YES if font metrics are available, NO if they're not. If flag is returned as NO, the result isn't valid and shouldn't be used. In that case, use
positionOfGlyph:struckOverRect:metricsExist: (page 1176) or
positionOfGlyph:forCharacter:struckOverRect: (page 1174) to calculate a reasonable offset.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

See Also
- positionsForCompositeSequence:numberOfGlyphs:pointArray: (page 1177)
- positionOfGlyph:struckOverRect:metricsExist: (page 1176)

Declared In
NSFont.h

positionOfGlyph:struckOverRect:metricsExist:

Overridden by subclasses to calculate and return a suitable location for a glyph to be drawn. (Deprecated in Mac OS X v10.4. Context-sensitive interglyph spacing is now performed at the typesetting stage.)

```
- (NSPoint)positionOfGlyph:(NSGlyph)aGlyph struckOverRect:(NSRect)aRect
    metricsExist:(BOOL *)flag
```

Discussion
Overridden by subclasses to calculate and return a suitable location for *aGlyph* to be drawn as a diacritic or nonspacing mark relative to *aRect*, provided metrics exist. Returns NSZeroRect if the location can't be determined. If *flag* is non-nil it's filled with YES if font metrics are available, NO if they're not. If *flag* is returned as NO, the result isn't valid and shouldn't be used. In that case, use
positionOfGlyph:forCharacter:struckOverRect: (page 1174) to calculate a reasonable offset.

Because current PostScript font metrics don't include support for generic placement relative to rectangles, NSFont's implementation of this method always returns NSZeroPoint and returns *flag* as NO.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
NSFont.h

positionOfGlyph:withRelation:toBaseGlyph:totalAdvancement:metricsExist:

Calculates and returns a suitable location for a glyph to be drawn. (Deprecated in Mac OS X v10.4. Context-sensitive interglyph spacing is now performed at the typesetting stage.)

```
- (NSPoint)positionOfGlyph:(NSGlyph)aGlyph withRelation:(NSGlyphRelation)relation
    toBaseGlyph:(NSGlyph)baseGlyph totalAdvancement:(NSSizePointer)offset
  metricsExist:(BOOL *)flag
```

Discussion
Calculates and returns a suitable location for *aGlyph* to be drawn relative to *baseGlyph*, where *relation* is `NSGlyphBelow` or `NSGlyphAbove`. The point returned should be used relative to whatever location is used for *baseGlyph*. This method is useful for calculating the layout of stacked glyphs, found in some non-Western scripts.

If *offset* is non-`NULL`, this method sets it to the larger of the two glyphs' advancements, allowing for reasonable layout of following glyphs.

If *flag* is non-`nil`, this method sets it to whether font metrics are available: `YES` if they are, `NO` if they're not. If metrics aren't available, the location is calculated as a simple stacking with no gap between *baseGlyph* and *aGlyph*. Current Postscript fonts do not contain appropriate font metrics, so this method always sets *flag* to `NO`. If you subclass `NSFont` to handle fonts that do contain metrics, override this method.

This method supports only horizontally laid out base glyphs.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`NSFont.h`

positionsForCompositeSequence:numberOfGlyphs:pointArray:

Calculates glyph locations. (Deprecated in Mac OS X v10.4. Context-sensitive interglyph spacing is now performed at the typesetting stage.)

```
- (NSInteger)positionsForCompositeSequence:(NSGlyph *)glyphs
    numberOfGlyphs:(NSInteger)numGlyphs pointArray:(NSPointArray)points
```

Discussion
Calculates and fills *points* with the locations for *glyphs*, assuming the first glyph is a base character and those following are nonspacing marks. These points should all be interpreted as relative to the location of the first glyph in *glyphs*. The storage block *points* points to should be large enough for at least *numGlyphs* points. Returns the number of points that could be calculated.

If the number of points calculated is less than *numGlyphs*, the number of glyphs provided, you can use `positionOfGlyph:struckOverRect:metricsExist:` (page 1176) to determine the positions for the remaining glyphs. When using that method, calculate the base rectangle for each glyph from the bounding rectangles and positions of all preceding glyphs.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`NSFont.h`

printerFont

Returns the scalable PostScript font corresponding to itself.

```
- (NSFont *)printerFont
```

Discussion
When sent to a font object representing a scalable PostScript font, returns `self`. When sent to a font object representing a bitmapped screen font, returns its corresponding scalable PostScript font.

Availability
Available in Mac OS X v10.0 and later.

renderingMode

Returns the rendering mode of the receiver.

```
- (NSFontRenderingMode)renderingMode
```

Return Value
The rendering mode of the receiver.

Discussion
For valid rendering modes, see "Constants" (page 1182).

Availability
Available in Mac OS X v10.4 and later.

See Also
- `screenFontWithRenderingMode:` (page 1179)

Declared In
`NSFont.h`

screenFont

Returns the bitmapped screen font corresponding to itself.

```
- (NSFont *)screenFont
```

Discussion
When sent to a font object representing a scalable PostScript font, returns a bitmapped screen font matching the receiver in typeface and matrix (or size), or `nil` if such a font can't be found. When sent to a font object representing a bitmapped screen font, returns `nil`.

Screen fonts are for direct use with the window server only. Never use them with Application Kit objects, such as in `setFont:` methods. Internally, the Application Kit automatically uses the corresponding screen font for a font object as long as the view is not rotated or scaled.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `printerFont` (page 1178)
- `screenFontWithRenderingMode:` (page 1179)

Declared In
`NSFont.h`

screenFontWithRenderingMode:

Returns a bitmapped screen font, when sent to a font object representing a scalable PostScript font, with the specified rendering mode, matching the receiver in typeface and matrix (or size), or `nil` if such a font can't be found.

```
- (NSFont *)screenFontWithRenderingMode:(NSFontRenderingMode)renderingMode
```

Discussion
For valid rendering modes, see `NSFontRenderingMode` (page 1182).

Screen fonts are for direct use with the window server only. Never use them with Application Kit objects, such as in `setFont:` methods. Internally, the Application Kit automatically uses the corresponding screen font for a font object as long as the view is not rotated or scaled.

Constants

NSFontRenderingMode

These constants specify the font rendering mode.

```
typedef enum {
    NSFontDefaultRenderingMode = 0,
    NSFontAntialiasedRenderingMode = 1,
    NSFontIntegerAdvancementsRenderingMode = 2,
    NSFontAntialiasedIntegerAdvancementsRenderingMode = 3
} NSFontRenderingMode;
```

Constants

`NSFontDefaultRenderingMode`

Determines the actual mode based on the user preference settings.

Available in Mac OS X v10.4 and later.

Declared in `NSFont.h`.

`NSFontAntialiasedRenderingMode`

Specifies antialiased, floating-point advancements rendering mode (synonymous with printerFont).

Available in Mac OS X v10.4 and later.

Declared in `NSFont.h`.

`NSFontIntegerAdvancementsRenderingMode`

Specifies integer advancements rendering mode.

Available in Mac OS X v10.4 and later.

Declared in `NSFont.h`.

`NSFontAntialiasedIntegerAdvancementsRenderingMode`

Specifies antialiased, integer advancements rendering mode.

Available in Mac OS X v10.4 and later.

Declared in `NSFont.h`.

Declared In

`NSFont.h`

PostScript Transformation Matrix

The identity matrix.

```
const float *NSFontIdentityMatrix;
```

Constants

`NSFontIdentityMatrix`

A transformation matrix useful as a parameter to fontWithDescriptor:size: (page 1150).

Available in Mac OS X v10.0 and later.

Declared in `NSFont.h`.

Declared In

`NSFont.h`

NSMultibyteGlyphPacking

A constant for glyph packing.

```
typedef enum {
     NSNativeShortGlyphPacking = 5
} NSMultibyteGlyphPacking;
```

Constants

`NSNativeShortGlyphPacking`

The native format for Mac OS X.

Available in Mac OS X v10.0 and later.

Declared in `NSFont.h`.

Discussion

Cocoa stores all text data as Unicode. The text system converts Unicode into glyph IDs and places them in 1-, 2-, or 4-byte storage depending on the context. To render text, you must convert the storage into a format the text engine understands. The following constants describe the glyph packing schemes the text rendering engine can use. They are used to extract glyphs from a font for making a multibyte (or single-byte) array of glyphs for passing to an interpreter, such as the window server, which expects a big-endian multibyte stream (that is, "packed glyphs") instead of a pure `NSGlyph` stream. They're used by `glyphPacking` (page 1170). With Quartz, the engine always expects the format to be in 2-byte short array, so `NSNativeShortGlyphPacking` is the only format currently in use.

Declared In

`NSFont.h`

Reserved Glyph Codes

These constants define reserved glyph codes.

```
enum {
   NSControlGlyph = 0x00FFFFFF,
   NSNullGlyph = 0x0
};
```

Constants

`NSControlGlyph`

`NSGlyphGenerator` generates `NSControlGlyph` for all characters in the Unicode General Category C* and U200B (ZERO WIDTH SPACE).

Available in Mac OS X v10.0 and later.

Declared in `NSFont.h`.

`NSNullGlyph`

A null glyph.

Available in Mac OS X v10.0 and later.

Declared in `NSFont.h`.

Declared In

`NSFont.h`

Keys to the AFM Dictionary

These constants are used as keys retrieve information from an AFM dictionary. (Deprecated. The AFM dictionary is no longer used in Mac OS X. Use the font metrics accessor methods listed with the individual constants instead.)

```

NSString *NSAFMDescender;
NSString *NSAFMUnderlinePosition;
NSString *NSAFMUnderlineThickness;
NSString *NSAFMItalicAngle;
NSString *NSAFMMappingScheme;
```

Constants

`NSAFMFamilyName`

Font family name key. (Deprecated. Use `familyName` (page 1167) instead.)

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared in `NSFont.h`.

`NSAFMFontName`

Font name key. (Deprecated. Use `displayName` (page 1166) instead.)

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared in `NSFont.h`.

`NSAFMFormatVersion`

Format version name key. (Deprecated. This information is not relevant to Mac OS X.)

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared in `NSFont.h`.

`NSAFMFullName`

Full font name key. (Deprecated. Use `fontName` (page 1167) instead.)

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared in `NSFont.h`.

`NSAFMNotice`

Font notice key. (Deprecated. Use Apple Type Services instead.)

Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.
Declared in `NSFont.h`.

`NSAFMVersion`

Font version key. (Deprecated. Use Apple Type Services instead.)

Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.
Declared in `NSFont.h`.

`NSAFMWeight`

Font weight key. (Deprecated. Use the `NSFontManager` method `weightOfFont:` (page 1239) instead.)

Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.
Declared in `NSFont.h`.

`NSAFMEncodingScheme`

Font encoding scheme key. (Deprecated. Use `mostCompatibleStringEncoding` (page 1173) instead.)

Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.
Declared in `NSFont.h`.

`NSAFMCharacterSet`

Font character set key. (Deprecated. Use `coveredCharacterSet` (page 1165) instead.)

Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.
Declared in `NSFont.h`.

`NSAFMCapHeight`

Font cap-height key. (Deprecated. Use `capHeight` (page 1164) instead.)

Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.
Declared in `NSFont.h`.

`NSAFMXHeight`

Font x-height key. (Deprecated. Use `xHeight` (page 1182) instead.)

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared in `NSFont.h`.

`NSAFMAscender`

Font ascender height key. (Deprecated. Use `ascender` (page 1163) instead.)

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared in `NSFont.h`.

`NSAFMDescender`

Font descender depth key. (Deprecated. Use `descender` (page 1166) instead.)

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared in `NSFont.h`.

`NSAFMUnderlinePosition`

Font underline rule position key. (Deprecated. Use `underlinePosition` (page 1181) instead.)

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared in `NSFont.h`.

`NSAFMUnderlineThickness`

Font underline rule thickness key. (Deprecated. Use `underlineThickness` (page 1181) instead.)

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared in `NSFont.h`.

`NSAFMItalicAngle`

Font italic angle key. (Deprecated. Use `italicAngle` (page 1171) instead.)

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared in `NSFont.h`.

`NSAFMMappingScheme`

Font mapping scheme key. (Deprecated. This information is irrelevant to Mac OS X.)

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared in `NSFont.h`.

Declared In
`NSFont.h`

NSGlyph

This type is used to specify glyphs in such methods as `glyphWithName:`.

```
typedef unsigned int NSGlyph;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSFont.h`

NSGlyphRelation

These constants are used for calculating the layout of stacked glyphs. (Deprecated. Context-sensitive interglyph spacing is now performed at the typesetting stage)

```
typedef enum _NSGlyphRelation {
    NSGlyphBelow = 1,
    NSGlyphAbove = 2
} NSGlyphRelation;
```

Constants
`NSGlyphBelow`

The glyph is located below the base glyph. (Deprecated. Context-sensitive interglyph spacing is now performed at the typesetting stage.)

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in `NSFont.h`.

`NSGlyphAbove`

The glyph is located above the base glyph. (Deprecated. Context-sensitive interglyph spacing is now performed at the typesetting stage.)

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in `NSFont.h`.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
NSFont.h

NSMultibyteGlyphPacking

Glyph packing constants are used to extract glyphs from a font for making a multibyte (or single-byte) array of glyphs for passing to an interpreter, such as the window server. With Quartz, the engine always expects the format to be in 2-byte short array, so NSNativeShortGlyphPacking (page 1184) is the only format currently in use. (Deprecated. Use NSNativeShortGlyphPacking (page 1184) instead.)

```
enum {
    NSOneByteGlyphPacking,
    NSJapaneseEUCGlyphPacking,
    NSAsciiWithDoubleByteEUCGlyphPacking,
    NSTwoByteGlyphPacking,
    NSFourByteGlyphPacking,
}
```

Constants

NSOneByteGlyphPacking

One-byte storage format. (Deprecated. Use NSNativeShortGlyphPacking (page 1184) instead.)

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in NSFont.h.

NSJapaneseEUCGlyphPacking

Extended Unix Code for Japanese format. (Deprecated. Use NSNativeShortGlyphPacking (page 1184) instead.)

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in NSFont.h.

NSAsciiWithDoubleByteEUCGlyphPacking

Two-byte Extended Unix Code format. (Deprecated. Use NSNativeShortGlyphPacking (page 1184) instead.)

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in NSFont.h.

NSTwoByteGlyphPacking

Two-byte storage format. (Deprecated. Use NSNativeShortGlyphPacking (page 1184) instead.)

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in NSFont.h.

NSFourByteGlyphPacking

Four-byte storage format. (Deprecated. Use NSNativeShortGlyphPacking (page 1184) instead.)

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in NSFont.h.

Declared In
NSFont.h

Notifications

NSAntialiasThresholdChangedNotification

Posted after the threshold for anti-aliasing changes.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`NSFont.h`

NSFontSetChangedNotification

Posted after the the currently-set font changes.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`NSFont.h`

NSFontDescriptor Class Reference

Inherits from	NSObject
Conforms to	NSCoding NSCopying NSObject (NSObject)
Framework	/System/Library/Frameworks/AppKit.framework
Declared in	AppKit/NSFontDescriptor.h
Availability	Available in Mac OS X v10.3 and later.
Companion guide	Font Handling

Overview

`NSFontDescriptor` objects provide a mechanism to describe a font with a dictionary of attributes. This font descriptor can be used later to create or modify an `NSFont` object. Mac OS X v10.4 and later provides a font matching capability, so that you can partially describe a font by creating a font descriptor with, for example, just a family name. You can then find all the available fonts on the system with a matching family name using `matchingFontDescriptorsWithMandatoryKeys:` (page 1198).

There are several ways to create a new `NSFontDescriptor` object. You can use `alloc` and `initWithFontAttributes:` (page 1197), `fontDescriptorWithFontAttributes:` (page 1193), `fontDescriptorWithName:matrix:` (page 1193), or `fontDescriptorWithName:size:` (page 1194). to create a font descriptor based on either your custom attributes dictionary or on a specific font's name and size. Alternatively you can use one of the `fontDescriptor...` instance methods (such as `fontDescriptorWithFace:` (page 1195)) to create a modified version of an existing descriptor. The latter methods are useful if you have an existing descriptor and simply want to change one aspect.

All attributes in the attributes dictionary are optional.

Adopted Protocols

NSCoding

- `encodeWithCoder:`
- `initWithCoder:`

NSCopying

- `copyWithZone:`

Tasks

Creating a Font Descriptor

`+ fontDescriptorWithFontAttributes:` (page 1193)
Returns a font descriptor with a dictionary of attributes.

`+ fontDescriptorWithName:matrix:` (page 1193)
Returns a font descriptor with the `NSFontNameAttribute` and `NSFontMatrixAttribute` dictionary attributes set to the given values.

`+ fontDescriptorWithName:size:` (page 1194)
Returns a font descriptor with the `NSFontNameAttribute` and `NSFontSizeAttribute` dictionary attributes set to the given values.

`- fontDescriptorByAddingAttributes:` (page 1195)
Returns a new font descriptor that is the same as the receiver but with the specified attributes taking precedence over the existing ones.

`- fontDescriptorWithFace:` (page 1195)
Returns a new font descriptor that is the same as the receiver but with the specified face.

`- fontDescriptorWithFamily:` (page 1196)
Returns a new font descriptor whose attributes are the same as the receiver but from the specified family.

`- fontDescriptorWithMatrix:` (page 1196)
Returns a new font descriptor that is the same as the receiver but with the specified matrix.

`- fontDescriptorWithSize:` (page 1196)
Returns a new font descriptor that is the same as the receiver but with the specified point size.

`- fontDescriptorWithSymbolicTraits:` (page 1197)
Returns a new font descriptor that is the same as the receiver but with the specified symbolic traits taking precedence over the existing ones.

Initializing a Font Descriptor

`- initWithFontAttributes:` (page 1197)
Initializes and returns a new font descriptor with the specified attributes.

Finding Fonts

`- matchingFontDescriptorsWithMandatoryKeys:` (page 1198)
Returns all the fonts available on the system whose specified attributes match those of the receiver.

`- matchingFontDescriptorWithMandatoryKeys:` (page 1198)
Returns a normalized font descriptor whose specified attributes match those of the receiver.

Querying a Font Descriptor

- `fontAttributes` (page 1194)
  Returns the receiver's dictionary of attributes.
- `matrix` (page 1199)
  Returns the current transform matrix of the receiver.
- `objectForKey:` (page 1199)
  Returns the font attribute specified by the given key.
- `pointSize` (page 1199)
  Returns the point size of the receiver.
- `postscriptName` (page 1200)
  Returns the PostScript name of the receiver.
- `symbolicTraits` (page 1200)
  Returns a bit mask that describes the traits of the receiver.

Class Methods

fontDescriptorWithFontAttributes:

Returns a font descriptor with a dictionary of attributes.

```
+ (NSFontDescriptor *)fontDescriptorWithFontAttributes:(NSDictionary *)attributes
```

Parameters

attributes
  The attributes for the font descriptor. If `nil`, the font descriptor's dictionary will be empty.

Return Value
The new font descriptor.

Availability
Available in Mac OS X v10.3 and later.

See Also
`+ fontDescriptorWithName:matrix:` (page 1193)
`+ fontDescriptorWithName:matrix:` (page 1193)

Declared In
`NSFontDescriptor.h`

fontDescriptorWithName:matrix:

Returns a font descriptor with the `NSFontNameAttribute` and `NSFontMatrixAttribute` dictionary attributes set to the given values.

```
+ (NSFontDescriptor *)fontDescriptorWithName:(NSString *)fontName
    matrix:(NSAffineTransform *)matrix
```

Parameters

fontName

The value for `NSFontNameAttribute`.

matrix

The value for `NSFontMatrixAttribute`.

Return Value
The new font descriptor.

Availability
Available in Mac OS X v10.4 and later.

See Also
`+ fontDescriptorWithFontAttributes:` (page 1193)
`+ fontDescriptorWithName:size:` (page 1194)

Declared In
`NSFontDescriptor.h`

fontDescriptorWithName:size:

Returns a font descriptor with the `NSFontNameAttribute` and `NSFontSizeAttribute` dictionary attributes set to the given values.

```
+ (NSFontDescriptor *)fontDescriptorWithName:(NSString *)fontName size:(CGFloat)size
```

Parameters

fontName

The value for `NSFontNameAttribute`.

size

The value for `NSFontSizeAttribute`.

Return Value
The new font descriptor.

Availability
Available in Mac OS X v10.3 and later.

See Also
`+ fontDescriptorWithFontAttributes:` (page 1193)
`+ fontDescriptorWithName:matrix:` (page 1193)

Declared In
`NSFontDescriptor.h`

Instance Methods

fontAttributes

Returns the receiver's dictionary of attributes.

```
- (NSDictionary *)fontAttributes
```

Return Value
The attribute dictionary.

Availability
Available in Mac OS X v10.3 and later.

Declared In
NSFontDescriptor.h

fontDescriptorByAddingAttributes:

Returns a new font descriptor that is the same as the receiver but with the specified attributes taking precedence over the existing ones.

```
- (NSFontDescriptor *)fontDescriptorByAddingAttributes:(NSDictionary *)attributes
```

Parameters
attributes
The new attributes.

Return Value
The new font descriptor.

Availability
Available in Mac OS X v10.4 and later.

See Also
+ fontDescriptorWithFontAttributes: (page 1193)

Declared In
NSFontDescriptor.h

fontDescriptorWithFace:

Returns a new font descriptor that is the same as the receiver but with the specified face.

```
- (NSFontDescriptor *)fontDescriptorWithFace:(NSString *)newFace
```

Parameters
newFace
The new font face.

Return Value
The new font descriptor.

Availability
Available in Mac OS X v10.4 and later.

See Also
+ fontDescriptorWithFontAttributes: (page 1193)

Declared In
NSFontDescriptor.h

fontDescriptorWithFamily:

Returns a new font descriptor whose attributes are the same as the receiver but from the specified family.

```
- (NSFontDescriptor *)fontDescriptorWithFamily:(NSString *)newFamily
```

Parameters

newFamily
The new font family.

Return Value
The new font descriptor.

Availability
Available in Mac OS X v10.4 and later.

See Also
+ fontDescriptorWithFontAttributes: (page 1193)

Declared In
NSFontDescriptor.h

fontDescriptorWithMatrix:

Returns a new font descriptor that is the same as the receiver but with the specified matrix.

```
- (NSFontDescriptor *)fontDescriptorWithMatrix:(NSAffineTransform *)matrix
```

Parameters

matrix
The new font matrix.

Return Value
The new font descriptor.

Availability
Available in Mac OS X v10.4 and later.

See Also
+ fontDescriptorWithFontAttributes: (page 1193)

Declared In
NSFontDescriptor.h

fontDescriptorWithSize:

Returns a new font descriptor that is the same as the receiver but with the specified point size.

```
- (NSFontDescriptor *)fontDescriptorWithSize:(CGFloat)newPointSize
```

Parameters

newPointSize

The new point size.

Return Value

The new font descriptor.

Availability

Available in Mac OS X v10.4 and later.

See Also

+ fontDescriptorWithFontAttributes: (page 1193)

Declared In

NSFontDescriptor.h

fontDescriptorWithSymbolicTraits:

Returns a new font descriptor that is the same as the receiver but with the specified symbolic traits taking precedence over the existing ones.

```
- (NSFontDescriptor
    *)fontDescriptorWithSymbolicTraits:(NSFontSymbolicTraits)symbolicTraits
```

Parameters

symbolicTraits

The new symbolic traits.

Return Value

The new font descriptor.

Availability

Available in Mac OS X v10.4 and later.

See Also

+ fontDescriptorWithFontAttributes: (page 1193)

Declared In

NSFontDescriptor.h

initWithFontAttributes:

Initializes and returns a new font descriptor with the specified attributes.

```
- (id)initWithFontAttributes:(NSDictionary *)attributes
```

Parameters

attributes

The attributes for the new font descriptor. If nil, the font descriptor's attribute dictionary will be empty.

Return Value

The new font descriptor.

Availability
Available in Mac OS X v10.3 and later.

See Also
`+ fontDescriptorWithFontAttributes:` (page 1193)

Declared In
`NSFontDescriptor.h`

matchingFontDescriptorsWithMandatoryKeys:

Returns all the fonts available on the system whose specified attributes match those of the receiver.

```
- (NSArray *)matchingFontDescriptorsWithMandatoryKeys:(NSSet *)mandatoryKeys
```

Parameters

mandatoryKeys
Keys that must be identical to be matched. Can be `nil`.

Return Value
The matching font descriptors.

Discussion
For example, suppose there are two versions of a given font installed that differ in the number of glyphs covered (the new version has more glyphs). If you explicitly specify `NSFontNameAttribute` (page 1201) as the only mandatory key, then a font descriptor that specifies a font name and character set by default matches both versions, since the character set attribute is not used for matching. If you specify that font name and character set keys are mandatory, the returned array contains only the font that matches both keys.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`NSFontDescriptor.h`

matchingFontDescriptorWithMandatoryKeys:

Returns a normalized font descriptor whose specified attributes match those of the receiver.

```
- (NSFontDescriptor *)matchingFontDescriptorWithMandatoryKeys:(NSSet *)mandatoryKeys
```

Parameters

mandatoryKeys
Keys that must be identical to be matched. Can be `nil`.

Return Value
The matching font descriptor.

Discussion
The returned font descriptor is the first element returned from `matchingFontDescriptorsWithMandatoryKeys:` (page 1198).

Availability
Available in Mac OS X v10.5 and later.

Declared In
NSFontDescriptor.h

matrix

Returns the current transform matrix of the receiver.

```
- (NSAffineTransform *)matrix
```

Return Value
The transform matrix.

Availability
Available in Mac OS X v10.4 and later.

See Also
- pointSize (page 1199)

Declared In
NSFontDescriptor.h

objectForKey:

Returns the font attribute specified by the given key.

```
- (id)objectForKey:(NSString *)anAttribute
```

Parameters
anAttribute
The font attribute key.

Return Value
The font attribute corresponding to *anAttribute*. For valid values of *anAttribute*, see "Font attributes" (page 1201).

Availability
Available in Mac OS X v10.4 and later.

See Also
+ fontDescriptorWithFontAttributes: (page 1193)
- fontAttributes (page 1194)
- symbolicTraits (page 1200)

Declared In
NSFontDescriptor.h

pointSize

Returns the point size of the receiver.

```
- (CGFloat)pointSize
```

Return Value
The receiver's point size.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `fontAttributes` (page 1194)
- `matrix` (page 1199)

Declared In
`NSFontDescriptor.h`

postscriptName

Returns the PostScript name of the receiver.

```
- (NSString *)postscriptName
```

Return Value
The receiver's Postscript name.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `fontAttributes` (page 1194)
- `symbolicTraits` (page 1200)

Declared In
`NSFontDescriptor.h`

symbolicTraits

Returns a bit mask that describes the traits of the receiver.

```
- (NSFontSymbolicTraits)symbolicTraits
```

Return Value
The receiver's font traits.

Discussion
The traits describe the font's characteristics—see `NSFontSymbolicTraits` (page 1205).

Availability
Available in Mac OS X v10.4 and later.

See Also
- `fontAttributes` (page 1194)
- `postscriptName` (page 1200)

Declared In
`NSFontDescriptor.h`

Constants

Font Attributes

These font attributes are defined by `NSFontDescriptor`.

```
NSString *NSFontFamilyAttribute;
NSString *NSFontNameAttribute;
NSString *NSFontFaceAttribute;
NSString *NSFontSizeAttribute;
NSString *NSFontVisibleNameAttribute;
NSString *NSFontColorAttribute;
NSString *NSFontMatrixAttribute;
NSString *NSFontVariationAttribute;
NSString *NSFontCharacterSetAttribute;
NSString *NSFontCascadeListAttribute;
NSString *NSFontTraitsAttribute;
NSString *NSFontFixedAdvanceAttribute;
NSString *NSFontFeatureSettingsAttribute
```

Constants

`NSFontFamilyAttribute`

An optional `NSString` object that specifies the font family.

Available in Mac OS X v10.3 and later.

Declared in `NSFontDescriptor.h`.

`NSFontNameAttribute`

An optional `NSString` object that specifies the font name.

Available in Mac OS X v10.3 and later.

Declared in `NSFontDescriptor.h`.

`NSFontFaceAttribute`

An optional `NSString` object that specifies the font face.

Available in Mac OS X v10.3 and later.

Declared in `NSFontDescriptor.h`.

`NSFontSizeAttribute`

An optional `NSString` object, containing a float value, that specifies the font size.

Available in Mac OS X v10.3 and later.

Declared in `NSFontDescriptor.h`.

`NSFontVisibleNameAttribute`

An optional `NSString` object that specifies the font's visible name.

Available in Mac OS X v10.3 and later.

Declared in `NSFontDescriptor.h`.

`NSFontColorAttribute`

An optional `NSData` object that specifies the font color. (Deprecated. Use `NSForegroundColorAttributeName` (page 271) instead.)

Available in Mac OS X v10.3 and later.

Deprecated in Mac OS X v10.4.

Declared in `NSFontDescriptor.h`.

`NSFontMatrixAttribute`

An `NSAffineTransform` instance that specifies the font's transformation matrix.

The default value is the identity matrix.

Available in Mac OS X v10.4 and later.

Declared in `NSFontDescriptor.h`.

`NSFontVariationAttribute`

An `NSDictionary` instance that describes the font's variation axis.

The default value is supplied by the font. See "Font variation axis dictionary keys" (page 1204) for dictionary keys.

Available in Mac OS X v10.4 and later.

Declared in `NSFontDescriptor.h`.

`NSFontCharacterSetAttribute`

An `NSCharacterSet` instance that represents the set of Unicode characters covered by the font.

The default value is supplied by the font.

Available in Mac OS X v10.4 and later.

Declared in `NSFontDescriptor.h`.

`NSFontCascadeListAttribute`

An `NSArray` instance—each member of the array is a sub-descriptor.

The default value is the system default cascading list for user's locale.

Available in Mac OS X v10.4 and later.

Declared in `NSFontDescriptor.h`.

`NSFontTraitsAttribute`

An `NSDictionary` instance instance fully describing font traits.

The default value is supplied by the font. See "Font traits dictionary keys" (page 1203) for dictionary keys.

Available in Mac OS X v10.4 and later.

Declared in `NSFontDescriptor.h`.

`NSFontFixedAdvanceAttribute`

An `NSNumber` instance containing a float value that overrides the glyph advancement specified by the font.

The default value is `0.0`.

Available in Mac OS X v10.4 and later.

Declared in `NSFontDescriptor.h`.

`NSFontFeatureSettingsAttribute`
An array of dictionaries representing non-default font feature settings.

Each dictionary contains `NSFontFeatureTypeIdentifierKey` (page 1205) and `NSFontFeatureSelectorIdentifierKey` (page 1205).

Available in Mac OS X v10.5 and later.

Declared in `NSFontDescriptor.h`.

Discussion
You can retrieve the values for these attributes using `objectForKey:` (page 1199).

Declared In
`NSFontDescriptor.h`

Font Traits Dictionary Keys

The following constants can be used as keys to retrieve information about a font descriptor from its trait dictionary.

```
NSString *NSFontSymbolicTrait;
NSString *NSFontWeightTrait;
NSString *NSFontWidthTrait;
NSString *NSFontSlantTrait;
```

Constants
`NSFontSymbolicTrait`
The symbolic traits value as an `NSNumber` object.

Available in Mac OS X v10.4 and later.

Declared in `NSFontDescriptor.h`.

`NSFontWeightTrait`
The normalized weight value as an `NSNumber` object.

The valid value range is from `-1.0` to `1.0`. The value of `0.0` corresponds to the regular or medium font weight.

Available in Mac OS X v10.4 and later.

Declared in `NSFontDescriptor.h`.

`NSFontWidthTrait`
The relative inter-glyph spacing value as an `NSNumber` object.

The valid value range is from `-1.0` to `1.0`. The value of `0.0` corresponds to the regular glyph spacing.

Available in Mac OS X v10.4 and later.

Declared in `NSFontDescriptor.h`.

`NSFontSlantTrait`
The relative slant angle value as an `NSNumber` object.

The valid value range is from `-1.0` to `1.0`. The value of `0.0` corresponds to `0` degree clockwise rotation from the vertical and `1.0` corresponds to `30` degrees clockwise rotation.

Available in Mac OS X v10.4 and later.

Declared in `NSFontDescriptor.h`.

Discussion
These keys are used with `NSFontTraitsAttribute` (page 1202).

Declared In
NSFontDescriptor.h

Font Variation Axis Dictionary Keys

The following constants can be used as keys to retrieve information about a font descriptor from its variation axis dictionary.

```
NSString *NSFontVariationAxisIdentifierKey;
NSString *NSFontVariationAxisMinimumValueKey;
NSString *NSFontVariationAxisMaximumValueKey;
NSString *NSFontVariationAxisDefaultValueKey;
NSString *NSFontVariationAxisNameKey;
```

Constants

`NSFontVariationAxisIdentifierKey`
The axis identifier value as an `NSNumber` object.
Available in Mac OS X v10.4 and later.
Declared in `NSFontDescriptor.h`.

`NSFontVariationAxisMinimumValueKey`
The minimum axis value as an `NSNumber` object.
Available in Mac OS X v10.4 and later.
Declared in `NSFontDescriptor.h`.

`NSFontVariationAxisMaximumValueKey`
The maximum axis value as an `NSNumber` object.
Available in Mac OS X v10.4 and later.
Declared in `NSFontDescriptor.h`.

`NSFontVariationAxisDefaultValueKey`
The default axis value as an `NSNumber` object.
Available in Mac OS X v10.4 and later.
Declared in `NSFontDescriptor.h`.

`NSFontVariationAxisNameKey`
The localized variation axis name.
Available in Mac OS X v10.4 and later.
Declared in `NSFontDescriptor.h`.

Discussion
These keys are used with `NSFontVariationAttribute` (page 1202).

Declared In
NSFontDescriptor.h

Font Feature Keys

The following constants can be used as keys to retrieve information about a font descriptor from its feature dictionary.

```
NSString *NSFontFeatureTypeIdentifierKey;
NSString *NSFontFeatureSelectorIdentifierKey;
```

Constants

`NSFontFeatureTypeIdentifierKey`

An `NSNumber` object specifying a font feature type such as ligature, character shape, and so on. See "Font Features" in *ATSUI Programming Guide* for predefined feature types.

Available in Mac OS X v10.5 and later.

Declared in `NSFontDescriptor.h`.

`NSFontFeatureSelectorIdentifierKey`

An `NSNumber` object specifying a font feature selector such as common ligature off, traditional character shape, and so on. See "Font Features" in *ATSUI Programming Guide* for predefined feature selectors.

Available in Mac OS X v10.5 and later.

Declared in `NSFontDescriptor.h`.

Discussion

These keys are used with `NSFontFeatureSettingsAttribute` (page 1203).

Declared In

`NSFontDescriptor.h`

NSFontSymbolicTraits

`NSFontSymbolicTraits` symbolically describes stylistic aspects of a font.

```
typedef uint32_t NSFontSymbolicTraits;
```

Discussion

The upper 16 bits is used to describe appearance of the font (see `NSFontFamilyClass` (page 1205)) whereas the lower 16 bits is used for typeface information (see `Typeface information` (page 1207)). The font appearance information represented by the upper 16 bits can be used for stylistic font matching. The symbolic traits supersede the existing `NSFontTraitMask` type used by `NSFontManager`. The corresponding values are kept compatible between `NSFontTraitMask` and `NSFontSymbolicTraits`.

Availability

Available in Mac OS X v10.4 and later.

Declared In

`NSFontDescriptor.h`

NSFontFamilyClass

These constants classify certain stylistic qualities of the font. These values correspond closely to the font class values in the OpenType OS/2 table. The class values are bundled in the upper four bits of the `NSFontSymbolicTraits` and can be accessed via `NSFontFamilyClassMask`. For more information about the specific meaning of each identifier, refer to the OpenType specification.

```
enum {
    NSFontUnknownClass = 0 << 28,
    NSFontOldStyleSerifsClass = 1 << 28,
    NSFontTransitionalSerifsClass = 2 << 28,
    NSFontModernSerifsClass = 3 << 28,
    NSFontClarendonSerifsClass = 4 << 28,
    NSFontSlabSerifsClass = 5 << 28,
    NSFontFreeformSerifsClass = 7 << 28,
    NSFontSansSerifClass = 8 << 28,
    NSFontOrnamentalsClass = 9 << 28,
    NSFontScriptsClass = 10 << 28,
    NSFontSymbolicClass = 12 << 28
};
typedef uint32_t NSFontFamilyClass;
```

Constants

`NSFontUnknownClass`

The font has no design classification.

Available in Mac OS X v10.4 and later.

Declared in `NSFontDescriptor.h`.

`NSFontOldStyleSerifsClass`

The font's style is based on the Latin printing style of the 15th to 17th century.

Available in Mac OS X v10.4 and later.

Declared in `NSFontDescriptor.h`.

`NSFontTransitionalSerifsClass`

The font's style is based on the Latin printing style of the 18th to 19th century.

Available in Mac OS X v10.4 and later.

Declared in `NSFontDescriptor.h`.

`NSFontModernSerifsClass`

The font's style is based on the Latin printing style of the 20th century.

Available in Mac OS X v10.4 and later.

Declared in `NSFontDescriptor.h`.

`NSFontClarendonSerifsClass`

The font's style is a variation of the Oldstyle Serifs and the Transitional Serifs.

Available in Mac OS X v10.4 and later.

Declared in `NSFontDescriptor.h`.

`NSFontSlabSerifsClass`

The font's style is characterized by serifs with a square transition between the strokes and the serifs (no brackets).

Available in Mac OS X v10.4 and later.

Declared in `NSFontDescriptor.h`.

`NSFontFreeformSerifsClass`

The font's style includes serifs, but it expresses a design freedom that does not generally fit within the other serif design classifications.

Available in Mac OS X v10.4 and later.

Declared in `NSFontDescriptor.h`.

`NSFontSansSerifClass`
: The font's style includes most basic letter forms (excluding Scripts and Ornamentals) that do not have serifs on the strokes.

  Available in Mac OS X v10.4 and later.

  Declared in `NSFontDescriptor.h`.

`NSFontOrnamentalsClass`
: The font's style includes highly decorated or stylized character shapes such as those typically used in headlines.

  Available in Mac OS X v10.4 and later.

  Declared in `NSFontDescriptor.h`.

`NSFontScriptsClass`
: The font's style is among those typefaces designed to simulate handwriting.

  Available in Mac OS X v10.4 and later.

  Declared in `NSFontDescriptor.h`.

`NSFontSymbolicClass`
: The font's style is generally design independent, making it suitable for special characters (icons, dingbats, technical symbols, and so on) that may be used equally well with any font.

  Available in Mac OS X v10.4 and later.

  Declared in `NSFontDescriptor.h`.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`NSFontDescriptor.h`

NSFontFamilyClassMask

This constant is used to access `NSFontFamilyClass` values in the upper four bits of `NSFontSymbolicTraits`.

```
enum {
    NSFontFamilyClassMask = 0xF0000000
};
```

Constants
`NSFontFamilyClassMask`
: The font family class mask used to access `NSFontFamilyClass` values.

  Available in Mac OS X v10.4 and later.

  Declared in `NSFontDescriptor.h`.

Typeface Information

Typeface information is specified by the lower 16 bits of `NSFontSymbolicTraits` using the following constants.

```
enum {
    NSFontItalicTrait = (1 << 0),
    NSFontBoldTrait = (1 << 1),
    NSFontExpandedTrait = (1 << 5),
    NSFontCondensedTrait = (1 << 6),
    NSFontMonoSpaceTrait = (1 << 10),
    NSFontVerticalTrait = (1 << 11),
    NSFontUIOptimizedTrait = (1 << 12)
};
```

Constants

`NSFontItalicTrait`

The font's typestyle is italic.

Available in Mac OS X v10.4 and later.

Declared in `NSFontDescriptor.h`.

`NSFontBoldTrait`

The font's typestyle is boldface.

Available in Mac OS X v10.4 and later.

Declared in `NSFontDescriptor.h`.

`NSFontExpandedTrait`

The font's typestyle is expanded. Expanded and condensed traits are mutually exclusive.

Available in Mac OS X v10.4 and later.

Declared in `NSFontDescriptor.h`.

`NSFontCondensedTrait`

The font's typestyle is condensed. Expanded and condensed traits are mutually exclusive.

Available in Mac OS X v10.4 and later.

Declared in `NSFontDescriptor.h`.

`NSFontMonoSpaceTrait`

The font uses fixed-pitch glyphs if available. The font may have multiple glyph advances (many CJK glyphs contain two spaces).

Available in Mac OS X v10.4 and later.

Declared in `NSFontDescriptor.h`.

`NSFontVerticalTrait`

The font uses vertical glyph variants and metrics.

Available in Mac OS X v10.4 and later.

Declared in `NSFontDescriptor.h`.

`NSFontUIOptimizedTrait`

The font synthesizes appropriate attributes for user interface rendering, such as control titles, if necessary.

Available in Mac OS X v10.4 and later.

Declared in `NSFontDescriptor.h`.

Declared In

`NSFontDescriptor.h`

Overview

`NSFontManager` is the center of activity for the font conversion system. It records the currently selected font, updates the Font panel and Font menu to reflect the selected font, initiates font changes, and converts fonts in response to requests from text-bearing objects. In a more prosaic role, `NSFontManager` can be queried for the fonts available to the application and for the particular attributes of a font, such as whether it's condensed or extended.

You normally set up a font manager and the Font menu using Interface Builder. However, you can also do so programmatically by getting the shared font manager instance and having it create the standard Font menu at runtime:

```
NSFontManager *fontManager = [NSFontManager sharedFontManager];
NSMenu *fontMenu = [fontManager fontMenu:YES];
```

You can then add the Font menu to your application's main menu. Once the Font menu is installed, your application automatically gains the functionality of both the Font menu and the Font panel.

As of Mac OS X version 10.3, font collections are managed by `NSFontManager`.

Tasks

Getting the Shared Font Manager

`+ sharedFontManager` (page 1215)
Returns the shared instance of the font manager for the application, creating it if necessary.

Changing the Default Font Conversion Classes

`+ setFontManagerFactory:` (page 1214)
Sets the class object used to create the font manager to the given class.

`+ setFontPanelFactory:` (page 1214)
Sets the class used to create the Font panel to the given class.

Getting Available Fonts

`- availableFonts` (page 1218)
Returns the names of the fonts available in the system (not the `NSFont` objects themselves).

`- availableFontFamilies` (page 1217)
Returns the names of the font families available in the system.

`- availableFontNamesWithTraits:` (page 1218)
Returns the names of the fonts available in the system whose traits are described exactly by the given font trait mask (not the `NSFont` objects themselves).

`- availableMembersOfFontFamily:` (page 1219)
Returns an array with one entry for each available member of a font family.

Setting and Examining the Selected Font

`- setSelectedFont:isMultiple:` (page 1237)
Records the given font as the currently selected font and updates the Font panel to reflect this.

`- selectedFont` (page 1234)
Returns the last font recorded.

`- isMultiple` (page 1230)
Indicates whether the last font selection recorded has multiple fonts.

`- sendAction` (page 1234)
Sends the receiver's action message up the responder chain, initiating a font change for whatever conversion and trait to change were last requested.

`- localizedNameForFamily:face:` (page 1230)
Returns a localized string with the name of the specified font family and face, if one exists.

Sending Action Methods

- `addFontTrait:` (page 1216)
  This action method causes the receiver to send its action message up the responder chain.
- `removeFontTrait:` (page 1233)
  This action method causes the receiver to send its action message up the responder chain.
- `modifyFont:` (page 1230)
  This action method causes the receiver to send its action message up the responder chain.
- `modifyFontViaPanel:` (page 1231)
  This action method causes the receiver to send its action message up the responder chain.
- `orderFrontStylesPanel:` (page 1232)
  This action method opens the Font styles panel.
- `orderFrontFontPanel:` (page 1232)
  This action method opens the Font panel by sending it an `orderFront:` (page 3351) message, creating the Font panel if necessary.

Converting Fonts Automatically

- `convertFont:` (page 1220)
  Converts the given font according to the object that initiated a font change, typically the Font panel or Font menu.
- `changeFont:` (page 1239) *delegate method*
  Informs responders of a font change.

Converting Fonts Manually

- `convertFont:toFace:` (page 1221)
  Returns a font whose traits are as similar as possible to those of the given font except for the typeface, which is changed to the given typeface.
- `convertFont:toFamily:` (page 1222)
  Returns a font whose traits are as similar as possible to those of the given font except for the font family, which is changed to the given family.
- `convertFont:toHaveTrait:` (page 1222)
  Returns a font whose traits are the same as those of the given font, except that the traits are changed to include the single specified trait.
- `convertFont:toNotHaveTrait:` (page 1223)
  Returns an `NSFont` object with the same traits as the given font, except for the traits in the given font trait mask, which are removed.
- `convertFont:toSize:` (page 1224)
  Returns an `NSFont` object whose traits are the same as those of the given font, except for the size, which is changed to the given size.
- `convertWeight:ofFont:` (page 1225)
  Returns an `NSFont` object whose weight is greater or lesser than that of the given font, if possible.
- `currentFontAction` (page 1226)
  Returns the current font conversion action.

- `convertFontTraits:` (page 1224)
  Converts font traits to a new traits mask value.

Getting a Particular Font

- `fontWithFamily:traits:weight:size:` (page 1229)
  Attempts to load a font with the specified characteristics.

Examining Fonts

- `traitsOfFont:` (page 1238)
  Returns the traits of the given font.
- `fontNamed:hasTraits:` (page 1228)
  Indicates whether the given font has all the specified traits.
- `weightOfFont:` (page 1239)
  Returns a rough numeric measure the weight of the given font.

Managing the Font Panel and Font Menu

- `setEnabled:` (page 1236)
  Controls whether the font conversion system's user interface items (the Font panel and Font menu items) are enabled.
- `isEnabled` (page 1229)
  Indicates whether the font conversion system's user interface items (the Font panel and Font menu items) are enabled.
- `fontManager:willIncludeFont:` (page 1240) *delegate method*
  Requests permission from the Font panel delegate to display the given font name in the Font panel.
- `fontPanel:` (page 1228)
  Returns the application's shared Font panel object, optionally creating it if necessary.
- `setFontMenu:` (page 1236)
  Records the given menu as the application's Font menu.
- `fontMenu:` (page 1227)
  Returns the menu that's hooked up to the font conversion system, optionally creating it if necessary.

Setting the Delegate

- `setDelegate:` (page 1235)
  Sets the receiver's delegate to the given object.
- `delegate` (page 1226)
  Returns the receiver's delegate.

Accessing the Action Method

- `setAction:` (page 1235)
  Sets the action that's sent to the first responder, when the user selects a new font from the Font panel or chooses a command from the Font menu, to the given selector.
- `action` (page 1215)
  Returns the action sent to the first responder when the user selects a new font from the Font panel or chooses a command from the Font menu.
- `setTarget:` (page 1238)
  Sets the target for the `sendAction` (page 1234) method.
- `target` (page 1238)
  Returns the target for the `sendAction` (page 1234) method.

Setting Attributes

- `setSelectedAttributes:isMultiple:` (page 1236)
  Informs the paragraph and character formatting panels when text in a selection has changed attributes.
- `convertAttributes:` (page 1220)
  Converts attributes in response to an object initiating an attribute change, typically the Font panel or Font menu.

Working with Font Descriptors

- `availableFontNamesMatchingFontDescriptor:` (page 1217)
  Returns the names of the fonts that match the attributes in the given font descriptor.
- `collectionNames` (page 1219)
  Returns the names of the currently loaded font collections.
- `fontDescriptorsInCollection:` (page 1227)
  Returns an array of the font descriptors in the collection specified by the given collection name.
- `addCollection:options:` (page 1216)
  Adds a specified font collection to the font manager with a given set of options.
- `removeCollection:` (page 1233)
  Removes the specified font collection.
- `addFontDescriptors:toCollection:` (page 1216)
  Adds an array of font descriptors to the specified font collection.
- `removeFontDescriptor:fromCollection:` (page 1233)
  Removes the specified font descriptor from the specified collection.

Class Methods

setFontManagerFactory:

Sets the class object used to create the font manager to the given class.

```
+ (void)setFontManagerFactory:(Class)aClass
```

Parameters

aClass

The new font manager factory class, which should be a subclass of `NSFontManager`.

Discussion

When the `NSFontManager` class object receives a `sharedFontManager` (page 1215) message, it creates an instance of *aClass*, if no instance already exists. Your font manager class should implement `init` as its designated initializer. The default font manager factory is `NSFontManager`.

This method must be invoked before your application's main nib file is loaded, such as in the application delegate's `applicationWillFinishLaunching:` method.

Availability

Available in Mac OS X v10.0 and later.

See Also

`+ setFontPanelFactory:` (page 1214)

Declared In

`NSFontManager.h`

setFontPanelFactory:

Sets the class used to create the Font panel to the given class.

```
+ (void)setFontPanelFactory:(Class)factoryId
```

Parameters

factoryId

The new font panel factory class, which should be a subclass of `NSFontPanel`.

Discussion

Invoke this method before accessing the Font panel in any way, such as in the application delegate's `applicationWillFinishLaunching:` method.

Availability

Available in Mac OS X v10.0 and later.

See Also

`+ setFontManagerFactory:` (page 1214)

Declared In

`NSFontManager.h`

sharedFontManager

Returns the shared instance of the font manager for the application, creating it if necessary.

```
+ (NSFontManager *)sharedFontManager
```

Return Value
The shared font manager.

Availability
Available in Mac OS X v10.0 and later.

See Also
`+ setFontManagerFactory:` (page 1214)

Related Sample Code
CoreTextArcCocoa
NewsReader
QTKitTimeCode
Quartz Composer WWDC 2005 TextEdit
ToolbarSample

Declared In
`NSFontManager.h`

Instance Methods

action

Returns the action sent to the first responder when the user selects a new font from the Font panel or chooses a command from the Font menu.

```
- (SEL)action
```

Return Value
The selector for the action.

Discussion
The default action is `changeFont:` (page 1239).

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setAction:` (page 1235)

Declared In
`NSFontManager.h`

addCollection:options:

Adds a specified font collection to the font manager with a given set of options.

```
- (BOOL)addCollection:(NSString *)collectionName options:(NSInteger)collectionOptions
```

Parameters

collectionName

The collection to add.

collectionOptions

The option described in "Font Collection Mask" (page 1241). This option is not yet implemented.

Return Value

YES if the font collection was successfully added; otherwise, NO.

Availability

Available in Mac OS X v10.3 and later.

See Also

- removeCollection: (page 1233)

Declared In

NSFontManager.h

addFontDescriptors:toCollection:

Adds an array of font descriptors to the specified font collection.

```
- (void)addFontDescriptors:(NSArray *)descriptors toCollection:(NSString
    *)collectionName
```

Parameters

descriptors

The font descriptors to add.

collectionName

The font collection to which descriptors are added.

Availability

Available in Mac OS X v10.3 and later.

See Also

- removeFontDescriptor:fromCollection: (page 1233)

Declared In

NSFontManager.h

addFontTrait:

This action method causes the receiver to send its action message up the responder chain.

```
- (void)addFontTrait:(id)sender
```

Parameters

sender

The control that sent the message.

Discussion

By default, the action message is `changeFont:` (page 1239).

When a responder replies by providing a font to convert in a `convertFont:` (page 1220) message, the receiver converts the font by adding the trait specified by *sender*. This trait is determined by sending a `tag` message to *sender* and interpreting it as a font trait mask for a `convertFont:toHaveTrait:` (page 1222) message.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `removeFontTrait:` (page 1233)
- `modifyFont:` (page 1230)
- `modifyFontViaPanel:` (page 1231)

Declared In

`NSFontManager.h`

availableFontFamilies

Returns the names of the font families available in the system.

```
- (NSArray *)availableFontFamilies
```

Return Value

The names of the available font families.

Discussion

These fonts are in various system font directories.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `availableFontNamesWithTraits:` (page 1218)
- `availableFonts` (page 1218)

Declared In

`NSFontManager.h`

availableFontNamesMatchingFontDescriptor:

Returns the names of the fonts that match the attributes in the given font descriptor.

```
- (NSArray *)availableFontNamesMatchingFontDescriptor:(NSFontDescriptor *)descriptor
```

Parameters

descriptor

The font descriptor whose attributes are matched.

Return Value
The names of the matching fonts.

Availability
Available in Mac OS X v10.3 and later.

Declared In
NSFontManager.h

availableFontNamesWithTraits:

Returns the names of the fonts available in the system whose traits are described exactly by the given font trait mask (not the NSFont objects themselves).

```
- (NSArray *)availableFontNamesWithTraits:(NSFontTraitMask)fontTraitMask
```

Parameters

fontTraitMask

The font traits for which to return font names. You specify the desired traits by combining the font trait mask values described in "Constants" (page 1241) using the C bitwise OR operator.

Return Value
The names of the corresponding fonts.

Discussion
These fonts are in various system font directories.

If *fontTraitMask* is 0, this method returns all fonts that are neither italic nor bold. This result is the same one you'd get if *fontTraitMask* were NSUnitalicFontMask | NSUnboldFontMask.

Availability
Available in Mac OS X v10.0 and later.

See Also
- availableFontFamilies (page 1217)
- availableFonts (page 1218)

Declared In
NSFontManager.h

availableFonts

Returns the names of the fonts available in the system (not the NSFont objects themselves).

```
- (NSArray *)availableFonts
```

Return Value
The names of the available fonts.

Discussion
These fonts are in various system font directories.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `availableFontFamilies` (page 1217)
- `availableFontNamesWithTraits:` (page 1218)

Related Sample Code
NSFontAttributeExplorer

Declared In
`NSFontManager.h`

availableMembersOfFontFamily:

Returns an array with one entry for each available member of a font family.

```
- (NSArray *)availableMembersOfFontFamily:(NSString *)family
```

Parameters

family
The name of a font family, like one that `availableFontFamilies` (page 1217) returns.

Return Value
The available members of *family*. See the following discussion for a specific description.

Discussion
Each entry of the returned `NSArray` is another `NSArray` with four members, as follows:

0. The PostScript font name, as an `NSString` object.
1. The part of the font name used in the font panel that's not the font name, as an `NSString` object. This value is not localized—for example, `"Roman"`, `"Italic"`, or `"Bold"`.
2. The font's weight, as an `NSNumber`.
3. The font's traits, as an `NSNumber`.

The members of the family are arranged in the font panel order (narrowest to widest, lightest to boldest, plain to italic).

For example, if you call `availableMembersOfFontFamily:@"Times"`, it might return an array like this:

```
(("Times-Roman", "Roman", 5, 4),
 ("Times-Italic", "Italic", 6, 5),
 ("Times-Bold", "Bold", 9, 2),
 ("Times-BoldItalic", "Bold Italic", 9, 3)
)
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSFontManager.h`

collectionNames

Returns the names of the currently loaded font collections.

```
- (NSArray *)collectionNames
```

Return Value
The names of the current font collections.

Availability
Available in Mac OS X v10.3 and later.

See Also
- `fontDescriptorsInCollection:` (page 1227)

Declared In
`NSFontManager.h`

convertAttributes:

Converts attributes in response to an object initiating an attribute change, typically the Font panel or Font menu.

```
- (NSDictionary *)convertAttributes:(NSDictionary *)attributes
```

Parameters
attributes
The current attributes.

Return Value
The converted attributes, or *attributes* itself if the conversion isn't possible.

Discussion
Attributes unused by the sender should not be changed or removed.

This method is usually invoked on the sender of `changeAttributes:` (page 2883). See NSTextView for more information.

Availability
Available in Mac OS X v10.3 and later.

See Also
- `setSelectedAttributes:isMultiple:` (page 1236)

Declared In
`NSFontManager.h`

convertFont:

Converts the given font according to the object that initiated a font change, typically the Font panel or Font menu.

```
- (NSFont *)convertFont:(NSFont *)aFont
```

Parameters
aFont
The font to convert.

Return Value
The converted font, or `aFont` itself if the conversion isn't possible.

Discussion
This method is invoked in response to an action message such as `addFontTrait:` (page 1216) or `modifyFontViaPanel:` (page 1231). These initiating methods cause the font manager to query the sender for the action to take and the traits to change. See "Converting Fonts Manually" (page 1211) for more information.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `convertFont:toFace:` (page 1221)
- `convertFont:toFamily:` (page 1222)
- `convertFont:toHaveTrait:` (page 1222)
- `convertFont:toNotHaveTrait:` (page 1223)
- `convertFont:toSize:` (page 1224)
- `convertWeight:ofFont:` (page 1225)

Declared In
`NSFontManager.h`

convertFont:toFace:

Returns a font whose traits are as similar as possible to those of the given font except for the typeface, which is changed to the given typeface.

```
- (NSFont *)convertFont:(NSFont *)aFont toFace:(NSString *)typeface
```

Parameters

`aFont`
The font whose traits are matched.

`typeface`
The new typeface; a fully specified family-face name, such as Helvetica-BoldOblique or Times-Roman.

Return Value
A font with matching traits and the given typeface, or `aFont` if it can't be converted.

Discussion
This method attempts to match the weight and posture of `aFont` as closely as possible. Italic is mapped to Oblique, for example. Weights are mapped based on an approximate numeric scale of 0 to 15.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `convertFont:toFamily:` (page 1222)
- `convertFont:toHaveTrait:` (page 1222)
- `convertFont:toNotHaveTrait:` (page 1223)

- `convertWeight:ofFont:` (page 1225)
- `convertFont:` (page 1220)

Declared In
NSFontManager.h

convertFont:toFamily:

Returns a font whose traits are as similar as possible to those of the given font except for the font family, which is changed to the given family.

```
- (NSFont *)convertFont:(NSFont *)aFont toFamily:(NSString *)family
```

Parameters

aFont
The font whose traits are matched.

family
The new font famliy; a generic font name, such as Helvetica or Times.

Return Value
A font with matching traits and the given family, or *aFont* if it can't be converted.

Discussion
This method attempts to match the weight and posture of *aFont* as closely as possible. Italic is mapped to Oblique, for example. Weights are mapped based on an approximate numeric scale of 0 to 15.

Availability
Available in Mac OS X v10.0 and later.

See Also
- convertFont:toFace: (page 1221)

- convertFont:toSize: (page 1224)
- convertWeight:ofFont: (page 1225)
- convertFont: (page 1220)

Declared In
NSFontManager.h

convertFont:toHaveTrait:

Returns a font whose traits are the same as those of the given font, except that the traits are changed to include the single specified trait.

```
- (NSFont *)convertFont:(NSFont *)aFont toHaveTrait:(NSFontTraitMask)fontTrait
```

Parameters

aFont
The font whose traits are matched.

fontTrait
The new trait; may be any one of the traits described in "Constants" (page 1241). Using NSUnboldFontMask or NSUnitalicFontMask removes the bold or italic trait, respectively.

Return Value
A font with matching traits including the given trait, or *aFont* if it can't be converted.

Discussion
Using `NSUnboldFontMask` or `NSUnitalicFontMask` removes the bold or italic trait, respectively.

Availability
Available in Mac OS X v10.0 and later.

See Also

Declared In
`NSFontManager.h`

convertFont:toNotHaveTrait:

Returns an `NSFont` object with the same traits as the given font, except for the traits in the given font trait mask, which are removed.

```
- (NSFont *)convertFont:(NSFont *)aFont toNotHaveTrait:(NSFontTraitMask)fontTraitMask
```

Parameters

aFont
The font whose traits are matched.

fontTraitMask
The mask for the traits to remove, created using the C bitwise OR operator to combine the traits described in "Constants" (page 1241). Using `NSUnboldFontMask` or `NSUnitalicFontMask` removes the bold or italic trait, respectively.

Return Value
A font with matching traits minus the given traits, or *aFont* if it can't be converted.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `convertFont:toHaveTrait:` (page 1222)

Related Sample Code
CoreTextArcCocoa
ToolbarSample

Declared In
NSFontManager.h

convertFont:toSize:

Returns an NSFont object whose traits are the same as those of the given font, except for the size, which is changed to the given size.

```
- (NSFont *)convertFont:(NSFont *)aFont toSize:(CGFloat)size
```

Parameters

aFont

The font whose traits are matched.

size

The new font size.

Return Value
A font with matching traits except in the new size, or *aFont* if it can't be converted.

Availability
Available in Mac OS X v10.0 and later.

See Also
- convertFont:toFace: (page 1221)
- convertFont:toFamily: (page 1222)
- convertFont:toHaveTrait: (page 1222)
- convertFont:toNotHaveTrait: (page 1223)
- convertWeight:ofFont: (page 1225)
- convertFont: (page 1220)

Related Sample Code
ToolbarSample

Declared In
NSFontManager.h

convertFontTraits:

Converts font traits to a new traits mask value.

```
- (NSFontTraitMask)convertFontTraits:(NSFontTraitMask)traits
```

Parameters

traits

The current font traits.

Return Value
The new traits mask value to be used by `convertFont:` (page 1220).

Discussion
This method is intended to be invoked to query the font traits while the action message (usually `changeFont:` (page 1239)) is being invoked when the current font action is either `NSAddTraitFontAction` (page 1244) or `NSRemoveTraitFontAction` (page 1244).

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSFontManager.h`

convertWeight:ofFont:

Returns an `NSFont` object whose weight is greater or lesser than that of the given font, if possible.

```
- (NSFont *)convertWeight:(BOOL)increaseFlag ofFont:(NSFont *)aFont
```

Parameters

increaseFlag
If `YES`, a heavier font is returned; if it's `NO`, a lighter font is returned.

aFont
The font whose weight is increased or decreased.

Return Value
A font with matching traits except for the new weight, or *aFont* if it can't be converted.

Discussion
Weights are graded along the following scale. The list on the left gives Apple's terminology, and the list on the right gives the ISO equivalents. Names on the same line are treated as identical:

Apple Terminology	ISO Equivalent
1. ultralight	
2. thin	W1. ultralight
3. light, extralight	W2. extralight
4. book	W3. light
5. regular, plain, display, roman	W4. semilight
6. medium	W5. medium
7. demi, demibold	
8. semi, semibold	W6. semibold
9. bold	W7. bold
10. extra, extrabold	W8. extrabold

Apple Terminology	ISO Equivalent
11. heavy, heavyface	
12. black, super	W9. ultrabold
13. ultra, ultrablack, fat	
14. extrablack, obese, nord	

The `NSFontManager` implementation of this method refuses to convert a font's weight if it can't maintain all other traits, such as italic and condensed. You might wish to override this method to allow a looser interpretation of weight conversion.

Availability
Available in Mac OS X v10.0 and later.

See Also

- `convertFont:` (page 1220)

Declared In
`NSFontManager.h`

currentFontAction

Returns the current font conversion action.

```
- (NSFontAction)currentFontAction
```

Return Value
The current font action used by the `convertFont:` (page 1220) method.

Discussion
This method is intended to be invoked to query the font conversion action while the action message (usually `changeFont:` (page 1239)) is being invoked.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSFontManager.h`

delegate

Returns the receiver's delegate.

```
- (id)delegate
```

Return Value
The receiver's delegate.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setDelegate: (page 1235)

Declared In
NSFontManager.h

fontDescriptorsInCollection:

Returns an array of the font descriptors in the collection specified by the given collection name.

```
- (NSArray *)fontDescriptorsInCollection:(NSString *)collectionName
```

Parameters
collectionName
The font collection for which to return descriptors.

Return Value
The font descriptors.

Availability
Available in Mac OS X v10.3 and later.

See Also
- collectionNames (page 1219)

Declared In
NSFontManager.h

fontMenu:

Returns the menu that's hooked up to the font conversion system, optionally creating it if necessary.

```
- (NSMenu *)fontMenu:(BOOL)createFlag
```

Parameters
createFlag
If YES, the menu object is created if necessary; if NO, it is not.

Return Value
The font conversion system menu.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setFontMenu: (page 1236)

Declared In
NSFontManager.h

fontNamed:hasTraits:

Indicates whether the given font has all the specified traits.

```
- (BOOL)fontNamed:(NSString *)typeface hasTraits:(NSFontTraitMask)fontTraitMask
```

Parameters

typeface
The name of the font.

fontTraitMask
The font traits to test, specified by combining the font trait mask values described in "Constants" (page 1241) using the C bitwise OR operator.

Return Value
YES if the font named *typeface* has all the traits specified in *fontTraitMask*; NO if it doesn't.

Discussion
Using NSUnboldFontMask returns YES if the font is not bold, NO otherwise. Using NSUnitalicFontMask returns YES if the font is not italic, NO otherwise.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSFontManager.h

fontPanel:

Returns the application's shared Font panel object, optionally creating it if necessary.

```
- (NSFontPanel *)fontPanel:(BOOL)createFlag
```

Parameters

createFlag
If YES, the Font panel object is created if necessary; if NO, it is not.

Return Value
The application's shared Font panel object.

Availability
Available in Mac OS X v10.0 and later.

See Also
+ sharedFontPanel (page 1248) (NSFontPanel)
+ sharedFontPanelExists (page 1249) (NSFontPanel)
+ setFontPanelFactory: (page 1214)

Declared In
NSFontManager.h

fontWithFamily:traits:weight:size:

Attempts to load a font with the specified characteristics.

```
- (NSFont *)fontWithFamily:(NSString *)family traits:(NSFontTraitMask)fontTraitMask
    weight:(NSInteger)weight size:(CGFloat)size
```

Parameters

family

The generic name of the desired font, such as Times or Helvetica.

fontTraitMask

The font traits, specified by combining the font trait mask values described in "Constants" (page 1241) using the C bitwise OR operator. Using `NSUnboldFontMask` or `NSUnitalicFontMask` loads a font that doesn't have either the bold or italic trait, respectively.

weight

A hint for the weight desired, on a scale of 0 to 15: a value of 5 indicates a normal or book weight, and 9 or more a bold or heavier weight. The weight is ignored if *fontTraitMask* includes `NSBoldFontMask`.

size

The point size of the desired font.

Return Value
A font with the specified characteristics if successful, or `nil` if not.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSFontManager.h`

isEnabled

Indicates whether the font conversion system's user interface items (the Font panel and Font menu items) are enabled.

```
- (BOOL)isEnabled
```

Return Value
`YES` if the font conversion system's user interface items (the Font panel and Font menu items) are enabled; `NO` if they're not.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `isEnabled` (page 1250) (NSFontPanel)
- `isEnabled` (NSMenuItem)
- `setEnabled:` (page 1236)

Declared In
`NSFontManager.h`

isMultiple

Indicates whether the last font selection recorded has multiple fonts.

```
- (BOOL)isMultiple
```

Return Value
`YES` if the last font selection recorded has multiple fonts; `NO` if it's a single font.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setSelectedFont:isMultiple:` (page 1237)
- `selectedFont` (page 1234)

Declared In
`NSFontManager.h`

localizedNameForFamily:face:

Returns a localized string with the name of the specified font family and face, if one exists.

```
- (NSString *)localizedNameForFamily:(NSString *)family face:(NSString *)face
```

Parameters
family
The font family, for example, `@"Times"`.

face
The font face, for example, `@"Roman"`.

Return Value
A localized string with the name of the specified font family and face, or, if *face* is `nil`, the font family only.

Discussion
The user's locale is determined from the user's `NSLanguages` default setting. The method also loads the localized strings for the font, if they aren't already loaded.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSFontManager.h`

modifyFont:

This action method causes the receiver to send its action message up the responder chain.

```
- (void)modifyFont:(id)sender
```

Parameters
sender
The control that sent the message.

Discussion
By default, the action message is `changeFont:` (page 1239).

When a responder replies by providing a font to convert in a `convertFont:` (page 1220) message, the receiver converts the font in the manner specified by *sender*. The conversion is determined by sending a `tag` message to *sender* and invoking a corresponding method:

Sender's Tag	Method Used
`NSNoFontChangeAction`	None; the font is returned unchanged.
`NSViaPanelFontAction`	The Font panel's `panelConvertFont:` (page 1250).
`NSAddTraitFontAction`	`convertFont:toHaveTrait:` (page 1222).
`NSRemoveTraitFontAction`	`convertFont:toNotHaveTrait:` (page 1223).
`NSSizeUpFontAction`	`convertFont:toSize:` (page 1224).
`NSSizeDownFontAction`	`convertFont:toSize:` (page 1224).
`NSHeavierFontAction`	`convertWeight:ofFont:` (page 1225).
`NSLighterFontAction`	`convertWeight:ofFont:` (page 1225).

Availability
Available in Mac OS X v10.0 and later.

See Also
- `addFontTrait:` (page 1216)
- `removeFontTrait:` (page 1233)
- `modifyFontViaPanel:` (page 1231)

Declared In
`NSFontManager.h`

modifyFontViaPanel:

This action method causes the receiver to send its action message up the responder chain.

```
- (void)modifyFontViaPanel:(id)sender
```

Parameters
sender
The control that sent the message.

Discussion
By default, the action message is `changeFont:` (page 1239).

When a responder replies by providing a font to convert in a `convertFont:` (page 1220) message, the receiver converts the font by sending a `panelConvertFont:` (page 1250) message to the Font panel. The panel in turn may send `convertFont:toFamily:` (page 1222), `convertFont:toHaveTrait:` (page 1222), and other specific conversion methods to make its change.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `addFontTrait:` (page 1216)
- `removeFontTrait:` (page 1233)
- `modifyFont:` (page 1230)

Declared In
`NSFontManager.h`

orderFrontFontPanel:

This action method opens the Font panel by sending it an `orderFront:` (page 3351) message, creating the Font panel if necessary.

```
- (void)orderFrontFontPanel:(id)sender
```

Parameters

sender
The control that sent the message.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `fontPanel:` (page 1228)
+ `setFontPanelFactory:` (page 1214)

Related Sample Code
Quartz Composer WWDC 2005 TextEdit

Declared In
`NSFontManager.h`

orderFrontStylesPanel:

This action method opens the Font styles panel.

```
- (void)orderFrontStylesPanel:(id)sender
```

Parameters

sender
The control that sent the message.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`NSFontManager.h`

removeCollection:

Removes the specified font collection.

```
- (BOOL)removeCollection:(NSString *)collectionName
```

Parameters

collectionName

The collection to remove.

Return Value

`YES` if the font collection was successfully removed; otherwise, `NO`.

Availability

Available in Mac OS X v10.3 and later.

See Also

`- addCollection:options:` (page 1216)

Declared In

`NSFontManager.h`

removeFontDescriptor:fromCollection:

Removes the specified font descriptor from the specified collection.

```
- (void)removeFontDescriptor:(NSFontDescriptor *)descriptor fromCollection:(NSString
    *)collection
```

Parameters

descriptor

The font descriptor to remove.

collection

The font collection from which to remove the descriptor.

Availability

Available in Mac OS X v10.3 and later.

See Also

`- addFontDescriptors:toCollection:` (page 1216)

Declared In

`NSFontManager.h`

removeFontTrait:

This action method causes the receiver to send its action message up the responder chain.

```
- (void)removeFontTrait:(id)sender
```

Parameters

sender

The control that sent the message.

Discussion
By default, the action message is `changeFont:` (page 1239).

When a responder replies by providing a font to convert in a `convertFont:` (page 1220) message, the receiver converts the font by removing the trait specified by *sender*. This trait is determined by sending a `tag` message to *sender* and interpreting it as a font trait mask for a `convertFont:toNotHaveTrait:` (page 1223) message.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `addFontTrait:` (page 1216)
- `modifyFont:` (page 1230)
- `modifyFontViaPanel:` (page 1231)

Declared In
`NSFontManager.h`

selectedFont

Returns the last font recorded.

```
- (NSFont *)selectedFont
```

Return Value
The last font recorded with a `setSelectedFont:isMultiple:` (page 1237) message

Discussion
While fonts are being converted in response to a `convertFont:` (page 1220) message, you can determine the font selected in the Font panel like this:

```
NSFontManager *fontManager = [NSFontManager sharedFontManager];
panelFont = [fontManager convertFont:[fontManager selectedFont]];
```

Availability
Available in Mac OS X v10.0 and later.

See Also
- `isMultiple` (page 1230)

Related Sample Code
QTKitTimeCode

Declared In
`NSFontManager.h`

sendAction

Sends the receiver's action message up the responder chain, initiating a font change for whatever conversion and trait to change were last requested.

```
- (BOOL)sendAction
```

Return Value
YES if some object handled the changeFont: (page 1239) message; NO if the message went unheard.

Discussion
By default, the receiver's action message is changeFont: (page 1239).

This method is used internally by the font conversion system. You should never need to invoke it directly. Instead, use the action methods such as addFontTrait: (page 1216) or modifyFontViaPanel: (page 1231).

Availability
Available in Mac OS X v10.0 and later.

See Also
- setAction: (page 1235)

Declared In
NSFontManager.h

setAction:

Sets the action that's sent to the first responder, when the user selects a new font from the Font panel or chooses a command from the Font menu, to the given selector.

```
- (void)setAction:(SEL)aSelector
```

Parameters
aSelector
The selector to set.

Discussion
The default action is changeFont: (page 1239). You should rarely need to change this setting.

Availability
Available in Mac OS X v10.0 and later.

See Also
- action (page 1215)

Declared In
NSFontManager.h

setDelegate:

Sets the receiver's delegate to the given object.

```
- (void)setDelegate:(id)anObject
```

Parameters
anObject
The new delegate.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `delegate` (page 1226)

Related Sample Code
PDF Annotation Editor

Declared In
`NSFontManager.h`

setEnabled:

Controls whether the font conversion system's user interface items (the Font panel and Font menu items) are enabled.

```
- (void)setEnabled:(BOOL)flag
```

Parameters

flag
If `YES`, they're enabled; if `NO`, they're disabled.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setEnabled:` (page 1251) (NSFontPanel)
- `isEnabled` (page 1229)

Declared In
`NSFontManager.h`

setFontMenu:

Records the given menu as the application's Font menu.

```
- (void)setFontMenu:(NSMenu *)aMenu
```

Parameters

aMenu
The new Font menu.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `fontMenu:` (page 1227)

Declared In
`NSFontManager.h`

setSelectedAttributes:isMultiple:

Informs the paragraph and character formatting panels when text in a selection has changed attributes.

```
- (void)setSelectedAttributes:(NSDictionary *)attributes isMultiple:(BOOL)flag
```

Parameters

attributes

The new attributes.

flag

If YES, informs the panel that multiple fonts or attributes are enclosed within the selection.

Discussion

This method is used primarily by NSTextView.

Availability

Available in Mac OS X v10.3 and later.

See Also

- convertAttributes: (page 1220)

Declared In

NSFontManager.h

setSelectedFont:isMultiple:

Records the given font as the currently selected font and updates the Font panel to reflect this.

```
- (void)setSelectedFont:(NSFont *)aFont isMultiple:(BOOL)flag
```

Parameters

aFont

The font to set as selected.

flag

If YES, the Font panel indicates that more than one font is contained in the selection; if NO, it does not.

Discussion

An object that manipulates fonts should invoke this method whenever it becomes first responder and whenever its selection changes. It shouldn't invoke this method in the process of handling a changeFont: (page 1239) message, as this causes the font manager to lose the information necessary to effect the change. After all fonts have been converted, the font manager itself records the new selected font.

Availability

Available in Mac OS X v10.0 and later.

See Also

- selectedFont (page 1234)
- isMultiple (page 1230)

Related Sample Code

CoreTextArcCocoa

Declared In
`NSFontManager.h`

target

Returns the target for the `sendAction` (page 1234) method.

```
- (id)target
```

Return Value
The target for the receiver's `sendAction` (page 1234) method.

Availability
Available in Mac OS X v10.5 and later.

See Also
`- setTarget:` (page 1238)

Declared In
`NSFontManager.h`

traitsOfFont:

Returns the traits of the given font.

```
- (NSFontTraitMask)traitsOfFont:(NSFont *)aFont
```

Parameters

aFont

The font whose traits are returned.

Return Value
The font traits, returned as a mask created by combining values listed in "Constants" (page 1241) with the C bitwise OR operator.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
QTKitTimeCode

Declared In
`NSFontManager.h`

weightOfFont:

Returns a rough numeric measure the weight of the given font.

```
- (NSInteger)weightOfFont:(NSFont *)aFont
```

Parameters

aFont

The font whose weight is returned.

Return Value
A rough numeric measure the weight of the given font, where 0 indicates the lightest possible weight, 5 indicates a normal or book weight, and 9 or more indicates a bold or heavier weight.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSFontManager.h`

Delegate Methods

changeFont:

Informs responders of a font change.

```
- (void)changeFont:(id)sender
```

Parameters

sender

The object that sent the message.

Discussion
Generally this change is because the user changed the font either in the selection of a rich text field or in a whole plain text field. Any object that contains a font the user can change must respond to the `changeFont:` message by sending a `convertFont:` (page 1220) message back to *sender* (an NSFontManager object) for each font in the selection. For more information, see "Responding to Font Changes".

Be aware that `selectedFont` (page 1234) at this point may return unpredictable results. The font returned from this method may not be the last font selected, or there may be multiple fonts selected at the time `changeFont:` is called. The use of `selectedFont` from within `changeFont:` is strongly discouraged.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `addFontTrait:` (page 1216)
- `convertFont:toHaveTrait:` (page 1222)

- `modifyFontViaPanel:` (page 1231)
- `modifyFont:` (page 1230)

Declared In
`NSFontManager.h`

fontManager:willIncludeFont:

Requests permission from the Font panel delegate to display the given font name in the Font panel.

```
- (BOOL)fontManager:(id)theFontManager willIncludeFont:(NSString *)fontName
```

Parameters

`theFontManager`
The font manager making the request.

`fontName`
The full PostScript name of the font to display, such as Helvetica-BoldOblique or Helvetica-Narrow-Bold.

Return Value
If the Font panel delegate returns `YES`, *`fontName`* is listed; if the delegate returns `NO`, it isn't.

Discussion
In Mac OS X versions 10.2 and earlier, this method is invoked repeatedly as necessary whenever the Font panel needs updating, such as when the Font panel is first loaded, and when the user selects a family name to see which typefaces in that family are available. Your implementation should execute fairly quickly to ensure the responsiveness of the Font panel.

Important: This delegate method is not called in Mac OS X versions 10.3 and later.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSFontManager.h`

Constants

Font Collection Mask

This constant specifies options accepted by `addCollection:options:` (page 1216).

```
enum {
   NSFontCollectionApplicationOnlyMask = 1 << 0
};
```

Constants

`NSFontCollectionApplicationOnlyMask`

Makes the collection available only to the application. This option is not yet implemented.

Available in Mac OS X v10.3 and later.

Declared in `NSFontManager.h`.

Declared In

`NSFontManager.h`

NSFontTraitMask

Mask of traits assigned to a font, assigned using the values in `Font traits` (page 1241).

```
typedef unsigned int NSFontTraitMask;
```

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSFontManager.h`

Font traits

Font traits defined and supported by `NSFontManager`.

```
enum {
   NSItalicFontMask = 0x00000001,
   NSBoldFontMask = 0x00000002,
   NSUnboldFontMask = 0x00000004,
   NSNonStandardCharacterSetFontMask = 0x00000008,
   NSNarrowFontMask = 0x00000010,
   NSExpandedFontMask = 0x00000020,
   NSCondensedFontMask = 0x00000040,
   NSSmallCapsFontMask = 0x00000080,
   NSPosterFontMask = 0x00000100,
   NSCompressedFontMask = 0x00000200,
   NSFixedPitchFontMask = 0x00000400,
   NSUnitalicFontMask = 0x01000000
};
```

Constants

`NSItalicFontMask`

A mask that specifies an italic font.

Available in Mac OS X v10.0 and later.

Declared in `NSFontManager.h`.

`NSBoldFontMask`

A mask that specifies a bold font.

Available in Mac OS X v10.0 and later.

Declared in `NSFontManager.h`.

`NSUnboldFontMask`

A mask that specifies a font that is not bold.

Available in Mac OS X v10.0 and later.

Declared in `NSFontManager.h`.

`NSNonStandardCharacterSetFontMask`

A mask that specifies a font that uses a non-standard character set.

Available in Mac OS X v10.0 and later.

Declared in `NSFontManager.h`.

`NSNarrowFontMask`

A mask that specifies a narrow font.

Available in Mac OS X v10.0 and later.

Declared in `NSFontManager.h`.

`NSExpandedFontMask`

A mask that specifies an expanded font.

Available in Mac OS X v10.0 and later.

Declared in `NSFontManager.h`.

`NSCondensedFontMask`

A mask that specifies a condensed font.

Available in Mac OS X v10.0 and later.

Declared in `NSFontManager.h`.

`NSSmallCapsFontMask`
A mask that specifies a small-caps font.
Available in Mac OS X v10.0 and later.
Declared in `NSFontManager.h`.

`NSPosterFontMask`
A mask that specifies a poster-style font.
Available in Mac OS X v10.0 and later.
Declared in `NSFontManager.h`.

`NSCompressedFontMask`
A mask that specifies a compressed font.
Available in Mac OS X v10.0 and later.
Declared in `NSFontManager.h`.

`NSFixedPitchFontMask`
A mask that specifies a fixed pitch font.
Available in Mac OS X v10.0 and later.
Declared in `NSFontManager.h`.

`NSUnitalicFontMask`
A mask that specifies a font that is not italic.
Available in Mac OS X v10.0 and later.
Declared in `NSFontManager.h`.

Discussion
`NSFontManager` categorizes fonts according to a small set of traits. You can convert fonts by adding and removing individual traits, and you can get a font with a specific combination of traits.

These pairs of traits are mutually exclusive:

`NSCondensedFontMask` and `NSExpandedFontMask`
`NSBoldFontMask` and `NSUnboldFontMask`
`NSItalicFontMask` and `NSUnitalicFontMask`

Declared In
`NSFontManager.h`

NSFontAction

These constants specify what action `modifyFont:` (page 1230) will take.

```
typedef enum _NSFontAction {
    NSNoFontChangeAction = 0,
    NSViaPanelFontAction = 1,
    NSAddTraitFontAction = 2,
    NSSizeUpFontAction = 3,
    NSSizeDownFontAction = 4,
    NSHeavierFontAction = 5,
    NSLighterFontAction = 6,
    NSRemoveTraitFontAction = 7
} NSFontAction;
```

Constants

`NSNoFontChangeAction`
No action; the font is returned unchanged.

Available in Mac OS X v10.0 and later.

Declared in `NSFontManager.h`.

`NSViaPanelFontAction`
Converts the font according to the `NSFontPanel` method `panelConvertFont:`.

Available in Mac OS X v10.0 and later.

Declared in `NSFontManager.h`.

`NSAddTraitFontAction`
Converts the font to have an additional trait using `convertFont:toHaveTrait:` (page 1222).

Available in Mac OS X v10.0 and later.

Declared in `NSFontManager.h`.

`NSSizeUpFontAction`
Converts the font to a larger size using `convertFont:toSize:` (page 1224).

Available in Mac OS X v10.0 and later.

Declared in `NSFontManager.h`.

`NSSizeDownFontAction`
Converts the font to a smaller size using `convertFont:toSize:` (page 1224).

Available in Mac OS X v10.0 and later.

Declared in `NSFontManager.h`.

`NSHeavierFontAction`
Converts the font to a heavier weight using `convertWeight:ofFont:` (page 1225).

Available in Mac OS X v10.0 and later.

Declared in `NSFontManager.h`.

`NSLighterFontAction`
Converts the font to a lighter weight using `convertWeight:ofFont:` (page 1225).

Available in Mac OS X v10.0 and later.

Declared in `NSFontManager.h`.

`NSRemoveTraitFontAction`
Converts the font to remove a trait using `convertFont:toNotHaveTrait:` (page 1223).

Available in Mac OS X v10.0 and later.

Declared in `NSFontManager.h`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSFontManager.h`

Overview

The `NSFontPanel` class implements the Font panel—a user interface object that displays a list of available fonts, letting the user preview them and change the font used to display text. The actual changes are made through conversion messages sent to the shared `NSFontManager` instance. There's only one Font panel for each application.

Tasks

Getting the Font Panel

`+ sharedFontPanel` (page 1248)
Returns the single `NSFontPanel` instance for the application, creating it if necessary.

`+ sharedFontPanelExists` (page 1249)
Returns `YES` if the shared Font panel has been created, `NO` if it hasn't.

Enabling Font Changes

- `isEnabled` (page 1250)
  Indicates whether the receiver's Set button is enabled.
- `reloadDefaultFontFamilies` (page 1250)
  Triggers a reload to the default state, so that the delegate is called.
- `setEnabled:` (page 1251) Available in Mac OS X v10.0 through Mac OS X v10.5
  Specifies whether the receiver's Set button is enabled.

Updating the Font Panel

- `setPanelFont:isMultiple:` (page 1252)
  Sets the selected font in the receiver to the specified font.

Converting Fonts

- `panelConvertFont:` (page 1250)
  Converts the specified font using the settings in the receiver, with the aid of the shared `NSFontManager` if necessary.

Working in Modal Loops

- `worksWhenModal` (page 1252)
  Indicates whether the receiver allows fonts to be changed in modal windows and panels.

Setting an Accessory View

- `setAccessoryView:` (page 1251)
  Establishes the specified view as the receiver's accessory view, allowing you to add custom controls to your application's Font panel without having to create a subclass.
- `accessoryView` (page 1249)
  Returns the receiver's accessory view.

Class Methods

sharedFontPanel

Returns the single `NSFontPanel` instance for the application, creating it if necessary.

```
+ (NSFontPanel *)sharedFontPanel
```

Return Value
The `NSFontPanel` instance for the application.

Availability
Available in Mac OS X v10.0 and later.

See Also
`+ sharedFontPanelExists` (page 1249)
`+ setFontPanelFactory:` (page 1214) (`NSFontManager`)

Related Sample Code
Aperture Edit Plugin - Borders & Titles
CoreAnimationText
CoreTextArcCocoa
PDF Annotation Editor

Declared In
`NSFontPanel.h`

sharedFontPanelExists

Returns `YES` if the shared Font panel has been created, `NO` if it hasn't.

```
+ (BOOL)sharedFontPanelExists
```

Availability
Available in Mac OS X v10.0 and later.

See Also
`+ sharedFontPanel` (page 1248)

Declared In
`NSFontPanel.h`

Instance Methods

accessoryView

Returns the receiver's accessory view.

```
- (NSView *)accessoryView
```

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setAccessoryView:` (page 1251)

Declared In
`NSFontPanel.h`

isEnabled

Indicates whether the receiver's Set button is enabled.

```
- (BOOL)isEnabled
```

Return Value
`YES` if the receiver's Set button is enabled; `NO` if it isn't.

Discussion
The receiver continues to reflect the font of the selection for cooperating text objects regardless of this setting.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setEnabled:` (page 1251)

Declared In
`NSFontPanel.h`

panelConvertFont:

Converts the specified font using the settings in the receiver, with the aid of the shared `NSFontManager` if necessary.

```
- (NSFont *)panelConvertFont:(NSFont *)aFont
```

Parameters

aFont
The font to be converted.

Return Value
The converted font, or *aFont* itself if it can't be converted.

Discussion
For example, if *aFont* is Helvetica Oblique 12.0 point and the user has selected the Times font family (and nothing else) in the Font panel, the font returned is Times Italic 12.0 point.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- convertFont:` (page 1220) (NSFontManager)

Declared In
`NSFontPanel.h`

reloadDefaultFontFamilies

Triggers a reload to the default state, so that the delegate is called.

```
- (void)reloadDefaultFontFamilies
```

Discussion
This reloading provides the delegate opportunity to scrutinize the default list of fonts to be displayed in the panel.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSFontPanel.h

setAccessoryView:

Establishes the specified view as the receiver's accessory view, allowing you to add custom controls to your application's Font panel without having to create a subclass.

```
- (void)setAccessoryView:(NSView *)aView
```

Parameters

aView

The view to set.

Availability
Available in Mac OS X v10.0 and later.

See Also
- accessoryView (page 1249)

Declared In
NSFontPanel.h

setEnabled:

Specifies whether the receiver's Set button is enabled.

```
- (void)setEnabled:(BOOL)flag
```

Parameters

flag

If YES the Set button is enabled; if NO, it's disabled.

Discussion
The receiver continues to reflect the font of the selection for cooperating text objects regardless of this setting.

Availability
Available in Mac OS X v10.0 and later.

See Also
- isEnabled (page 1250)

Declared In
NSFontPanel.h

setPanelFont:isMultiple:

Sets the selected font in the receiver to the specified font.

```
- (void)setPanelFont:(NSFont *)aFont isMultiple:(BOOL)flag
```

Parameters

aFont

The font to be selected.

flag

If NO, selects the specified font; otherwise selects no font and displays a message in the preview area indicating that multiple fonts are selected.

Discussion

You normally don't use this method directly; instead, you send `setSelectedFont:isMultiple:` (page 1237) to the shared `NSFontManager`, which in turn invokes this method.

Availability

Available in Mac OS X v10.0 and later.

Related Sample Code

Declared In

`NSFontPanel.h`

worksWhenModal

Indicates whether the receiver allows fonts to be changed in modal windows and panels.

```
- (BOOL)worksWhenModal
```

Return Value

YES, regardless of the setting established using the `NSPanel` method `setWorksWhenModal:` (page 1862).

Availability

Available in Mac OS X v10.0 and later.

See Also

- `worksWhenModal` (page 3409) (`NSWindow`)
- `worksWhenModal` (page 1862) (`NSPanel`)

Constants

Tags of Views in the FontPanel

These constants are obsolete and should not be used. (Deprecated. Use the method and constants described in *NSFontPanelValidation Protocol Reference* instead.)

```
enum {
    NSFPPreviewButton = 131,
    NSFPRevertButton = 130,
    NSFPSetButton = 132,
    NSFPPreviewField = 128,
    NSFPSizeField = 129,
    NSFPSizeTitle = 133,
    NSFPCurrentField = 134
};
```

Constants

`NSFPPreviewButton`
Show the Preview button.
Available in Mac OS X v10.0 and later.
Declared in `NSFontPanel.h`.

`NSFPRevertButton`
Show the Revert button.
Available in Mac OS X v10.0 and later.
Declared in `NSFontPanel.h`.

`NSFPSetButton`
Show the Set button.
Available in Mac OS X v10.0 and later.
Declared in `NSFontPanel.h`.

`NSFPPreviewField`
Show the Preview field.
Available in Mac OS X v10.0 and later.
Declared in `NSFontPanel.h`.

`NSFPSizeField`
Show the Size field.
Available in Mac OS X v10.0 and later.
Declared in `NSFontPanel.h`.

`NSFPSizeTitle`
Show the Size title.
Available in Mac OS X v10.0 and later.
Declared in `NSFontPanel.h`.

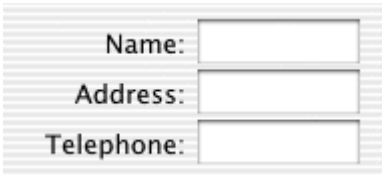
`NSFPCurrentField`
Show the Current field.
Available in Mac OS X v10.0 and later.
Declared in `NSFontPanel.h`.

NSForm Class Reference

Inherits from	NSMatrix : NSControl : NSView : NSResponder : NSObject
Conforms to	NSUserInterfaceValidations (NSMatrix) NSAnimatablePropertyContainer (NSView) NSCoding (NSResponder) NSObject (NSObject)
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.0 and later.
Declared in	AppKit/NSForm.h
Companion guides	Forms Matrix Programming Guide
Related sample code	SimpleComboBox SourceView

Overview

An `NSForm` object is a vertical matrix of `NSFormCell` objects. Here's an example:



An `NSForm` object uses NSFormCell to implement its user interface.

Tasks

Adding and Removing Entries

`- addEntry:` (page 1257)
Adds a new entry to the end of the receiver and gives it the specified title.

- `insertEntry:atIndex:` (page 1259)
  Inserts an entry with the specified title into the receiver.
- `removeEntryAtIndex:` (page 1259)
  Removes and releases the entry at the specified index.

Changing the Appearance of All the Entries

- `setBezeled:` (page 1260)
  Sets whether the receiver's entries should display a bezel around their editable text.
- `setBordered:` (page 1260)
  Sets whether the receiver's entries should display a border around their editable text fields.
- `setEntryWidth:` (page 1261)
  Sets the width of all the entries in the receiver.
- `setFrameSize:` (page 1261)
  Sets the size of the receiver's frame size to the specified value.
- `setInterlineSpacing:` (page 1262)
  Sets the spacing between entries
- `setTitleAlignment:` (page 1263)
  Sets the alignment for all of the entry titles.
- `setTitleBaseWritingDirection:` (page 1263)
  Sets the writing direction for the title of every control embedded in the form.
- `setTextAlignment:` (page 1262)
  Sets the alignment for all of the receiver's editable text.
- `setTextBaseWritingDirection:` (page 1262)
  Sets the writing direction for the text content of every control embedded in the form.
- `setTitleFont:` (page 1264)
  Sets the font for all of the entry titles.
- `setTextFont:` (page 1263)
  Sets the font for all of the receiver's editable text fields

Getting Cells and Indices

- `indexOfCellWithTag:` (page 1258)
  Returns the index of the entry whose tag is *`tag`*.
- `indexOfSelectedItem` (page 1259)
  Returns the index of the selected entry.
- `cellAtIndex:` (page 1257)
  Returns the entry at the specified index.

Displaying a Cell

- `drawCellAtIndex:` (page 1258)
  Displays the entry at the specified index.

Editing Text

`- selectTextAtIndex:` (page 1260)
Selects the entry at the specified index.

Instance Methods

addEntry:

Adds a new entry to the end of the receiver and gives it the specified title.

```
- (NSFormCell *)addEntry:(NSString *)title
```

Parameters

title
The title for the new form entry.

Return Value
The form cell object that was created for the entry.

Discussion
The new entry has no tag, target, or action, but is enabled and editable.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `insertEntry:atIndex:` (page 1259)
- `setEditable:` (page 584) (NSCell)
- `setTag:` (page 69) (NSActionCell)
- `setTarget:` (page 70) (NSActionCell)
- `setAction:` (page 65) (NSActionCell)
- `setEnabled:` (page 67) (NSActionCell)

Declared In
`NSForm.h`

cellAtIndex:

Returns the entry at the specified index.

```
- (id)cellAtIndex:(NSInteger)entryIndex
```

Parameters

entryIndex
The index of the desired entry.

Return Value
The form cell object at the specified index.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `indexOfCellWithTag:` (page 1258)
- `indexOfSelectedItem` (page 1259)

Declared In
`NSForm.h`

drawCellAtIndex:

Displays the entry at the specified index.

```
- (void)drawCellAtIndex:(NSInteger)entryIndex
```

Parameters

entryIndex
The index of the entry to draw.

Discussion
Because this method is called automatically whenever a cell needs drawing, you never need to invoke it explicitly. It is included in the API so you can override it if you subclass `NSFormCell`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `indexOfCellWithTag:` (page 1258)
- `indexOfSelectedItem` (page 1259)

Declared In
`NSForm.h`

indexOfCellWithTag:

Returns the index of the entry whose tag is *tag*.

```
- (NSInteger)indexOfCellWithTag:(NSInteger)tag
```

Parameters

tag
The tag of the desired entry.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `tag` (page 605) (NSCell)

Declared In
`NSForm.h`

indexOfSelectedItem

Returns the index of the selected entry.

```
- (NSInteger)indexOfSelectedItem
```

Return Value
The index of the selected entry, or `-1` if no entry is selected.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSForm.h`

insertEntry:atIndex:

Inserts an entry with the specified title into the receiver.

```
- (NSFormCell *)insertEntry:(NSString *)title atIndex:(NSInteger)entryIndex
```

Parameters
title
The title for the new form entry.

entryIndex
The zero-based index at which to insert the entry.

Return Value
The form cell object that was created for the entry.

Discussion
The new entry has no tag, target, or action, but is enabled and editable.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `addEntry:` (page 1257)
- `removeEntryAtIndex:` (page 1259)

Declared In
`NSForm.h`

removeEntryAtIndex:

Removes and releases the entry at the specified index.

```
- (void)removeEntryAtIndex:(NSInteger)entryIndex
```

Parameters
entryIndex
The zero-based index identifying the desired entry.

Discussion
If the specified index is invalid, this method does nothing.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSForm.h

selectTextAtIndex:

Selects the entry at the specified index.

```
- (void)selectTextAtIndex:(NSInteger)entryIndex
```

Parameters

entryIndex
The index of the entry to select. If the specified index is invalid, this method does nothing.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSForm.h

setBezeled:

Sets whether the receiver's entries should display a bezel around their editable text.

```
- (void)setBezeled:(BOOL)flag
```

Parameters

flag
YES to display a bezel around all entries; otherwise, NO to show no bezel around all entries.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setBordered: (page 1260)
- isBezeled (page 566) (NSCell)

Declared In
NSForm.h

setBordered:

Sets whether the receiver's entries should display a border around their editable text fields.

```
- (void)setBordered:(BOOL)flag
```

Parameters

flag

YES to display a border around all entries; otherwise, NO to show no border around all entries.

Discussion

The border is drawn as a thin line around the editable text field. An entry can have a border or a bezel, but not both.

Availability

Available in Mac OS X v10.0 and later.

See Also

- setBezeled: (page 1260)
- isBordered (page 566) (NSCell)

Declared In

NSForm.h

setEntryWidth:

Sets the width of all the entries in the receiver.

```
- (void)setEntryWidth:(CGFloat)width
```

Parameters

width

The width of all entries, measured in points in the user coordinate space. This value represents the width of both the title and the text field.

Availability

Available in Mac OS X v10.0 and later.

Declared In

NSForm.h

setFrameSize:

Sets the size of the receiver's frame size to the specified value.

```
- (void)setFrameSize:(NSSize)newSize
```

Parameters

newSize

The new size of the form.

Discussion

The width of NSFormCell objects always match the width of their encompassing NSForm object. The cell width is always changed to match the view regardless of the value returned by autosizesCells (page 1556).

Availability

Available in Mac OS X v10.3 and later.

Declared In

NSForm.h

setInterlineSpacing:

Sets the spacing between entries

```
- (void)setInterlineSpacing:(CGFloat)spacing
```

Parameters

spacing

The spacing between entries, measured in points in the user coordinate space.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSForm.h

setTextAlignment:

Sets the alignment for all of the receiver's editable text.

```
- (void)setTextAlignment:(NSInteger)alignment
```

Parameters

alignment

The alignment can be one of the following constants: `NSRightTextAlignment`, `NSCenterTextAlignment`, or `NSLeftTextAlignment`.

Discussion
The default alignment is `NSLeftTextAlignment`.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setTitleAlignment:` (page 1263)

Declared In
NSForm.h

setTextBaseWritingDirection:

Sets the writing direction for the text content of every control embedded in the form.

```
- (void)setTextBaseWritingDirection:(NSWritingDirection)writingDirection
```

Parameters

writingDirection

This value can be one of the following constants: `NSWritingDirectionNatural`, `NSWritingDirectionLeftToRight`, or `NSWritingDirectionRightToLeft`.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `baseWritingDirection` (page 815) (NSControl)

Declared In
`NSForm.h`

setTextFont:

Sets the font for all of the receiver's editable text fields

```
- (void)setTextFont:(NSFont *)font
```

Parameters

font

The font to use for all editable text fields.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setTextFont:` (page 1263)

Declared In
`NSForm.h`

setTitleAlignment:

Sets the alignment for all of the entry titles.

```
- (void)setTitleAlignment:(NSTextAlignment)alignment
```

Parameters

alignment

The alignment can be one of the following constants: `NSRightTextAlignment`, `NSCenterTextAlignment`, or `NSLeftTextAlignment`.

Discussion
The default alignment is `NSRightTextAlignment`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setTextAlignment:` (page 1262)

Declared In
`NSForm.h`

setTitleBaseWritingDirection:

Sets the writing direction for the title of every control embedded in the form.

```
- (void)setTitleBaseWritingDirection:(NSWritingDirection)writingDirection
```

Parameters

writingDirection

This value can be one of the following constants: `NSWritingDirectionNatural`, `NSWritingDirectionLeftToRight`, or `NSWritingDirectionRightToLeft`.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`NSForm.h`

setTitleFont:

Sets the font for all of the entry titles.

```
- (void)setTitleFont:(NSFont *)font
```

Parameters

font

The font to use for all entry titles.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setTextFont:` (page 1263)

Declared In
`NSForm.h`

NSFormCell Class Reference

Inherits from	NSActionCell : NSCell : NSObject
Conforms to	NSCoding (NSCell) NSCopying (NSCell) NSObject (NSObject)
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.0 and later.
Declared in	AppKit/NSFormCell.h
Companion guide	Forms

Overview

The `NSFormCell` class is used to implement text entry fields in a form. The left part of an `NSFormCell` object contains a title. The right part contains an editable text entry field.

An `NSFormCell` object implements the user interface of an NSForm object.

Tasks

Initializing an NSFormCell

`- initTextCell:` (page 1267)
Returns an `NSFormCell` object initialized with the specified title string.

Asking About a Cell's Appearance

`- isOpaque` (page 1268)
Returns a Boolean value indicating whether the title is empty and an opaque bezel is set.

Asking About a Cell's Title

- `attributedTitle` (page 1267)
  Returns the title of the cell as an attributed string.
- `title` (page 1272)
  Returns the receiver's title.
- `titleAlignment` (page 1272)
  Returns the alignment of the title.
- `titleBaseWritingDirection` (page 1273)
  Returns the default writing direction used to render the form cell's title.
- `titleFont` (page 1273)
  Returns the font used to draw the receiver's title.
- `titleWidth` (page 1273)
  Returns the width of the title field.
- `titleWidth:` (page 1274)
  Returns the width of the title field constrained to the specified size.

Changing the Cell's Title

- `setAttributedTitle:` (page 1269)
  Sets the receiver's title using an attributed string.
- `setTitle:` (page 1270)
  Sets the receiver's title to the specified plain-text string.
- `setTitleAlignment:` (page 1270)
  Sets the alignment of the title.
- `setTitleBaseWritingDirection:` (page 1271)
  Sets the default writing direction used to render the form cell's title.
- `setTitleFont:` (page 1271)
  Sets the font of the receiver's title.
- `setTitleWidth:` (page 1271)
  Sets the width of the title.

Setting a Keyboard Equivalent

- `setTitleWithMnemonic:` (page 1272)
  Sets the cell title and mnemonic character.

Asking About Placeholder Values

- `placeholderAttributedString` (page 1268)
  Returns the cell's attributed placeholder string.
- `placeholderString` (page 1268)
  Returns the cell's plain text placeholder string.

- `setPlaceholderAttributedString:` (page 1269)
  Sets the attributed placeholder string for the cell.
- `setPlaceholderString:` (page 1269)
  Sets the plain-text placeholder string for the cell.

Instance Methods

attributedTitle

Returns the title of the cell as an attributed string.

```
- (NSAttributedString *)attributedTitle
```

Return Value
The title of the cell.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSFormCell.h`

initTextCell:

Returns an `NSFormCell` object initialized with the specified title string.

```
- (id)initTextCell:(NSString *)aString
```

Parameters

aString
The title for the new form cell object.

Return Value
An initialized `NSFormCell` object.

Discussion
The contents of the cell's editable text entry field are set to the empty string (@""). The font for both title and text is the user's chosen system font in 12.0 point, and the text area is drawn with a bezel. This method is the designated initializer for the `NSFormCell` class.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setTitle:` (page 1270)

Declared In
`NSFormCell.h`

isOpaque

Returns a Boolean value indicating whether the title is empty and an opaque bezel is set.

```
- (BOOL)isOpaque
```

Return Value
`YES` if the title is empty and an opaque bezel is set; otherwise, `NO`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSFormCell.h`

placeholderAttributedString

Returns the cell's attributed placeholder string.

```
- (NSAttributedString *)placeholderAttributedString
```

Return Value
The attributed placeholder string, or `nil` if the cell has no attributed placeholder string.

Discussion
If this method returns `nil`, you can also call `placeholderString` to see if the cell has a plain text placeholder string.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `placeholderString` (page 1268)
- `setPlaceholderAttributedString:` (page 1269)

Declared In
`NSFormCell.h`

placeholderString

Returns the cell's plain text placeholder string.

```
- (NSString *)placeholderString
```

Return Value
The plain-text placeholder string, or `nil` if the cell has no plain-text placeholder string.

Discussion
If this method returns `nil`, you can also call `placeholderAttributedString` to see if the cell has an attributed placeholder string.

Availability
Available in Mac OS X v10.4 and later.

See Also
- placeholderAttributedString (page 1268)
- setPlaceholderString: (page 1269)

Declared In
NSFormCell.h

setAttributedTitle:

Sets the receiver's title using an attributed string.

```
- (void)setAttributedTitle:(NSAttributedString *)anAttributedString
```

Parameters
anAttributedString
The formatted title of the cell.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSFormCell.h

setPlaceholderAttributedString:

Sets the attributed placeholder string for the cell.

```
- (void)setPlaceholderAttributedString:(NSAttributedString *)string
```

Parameters
string
The attributed placeholder string.

Discussion
Note that invoking this method clears out any plain text string set by calling the setPlaceholderString: (page 1269) method.

Availability
Available in Mac OS X v10.4 and later.

See Also
- placeholderAttributedString (page 1268)
- setPlaceholderString: (page 1269)

Declared In
NSFormCell.h

setPlaceholderString:

Sets the plain-text placeholder string for the cell.

```
- (void)setPlaceholderString:(NSString *)string
```

Parameters

string

The plain-text placeholder string.

Discussion

Note that invoking this method clears out any attributed string set by the `setPlaceholderAttributedString:` (page 1269) method.

Availability

Available in Mac OS X v10.4 and later.

See Also

`- placeholderString` (page 1268)

`- setPlaceholderAttributedString:` (page 1269)

Declared In

`NSFormCell.h`

setTitle:

Sets the receiver's title to the specified plain-text string.

```
- (void)setTitle:(NSString *)aString
```

Parameters

aString

The plain-text title of the cell.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSFormCell.h`

setTitleAlignment:

Sets the alignment of the title.

```
- (void)setTitleAlignment:(NSTextAlignment)alignment
```

Parameters

alignment

The alignment can be one of the following constants: `NSRightTextAlignment`, `NSCenterTextAlignment`, or `NSLeftTextAlignment`.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSFormCell.h`

setTitleBaseWritingDirection:

Sets the default writing direction used to render the form cell's title.

```
- (void)setTitleBaseWritingDirection:(NSWritingDirection)writingDirection
```

Parameters

writingDirection

This value can be one of the following constants: `NSWritingDirectionNatural`, `NSWritingDirectionLeftToRight`, or `NSWritingDirectionRightToLeft`.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `setTitleBaseWritingDirection:` (page 1271)
- `baseWritingDirection` (page 547) (NSCell)

Declared In
`NSFormCell.h`

setTitleFont:

Sets the font of the receiver's title.

```
- (void)setTitleFont:(NSFont *)font
```

Parameters

font

The font to use.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSFormCell.h`

setTitleWidth:

Sets the width of the title.

```
- (void)setTitleWidth:(CGFloat)width
```

Parameters

width

The width of the title, measured in points in the user coordinate space.

Discussion
You usually do not need to invoke this method. The Application Kit automatically sets the title width whenever the title changes. If the automatic width doesn't suit your needs, though, you can use this method to set the width explicitly.

Once you have set the width this way, the Application Kit stops setting the width automatically; you must invoke this method every time the title changes. If you want the Application Kit to resume automatic width assignments, invoke this method with a negative *width* value.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSFormCell.h

setTitleWithMnemonic:

Sets the cell title and mnemonic character.

```
- (void)setTitleWithMnemonic:(NSString *)titleWithAmpersand
```

Parameters

titleWithAmpersand
The title of the cell, including a mnemonic identifier. To specify the mnemonic character, place an ampersand (&) in the front of the desired character.

Discussion
Mnemonics are not supported in Mac OS X.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setTitle: (page 1270)

Declared In
NSFormCell.h

title

Returns the receiver's title.

```
- (NSString *)title
```

Return Value
The title of the cell. The default value is "Field:".

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSFormCell.h

titleAlignment

Returns the alignment of the title.

```
- (NSTextAlignment)titleAlignment
```

Return Value
The alignment can be one of the following values: `NSLeftTextAlignment`, `NSCenterTextAlignment`, or `NSRightTextAlignment`. The default alignment is `NSRightTextAlignment`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSFormCell.h`

titleBaseWritingDirection

Returns the default writing direction used to render the form cell's title.

```
- (NSWritingDirection)titleBaseWritingDirection
```

Return Value
One of the following constants: `NSWritingDirectionNatural`, `NSWritingDirectionLeftToRight`, or `NSWritingDirectionRightToLeft`.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- setTitleBaseWritingDirection:` (page 1271)

Declared In
`NSFormCell.h`

titleFont

Returns the font used to draw the receiver's title.

```
- (NSFont *)titleFont
```

Return Value
The font object used for the title.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSFormCell.h`

titleWidth

Returns the width of the title field.

```
- (CGFloat)titleWidth
```

Return Value
The width of the title field, measured in points in the user coordinate space.

Discussion
If you set the width using `setTitleWidth:` (page 1271), this method returns the value you set; otherwise, it returns the width calculated automatically by the Application Kit.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- titleWidth:` (page 1274)

Declared In
`NSFormCell.h`

titleWidth:

Returns the width of the title field constrained to the specified size.

```
- (CGFloat)titleWidth:(NSSize)aSize
```

Parameters

aSize

The maximum size of the field when calculated by the Application Kit.

Return Value
The width of the title field, measured in points in the user coordinate space.

Discussion
If you set the width using `setTitleWidth:` (page 1271), this method returns the value you set; otherwise, the Application Kit calculates the width, constraining the field size to the specified value.

Availability
Available in Mac OS X v10.0 and later.

NSGlyphGenerator Class Reference

Inherits from	NSObject
Conforms to	NSObject (NSObject)
Framework	/System/Library/Frameworks/AppKit.framework
Declared in	AppKit/NSGlyphGenerator.h
Availability	Available in Mac OS X v10.3 and later.
Companion guides	Text System Overview Text Layout Programming Guide

Overview

An `NSGlyphGenerator` object performs the initial, nominal glyph generation phase in the layout process.

The nominal glyph generation pass essentially generates one glyph per character; the typesetter may later make substitutions in the glyph stream, for example, changing an acute accent glyph followed by an "e" glyph into a single acute-accented "é" glyph.

`NSGlyphGenerator` communicates via the `NSGlyphStorage` protocol. An example of a class conforming to the protocol is `NSLayoutManager`.

Tasks

Obtaining a Glyph Generator

`+ sharedGlyphGenerator` (page 1276)
Returns a shared instance of `NSGlyphGenerator`.

Generating Glyphs

`- generateGlyphsForGlyphStorage:desiredNumberOfCharacters:glyphIndex:characterIndex:` (page 1276)
Generates glyphs for the specified glyph storage object (`NSLayoutManager` by default).

Class Methods

sharedGlyphGenerator

Returns a shared instance of `NSGlyphGenerator`.

```
+ (id)sharedGlyphGenerator
```

Availability
Available in Mac OS X v10.3 and later.

Declared In
`NSGlyphGenerator.h`

Instance Methods

generateGlyphsForGlyphStorage:desiredNumberOfCharacters:glyphIndex:characterIndex:

Generates glyphs for the specified glyph storage object (`NSLayoutManager` by default).

```
- (void)generateGlyphsForGlyphStorage:(id < NSGlyphStorage >)glyphStorage
    desiredNumberOfCharacters:(NSUInteger)nChars glyphIndex:(NSUInteger *)glyphIndex
     characterIndex:(NSUInteger *)charIndex
```

Discussion
Generates glyphs for the glyph storage object specified by *glyphStorage*, beginning with the character at *charIndex* and continuing for *nChars* characters. The *glyphIndex* specifies the index of the first glyph generated.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`NSGlyphGenerator.h`

NSGlyphInfo Class Reference

Inherits from	NSObject
Conforms to	NSCoding NSCopying NSObject (NSObject)
Framework	/System/Library/Frameworks/AppKit.framework
Declared in	AppKit/NSGlyphInfo.h
Availability	Available in Mac OS X v10.2 and later.
Companion guide	Font Handling

Overview

An `NSGlyphInfo` object represents a glyph attribute value (`NSGlyphInfoAttributeName`) in an attributed string. `NSGlyphInfo` allows you to override a font's specified mapping from Unicode to the glyph ID. Overriding the mapping allows you to specify a variant glyph for a given character if the font contains multiple variations for that character or to specify a glyph that doesn't have a standard mapping (such as some ligature glyphs).

Adopted Protocols

NSCoding

- `encodeWithCoder:`
- `initWithCoder:`

Tasks

Creating an NSGlyphInfo Object

`+ glyphInfoWithCharacterIdentifier:collection:baseString:` (page 1278)
Instantiates and returns an `NSGlyphInfo` object using a character identifier and a character collection.

+ glyphInfoWithGlyph:forFont:baseString: (page 1278)
Instantiates and returns an NSGlyphInfo object using a glyph index and a specified font.

+ glyphInfoWithGlyphName:forFont:baseString: (page 1279)
Instantiates and returns an NSGlyphInfo object using a glyph name and a specified font.

Getting Information About an NSGlyphInfo Object

- characterIdentifier (page 1280)
Returns the receiver's character identifier (CID).

- characterCollection (page 1279)
Returns an NSCharacterCollection value specifying the glyph–to–character identifier mapping of the receiver.

- glyphName (page 1280)
Returns the receiver's glyph name.

Class Methods

glyphInfoWithCharacterIdentifier:collection:baseString:

Instantiates and returns an NSGlyphInfo object using a character identifier and a character collection.

```
+ (NSGlyphInfo *)glyphInfoWithCharacterIdentifier:(NSUInteger)cid
    collection:(NSCharacterCollection)characterCollection baseString:(NSString
    *)theString
```

Parameters

cid
A character identifier.

characterCollection
A string constant representing a character collection. Possible values for *characterCollection* are described in "Constants" (page 1281).

theString
The part of the attributed string the returned instance is intended to override.

Return Value
The created NSGlyphInfo object or nil if the object couldn't be created.

Availability
Available in Mac OS X v10.2 and later.

Declared In
NSGlyphInfo.h

glyphInfoWithGlyph:forFont:baseString:

Instantiates and returns an NSGlyphInfo object using a glyph index and a specified font.

```
+ (NSGlyphInfo *)glyphInfoWithGlyph:(NSGlyph)glyph forFont:(NSFont *)font
    baseString:(NSString *)theString
```

Parameters

glyph

The identifier of the glyph.

font

The font object to be associated with the returned `NSGlyphInfo` object,

theString

The part of the attributed string the returned instance is intended to override.

Return Value

The created `NSGlyphInfo` object or `nil` if the object couldn't be created.

Availability

Available in Mac OS X v10.2 and later.

Declared In

`NSGlyphInfo.h`

glyphInfoWithGlyphName:forFont:baseString:

Instantiates and returns an `NSGlyphInfo` object using a glyph name and a specified font.

```
+ (NSGlyphInfo *)glyphInfoWithGlyphName:(NSString *)glyphName forFont:(NSFont *)font
     baseString:(NSString *)theString
```

Parameters

glyphName

The name of the glyph.

font

The font object to be associated with the returned `NSGlyphInfo` object,

theString

The part of the attributed string the returned instance is intended to override.

Return Value

The created `NSGlyphInfo` object or `nil` if the object couldn't be created.

Availability

Available in Mac OS X v10.2 and later.

Declared In

`NSGlyphInfo.h`

Instance Methods

characterCollection

Returns an `NSCharacterCollection` value specifying the glyph–to–character identifier mapping of the receiver.

```
- (NSCharacterCollection)characterCollection
```

Discussion
This method returns `NSIdentityMappingCharacterCollection` if the receiver was instantiated with either an `NSGlyph` identifier or a glyph name. It returns other possible values if the receiver was instantiated using `glyphInfoWithCharacterIdentifier:collection:baseString:` (page 1278). These constants are described in `NSCharacterCollection` (page 1281).

Availability
Available in Mac OS X v10.2 and later.

Declared In
`NSGlyphInfo.h`

characterIdentifier

Returns the receiver's character identifier (CID).

```
- (NSUInteger)characterIdentifier
```

Discussion
If the receiver was instantiated with a method other than `glyphInfoWithCharacterIdentifier:collection:baseString:` (page 1278), this method returns `NULL`.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`NSGlyphInfo.h`

glyphName

Returns the receiver's glyph name.

```
- (NSString *)glyphName
```

Discussion
If the receiver was instantiated with a method other than `glyphInfoWithGlyphName:forFont:baseString:` (page 1279), this method returns `nil`.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`NSGlyphInfo.h`

Constants

NSCharacterCollection

The following values specify the mapping of character identifiers to glyphs, and are returned by `characterCollection` (page 1279).

```
typedef enum {
    NSIdentityMappingCharacterCollection = 0,
    NSAdobeCNS1CharacterCollection       = 1,
    NSAdobeGB1CharacterCollection        = 2,
    NSAdobeJapan1CharacterCollection     = 3,
    NSAdobeJapan2CharacterCollection     = 4,
    NSAdobeKorea1CharacterCollection     = 5,
} NSCharacterCollection;
```

Constants

`NSIdentityMappingCharacterCollection`
Indicates that the character identifier is equal to the glyph index.

Available in Mac OS X v10.2 and later.

Declared in `NSGlyphInfo.h`.

`NSAdobeCNS1CharacterCollection`
Indicates the Adobe-CNS1 mapping.

Available in Mac OS X v10.2 and later.

Declared in `NSGlyphInfo.h`.

`NSAdobeGB1CharacterCollection`
Indicates the Adobe-GB1 mapping.

Available in Mac OS X v10.2 and later.

Declared in `NSGlyphInfo.h`.

`NSAdobeJapan1CharacterCollection`
Indicates the Adobe-Japan1 mapping.

Available in Mac OS X v10.2 and later.

Declared in `NSGlyphInfo.h`.

`NSAdobeJapan2CharacterCollection`
Indicates the Adobe-Japan2 mapping.

Available in Mac OS X v10.2 and later.

Declared in `NSGlyphInfo.h`.

`NSAdobeKorea1CharacterCollection`
Indicates the Adobe-Korea1 mapping.

Available in Mac OS X v10.2 and later.

Declared in `NSGlyphInfo.h`.

Availability

Available in Mac OS X v10.2 and later.

Declared In

`NSGlyphInfo.h`

NSGradient Class Reference

Inherits from	NSObject
Conforms to	NSCoding NSCopying NSObject (NSObject)

Overview

The `NSGradient` class provides support for drawing gradient fill colors, also known as shadings in Quartz. This class provides convenience methods for drawing radial or linear (axial) gradients for rectangles and `NSBezierPath` objects. It also supports primitive methods that let you customize the shape of the gradient fill.

A gradient consists of two or more color changes over the range of the gradient shape. When creating a gradient object, you specify the colors and their locations relative to the start and end of the gradient. This combination of color and location is known as a **color stop**. During drawing, the `NSGradient` object uses the color stop information to compute color changes for you and passes that information to the Quartz shading functions.

Because the `NSGradient` class uses Quartz shadings, drawing is handled by computing the colors at a given point mathematically. This technique results in smooth gradients regardless of the resolution of the target device.

For more information about gradients and their appearance, see Gradients in *Quartz 2D Programming Guide*.

Tasks

Initialization

- `initWithStartingColor:endingColor:` (page 1292)
  Initializes a newly allocated gradient object with two colors.
- `initWithColors:` (page 1290)
  Initializes a newly allocated gradient object with an array of colors.
- `initWithColorsAndLocations:` (page 1291)
  Initializes a newly allocated gradient object with a comma-separated list of arguments.
- `initWithColors:atLocations:colorSpace:` (page 1291)
  Initializes a newly allocated gradient object with the specified colors, color locations, and color space.

Primitive Drawing Methods

- `drawFromPoint:toPoint:options:` (page 1286)
  Draws a linear gradient between the specified start and end points.
- `drawFromCenter:radius:toCenter:radius:options:` (page 1285)
  Draws a radial gradient between the specified circles.

Drawing Linear Gradients

- `drawInRect:angle:` (page 1288)
  Fills the specified rectangle with a linear gradient.
- `drawInBezierPath:angle:` (page 1286)
  Fills the specified path with a linear gradient.

Drawing Radial Gradients

- `drawInRect:relativeCenterPosition:` (page 1289)
  Draws a radial gradient starting at the center of the specified rectangle.
- `drawInBezierPath:relativeCenterPosition:` (page 1287)
  Draws a radial gradient starting at the center point of the specified path.

Getting Gradient Properties

- `colorSpace` (page 1285)
  Returns the color space of the colors associated with the receiver.
- `numberOfColorStops` (page 1293)
  Returns the number of color stops associated with the receiver.

- `getColor:location:atIndex:` (page 1289)
  Returns information about the color stop at the specified index in the receiver's color array.
- `interpolatedColorAtLocation:` (page 1292)
  Returns the color of the rendered gradient at the specified relative location.

Instance Methods

colorSpace

Returns the color space of the colors associated with the receiver.

```
- (NSColorSpace *)colorSpace
```

Return Value
The color space object used by the receiver's colors.

Discussion
When the receiver is initialized, colors that do not conform to the receiver's color space are converted automatically.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSGradient.h`

drawFromCenter:radius:toCenter:radius:options:

Draws a radial gradient between the specified circles.

```
- (void)drawFromCenter:(NSPoint)startCenter radius:(CGFloat)startRadius
    toCenter:(NSPoint)endCenter radius:(CGFloat)endRadius
    options:(NSGradientDrawingOptions)options
```

Parameters

startCenter
The center point of the circle that represents the beginning of the gradient.

startRadius
The radius of the circle that represents the beginning of the gradient.

endCenter
The center point of the circle that represents the end of the gradient.

endRadius
The radius of the circle that represents the end of the gradient.

options
The gradient options, if any. You can use these options to extend the gradient size beyond the start and end circles. For more information, see "Gradient Drawing Options" (page 1294).

Discussion
This method draws a radial gradient pattern starting at the first circle and ending at the second circle. The gradient color transitions occur in circular bands emanating from the starting circle and ending at the second circle.

This is a primitive method used by the `NSGradient` class to draw radial gradients. Because this method does not perform any clipping of the gradient fill pattern, you must ensure that the clipping region is configured properly if you intend to invoke this method directly. By default, the clipping region is set to the current view or window in which drawing occurs.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSGradient.h`

drawFromPoint:toPoint:options:

Draws a linear gradient between the specified start and end points.

```
- (void)drawFromPoint:(NSPoint)startingPoint toPoint:(NSPoint)endingPoint
    options:(NSGradientDrawingOptions)options
```

Parameters

startingPoint
The starting point for the gradient, in the local coordinate system. The gradient's first color is drawn at this point.

endingPoint
The end point for the gradient, in the local coordinate system. The gradient's last color is drawn at this point.

options
The gradient options, if any. You can use these options to extend the gradient size beyond the start and end points. For more information, see "Gradient Drawing Options" (page 1294).

Discussion
This method draws the gradient color changes along the line formed by the two points. The gradient fill extends perpendicularly outward from line until it reaches the edges of the current clipping region.

This is a primitive method used by the `NSGradient` class to draw linear gradients. Because this method does not perform any clipping of the gradient fill pattern, you must ensure that the clipping region is configured properly if you intend to invoke this method directly. By default, the clipping region is set to the current view or window in which drawing occurs.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSGradient.h`

drawInBezierPath:angle:

Fills the specified path with a linear gradient.

```
- (void)drawInBezierPath:(NSBezierPath *)path angle:(CGFloat)angle
```

Parameters

path

The path object to fill.

angle

The angle of the linear gradient, specified in degrees. Positive values indicate rotation in the counter-clockwise direction relative to the horizontal axis.

Discussion

This convenience method behaves in a similar way to the `drawInRect:angle:` method, with the path object replacing the rectangle as the clipping region. Like the other method, the start and end colors are guaranteed to be visible at the farthest ends of the path.

The gradient formed by this method is clipped to *path*.

Availability

Available in Mac OS X v10.5 and later.

See Also

- `drawInRect:angle:` (page 1288)
- `drawFromPoint:toPoint:options:` (page 1286)

Related Sample Code

CocoaSlides

Declared In

`NSGradient.h`

drawInBezierPath:relativeCenterPosition:

Draws a radial gradient starting at the center point of the specified path.

```
- (void)drawInBezierPath:(NSBezierPath *)path
    relativeCenterPosition:(NSPoint)relativeCenterPosition
```

Parameters

path

The path to fill.

relativeCenterPosition

The relative location within the bounding rectangle of *path* to use as the center point of the gradient's end circle. Each coordinate must contain a value between -1.0 and 1.0. A coordinate value of 0 represents the center of the path's bounding rectangle along the given axis. In the default coordinate system, a value of -1.0 corresponds to the bottom or left edge of the bounding rectangle and a value of 1.0 corresponds to the top or right edge.

Discussion

The center point of the starting circle is the same as the center point of *path*. The radius of the starting circle is 0, resulting in the starting circle being just a point.

The center point of the end circle starts at the center point of *path* and is modified by the value in the *relativeCenterPosition* parameter. For example, if *relativeCenterPosition* contains the point (1.0, 1.0), the center of the end circle is located in the top-right corner of the path's bounding rectangle. The radius of the end circle is set to the smallest value that ensures `rect` is covered by the end circle.

The gradient formed by this method is clipped to *path*.

Availability
Available in Mac OS X v10.5 and later.

See Also
- `drawInRect:relativeCenterPosition:` (page 1289)
- `drawFromCenter:radius:toCenter:radius:options:` (page 1285)

Declared In
`NSGradient.h`

drawInRect:angle:

Fills the specified rectangle with a linear gradient.

```
- (void)drawInRect:(NSRect)rect angle:(CGFloat)angle
```

Parameters

rect
The rectangle to fill.

angle
The angle of the linear gradient, specified in degrees. Positive values indicate rotation in the counter-clockwise direction relative to the horizontal axis.

Discussion
This convenience method draws a linear gradient inside the specified rectangle. The gradient is drawn so that the start and end colors are guaranteed to be visible in opposite corners of the rectangle. The angle of rotation determines which corner contains the start color; see Table 58-1.

Table 58-1 Linear gradient starting points.

Rotation angle	Start corner
0-89 degrees	Lower-left
90-179 degrees	Lower-right
180-269 degrees	Upper-right
270-359 degrees	Upper-left

The gradient's color transitions occur along the line formed by the angle of rotation. For example, a rotation of 0 degrees results in colors changing from left-to-right across the rectangle, while a rotation of 90 degrees results in colors changing from bottom to top.

The gradient drawn by this method is clipped to *rect*.

Availability
Available in Mac OS X v10.5 and later.

See Also
- `drawInBezierPath:angle:` (page 1286)
- `drawFromPoint:toPoint:options:` (page 1286)

Declared In
`NSGradient.h`

drawInRect:relativeCenterPosition:

Draws a radial gradient starting at the center of the specified rectangle.

```
- (void)drawInRect:(NSRect)rect
    relativeCenterPosition:(NSPoint)relativeCenterPosition
```

Parameters

rect
The rectangle to fill.

relativeCenterPosition
The relative location within the rectangle to use as the center point of the gradient's end circle. Each coordinate must contain a value between -1.0 and 1.0. A coordinate value of 0 represents the center of *rect* along the given axis. In the default coordinate system, a value of -1.0 corresponds to the bottom or left edge of the rectangle and a value of 1.0 corresponds to the top or right edge.

Discussion
The center point of the starting circle is the same as the center point of *rect*. The radius of the starting circle is 0, resulting in the starting circle being just a point.

The center point of the end circle starts at the center point of *rect* and is modified by the value in the *relativeCenterPosition* parameter. For example, if *relativeCenterPosition* contains the point (1.0, 1.0), the center of the end circle is located in the top-right corner of *rect*. The radius of the end circle is set to the smallest value that ensures `rect` is covered by the end circle.

The gradient formed by this method is clipped to *rect*.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSGradient.h`

getColor:location:atIndex:

Returns information about the color stop at the specified index in the receiver's color array.

```
- (void)getColor:(NSColor **)color location:(CGFloat *)location
    atIndex:(NSInteger)index
```

Parameters

color

On input, a pointer to a color object. On output, the color at the specified index in the receiver's color array. You may specify `nil` if you are not interested in this parameter.

location

On input, a pointer to a floating point number. On output, contains the location value associated with the color. This value is between 0.0 and 1.0. It is used to determine the position of the color relative to the start and end points of the gradient. You may specify `NULL` if you are not interested in this parameter.

index

The index of the color you want.

Discussion

This method returns the color stop information that was used to create the receiver. It does not return the interpolated color values at any point along the gradient. The location of the gradient's first color is typically 0.0 and the location of the last color is typically 1.0, although the locations can vary depending on how the receiver was created.

Availability

Available in Mac OS X v10.5 and later.

See Also

- `interpolatedColorAtLocation:` (page 1292)

Declared In

`NSGradient.h`

initWithColors:

Initializes a newly allocated gradient object with an array of colors.

```
- (id)initWithColors:(NSArray *)colorArray
```

Parameters

colorArray

An array of `NSColor` objects representing the colors to use to initialize the gradient. There must be at least two colors in the array. The first color is placed at location 0.0 and the last at location 1.0. If there are more than two colors, the additional colors are placed at evenly spaced intervals between the first and last colors.

Return Value

The initialized `NSGradient` object.

Availability

Available in Mac OS X v10.5 and later.

See Also

- `initWithColors:atLocations:colorSpace:` (page 1291)

Related Sample Code
DispatchFractal

Declared In
NSGradient.h

initWithColors:atLocations:colorSpace:

Initializes a newly allocated gradient object with the specified colors, color locations, and color space.

```
- (id)initWithColors:(NSArray *)colorArray atLocations:(const CGFloat *)locations
    colorSpace:(NSColorSpace *)colorSpace
```

Parameters

colorArray
An array of `NSColor` objects representing the colors in the gradient.

locations
An array of `CGFloat` values containing the location for each color in the gradient. Each value must be in the range 0.0 to 1.0. There must be the same number of locations as are colors in the *colorArray* parameter.

colorSpace
The color space to use for the gradient.

Return Value
The initialized `NSGradient` object.

Discussion
This method is the designated initializer of `NSGradient`. The colors in the *colorArray* parameter are converted to the specified color space if they are not already in that color space.

Typically, at least one color should have a location of 0.0 and one should have a location of 1.0. If these locations are not specified, the color at the closest color stop is used to fill the gap.

Availability
Available in Mac OS X v10.5 and later.

Declared In
NSGradient.h

initWithColorsAndLocations:

Initializes a newly allocated gradient object with a comma-separated list of arguments.

```
- (id)initWithColorsAndLocations:(NSColor *)firstColor, ...
```

Parameters

firstColor
The first color in the gradient.

...
A comma-separated list of alternating `NSColor` objects and location arguments (specified as `CGFloat` values). The first value after `firstColor` must be a location. Each location value must be between 0.0 and 1.0. The list must be `nil`-terminated.

Return Value
The initialized `NSGradient` object.

Discussion
Typically, at least one color should have a location of 0.0 and one should have a location of 1.0. If these locations are not specified, the color at the closest color stop is used to fill the gap.

Availability
Available in Mac OS X v10.5 and later.

See Also
`- initWithColors:atLocations:colorSpace:` (page 1291)

Declared In
`NSGradient.h`

initWithStartingColor:endingColor:

Initializes a newly allocated gradient object with two colors.

```
- (id)initWithStartingColor:(NSColor *)startingColor endingColor:(NSColor
    *)endingColor
```

Parameters

startingColor
The starting color of the gradient. The location of this color is fixed at 0.0.

endingColor
The ending color of the gradient. The location of this color is fixed at 1.0.

Return Value
The initialized `NSGradient` object.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSGradient.h`

interpolatedColorAtLocation:

Returns the color of the rendered gradient at the specified relative location.

```
- (NSColor *)interpolatedColorAtLocation:(CGFloat)location
```

Parameters

location

The location value for the color you want. This value must be between 0.0 and 1.0. This value need not correspond to the location of one of the color objects used to create the gradient.

Discussion

This method does not simply return the color values used to initialize the receiver. Instead, it computes the value that would be drawn at the specified location.

The start color of the gradient is always located at 0.0 and the end color is always at 1.0.

Availability

Available in Mac OS X v10.5 and later.

Related Sample Code

DispatchFractal

Declared In

`NSGradient.h`

numberOfColorStops

Returns the number of color stops associated with the receiver.

```
- (NSInteger)numberOfColorStops
```

Return Value

The number of colors in the receiver's color array.

Discussion

Gradients must have at least two color stops: one defining the location of the start color and one defining the location of the end color. Gradients may have additional color stops located at different transition points in between the start and end stops.

Availability

Available in Mac OS X v10.5 and later.

Declared In

`NSGradient.h`

Constants

NSGradientDrawingOptions

Specifies gradient drawing options.

```
typedef NSUInteger NSGradientDrawingOptions;
```

Discussion

The constant values associated with this type are listed in "Gradient Drawing Options" (page 1294).

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSGradient.h`

Gradient Drawing Options

These constants are used by the primitive drawing methods to determine if drawing occurs outside of the gradient start and end locations.

```
enum {
    NSGradientDrawsBeforeStartingLocation =   (1 << 0),
    NSGradientDrawsAfterEndingLocation =    (1 << 1),
};
```

Constants

`NSGradientDrawsBeforeStartingLocation`
Drawing extends before the gradient starting point.
Available in Mac OS X v10.5 and later.
Declared in `NSGradient.h`.

`NSGradientDrawsAfterEndingLocation`
Drawing extends beyond the gradient end point.
Available in Mac OS X v10.5 and later.
Declared in `NSGradient.h`.

Overview

The `NSGraphicsContext` class is the programmatic interface to objects that represent graphics contexts. A context can be thought of as a destination to which drawing and graphics state operations are sent for execution. Each graphics context contains its own graphics environment and state.

The `NSGraphicsContext` class is an abstract superclass for destination-specific graphics contexts. You obtain instances of concrete subclasses with the class methods `currentContext` (page 1298), `graphicsContextWithAttributes:` (page 1299), `graphicsContextWithBitmapImageRep:` (page 1299), `graphicsContextWithGraphicsPort:flipped:` (page 1300), and `graphicsContextWithWindow:` (page 1300).

At any time there is the notion of the current context. The current context for the current thread may be set using `setCurrentContext:` (page 1302).

Graphics contexts are maintained on a stack. You push a graphics context onto the stack by sending it a `saveGraphicsState` (page 1308) message, and pop it off the stack by sending it a `restoreGraphicsState` (page 1307) message. By sending `restoreGraphicsState` (page 1307) to an `NSGraphicsContext` object you remove it from the stack, and the next graphics context on the stack becomes the current graphics context.

Tasks

Creating a Graphics Context

`+ graphicsContextWithAttributes:` (page 1299)
Instantiates and returns an instance of `NSGraphicsContext` using the specified attributes.

`+ graphicsContextWithBitmapImageRep:` (page 1299)
Instantiates and returns a new graphics context using the supplied `NSBitmapImageRep` object as the context destination.

`+ graphicsContextWithGraphicsPort:flipped:` (page 1300)
Instantiates and returns a new graphics context from the given graphics port.

`+ graphicsContextWithWindow:` (page 1300)
Creates and returns a new graphics context for drawing into a window.

Managing the Current Context

`+ currentContext` (page 1298)
Returns the current graphics context of the current thread.

`+ setCurrentContext:` (page 1302)
Sets the current graphics context of the current thread.

`- graphicsPort` (page 1305)
Returns the low-level, platform-specific graphics context represented by the receiver.

Managing the Graphics State

`+ setGraphicsState:` (page 1302)
Makes the graphics context of the specified graphics state current, and resets graphics state.

`+ restoreGraphicsState` (page 1301)
Pops a graphics context from the per-thread stack, makes it current, and sends the context a `restoreGraphicsState` (page 1307) message.

`- restoreGraphicsState` (page 1307)
Removes the receiver's graphics state from the top of the graphics state stack and makes the next graphics state the current graphics state.

`+ saveGraphicsState` (page 1301)
Saves the graphics state of the current graphics context.

`- saveGraphicsState` (page 1308)
Saves the current graphics state and creates a new graphics state on the top of the stack.

Testing the Drawing Destination

`+ currentContextDrawingToScreen` (page 1298)
Returns a Boolean value that indicates whether the current context is drawing to the screen.

- `isDrawingToScreen` (page 1306)
  Returns a Boolean value that indicates whether the drawing destination is the screen.

Getting Information About a Context

- `attributes` (page 1303)
  Returns the receiver's attributes.
- `isFlipped` (page 1306)
  Returns a Boolean value that indicates the receiver's flipped state.

Flushing Graphics to the Context

- `flushGraphics` (page 1305)
  Forces any buffered operations or data to be sent to the receiver's destination.

Managing the Focus Stack

- `focusStack` (page 1305) Available in Mac OS X v10.0 through Mac OS X v10.5
  Returns the object used by the context to track the hierarchy of views with locked focus.
- `setFocusStack:` (page 1309) Available in Mac OS X v10.0 through Mac OS X v10.5
  Sets the object used by the receiver to track the hierarchy of views with locked focus.

Configuring Rendering Options

- `setCompositingOperation:` (page 1309)
  Sets the receiver's global compositing operation.
- `compositingOperation` (page 1304)
  Returns the receiver's global compositing operation setting.
- `setImageInterpolation:` (page 1310)
  Sets the receiver's interpolation behavior.
- `imageInterpolation` (page 1306)
  Returns a constant that specifies the receiver's interpolation behavior.
- `setShouldAntialias:` (page 1311)
  Sets whether the receiver should use antialiasing.
- `shouldAntialias` (page 1311)
  Returns a Boolean value that indicates whether the receiver uses antialiasing.
- `setPatternPhase:` (page 1310)
  Sets the amount to offset the pattern color when filling the receiver.
- `patternPhase` (page 1307)
  Returns the amount to offset the pattern color when filling the receiver.

Getting the Core Image Context

- `CIContext` (page 1303)
  Returns a `CIContext` object that you can use to render into the receiver.

Managing the Color Rendering Intent

- `colorRenderingIntent` (page 1304)
  Returns the current rendering intent in the receiver's graphics state.
- `setColorRenderingIntent:` (page 1308)
  Sets the rendering intent in the receiver's graphics state.

Class Methods

currentContext

Returns the current graphics context of the current thread.

```
+ (NSGraphicsContext *)currentContext
```

Return Value
The current graphics context of the current thread.

Discussion
Returns an instance of a concrete subclass of `NSGraphicsContext`.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
FunHouse
Quartz EB
QuickLookSketch
Sketch+Accessibility
Sketch-112

Declared In
`NSGraphicsContext.h`

currentContextDrawingToScreen

Returns a Boolean value that indicates whether the current context is drawing to the screen.

```
+ (BOOL)currentContextDrawingToScreen
```

Return Value
`YES` if the current context is drawing to the screen, otherwise `NO`.

Discussion
This convenience method is equivalent to sending `isDrawingToScreen` (page 1306) to the result of `currentContext` (page 1298).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSGraphicsContext.h`

graphicsContextWithAttributes:

Instantiates and returns an instance of `NSGraphicsContext` using the specified attributes.

```
+ (NSGraphicsContext *)graphicsContextWithAttributes:(NSDictionary *)attributes
```

Parameters

attributes
A dictionary of values associated with the keys described in "Attribute dictionary keys" (page 1312). The attributes specify such things as representation format and destination.

Return Value
A new `NSGraphicsContext` object or `nil` if the object could not be created.

Discussion
Use this method to create a graphics context for a window or bitmap destination. If you want to create a graphics context for a PDF or PostScript destination, do not use this method; instead, use the `NSPrintOperation` class to set up the printing environment needed to generate that type of information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSGraphicsContext.h`

graphicsContextWithBitmapImageRep:

Instantiates and returns a new graphics context using the supplied `NSBitmapImageRep` object as the context destination.

```
+ (NSGraphicsContext *)graphicsContextWithBitmapImageRep:(NSBitmapImageRep
    *)bitmapRep
```

Parameters

bitmapRep
The `NSBitmapImageRep` object to use as the destination.

Return Value
The created `NSGraphicsContext` object or `nil` if the object could not be created.

Discussion
This method accepts only single plane `NSBitmapImageRep` instances. It is the equivalent of using `graphicsContextWithAttributes:` (page 1299) and passing *bitmapRep* as the value for the dictionary's `NSGraphicsContextDestinationAttributeName` key.

Availability
Available in Mac OS X v10.4 and later.

See Also
`+ graphicsContextWithAttributes:` (page 1299)

Reducer

Declared In
`NSGraphicsContext.h`

graphicsContextWithGraphicsPort:flipped:

Instantiates and returns a new graphics context from the given graphics port.

```
+ (NSGraphicsContext *)graphicsContextWithGraphicsPort:(void *)graphicsPort
    flipped:(BOOL)initialFlippedState
```

Parameters

graphicsPort
The graphics port used to create the graphics-context object. Typically `graphicsPort` is a `CGContextRef` (opaque type) object.

initialFlippedState
Specifies the receiver's initial flipped state. This is the value returned by `isFlipped` (page 1306) when no view has focus.

Return Value
The created `NSGraphicsContext` object or `nil` if the object could not be created.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`NSGraphicsContext.h`

graphicsContextWithWindow:

Creates and returns a new graphics context for drawing into a window.

```
+ (NSGraphicsContext *)graphicsContextWithWindow:(NSWindow *)aWindow
```

Parameters

aWindow

The window object representing the window to use for drawing.

Return Value

The created `NSGraphicsContext` object or `nil` if the object could not be created.

Availability

Available in Mac OS X v10.0 and later.

Related Sample Code

JAWTExample

Declared In

`NSGraphicsContext.h`

restoreGraphicsState

Pops a graphics context from the per-thread stack, makes it current, and sends the context a `restoreGraphicsState` (page 1307) message.

```
+ (void)restoreGraphicsState
```

Availability

Available in Mac OS X v10.0 and later.

Related Sample Code

QuickLookSketch

Reducer

Sketch+Accessibility

Sketch-112

TrackBall

Declared In

`NSGraphicsContext.h`

saveGraphicsState

Saves the graphics state of the current graphics context.

```
+ (void)saveGraphicsState
```

Discussion

This method sends the current graphics context a `saveGraphicsState` (page 1308) message and pushes the context onto the per-thread stack.

Availability

Available in Mac OS X v10.0 and later.

Related Sample Code

QuickLookSketch

Reducer

TrackBall

Declared In
`NSGraphicsContext.h`

setCurrentContext:

Sets the current graphics context of the current thread.

```
+ (void)setCurrentContext:(NSGraphicsContext *)context
```

Parameters

context

The graphics-context object to set as the current one. This must be an instance of a concrete subclass of `NSGraphicsContext`.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
CIAnnotation
CIVideoDemoGL
FunHouse
iChatTheater
QuickLookSketch

Declared In
`NSGraphicsContext.h`

setGraphicsState:

Makes the graphics context of the specified graphics state current, and resets graphics state.

```
+ (void)setGraphicsState:(NSInteger)graphicsState
```

Discussion
The *graphicState* identifier must be created in the calling thread.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSGraphicsContext.h`

Instance Methods

attributes

Returns the receiver's attributes.

```
- (NSDictionary *)attributes
```

Return Value
The receiver's attributes, if any.

Discussion
Screen-based graphics contexts do not store attributes, even if you create them using `graphicsContextWithAttributes:` (page 1299).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSGraphicsContext.h`

CIContext

Returns a `CIContext` object that you can use to render into the receiver.

```
- (CIContext *)CIContext
```

Return Value
A `CIContext` object or `nil` if the object could not be created.

Discussion
The `CIContext` object is created on demand and remains in existence for the lifetime of its owning `NSGraphicsContext` object. A `CIContext` object is an evaluation context for rendering a `CIImage` object through Quartz 2D or OpenGL. You use `CIContext`objects in conjunction with `CIFilter`, `CIImage`, `CIVector`, and `CIColor` objects to take advantage of the built-in Core Image filters when processing images.

For more on `CIContext` objects and related Core Image objects, see *Core Image Programming Guide*.

Availability
Available in Mac OS X v10.4 and later.

CITransitionSelectorSample
FunHouse
Reducer

Declared In
`NSGraphicsContext.h`

colorRenderingIntent

Returns the current rendering intent in the receiver's graphics state.

```
- (NSColorRenderingIntent)colorRenderingIntent
```

Return Value
An "Creating a Graphics Context" (page 1296)value that specifies the rendering intent currently used by the receiver. For possible values see "Color Rendering Intent Constants" (page 1313).

Discussion
The rendering intent specifies how Cocoa should handle colors that are not located within the gamut of the destination color space of a graphics context.

Availability
Available in Mac OS X v10.5 and later.

See Also
- setColorRenderingIntent: (page 1308)

Declared In
NSGraphicsContext.h

compositingOperation

Returns the receiver's global compositing operation setting.

```
- (NSCompositingOperation)compositingOperation
```

Return Value
The receiver's global compositing operation setting. See NSCompositingOperation (page 1375) for valid constants.

Discussion
The compositing operation is a global attribute of the graphics context and affects drawing operations that do not take an explicit compositing operation parameter. For methods that do take an explicit compositing operation parameter, the value of that parameter supersedes the global value.

The compositing operations are related to (but different from) the blend mode settings used in Quartz. Only the default compositing operation (NSCompositeCopy) is supported for PDF or PostScript content.

Availability
Available in Mac OS X v10.4 and later.

See Also
- setCompositingOperation: (page 1309)

Related Sample Code
ImageMap
ImageMapExample

Declared In
NSGraphicsContext.h

flushGraphics

Forces any buffered operations or data to be sent to the receiver's destination.

```
- (void)flushGraphics
```

Discussion
Graphics contexts use buffers to queue pending operations but for efficiency reasons may not always empty those buffers immediately. This method forces the buffers to be emptied.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
CocoaAUHost
iChatTheater

Declared In
`NSGraphicsContext.h`

focusStack

Returns the object used by the context to track the hierarchy of views with locked focus. (Available in Mac OS X v10.0 through Mac OS X v10.5.)

```
- (void *)focusStack
```

Return Value
The object used by the context to track the hierarchy of views with locked focus.

Discussion
You should never need to get or modify the focus stack information. The use of focus stacks may be deprecated in a future release.

Availability
Available in Mac OS X v10.0 through Mac OS X v10.5.

Declared In
`NSGraphicsContext.h`

graphicsPort

Returns the low-level, platform-specific graphics context represented by the receiver.

```
- (void *)graphicsPort
```

Discussion
In Mac OS X, this is the Core Graphics context, a `CGContextRef` object (opaque type).

Availability
Available in Mac OS X v10.0 and later.

FunHouse

ImageApp
Quartz EB
UnsharpMask
WebKitDOMElementPlugIn

Declared In
NSGraphicsContext.h

imageInterpolation

Returns a constant that specifies the receiver's interpolation behavior.

```
- (NSImageInterpolation)imageInterpolation
```

Return Value
The receiver's interpolation (image smoothing) behavior.

Discussion
The NSImageInterpolation constants are described in NSImageInterpolation (page 1313).

Availability
Available in Mac OS X v10.0 and later.

See Also
- setImageInterpolation: (page 1310)

Declared In
NSGraphicsContext.h

isDrawingToScreen

Returns a Boolean value that indicates whether the drawing destination is the screen.

```
- (BOOL)isDrawingToScreen
```

Return Value
YES if the drawing destination is the screen, otherwise NO.

Discussion
A return value of NO may mean that the drawing destination is a printer, but the destination may also be a PDF or EPS file. If this method returns NO, you can call attributes (page 1303) to see if additional information is available about the drawing destination.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSGraphicsContext.h

isFlipped

Returns a Boolean value that indicates the receiver's flipped state.

```
- (BOOL)isFlipped
```

Return Value
`YES` if the receiver is flipped, otherwise `NO`.

Discussion
The state is determined by sending `isFlipped` to the receiver's view that has focus. If no view has focus, returns `NO` unless the receiver is instantiated using `graphicsContextWithGraphicsPort:flipped:` (page 1300) specifying `YES` as the flipped parameter.

Availability
Available in Mac OS X v10.4 and later.

See Also
`+ graphicsContextWithGraphicsPort:flipped:` (page 1300)

Declared In
`NSGraphicsContext.h`

patternPhase

Returns the amount to offset the pattern color when filling the receiver.

```
- (NSPoint)patternPhase
```

Return Value
The amount to offset the pattern color when filling the receiver.

Discussion
The pattern phase is a translation (width, height) applied before a pattern is drawn in the current context and is part of the saved graphics state of the context. The default pattern phase is (0,0). Setting the pattern phase has the effect of temporarily changing the pattern matrix of any pattern you decide to draw. For example, setting the pattern phase to (2,3) has the effect of moving the start of pattern cell tiling to the point (2,3) in default user space.

Availability
Available in Mac OS X v10.2 and later.

See Also
`- setPatternPhase:` (page 1310)

Declared In
`NSGraphicsContext.h`

restoreGraphicsState

Removes the receiver's graphics state from the top of the graphics state stack and makes the next graphics state the current graphics state.

```
- (void)restoreGraphicsState
```

Discussion
This method must have been preceded with a `saveGraphicsState` (page 1308) message to add the graphics state to the stack. Invocations of `saveGraphicsState` and `restoreGraphicsState` methods may be nested.

Restoring the graphics state restores such attributes as the current drawing style, transformation matrix, color, and font of the original graphics state.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSGraphicsContext.h`

saveGraphicsState

Saves the current graphics state and creates a new graphics state on the top of the stack.

```
- (void)saveGraphicsState
```

Discussion
The new graphics state is a copy of the previous state that can be modified to handle new drawing operations.

Saving the graphics state saves such attributes as the current drawing style, transformation matrix, color, and font. To set drawing style attributes, use the methods of `NSBezierPath`. Other attributes are accessed through appropriate objects such as `NSAffineTransform`, `NSColor`, and `NSFont`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSGraphicsContext.h`

setColorRenderingIntent:

Sets the rendering intent in the receiver's graphics state.

```
- (void)setColorRenderingIntent:(NSColorRenderingIntent)renderingIntent
```

Parameters
renderingIntent
An "Creating a Graphics Context" (page 1296)value that specifies the rendering intent to be used. For possible values see "NSColorRenderingIntent" (page 1313).

Discussion
The rendering intent specifies how Cocoa should handle colors that are not located within the gamut of the destination color space of a graphics context. If you do not explicitly set the rendering intent, and sampled images are being drawn, `NSGraphicsContext` uses perceptual rendering intent. Otherwise, `NSGraphicsContext` uses relative colorimetric rendering intent

Availability
Available in Mac OS X v10.5 and later.

See Also
- `colorRenderingIntent` (page 1304)

Declared In
`NSGraphicsContext.h`

setCompositingOperation:

Sets the receiver's global compositing operation.

```
- (void)setCompositingOperation:(NSCompositingOperation)operation
```

Parameters

operation

A constant that specifies a compositing operating. See `NSCompositingOperation` (page 1375) for valid constants.

Discussion
The compositing operation is a global attribute of the graphics context and affects drawing operations that do not take an explicit compositing operation parameter. For methods that do take an explicit compositing operation parameter, the value of that parameter supersedes the global value.

The compositing operations are related to (but different from) the blend mode settings used in Quartz. Only the default compositing operation (`NSCompositeCopy`) is supported when rendering PDF or PostScript content.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `compositingOperation` (page 1304)

Related Sample Code
ImageMap

ImageMapExample

Declared In
`NSGraphicsContext.h`

setFocusStack:

Sets the object used by the receiver to track the hierarchy of views with locked focus. (Available in Mac OS X v10.0 through Mac OS X v10.5.)

```
- (void)setFocusStack:(void *)stack
```

Parameters

stack

The object used by the graphics context for view-hierarchy tracking.

Discussion
You should never need to get or modify the focus stack information. The use of focus stacks may be deprecated in a future release.

Availability
Available in Mac OS X v10.0 through Mac OS X v10.5.

Declared In
NSGraphicsContext.h

setImageInterpolation:

Sets the receiver's interpolation behavior.

```
- (void)setImageInterpolation:(NSImageInterpolation)interpolation
```

Parameters

interpolation
A constant specifying the image-interpolation behavior. The `NSImageInterpolation` constants are described in `NSImageInterpolation` (page 1313).

Discussion
Note that this value is not part of the graphics state, so it cannot be reset using `restoreGraphicsState` (page 1307).

Availability
Available in Mac OS X v10.0 and later.

See Also
`- imageInterpolation` (page 1306)

Related Sample Code
WebKitDOMElementPlugIn

Declared In
NSGraphicsContext.h

setPatternPhase:

Sets the amount to offset the pattern color when filling the receiver.

```
- (void)setPatternPhase:(NSPoint)phase
```

Parameters

phase
A point specifying the offset.

Discussion
Use this method when you need to line up the pattern color with another pattern, such as the pattern in a superview.

The pattern phase is a translation (width, height) applied before a pattern is drawn in the current context and is part of the saved graphics state of the context. The default pattern phase is (0,0). Setting the pattern phase has the effect of temporarily changing the pattern matrix of any pattern you decide to draw. For example, setting the pattern phase to (2,3) has the effect of moving the start of pattern cell tiling to the point (2,3) in default user space.

Availability
Available in Mac OS X v10.2 and later.

See Also
- `patternPhase` (page 1307)

Declared In
`NSGraphicsContext.h`

setShouldAntialias:

Sets whether the receiver should use antialiasing.

```
- (void)setShouldAntialias:(BOOL)antialias
```

Parameters

antialias
`YES` if the receiver should use antialiasing, otherwise `NO`.

Discussion
This value is part of the graphics state and is restored by `restoreGraphicsState` (page 1307).

Availability
Available in Mac OS X v10.0 and later.

See Also
- `shouldAntialias` (page 1311)

Related Sample Code

shouldAntialias

Returns a Boolean value that indicates whether the receiver uses antialiasing.

```
- (BOOL)shouldAntialias
```

Return Value
`YES` if the receiver uses antialiasing, otherwise `NO`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setShouldAntialias:` (page 1311)

Declared In
NSGraphicsContext.h

Constants

Attribute dictionary keys

These constants are dictionary keys used by graphicsContextWithAttributes: (page 1299) and attributes (page 1303).

```
NSString *NSGraphicsContextDestinationAttributeName;
NSString *NSGraphicsContextRepresentationFormatAttributeName;
```

Constants

NSGraphicsContextDestinationAttributeName
Can be an instance of NSWindow or NSBitmapImageRep when creating a graphics context.

When determining the type of a graphics context, this value can be an NSMutableData, NSString, or NSURL object.

Available in Mac OS X v10.0 and later.

Declared in NSGraphicsContext.h.

NSGraphicsContextRepresentationFormatAttributeName
Specifies the destination file format.

This value should be retrieved only and not used to create a graphics context.

Available in Mac OS X v10.0 and later.

Declared in NSGraphicsContext.h.

Representation format attribute keys

These constants are possible values for the NSGraphicsContextRepresentationFormatAttributeName key in a graphic context's attribute dictionary.

```
NSString *NSGraphicsContextPSFormat;
NSString *NSGraphicsContextPDFFormat;
```

Constants

NSGraphicsContextPDFFormat
Destination file format is PDF.

Available in Mac OS X v10.0 and later.

Declared in NSGraphicsContext.h.

NSGraphicsContextPSFormat
Destination file format is PostScript.

Available in Mac OS X v10.0 and later.

Declared in NSGraphicsContext.h.

NSImageInterpolation

These interpolations are used by `imageInterpolation` (page 1306) and `setImageInterpolation:` (page 1310).

```
enum {
    NSImageInterpolationDefault,
    NSImageInterpolationNone,
    NSImageInterpolationLow,
    NSImageInterpolationMedium,
    NSImageInterpolationHigh
};
typedef NSUInteger NSImageInterpolation;
```

Constants

`NSImageInterpolationDefault`
Use the context's default interpolation.
Available in Mac OS X v10.0 and later.
Declared in `NSGraphicsContext.h`.

`NSImageInterpolationNone`
No interpolation.
Available in Mac OS X v10.0 and later.
Declared in `NSGraphicsContext.h`.

`NSImageInterpolationLow`
Fast, low-quality interpolation.
Available in Mac OS X v10.0 and later.
Declared in `NSGraphicsContext.h`.

`NSImageInterpolationMedium`
Medium quality, slower than `NSImageInterpolationLow`.
Available in Mac OS X v10.6 and later.
Declared in `NSGraphicsContext.h`.

`NSImageInterpolationHigh`
Slower, higher-quality interpolation.
Available in Mac OS X v10.0 and later.
Declared in `NSGraphicsContext.h`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSGraphicsContext.h`

NSColorRenderingIntent

These constants specify how Cocoa should handle colors that are not located within the destination color space of a graphics context. These constants are used by the methods `setColorRenderingIntent:` (page 1308) and `colorRenderingIntent` (page 1304).

```
enum {
    NSColorRenderingIntentDefault,
    NSColorRenderingIntentAbsoluteColorimetric,
    NSColorRenderingIntentRelativeColorimetric,
    NSColorRenderingIntentPerceptual,
    NSColorRenderingIntentSaturation
};
typedef NSInteger NSColorRenderingIntent;
```

Constants

`NSColorRenderingIntentDefault`

Use the default rendering intent for the graphics context.

Available in Mac OS X v10.5 and later.

Declared in `NSGraphics.h`.

`NSColorRenderingIntentAbsoluteColorimetric`

Map colors outside of the gamut of the output device to the closest possible match inside the gamut of the output device.

This operation can produce a clipping effect, where two different color values in the gamut of the graphics context are mapped to the same color value in the output device's gamut. Unlike the relative colorimetric, absolute colorimetric does not modify colors inside the gamut of the output device.

Available in Mac OS X v10.5 and later.

Declared in `NSGraphics.h`.

`NSColorRenderingIntentRelativeColorimetric`

Map colors outside of the gamut of the output device to the closest possible match inside the gamut of the output device.

This operation can produce a clipping effect, where two different color values in the gamut of the graphics context are mapped to the same color value in the output device's gamut. The relative colorimetric shifts all colors (including those within the gamut) to account for the difference between the white point of the graphics context and the white point of the output device.

Available in Mac OS X v10.5 and later.

Declared in `NSGraphics.h`.

`NSColorRenderingIntentPerceptual`

Preserve the visual relationship between colors by compressing the gamut of the graphics context to fit inside the gamut of the output device.

Perceptual intent is good for photographs and other complex, detailed images.

Available in Mac OS X v10.5 and later.

Declared in `NSGraphics.h`.

`NSColorRenderingIntentSaturation`

Preserve the relative saturation value of the colors when converting into the gamut of the output device.

The result is an image with bright, saturated colors. Saturation intent is good for reproducing images with low detail, such as presentation charts and graphs.

Available in Mac OS X v10.5 and later.

Declared in `NSGraphics.h`.

NSHelpManager Class Reference

Inherits from	NSObject
Conforms to	NSObject (NSObject)
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.0 and later.
Declared in	AppKit/NSHelpManager.h
Companion guide	Online Help

Overview

The `NSHelpManager` class provides an approach to displaying online help. An application contains one `NSHelpManager` object.

Tasks

Getting the Help Manager

`+ sharedHelpManager` (page 1317)
Returns the shared `NSHelpManager` (page 1315) instance, creating it if it does not already exist.

Displaying Help

`- findString:inBook:` (page 1318)
Performs a search for the specified string in the specified book.

`- openHelpAnchor:inBook:` (page 1318)
Finds and displays the text at the given anchor location in the given book.

Dynamically Adding Help Books

`- registerBooksInBundle:` (page 1319)
Registers one or more help books in the given bundle.

Configuring Context-Sensitive Help

`+ isContextHelpModeActive` (page 1316)
Indicates whether context-sensitive help mode is active.

`+ setContextHelpModeActive:` (page 1316)
Specifies whether context-sensitive help mode is active.

`- setContextHelp:forObject:` (page 1320)
Associates help content with an object.

`- removeContextHelpForObject:` (page 1319)
Removes the association between an object and its context-sensitive help.

Displaying Context-Sensitive Help

`- contextHelpForObject:` (page 1317)
Returns context-sensitive help for an object.

`- showContextHelpForObject:locationHint:` (page 1320)
Displays the context-sensitive help for a given object at or near the point on the screen specified by a given point.

Class Methods

isContextHelpModeActive

Indicates whether context-sensitive help mode is active.

```
+ (BOOL)isContextHelpModeActive
```

Return Value
`YES` when the application is in context-sensitive help mode, `NO` otherwise.

Discussion
In context-sensitive help mode, when a user clicks a user interface item, help for that item is displayed in a small window just below the cursor.

Availability
Available in Mac OS X v10.0 and later.

See Also
`+ setContextHelpModeActive:` (page 1316)

Declared In
`NSHelpManager.h`

setContextHelpModeActive:

Specifies whether context-sensitive help mode is active.

```
+ (void)setContextHelpModeActive:(BOOL)contextHelpActive
```

Parameters

contextHelpActive

YES turns on context-sensitive help, NO turns it off.

Discussion

You never send this message directly; instead, the NSApplication method activateContextHelpMode: (page 136) activates context-sensitive help mode, and the first mouse click after displaying the context-sensitive help window deactivates it.

When the application enters context-sensitive help mode, the help manager posts an NSContextHelpModeDidActivateNotification (page 1321) to the default notification center. When the application returns to normal operation, the help manager posts an NSContextHelpModeDidDeactivateNotification (page 1321).

Availability

Available in Mac OS X v10.0 and later.

See Also

+ isContextHelpModeActive (page 1316)

Declared In

NSHelpManager.h

sharedHelpManager

Returns the shared NSHelpManager (page 1315) instance, creating it if it does not already exist.

```
+ (NSHelpManager *)sharedHelpManager
```

Return Value

Shared help manager.

Availability

Available in Mac OS X v10.0 and later.

Declared In

NSHelpManager.h

Instance Methods

contextHelpForObject:

Returns context-sensitive help for an object.

```
- (NSAttributedString *)contextHelpForObject:(id)object
```

Parameters

object

Object for which context-sensitive help is sought.

Return Value
Context-sensitive help content.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setContextHelp:forObject:` (page 1320)
- `showContextHelpForObject:locationHint:` (page 1320)

Declared In
`NSHelpManager.h`

findString:inBook:

Performs a search for the specified string in the specified book.

```
- (void)findString:(NSString *)query inBook:(NSString *)book
```

Parameters

query
String to search for.

book
Localized help book to search. When `nil`, all installed help books are searched.

Discussion
To search for a string in your bundle's localized help book, you could use code similar to the following:

```
NSString *locBookName = [[NSBundle mainBundle] objectForInfoDictionaryKey:
@"CFBundleHelpBookName"];
[[NSHelpManager sharedHelpManager] findString:@"Hello"  inBook:locBookName];
```

This is a wrapper for `AHRegisterHelpBook` (which is called only once to register the help book specified in the application's main bundle) and `AHSearch`.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`NSHelpManager.h`

openHelpAnchor:inBook:

Finds and displays the text at the given anchor location in the given book.

```
- (void)openHelpAnchor:(NSString *)anchor inBook:(NSString *)book
```

Parameters

anchor
Location of the desired text.

book
Help book containing the anchor. When `nil`, all installed help books are searched.

Discussion
To open an anchor in your bundle's localized help book, you could use code similar to the following:

```
NSString *locBookName = [[NSBundle mainBundle] objectForInfoDictionaryKey:
@"CFBundleHelpBookName"];
[[NSHelpManager sharedHelpManager] openHelpAnchor:@"anchor1"  inBook:locBookName];
```

This method is a wrapper for `AHRegisterHelpBook` (which is called only once to register the help book specified in the application's main bundle) and `AHLookupAnchor`.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`NSHelpManager.h`

registerBooksInBundle:

Registers one or more help books in the given bundle.

```
- (BOOL)registerBooksInBundle:(NSBundle *)bundle
```

Parameters
bundle
The bundle for additional help books. Books in the main bundle are automatically registered.

Return Value
`YES` if registration is successful, `NO` if if the bundle doesn't contain any help books or if registration fails.

Discussion
You use `registerBooksInBundle:` to register help books in, for example, a plug-in bundle. The `Info.plist` in the bundle should contain a help book directory path, which specifies one or more folders containing help books.

The main bundle is automatically registered by `openHelpAnchor:inBook:` (page 1318) and `findString:inBook:` (page 1318).

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSHelpManager.h`

removeContextHelpForObject:

Removes the association between an object and its context-sensitive help.

```
- (void)removeContextHelpForObject:(id)object
```

Parameters
object
Object to disassociate from its help content.

Discussion
If *object* does not have context-sensitive help associated with it, this method does nothing.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setContextHelp:forObject: (page 1320)

Declared In
NSHelpManager.h

setContextHelp:forObject:

Associates help content with an object.

```
- (void)setContextHelp:(NSAttributedString *)help forObject:(id)object
```

Parameters

help
Help content to associate with *object*.

object
Object to associate with *help*.

Discussion
When the application enters context-sensitive help mode, if *object* is clicked, *help* appears in the context-sensitive help window.

Availability
Available in Mac OS X v10.0 and later.

See Also
- removeContextHelpForObject: (page 1319)

Declared In
NSHelpManager.h

showContextHelpForObject:locationHint:

Displays the context-sensitive help for a given object at or near the point on the screen specified by a given point.

```
- (BOOL)showContextHelpForObject:(id)object locationHint:(NSPoint)point
```

Parameters

object
Object for which context-sensitive help is sought.

point
Screen location at which to display the help content; it's usually under the cursor.

Return Value
YES when help content is successfully displayed. NO if help content is not displayed (for example, when there is no context-sensitive help associated with *object*).

Availability
Available in Mac OS X v10.0 and later.

See Also
`- contextHelpForObject:` (page 1317)

Declared In
`NSHelpManager.h`

Notifications

NSContextHelpModeDidActivateNotification

Posted when the application enters context-sensitive help mode. This typically happens when the user holds down the Help key.

The notification object is the help manager. This notification does not contain a *`userInfo`* dictionary.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSHelpManager.h`

NSContextHelpModeDidDeactivateNotification

Posted when the application exits context-sensitive help mode. This happens when the user clicks the mouse button while the cursor is anywhere on the screen after displaying a context-sensitive help topic.

The notification object is the help manager. This notification does not contain a *`userInfo`* dictionary.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSHelpManager.h`

Overview

An `NSImage` object is a high-level class for manipulating image data. You use this class to load existing images or create new ones and composite them into a view or other image. This class works in conjunction with one or more image representation objects (subclasses of `NSImageRep`), which manage the actual image data.

Tasks

Initializing a New NSImage Object

`- initByReferencingFile:` (page 1350)
Initializes and returns an `NSImage` instance and associates it with the specified file.

`- initByReferencingURL:` (page 1351)
Initializes and returns an `NSImage` instance and associates it with the specified URL.

`- initWithCGImage:size:` (page 1351)
Initializes and returns an `NSImage` instance with the contents of the CGImage.

- `initWithContentsOfFile:` (page 1352)
  Initializes and returns an `NSImage` instance with the contents of the specified file.
- `initWithContentsOfURL:` (page 1352)
  Initializes and returns an `NSImage` instance with the contents of the specified URL.
- `initWithData:` (page 1353)
  Initializes and returns an `NSImage` instance with the contents of the specified `NSData` object.
- `initWithDataIgnoringOrientation:` (page 1353)
  Initializes and returns an `NSImage` instance with the contents of the specified `NSData` object, ignoring the EXIF orientation tags..
- `initWithPasteboard:` (page 1354)
  Initializes and returns an `NSImage` instance with data from the specified pasteboard.
- `initWithSize:` (page 1355)
  Initializes and returns an `NSImage` instance whose size is set to the specified value.
- `initWithIconRef:` (page 1354)
  Initializes the image object with a Carbon-style icon resource.

Setting the Image Attributes

- `setSize:` (page 1370)
  Sets the width and height of the image.
- `size` (page 1372)
  Returns the size of the receiver.
- `isTemplate` (page 1357)
  Returns a Boolean value indicating whether the image is a template image.
- `setTemplate:` (page 1371)
  Sets whether the image represents a template image.

Referring to Images by Name

+ `imageNamed:` (page 1330)
  Returns the `NSImage` instance associated with the specified name.
- `setName:` (page 1368)
  Registers the receiver under the specified name.
- `name` (page 1360)
  Returns the name associated with the receiver, if any.

Determining the Supported Image Types

+ `canInitWithPasteboard:` (page 1329)
  Tests whether the receiver can create an instance of itself using pasteboard data.
+ `imageTypes` (page 1332)
  Returns an array of UTI strings identifying the image types supported by the registered `NSImageRep` objects, either directly or through a user-installed filter service.

+ `imageUnfilteredTypes` (page 1334)
  Returns an array of UTI strings identifying the image types supported directly by the registered `NSImageRep` objects.
+ `imageFileTypes` (page 1330)
  Returns an array of strings identifying the image types supported by the registered `NSImageRep` objects.
+ `imageUnfilteredFileTypes` (page 1333)
  Returns an array of strings identifying the file types supported directly by the registered `NSImageRep` objects.
+ `imagePasteboardTypes` (page 1332)
  Returns an array of strings identifying the pasteboard types supported directly by the registered `NSImageRep` objects.
+ `imageUnfilteredPasteboardTypes` (page 1333)
  Returns an array of strings identifying the pasteboard types supported directly by the registered `NSImageRep` objects.

Working With Image Representations

- `addRepresentation:` (page 1335)
  Adds the specified image representation object to to the receiver.
- `addRepresentations:` (page 1335)
  Adds an array of image representation objects to the receiver.
- `representations` (page 1362)
  Returns an array containing all of the receiver's image representations.
- `removeRepresentation:` (page 1362)
  Removes the specified image representation from the receiver and releases it.
- `bestRepresentationForRect:context:hints:` (page 1338)
  Returns the best representation of the image for the specified rect using the provided hints.
- `bestRepresentationForDevice:` (page 1337) Deprecated in Mac OS X v10.6
  Returns the best representation for the device with the specified characteristics.

Hit Testing an Image

- `hitTestRect:withImageDestinationRect:context:hints:flipped:` (page 1349)
  Returns whether the destination rectangle would intersect a non-transparent portion of the image.

Setting the Image Representation Selection Criteria

- `setPrefersColorMatch:` (page 1369)
  Sets whether choosing an image representation favors color matching over resolution matching.
- `prefersColorMatch` (page 1361)
  Returns a Boolean value indicating whether the image prefers to choose image representations using color matching or resolution matching.

- `setUsesEPSOnResolutionMismatch:` (page 1371)
  Sets whether EPS image representations are preferred when no other representations match the resolution of the device.
- `usesEPSOnResolutionMismatch` (page 1374)
  Returns a Boolean value indicating whether EPS representations are preferred when no other representations match the resolution of the device.
- `setMatchesOnMultipleResolution:` (page 1368)
  Sets whether image representations whose resolutions are integral multiples of the device resolution are considered a match.
- `matchesOnMultipleResolution` (page 1360)
  Returns a Boolean value indicating whether image representations whose resolution is an integral multiple of the device resolution are considered a match.

Managing the Focus

- `lockFocus` (page 1358)
  Prepares the image to receive drawing commands.
- `lockFocusFlipped:` (page 1359)
  Prepares the image to receive drawing commands using the specified flipped state.
- `unlockFocus` (page 1374)
  Removes the focus from the receiver.
- `lockFocusOnRepresentation:` (page 1359) Deprecated in Mac OS X v10.6
  Prepares the specified image representation to receive drawing commands. (Deprecated. Use the code fragment shown in the special considerations below.)

Drawing the Image

- `drawAtPoint:fromRect:operation:fraction:` (page 1346)
  Draws all or part of the image at the specified point in the current coordinate system.
- `drawInRect:fromRect:operation:fraction:` (page 1347)
  Draws all or part of the image in the specified rectangle in the current coordinate system.
- `drawRepresentation:inRect:` (page 1348)
  Draws the image using the specified image representation object.
- `drawInRect:fromRect:operation:fraction:respectFlipped:hints:` (page 1347)
  Draws all or part of the image in the specified rectangle respecting the flippedness and hints.
- `compositeToPoint:fromRect:operation:` (page 1340) Deprecated in Mac OS X v10.6
  Composites a portion of the image to the specified point in the current coordinate system.
- `compositeToPoint:fromRect:operation:fraction:` (page 1341) Deprecated in Mac OS X v10.6
  Composites a portion of the image at the specified opacity to the current coordinate system.
- `compositeToPoint:operation:` (page 1342) Deprecated in Mac OS X v10.6
  Composites the entire image to the specified point in the current coordinate system.
- `compositeToPoint:operation:fraction:` (page 1343) Deprecated in Mac OS X v10.6
  Composites the entire image at the specified opacity in the current coordinate system.

- `dissolveToPoint:fraction:` (page 1344) Deprecated in Mac OS X v10.6
  Composites the entire image to the specified location using the `NSCompositeSourceOver` operator.
- `dissolveToPoint:fromRect:fraction:` (page 1345) Deprecated in Mac OS X v10.6
  Composites a portion of the image to the specified location using the `NSCompositeSourceOver` operator.

Working With Alignment Metadata

- `alignmentRect` (page 1336)
  Returns alignment metadata that your code can use to position the image during layout.
- `setAlignmentRect:` (page 1363)
  Sets the alignment metadata that your code can use to position the image during layout.

Setting the Image Storage Options

- `cacheMode` (page 1339)
  Returns the receiver's caching mode.
- `setCacheMode:` (page 1365)
  Set the receiver's caching mode.
- `cacheDepthMatchesImageDepth` (page 1338) Deprecated in Mac OS X v10.6
  Returns a Boolean value indicating whether an image's offscreen window caches use the same bit depth as the image data itself. (Deprecated. `NSImage` no longer caches to windows. A cache is now generated appropriate for the destination where an image is drawn. There is no replacement method.)
- `isCachedSeparately` (page 1356) Deprecated in Mac OS X v10.6
  Returns a Boolean value indicating whether each image representation caches its contents in a separate offscreen window. (Deprecated. NSImage no longer caches to windows. There is no replacement method)
- `isDataRetained` (page 1356) Deprecated in Mac OS X v10.6
  Returns a Boolean value indicating whether the receiver retains its source image data. (Deprecated. In Mac OS v10.6, `NSImage` no longer discards data in such a way that the original can no longer be reconstructed. There is no replacement method.)
- `setCacheDepthMatchesImageDepth:` (page 1364) Deprecated in Mac OS X v10.6
  Sets whether the receiver's offscreen window caches use the same bit depth as the image data itself. (Deprecated. `NSImage` no longer caches to windows. A cache is now generated appropriate for the destination where an image is drawn. There is no replacement method.)
- `setCachedSeparately:` (page 1365) Deprecated in Mac OS X v10.6
  Sets whether each image representation uses a separate offscreen window to cache its contents. (Deprecated. `NSImage` no longer caches to windows. There is no replacement method)
- `setDataRetained:` (page 1366) Deprecated in Mac OS X v10.6
  Sets whether the receiver retains its source image data. (Deprecated. In Mac OS v10.6, `NSImage` no longer discards data in such a way that the original can no longer be reconstructed. There is no replacement method.)

Setting the Image Drawing Options

- `isValid` (page 1357)
  Returns a Boolean value indicating whether an image representation from the receiver can be drawn.
- `setBackgroundColor:` (page 1364)
  Sets the background color of the image.
- `backgroundColor` (page 1336)
  Returns the background color of image.
- `isFlipped` (page 1357)
  Returns a Boolean value indicating whether the image uses a flipped coordinate system. (Deprecated. The flipped property of an image was widely misunderstood and has been deprecated. Use `drawInRect:fromRect:operation:fraction:respectFlipped:hints:` (page 1347) to draw respecting a context's flipped status and `lockFocusFlipped:` (page 1359) to draw into a flipped image.)
- `recache` (page 1361)
  Invalidates and frees the offscreen caches of all image representations.
- `scalesWhenResized` (page 1362) Deprecated in Mac OS X v10.6
  Returns a Boolean value indicating whether image representations are scaled to fit the receiver's size. (Deprecated. This method was related to caching behavior. In Mac OS X v10.6 and later image caching is no long necessary and as a resuilt there is no replacement necessary.)
- `setFlipped:` (page 1367) Deprecated in Mac OS X v10.6
  Sets whether the polarity of the y axis is inverted when drawing an image. (Deprecated. The flipped property of an image was widely misunderstood and has been deprecated. Use `drawInRect:fromRect:operation:fraction:respectFlipped:hints:` (page 1347) to draw respecting a context's flipped status and `lockFocusFlipped:` (page 1359) to draw into a flipped image.)
- `setScalesWhenResized:` (page 1369) Deprecated in Mac OS X v10.6
  Sets whether different-sized image representations are scaled to fit the receiver's size. (Deprecated. This method was related to caching behavior. In Mac OS X v10.6 and later image caching is no long necessary and as a resuilt there is no replacement necessary.)

Assigning a Delegate

- `setDelegate:` (page 1366)
  Sets the delegate object of the receiver.
- `delegate` (page 1344)
  Returns the delegate object of the receiver

Producing TIFF Data for the Image

- `TIFFRepresentation` (page 1372)
  Returns a data object containing TIFF data for all of the image representations in the receiver.
- `TIFFRepresentationUsingCompression:factor:` (page 1373)
  Returns a data object containing TIFF data with the specified compression settings for all of the image representations in the receiver.

Producing a CGImage from an Image

- `CGImageForProposedRect:context:hints:` (page 1339)
  Returns a `CGImage` capturing the drawing of the receiver.

Managing Incremental Loads

- `cancelIncrementalLoad` (page 1339)
  Cancels the current download operation immediately, if the image is being incrementally loaded.

Image Accessibility

- `accessibilityDescription` (page 1334)
  Returns the image's accessibility description.
- `setAccessibilityDescription:` (page 1363)
  Sets the image's accessibility description.

Class Methods

canInitWithPasteboard:

Tests whether the receiver can create an instance of itself using pasteboard data.

```
+ (BOOL)canInitWithPasteboard:(NSPasteboard *)pasteboard
```

Parameters

pasteboard
  The pasteboard containing the image data.

Return Value
`YES` if the receiver knows how to handle the data on the pasteboard; otherwise, `NO`.

Discussion
This method uses the `NSImageRep` class method `imageUnfilteredPasteboardTypes` (page 1411) to find a class that can handle the data in the specified pasteboard. If you create your own `NSImageRep` subclasses, override the `imageUnfilteredPasteboardTypes` (page 1411) method to notify `NSImage` of the pasteboard types your class supports.

Availability
Available in Mac OS X v10.0 and later.

See Also
`+ imagePasteboardTypes` (page 1332)

Related Sample Code
CocoaDragAndDrop
People

Declared In
NSImage.h

imageFileTypes

Returns an array of strings identifying the image types supported by the registered NSImageRep objects.

```
+ (NSArray *)imageFileTypes
```

Return Value
An array of NSString objects, each of which identifies a single supported file type. The array can include encoded HFS file types as well as filename extensions.

Discussion
This list includes all file types supported by registered subclasses of NSImageRep plus those that can be converted to a supported type by a user-installed filter service. You can pass the array returned by this method directly to the runModalForTypes: (page 1821) method of NSOpenPanel.

When creating a subclass of NSImageRep, do not override this method. Instead, override the imageUnfilteredFileTypes (page 1410) method to notify NSImage of the file types your class supports directly.

Availability
Available in Mac OS X v10.0 and later.

See Also
+ imageUnfilteredFileTypes (page 1333)

Declared In
NSImage.h

imageNamed:

Returns the NSImage instance associated with the specified name.

```
+ (id)imageNamed:(NSString *)name
```

Parameters
name
The name associated with the desired image.

Return Value
The NSImage object associated with the specified name, or nil if no such image was found.

Discussion
This method searches for named images in several places, returning the first image it finds matching the given name. The order of the search is as follows:

1. Search for an object whose name was set explicitly using the setName: method and currently resides in the image cache.
2. Search the application's main bundle for a file whose name matches the specified string. (For information on how the bundle is searched, see ""Accessing a Bundle's Contents"" in *Bundle Programming Guide*.)
3. Search the Application Kit framework for a shared image with the specified name.

When looking for files in the application bundle, it is better (but not required) to include the filename extension in the `name` parameter. When naming an image with the setName: method, it is also convention not to include filename extensions in the names you specify. That way, you can easily distinguish between images you have named explicitly and those you want to load from the application's bundle.

One particularly useful image you can retrieve is your application's icon. This image is set by Cocoa automatically and referenced by the string `@"NSApplicationIcon"`. Icons for other applications can be obtained through the use of methods declared in the `NSWorkspace` class. You can also retrieve many of the standard system images using Cocoa defined constants; for more information, see the "Image Template Constants" (page 1380), "Sharing Permissions Named Images" (page 1385), "System Entity Images" (page 1386), "Toolbar Named Images" (page 1387), and "View Type Template Images" (page 1390) sections for applicable constants.

If an application is linked in Mac OS X v10.5 or later, images requested using this method and whose name ends in the word "Template" are automatically marked as template images.

The `NSImage` class may cache a reference to the returned image object for performance in some cases. However, the class holds onto cached objects only while the object exists. If the image object is subsequently released, either because its retain count was 0 or it was not referenced anywhere in a garbage-collected application, the object may be quietly removed from the cache. Thus, if you plan to hold onto a returned image object, you must retain it like you would any Cocoa object. You can clear an image object from the cache explicitly by calling the object's setName: method and passing `nil` for the image name.

Availability
Available in Mac OS X v10.0 and later.

`NSImage.h`

imagePasteboardTypes

Returns an array of strings identifying the pasteboard types supported directly by the registered `NSImageRep` objects.

```
+ (NSArray *)imagePasteboardTypes
```

Return Value
An array of `NSString` objects, each of which identifies a single supported pasteboard type. By default, this list contains the `NSPDFPboardType`, `NSPICTPboardType`, `NSPostScriptPboardType`, and `NSTIFFPboardType` types.

Discussion
This list includes all pasteboard types supported by registered subclasses of `NSImageRep` plus those that can be converted to a supported type by a user-installed filter service.

When creating a subclass of `NSImageRep`, do not override this method. Instead, override the `imageUnfilteredPasteboardTypes` (page 1411) method to notify `NSImage` of the pasteboard types your class supports.

Availability
Available in Mac OS X v10.0 and later.

imageTypes

Returns an array of UTI strings identifying the image types supported by the registered `NSImageRep` objects, either directly or through a user-installed filter service.

```
+ (NSArray *)imageTypes
```

Return Value
An array of `NSString` objects, each of which contains a UTI identifying a supported image type. Some sample image-related UTI strings include "`public.image`", "`public.jpeg`", and "`public.tiff`". For a list of supported types, see `UTCoreTypes.h`.

Discussion
The returned list includes UTIs all file types supported by registered subclasses of `NSImageRep` plus those that can be converted to a supported type by a user-installed filter service. You can use the returned UTI strings with any method that supports UTIs.

You should not override this method directly. Instead, you should override the `imageTypes` method of `NSImageRep`.

Availability
Available in Mac OS X v10.5 and later.

See Also

LightTable

Declared In
`NSImage.h`

imageUnfilteredFileTypes

Returns an array of strings identifying the file types supported directly by the registered `NSImageRep` objects.

```
+ (NSArray *)imageUnfilteredFileTypes
```

Return Value
An array of `NSString` objects, each of which identifies a single supported file type. File types are identified by file extension and HFS file types.

Discussion
The returned list does not contain pasteboard types that are available only through a user-installed filter service.

Availability
Available in Mac OS X v10.0 and later.

See Also

Instance Methods

accessibilityDescription

Returns the image's accessibility description.

```
- (NSString *)accessibilityDescription
```

Return Value
A short localized string that does not include the name of the interface element.

Availability
Available in Mac OS X v10.6 and later.

See Also
- `setAccessibilityDescription:` (page 1363)

Declared In
`NSImage.h`

addRepresentation:

Adds the specified image representation object to to the receiver.

```
- (void)addRepresentation:(NSImageRep *)imageRep
```

Parameters

imageRep
The image representation to add.

Discussion
After invoking this method, you may need to explicitly set features of the new image representation, such as the size, number of colors, and so on. This is true particularly when the `NSImage` object has multiple image representations to choose from. See `NSImageRep` and its subclasses for the methods you use to complete initialization.

Any representation added by this method is retained by the receiver. Image representations cannot be shared among multiple `NSImage` objects.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `representations` (page 1362)
- `removeRepresentation:` (page 1362)

`NSImage.h`

addRepresentations:

Adds an array of image representation objects to the receiver.

```
- (void)addRepresentations:(NSArray *)imageReps
```

Parameters

imageReps

An array of `NSImageRep` objects.

Discussion

After invoking this method, you may need to explicitly set features of the new image representations, such as their size, number of colors, and so on. This is true particularly when the `NSImage` object has multiple image representations to choose from. See `NSImageRep` and its subclasses for the methods you use to complete initialization.

Representations added by this method are retained by the receiver. Image representations cannot be shared among multiple `NSImage` objects.

Availability

Available in Mac OS X v10.0 and later.

- `representations` (page 1362)
- `removeRepresentation:` (page 1362)

Declared In

`NSImage.h`

alignmentRect

Returns alignment metadata that your code can use to position the image during layout.

```
- (NSRect)alignmentRect
```

Return Value

A rectangle containing the layout information for the image. If not set, the returned rectangle has an origin of (0, 0) and a size that matches the size of the image.

Discussion

The returned rectangle is merely a hint that your own code can use to determine positioning. The `NSImage` class does not use this rectangle during drawing. However, instances of `NSCell` typically use this information when laying out images within their own boundaries.

Availability

Available in Mac OS X v10.5 and later.

See Also

- `setAlignmentRect:` (page 1363)

Declared In

`NSImage.h`

backgroundColor

Returns the background color of image.

```
- (NSColor *)backgroundColor
```

Return Value
The background color of the image. The default color is transparent, as returned by the `clearColor` (page 668) method of `NSColor`.

Discussion
The background color is visible only if the drawn image representation does not completely cover all of the pixels available for the image's current size.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSImage.h`

bestRepresentationForDevice:

Returns the best representation for the device with the specified characteristics. (Deprecated in Mac OS X v10.6.)

```
- (NSImageRep *)bestRepresentationForDevice:(NSDictionary *)deviceDescription
```

Parameters

deviceDescription
A dictionary of attributes for the specified device, or `nil` to specify the current device. For a list of dictionary keys and values appropriate to display and print devices, see the constants in `NSScreen`.

Return Value
The image representation that most closely matches the specified criteria.

Discussion
If *deviceDescription* is `nil`, this method uses the attributes of the device on which the content is to be drawn.

For information on how the "best" representation is chosen, see the “Images” chapter of *Cocoa Drawing Guide*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.6.

bestRepresentationForRect:context:hints:

Returns the best representation of the image for the specified rect using the provided hints.

```
- (NSImageRep *)bestRepresentationForRect:(NSRect)rect context:(NSGraphicsContext
    *)referenceContext hints:(NSDictionary *)hints
```

Parameters

rect
The area of the image to return.

referenceContext
A graphics context. This value can be nil.

hints
An optional dictionary of hints that provide more context for selecting or generating a CGImage, and may override properties of the *referenceContext*. See "Image Hint Dictionary Keys" (page 1375) for a summary of the possible key-value pairs.

Return Value
The image representation that most closely matches the specified criteria.

Availability
Available in Mac OS X v10.6 and later.

Declared In
NSImage.h

cacheDepthMatchesImageDepth

Returns a Boolean value indicating whether an image's offscreen window caches use the same bit depth as the image data itself. (Deprecated in Mac OS X v10.6. NSImage no longer caches to windows. A cache is now generated appropriate for the destination where an image is drawn. There is no replacement method.)

```
- (BOOL)cacheDepthMatchesImageDepth
```

Return Value
YES if the offscreen window caches use the same bit depth as the image data; otherwise, NO. The default value is NO.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.6.

See Also
- setCacheDepthMatchesImageDepth: (page 1364)

Declared In
NSImage.h

cacheMode

Returns the receiver's caching mode.

```
- (NSImageCacheMode)cacheMode
```

Return Value
A value indicating the caching mode. For a list of possible values, see `NSImageCacheMode` (page 1379). This value is set to `NSImageCacheDefault` by default.

Availability
Available in Mac OS X v10.2 and later.

See Also
`- setCacheMode:` (page 1365)

Declared In
`NSImage.h`

cancelIncrementalLoad

Cancels the current download operation immediately, if the image is being incrementally loaded.

```
- (void)cancelIncrementalLoad
```

Discussion
This call has no effect if the image is not loading.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`NSImage.h`

CGImageForProposedRect:context:hints:

Returns a `CGImage` capturing the drawing of the receiver.

```
- (CGImageRef)CGImageForProposedRect:(NSRect *)proposedDestRect
    context:(NSGraphicsContext *)referenceContext hints:(NSDictionary *)hints
```

Parameters

proposedDestRect
On input, the proposed destination rectangle for drawing the image. If `NULL`, it defaults to the smallest pixel-integral rectangle containing {{0,0}, [self size]}. The *proposedDestRect* is in user space in the reference context.

referenceContext
A graphics context.

hints
A dictionary of hints that provide more context for selecting or generating a `CGImage`, and may override properties of the *referenceContext*.

Return Value
A `CGImageRef`. This may be an existing `CGImage` if one is available. If not, a new `CGImage` is created.

Discussion
An `NSImage` is potentially resolution independent, and may have representations that allow it to draw well in many contexts. A `CGImage` is more like a single pixel-based representation. This method produces a snapshot of how the `NSImage` would draw if it was asked to draw in the proposed rectangle in the graphics context.

All input parameters are optional. They provide hints for how to choose among existing CGImages, or how to create one if there isn't already a CGImage available. The parameters are only hints.

This method is typically called, not overridden.

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSImage.h`

compositeToPoint:fromRect:operation:

Composites a portion of the image to the specified point in the current coordinate system. (Deprecated in Mac OS X v10.6.)

```
- (void)compositeToPoint:(NSPoint)aPoint fromRect:(NSRect)srcRect
    operation:(NSCompositingOperation)op
```

Parameters

aPoint
The point at which to draw the image, specified in the current coordinate system.

srcRect
The portion of the image you want to draw, specified in the image's coordinate system.

op
The compositing operation to use when drawing the image to the screen. The supported compositing operations are described in "Constants" (page 1375).

Discussion
This method draws the specified portion of the image without checking the bounds rectangle you pass into the *srcRect* parameter. If you specify a source rectangle that strays outside of the image's bounds rectangle, it is conceivable that you could composite parts of the offscreen cache window that do not belong to the receiver's image. You can avoid this problem using the `drawAtPoint:fromRect:operation:fraction:` (page 1346) method, which checks the source rectangle before drawing.

During drawing, the image is composited from its offscreen window cache. Because the offscreen cache is not created until the image representation is first used, this method may need to render the image before compositing. Bitmap representations in particular are not cached until they are explicitly rendered. You can use the `lockFocus` (page 1358) and `unlockFocus` (page 1374) methods to force the cached version to be created.

Compositing part of an image is as efficient as compositing the whole image, but printing just part of an image is not. When printing, it's necessary to draw the whole image and rely on a clipping path to be sure that only the desired portion appears.

During printing, this method ignores the `op` parameter. Even though this parameter is ignored, this method attempts to render the image as close as possible to its appearance when the compositing operation is used on the screen. In either case, the best image representation is chosen for the printing context.

Important: If you are writing new code, or updating old code, you should avoid using this method. Instead, you should use the drawAtPoint:fromRect:operation:fraction: or `drawInRect:fromRect:operation:fraction:` method to draw the image. Although the method itself is not deprecated, the behavior it provides is not recommended for general use.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.6.

See Also
- `dissolveToPoint:fromRect:fraction:` (page 1345)

Declared In
`NSImage.h`

compositeToPoint:fromRect:operation:fraction:

Composites a portion of the image at the specified opacity to the current coordinate system. (Deprecated in Mac OS X v10.6.)

```
- (void)compositeToPoint:(NSPoint)aPoint fromRect:(NSRect)srcRect
    operation:(NSCompositingOperation)op fraction:(CGFloat)delta
```

Parameters

aPoint
The point at which to draw the image, specified in the current coordinate system.

srcRect
The portion of the image you want to draw, specified in the image's coordinate system.

op
The compositing operation to use when drawing the image to the screen. The supported compositing operations are described in "Constants" (page 1375).

delta
The desired opacity of the image, specified as a value between 0.0 and 1.0, with 1.0 representing total opacity. Values larger than 1.0 are interpreted as 1.0. This method always expects to render something, so for values that are equal to or less than 0, this method renders at full opacity.

Discussion
Behaves the same as `compositeToPoint:fromRect:operation:` (page 1340) except that you can specify the amount of opacity to use when drawing the image.

Important: If you are writing new code, or updating old code, you should avoid using this method. Instead, you should use the drawAtPoint:fromRect:operation:fraction: or `drawInRect:fromRect:operation:fraction:` method to draw the image. Although the method itself is not deprecated, the behavior it provides is not recommended for general use.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.6.

Declared In
`NSImage.h`

compositeToPoint:operation:

Composites the entire image to the specified point in the current coordinate system. (Deprecated in Mac OS X v10.6.)

```
- (void)compositeToPoint:(NSPoint)aPoint operation:(NSCompositingOperation)op
```

Parameters

aPoint
The point at which to draw the image, specified in the current coordinate system.

op
The compositing operation to use when drawing the image to the screen. The supported compositing operations are described in "Constants" (page 1375).

Discussion
This method draws the receiver's best image representation at the specified point in the currently focused view. The entire image is drawn using its current size information. During drawing, the image is composited from its offscreen window cache. Because the offscreen cache is not created until the image representation is first used, this method may need to render the image before compositing. Bitmap representations in particular are not cached until they are explicitly rendered. You can use the `lockFocus` (page 1358) and `unlockFocus` (page 1374) methods to force the cached version to be created.

During printing, this method ignores the `op` parameter. Even though this parameter is ignored, this method attempts to render the image as close as possible to its appearance when the compositing operation is used on the screen. In either case, the best image representation is chosen for the printing context.

Important: If you are writing new code, or updating old code, you should avoid using this method. Instead, you should use the drawAtPoint:fromRect:operation:fraction: or `drawInRect:fromRect:operation:fraction:` method to draw the image. Although the method itself is not deprecated, the behavior it provides is not recommended for general use.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.6.

compositeToPoint:operation:fraction:

Composites the entire image at the specified opacity in the current coordinate system. (Deprecated in Mac OS X v10.6.)

```
- (void)compositeToPoint:(NSPoint)aPoint operation:(NSCompositingOperation)op
    fraction:(CGFloat)delta
```

Parameters

aPoint
The point at which to draw the image, specified in the current coordinate system.

op
The compositing operation to use when drawing the image to the screen. The supported compositing operations are described in "Constants" (page 1375).

delta
The desired opacity of the image, specified as a value between 0.0 and 1.0, with 1.0 representing total opacity. Values larger than 1.0 are interpreted as 1.0. This method always expects to render something, so for values that are equal to or less than 0, this method renders at full opacity.

Discussion
Behaves the same as `compositeToPoint:operation:` (page 1342) except that you can specify the amount of opacity to use when drawing the image.

Important: If you are writing new code, or updating old code, you should avoid using this method. Instead, you should use the drawAtPoint:fromRect:operation:fraction: or `drawInRect:fromRect:operation:fraction:` method to draw the image. Although the method itself is not deprecated, the behavior it provides is not recommended for general use.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.6.

delegate

Returns the delegate object of the receiver

```
- (id < NSImageDelegate >)delegate
```

Return Value
The current delegate object, or `nil` if no delegate has been set.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setDelegate:` (page 1366)

Declared In
`NSImage.h`

dissolveToPoint:fraction:

Composites the entire image to the specified location using the `NSCompositeSourceOver` operator. (Deprecated in Mac OS X v10.6.)

```
- (void)dissolveToPoint:(NSPoint)aPoint fraction:(CGFloat)delta
```

Parameters

aPoint
The point at which to draw the image, specified in the current coordinate system.

delta
The desired opacity of the image, specified as a value between 0.0 and 1.0. A value of 0.0 renders the image totally transparent while 1.0 renders it fully opaque. Values larger than 1.0 are interpreted as 1.0.

Discussion
Except for the choice of compositing operator, this method behaves in the same way as the `compositeToPoint:operation:` (page 1342) method. During printing, the *delta* parameter is ignored.

If the source image contains alpha information, this operation may promote the destination `NSWindow` object to contain alpha information.

To slowly dissolve this image onto another, you can invoke this method (or the `dissolveToPoint:fromRect:fraction:` (page 1345) method) repeatedly with an ever-increasing *delta* value. Because the *delta* parameter refers to the visible fraction of the source image, increasing the value causes the source image to replace the destination content gradually. You should generally perform this type of operation using a buffered window or other offscreen drawing environment.

Special Considerations

If you are writing new code, or updating old code, you should avoid using this method. Instead, you should use the drawAtPoint:fromRect:operation:fraction: or `drawInRect:fromRect:operation:fraction:` method to draw the image. Although the method itself is not deprecated, the behavior it provides is not recommended for general use.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.6.

Declared In
`NSImage.h`

dissolveToPoint:fromRect:fraction:

Composites a portion of the image to the specified location using the `NSCompositeSourceOver` operator. (Deprecated in Mac OS X v10.6.)

```
- (void)dissolveToPoint:(NSPoint)aPoint fromRect:(NSRect)srcRect
    fraction:(CGFloat)delta
```

Parameters

aPoint

The point at which to draw the image, specified in the current coordinate system.

srcRect

The portion of the image you want to draw, specified in the image's coordinate system.

delta

The desired opacity of the image, specified as a value between 0.0 and 1.0. A value of 0.0 renders the image totally transparent while 1.0 renders it fully opaque. Values larger than 1.0 are interpreted as 1.0.

Discussion
Except for the choice of compositing operator, this method behaves in the same way as the `compositeToPoint:fromRect:operation:` (page 1340) method. During printing, the *delta* parameter is ignored.

If the source image contains alpha information, this operation may promote the destination `NSWindow` object to contain alpha information.

Special Considerations

If you are writing new code, or updating old code, you should avoid using this method. Instead, you should use the drawAtPoint:fromRect:operation:fraction: or `drawInRect:fromRect:operation:fraction:` method to draw the image. Although the method itself is not deprecated, the behavior it provides is not recommended for general use.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.6.

See Also
- `dissolveToPoint:fraction:` (page 1344)

Declared In
`NSImage.h`

drawAtPoint:fromRect:operation:fraction:

Draws all or part of the image at the specified point in the current coordinate system.

```
- (void)drawAtPoint:(NSPoint)point fromRect:(NSRect)srcRect
    operation:(NSCompositingOperation)op fraction:(CGFloat)delta
```

Parameters

point

The location in the current coordinate system at which to draw the image.

srcRect

The source rectangle specifying the portion of the image you want to draw. The coordinates of this rectangle are specified in the image's own coordinate system. If you pass in `NSZeroRect`, the entire image is drawn.

op

The compositing operation to use when drawing the image. See the `NSCompositingOperation` (page 1375) constants.

delta

The opacity of the image, specified as a value from 0.0 to 1.0. Specifying a value of 0.0 draws the image as fully transparent while a value of 1.0 draws the image as fully opaque. Values greater than 1.0 are interpreted as 1.0.

Discussion
The image content is drawn at its current resolution and is not scaled unless the CTM of the current coordinate system itself contains a scaling factor. The image is otherwise positioned and oriented using the current coordinate system.

Unlike the `compositeToPoint:fromRect:operation:` (page 1340) and `compositeToPoint:fromRect:operation:fraction:` (page 1341) methods, this method checks the rectangle you pass to the *srcRect* parameter and makes sure it does not lie outside the image bounds.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `dissolveToPoint:fraction:` (page 1344)
- `drawInRect:fromRect:operation:fraction:` (page 1347)

ComplexBrowser
Reducer

Declared In
`NSImage.h`

drawInRect:fromRect:operation:fraction:

Draws all or part of the image in the specified rectangle in the current coordinate system.

```
- (void)drawInRect:(NSRect)dstRect fromRect:(NSRect)srcRect
    operation:(NSCompositingOperation)op fraction:(CGFloat)delta
```

Parameters

dstRect

The rectangle in which to draw the image, specified in the current coordinate system.

srcRect

The source rectangle specifying the portion of the image you want to draw. The coordinates of this rectangle must be specified using the image's own coordinate system. If you pass in `NSZeroRect`, the entire image is drawn.

op

The compositing operation to use when drawing the image. See the `NSCompositingOperation` (page 1375) constants.

delta

The opacity of the image, specified as a value from 0.0 to 1.0. Specifying a value of 0.0 draws the image as fully transparent while a value of 1.0 draws the image as fully opaque. Values greater than 1.0 are interpreted as 1.0.

Discussion

If the `srcRect` and `dstRect` rectangles have different sizes, the source portion of the image is scaled to fit the specified destination rectangle. The image is otherwise positioned and oriented using the current coordinate system.

Unlike the `compositeToPoint:fromRect:operation:` (page 1340) and `compositeToPoint:fromRect:operation:fraction:` (page 1341) methods, this method checks the rectangle you pass to the *srcRect* parameter and makes sure it does not lie outside the image bounds.

Availability

Available in Mac OS X v10.0 and later.

Transformed Image

WebKitDOMElementPlugIn

Declared In

`NSImage.h`

drawInRect:fromRect:operation:fraction:respectFlipped:hints:

Draws all or part of the image in the specified rectangle respecting the flippedness and hints.

```
- (void)drawInRect:(NSRect)dstSpacePortionRect fromRect:(NSRect)srcSpacePortionRect
    operation:(NSCompositingOperation)op fraction:(CGFloat)requestedAlpha
   respectFlipped:(BOOL)respectContextIsFlipped hints:(NSDictionary *)hints
```

Parameters

dstSpacePortionRect

The rectangle in which to draw the image, specified in the current coordinate system.

srcSpacePortionRect

The source rectangle specifying the portion of the image you want to draw. The coordinates of this rectangle must be specified using the image's own coordinate system. If you pass in `NSZeroRect`, the entire image is drawn.

op

The compositing operation to use when drawing the image. See the `NSCompositingOperation` (page 1375) constants.

requestedAlpha

The alpha of the image, specified as a value from 0.0 to 1.0. Specifying a value of 0.0 draws the image as fully transparent while a value of 1.0 draws the image as fully opaque. Values greater than 1.0 are interpreted as 1.0.

respectContextIsFlipped

`YES` if the drawing should respect the context flipped state, otherwise `NO`.

hints

An optional dictionary of hints that provide more context for selecting or generating the image. See "Image Hint Dictionary Keys" (page 1375) for a summary of the possible key-value pairs.

Discussion

If the *srcSpacePortionRect* and *dstSpacePortionRect* rectangles have different sizes, the source portion of the image is scaled to fit the specified destination rectangle.

Availability

Available in Mac OS X v10.6 and later.

Declared In

`NSImage.h`

drawRepresentation:inRect:

Draws the image using the specified image representation object.

```
- (BOOL)drawRepresentation:(NSImageRep *)imageRep inRect:(NSRect)dstRect
```

Parameters

imageRep

The image representation object to be drawn.

dstRect

The rectangle in which to draw the image representation, specified in the current coordinate system.

Return Value

`YES` if the image was successfully drawn; otherwise, returns `NO`.

Discussion
This method fills the specified rectangle with the image's current background color and then sends a message to the specified image representation asking if to draw itself. If the image supports the ability to scale itself when it is resized, this method sends a `drawInRect:` (page 1417) message; otherwise, it sends a `drawAtPoint:` (page 1416) message.

You should not call this method directly; an `NSImage` object uses it to cache and print its image representations. You can override this method to change the way images are rendered into their caches and onto the printed page. For example, you could scale or rotate the coordinate system before sending this message to `super` to continue rendering the image representation.

If the background color is fully transparent and the image data is not being cached, the specified rectangle is not to be filled before the representation draws.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- backgroundColor` (page 1336)

hitTestRect:withImageDestinationRect:context:hints:flipped:

Returns whether the destination rectangle would intersect a non-transparent portion of the image.

```
- (BOOL)hitTestRect:(NSRect)testRectDestSpace withImageDestinationRect:(NSRect)imageRectDestSpace context:(NSGraphicsContext *)referenceContext hints:(NSDictionary *)hints flipped:(BOOL)flipped
```

Parameters

testRectDestSpace
The rectangle to hit test.

imageRectDestSpace
A rectangle representing the drawn size of the image.

referenceContext
A graphics context. This value can be `nil`.

hints
An optional dictionary of hints that provide more context for selecting or generating a `CGImage`, and may override properties of the *referenceContext*. See "Image Hint Dictionary Keys" (page 1375) for a summary of the possible key-value pairs.

flipped
`YES` if the image is flipped, otherwise `NO`.

Return Value
YES if the *testRectDestSpace* intersects with non-transparent content within the *imageRectDestSpace*, otherwise NO.

Discussion
This method simulates the results of hit-testing the test rectangle as if the image was drawn in the graphics context using the provided hints and respecting the specified flippedness..

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSImage.h`

initByReferencingFile:

Initializes and returns an `NSImage` instance and associates it with the specified file.

```
- (id)initByReferencingFile:(NSString *)filename
```

Parameters

filename

A full or relative path name specifying the file with the desired image data. Relative paths must be relative to the current working directory.

Return Value
An initialized `NSImage` instance, or `nil` if the new instance cannot be initialized.

Discussion
This method initializes the image object lazily. It does not actually open the specified file or create any image representations from its data until an application attempts to draw the image or request information about it.

The *filename* parameter should include the file extension that identifies the type of the image data. The mechanism that actually creates the image representation for *filename* looks for an `NSImageRep` subclass that handles that data type from among those registered with `NSImage`.

Because this method doesn't actually create image representations for the image data, your application should do error checking before attempting to use the image; one way to do so is by invoking the `isValid` (page 1357) method to check whether the image can be drawn.

This method invokes `setDataRetained:` (page 1366) with an argument of `YES`, thus enabling it to hold onto its filename. When archiving an image created with this method, only the image's filename is written to the archive.

If the cached version of the image uses less memory than the original image data, the original data is flushed and the cached image is used. (This can occur for images whose resolution is greater than 72 dpi.) If you resize the image by less than 50%, the data is loaded in again from the file. If you expect the file to change or be deleted, you should use `initWithContentsOfFile:` (page 1352) instead.

Availability
Available in Mac OS X v10.0 and later.

Rulers

Declared In
`NSImage.h`

initByReferencingURL:

Initializes and returns an `NSImage` instance and associates it with the specified URL.

```
- (id)initByReferencingURL:(NSURL *)url
```

Parameters

url

The URL identifying the image.

Return Value

An initialized `NSImage` instance, or `nil` if the new instance cannot be initialized.

Discussion

This method initializes the image object lazily. It does not attempt to retrieve the data from the specified URL or create any image representations from that data until an application attempts to draw the image or request information about it.

This `url` parameter should include a file extension that identifies the type of the image data. The mechanism that actually creates the image representation looks for an `NSImageRep` subclass that handles that data type from among those registered with `NSImage`.

Because this method doesn't actually create image representations for the image data, your application should do error checking before attempting to use the image; one way to do so is by invoking the `isValid` (page 1357) method to check whether the image can be drawn.

This method invokes `setDataRetained:` (page 1366) with an argument of `YES`, thus enabling it to hold onto its URL. When archiving an image created with this method, only the image's URL is written to the archive.

Availability

Available in Mac OS X v10.2 and later.

Related Sample Code

AnimatedTableView

TrackBall

Declared In

`NSImage.h`

initWithCGImage:size:

Initializes and returns an `NSImage` instance with the contents of the CGImage.

```
- (id)initWithCGImage:(CGImageRef)cgImage size:(NSSize)size
```

Parameters

cgImage

The source `CGImage`.

size

The size of the new image. If size is `NSZeroSize`, the pixel dimensions of *cgImage* are assumed as the image's size.

Return Value

An initialized `NSImage` instance, or `nil` if the new instance cannot be initialized.

Discussion
You should not assume anything about the image, other than that drawing it is equivalent to drawing the `CGImage`.

This is not a designated initializer.

Availability
Available in Mac OS X v10.6 and later.

CameraBrowser
QuickLookDownloader
SimpleCameraBrowser

Declared In
`NSImage.h`

initWithContentsOfFile:

Initializes and returns an `NSImage` instance with the contents of the specified file.

```
- (id)initWithContentsOfFile:(NSString *)filename
```

Parameters

filename

A full or relative path name specifying the file with the desired image data. Relative paths must be relative to the current working directory.

Return Value
An initialized `NSImage` instance, or `nil` if the method cannot create an image representation from the contents of the specified file.

Discussion
Unlike `initByReferencingFile:` (page 1350), which initializes an `NSImage` object lazily, this method immediately opens the specified file and creates one or more image representations from its data.

The *filename* parameter should include the file extension that identifies the type of the image data. This method looks for an `NSImageRep` subclass that handles that data type from among those registered with `NSImage`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSImage.h`

initWithContentsOfURL:

Initializes and returns an `NSImage` instance with the contents of the specified URL.

```
- (id)initWithContentsOfURL:(NSURL *)aURL
```

Parameters

aUrl

The URL identifying the image.

Return Value

An initialized `NSImage` instance, or `nil` if the method cannot create an image representation from the contents of the specified URL.

Availability

Available in Mac OS X v10.0 and later.

CocoaCreateMovie

Declared In

`NSImage.h`

initWithData:

Initializes and returns an `NSImage` instance with the contents of the specified `NSData` object.

```
- (id)initWithData:(NSData *)data
```

Parameters

data

The data object containing the image data.

Return Value

An initialized `NSImage` instance, or `nil` if the method cannot create an image representation from the contents of the specified data object.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSImage.h`

initWithDataIgnoringOrientation:

Initializes and returns an `NSImage` instance with the contents of the specified `NSData` object, ignoring the EXIF orientation tags..

```
- (id)initWithDataIgnoringOrientation:(NSData *)data
```

Parameters

data

The data object containing the image data.

Return Value

An initialized `NSImage` instance, or `nil` if the method cannot create an image representation from the contents of the specified data object.

Availability

Available in Mac OS X v10.6 and later.

Declared In
NSImage.h

initWithIconRef:

Initializes the image object with a Carbon-style icon resource.

```
- (id)initWithIconRef:(IconRef)iconRef
```

Parameters

iconRef

A reference to a Carbon icon resource.

Return Value
An initialized NSImage instance.

Discussion
Creates one or more bitmap image representations, one for each size icon contained in the IconRef data structure. This initialization method automatically retains the data in the iconRef parameter and loads the bitmaps from that data file lazily.

Availability
Available in Mac OS X v10.5 and later.

Declared In
NSImage.h

initWithPasteboard:

Initializes and returns an NSImage instance with data from the specified pasteboard.

```
- (id)initWithPasteboard:(NSPasteboard *)pasteboard
```

Parameters

pasteboard

The pasteboard containing the image data.

Return Value
An initialized NSImage instance, or nil if the method cannot create an image representation from the contents of the pasteboard.

Discussion
The specified pasteboard should contain a type supported by one of the registered NSImageRep subclasses. Table 61-1 lists the default pasteboard types and file extensions for several NSImageRep subclasses.

Table 61-1 Default pasteboard types for image representations

Image representation class	Default pasteboard type	Default file extensions
NSBitmapImageRep	NSTIFFPboardType	tiff, gif, jpg, and others
NSPDFImageRep	NSPDFPboardType	pdf
NSEPSImageRep	NSPostscriptPboardType	eps

Image representation class	Default pasteboard type	Default file extensions
NSPICTImageRep	NSPICTPboardType	pict

If the specified pasteboard contains the value NSFilenamesPboardType, each filename on the pasteboard should have an extension supported by one of the registered NSImageRep subclasses. You can use the imageUnfilteredFileTypes (page 1410) method of a given subclass to obtain the list of supported types for that class.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSImage.h

initWithSize:

Initializes and returns an NSImage instance whose size is set to the specified value.

```
- (id)initWithSize:(NSSize)aSize
```

Parameters

aSize

The size of the image, measured in points.

Return Value
An initialized NSImage instance.

Discussion
This method does not add any image representations to the image object.. It is permissible to initialize the receiver by passing a size of (0.0, 0.0); however, the receiver's size must be set to a non-zero value before the NSImage object is used or an exception will be raised.

Availability
Available in Mac OS X v10.0 and later.

Sketch-112

Declared In
NSImage.h

isCachedSeparately

Returns a Boolean value indicating whether each image representation caches its contents in a separate offscreen window. (Deprecated in Mac OS X v10.6. NSImage no longer caches to windows. There is no replacement method)

```
- (BOOL)isCachedSeparately
```

Return Value
`YES` if the image representations cache their content in separate offscreen windows; otherwise, `NO`. The default value is `NO`.

Discussion
If this method returns `NO`, it means that the image may be cached in a shared window but is not required to be. Images are cached in a shared window if they have the same general attributes, such as color space, resolution, and bit depth.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.6.

Declared In
`NSImage.h`

isDataRetained

Returns a Boolean value indicating whether the receiver retains its source image data. (Deprecated in Mac OS X v10.6. In Mac OS v10.6, `NSImage` no longer discards data in such a way that the original can no longer be reconstructed. There is no replacement method.)

```
- (BOOL)isDataRetained
```

Return Value
`YES` if the image retains its source data; otherwise, `NO`. The default value is `NO` with some exceptions, which are covered in the discussion.

Discussion
For image objects initialized using either the `initByReferencingFile:` (page 1350) or `initByReferencingURL:` (page 1351) method, this value is `YES` by default. The reason is that for these methods, data retention simply involves retaining the filename or URL.

Data retention increases the memory used by the `NSImage` object and its image representations.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.6.

Declared In
`NSImage.h`

isFlipped

Returns a Boolean value indicating whether the image uses a flipped coordinate system. (Deprecated in Mac OS X v10.6. The flipped property of an image was widely misunderstood and has been deprecated. Use `drawInRect:fromRect:operation:fraction:respectFlipped:hints:` (page 1347) to draw respecting a context's flipped status and `lockFocusFlipped:` (page 1359) to draw into a flipped image.)

```
- (BOOL)isFlipped
```

Return Value
`YES` if the image's coordinate system is flipped; otherwise, `NO`. The default is `NO`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.6.

See Also
`- setFlipped:` (page 1367)

Declared In
`NSImage.h`

isTemplate

Returns a Boolean value indicating whether the image is a template image.

```
- (BOOL)isTemplate
```

Return Value
`YES` if the image is a template image; otherwise, `NO`.

Discussion
Template images consist of black and clear colors (and an alpha channel). Template images are not intended to be used as standalone images and are usually mixed with other content to create the desired final appearance.

Availability
Available in Mac OS X v10.5 and later.

See Also
`- setTemplate:` (page 1371)

Declared In
`NSImage.h`

isValid

Returns a Boolean value indicating whether an image representation from the receiver can be drawn.

```
- (BOOL)isValid
```

Return Value
`YES` if the receiver can be drawn; otherwise, `NO`.

Discussion
If the receiver is initialized with an existing image file, but the corresponding image data is not yet loaded into memory, this method loads the data and expands it as needed. If the receiver contains no image representations and no associated image file, this method creates a valid cached image representation and initializes it to the default bit depth. This method returns `NO` in cases where the file or URL from which it was initialized is nonexistent or when the data in an existing file is invalid.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `initByReferencingFile:` (page 1350)
- `initByReferencingURL:` (page 1351)

Declared In
`NSImage.h`

lockFocus

Prepares the image to receive drawing commands.

```
- (void)lockFocus
```

Discussion
This method sets the current drawing context to the area of the offscreen window used to cache the receiver's contents. Subsequent drawing commands are composited to this offscreen window. If the offscreen drawing area already has some content, any new drawing commands are composited with that content. This method does not modify the original image data directly.

When locking focus, this method chooses the best image representation object available and locks focus on that object. If the receiver has no image representations, this method creates one with the default depth and locks focus on it. For information on how the "best" representation is chosen, see the “Images” chapter of *Cocoa Drawing Guide*.

A successful `lockFocus` message must be balanced with a matching `unlockFocus` (page 1374) message to the same `NSImage` object. These messages bracket the code that draws the image.

If `lockFocus` is unable to focus on the image, it raises an `NSImageCacheException`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `bestRepresentationForDevice:` (page 1337)

Sketch-112

Declared In
NSImage.h

lockFocusFlipped:

Prepares the image to receive drawing commands using the specified flipped state.

```
- (void)lockFocusFlipped:(BOOL)flipped
```

Parameters

flipped

YES if the drawing context should be flipped, otherwise NO.

Availability
Available in Mac OS X v10.6 and later.

Declared In
NSImage.h

lockFocusOnRepresentation:

Prepares the specified image representation to receive drawing commands. (Deprecated in Mac OS X v10.6. Use the code fragment shown in the special considerations below.)

```
- (void)lockFocusOnRepresentation:(NSImageRep *)imageRepresentation
```

Parameters

imageRepresentation

An image representation belonging to the receiver, or nil if you want the receiver to choose which image representation to use.

Discussion
This method sets the current drawing context to the area of the offscreen window used to cache the specified image representation's contents. Subsequent drawing commands are composited to this offscreen window. If the offscreen drawing area already has some content, any new drawing commands are composited with that content. This method does not modify the original image data directly.

If *imageRepresentation* is nil, this method acts like the lockFocus (page 1358) method, setting the focus to the best representation for the NSImage object.

A successful lockFocusOnRepresentation: message must be balanced with a matching unlockFocus (page 1374) message to the same NSImage object. These messages bracket the code that draws the image.

If lockFocusOnRepresentation: is unable to focus on the specified image representation, it raises an NSImageCacheException.

Special Considerations

This method is deprecated as it did not set up *imageRepresentation* as a drawing destination, it set the image up as a drawing destination, then drew *imageRepresentation* into it. You can replace this functionality with the following code fragment

```
[image lockFocus];
[imageRepresentation drawInRect:NSMakeRect(0,0,[image size].width, [image
size].height)];

image unlockFocus;
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.6.

See Also
- `isValid` (page 1357)

Declared In
`NSImage.h`

matchesOnMultipleResolution

Returns a Boolean value indicating whether image representations whose resolution is an integral multiple of the device resolution are considered a match.

```
- (BOOL)matchesOnMultipleResolution
```

Return Value
`YES` if image representations whose resolution is an integral multiple of the device resolution are considered a match; otherwise, `NO`.

Discussion
When this method returns `NO`, only image representations whose resolution is exactly the same as the device resolution are considered matches. If this method returns `YES` and multiple image representations fit this criteria, the one whose resolution is closest to the device resolution is chosen.

The default value is `YES`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setMatchesOnMultipleResolution:` (page 1368)

Declared In
`NSImage.h`

name

Returns the name associated with the receiver, if any.

```
- (NSString *)name
```

Return Value
The name associated with the receiver, or `nil` if no name is assigned.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setName:` (page 1368)

Declared In
`NSImage.h`

prefersColorMatch

Returns a Boolean value indicating whether the image prefers to choose image representations using color matching or resolution matching.

```
- (BOOL)prefersColorMatch
```

Return Value
`YES` if color matching is preferred over resolution matching; otherwise `NO` if resolution matching is preferred.

Discussion
Both color matching and resolution matching may influence the choice of an image representation. This method simply indicates which technique is used first during the selection process. The default value is `YES`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setPrefersColorMatch:` (page 1369)

Declared In
`NSImage.h`

recache

Invalidates and frees the offscreen caches of all image representations.

```
- (void)recache
```

Discussion
If you modify an image representation, you must send a `recache` (page 1361) message to the corresponding image object to force the changes to be recached. The next time any image representation is drawn, it is asked to recreate its cached image. If you do not send this message, the image representation may use the old cache data. This method simply clears the cached image data; it does not delete the `NSCachedImageRep` objects associated with any image representations.

If you do not plan to use an image again right away, you can free its caches to reduce the amount of memory consumed by your program.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
TextInputView

Declared In
`NSImage.h`

removeRepresentation:

Removes the specified image representation from the receiver and releases it.

```
- (void)removeRepresentation:(NSImageRep *)imageRep
```

Parameters

imageRep

The image representation object you want to remove.

Availability
Available in Mac OS X v10.0 and later.

See Also
- representations (page 1362)

Declared In
NSImage.h

representations

Returns an array containing all of the receiver's image representations.

```
- (NSArray *)representations
```

Return Value
An array containing zero or more NSImageRep objects.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
CocoaCreateMovie
Reducer

Declared In
NSImage.h

scalesWhenResized

Returns a Boolean value indicating whether image representations are scaled to fit the receiver's size. (Deprecated in Mac OS X v10.6. This method was related to caching behavior. In Mac OS X v10.6 and later image caching is no long necessary and as a resuilt there is no replacement necessary.)

```
- (BOOL)scalesWhenResized
```

Return Value
YES if image representations are scaled to fit the receiver; otherwise, NO. The default value is NO.

Discussion
Images are not resized during drawing if this method returns YES. They are only resized when you change the size by sending the receiver a setSize: (page 1370) message.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.6.

See Also
- `setScalesWhenResized:` (page 1369)

Declared In
`NSImage.h`

setAccessibilityDescription:

Sets the image's accessibility description.

```
- (void)setAccessibilityDescription:(NSString *)description
```

Parameters
description
A short localized string that does not include the name of the interface element.

Discussion
This description will be used automatically by interface elements that display images. Like all accessibility descriptions, the string should be a short localized string that does not include the name of the interface element. For instance, "delete" rather than "delete button".

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSImage.h`

setAlignmentRect:

Sets the alignment metadata that your code can use to position the image during layout.

```
- (void)setAlignmentRect:(NSRect)rect
```

Parameters
rect
The alignment rectangle for the image.

Discussion
Alignment rectangles specify baselines that you can use to position the content of an image more accurately. These baselines are merely hints that your own code can use to determine positioning and are not used internally by `NSImage` itself during drawing. For example, if you have a 20 x 20 pixel icon that includes a glow effect, you might set the alignment rectangle to {{2, 2}, {16, 16}} to indicate the position of the underlying icon without the glow effect.

Availability
Available in Mac OS X v10.5 and later.

See Also
- `alignmentRect` (page 1336)

Declared In
NSImage.h

setBackgroundColor:

Sets the background color of the image.

```
- (void)setBackgroundColor:(NSColor *)aColor
```

Parameters

aColor

The new background color for the image.

Discussion
The background color is visible only if the drawn image representation does not completely cover all of the pixels available for the image's current size. The background color is ignored for cached image representations; such caches are always created with a white background. This method does not cause the receiver to recache itself.

Availability
Available in Mac OS X v10.0 and later.

See Also
- recache (page 1361)
- backgroundColor (page 1336)

Declared In
NSImage.h

setCacheDepthMatchesImageDepth:

Sets whether the receiver's offscreen window caches use the same bit depth as the image data itself. (Deprecated in Mac OS X v10.6. NSImage no longer caches to windows. A cache is now generated appropriate for the destination where an image is drawn. There is no replacement method.)

```
- (void)setCacheDepthMatchesImageDepth:(BOOL)flag
```

Parameters

flag

YES if the offscreen caches use the same bit-depth associated with the image data; otherwise, NO to indicate they should use the default bit depth.

Discussion
This method does not cause the receiver to recache itself. The default depth limit is equal to the bit depth of the deepest screen on the system.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.6.

See Also
- cacheDepthMatchesImageDepth (page 1338)
- lockFocus (page 1358)

- recache (page 1361)

Declared In
NSImage.h

setCachedSeparately:

Sets whether each image representation uses a separate offscreen window to cache its contents. (Deprecated in Mac OS X v10.6. NSImage no longer caches to windows. There is no replacement method)

```
- (void)setCachedSeparately:(BOOL)flag
```

Parameters

flag

YES if you want each of the receiver's image representation objects to use a separate offscreen window for caching; otherwise, NO.

Discussion
If you specify NO, a representation can be cached together with other images, though in practice it might not be. This method does not invalidate any existing caches.

If you plan to resize an NSImage object frequently, it is usually more efficient to cache its representations separately. In some situations, you might also want to enable separate caching if you plan to use the compositeToPoint:fromRect:operation: (page 1340) or compositeToPoint:fromRect:operation:fraction: (page 1341)methods to draw the image.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.6.

See Also
- recache (page 1361)

Declared In
NSImage.h

setCacheMode:

Set the receiver's caching mode.

```
- (void)setCacheMode:(NSImageCacheMode)mode
```

Parameters

mode

The caching mode to use with this image. For a list of possible values, see NSImageCacheMode (page 1379).

Discussion
The caching mode determines when the receiver's image representations use offscreen caches. Offscreen caches speed up rendering time but do so by using extra memory. In the default caching mode (NSImageCacheDefault), each image representation chooses the caching technique that produces the

fastest drawing times. For example, in the default mode, the `NSPDFImageRep` and `NSEPSImageRep` classes use the `NSImageCacheAlways` mode but the `NSBitmapImageRep` class uses the `NSImageCacheBySize` mode.

For more information on image caching behavior, see the "Images" chapter of *Cocoa Drawing Guide*.

Availability
Available in Mac OS X v10.2 and later.

See Also
`- cacheMode` (page 1339)

Declared In
`NSImage.h`

setDataRetained:

Sets whether the receiver retains its source image data. (Deprecated in Mac OS X v10.6. In Mac OS v10.6, `NSImage` no longer discards data in such a way that the original can no longer be reconstructed. There is no replacement method.)

```
- (void)setDataRetained:(BOOL)flag
```

Parameters

flag

`YES` if you want the source image data to be retained; otherwise `NO`.

Discussion
Retention of the source image data is important if the source of the image data could change, be moved, or be deleted. Data retention is also useful if you plan to resize an image frequently; otherwise, resizing occurs on a cached copy of the image, which can lose image quality during successive scaling operations. With data retention enabled, the image is resized from the original source data.

If the responsibility for drawing the image is delegated to another object, there is no reason to retain the image data. Similarly, if the source of the image data is not expected to change or you do not plan to resize the image, you do not need to retain the data. In fact, retaining the data leads to increased memory usage, which could have a negative impact on performance.

If you create your image object using the `initByReferencingFile:` (page 1350) method, the only data retained is the name of the source file.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.6.

Declared In
`NSImage.h`

setDelegate:

Sets the delegate object of the receiver.

```
- (void)setDelegate:(id < NSImageDelegate >)anObject
```

Parameters

anObject

The new delegate object.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `delegate` (page 1344)

Declared In

`NSImage.h`

setFlipped:

Sets whether the polarity of the y axis is inverted when drawing an image. (Deprecated in Mac OS X v10.6. The flipped property of an image was widely misunderstood and has been deprecated. Use `drawInRect:fromRect:operation:fraction:respectFlipped:hints:` (page 1347) to draw respecting a context's flipped status and `lockFocusFlipped:` (page 1359) to draw into a flipped image.)

```
- (void)setFlipped:(BOOL)flag
```

Parameters

flag

`YES` if you want the image data to be inverted before drawing; otherwise, `NO`.

Discussion

If *flag* is `YES`, the y-axis of the image's internal coordinate system is inverted, with the origin in the upper-left corner and the positive y axis extending downward. This method affects only the coordinate system used internally by the image and the orientation of the image when it is drawn; it does not affect the coordinate system used to specify the position of an image in a view. This method does not cause the receiver to recache itself.

If you set *flag* to `YES` and then lock focus and draw into the image, the content you draw is cached in the inverted (flipped) orientation. Changing the value for *flag* does not affect the orientation of the cached image.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.6.

setMatchesOnMultipleResolution:

Sets whether image representations whose resolutions are integral multiples of the device resolution are considered a match.

```
- (void)setMatchesOnMultipleResolution:(BOOL)flag
```

Parameters

flag

YES if image representations whose resolution is an integral multiple of the device resolution should be considered a match; otherwise, NO.

Availability
Available in Mac OS X v10.0 and later.

See Also
- matchesOnMultipleResolution (page 1360)

Declared In
NSImage.h

setName:

Registers the receiver under the specified name.

```
- (BOOL)setName:(NSString *)aString
```

Parameters

aString

The name to associate with the receiver.

Return Value
YES if the receiver was successfully registered with the given name; otherwise, NO.

Discussion
If the receiver is already registered under a different name, this method unregisters the other name. If a different image is registered under the name specified in *aString*, this method does nothing and returns NO.

When naming an image using this method, it is convention not to include filename extensions in the names you specify. That way, you can easily distinguish between images you have named explicitly and those you want to load from the application's bundle. For information about the rules used to search for images, and for information about the ownership policy of named images, see the imageNamed: method.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSImage.h

setPrefersColorMatch:

Sets whether choosing an image representation favors color matching over resolution matching.

```
- (void)setPrefersColorMatch:(BOOL)flag
```

Parameters

flag

YES if the receiver should match the color capabilities of the rendering device first; otherwise, NO to indicate that resolution matching is preferred.

Discussion
Both color matching and resolution matching may influence the choice of an image representation. You use this method to choose which technique should be used first during the selection process.

Availability
Available in Mac OS X v10.0 and later.

See Also
- prefersColorMatch (page 1361)

Declared In
NSImage.h

setScalesWhenResized:

Sets whether different-sized image representations are scaled to fit the receiver's size. (Deprecated in Mac OS X v10.6. This method was related to caching behavior. In Mac OS X v10.6 and later image caching is no long necessary and as a resuilt there is no replacement necessary.)

```
- (void)setScalesWhenResized:(BOOL)flag
```

Parameters

flag

YES if image representations are scaled to fit; otherwise NO.

Discussion
Most images (especially those loaded from files and URLs) contain only a single image representation whose size is the same as the receiver. It is possible to add image representations using the addRepresentation: (page 1335) or addRepresentations: (page 1335) methods but doing so is rarely necessary because modern hardware is powerful enough to resize and scale images quickly. The only reason to consider creating new representations is if each representations contains a customized version of the image at a specific size. (TIFF images may also contain a thumbnail version of an image, which is stored using a separate image representation.) If you pass YES in the *flag* parameter, and subsequently send a setSize: (page 1370) message to the receiver, all such image representations would be scaled to the same size. Scaling of bitmap images usually results in the interpolation of the bitmap data.

This method does not invalidate the caches of any of the receiver's image representations. The caches are not invalidated until you change the image size using a `setSize:` (page 1370) message. Scaling affects only the cached offscreen data for a given image representation.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.6.

`NSImage.h`

setSize:

Sets the width and height of the image.

```
- (void)setSize:(NSSize)aSize
```

Parameters

aSize
The new size of the image, measured in points.

Discussion
The size of an `NSImage` object must be set before it can be used. If the size of the image hasn't already been set when an image representation is added, the size is taken from the image representation's data. For EPS images, the size is taken from the image's bounding box. For TIFF images, the size is taken from the `ImageLength` and `ImageWidth` attributes.

Changing the size of an `NSImage` after it has been used effectively resizes the image. Changing the size invalidates all its caches and frees them. When the image is next composited, the selected representation will draw itself in an offscreen window to recreate the cache.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSImage.h

setTemplate:

Sets whether the image represents a template image.

```
- (void)setTemplate:(BOOL)isTemplate
```

Parameters

isTemplate

Specify YES if the image is a template image; otherwise, NO.

Discussion
Images you mark as template images should consist of only black and clear colors. You can use the alpha channel in the image to adjust the opacity of black content, however.

Template images are not intended to be used as standalone images. They are always mixed with other content and processed to create the desired appearance. You can mark an image as a "template image" to notify clients who care that the image contains only black and clear content. The most common use for template images is in image cells. For example, you might use a template image to provide the content for a button or segmented control. Cocoa cells take advantage of the nature of template images—that is, their simplified color scheme and use of transparency—to improve the appearance of the corresponding control in each of its supported states.

Availability
Available in Mac OS X v10.5 and later.

NSImage.h

setUsesEPSOnResolutionMismatch:

Sets whether EPS image representations are preferred when no other representations match the resolution of the device.

```
- (void)setUsesEPSOnResolutionMismatch:(BOOL)flag
```

Parameters

flag

YES if EPS image representations are preferred; otherwise NO.

Availability
Available in Mac OS X v10.0 and later.

See Also
- usesEPSOnResolutionMismatch (page 1374)

- setMatchesOnMultipleResolution: (page 1368)

Declared In
NSImage.h

size

Returns the size of the receiver.

- (NSSize)size

Return Value
The size of the receiver or (0.0, 0.0) if no size has been set and the size cannot be determined from any of the receiver's image representations.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setSize: (page 1370)

Declared In
NSImage.h

TIFFRepresentation

Returns a data object containing TIFF data for all of the image representations in the receiver.

- (NSData *)TIFFRepresentation

Return Value
A data object containing the TIFF data, or nil if the TIFF data could not be created.

Discussion
You can use the returned data object to write the TIFF data to a file. For each image representation, this method uses the TIFF compression option associated with that representation or NSTIFFCompressionNone, if no option is set.

If one of the receiver's image representations does not support the creation of TIFF data natively (PDF and EPS images, for example), this method creates the TIFF data from that representation's cached content.

Additional image formats can be saved by using the NSBitmapImageRep method representationUsingType:properties: (page 363).

Availability
Available in Mac OS X v10.0 and later.

`NSImage.h`

TIFFRepresentationUsingCompression:factor:

Returns a data object containing TIFF data with the specified compression settings for all of the image representations in the receiver.

```
- (NSData *)TIFFRepresentationUsingCompression:(NSTIFFCompression)comp
    factor:(float)aFloat
```

Parameters

comp
The type of compression to use. For a list of values, see the constants in `NSBitmapImageRep`.

aFloat
Provides a hint for compression types that implement variable compression ratios. Currently, only JPEG compression uses a compression factor.

Return Value
A data object containing the TIFF data, or `nil` if the TIFF data could not be created.

Discussion
You can use the returned data object to write the TIFF data to a file. If the specified compression isn't applicable, no compression is used. If a problem is encountered during generation of the TIFF data, this method may raise an exception.

If one of the receiver's image representations does not support the creation of TIFF data natively (PDF and EPS images, for example), this method creates the TIFF data from that representation's cached content.

Additional image formats can be saved by using the `NSBitmapImageRep` method `representationUsingType:properties:` (page 363).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSImage.h`

unlockFocus

Removes the focus from the receiver.

```
- (void)unlockFocus
```

Discussion
This message must be sent after a successful `lockFocus` or `lockFocusOnRepresentation:` message and the completion of any intermediate drawing commands. This method restores the focus to the previous owner, if any.

Do not send this message if the preceding call to lock focus raised an `NSImageCacheException`.

Availability
Available in Mac OS X v10.0 and later.

Constants

Image Hint Dictionary Keys

These constants are a subset of the dictionary keys used in the hints dictionary for the methods CGImageForProposedRect:context:hints: (page 1339), bestRepresentationForRect:context:hints: (page 1338), drawInRect:fromRect:operation:fraction:respectFlipped:hints: (page 1347), and hitTestRect:withImageDestinationRect:context:hints:flipped: (page 1349). Additional hint keys are also valid including: Context Options in CIContext, and the entries in an NSScreen device description dictionary as described in deviceDescription (page 2317).

```
NSString *const NSImageHintCTM;
NSString *const NSImageHintInterpolation;
```

Constants

NSImageHintCTM
: Provides a context transform hint. The value for this key is an NSAffineTransform.

  Available in Mac OS X v10.6 and later.

  Declared in NSImage.h.

NSImageHintInterpolation
: Provides an interpolation hint. The value for this key is an NSNumber with an NSImageInterpolation (page 1313) value.

  Available in Mac OS X v10.6 and later.

  Declared in NSImage.h.

NSCompositingOperation

These constants specify compositing operators described in terms of having source and destination images, each having an opaque and transparent region. The destination image after the operation is defined in terms of the source and destination before images.

```
enum {
    NSCompositeClear           = 0,
    NSCompositeCopy            = 1,
    NSCompositeSourceOver      = 2,
    NSCompositeSourceIn        = 3,
    NSCompositeSourceOut       = 4,
    NSCompositeSourceAtop      = 5,
    NSCompositeDestinationOver = 6,
    NSCompositeDestinationIn   = 7,
    NSCompositeDestinationOut  = 8,
    NSCompositeDestinationAtop = 9,
    NSCompositeXOR             = 10,
    NSCompositePlusDarker      = 11,
    NSCompositeHighlight       = 12,
    NSCompositePlusLighter     = 13
}
typedef NSUInteger NSCompositingOperation;
```

Constants

`NSCompositeClear`

Transparent. (`R = 0`)

Available in Mac OS X v10.0 and later.

Declared in `NSGraphics.h`.

`NSCompositeCopy`

Source image. (`R = S`)

Available in Mac OS X v10.0 and later.

Declared in `NSGraphics.h`.

`NSCompositeSourceOver`

Source image wherever source image is opaque, and destination image elsewhere. (`R = S + D*(1 - Sa)`)

Available in Mac OS X v10.0 and later.

Declared in `NSGraphics.h`.

`NSCompositeSourceIn`

Source image wherever both images are opaque, and transparent elsewhere. (`R = S*Da`)

Available in Mac OS X v10.0 and later.

Declared in `NSGraphics.h`.

`NSCompositeSourceOut`

Source image wherever source image is opaque but destination image is transparent, and transparent elsewhere. (`R = S*(1 - Da)`)

Available in Mac OS X v10.0 and later.

Declared in `NSGraphics.h`.

`NSCompositeSourceAtop`

Source image wherever both images are opaque, destination image wherever destination image is opaque but source image is transparent, and transparent elsewhere. (`R = S*Da + D*(1 - Sa)`)

Available in Mac OS X v10.0 and later.

Declared in `NSGraphics.h`.

`NSCompositeDestinationOver`
Destination image wherever destination image is opaque, and source image elsewhere. (`R = S*(1 - Da) + D`)

Available in Mac OS X v10.0 and later.

Declared in `NSGraphics.h`.

`NSCompositeDestinationIn`
Destination image wherever both images are opaque, and transparent elsewhere. (`R = D*Sa`)

Available in Mac OS X v10.0 and later.

Declared in `NSGraphics.h`.

`NSCompositeDestinationOut`
Destination image wherever destination image is opaque but source image is transparent, and transparent elsewhere. (`R = D*(1 - Sa)`)

Available in Mac OS X v10.0 and later.

Declared in `NSGraphics.h`.

`NSCompositeDestinationAtop`
Destination image wherever both images are opaque, source image wherever source image is opaque but destination image is transparent, and transparent elsewhere. (`R = S*(1 - Da) + D*Sa`)

Available in Mac OS X v10.0 and later.

Declared in `NSGraphics.h`.

`NSCompositeXOR`
Exclusive OR of source and destination images. (`R = S*(1 - Da) + D*(1 - Sa)`)

Works only with black and white images and is not recommended for color contexts.

Available in Mac OS X v10.0 and later.

Declared in `NSGraphics.h`.

`NSCompositePlusDarker`
Sum of source and destination images, with color values approaching 0 as a limit. (`R = MAX(0, (1 - D) + (1 - S))`)

Available in Mac OS X v10.0 and later.

Declared in `NSGraphics.h`.

`NSCompositeHighlight`

Source image wherever source image is opaque, and destination image elsewhere. (Deprecated. Mapped to `NSCompositeSourceOver`.)

Available in Mac OS X v10.0 and later.

Declared in `NSGraphics.h`.

`NSCompositePlusLighter`
Sum of source and destination images, with color values approaching 1 as a limit. (`R = MIN(1, S + D)`)

Available in Mac OS X v10.0 and later.

Declared in `NSGraphics.h`.

Discussion
These compositing operators are defined in and used by `compositeToPoint:fromRect:operation:` (page 1340), `compositeToPoint:operation:` (page 1342), `compositeToPoint:fromRect:operation:fraction:` (page 1341), `compositeToPoint:operation:fraction:` (page 1343),

`drawAtPoint:fromRect:operation:fraction:` (page 1346), and `drawInRect:fromRect:operation:fraction:` (page 1347). They are also used by drawing methods in other classes that take a compositing operator.

The equations after each constant represent the mathematical formulas used to calculate the color value of the resulting pixel. Table 61-2 lists the meaning of each placeholder value in the equations.

Table 61-2 Placeholder values for compositing equations

Para	Para
`R`	The premultiplied result color.
`S`	The source color
`D`	The destination color
`Sa`	The alpha value of the source color
`Da`	The alpha value of the destination color

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSGraphics.h`

NSImageLoadStatus

These constants are status values passed to the incremental loading delegate method `image:didLoadRepresentation:withStatus:` (page 3694).

```
enum {
    NSImageLoadStatusCompleted,
    NSImageLoadStatusCancelled,
    NSImageLoadStatusInvalidData,
    NSImageLoadStatusUnexpectedEOF,
    NSImageLoadStatusReadError
}
typedef NSUInteger NSImageLoadStatus;
```

Constants

`NSImageLoadStatusCompleted`

Enough data has been provided to completely decompress the image.

Available in Mac OS X v10.2 and later.

Declared in `NSImage.h`.

`NSImageLoadStatusCancelled`

Image loading was canceled.

The image contains the portions of the data that have already been successfully decompressed, if any.

Available in Mac OS X v10.2 and later.

Declared in `NSImage.h`.

`NSImageLoadStatusInvalidData`
: An error occurred during image decompression.

  The image data is probably corrupt. The image contains the portions of the data that have already been successfully decompressed, if any.

  Available in Mac OS X v10.2 and later.

  Declared in `NSImage.h`.

`NSImageLoadStatusUnexpectedEOF`
: Not enough data was available for full decompression of the image.

  The image contains the portions of the data that have already been successfully decompressed, if any.

  Available in Mac OS X v10.2 and later.

  Declared in `NSImage.h`.

`NSImageLoadStatusReadError`
: Not enough data was available for full decompression of the image.

  The image contains the portions of the data that have already been successfully decompressed, if any.

  Available in Mac OS X v10.2 and later.

  Declared in `NSImage.h`.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`NSImage.h`

NSImageCacheMode

These constants specify the caching policy on a per `NSImage` basis. The caching policy is set using `cacheMode` (page 1339) and `setCacheMode:` (page 1365).

```
enum {
    NSImageCacheDefault,
    NSImageCacheAlways,
    NSImageCacheBySize,
    NSImageCacheNever
}
typedef NSUInteger NSImageCacheMode;
```

Constants
`NSImageCacheDefault`
: Caching is unspecified.

  Use the image rep's default.

  Available in Mac OS X v10.2 and later.

  Declared in `NSImage.h`.

`NSImageCacheAlways`
: Always generate a cache when drawing.

  Available in Mac OS X v10.2 and later.

  Declared in `NSImage.h`.

`NSImageCacheBySize`
Cache if cache size is smaller than the original data.

Available in Mac OS X v10.2 and later.

Declared in `NSImage.h`.

`NSImageCacheNever`
Never cache; always draw direct.

Available in Mac OS X v10.2 and later.

Declared in `NSImage.h`.

Discussion
The following table specifies the default caching policy for the various types of image representation.

Image Rep Class	Default caching policy
`NSBitmapImageRep`	`NSImageCacheBySize`. Cache if bitmap is 32-bits in 16-bit world or greater than 72 dpi.
`NSPICTImageRep`	`NSImageCacheBySize`. Same reasoning as `NSBitmapImageRep` in the event the PICT contains a bitmap.
`NSPDFImageRep`	`NSImageCacheAlways`
`NSCIImageRep`	`NSImageCacheBySize`. Cache if the bitmap depth does not match the screen depth or the resolution is greater than 72 dpi.
`NSEPSImageRep`	`NSImageCacheAlways`
`NSCustomImageRep`	`NSImageCacheAlways`

Availability
Available in Mac OS X v10.2 and later.

Declared In
`NSImage.h`

Image Template Constants

Images representing standard artwork and icons that you can use in your applications

```
NSString *const NSImageNameQuickLookTemplate;

NSString *const NSImageNameStatusNone;
NSString *const NSImageNameApplicationIcon;
NSString *const NSImageNameMenuOnStateTemplate;
NSString *const NSImageNameMenuMixedStateTemplate;
NSString *const NSImageNameUserGuest;
NSString *const NSImageNameMobileMe;
```

Constants

`NSImageNameQuickLookTemplate`

A Quick Look template image. 

Available in Mac OS X v10.5 and later.

Declared in `NSImage.h`.

`NSImageNameBluetoothTemplate`

A Bluetooth template image. 

Available in Mac OS X v10.5 and later.

Declared in `NSImage.h`.

`NSImageNameIChatTheaterTemplate`

An iChat Theater template image. 

Available in Mac OS X v10.5 and later.

Declared in `NSImage.h`.

`NSImageNameSlideshowTemplate`

A slideshow template image. 

Available in Mac OS X v10.5 and later.

Declared in `NSImage.h`.

`NSImageNameActionTemplate`

An action menu template image. 

Available in Mac OS X v10.5 and later.

Declared in `NSImage.h`.

`NSImageNameSmartBadgeTemplate`

A badge for a “smart” item. 

Available in Mac OS X v10.5 and later.

Declared in `NSImage.h`.

`NSImageNamePathTemplate`

A path button template image. 

Available in Mac OS X v10.5 and later.

Declared in `NSImage.h`.

`NSImageNameInvalidDataFreestandingTemplate`

An invalid data template image. Place this icon to the right of any fields containing invalid data. You can use this image to implement a borderless button. 

Available in Mac OS X v10.5 and later.

Declared in `NSImage.h`.

`NSImageNameLockLockedTemplate`

A locked lock template image. Use to indicate locked content. 

Available in Mac OS X v10.5 and later.

Declared in `NSImage.h`.

`NSImageNameLockUnlockedTemplate`

An unlocked lock template image. Use to indicate modifiable content that can be locked. 

Available in Mac OS X v10.5 and later.

Declared in `NSImage.h`.

`NSImageNameGoRightTemplate`

A “go forward” template image. 

Available in Mac OS X v10.5 and later.

Declared in `NSImage.h`.

`NSImageNameGoLeftTemplate`

A “go back” template image. 

Available in Mac OS X v10.5 and later.

Declared in `NSImage.h`.

`NSImageNameRightFacingTriangleTemplate`

A generic right-facing triangle template image. 

Available in Mac OS X v10.5 and later.

Declared in `NSImage.h`.

`NSImageNameLeftFacingTriangleTemplate`

A generic left-facing triangle template image. 

Available in Mac OS X v10.5 and later.

Declared in `NSImage.h`.

`NSImageNameAddTemplate`

An add item template image. 

Available in Mac OS X v10.5 and later.

Declared in `NSImage.h`.

`NSImageNameRemoveTemplate`

A remove item template image. 

Available in Mac OS X v10.5 and later.

Declared in `NSImage.h`.

`NSImageNameRevealFreestandingTemplate`

A reveal contents template image. You can use this image to implement a borderless button. 

Available in Mac OS X v10.5 and later.

Declared in `NSImage.h`.

`NSImageNameFollowLinkFreestandingTemplate`

A link template image. You can use this image to implement a borderless button. 

Available in Mac OS X v10.5 and later.

Declared in `NSImage.h`.

`NSImageNameEnterFullScreenTemplate`

An enter full-screen mode template image. 

Available in Mac OS X v10.5 and later.

Declared in `NSImage.h`.

`NSImageNameExitFullScreenTemplate`

An exit full-screen mode template image. 

Available in Mac OS X v10.5 and later.

Declared in `NSImage.h`.

`NSImageNameStopProgressTemplate`

A stop progress button template image.

Available in Mac OS X v10.5 and later.

Declared in `NSImage.h`.

`NSImageNameStopProgressFreestandingTemplate`

A stop progress template image. You can use this image to implement a borderless button. 

Available in Mac OS X v10.5 and later.

Declared in `NSImage.h`.

`NSImageNameRefreshTemplate`

A refresh template image. 

Available in Mac OS X v10.5 and later.

Declared in `NSImage.h`.

`NSImageNameRefreshFreestandingTemplate`

A refresh template image. You can use this image to implement a borderless button. 

Available in Mac OS X v10.5 and later.

Declared in `NSImage.h`.

Discussion
To access these images, pass the specified constant to the `imageNamed:` (page 1330) method.

Images with the word "Template" in their title identify shapes that are not intended as standalone images. You would typically use these icons as the custom image for a button, or you might apply them to a cell in a control. For example, you might use the `NSImageNameLockLockedTemplate` image to indicate an item is not modifiable. Template images should use black and clear colors only and it is fine to include varying levels of alpha.

Images with the word "Freestanding" in their title can be used to implement borderless buttons. You do not need to include any extra bezel artwork behind such images.

You should always use named images according to their intended purpose, and not according to how the image appears when loaded. The appearance of images can change between releases. If you use an image for its intended purpose (and not because of it looks), your code should look correct from release to release.

The size and aspect ratio of system images may change from release to release. In some situations, you should explicitly resize images as appropriate for your use. If you use these images in conjunction with an `NSButtonCell` object, however, you can use the `setImageScaling:` method of the cell to control scaling instead. Similarly, for an `NSSegmentedCell` object, you can use the `setImageScaling:forSegment:` method to control scaling.

The string value for each constant is equal to the constant name without the "ImageName" portion. You might need this information to locate images by name in Interface Builder. For example, the constant `NSImageNameRefreshFreestandingTemplate` would correspond to an image named "NSRefreshFreestandingTemplate" in Interface Builder.

Declared In
`NSImage.h`

Multiple Documents Drag Image

Drag images you can use in your applications. To access this image, pass the specified constant to the `imageNamed:` (page 1330) method.

```
NSString *const NSImageNameMultipleDocuments;
```

Constants

`NSImageNameMultipleDocuments`

A drag image for multiple items. 

Available in Mac OS X v10.5 and later.

Declared in `NSImage.h`.

Discussion

You can use this icon as the drag image when dragging multiple items. You should not use this image for any other intended purpose, however. The appearance of images can change between releases. If you use an image for its intended purpose (and not because of how it looks), your code should look correct from release to release.

The size and aspect ratio of system images may change from release to release. In some situations, you should explicitly resize images as appropriate for your use. If you use these images in conjunction with an `NSButtonCell` object, however, you can use the `setImageScaling:` method of the cell to control scaling instead. Similarly, for an `NSSegmentedCell` object, you can use the `setImageScaling:forSegment:` method to control scaling.

The string value for each constant is equal to the constant name without the "ImageName" portion. You might need this information to locate images by name in Interface Builder. For example, the constant `NSImageNameMultipleDocuments` would correspond to an image named "NSMultipleDocuments" in Interface Builder.

Sharing Permissions Named Images

Images representing sharing permission icons that you can use in your applications. To access this image, pass the specified constant to the `imageNamed:` (page 1330) method.

```
NSString *const NSImageNameUser;
NSString *const NSImageNameUserGroup;
NSString *const NSImageNameEveryone;
```

Constants

`NSImageNameUser`

Permissions for a single user. 

Available in Mac OS X v10.5 and later.

Declared in `NSImage.h`.

`NSImageNameUserGroup`

Permissions for a group of users. 

Available in Mac OS X v10.5 and later.

Declared in `NSImage.h`.

`NSImageNameEveryone`

Permissions for all users. 

Available in Mac OS X v10.5 and later.

Declared in `NSImage.h`.

Discussion
You should use these images to reflect user and group permission or sharing information. The appearance of images can change between releases. If you use an image for its intended purpose (and not because of how it looks), your code should look correct from release to release.

The size and aspect ratio of system images may change from release to release. In some situations, you should explicitly resize images as appropriate for your use. If you use these images in conjunction with an `NSButtonCell` object, however, you can use the `setImageScaling:` method of the cell to control scaling instead. Similarly, for an `NSSegmentedCell` object, you can use the `setImageScaling:forSegment:` method to control scaling.

The string value for each constant is equal to the constant name without the "ImageName" portion. You might need this information to locate images by name in Interface Builder. For example, the constant `NSImageNameEveryone` would correspond to an image named "NSEveryone" in Interface Builder.

System Entity Images

Images representing Finder items. To access this image, pass the specified constant to the `imageNamed:` (page 1330) method.

```
NSString *const NSImageNameBonjour;
NSString *const NSImageNameDotMac;
NSString *const NSImageNameComputer;
NSString *const NSImageNameFolderBurnable;
NSString *const NSImageNameFolderSmart;
NSString *const NSImageNameNetwork;
```

Constants

`NSImageNameBonjour`

A Bonjour icon. 

Available in Mac OS X v10.5 and later.

Declared in `NSImage.h`.

`NSImageNameDotMac`

A Dot Mac icon. 

Available in Mac OS X v10.5 and later.

Declared in `NSImage.h`.

`NSImageNameComputer`

A computer icon. 

Available in Mac OS X v10.5 and later.

Declared in `NSImage.h`.

`NSImageNameFolderBurnable`

A burnable folder icon. 

Available in Mac OS X v10.5 and later.

Declared in `NSImage.h`.

`NSImageNameFolderSmart`

A smart folder icon. 

Available in Mac OS X v10.5 and later.

Declared in `NSImage.h`.

`NSImageNameNetwork`

A network icon. 

Available in Mac OS X v10.5 and later.

Declared in `NSImage.h`.

Discussion

You should use these images to reflect specific elements of the Mac OS X environment. For example, you might use the burnable folder icon if your software allows the user to organize content for burning onto an optical disk. The appearance of images can change between releases. If you use an image for its intended purpose (and not because of how it looks), your code should look correct from release to release.

The size and aspect ratio of system images may change from release to release. In some situations, you should explicitly resize images as appropriate for your use. If you use these images in conjunction with an `NSButtonCell` object, however, you can use the `setImageScaling:` method of the cell to control scaling instead. Similarly, for an `NSSegmentedCell` object, you can use the `setImageScaling:forSegment:` method to control scaling.

The string value for each constant is equal to the constant name without the “ImageName” portion. You might need this information to locate images by name in Interface Builder. For example, the constant `NSImageNameNetwork` would correspond to an image named “NSNetwork” in Interface Builder.

Declared In

`NSImage.h`

Toolbar Named Images

Images that you can use in application toolbars. To access this image, pass the specified constant to the `imageNamed:` (page 1330) method.

```
NSString *const NSImageNameUserAccounts;
NSString *const NSImageNamePreferencesGeneral;
NSString *const NSImageNameAdvanced;
NSString *const NSImageNameInfo;
NSString *const NSImageNameFontPanel;
NSString *const NSImageNameColorPanel;
```

Constants

`NSImageNameUserAccounts`

User account toolbar icon. Use in a preferences window only. 

Available in Mac OS X v10.5 and later.

Declared in `NSImage.h`.

`NSImageNamePreferencesGeneral`

General preferences toolbar icon. Use in a preferences window only. 

Available in Mac OS X v10.5 and later.

Declared in `NSImage.h`.

`NSImageNameAdvanced`

Advanced preferences toolbar icon. Use in a preferences window only. 

Available in Mac OS X v10.5 and later.

Declared in `NSImage.h`.

`NSImageNameInfo`

An information toolbar icon. 

Available in Mac OS X v10.5 and later.

Declared in `NSImage.h`.

`NSImageNameFontPanel`

A font panel toolbar icon. 

Available in Mac OS X v10.5 and later.

Declared in `NSImage.h`.

`NSImageNameColorPanel`

A color panel toolbar icon. 

Available in Mac OS X v10.5 and later.

Declared in `NSImage.h`.

`NSImageNameFolder`

A folder image. 

Available in Mac OS X v10.6 and later.

Declared in `NSImage.h`.

`NSImageNameTrashEmpty`

An image of the empty trash can. 

Available in Mac OS X v10.6 and later.

Declared in `NSImage.h`.

`NSImageNameTrashFull`

An image of the full trash can. 

Available in Mac OS X v10.6 and later.

Declared in `NSImage.h`.

`NSImageNameHomeTemplate`

Home image suitable for a template. 

Available in Mac OS X v10.6 and later.

Declared in `NSImage.h`.

`NSImageNameBookmarksTemplate`

Bookmarks image suitable for a template. 
Available in Mac OS X v10.6 and later.

Declared in `NSImage.h`.

`NSImageNameCaution`

Caution Image. 

Available in Mac OS X v10.6 and later.

Declared in `NSImage.h`.

`NSImageNameStatusAvailable`

Small green indicator, similar to iChat's available image. 

Available in Mac OS X v10.6 and later.

Declared in `NSImage.h`.

`NSImageNameStatusPartiallyAvailable`

Small yellow indicator, similar to iChat's idle image. 

Available in Mac OS X v10.6 and later.

Declared in `NSImage.h`.

`NSImageNameStatusUnavailable`

Small red indicator, similar to iChat's unavailable image. 

Available in Mac OS X v10.6 and later.

Declared in `NSImage.h`.

`NSImageNameStatusNone`

Small clear indicator. 

Available in Mac OS X v10.6 and later.

Declared in `NSImage.h`.

`NSImageNameApplicationIcon`

Generic application icon. 

Available in Mac OS X v10.6 and later.

Declared in `NSImage.h`.

`NSImageNameMenuOnStateTemplate`

A check mark. Drawing these outside of menus is discouraged. 

Available in Mac OS X v10.6 and later.

Declared in `NSImage.h`.

`NSImageNameMenuMixedStateTemplate`

A horizontal dash. Drawing these outside of menus is discouraged.

Available in Mac OS X v10.6 and later.

Declared in `NSImage.h`.

`NSImageNameUserGuest`

Shaded user figure. 

Available in Mac OS X v10.6 and later.

Declared in `NSImage.h`.

`NSImageNameMobileMe`

MobileMe logo. Note that this is preferred to using the `NSImageNameDotMac` (page 1386) image, although that image is not expected to be deprecated. 

Available in Mac OS X v10.6 and later.

Declared in `NSImage.h`.

Discussion
You should use these images as icons for toolbar items. The appearance of images can change between releases. If you use an image for its intended purpose (and not because of how it looks), your code should look correct from release to release.

The size and aspect ratio of system images may change from release to release. In some situations, you should explicitly resize images as appropriate for your use. If you use these images in conjunction with an `NSButtonCell` object, however, you can use the `setImageScaling:` method of the cell to control scaling instead. Similarly, for an `NSSegmentedCell` object, you can use the `setImageScaling:forSegment:` method to control scaling.

Constants that end in the word "Template" name black and clear images that return `YES` for `isTemplate` (page 1357). These images can be processed into variants appropriate for different situations. For example, these images can invert in a selected table view row. See `setTemplate:` (page 1371): for more comments. These images are inappropriate for display without further processing, but `NSCell` and its subclasses will perform the processing.

Some images also contain the word "Freestanding". This indicates that an image is appropriate for use as a borderless button, it doesn't need any extra bezel artwork behind it. For example, Safari uses `NSImageNameStopProgressFreestandingTemplate` (page 1383) as the stop button in a button on its toolbar, while it uses `NSImageNameStopProgressFreestandingTemplate` (page 1383) in the downloads window where it appears inline with a progress indicator.

The string value for each constant is equal to the constant name without the “ImageName” portion. You might need this information to locate images by name in Interface Builder. For example, the constant `NSImageNameColorPanel` would correspond to an image named “NSColorPanel” in Interface Builder.

Declared In
`NSImage.h`

View Type Template Images

Images used in segmented controls to switch the current view type. To access this image, pass the specified constant to the `imageNamed:` (page 1330) method.

```
NSString *const NSImageNameIconViewTemplate;
NSString *const NSImageNameListViewTemplate;
NSString *const NSImageNameColumnViewTemplate;
NSString *const NSImageNameFlowViewTemplate;
```

Constants

`NSImageNameIconViewTemplate`

An icon view mode template image. 

Available in Mac OS X v10.5 and later.

Declared in `NSImage.h`.

`NSImageNameListViewTemplate`

A list view mode template image. 

Available in Mac OS X v10.5 and later.

Declared in `NSImage.h`.

`NSImageNameColumnViewTemplate`

A column view mode template image. 

Available in Mac OS X v10.5 and later.

Declared in `NSImage.h`.

`NSImageNameFlowViewTemplate`

A cover flow view mode template image. 

Available in Mac OS X v10.5 and later.

Declared in `NSImage.h`.

Discussion

Images with the word "Template" in their title identify shapes that are not intended as standalone images. You would typically use these icons as the custom image for a button, or you might apply them to a cell in a control. For example, you might use the `NSImageNameIconViewTemplate` image to indicate an item is not modifiable. Template images should use black and clear colors only and it is fine to include varying levels of alpha.

You should use these images in conjunction with the buttons (usually part of a segmented control) that change the current viewing mode. The appearance of images can change between releases. If you use an image for its intended purpose (and not because of how it looks), your code should look correct from release to release.

The size and aspect ratio of system images may change from release to release. In some situations, you should explicitly resize images as appropriate for your use. If you use these images in conjunction with an `NSButtonCell` object, however, you can use the `setImageScaling:` method of the cell to control scaling instead. Similarly, for an `NSSegmentedCell` object, you can use the `setImageScaling:forSegment:` method to control scaling.

The string value for each constant is equal to the constant name without the "ImageName" portion. You might need this information to locate images by name in Interface Builder. For example, the constant `NSImageNameFlowViewTemplate` would correspond to an image named "NSFlowViewTemplate" in Interface Builder.

Overview

An `NSImageCell` object displays a single image (encapsulated in an `NSImage` object) in a frame. This class provides methods for choosing the frame and for aligning and scaling the image to fit the frame.

The object value of an `NSImageCell` object must be an `NSImage` object, so if you use the `setObjectValue:` (page 592) method of `NSCell`, be sure to supply an `NSImage` object as an argument. Because an `NSImage` object does not need to be converted for display, do not use the `NSCell` methods relating to formatters.

An `NSImageCell` object is usually associated with some kind of control object. For example, an `NSMatrix` or an `NSTableView`.

Designated Initializers

When subclassing `NSImageCell` you must implement all of the designated initializers. Those methods are: init, `initWithCoder:`, `initTextCell:` (page 564), and `initImageCell:` (page 563).

Tasks

Aligning and Scaling the Image

- `imageAlignment` (page 1394)
  Returns the alignment of the receiver's image relative to its frame.
- `setImageAlignment:` (page 1395)
  Sets the alignment of the image in its frame.
- `imageScaling` (page 1395)
  Returns the scaling mode used to fit the receiver's image into the frame.
- `setImageScaling:` (page 1396)
  Sets the scaling mode used to fit the receiver's image into the frame.

Choosing the Frame

- `imageFrameStyle` (page 1394)
  Returns the style of the frame that borders the image.
- `setImageFrameStyle:` (page 1396)
  Sets the style of the frame that borders the image.

Instance Methods

imageAlignment

Returns the alignment of the receiver's image relative to its frame.

```
- (NSImageAlignment)imageAlignment
```

Return Value
One of the image alignment constants. For a list of possible values, see `NSImageAlignment` (page 1396). The default value is `NSImageAlignCenter`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setImageAlignment:` (page 1395)

Declared In
`NSImageCell.h`

imageFrameStyle

Returns the style of the frame that borders the image.

```
- (NSImageFrameStyle)imageFrameStyle
```

Return Value
One of the frame style constants. For a list of frame styles, see `NSImageFrameStyle` (page 1398). The default value is `NSImageFrameNone`.

Availability
Available in Mac OS X v10.0 and later.

See Also

imageScaling

Returns the scaling mode used to fit the receiver's image into the frame.

```
- (NSImageScaling)imageScaling
```

Return Value
One of the image scaling constants. For a list of possible values, see `NSImageScaling` (page 617). The default value is `NSImageScaleProportionallyDown` (page 617).

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setImageScaling:` (page 1396)

Declared In
`NSImageCell.h`

setImageAlignment:

Sets the alignment of the image in its frame.

```
- (void)setImageAlignment:(NSImageAlignment)alignment
```

Parameters
alignment
One of the image alignment constants. For a list of possible values, see `NSImageAlignment` (page 1396).

Availability
Available in Mac OS X v10.0 and later.

See Also
`- imageAlignment` (page 1394)

Declared In
`NSImageCell.h`

setImageFrameStyle:

Sets the style of the frame that borders the image.

```
- (void)setImageFrameStyle:(NSImageFrameStyle)frameStyle
```

Parameters

frameStyle

One of the frame style constants. For a list of frame styles, see `NSImageFrameStyle` (page 1398).

Availability

Available in Mac OS X v10.0 and later.

See Also

`- imageFrameStyle` (page 1394)

Declared In

`NSImageCell.h`

setImageScaling:

Sets the scaling mode used to fit the receiver's image into the frame.

```
- (void)setImageScaling:(NSImageScaling)scaling
```

Parameters

scaling

One of the image scaling constants. For a list of possible values, see `NSImageScaling` (page 617).

Availability

Available in Mac OS X v10.0 and later.

See Also

`- imageScaling` (page 1395)

Constants

NSImageAlignment

These constants allow you to specify the location of the image in the frame and are used by `imageAlignment` (page 1394) and `setImageAlignment:` (page 1395).

```
enum {
    NSImageAlignCenter = 0,
    NSImageAlignTop,
    NSImageAlignTopLeft,
    NSImageAlignTopRight,
    NSImageAlignLeft,
    NSImageAlignBottom,
    NSImageAlignBottomLeft,
    NSImageAlignBottomRight,
    NSImageAlignRight
};
typedef NSUInteger NSImageAlignment;
```

Constants

`NSImageAlignCenter`
Center the image in the cell.
Available in Mac OS X v10.0 and later.
Declared in `NSImageCell.h`.

`NSImageAlignTop`
Position the image along the top edge of the cell.
Available in Mac OS X v10.0 and later.
Declared in `NSImageCell.h`.

`NSImageAlignTopLeft`
Align the image with the top and left edges of the cell.
Available in Mac OS X v10.0 and later.
Declared in `NSImageCell.h`.

`NSImageAlignTopRight`
Align the image with the top and right edges of the cell.
Available in Mac OS X v10.0 and later.
Declared in `NSImageCell.h`.

`NSImageAlignLeft`
Align the image with the left edge of the cell.
Available in Mac OS X v10.0 and later.
Declared in `NSImageCell.h`.

`NSImageAlignBottom`
Align the image with the bottom edge of the cell.
Available in Mac OS X v10.0 and later.
Declared in `NSImageCell.h`.

`NSImageAlignBottomLeft`
Align the image with the bottom and left edges of the cell.
Available in Mac OS X v10.0 and later.
Declared in `NSImageCell.h`.

`NSImageAlignBottomRight`
Align the image with the bottom and right edges of the cell.
Available in Mac OS X v10.0 and later.
Declared in `NSImageCell.h`.

`NSImageAlignRight`
Position the image along the right edge of the cell.

Available in Mac OS X v10.0 and later.

Declared in `NSImageCell.h`.

Declared In
`NSImageCell.h`

NSImageFrameStyle

These constants allow you to specify the kind of frame bordering the image and are used by `imageFrameStyle` (page 1394) and `setImageFrameStyle:` (page 1396). (Deprecated. These constants are obsolete, and are not compliant with the *Apple Human Interface Guidelines*.)

```
enum {
    NSImageFrameNone = 0,
    NSImageFramePhoto,
    NSImageFrameGrayBezel,
    NSImageFrameGroove,
    NSImageFrameButton
};
typedef NSUInteger NSImageFrameStyle;
```

Constants
`NSImageFrameNone`
An invisible frame

Available in Mac OS X v10.0 and later.

Declared in `NSImageCell.h`.

`NSImageFramePhoto`
A thin black outline and a dropped shadow

Available in Mac OS X v10.0 and later.

Declared in `NSImageCell.h`.

`NSImageFrameGrayBezel`
A gray, concave bezel that makes the image look sunken

Available in Mac OS X v10.0 and later.

Declared in `NSImageCell.h`.

`NSImageFrameGroove`
A thin groove that looks etched around the image

Available in Mac OS X v10.0 and later.

Declared in `NSImageCell.h`.

`NSImageFrameButton`
A convex bezel that makes the image stand out in relief, like a button

Available in Mac OS X v10.0 and later.

Declared in `NSImageCell.h`.

Declared In
`NSImageCell.h`

NSImageRep Class Reference

Inherits from	NSObject
Conforms to	NSCoding NSCopying NSObject (NSObject)
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.0 and later.
Declared in	AppKit/NSImageRep.h
Companion guide	Cocoa Drawing Guide
Related sample code	LayerBackedOpenGLView NSOpenGL Fullscreen Reducer

Overview

The `NSImageRep` class is a semiabstract superclass ("semi" because it has some instance variables and implementation of its own). Each of its subclasses knows how to draw an image from a particular kind of source data. While an `NSImageRep` subclass can be used directly, it is typically through an `NSImage` object. An `NSImage` object manages a group of image representations, choosing the best one for the current output device.

Tasks

Creating an NSImageRep

`+ imageRepsWithContentsOfFile:` (page 1405)
Creates and returns an array of image representation objects initialized using the contents of the specified file.

`+ imageRepsWithPasteboard:` (page 1407)
Creates and returns an array of image representation objects initialized using the contents of the pasteboard.

+ `imageRepsWithContentsOfURL:` (page 1406)
Creates and returns an array of image representation objects initialized using the contents of the specified URL.

+ `imageRepWithContentsOfFile:` (page 1408)
Creates and returns an image representation object using the contents of the specified file.

+ `imageRepWithPasteboard:` (page 1409)
Creates and returns an image representation object using the contents of the specified pasteboard.

+ `imageRepWithContentsOfURL:` (page 1409)
Creates and returns an image representation object using the data at the specified URL

Determining the Supported Image Types

+ `canInitWithData:` (page 1402)
Returns a Boolean value indicating whether the receiver can initialize itself from the specified data.

+ `canInitWithPasteboard:` (page 1403)
Returns a Boolean value indicating whether the receiver can initialize itself from the data on the specified pasteboard.

+ `imageTypes` (page 1410)
Returns an array of UTI strings identifying the image types supported by the receiver, either directly or through a user-installed filter service.

+ `imageUnfilteredTypes` (page 1412)
Returns an array of UTI strings identifying the image types supported directly by the receiver.

+ `imageFileTypes` (page 1403)
Returns the file types supported by `NSImageRep` or one of its subclasses.

+ `imagePasteboardTypes` (page 1404)
Returns the pasteboard types supported by `NSImageRep` or one of its subclasses.

+ `imageUnfilteredFileTypes` (page 1410)
Returns the list of file types supported directly by the receiver.

+ `imageUnfilteredPasteboardTypes` (page 1411)
Returns the list of pasteboard types supported directly by the receiver.

Setting the Size of the Image

- `setSize:` (page 1423)
Sets the size of the image representation to the specified value.

- `size` (page 1424)
Returns the size of the image representation.

Specifying Information About the Representation

- `bitsPerSample` (page 1414)
Returns the number of bits per sample in the receiver.

- `colorSpaceName` (page 1415)
  Returns the name of the receiver's color space.
- `hasAlpha` (page 1418)
  Returns a Boolean value indicating whether the receiver has an alpha channel.
- `isOpaque` (page 1419)
  Returns a Boolean value indicating whether the receiver is opaque.
- `pixelsHigh` (page 1419)
  Returns the height of the image, measured in pixels.
- `pixelsWide` (page 1420)
  Returns the width of the image, measured in pixels.
- `setAlpha:` (page 1420)
  Informs the receiver that its image data has an alpha component.
- `setBitsPerSample:` (page 1421)
  Informs the receiver that its image data has the specified number of bits for each component of a pixel.
- `setColorSpaceName:` (page 1421)
  Informs the receiver of the color space used by the image data.
- `setOpaque:` (page 1422)
  Sets whether the receiver's image is opaque.
- `setPixelsHigh:` (page 1422)
  Informs the receiver of the image data height.
- `setPixelsWide:` (page 1423)
  Informs the receiver of the image data width.

Getting a CGImage

- `CGImageForProposedRect:context:hints:` (page 1414)
  Returns a `CGImage` capturing the drawing of the receiver.

Drawing the Image

- `draw` (page 1415)
  Implemented by subclasses to draw the image in the current coordinate system.
- `drawAtPoint:` (page 1416)
  Draws the receiver's image data at the specified point in the current coordinate system.
- `drawInRect:` (page 1417)
  Draws the image, scaling it (as needed) to fit the specified rectangle.
- `drawInRect:fromRect:operation:fraction:respectFlipped:hints:` (page 1417)
  Draws all or part of the image in the specified rectangle in the current coordinate system.

Managing NSImageRep Subclasses

`+ imageRepClassForType:` (page 1405)
Returns the `NSImageRep` subclass that handles image data for the specified UTI.

`+ imageRepClassForData:` (page 1404)
Returns the `NSImageRep` subclass that handles the specified type of data.

`+ imageRepClassForFileType:` (page 1404)
Returns the `NSImageRep` subclass that handles data with the specified type.

`+ imageRepClassForPasteboardType:` (page 1405)
Returns the `NSImageRep` subclass that handles data with the specified pasteboard type.

`+ registeredImageRepClasses` (page 1412)
Returns an array containing the registered `NSImageRep` classes.

`+ registerImageRepClass:` (page 1413)
Adds the specified class to the registry of available `NSImageRep` subclasses.

`+ unregisterImageRepClass:` (page 1413)
Removes the specified `NSImageRep` subclass from the registry of available image representations.

Class Methods

canInitWithData:

Returns a Boolean value indicating whether the receiver can initialize itself from the specified data.

```
+ (BOOL)canInitWithData:(NSData *)data
```

Parameters

data
The image data.

Return Value
`YES` if the receiver understands the format of the specified data and can use it to initialize itself; otherwise, `NO`.

Discussion
This method should be overridden by subclasses. Note that this method does not need to do a comprehensive check of the image data; it should return `NO` only if it knows it cannot initialize itself from the data.

Availability
Available in Mac OS X v10.0 and later.

See Also
`+ canInitWithPasteboard:` (page 1403)

Declared In
`NSImageRep.h`

canInitWithPasteboard:

Returns a Boolean value indicating whether the receiver can initialize itself from the data on the specified pasteboard.

```
+ (BOOL)canInitWithPasteboard:(NSPasteboard *)pasteboard
```

Parameters

pasteboard

The pasteboard containing the image data.

Return Value

`YES` if the receiver understands the format of the specified data and can use it to initialize itself; otherwise, `NO`.

Discussion

This method invokes the `imageUnfilteredPasteboardTypes` (page 1411) class method and checks the list of types returned by that method against the data types in *pasteboard*. If it finds a match, it returns `YES`. When creating a subclass of `NSImageRep` that accepts image data from a non-default pasteboard type, override the `imageUnfilteredPasteboardTypes` (page 1411) method to assure this method returns the correct response.

Availability

Available in Mac OS X v10.0 and later.

See Also

`+ canInitWithData:` (page 1402)

Declared In

`NSImageRep.h`

imageFileTypes

Returns the file types supported by `NSImageRep` or one of its subclasses.

```
+ (NSArray *)imageFileTypes
```

Return Value

An array of `NSString` objects, each of which contains a filename extension or HFS file type of a supported format.

Discussion

The list includes both those types returned by the `imageUnfilteredFileTypes` (page 1410) class method plus those that can be converted to a supported type by a user-installed filter service. The returned file types can include encoded HFS file types as well as filename extensions.

Don't override this method when subclassing `NSImageRep`—it always returns a valid list for any subclass of `NSImageRep` that correctly overrides the `imageUnfilteredFileTypes` (page 1410) method.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSImageRep.h`

imagePasteboardTypes

Returns the pasteboard types supported by `NSImageRep` or one of its subclasses.

```
+ (NSArray *)imagePasteboardTypes
```

Return Value
An array of `NSString` objects, each of which contains a supported pasteboard format.

Discussion
The list includes both those types returned by the `imageUnfilteredPasteboardTypes` (page 1411) class method plus those that can be converted to a supported type by a user-installed filter service. Don't override this method when subclassing `NSImageRep`—it always returns a valid list for any subclass of `NSImageRep` that correctly overrides the `imageUnfilteredPasteboardTypes` (page 1411) method.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSImageRep.h`

imageRepClassForData:

Returns the `NSImageRep` subclass that handles the specified type of data.

```
+ (Class)imageRepClassForData:(NSData *)data
```

Parameters

data
The image data.

Return Value
A `Class` object for the image representation that can handle the data, or `nil` if no image representation could handle the data.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSImageRep.h`

imageRepClassForFileType:

Returns the `NSImageRep` subclass that handles data with the specified type.

```
+ (Class)imageRepClassForFileType:(NSString *)type
```

Parameters

type
A string containing the filename extension or an encoded HFS type.

Return Value
A `Class` object for the image representation that can handle the type of data, or `nil` if no image representation could handle the type.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSImageRep.h`

imageRepClassForPasteboardType:

Returns the `NSImageRep` subclass that handles data with the specified pasteboard type.

```
+ (Class)imageRepClassForPasteboardType:(NSString *)type
```

Parameters

type

The pasteboard type.

Return Value
A `Class` object for the image representation that can handle the specified pasteboard type, or `nil` if no image representation could handle the type.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSImageRep.h`

imageRepClassForType:

Returns the `NSImageRep` subclass that handles image data for the specified UTI.

```
+ (Class)imageRepClassForType:(NSString *)type
```

Parameters

type

The UTI string identifying the desired image type. Some sample image-related UTI strings include "`public.image`", "`public.jpeg`", and "`public.tiff`". For a list of supported types, see `UTCoreTypes.h`.

Return Value
A `Class` object for the image representation that can handle the UTI, or `nil` if no image representation could handle the data.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSImageRep.h`

imageRepsWithContentsOfFile:

Creates and returns an array of image representation objects initialized using the contents of the specified file.

```
+ (NSArray *)imageRepsWithContentsOfFile:(NSString *)filename
```

Parameters

filename

A full or relative pathname specifying the file to open. This string should include the filename extension.

Return Value

An array of image representation objects. The array contains one object for each image in the specified file.

Discussion

If sent to the `NSImageRep` class object, this method returns an array of objects (all newly allocated instances of a subclass of `NSImageRep`, chosen through the use of `imageRepClassForFileType:` (page 1404)) that have been initialized with the contents of the file. If sent to a subclass of `NSImageRep` that recognizes the file type, this method returns an array of objects (all instances of that subclass) that have been initialized with the contents of the file.

This method returns `nil` in any of the following cases:

- The message is sent to the `NSImageRep` class object and there are no subclasses in the `NSImageRep` class registry that handle the data in the file.
- The message is sent to a subclass of `NSImageRep` and that subclass cannot handle the data in the file.
- The `NSImageRep` subclass is unable to initialize itself with the contents of *filename*.

The `NSImageRep` subclass is initialized by creating an `NSData` object based on the contents of the file and passing it to the `imageRepsWithData:` method of the subclass. By default, the files handled include those with the extensions "`tiff`", "`gif`", "`jpg`", "`pict`", "`pdf`", and "`eps`".

Availability

Available in Mac OS X v10.0 and later.

See Also

`+ imageFileTypes` (page 1403)

Declared In

`NSImageRep.h`

imageRepsWithContentsOfURL:

Creates and returns an array of image representation objects initialized using the contents of the specified URL.

```
+ (NSArray *)imageRepsWithContentsOfURL:(NSURL *)aURL
```

Parameters

aURL

The URL pointing to the image data.

Return Value

An array of image representation objects. The array contains one object for each image in the data at the specified URL.

Discussion
If sent to the `NSImageRep` class object, this method returns an array of objects (all newly allocated instances of a subclass of `NSImageRep`) that have been initialized with the contents of the specified URL. If sent to a subclass of `NSImageRep` that recognizes the data at the specified URL, it returns an array of objects (all instances of that subclass) that have been initialized with the contents of that URL.

This method returns `nil` in any of the following cases:

- The message is sent to the `NSImageRep` class object and there are no subclasses in the `NSImageRep` class registry that handle data in the specified URL.
- The message is sent to a subclass of `NSImageRep` and that subclass cannot handle data in the specified URL.
- The `NSImageRep` subclass is unable to initialize itself with the contents of the specified URL.

The `NSImageRep` subclass is initialized by creating an `NSData` object based on the contents of the specified URL and passing it to the `imageRepsWithData:` method.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSImageRep.h`

imageRepsWithPasteboard:

Creates and returns an array of image representation objects initialized using the contents of the pasteboard.

```
+ (NSArray *)imageRepsWithPasteboard:(NSPasteboard *)pasteboard
```

Parameters
pasteboard
The pasteboard containing the image data.

Return Value
An array of image representation objects. The array contains one object for each image in the specified pasteboard.

Discussion
If sent to the `NSImageRep` class object, this method returns an array of objects (all newly-allocated instances of a subclass of `NSImageRep`) that have been initialized with the data in the specified pasteboard. If sent to a subclass of `NSImageRep` that recognizes the pasteboard data, it returns an array of objects (all instances of that subclass) initialized with the pasteboard data.

This method returns `nil` in any of the following cases:

- The message is sent to the `NSImageRep` class object and there are no subclasses in the `NSImageRep` class registry that handle the pasteboard data.
- The message is sent to a subclass of `NSImageRep` and that subclass cannot handle the pasteboard data.
- The `NSImageRep` subclass is unable to initialize itself with the contents the pasteboard.

The NSImageRep subclass is initialized by creating an NSData object based on the data in *pasteboard* and passing it to the imageRepsWithData: method.

Availability
Available in Mac OS X v10.0 and later.

See Also
+ imagePasteboardTypes (page 1404)

Declared In
NSImageRep.h

imageRepWithContentsOfFile:

Creates and returns an image representation object using the contents of the specified file.

```
+ (id)imageRepWithContentsOfFile:(NSString *)filename
```

Parameters

filename

A full or relative pathname specifying the file to open. This string should include the filename extension.

Return Value
An initialized instance of an NSImageRep subclass, or nil if the image data could not be read.

Discussion
If sent to the NSImageRep class object, this method returns a newly allocated instance of a subclass of NSImageRep (chosen through the use of imageRepClassForFileType: (page 1404)) initialized with the contents of the specified file. If sent to a subclass of NSImageRep that recognizes the type of data in the file, it returns an instance of that subclass initialized with the contents of the file.

This method returns nil in any of the following cases:

- The message is sent to the NSImageRep class object and there are no subclasses in the NSImageRep class registry that handle the type of data in the specified file.
- The message is sent to a subclass of NSImageRep and that subclass cannot handle the type of data in the specified file.
- The NSImageRep subclass is unable to initialize itself with the contents of the specified file.

The NSImageRep subclass is initialized by creating an NSData object based on the contents of the file and passing it to the imageRepWithData: method. By default, the files handled include those with the extensions "tiff", "gif", "jpg", "pict", "pdf", and "eps".

Availability
Available in Mac OS X v10.0 and later.

See Also
+ imageFileTypes (page 1403)

Related Sample Code
PDFView

Declared In
NSImageRep.h

imageRepWithContentsOfURL:

Creates and returns an image representation object using the data at the specified URL

```
+ (id)imageRepWithContentsOfURL:(NSURL *)aURL
```

Parameters

aURL

The URL pointing to the image data.

Return Value
An initialized instance of an NSImageRep subclass, or nil if the image data could not be read.

Discussion
If sent to the NSImageRep class object, this method returns a newly allocated instance of a subclass of NSImageRep initialized with the contents of the specified URL. If sent to a subclass of NSImageRep that recognizes the data contained in the URL, it returns an instance of that subclass initialized with the data in the URL.

This method returns nil in any of the following cases:

- The message is sent to the NSImageRep class object and there are no subclasses in the NSImageRep class registry that handle the data contained in the specified URL.
- The message is sent to a subclass of NSImageRep and that subclass cannot handle the data contained in the specified URL.
- The NSImageRep subclass is unable to initialize itself with the contents of the specified URL.

The NSImageRep subclass is initialized by creating an NSData object based on the contents of the file, then passing it to the imageRepWithData: method.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSImageRep.h

imageRepWithPasteboard:

Creates and returns an image representation object using the contents of the specified pasteboard.

```
+ (id)imageRepWithPasteboard:(NSPasteboard *)pasteboard
```

Parameters

pasteboard

The pasteboard containing the image data.

Return Value
An initialized instance of an NSImageRep subclass, or nil if the image data could not be read.

Discussion
If sent to the `NSImageRep` class object, this method returns a newly allocated instance of a subclass of `NSImageRep` initialized with the data in the specified pasteboard. If sent to a subclass of `NSImageRep` that recognizes the data on the pasteboard, it returns an instance of that subclass initialized with that data.

This method returns `nil` in any of the following cases:

- The message is sent to the `NSImageRep` class object and there are no subclasses in the `NSImageRep` class registry that handle data of the type contained in the specified pasteboard.
- The message is sent to a subclass of `NSImageRep` and that subclass cannot handle data of the type contained in the specified pasteboard.
- The `NSImageRep` subclass is unable to initialize itself with the contents of the pasteboard.

The `NSImageRep` subclass is initialized by creating an `NSData` object based on the data the specified pasteboard and passing it to the `imageRepWithData:` method.

Availability
Available in Mac OS X v10.0 and later.

See Also
`+ imagePasteboardTypes` (page 1404)

Declared In
`NSImageRep.h`

imageTypes

Returns an array of UTI strings identifying the image types supported by the receiver, either directly or through a user-installed filter service.

```
+ (NSArray *)imageTypes
```

Return Value
An array of `NSString` objects, each of which contains a UTI identifying a supported image type. Some sample image-related UTI strings include "`public.image`", "`public.jpeg`", and "`public.tiff`". For a list of supported types, see `UTCoreTypes.h`.

Discussion
The returned list includes UTIs all file types supported by this image representation object plus those that can be opened by this image representation after being converted by a user-installed filter service. You can use the returned UTI strings with any method that supports UTIs.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSImageRep.h`

imageUnfilteredFileTypes

Returns the list of file types supported directly by the receiver.

```
+ (NSArray *)imageUnfilteredFileTypes
```

Return Value
An array of `NSString` objects. This array is empty by default. Subclasses must override to return the list of file formats they support.

Discussion
The returned file types can include encoded HFS file types as well as filename extensions. When creating a subclass of `NSImageRep`, override this method to return a list of strings representing the supported file types. For example, the `NSBitmapImageRep` class implements code similar to the following for this method:

```
+ (NSArray *)imageUnfilteredFileTypes {
    static NSArray *types = nil;

    if (!types) types = [[NSArray alloc]
        initWithObjects:@"tiff", @"gif", @"jpg",  @"bmp", nil];
    return types;
}
```

If your subclass supports the types supported by its superclass, you must explicitly get the array of types from the superclass and put them in the array returned by this method.

Availability
Available in Mac OS X v10.0 and later.

See Also
`+ imageFileTypes` (page 1403)
`+ imageUnfilteredFileTypes` (page 1333) (NSImage)

Declared In
`NSImageRep.h`

imageUnfilteredPasteboardTypes

Returns the list of pasteboard types supported directly by the receiver.

```
+ (NSArray *)imageUnfilteredPasteboardTypes
```

Return Value
An array of `NSString` objects. This array is empty by default. Subclasses must override to return the list of pasteboard formats they support.

Discussion
When creating a subclass of `NSImageRep`, override this method to return a list representing the supported pasteboard types. For example, the `NSBitmapImageRep` class implements code similar to the following for this method:

```
+ (NSArray *)imageUnfilteredPasteboardTypes {
    static NSArray *types = nil;

    if (!types) types = [[NSArray alloc] initWithObjects:NSTIFFPboardType,
nil];
    return types;
}
```

If your subclass supports the types supported by its superclass, you must explicitly get the list of types from the superclass and add them to the array returned by this method.

Availability
Available in Mac OS X v10.0 and later.

See Also
`+ imagePasteboardTypes` (page 1404)
`+ imageUnfilteredPasteboardTypes` (page 1333) (NSImage)

Declared In
`NSImageRep.h`

imageUnfilteredTypes

Returns an array of UTI strings identifying the image types supported directly by the receiver.

```
+ (NSArray *)imageUnfilteredTypes
```

Return Value
An array of `NSString` objects, each of which contains a UTI identifying a supported image type. Some sample image-related UTI strings include "`public.image`", "`public.jpeg`", and "`public.tiff`". For a list of supported types, see `UTCoreTypes.h`.

Discussion
The returned list includes UTI strings only for those file types that are supported directly by the receiver. It does not include types that are supported through user-installed filter services. You can use the returned UTI strings with any method that supports UTIs.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSImageRep.h`

registeredImageRepClasses

Returns an array containing the registered `NSImageRep` classes.

```
+ (NSArray *)registeredImageRepClasses
```

Return Value
An array of `Class` objects identifying the registered `NSImageRep` subclasses.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSImageRep.h`

registerImageRepClass:

Adds the specified class to the registry of available `NSImageRep` subclasses.

```
+ (void)registerImageRepClass:(Class)imageRepClass
```

Parameters

imageRepClass
The `Class` object for an `NSImageRep` subclass.

Discussion
This method posts an `NSImageRepRegistryDidChangeNotification` (page 1425), along with the receiving object, to the default notification center.

A good place to add image representation classes to the registry is in the `load` class method.

Availability
Available in Mac OS X v10.0 and later.

See Also
`+ unregisterImageRepClass:` (page 1413)
`load` (NSObject)

Declared In
`NSImageRep.h`

unregisterImageRepClass:

Removes the specified `NSImageRep` subclass from the registry of available image representations.

```
+ (void)unregisterImageRepClass:(Class)imageRepClass
```

Parameters

imageRepClass
The `Class` object for an `NSImageRep` subclass.

Discussion
This method posts the `NSImageRepRegistryDidChangeNotification` (page 1425), along with the receiving object, to the default notification center.

Availability
Available in Mac OS X v10.0 and later.

See Also
`+ registerImageRepClass:` (page 1413)

Declared In
`NSImageRep.h`

Instance Methods

bitsPerSample

Returns the number of bits per sample in the receiver.

```
- (NSInteger)bitsPerSample
```

Return Value
The number of bits used to specify each component of data in a single pixel (for example, a value of 8 for an RGBA image means that each pixel is comprised of four 8-bit values). May also return `NSImageRepMatchesDevice` (page 1425).

Discussion
If the receiver is a planar image, this method returns the number of bits per sample per plane.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setBitsPerSample:` (page 1421)
- `bitsPerPixel` (page 348) (NSBitmapImageRep)
- `samplesPerPixel` (page 364) (NSBitmapImageRep)

Related Sample Code
Quartz EB

Declared In
`NSImageRep.h`

CGImageForProposedRect:context:hints:

Returns a `CGImage` capturing the drawing of the receiver.

```
- (CGImageRef)CGImageForProposedRect:(NSRect *)proposedDestRect
    context:(NSGraphicsContext *)context hints:(NSDictionary *)hints
```

Parameters

`proposedDestRect`

On input, the proposed destination rectangle for drawing the image. If `NULL`, it defaults to the smallest pixel-integral rectangle containing {{0,0}, [self size]}. The *`proposedDestRect`* is in user space in the reference context.

On output the proposedDestRect may have been altered. This is because a `CGImage` is necessarily pixel-integral, while an `NSImage` is not. In order to produce a `CGImage` for rect `(0.5, 0.5, 4.0, 4.0)` without distortion or double-antialiasing, we may have to produce a 5x5 `CGImage`, and also inflate the *`proposedDestRect`*. Drawing the `CGImage` in the out-value *`proposedDestRect`* is the same as drawing the NSImage in the in-value of proposed rect.

`context`

A graphics context., Can be `NULL`.

hints

An optional dictionary of hints that provide more context for selecting or generating the image. See `Image_Hint_Dictionary_Keys` (page 1375) for a summary of the possible key-value pairs.

Return Value
A `CGImageRef`. This may be an existing `CGImage` if one is available. If not, a new `CGImage` is created.

Discussion
An `NSImage` is potentially resolution independent, and may have representations that allow it to draw well in many contexts. A `CGImage` is more like a single pixel-based representation. This method produces a snapshot of how the `NSImage` would draw if it was asked to draw in the proposed rectangle in the graphics context.

All input parameters are optional. They provide hints for how to choose among existing CGImages, or how to create one if there isn't already a CGImage available. The parameters are only hints.

This method is intended as an override point for image rep subclasses that naturally have a `CGImage` available. For example, `NSBitmapImageRep` overrides it to return the `CGImage` that naturally backs the rep. You don't need to override the method except possibly for performance, though. The NSImageRep-level implementation will produce a CGImage by making a buffer and calling `[self draw]`. That's likely to be the best possible implementation for reps that aren't naturally CGImage backed. The `draw` (page 1415) remains the only method of NSImageRep that a subclasser really needs to override.

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSImageRep.h`

colorSpaceName

Returns the name of the receiver's color space.

```
- (NSString *)colorSpaceName
```

Return Value
The colorspace name, or `NSCalibratedRGBColorSpace` if no name has been assigned.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setColorSpaceName:` (page 1421)

Declared In
`NSImageRep.h`

draw

Implemented by subclasses to draw the image in the current coordinate system.

```
- (BOOL)draw
```

Return Value
`YES` if the image was successfully drawn; otherwise, `NO` if there was a problem. The default version of this method simply returns `YES`.

Discussion
Subclass override this method to draw the image using the image data. By the time this method is called, the graphics state is already configured for you to draw the image at location (0.0, 0.0) in the current coordinate system.

The standard Application Kit subclasses all draw the image using the `NSCompositeCopy` composite operation defined in the "Constants" (page 1375) section of `NSImage`. Using the copy operator, the image data overwrites the destination without any blending effects. Transparent (alpha) regions in the source image appear black. To use other composite operations, you must place the representation into an `NSImage` object and use its `drawAtPoint:fromRect:operation:fraction:` (page 1346) or `drawInRect:fromRect:operation:fraction:` (page 1347) methods.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
GLUT

Declared In
`NSImageRep.h`

drawAtPoint:

Draws the receiver's image data at the specified point in the current coordinate system.

```
- (BOOL)drawAtPoint:(NSPoint)aPoint
```

Parameters
aPoint
The point in the current coordinate system at which to draw the image.

Return Value
`YES` if the image was successfully drawn; otherwise, `NO`. If the size of the image has not yet been set, this method returns `NO` immediately

Discussion
This method sets the origin of the current coordinate system to the specified point and then invokes the receiver's `draw` method to draw the image at that point. Upon completion, it restores the current coordinates to their original setting. If *aPoint* is (0.0, 0.0), this method simply invokes the `draw` (page 1415) method.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setSize:` (page 1423)
- `drawInRect:` (page 1417)
- `drawInRect:fromRect:operation:fraction:respectFlipped:hints:` (page 1417)

Declared In
`NSImageRep.h`

drawInRect:

Draws the image, scaling it (as needed) to fit the specified rectangle.

```
- (BOOL)drawInRect:(NSRect)rect
```

Parameters

rect

The rectangle in the current coordinate system in which to draw the image.

Return Value

`YES` if the image was successfully drawn; otherwise, `NO`. If the size of the image has not yet been set, this method returns `NO` immediately

Discussion

This method sets the origin of the current coordinate system to the origin of the specified rectangle before invoking the receiver's `draw` (page 1415) method. If the rectangle size is different from the image's native size, this method adjusts the coordinate transform, causing the image to be scaled appropriately. After the `draw` method returns, the coordinate system changes are undone, restoring the original graphics state.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `setSize:` (page 1423)

Sketch-112

Declared In

`NSImageRep.h`

drawInRect:fromRect:operation:fraction:respectFlipped:hints:

Draws all or part of the image in the specified rectangle in the current coordinate system.

```
- (BOOL)drawInRect:(NSRect)dstSpacePortionRect fromRect:(NSRect)srcSpacePortionRect
    operation:(NSCompositingOperation)op fraction:(CGFloat)requestedAlpha
  respectFlipped:(BOOL)respectContextIsFlipped hints:(NSDictionary *)hints
```

Parameters

dstSpacePortionRect

The rectangle in which to draw the image, specified in the current coordinate system.

srcSpacePortionRect

The source rectangle specifying the portion of the image you want to draw. The coordinates of this rectangle must be specified using the image's own coordinate system. If you pass in `NSZeroRect`, the entire image is drawn.

op

The compositing operation to use when drawing the image. See the `NSCompositingOperation` (page 1375) constants.

requestedAlpha

The opacity of the image, specified as a value from 0.0 to 1.0. Specifying a value of 0.0 draws the image as fully transparent while a value of 1.0 draws the image as fully opaque. Values greater than 1.0 are interpreted as 1.0.

respectContextIsFlipped

`YES` if the flipped context of the receiver should be respected, otherwise `NO`.

hints

An optional dictionary of hints that provide more context for selecting or generating the image. See `Image_Hint_Dictionary_Keys` (page 1375) for a summary of the possible key-value pairs.

Return Value
`YES` if the image was successfully drawn; otherwise, `NO`.

Discussion
If the *srcSpacePortionRect* and *dstSpacePortionRect* rectangles have different sizes, the source portion of the image is scaled to fit the specified destination rectangle.

Availability
Available in Mac OS X v10.6 and later.

See Also
- `draw` (page 1415)
- `drawAtPoint:` (page 1416)
- `drawInRect:` (page 1417)

Declared In
`NSImageRep.h`

hasAlpha

Returns a Boolean value indicating whether the receiver has an alpha channel.

```
- (BOOL)hasAlpha
```

Return Value
`YES` if the receiver has a known alpha channel; otherwise, `NO`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setAlpha:` (page 1420)

Related Sample Code
LayerBackedOpenGLView
NSOpenGL Fullscreen

Declared In
`NSImageRep.h`

isOpaque

Returns a Boolean value indicating whether the receiver is opaque.

```
- (BOOL)isOpaque
```

Return Value
`YES` if the receiver is opaque; otherwise, `NO`.

Discussion
Use this method to test whether an image representation completely covers the area within the rectangle returned by the `size` (page 1424) method.

The returned value does not indicate whether the image has an alpha channel or if there is partial or complete transparency when drawing the image rep. Use the `hasAlpha` (page 1418) method to determine if the image has an alpha channel.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setOpaque:` (page 1422)

Declared In
`NSImageRep.h`

pixelsHigh

Returns the height of the image, measured in pixels.

```
- (NSInteger)pixelsHigh
```

Return Value
The height of the image, measured in the units of the device coordinate space. This value is usually derived from the image data itself.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setPixelsHigh:` (page 1422)

GLUT
OpenCL_OceanWave
Quartz EB
Reducer

Declared In
NSImageRep.h

setAlpha:

Informs the receiver that its image data has an alpha component.

```
- (void)setAlpha:(BOOL)flag
```

Parameters
flag
YES if you want the receiver to have an alpha component; otherwise NO.

Discussion
Subclasses should call this method when loading image data to notify the parent class whether that data contains an alpha component. Passing in a value of YES does not add an alpha channel to the image data itself; it merely records the fact that the data has an alpha channel.

Availability
Available in Mac OS X v10.0 and later.

See Also
- hasAlpha (page 1418)

Declared In
NSImageRep.h

setBitsPerSample:

Informs the receiver that its image data has the specified number of bits for each component of a pixel.

```
- (void)setBitsPerSample:(NSInteger)anInt
```

Parameters

anInt
The number of bits used by each component of a pixel, or NSImageRepMatchesDevice (page 1425).

Discussion
Subclasses should call this method when loading image data to notify the parent class of how many bits each sample uses. Specifying a value that differs from the actual image data does not change the bit depth of the image.

Availability
Available in Mac OS X v10.0 and later.

See Also
- bitsPerSample (page 1414)

Declared In
NSImageRep.h

setColorSpaceName:

Informs the receiver of the color space used by the image data.

```
- (void)setColorSpaceName:(NSString *)string
```

Parameters

string
The name of the color space used by the image data.

Discussion
By default, an NSImageRep object's color space name is NSCalibratedRGBColorSpace. Color space names are defined as part of the NSColor class, in NSGraphics.h. The following are valid color space names:

```
NSCalibratedWhiteColorSpace
NSCalibratedBlackColorSpace
NSCalibratedRGBColorSpace
NSDeviceWhiteColorSpace
NSDeviceBlackColorSpace
NSDeviceRGBColorSpace
NSDeviceCMYKColorSpace
NSNamedColorSpace
NSCustomColorSpace
```

Availability
Available in Mac OS X v10.0 and later.

See Also
- `colorSpaceName` (page 1415)

Declared In
`NSImageRep.h`

setOpaque:

Sets whether the receiver's image is opaque.

```
- (void)setOpaque:(BOOL)flag
```

Parameters

flag

`YES` if the image should be treated as fully opaque; otherwise, `NO` to indicate the image may include some transparent regions.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `isOpaque` (page 1419)

Declared In
`NSImageRep.h`

setPixelsHigh:

Informs the receiver of the image data height.

```
- (void)setPixelsHigh:(NSInteger)anInt
```

Parameters

anInt

The height of the image, measured in pixels.

Discussion
Subclasses should call this method when loading image data to notify the parent class of the image height. You cannot use this method to change the actual number of pixels in the image.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `pixelsHigh` (page 1419)
- `setPixelsWide:` (page 1423)
- `setSize:` (page 1423)
- `NSImageRepMatchesDevice` (page 1425)

Declared In
NSImageRep.h

setPixelsWide:

Informs the receiver of the image data width.

```
- (void)setPixelsWide:(NSInteger)anInt
```

Parameters

anInt

The width of the image, measured in pixels.

Discussion
Subclasses should call this method when loading image data to notify the parent class of the image width. You cannot use this method to change the actual number of pixels in the image.

Availability
Available in Mac OS X v10.0 and later.

See Also
- pixelsWide (page 1420)
- setPixelsHigh: (page 1422)
- setSize: (page 1423)

NSImageRepMatchesDevice (page 1425)

Declared In
NSImageRep.h

setSize:

Sets the size of the image representation to the specified value.

```
- (void)setSize:(NSSize)aSize
```

Parameters

aSize

The new size of the image representation, measured in points in the user coordinate space.

Discussion
This method determines the size of the image when it's rendered. It is not necessarily the same as the width and height of the image in pixels as specified by the image data, nor must it be equal to the size set for the NSImage object that wraps this image representation. You must set the image size before you can render it.

The size of an image representation combined with the physical dimensions of the image data determine the resolution of the image.

Availability
Available in Mac OS X v10.0 and later.

size

Returns the size of the image representation.

```
- (NSSize)size
```

Return Value
The size of the image representation, measured in points in the user coordinate space.

Discussion
This size is the size of the image representation when it's rendered. It is not necessarily the same as the width and height of the image in pixels as specified by the image data, nor must it be equal to the size set for the NSImage object that wraps this image representation.

The size of an image representation combined with the physical dimensions of the image data determine the resolution of the image.

Availability
Available in Mac OS X v10.0 and later.

Constants

Display Device Matching

The following constant is used by `NSImageRep` to denote an attribute whose value changes to match the display device.

```
enum {
   NSImageRepMatchesDevice
};
```

Constants

`NSImageRepMatchesDevice`

Indicates that the value of certain attributes, such as the number of colors or bits per sample, will change to match the display device.

This value can be passed in (or received back) as the value of `bitsPerSample` (page 1414), `pixelsWide` (page 1420), and `pixelsHigh` (page 1419).

Available in Mac OS X v10.0 and later.

Declared in `NSImageRep.h`.

Deprecated Notification Name

The following constant maps to the new notification and is for legacy code only.

```
#define NSImageRepRegistryChangedNotification NSImageRepRegistryDidChangeNotification
```

Constants

`NSImageRepRegistryChangedNotification`

An older name for the `NSImageRepRegistryDidChangeNotification` (page 1425) notification. Do not use.

Available in Mac OS X v10.0 and later.

Declared in `NSImageRep.h`.

Notifications

NSImageRepRegistryDidChangeNotification

Posted whenever the `NSImageRep` class registry changes.

The notification object is the image class that is registered or unregistered. This notification does not contain a *`userInfo`* dictionary.

Availability
Available in Mac OS X v10.0 and later.

Overview

An `NSImageView` object displays a single image from an `NSImage` object in a frame and can optionally allow a user to drag an image to it.

Tasks

Choosing the Image

- `image` (page 1429)
  Returns the `NSImage` object displayed by the receiver.
- `setImage:` (page 1432)
  Sets the image of the receiver.

Choosing the Frame

- `imageFrameStyle` (page 1430)
  Returns the style of frame that appears around the image.
- `setImageFrameStyle:` (page 1434)
  Sets the kind of frame that borders the image.

Aligning and Scaling the Image

- `imageAlignment` (page 1430)
  Returns the position of the cell's image in the frame.
- `setImageAlignment:` (page 1433)
  Sets the position of the image in the frame.
- `imageScaling` (page 1431)
  Returns the way the cell's image alters to fit the frame.
- `setImageScaling:` (page 1434)
  Sets the way the image alters to fit the frame.

Responding to User Events

- `isEditable` (page 1431)
  Returns a Boolean value indicating whether the user can drag a new image into the frame.
- `setEditable:` (page 1432)
  Sets whether the user can drag a new image into the frame.

Animating Image Playback

- `animates` (page 1429)
  Returns a Boolean value indicating whether the receiver automatically plays animated images.
- `setAnimates:` (page 1432)
  Sets whether the receiver automatically plays an animated image that is assigned to it.

Pasteboard Support

- `setAllowsCutCopyPaste:` (page 1431)
  Sets whether the receiver allows the user to cut, copy and paste the image contents.
- `allowsCutCopyPaste` (page 1429)
  Returns a Boolean value indicating whether the receiver allows the user to cut, copy and paste of the image contents.

Instance Methods

allowsCutCopyPaste

Returns a Boolean value indicating whether the receiver allows the user to cut, copy and paste of the image contents.

```
- (BOOL)allowsCutCopyPaste
```

Return Value
`YES` if the user can cut, copy, and paste the image contents; otherwise, `NO`.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- setAllowsCutCopyPaste:` (page 1431)

Declared In
`NSImageView.h`

animates

Returns a Boolean value indicating whether the receiver automatically plays animated images.

```
- (BOOL)animates
```

Return Value
`YES` if the receiver automatically plays animated images; otherwise, `NO`. The default value is `YES` for `NSImageView` objects you create programmatically. For `NSImageView` objects loaded from a nib file, the control takes the value set in Interface Builder.

Discussion
The timing and looping characteristics of the animation are taken from the image data. If this method returns `NO`, the receiver displays the first frame of the animation only.

Availability
Available in Mac OS X v10.3 and later.

See Also
`- setAnimates:` (page 1432)

Declared In
`NSImageView.h`

image

Returns the `NSImage` object displayed by the receiver.

```
- (NSImage *)image
```

Return Value
The `NSImage` object.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setImage:` (page 1432)

Reducer

Declared In
`NSImageView.h`

imageAlignment

Returns the position of the cell's image in the frame.

```
- (NSImageAlignment)imageAlignment
```

Return Value
The image alignment. For a list of possible alignments, see `setImageAlignment:` (page 1433). The default value is `NSImageAlignCenter`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSImageView.h`

imageFrameStyle

Returns the style of frame that appears around the image.

```
- (NSImageFrameStyle)imageFrameStyle
```

Return Value
The current image style. For a list of frame styles, see `setImageFrameStyle:` (page 1434). The default value is `NSImageFrameNone`.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
Transformed Image

Declared In
`NSImageView.h`

imageScaling

Returns the way the cell's image alters to fit the frame.

```
- (NSImageScaling)imageScaling
```

Return Value
The scaling option. For a list of possible values, see `setImageScaling:` (page 1434). The default value is `NSScaleProportionally`.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
CocoaSlides

Declared In
`NSImageView.h`

isEditable

Returns a Boolean value indicating whether the user can drag a new image into the frame.

```
- (BOOL)isEditable
```

Return Value
`YES` if the user can drag an image into the receiver's frame; otherwise, `NO`. The default value is `YES`.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setEditable:` (page 1432)

Declared In
`NSImageView.h`

setAllowsCutCopyPaste:

Sets whether the receiver allows the user to cut, copy and paste the image contents.

```
- (void)setAllowsCutCopyPaste:(BOOL)allow
```

Parameters

allow

`YES` if the user can cut, copy, and paste the image contents; otherwise, `NO` to prevent the use of pasteboard operations.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- allowsCutCopyPaste` (page 1429)

Declared In
NSImageView.h

setAnimates:

Sets whether the receiver automatically plays an animated image that is assigned to it.

```
- (void)setAnimates:(BOOL)flag
```

Parameters

flag

YES if the receiver should automatically plays animated images; otherwise, NO.

Discussion
The timing and looping characteristics of the animation are taken from the image data. If you specify NO, the receiver displays the first frame of the animation only.

Availability
Available in Mac OS X v10.3 and later.

See Also
- animates (page 1429)

Declared In
NSImageView.h

setEditable:

Sets whether the user can drag a new image into the frame.

```
- (void)setEditable:(BOOL)flag
```

Parameters

flag

YES if the user can drag an image into the receiver's frame; otherwise, NO.

Availability
Available in Mac OS X v10.0 and later.

setImageAlignment:

Sets the position of the image in the frame.

```
- (void)setImageAlignment:(NSImageAlignment)alignment
```

Parameters

alignment

The possible values for this parameter are:

- NSImageAlignLeft
- NSImageAlignRight
- NSImageAlignCenter
- NSImageAlignTop
- NSImageAlignBottom
- NSImageAlignTopLeft
- NSImageAlignTopRight
- NSImageAlignBottomLeft
- NSImageAlignBottomRight

Availability
Available in Mac OS X v10.0 and later.

See Also
- imageAlignment (page 1430)

Related Sample Code
GLUT

Declared In
`NSImageView.h`

setImageFrameStyle:

Sets the kind of frame that borders the image.

```
- (void)setImageFrameStyle:(NSImageFrameStyle)frameStyle
```

Parameters

frameStyle

The possible values for this parameter are as follows:

- `NSImageFrameNone`—an invisible frame
- `NSImageFramePhoto`—a thin black outline and a dropped shadow
- `NSImageFrameGrayBezel`—a gray, concave bezel that makes the image look sunken
- `NSImageFrameGroove`—a thin groove that looks etched around the image
- `NSImageFrameButton`—a convex bezel that makes the image stand out in relief, like a button

Availability
Available in Mac OS X v10.0 and later.

See Also
- `imageFrameStyle` (page 1430)

Related Sample Code
FunHouse
Transformed Image

Declared In
`NSImageView.h`

setImageScaling:

Sets the way the image alters to fit the frame.

```
- (void)setImageScaling:(NSImageScaling)scaling
```

Parameters

scaling

The possible values for this parameter are:

- `NSScaleProportionally`. If the image is too large, it shrinks to fit inside the frame. The proportions of the image are preserved. The image is never scaled up to fit a larger frame.
- `NSScaleToFit`. The image shrinks or expands, and its proportions distort, until it exactly fits the frame.
- `NSScaleNone`. The size and proportions of the image don't change. If the frame is too small to display the whole image, the edges of the image are trimmed off.

Availability

Available in Mac OS X v10.0 and later.

NSLayoutManager Class Reference

Inherits from	NSObject
Conforms to	NSGlyphStorage NSCoding NSObject (NSObject)
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.0 and later.
Declared in	AppKit/NSLayoutManager.h
Companion guides	Text System Overview Text Layout Programming Guide
Related sample code	Quartz Composer WWDC 2005 TextEdit QuickLookSketch Sketch+Accessibility Sketch-112 TextSizingExample

Overview

An `NSLayoutManager` object coordinates the layout and display of characters held in an `NSTextStorage` object. It maps Unicode character codes to glyphs, sets the glyphs in a series of `NSTextContainer` objects, and displays them in a series of `NSTextView` objects. In addition to its core function of laying out text, an `NSLayoutManager` object coordinates its `NSTextView` objects, provides services to those text views to support `NSRulerView` instances for editing paragraph styles, and handles the layout and display of text attributes not inherent in glyphs (such as underline or strikethrough). You can create a subclass of `NSLayoutManager` to handle additional text attributes, whether inherent or not.

Text Antialiasing

`NSLayoutManager` provides the threshold for text antialiasing. It looks at the `AppleAntiAliasingThreshold` default value. If the font size is smaller than or equal to this threshold size, the text is rendered aliased by `NSLayoutManager`. You can change the threshold value from the Appearance pane of System Preferences.

Thread Safety of NSLayoutManager

Generally speaking, a given layout manager (and associated objects) should not be used in more than one block, operation, or thread at a time. Most layout managers are used on the main thread, since it is the main thread on which their text views are displayed, and since background layout occurs on the main thread. If it is intended that a layout manager should be used on a background thread, first make sure that text views associated with that layout manager (if any) are not displayed while the layout manager is being used on the background thread, and, second, turn off background layout for that layout manager while it is being used on the background thread.

Noncontiguous Layout

Noncontiguous layout is an optional layout manager behavior new in Mac OS X v10.5. Previously, both glyph generation and layout were always performed, in order, from the beginning to the end of the document. When noncontiguous layout is turned on, however, the layout manager gains the option of performing glyph generation or layout for one portion of the document without having done so for previous sections. This can provide significant performance improvements for large documents.

Noncontiguous layout is not turned on automatically because direct clients of `NSLayoutManager` typically have relied on the previous behavior—for example, by forcing layout for a given glyph range, and then assuming that previous glyphs would therefore be laid out. Clients who use `NSLayoutManager` only indirectly—for example, those who use `NSTextView` without directly calling the underlying layout manager—can usually turn on noncontiguous layout without difficulty. Clients using `NSLayoutManager` directly need to examine their usage before turning on noncontiguous layout.

To turn on noncontiguous layout, use `setAllowsNonContiguousLayout:` (page 1498). In addition, see the other methods in "Managing Noncontiguous Layout" (page 1447), many of which enable you to ensure that glyph generation and layout are performed for specified portions of the text. The behavior of a number of other layout manager methods is affected by the state of noncontiguous layout, as noted in the discussion sections of those method descriptions.

Adopted Protocols

NSCoding
- `encodeWithCoder:`
- `initWithCoder:`

NSGlyphStorage
- `- attributedString` (page 3688)
- `- insertGlyphs:length:forStartingGlyphAtIndex:characterIndex:` (page 3688)
- `- layoutOptions` (page 3689)
- `- setIntAttribute:value:forGlyphAtIndex:` (page 3689)

Tasks

Initializing

- `init` (page 1478)
  Initializes the receiver, a newly created `NSLayoutManager` object.

Setting the Text Storage

- `setTextStorage:` (page 1509)
  Sets the receiver's `NSTextStorage` object.
- `textStorage` (page 1520)
  Returns the receiver's text storage object.
- `attributedString` (page 1451)
  Returns the text storage object from which the `NSGlyphGenerator` object procures characters for glyph generation.
- `replaceTextStorage:` (page 1496)
  Replaces the `NSTextStorage` object for the group of text-system objects containing the receiver with the given text storage object.

Setting Text Containers

- `textContainers` (page 1520)
  Returns the receiver's text containers.
- `addTextContainer:` (page 1449)
  Appends the given text container to the series of text containers where the receiver arranges text.
- `insertTextContainer:atIndex:` (page 1480)
  Inserts the given text container into the series of text containers at the given index.
- `removeTextContainerAtIndex:` (page 1495)
  Removes the text container at the given index and invalidates the layout as needed.

Setting the Glyph Generator

- `setGlyphGenerator:` (page 1502)
  Sets the glyph generator used by this layout manager.
- `glyphGenerator` (page 1472)
  Returns the glyph generator used by this layout manager.

Invalidating Glyphs and Layout

- `invalidateGlyphsForCharacterRange:changeInLength:actualCharacterRange:` (page 1482)
  Invalidates the cached glyphs for the characters in the given character range, adjusts the character indices of all the subsequent glyphs by the change in length, and invalidates the new character range.
- `invalidateGlyphsOnLayoutInvalidationForGlyphRange:` (page 1483)
  Specifies explicitly when portions of the glyph stream depend on layout.
- `invalidateLayoutForCharacterRange:isSoft:actualCharacterRange:` (page 1483)
  Invalidates the layout information for the glyphs mapped to the given range of characters.
- `invalidateLayoutForCharacterRange:actualCharacterRange:` (page 1483)
  Invalidates the layout information for the glyphs mapped to the given range of characters.
- `invalidateDisplayForCharacterRange:` (page 1481)
  Invalidates display for the given character range.
- `invalidateDisplayForGlyphRange:` (page 1482)
  Marks the glyphs in the given glyph range as needing display, as well as the appropriate regions of the `NSTextView` objects that display those glyphs (using the `NSView` method `setNeedsDisplayInRect:` (page 3225)).
- `textContainerChangedGeometry:` (page 1518)
  Invalidates the layout information, and possibly glyphs, for the given text container and all subsequent `NSTextContainer` objects.
- `textContainerChangedTextView:` (page 1518)
  Updates information needed to manage `NSTextView` objects in the given text container.
- `textStorage:edited:range:changeInLength:invalidatedRange:` (page 1521)
  Invalidates glyph and layout information for a portion of the text in the given text storage object.

Enabling Background Layout

- `setBackgroundLayoutEnabled:` (page 1499)
  Specifies whether the receiver generates glyphs and lays them out when the application's run loop is idle.
- `backgroundLayoutEnabled` (page 1451)
  Indicates whether the receiver generates glyphs and lays out text when the application's run loop is idle.

Accessing Glyphs

- `insertGlyph:atGlyphIndex:characterIndex:` (page 1479)
  Inserts a single glyph into the glyph stream at the given index and maps it to the character at the given character index.
- `insertGlyphs:length:forStartingGlyphAtIndex:characterIndex:` (page 1479)
  Inserts the given glyphs into the glyph cache at the given index and maps them to characters beginning at the given character index.
- `isValidGlyphIndex:` (page 1484)
  Indicates whether the specified index refers to a valid glyph, otherwise `NO`.

- `glyphAtIndex:` (page 1471)
  Returns the glyph at *glyphIndex*.
- `glyphAtIndex:isValidIndex:` (page 1472)
  If the given index is valid, returns the glyph at that location and optionally returns a flag indicating whether the requested index is in range.
- `replaceGlyphAtIndex:withGlyph:` (page 1495)
  Replaces the glyph at the given index with a new glyph.
- `getGlyphs:range:` (page 1468)
  Fills the passed-in buffer with a sequence of glyphs
- `getGlyphsInRange:glyphs:characterIndexes:glyphInscriptions:elasticBits:` (page 1469)
  Returns the glyphs and information needed to perform layout for the given glyph range.
- `getGlyphsInRange:glyphs:characterIndexes:glyphInscriptions:elasticBits:bidiLevels:` (page 1469)
  Returns the glyphs and information needed to perform layout for the given glyph range.
- `deleteGlyphsInRange:` (page 1457)
  Deletes the glyphs in the given range from the receiver's glyph store.
- `numberOfGlyphs` (page 1491)
  Returns the number of glyphs in the receiver.

Mapping Characters to Glyphs

- `setCharacterIndex:forGlyphAtIndex:` (page 1500)
  Sets the index of the character corresponding to the glyph at the given glyph index.
- `characterIndexForGlyphAtIndex:` (page 1453)
  Returns the index in the text storage for the first character associated with the given glyph.
- `glyphIndexForCharacterAtIndex:` (page 1473)
  Returns the index of the first glyph associated with the character at the specified index.
- `characterRangeForGlyphRange:actualGlyphRange:` (page 1455)
  Returns the range of characters that generated the glyphs in the given glyph range.
- `glyphRangeForCharacterRange:actualCharacterRange:` (page 1476)
  Returns the range of glyphs that are generated from the characters in the given character range.

Setting Glyph Attributes

- `intAttribute:forGlyphAtIndex:` (page 1481)
  Returns the value of the attribute identified by the given attribute tag for the glyph at the given index.
- `setIntAttribute:value:forGlyphAtIndex:` (page 1503)
  Sets a custom attribute value for a given glyph.
- `setAttachmentSize:forGlyphRange:` (page 1498)
  Sets the size at which the given glyph (assumed to be an attachment) is asked to draw in the given glyph range.
- `attachmentSizeForGlyphAtIndex:` (page 1450)
  For a glyph corresponding to an attachment, returns the size for the attachment cell to occupy.

- `setDefaultAttachmentScaling:` (page 1500)
  Sets the default scaling behavior to the given scaling if an attachment image is too large to fit in a text container.
- `defaultAttachmentScaling` (page 1456)
  Returns the default behavior desired if an attachment image is too large to fit in a text container.
- `showAttachmentCell:inRect:characterIndex:` (page 1512)
  Draws an attachment cell.

Handling Layout for Text Containers

- `setTextContainer:forGlyphRange:` (page 1509)
  Sets text container where the glyphs in the given range are laid out.
- `glyphRangeForTextContainer:` (page 1477)
  Returns the range of glyphs laid out within the given text container.
- `textContainerForGlyphAtIndex:effectiveRange:` (page 1519)
  Returns the container in which the given glyph is laid out and (optionally) by reference the whole range of glyphs that are in that container.
- `textContainerForGlyphAtIndex:effectiveRange:withoutAdditionalLayout:` (page 1519)
  Returns the container in which the given glyph is laid out and (optionally) by reference the whole range of glyphs that are in that container.
- `usedRectForTextContainer:` (page 1524)
  Returns the bounding rectangle for the glyphs laid out in the given text container.
- `characterIndexForPoint:inTextContainer:fractionOfDistanceBetweenInsertionPoints:` (page 1454)
  Returns the index of the character falling under the given point, expressed in the given container's coordinate system.

Handling Line Fragment Rectangles

- `setLineFragmentRect:forGlyphRange:usedRect:` (page 1505)
  Associates the given line fragment bounds with the given range of glyphs.
- `lineFragmentRectForGlyphAtIndex:effectiveRange:` (page 1487)
  Returns the rectangle for the line fragment in which the given glyph is laid out and (optionally), by reference, the whole range of glyphs that are in that fragment.
- `lineFragmentRectForGlyphAtIndex:effectiveRange:withoutAdditionalLayout:` (page 1487)
  Returns the line fragment rectangle containing the glyph at the given glyph index.
- `lineFragmentUsedRectForGlyphAtIndex:effectiveRange:` (page 1488)
  Returns the usage rectangle for the line fragment in which the given glyph is laid and (optionally) by reference the whole range of glyphs that are in that fragment.
- `lineFragmentUsedRectForGlyphAtIndex:effectiveRange:withoutAdditionalLayout:` (page 1489)
  Returns the usage rectangle for the line fragment in which the given glyph is laid and (optionally) by reference the whole range of glyphs that are in that fragment.
- `setExtraLineFragmentRect:usedRect:textContainer:` (page 1502)
  Sets the bounds and container for the extra line fragment.

- `extraLineFragmentRect` (page 1464)
  Returns the rectangle defining the extra line fragment for the insertion point at the end of a text (either in an empty text or after a final paragraph separator).
- `extraLineFragmentUsedRect` (page 1465)
  Returns the rectangle enclosing the insertion point drawn in the extra line fragment rectangle.
- `extraLineFragmentTextContainer` (page 1465)
  Returns the text container that contains the extra line fragment rectangle.
- `setDrawsOutsideLineFragment:forGlyphAtIndex:` (page 1501)
  Specifies whether the given glyph exceeds the bounds of the line fragment where it's laid out.
- `drawsOutsideLineFragmentForGlyphAtIndex:` (page 1459)
  Indicates whether the glyph draws outside of its line fragment rectangle.

Laying Out Glyphs

- `setLocation:forStartOfGlyphRange:` (page 1506)
  Sets the location for the first glyph of the given range.
- `setLocations:startingGlyphIndexes:count:forGlyphRange:` (page 1506)
  Sets locations for many glyph ranges at once.
- `locationForGlyphAtIndex:` (page 1490)
  Returns the location for the given glyph within its line fragment.
- `rangeOfNominallySpacedGlyphsContainingIndex:` (page 1491)
  Returns the range for the glyphs around the given glyph that can be displayed using only their advancements from the font, without pairwise kerning or other adjustments to spacing.
- `getLineFragmentInsertionPointsForCharacterAtIndex:alternatePositions:inDisplayOrder:positions:characterIndexes:` (page 1470)
  Returns insertion points in bulk for a given line fragment.
- `rectArrayForCharacterRange:withinSelectedCharacterRange:inTextContainer:rectCount:` (page 1492)
  Returns an array of rectangles and, by reference, the number of such rectangles, that define the region in the given container enclosing the given character range.
- `rectArrayForGlyphRange:withinSelectedGlyphRange:inTextContainer:rectCount:` (page 1493)
  Returns an array of rectangles and, by reference, the number of such rectangles, that define the region in the given container enclosing the given glyph range.
- `boundingRectForGlyphRange:inTextContainer:` (page 1452)
  Returns a single bounding rectangle (in container coordinates) enclosing all glyphs and other marks drawn in the given text container for the given glyph range, including glyphs that draw outside their line fragment rectangles and text attributes such as underlining.
- `glyphRangeForBoundingRect:inTextContainer:` (page 1475)
  Returns the smallest contiguous range for glyphs that are laid out wholly or partially within the given rectangle in the given text container.
- `glyphRangeForBoundingRectWithoutAdditionalLayout:inTextContainer:` (page 1475)
  Returns the smallest contiguous range for glyphs that are laid out wholly or partially within the given rectangle in the given text container.

- `glyphIndexForPoint:inTextContainer:fractionOfDistanceThroughGlyph:` (page 1474)
  Returns the index of the glyph falling under the given point, expressed in the given container's coordinate system.
- `fractionOfDistanceThroughGlyphForPoint:inTextContainer:` (page 1468)
  This method is a primitive for `glyphIndexForPoint:inTextContainer:fractionOfDistanceThroughGlyph:` (page 1474). You should always call the main method, not the primitives.
- `glyphIndexForPoint:inTextContainer:` (page 1473)
  This method is a primitive for `glyphIndexForPoint:inTextContainer:fractionOfDistanceThroughGlyph:` (page 1474). You should always call the main method, not the primitives.

Handling Layout for Text Blocks

- `setLayoutRect:forTextBlock:glyphRange:` (page 1504)
  Sets the layout rectangle enclosing the given text block containing the given glyph range.
- `layoutRectForTextBlock:glyphRange:` (page 1486)
  Returns the layout rectangle within which the given text block containing the given glyph range is to be laid out.
- `setBoundsRect:forTextBlock:glyphRange:` (page 1499)
  Sets the bounding rectangle enclosing a given text block containing the given glyph range.
- `boundsRectForTextBlock:glyphRange:` (page 1453)
  Returns the bounding rectangle enclosing the given text block containing the given glyph range.
- `layoutRectForTextBlock:atIndex:effectiveRange:` (page 1486)
  Returns the layout rectangle within which the given text block containing the glyph at the given index is to be laid out.
- `boundsRectForTextBlock:atIndex:effectiveRange:` (page 1452)
  Returns the bounding rectangle within which the given text block containing the glyph at the given index is to be laid out.

Displaying Special Glyphs

- `setNotShownAttribute:forGlyphAtIndex:` (page 1507)
  Sets the glyph at the given index to be one that isn't shown.
- `notShownAttributeForGlyphAtIndex:` (page 1490)
  Indicates whether the glyph at the given index is one that isn't shown.
- `setShowsInvisibleCharacters:` (page 1508)
  Specifies whether to substitute visible glyphs for whitespace and other typically invisible characters in layout.
- `showsInvisibleCharacters` (page 1513)
  Indicates whether the receiver substitutes visible glyphs for whitespace and other typically invisible characters in layout.
- `setShowsControlCharacters:` (page 1507)
  Specifies whether to substitute visible glyphs for control characters in layout.

- `showsControlCharacters` (page 1513)
  Indicates whether the receiver substitutes visible glyphs for control characters.
- `layoutOptions` (page 1485)
  Returns the layout manager's current layout options.

Controlling Hyphenation

- `setHyphenationFactor:` (page 1503)
  Sets the threshold controlling when hyphenation is done.
- `hyphenationFactor` (page 1478)
  Returns the current hyphenation threshold.

Finding Characters and Glyphs Not Laid Out

- `getFirstUnlaidCharacterIndex:glyphIndex:` (page 1468)
  Returns the indexes for the first character and glyph that have invalid layout information.
- `firstUnlaidCharacterIndex` (page 1467)
  Returns the index for the first character in the layout manager that has not been laid out.
- `firstUnlaidGlyphIndex` (page 1467)
  Returns the index for the first glyph in the layout manager that has not been laid out.

Using Screen Fonts

- `setUsesScreenFonts:` (page 1511)
  Controls using screen fonts to calculate layout and display text.
- `usesScreenFonts` (page 1525)
  Indicates whether the receiver uses screen fonts to calculate layout and display text.
- `substituteFontForFont:` (page 1514)
  Returns a screen font suitable for use in place of the given font, if one is available.

Handling Rulers

- `rulerAccessoryViewForTextView:paragraphStyle:ruler:enabled:` (page 1496)
  Returns the the accessory view that the text system uses for its ruler.
- `rulerMarkersForTextView:paragraphStyle:ruler:` (page 1497)
  Returns an array of text ruler objects for the current selection.

Managing the Responder Chain

- `layoutManagerOwnsFirstResponderInWindow:` (page 1485)
  Indicates whether the first responder in the given window is a text view associated with the receiver.

- `firstTextView` (page 1467)
  Returns the first text view in the receiver's series of text views.
- `textViewForBeginningOfSelection` (page 1522)
  Returns the text view containing the first glyph in the selection.

Drawing

- `drawBackgroundForGlyphRange:atPoint:` (page 1458)
  Draws background marks for the given glyph range, which must lie completely within a single text container.
- `drawGlyphsForGlyphRange:atPoint:` (page 1459)
  Draws the glyphs in the given glyph range, which must lie completely within a single text container.
- `drawUnderlineForGlyphRange:underlineType:baselineOffset:lineFragmentRect:lineFragmentGlyphRange:containerOrigin:` (page 1461)
  Draws underlining for the glyphs in a given range.
- `underlineGlyphRange:underlineType:lineFragmentRect:lineFragmentGlyphRange:containerOrigin:` (page 1523)
  Calculates subranges to be underlined for the glyphs in a given range and draws the underlining as appropriate.
- `showPackedGlyphs:length:glyphRange:atPoint:font:color:printingAdjustment:` (page 1512)
  Draws a range of glyphs.
- `drawStrikethroughForGlyphRange:strikethroughType:baselineOffset:lineFragmentRect:lineFragmentGlyphRange:containerOrigin:` (page 1460)
  Draws a strikethrough for the glyphs in a given range.
- `strikethroughGlyphRange:strikethroughType:lineFragmentRect:lineFragmentGlyphRange:containerOrigin:` (page 1514)
  Calculates and draws strikethrough for the glyphs in the given range.
- `fillBackgroundRectArray:count:forCharacterRange:color:` (page 1466)
  Fills background rectangles with a color.

Accessing the Delegate

- `setDelegate:` (page 1501)
  Sets the receiver's delegate.
- `delegate` (page 1457)
  Returns the receiver's delegate.

Accessing the Typesetter

- `setTypesetter:` (page 1510)
  Sets the current typesetter.
- `typesetter` (page 1522)
  Returns the receiver's typesetter.

Managing Typesetter Compatibility

- `setTypesetterBehavior:` (page 1510)
  Sets the default typesetter behavior.
- `typesetterBehavior` (page 1522)
  Returns the current typesetter behavior.
- `defaultLineHeightForFont:` (page 1456)
  Returns the default line height for a line of text drawn using a given font.
- `defaultBaselineOffsetForFont:` (page 1456)
  Returns the default baseline offset specified by the layout manager's typesetter behavior for the given font.

Managing Temporary Attribute Support

- `addTemporaryAttributes:forCharacterRange:` (page 1449)
  Appends one or more temporary attributes to the attributes dictionary of the specified character range.
- `addTemporaryAttribute:value:forCharacterRange:` (page 1448)
  Adds a temporary attribute with the given name and value to the characters in the specified range.
- `setTemporaryAttributes:forCharacterRange:` (page 1508)
  Sets one or more temporary attributes for the specified character range.
- `removeTemporaryAttribute:forCharacterRange:` (page 1494)
  Removes a temporary attribute from the list of attributes for the specified character range.
- `temporaryAttribute:atCharacterIndex:effectiveRange:` (page 1515)
  Returns the value for the temporary attribute with a given name of the character at a given index, and by reference the range over which the attribute applies.
- `temporaryAttribute:atCharacterIndex:longestEffectiveRange:inRange:` (page 1516)
  Returns the value for the temporary attribute with a given name of the character at a given index, and by reference the maximum range over which the attribute applies.
- `temporaryAttributesAtCharacterIndex:effectiveRange:` (page 1517)
  Returns the dictionary of temporary attributes for the character range specified in *`effectiveCharRange`* at character index *`charIndex`*.
- `temporaryAttributesAtCharacterIndex:longestEffectiveRange:inRange:` (page 1517)
  Returns the temporary attributes for the character at a given index, and by reference the maximum range over which the attributes apply.

Managing Noncontiguous Layout

- `setAllowsNonContiguousLayout:` (page 1498)
  Enables or disables noncontiguous layout.
- `allowsNonContiguousLayout` (page 1450)
  Indicates whether noncontiguous layout is enabled or disabled.
- `hasNonContiguousLayout` (page 1477)
  Indicates whether the layout manager currently has any areas of noncontiguous layout.

- `ensureGlyphsForCharacterRange:` (page 1462)
  Forces the receiver to generate glyphs for the specified character range, if it has not already done so.
- `ensureGlyphsForGlyphRange:` (page 1462)
  Forces the receiver to generate glyphs for the specified glyph range, if it has not already done so.
- `ensureLayoutForCharacterRange:` (page 1463)
  Forces the receiver to perform layout for the specified character range, if it has not already done so.
- `ensureLayoutForGlyphRange:` (page 1463)
  Forces the receiver to perform layout for the specified glyph range, if it has not already done so.
- `ensureLayoutForTextContainer:` (page 1464)
  Forces the receiver to perform layout for the specified text container, if it has not already done so.
- `ensureLayoutForBoundingRect:inTextContainer:` (page 1463)
  Forces the receiver to perform layout for the specified area in the specified text container, if it has not already done so.

Accessing the Font Leading

- `usesFontLeading` (page 1524)
  Indicates whether the receiver uses the leading provided in the font.
- `setUsesFontLeading:` (page 1511)
  Specifies whether or not the receiver uses the leading provided in the font.

Instance Methods

addTemporaryAttribute:value:forCharacterRange:

Adds a temporary attribute with the given name and value to the characters in the specified range.

```
- (void)addTemporaryAttribute:(NSString *)attrName value:(id)value
    forCharacterRange:(NSRange)charRange
```

Parameters

attrName
The name of a temporary attribute.

value
The temporary attribute value associated with *attrName*.

charRange
The range of characters to which the specified attribute-value pair applies.

Discussion
Raises an `NSInvalidArgumentException` if *attrName* or *value* is `nil`.

Availability
Available in Mac OS X v10.5 and later.

See Also
- `addTemporaryAttributes:forCharacterRange:` (page 1449)

- setTemporaryAttributes:forCharacterRange: (page 1508)
- removeTemporaryAttribute:forCharacterRange: (page 1494)
- temporaryAttributesAtCharacterIndex:effectiveRange: (page 1517)

Declared In
NSLayoutManager.h

addTemporaryAttributes:forCharacterRange:

Appends one or more temporary attributes to the attributes dictionary of the specified character range.

```
- (void)addTemporaryAttributes:(NSDictionary *)attrs
    forCharacterRange:(NSRange)charRange
```

Parameters

attrs
Attributes dictionary containing the temporary attributes to add.

charRange
The range of characters to which the specified attributes apply.

Discussion
Temporary attributes are used only for onscreen drawing and are not persistent in any way. NSTextView uses them to color misspelled words when continuous spell checking is enabled. Currently the only temporary attributes recognized are those that do not affect layout (colors, underlines, and so on).

Availability
Available in Mac OS X v10.0 and later.

LayoutManagerDemo

Declared In
NSLayoutManager.h

addTextContainer:

Appends the given text container to the series of text containers where the receiver arranges text.

```
- (void)addTextContainer:(NSTextContainer *)aTextContainer
```

Parameters

aTextContainer
The text container to append.

Discussion
Invalidates glyphs and layout as needed, but doesn't perform glyph generation or layout.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `insertTextContainer:atIndex:` (page 1480)

Declared In
`NSLayoutManager.h`

allowsNonContiguousLayout

Indicates whether noncontiguous layout is enabled or disabled.

```
- (BOOL)allowsNonContiguousLayout
```

Return Value
`YES` if noncontiguous layout is enabled; otherwise, `NO`.

Discussion
For more information about noncontiguous layout, see "Noncontiguous Layout" (page 1438).

Availability
Available in Mac OS X v10.5 and later.

See Also
- `setAllowsNonContiguousLayout:` (page 1498)

Declared In
`NSLayoutManager.h`

attachmentSizeForGlyphAtIndex:

For a glyph corresponding to an attachment, returns the size for the attachment cell to occupy.

```
- (NSSize)attachmentSizeForGlyphAtIndex:(NSUInteger)glyphIndex
```

Parameters
glyphIndex
The index of the attachment glyph.

Return Value
The size for the attachment cell to occupy. Returns `{-1.0, -1.0}` if there is no attachment laid for the specified glyph.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setAttachmentSize:forGlyphRange:` (page 1498)
- `defaultAttachmentScaling` (page 1456)

Declared In
`NSLayoutManager.h`

attributedString

Returns the text storage object from which the `NSGlyphGenerator` object procures characters for glyph generation.

```
- (NSAttributedString *)attributedString
```

Return Value
The receiver's text storage object.

Discussion
This method is part of the `NSGlyphStorage` protocol, for use by the glyph generator. For `NSLayoutManager` the attributed string is equivalent to the text storage.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSLayoutManager.h`

backgroundLayoutEnabled

Indicates whether the receiver generates glyphs and lays out text when the application's run loop is idle.

```
- (BOOL)backgroundLayoutEnabled
```

Return Value
`YES` if the receiver generates glyphs and lays out text when the application's run loop is idle, `NO` if it performs glyph generation and layout only when necessary.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setBackgroundLayoutEnabled:` (page 1499)

Declared In
`NSLayoutManager.h`

boundingRectForGlyphRange:inTextContainer:

Returns a single bounding rectangle (in container coordinates) enclosing all glyphs and other marks drawn in the given text container for the given glyph range, including glyphs that draw outside their line fragment rectangles and text attributes such as underlining.

```
- (NSRect)boundingRectForGlyphRange:(NSRange)glyphRange
    inTextContainer:(NSTextContainer *)container
```

Parameters

glyphRange

The range of glyphs for which to return the bounding rectangle.

container

The text container in which the glyphs are laid out.

Return Value

The bounding rectangle enclosing the given range of glyphs.

Discussion

The range is intersected with the container's range before computing the bounding rectangle. This method can be used to translate glyph ranges into display rectangles for invalidation and redrawing when a range of glyphs changes. Bounding rectangles are always in container coordinates.

Performs glyph generation and layout if needed.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `glyphRangeForBoundingRect:inTextContainer:` (page 1475)
- `glyphRangeForTextContainer:` (page 1477)
- `drawsOutsideLineFragmentForGlyphAtIndex:` (page 1459)

LayoutManagerDemo

Declared In

`NSLayoutManager.h`

boundsRectForTextBlock:atIndex:effectiveRange:

Returns the bounding rectangle within which the given text block containing the glyph at the given index is to be laid out.

```
- (NSRect)boundsRectForTextBlock:(NSTextBlock *)block atIndex:(NSUInteger)glyphIndex
    effectiveRange:(NSRangePointer)effectiveGlyphRange
```

Parameters

block

The text block whose bounding rectangle is returned.

glyphIndex

Index of the glyph.

effectiveGlyphRange
If not NULL, on output, the range for all glyphs in the text block.

Return Value
The bounding rectangle of the text block, or NSZeroRect if no rectangle has been set for the specified block since the last invalidation.

Discussion
This method causes glyph generation but not layout. Block layout rectangles and bounds rectangles are always in container coordinates.

Availability
Available in Mac OS X v10.4 and later.

See Also
- setBoundsRect:forTextBlock:glyphRange: (page 1499)

Declared In
NSLayoutManager.h

boundsRectForTextBlock:glyphRange:

Returns the bounding rectangle enclosing the given text block containing the given glyph range.

```
- (NSRect)boundsRectForTextBlock:(NSTextBlock *)block glyphRange:(NSRange)glyphRange
```

Parameters
block
The text block whose bounds rectangle is returned.

glyphRange
The range of glyphs in the text block.

Return Value
The bounding rectangle, or NSZeroRect if no rectangle has been set for the specified block since the last invalidation

Discussion
This method causes glyph generation but not layout. Block layout rectangles and bounds rectangles are always in container coordinates.

Availability
Available in Mac OS X v10.4 and later.

See Also
- setBoundsRect:forTextBlock:glyphRange: (page 1499)

Declared In
NSLayoutManager.h

characterIndexForGlyphAtIndex:

Returns the index in the text storage for the first character associated with the given glyph.

```
- (NSUInteger)characterIndexForGlyphAtIndex:(NSUInteger)glyphIndex
```

Parameters

glyphIndex

The index of the glyph for which to return the associated character.

Return Value

The index of the first character associated with the glyph at the specified index.

Discussion

If noncontiguous layout is not enabled, this method causes generation of all glyphs up to and including *glyphIndex*. This method accepts an index beyond the last glyph, returning an index extrapolated from the last actual glyph index.

In many cases it's better to use the range-mapping methods, `characterRangeForGlyphRange:actualGlyphRange:` (page 1455) and `glyphRangeForCharacterRange:actualCharacterRange:` (page 1476), which provide more comprehensive information.

Availability

Available in Mac OS X v10.0 and later.

See Also

`- glyphIndexForCharacterAtIndex:` (page 1473)

Related Sample Code

LayoutManagerDemo

Declared In

`NSLayoutManager.h`

characterIndexForPoint:inTextContainer:fractionOfDistanceBetweenInsertionPoints:

Returns the index of the character falling under the given point, expressed in the given container's coordinate system.

```
- (NSUInteger)characterIndexForPoint:(NSPoint)point inTextContainer:(NSTextContainer
    *)container fractionOfDistanceBetweenInsertionPoints:(CGFloat *)partialFraction
```

Parameters

point

The point to test.

container

The text container within which the point is tested.

partialFraction

A fraction of the distance from the insertion point, logically before the given character to the next one.

Return Value

The index of the character falling under *point*.

Discussion

Analogous to `glyphIndexForPoint:inTextContainer:fractionOfDistanceThroughGlyph:` (page 1474), but expressed in character index terms. The method returns the index of the character falling under *point*, expressed in coordinate system of *container*; if no character is under the point, the nearest character is returned, where nearest is defined according to the requirements of selection by mouse. However, this is

not simply equivalent to taking the result of the corresponding glyph index method and converting it to a character index, because in some cases a single glyph represents more than one selectable character, for example an fi ligature glyph. In that case, there is an insertion point within the glyph, and this method returns one character or the other, depending on whether the specified point lies to the left or the right of that insertion point.

In general, this method returns only character indexes for which there is an insertion point. The *partialFraction* is a fraction of the distance from the insertion point, logically before the given character to the next one, which may be either to the right or to the left depending on directionality.

Availability
Available in Mac OS X v10.6 and later.

Declared In
NSLayoutManager.h

characterRangeForGlyphRange:actualGlyphRange:

Returns the range of characters that generated the glyphs in the given glyph range.

```
- (NSRange)characterRangeForGlyphRange:(NSRange)glyphRange
    actualGlyphRange:(NSRangePointer)actualGlyphRange
```

Parameters

glyphRange

The glyph range for which to return the character range.

actualGlyphRange

If not NULL, on output, points to the full range of glyphs generated by the character range returned. This range may be identical or slightly larger than the requested glyph range. For example, if the text storage contains the character "Ö" and the glyph cache contains the two atomic glyphs "O" and "¨", and if *glyphRange* encloses only the first or second glyph, then *actualGlyphRange* is set to enclose both glyphs.

Return Value
The range of characters that generated the glyphs in *glyphRange*.

Discussion
If the length of *glyphRange* is 0, the resulting character range is a zero-length range just after the character(s) corresponding to the preceding glyph, and *actualGlyphRange* is also zero-length. If *glyphRange* extends beyond the text length, the method truncates the result to the number of characters in the text.

If noncontiguous layout is not enabled, this method forces the generation of glyphs for all characters up to and including the end of the returned range.

Availability
Available in Mac OS X v10.0 and later.

See Also
- characterIndexForGlyphAtIndex: (page 1453)
- glyphRangeForCharacterRange:actualCharacterRange: (page 1476)

LayoutManagerDemo
TipWrapper

Declared In
NSLayoutManager.h

defaultAttachmentScaling

Returns the default behavior desired if an attachment image is too large to fit in a text container.

```
- (NSImageScaling)defaultAttachmentScaling
```

Discussion
Attachment cells control their own size and drawing, so this setting is only advisory to them, but Application Kit–supplied attachment cells respect it.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setDefaultAttachmentScaling: (page 1500)

Declared In
NSLayoutManager.h

defaultBaselineOffsetForFont:

Returns the default baseline offset specified by the layout manager's typesetter behavior for the given font.

```
- (CGFloat)defaultBaselineOffsetForFont:(NSFont *)theFont
```

Parameters
theFont
The font for which to return the default baseline offset.

Return Value
The default baseline offset for a line of text drawn using *theFont*.

Discussion
The value returned may vary according to the layout manager's typesetter behavior.

Availability
Available in Mac OS X v10.5 and later.

See Also
- setTypesetterBehavior: (page 1510)
- defaultLineHeightForFont: (page 1456)

Declared In
NSLayoutManager.h

defaultLineHeightForFont:

Returns the default line height for a line of text drawn using a given font.

```
- (CGFloat)defaultLineHeightForFont:(NSFont *)theFont
```

Parameters

theFont

The font for which to determine the default line height.

Return Value

The default line height for a line of text drawn using *theFont*.

Discussion

The value returned may vary according to the layout manager's typesetter behavior.

Availability

Available in Mac OS X v10.2 and later.

See Also

- `setTypesetterBehavior:` (page 1510)
- `defaultBaselineOffsetForFont:` (page 1456)

Declared In

`NSLayoutManager.h`

delegate

Returns the receiver's delegate.

```
- (id < NSLayoutManagerDelegate >)delegate
```

Return Value

The receiver's delegate.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `setDelegate:` (page 1501)

Declared In

`NSLayoutManager.h`

deleteGlyphsInRange:

Deletes the glyphs in the given range from the receiver's glyph store.

```
- (void)deleteGlyphsInRange:(NSRange)glyphRange
```

Parameters

glyphRange

The range of glyphs to delete.

Discussion
This method is for use by the glyph-generation mechanism and doesn't perform any invalidation or generation of the glyphs or layout. This method should be invoked only during glyph generation and typesetting, in almost all cases only by the glyph generator or typesetter. For example, a custom glyph generator or typesetter might invoke it.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `insertGlyph:atGlyphIndex:characterIndex:` (page 1479)

Declared In
`NSLayoutManager.h`

drawBackgroundForGlyphRange:atPoint:

Draws background marks for the given glyph range, which must lie completely within a single text container.

```
- (void)drawBackgroundForGlyphRange:(NSRange)glyphsToShow atPoint:(NSPoint)origin
```

Parameters

glyphsToShow
The range of glyphs for which the background is drawn.

origin
The position of the text container in the coordinate system of the currently focused view.

Discussion
This method is called by `NSTextView` for drawing. You can override it to perform additional drawing, or to replace text drawing entirely, but not to change layout. You can call this method directly, but focus must already be locked on the destination view or image.

Background marks are such things as selection highlighting, text background color, and any background for marked text, along with block decoration such as table backgrounds and borders.

Performs glyph generation and layout if needed.

Availability
Available in Mac OS X v10.0 and later.

QuickLookSketch
Sketch+Accessibility
Sketch-112

Declared In
`NSLayoutManager.h`

drawGlyphsForGlyphRange:atPoint:

Draws the glyphs in the given glyph range, which must lie completely within a single text container.

```
- (void)drawGlyphsForGlyphRange:(NSRange)glyphsToShow atPoint:(NSPoint)origin
```

Parameters

glyphsToShow

The range of glyphs that are drawn.

origin

The position of the text container in the coordinate system of the currently focused view.

Discussion

This method is called by `NSTextView` for drawing. You can override it to perform additional drawing, or to replace text drawing entirely, but not to change layout. You can call this method directly, but focus must already be locked on the destination view or image. This method expects the coordinate system of the view to be flipped.

This method draws the actual glyphs, including attachments, as well as any underlines or strikethoughs.

Performs glyph generation and layout if needed.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `drawBackgroundForGlyphRange:atPoint:` (page 1458)

CircleView
DockTile
QuickLookSketch
Sketch-112
SpeedometerView

Declared In

`NSLayoutManager.h`

drawsOutsideLineFragmentForGlyphAtIndex:

Indicates whether the glyph draws outside of its line fragment rectangle.

```
- (BOOL)drawsOutsideLineFragmentForGlyphAtIndex:(NSUInteger)glyphIndex
```

Parameters

glyphIndex

Index of the glyph.

Return Value

`YES` if the glyph at *glyphIndex* exceeds the bounds of the line fragment where it's laid out, `NO` otherwise.

Discussion
Exceeding bounds can happen when text is set at a fixed line height. For example, if the user specifies a fixed line height of 12 points and sets the font size to 24 points, the glyphs will exceed their layout rectangles.

This method causes glyph generation and layout for the line fragment containing the specified glyph, or if noncontiguous layout is not enabled, up to and including that line fragment.

Glyphs that draw outside their line fragment rectangles aren't considered when calculating enclosing rectangles with the `rectArrayForCharacterRange:withinSelectedCharacterRange:inTextContainer:rectCount:` (page 1492) and `rectArrayForGlyphRange:withinSelectedGlyphRange:inTextContainer:rectCount:` (page 1493) methods. They are, however, considered by `boundingRectForGlyphRange:inTextContainer:` (page 1452).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSLayoutManager.h`

drawStrikethroughForGlyphRange:strikethroughType:baselineOffset:lineFragmentRect:lineFragmentGlyphRange:containerOrigin:

Draws a strikethrough for the glyphs in a given range.

```
- (void)drawStrikethroughForGlyphRange:(NSRange)glyphRange
    strikethroughType:(NSInteger)strikethroughVal
    baselineOffset:(CGFloat)baselineOffset lineFragmentRect:(NSRect)lineRect
    lineFragmentGlyphRange:(NSRange)lineGlyphRange
    containerOrigin:(NSPoint)containerOrigin
```

Parameters

glyphRange
The range of glyphs for which to draw a strikethrough. The range must belong to a single line fragment rectangle (as returned by `lineFragmentRectForGlyphAtIndex:effectiveRange:` (page 1487)).

strikethroughVal
The style of strikethrough to draw. This value is a mask derived from the value for `NSUnderlineStyleAttributeName` (page 272)—for example, `(NSUnderlinePatternDash | NSUnderlineStyleThick)`. Subclasses can define custom strikethrough styles.

baselineOffset
Indicates how far above the text baseline the underline should be drawn.

lineRect
The line fragment rectangle containing the glyphs to draw strikethrough for.

lineGlyphRange
The range of all glyphs within *lineRect*.

containerOrigin
The origin of the line fragment rectangle's `NSTextContainer` in its `NSTextView`.

Discussion
This method is invoked automatically by `strikethroughGlyphRange:strikethroughType:lineFragmentRect:lineFragmentGlyphRange:containerOrigin:` (page 1514); you should rarely need to invoke it directly. This method's *strikethroughVal* parameter does not take account of any setting for`NSUnderlineByWordMask` (page 276) because that's taken care of by `underlineGlyphRange:underlineType:lineFragmentRect:lineFragmentGlyphRange:containerOrigin:` (page 1523).

Availability
Available in Mac OS X v10.3 and later.

Declared In
`NSLayoutManager.h`

drawUnderlineForGlyphRange:underlineType:baselineOffset:lineFragmentRect:lineFragmentGlyphRange:containerOrigin:

Draws underlining for the glyphs in a given range.

```
- (void)drawUnderlineForGlyphRange:(NSRange)glyphRange
    underlineType:(NSInteger)underlineVal baselineOffset:(CGFloat)baselineOffset
    lineFragmentRect:(NSRect)lineRect lineFragmentGlyphRange:(NSRange)lineGlyphRange
     containerOrigin:(NSPoint)containerOrigin
```

Parameters

glyphRange
A range of glyphs, which must belong to a single line fragment rectangle (as returned by `lineFragmentRectForGlyphAtIndex:effectiveRange:` (page 1487)).

underlineVal
The style of underlining to draw. This value is a mask derived from the value for `NSUnderlineStyleAttributeName` (page 272)—for example, `(NSUnderlinePatternDash | NSUnderlineStyleThick)`. Subclasses can define custom underlining styles.

baselineOffset
Specifies the distance from the bottom of the bounding box of the specified glyphs in the specified range to their baseline.

lineRect
The line fragment rectangle containing the glyphs to draw underlining for.

lineGlyphRange
The range of all glyphs within *lineRect*.

containerOrigin
The origin of the *lineRect*`NSTextContainer` in its `NSTextView`.

Discussion
This method is invoked automatically by `underlineGlyphRange:underlineType:lineFragmentRect:lineFragmentGlyphRange:containerOrigin:` (page 1523); you should rarely need to invoke it directly. This method's *underlineVal* parameter does not take account of any setting for`NSUnderlineByWordMask` (page 276) because that's taken care of by `underlineGlyphRange:underlineType:lineFragmentRect:lineFragmentGlyphRange:containerOrigin:` (page 1523).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSLayoutManager.h`

ensureGlyphsForCharacterRange:

Forces the receiver to generate glyphs for the specified character range, if it has not already done so.

```
- (void)ensureGlyphsForCharacterRange:(NSRange)charRange
```

Parameters

charRange
The character range for which glyphs are generated.

Discussion
The layout manager reserves the right to perform glyph generation for larger ranges. If noncontiguous layout is disabled, then the affected range is always effectively extended to start at the beginning of the text.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSLayoutManager.h`

ensureGlyphsForGlyphRange:

Forces the receiver to generate glyphs for the specified glyph range, if it has not already done so.

```
- (void)ensureGlyphsForGlyphRange:(NSRange)glyphRange
```

Parameters

glyphRange
The glyph range for which glyphs are generated.

Discussion
The layout manager reserves the right to perform glyph generation for larger ranges. If noncontiguous layout is disabled, then the affected range is always effectively extended to start at the beginning of the text.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSLayoutManager.h`

ensureLayoutForBoundingRect:inTextContainer:

Forces the receiver to perform layout for the specified area in the specified text container, if it has not already done so.

```
- (void)ensureLayoutForBoundingRect:(NSRect)bounds inTextContainer:(NSTextContainer
    *)container
```

Parameters

bounds

The area for which layout is performed.

container

The text container containing the area for which layout is performed.

Discussion

The layout manager reserves the right to perform layout for larger ranges. If noncontiguous layout is disabled, then the affected range is always effectively extended to start at the beginning of the text.

Availability

Available in Mac OS X v10.5 and later.

Declared In

`NSLayoutManager.h`

ensureLayoutForCharacterRange:

Forces the receiver to perform layout for the specified character range, if it has not already done so.

```
- (void)ensureLayoutForCharacterRange:(NSRange)charRange
```

Parameters

charRange

The character range for which layout is performed.

Discussion

The layout manager reserves the right to perform layout for larger ranges. If noncontiguous layout is disabled, then the affected range is always effectively extended to start at the beginning of the text.

Availability

Available in Mac OS X v10.5 and later.

Declared In

`NSLayoutManager.h`

ensureLayoutForGlyphRange:

Forces the receiver to perform layout for the specified glyph range, if it has not already done so.

```
- (void)ensureLayoutForGlyphRange:(NSRange)glyphRange
```

Parameters

glyphRange

The glyph range for which layout is performed.

Discussion
The layout manager reserves the right to perform layout for larger ranges. If noncontiguous layout is disabled, then the affected range is always effectively extended to start at the beginning of the text.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSLayoutManager.h`

ensureLayoutForTextContainer:

Forces the receiver to perform layout for the specified text container, if it has not already done so.

```
- (void)ensureLayoutForTextContainer:(NSTextContainer *)container
```

Parameters

container
The text container for which layout is performed.

Discussion
The layout manager reserves the right to perform layout for larger ranges. If noncontiguous layout is disabled, then the affected range is always effectively extended to start at the beginning of the text.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSLayoutManager.h`

extraLineFragmentRect

Returns the rectangle defining the extra line fragment for the insertion point at the end of a text (either in an empty text or after a final paragraph separator).

```
- (NSRect)extraLineFragmentRect
```

Return Value
The rectangle defining the extra line fragment for the insertion point.

Discussion
The rectangle is defined in the coordinate system of its `NSTextContainer`. Returns `NSZeroRect` if there is no such rectangle.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `extraLineFragmentUsedRect` (page 1465)
- `extraLineFragmentTextContainer` (page 1465)
- `setExtraLineFragmentRect:usedRect:textContainer:` (page 1502)

Declared In
NSLayoutManager.h

extraLineFragmentTextContainer

Returns the text container that contains the extra line fragment rectangle.

```
- (NSTextContainer *)extraLineFragmentTextContainer
```

Return Value
The text container that contains the extra line fragment rectangle, or `nil` if there is no extra line fragment rectangle.

Discussion
This rectangle is used to display the insertion point at the end of a text (either in an empty text or after a final paragraph separator).

Availability
Available in Mac OS X v10.0 and later.

See Also
- `extraLineFragmentRect` (page 1464)
- `extraLineFragmentUsedRect` (page 1465)
- `setExtraLineFragmentRect:usedRect:textContainer:` (page 1502)

Declared In
NSLayoutManager.h

extraLineFragmentUsedRect

Returns the rectangle enclosing the insertion point drawn in the extra line fragment rectangle.

```
- (NSRect)extraLineFragmentUsedRect
```

Return Value
The rectangle enclosing the insertion point.

Discussion
The rectangle is defined in the coordinate system of its `NSTextContainer`. Returns `NSZeroRect` if there is no extra line fragment rectangle.

The extra line fragment used rectangle is twice as wide (or tall) as the text container's line fragment padding, with the insertion point itself in the middle.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSLayoutManager.h

fillBackgroundRectArray:count:forCharacterRange:color:

Fills background rectangles with a color.

```
- (void)fillBackgroundRectArray:(NSRectArray)rectArray count:(NSUInteger)rectCount
    forCharacterRange:(NSRange)charRange color:(NSColor *)color
```

Parameters

rectArray
The array of rectangles to fill.

rectCount
The number of rectangles in *rectArray*.

charRange
The range of characters whose background rectangles are filled.

color
The fill color.

Discussion
This is the primitive method used by drawBackgroundForGlyphRange:atPoint: (page 1458), providing a finer-grained override point for actually filling rectangles with a particular background color for a background color attribute, a selected or marked range highlight, a block decoration, or any other rectangle fill needed by that method. As with showPackedGlyphs:length:glyphRange:atPoint:font:color:printingAdjustment: (page 1512), the *charRange* and *color* parameters are passed in merely for informational purposes; the color is already set in the graphics state. If for any reason you modify it, you must restore it before returning from this method.

This method operates in terms of character ranges, because the relevant attributes are expressed on characters, and they don't always lie on glyph boundaries—for example, when one character of an "fi" ligature is highlighted.

You should never call this method, but you might override it. The default implementation simply fills the rectangles in the specified array. The graphics operation used for this fill is controlled by a link check; for compatibility reasons, it is NSCompositeCopy (page 1376) for applications linked prior to Mac OS X v10.6 and NSCompositeSourceOver (page 1376) for applications linked on Mac OS X v10.6 or later. Applications can control the operation used, or modify the drawing, by overriding this method in an NSLayoutManager subclass.

Availability
Available in Mac OS X v10.6 and later.

Declared In
NSLayoutManager.h

firstTextView

Returns the first text view in the receiver's series of text views.

```
- (NSTextView *)firstTextView
```

Return Value
The receiver's first text view.

Discussion
This `NSTextView` object is the recipient of various `NSText` and `NSTextView` notifications.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSLayoutManager.h`

firstUnlaidCharacterIndex

Returns the index for the first character in the layout manager that has not been laid out.

```
- (NSUInteger)firstUnlaidCharacterIndex
```

Return Value
The character index.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSLayoutManager.h`

firstUnlaidGlyphIndex

Returns the index for the first glyph in the layout manager that has not been laid out.

```
- (NSUInteger)firstUnlaidGlyphIndex
```

Return Value
The glyph index.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSLayoutManager.h`

fractionOfDistanceThroughGlyphForPoint:inTextContainer:

This method is a primitive for `glyphIndexForPoint:inTextContainer:fractionOfDistanceThroughGlyph:` (page 1474). You should always call the main method, not the primitives.

```
- (CGFloat)fractionOfDistanceThroughGlyphForPoint:(NSPoint)point
    inTextContainer:(NSTextContainer *)container
```

Discussion
Overriding should be done for the primitive methods. Existing subclasses that do not do this overriding will not have their implementations available to Java developers.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- glyphIndexForPoint:inTextContainer:` (page 1473)

Declared In
`NSLayoutManager.h`

getFirstUnlaidCharacterIndex:glyphIndex:

Returns the indexes for the first character and glyph that have invalid layout information.

```
- (void)getFirstUnlaidCharacterIndex:(NSUInteger *)charIndex glyphIndex:(NSUInteger
    *)glyphIndex
```

Parameters

charIndex
On return, if not `NULL`, the index of the first character that has invalid layout information

glyphIndex
On return, if not `NULL`, the index of the first glyph that has invalid layout information.

Discussion
Either parameter may be `NULL`, in which case the receiver simply ignores it.

As part of its implementation, this method calls `firstUnlaidCharacterIndex` (page 1467) and `firstUnlaidGlyphIndex` (page 1467). To change this method's behavior, override those two methods instead of this one.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSLayoutManager.h`

getGlyphs:range:

Fills the passed-in buffer with a sequence of glyphs

```
- (NSUInteger)getGlyphs:(NSGlyph *)glyphArray range:(NSRange)glyphRange
```

Parameters

glyphArray

On output, the displayable glyphs from *glyphRange*, null-terminated. Does not include in the result any NSNullGlyph or other glyphs that are not shown. The memory passed in should be large enough for at least glyphRange.length+1 elements.

glyphRange

The range of glyphs from which to return the displayable glyphs.

Return Value

The actual number of glyphs filled into the array is returned (not counting the null-termination).

Discussion

Raises an NSRangeException if the range specified exceeds the bounds of the actual glyph range for the receiver. Performs glyph generation if needed.

Availability

Available in Mac OS X v10.0 and later.

Declared In

NSLayoutManager.h

getGlyphsInRange:glyphs:characterIndexes:glyphInscriptions:elasticBits:

Returns the glyphs and information needed to perform layout for the given glyph range.

```
- (NSUInteger)getGlyphsInRange:(NSRange)glyphRange glyphs:(NSGlyph *)glyphBuffer
    characterIndexes:(NSUInteger *)charIndexBuffer
    glyphInscriptions:(NSGlyphInscription *)inscribeBuffer elasticBits:(BOOL
    *)elasticBuffer
```

Discussion

This is a convenience method for getGlyphsInRange:glyphs:characterIndexes:glyphInscriptions:elasticBits:bidiLevels: (page 1469) that does not return a *bidiLevelBuffer*.

Availability

Available in Mac OS X v10.0 and later.

Declared In

NSLayoutManager.h

getGlyphsInRange:glyphs:characterIndexes:glyphInscriptions:elasticBits:bidiLevels:

Returns the glyphs and information needed to perform layout for the given glyph range.

```
- (NSUInteger)getGlyphsInRange:(NSRange)glyphRange glyphs:(NSGlyph *)glyphBuffer
    characterIndexes:(NSUInteger *)charIndexBuffer
    glyphInscriptions:(NSGlyphInscription *)inscribeBuffer elasticBits:(BOOL
    *)elasticBuffer bidiLevels:(unsigned char *)bidiLevelBuffer
```

Parameters

glyphRange

The range of glyphs to lay out.

glyphBuffer

On output, the sequence of glyphs needed to lay out the given glyph range.

charIndexBuffer

On output, the indexes of the original characters corresponding to the given glyph range. Note that a glyph at index 1 is not necessarily mapped to the character at index 1, since a glyph may be for a ligature or accent.

inscribeBuffer

On output, the inscription attributes for each glyph, which are used to lay out characters that are combined together. The possible values are described in "Constants" (page 1525).

elasticBuffer

On output, values indicating whether a glyph is elastic for each glyph. An elastic glyph can be made longer at the end of a line or when needed for justification.

bidiLevelBuffer

On output, the direction of each glyph for bidirectional text. The values range from 0 to 61 as defined by Unicode Standard Annex #9. An even value means the glyph goes left-to-right, and an odd value means the glyph goes right-to-left.

Return Value

The number of glyphs returned in *glyphBuffer*.

Discussion

This method and `getGlyphsInRange:glyphs:characterIndexes:glyphInscriptions:elasticBits:` (page 1469) are intended primarily to enable the typesetter to obtain in bulk the glyphs and other information that it needs to perform layout. These methods return all glyphs in the range, including `NSNullGlyph` and not-shown glyphs. They do not null-terminate the results. Each pointer passed in should either be `NULL`, or else point to sufficient memory to hold `glyphRange.length` elements.

Availability

Available in Mac OS X v10.2 and later.

Declared In

`NSLayoutManager.h`

getLineFragmentInsertionPointsForCharacterAtIndex:alternatePositions: inDisplayOrder:positions:characterIndexes:

Returns insertion points in bulk for a given line fragment.

```
- (NSUInteger)getLineFragmentInsertionPointsForCharacterAtIndex:(NSUInteger)charIndex
    alternatePositions:(BOOL)aFlag inDisplayOrder:(BOOL)dFlag positions:(CGFloat
    *)positions characterIndexes:(NSUInteger *)charIndexes
```

Parameters

charIndex

The character index of one character within the line fragment.

aFlag

If YES, returns alternate, rather than primary, insertion points.

dFlag

If YES, returns insertion points in display, rather than logical, order.

positions

On output, the positions of the insertion points, in the order specified.

charIndexes

On output, the indexes of the characters corresponding to the returned insertion points.

Return Value
The number of insertion points returned.

Discussion
The method allows clients to obtain all insertion points for a line fragment in one call. Each pointer passed in should either be NULL or else point to sufficient memory to hold as many elements as there are insertion points in the line fragment (which cannot be more than the number of characters + 1). The returned positions indicate a transverse offset relative to the line fragment rectangle's origin. Internal caching is used to ensure that repeated calls to this method for the same line fragment (possibly with differing values for other arguments) are not significantly more expensive than a single call.

Availability
Available in Mac OS X v10.5 and later.
