setPaletteLabel:

Sets the receiver's label that appears when it is in the customization palette.

```
- (void)setPaletteLabel:(NSString *)paletteLabel
```

Parameters

paletteLabel
The label that appears when the receiver is in the customization palette.

Discussion
An item must have a palette label if the customization palette is to be used, and for most items it is reasonable to set paletteLabel (page 3014) to be the same value as label (page 3013). One reason for paletteLabel (page 3014) to be different from label (page 3013) would be if it's more descriptive; another might be if there is no label (page 3013).

Availability
Available in Mac OS X v10.0 and later.

Constants

Standard Identifiers

`NSToolbarItem` defines the following standard toolbar item identifiers.

```
NSString *NSToolbarSeparatorItemIdentifier;
NSString *NSToolbarSpaceItemIdentifier;
NSString *NSToolbarFlexibleSpaceItemIdentifier;
NSString *NSToolbarShowColorsItemIdentifier;
NSString *NSToolbarShowFontsItemIdentifier;
NSString *NSToolbarCustomizeToolbarItemIdentifier;
NSString *NSToolbarPrintItemIdentifier;
```

Constants
`NSToolbarSeparatorItemIdentifier`
The Separator item.

Available in Mac OS X v10.0 and later.

Declared in `NSToolbarItem.h`.

`NSToolbarSpaceItemIdentifier`
The Space item.

Available in Mac OS X v10.0 and later.

Declared in `NSToolbarItem.h`.

`NSToolbarFlexibleSpaceItemIdentifier`
The Flexible Space item.

Available in Mac OS X v10.0 and later.

Declared in `NSToolbarItem.h`.

`NSToolbarShowColorsItemIdentifier`
The Colors item. Shows the color panel.

Available in Mac OS X v10.0 and later.

Declared in `NSToolbarItem.h`.

`NSToolbarShowFontsItemIdentifier`
The Fonts item. Shows the font panel.

Available in Mac OS X v10.0 and later.

Declared in `NSToolbarItem.h`.

`NSToolbarCustomizeToolbarItemIdentifier`
The Customize item. Shows the customization palette.

Available in Mac OS X v10.0 and later.

Declared in `NSToolbarItem.h`.

`NSToolbarPrintItemIdentifier`
The Print item. Sends `printDocument:` to `firstResponder`, but you can change this in `toolbarWillAddItem:` if you need to do so.

Available in Mac OS X v10.0 and later.

Declared in `NSToolbarItem.h`.

Discussion
The following figure illustrates the items in the order in which they are described above.

Declared In
`NSToolbarItem.h`

Item Priority

When a toolbar does not have enough space to fit all its items, it must push some items into the overflow menu. These values allow you to suggest a priority for a toolbar item.

```
enum {
   NSToolbarItemVisibilityPriorityStandard = 0,
   NSToolbarItemVisibilityPriorityLow  = -1000,
   NSToolbarItemVisibilityPriorityHigh  = 1000,
   NSToolbarItemVisibilityPriorityUser  = 2000
};
```

Constants

`NSToolbarItemVisibilityPriorityStandard`
The default visibility priority.

Available in Mac OS X v10.4 and later.

Declared in `NSToolbarItem.h`.

`NSToolbarItemVisibilityPriorityLow`
Items with this priority will be the first items to be pushed to the overflow menu.

Available in Mac OS X v10.4 and later.

Declared in `NSToolbarItem.h`.

`NSToolbarItemVisibilityPriorityHigh`
Items with this priority are less inclined to be pushed to the overflow menu.

Available in Mac OS X v10.4 and later.

Declared in `NSToolbarItem.h`.

`NSToolbarItemVisibilityPriorityUser`
Items with this priority are the last to be pushed to the overflow menu. Only the user should set items to this priority.

Available in Mac OS X v10.4 and later.

Declared in `NSToolbarItem.h`.

Discussion

To suggest that an item always remain visible, give it a value greater than `NSToolbarItemVisibilityPriorityStandard`, but less than `NSToolbarItemVisibilityPriorityUser`. In configurable toolbars, users can control the priority of an item and the priority is autosaved by the NSToolbar. These values are used by the `setVisibilityPriority:` (page 3022) and `visibilityPriority` (page 3025) methods:

`NSToolbarItem.h`

NSToolbarItemGroup Class Reference

Inherits from	NSToolbarItem : NSObject
Conforms to	NSValidatedUserInterfaceItem (NSToolbarItem) NSCopying (NSToolbarItem) NSObject (NSObject)
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.5 and later.
Declared in	NSToolbarItemGroup.h
Companion guide	Toolbar Programming Topics for Cocoa

Overview

`NSToolbarItemGroup` is a subclass of `NSToolbarItem` which contains subitems. The views and labels of the subitems are used, but the parent's attributes take precedence.

To configure an instance of `NSToolbarItemGroup`, you first create the individual toolbar items that will be the subitems:

```
NSToolbarItem *item1 = [[[NSToolbarItem alloc] initWithItemIdentifier:@"Item1"]
 autorelease];
NSToolbarItem *item2 = [[[NSToolbarItem alloc] initWithItemIdentifier:@"Item2"]
 autorelease];
[item1 setImage:[NSImage imageNamed:@"LeftArrow"]];
[item2 setImage:[NSImage imageNamed:@"RightArrow"]];
[item1 setLabel:@"Prev"];
[item2 setLabel:@"Next"];
```

and then put them in a grouped item:

```
NSToolbarItemGroup *group = [[[NSToolbarItemGroup alloc]
initWithItemIdentifier:@"GroupItem"] autorelease];
[group setSubitems:[NSArray arrayWithObjects:item1, item2, nil]];
```

In this configuration, you get two grouped items, and two labels. This differs from ordinary `NSToolbarItem` objects because they are attached—the user drags them together as a single item rather than separately.

If you set a label on the parent item:

```
[group setLabel:@"Navigate"];
```

you get two grouped items with one shared label.

If instead you set a view on the parent item, you get two labels with one shared view:

```
[group setView:someSegmentedControl];
```

Tasks

Working with Subitems

- `subitems` (page 3030)
  Returns the subitems for the receiver.
- `setSubitems:` (page 3030)
  Sets the subitems for the receiver.

Instance Methods

setSubitems:

Sets the subitems for the receiver.

```
- (void)setSubitems:(NSArray *)subitems
```

Parameters

subitems
An array of instances of `NSToolbarItem` objects that form the subitems for the receiver.

Discussion
You should call this method to set the subitems before returning the item to the toolbar. `NSToolbarItemGroup` objects cannot contain other `NSToolbarItemGroup` objects as subitems.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSToolbarItemGroup.h`

subitems

Returns the subitems for the receiver.

```
- (NSArray *)subitems
```

Return Value
The subitems for the receiver.

Discussion
By default, an `NSToolbarItemGroup` instance has an empty array of subitems.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSToolbarItemGroup.h`

NSTouch Class Reference

Inherits from	NSObject
Conforms to	NSCopying NSObject (NSObject)
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.6 and later.
Declared in	NSTouch.h
Related sample code	LightTable

Overview

An instance of the `NSTouch` class is a snapshot of a particular touch at an instant in time.

A touch event is not persistent throughout the touch, new instances are created as the touch progresses. The identity property is used to follow a specific touch across its lifetime.

Touches do not have a corresponding screen location. The first touch of a touch collection is latched to the view underlying the cursor using the same hit detection as mouse events. Additional touches on the same device are also latched to the same view as any other touching touches. A touch remains latched to its view until the touch has either ended or is cancelled.

Tasks

Properties of This Touch

`identity` (page 3034) *property*
Use this property to track changes to a particular touch during the touch's life. (read-only)

`phase` (page 3036) *property*
The current phase of the touch. (read-only)

`normalizedPosition` (page 3035) *property*
The normalized position of the touch. (read-only)

`isResting` (page 3035) *property*
Returns whether the touch is a resting touch. (read-only)

Properties of Touch Device

`device` (page 3034) *property*
The digitizer that generated the touch. Useful to distinguish touches emanating from multiple-device scenario. (read-only)

`deviceSize` (page 3034) *property*
The range of the touch device in points (72ppi). (read-only)

Properties

For more about Objective-C properties, see "Properties" in *The Objective-C Programming Language*.

device

The digitizer that generated the touch. Useful to distinguish touches emanating from multiple-device scenario. (read-only)

```
@property(readonly, retain) id device
```

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSTouch.h`

deviceSize

The range of the touch device in points (72ppi). (read-only)

```
@property(readonly) NSSize deviceSize
```

Discussion
The lower-left corner of the surface is considered (0,0).

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSTouch.h`

identity

Use this property to track changes to a particular touch during the touch's life. (read-only)

```
@property(readonly, retain) id<NSObject, NSCopying> identity
```

Discussion
While touch identities may be re-used, they are unique during the life of the touch, even when multiple devices are present.

Identity objects implement the `NSCopying` protocol so that they may be used as keys in an `NSDictionary`. Use `isEqual:` to compare two touch identities.

Availability
Available in Mac OS X v10.6 and later.

Related Sample Code
LightTable

Declared In
`NSTouch.h`

isResting

Returns whether the touch is a resting touch. (read-only)

```
@property(readonly) BOOL isResting
```

Discussion
Resting touches occur when a user simply rests their thumb on the trackpad device.

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSTouch.h`

normalizedPosition

The normalized position of the touch. (read-only)

```
@property(readonly) NSPoint normalizedPosition
```

Discussion
The normalized position is a scaled value between (0.0) and (1.0,1.0), where (0.0,0.0) is the lower-left position on the touch device.

Availability
Available in Mac OS X v10.6 and later.

Related Sample Code
LightTable

Declared In
`NSTouch.h`

phase

The current phase of the touch. (read-only)

```
@property(readonly) NSTouchPhase phase
```

Discussion
See "NSTouchPhase" (page 3036) for possible values.

Availability
Available in Mac OS X v10.6 and later.

Declared In
NSTouch.h

Constants

NSTouchPhase

The possible phases of a touch. These constants are used by `phase` (page 3036).

```
enum {
    NSTouchPhaseBegan           = 1U << 0,
    NSTouchPhaseMoved           = 1U << 1,
    NSTouchPhaseStationary      = 1U << 2,
    NSTouchPhaseEnded           = 1U << 3,
    NSTouchPhaseCancelled       = 1U << 4,
    NSTouchPhaseTouching        = NSTouchPhaseBegan | NSTouchPhaseMoved |
NSTouchPhaseStationary,
    NSTouchPhaseAny             = NSUIntegerMax
};
typedef NSUInteger NSTouchPhase;
```

Constants

`NSTouchPhaseBegan`
A finger touched the device. Or, a resting touch transitioned to an active touch and resting touches are not wanted by the view hierarchy.
Available in Mac OS X v10.6 and later.
Declared in `NSTouch.h`.

`NSTouchPhaseMoved`
A finger moved on the device.
Available in Mac OS X v10.6 and later.
Declared in `NSTouch.h`.

`NSTouchPhaseStationary`
A finger is touching the device, but hasn't moved since the previous event.
Available in Mac OS X v10.6 and later.
Declared in `NSTouch.h`.

`NSTouchPhaseEnded`

A finger was lifted from the screen. Or, an active touch transitioned to a resting touch and resting touches are not wanted by the view hierarchy.

Available in Mac OS X v10.6 and later.

Declared in `NSTouch.h`.

`NSTouchPhaseCancelled`

The system cancelled tracking for the touch, as when (for example) the window associated with the touch resigns key or is deactivated.

Available in Mac OS X v10.6 and later.

Declared in `NSTouch.h`.

`NSTouchPhaseTouching`

Matches the `NSTouchPhaseBegan` (page 3036), `NSTouchPhaseMoved` (page 3036), or `NSTouchPhaseStationary` (page 3036) phases of a touch.

Available in Mac OS X v10.6 and later.

Declared in `NSTouch.h`.

`NSTouchPhaseAny`

Matches any phase of a touch.

Available in Mac OS X v10.6 and later.

Declared in `NSTouch.h`.

NSTrackingArea Class Reference

Inherits from	NSObject
Conforms to	NSCoding NSCopying NSObject (NSObject)
Framework	/System/Library/Frameworks/AppKit.framework
Declared in	AppKit/NSTrackingArea.h
Availability	Available in Mac OS X v10.5 and later.
Companion guide	Cocoa Event-Handling Guide
Related sample code	BasicCocoaAnimations MenuItemView PhotoSearch TrackIt

Overview

An `NSTrackingArea` object defines a region of view that generates mouse-tracking and cursor-update events when the mouse is over that region.

When creating a tracking-area object, you specify a rectangle (in the view's coordinate system), an owning object, and one or more options, along with (optionally) a dictionary of data. Once it's created, you add the tracking-area object to a view using the `addTrackingArea:` (page 3142) method. Depending on the options specified, the owner of the tracking area receives `mouseEntered:` (page 2165), `mouseExited:` (page 2165), `mouseMoved:` (page 2166), and `cursorUpdate:` (page 2147) messages when the mouse cursor enters, moves within, and leaves the tracking area. Currently the tracking area is restricted to rectangles.

An `NSTrackingArea` object belongs to its view rather than to its window. Consequently, you can add and remove tracking rectangles without needing to worry if the view has been added to a window. In addition, this design makes it possible for the Application Kit to compute the geometry of tracking areas automatically when a view moves and, in some cases, when a view changes size.

With `NSTrackingArea`, you can configure the scope of activity for mouse tracking. There are four options:

- The tracking area is active only when the view is first responder.
- The tracking area is active when the view is in the key window.
- The tracking area is active when the application is active.

- The tracking area is active always (even when the application is inactive).

Other options for `NSTrackingArea` objects include specifying that the tracking area should be synchronized with the visible rectangle of the view (`visibleRect` (page 3245)) and for generating `mouseEntered:` and `mouseExited:` events when the mouse is dragged.

Other `NSView` methods related to `NSTrackingArea` objects (in addition to `addTrackingArea:`) include `removeTrackingArea:` (page 3204) and `updateTrackingAreas` (page 3239). Views can override the latter method to recompute and replace their `NSTrackingArea` objects in certain situations, such as a change in the size of the `visibleRect`.

Adopted Protocols

NSCoding
- `encodeWithCoder:`
- `initWithCoder:`

NSCopying
- `copyWithZone:`

Tasks

Initializing the Tracking-Area Object

- `initWithRect:options:owner:userInfo:` (page 3041)
  Initializes and returns an object defining a region of a view to receive mouse-tracking events, mouse-moved events, cursor-update events, or possibly all these events.

Getting Object Attributes

- `options` (page 3042)
  Returns the options specified for the receiver.
- `owner` (page 3042)
  Returns the object owning the receiver, which is the recipient of mouse-tracking, mouse-movement, and cursor-update messages.
- `rect` (page 3042)
  Returns the rectangle defining the area encompassed by the receiver.
- `userInfo` (page 3043)
  Returns the dictionary containing the data associated with the receiver when it was created.

Instance Methods

initWithRect:options:owner:userInfo:

Initializes and returns an object defining a region of a view to receive mouse-tracking events, mouse-moved events, cursor-update events, or possibly all these events.

```
- (id)initWithRect:(NSRect)rect options:(NSTrackingAreaOptions)options
    owner:(id)owner userInfo:(NSDictionary *)userInfo
```

Parameters

rect

A rectangle that defines a region of a target view, in the view's coordinate system, for tracking events related to mouse tracking and cursor updating. The specified rectangle should not exceed the view's bounds rectangle.

options

One or more constants that specify the type of tracking area, the situations when the area is active, and special behaviors of the tracking area. See the description of `NSTrackingAreaOptions` (page 3043) and related constants for details. You must specify one or more options for the initialized object, in particular the type of tracking area; zero is not a valid value.

owner

The object to receive the requested mouse-tracking, mouse-moved, or cursor-update messages. It does not necessarily have to be the view associated with the created `NSTrackingArea` object, but should be an object capable of responding to the `NSResponder` methods `mouseEntered:` (page 2165), `mouseExited:` (page 2165), `mouseMoved:` (page 2166), and `cursorUpdate:` (page 2147).

userInfo

A dictionary containing arbitrary data for each mouse-entered, mouse-exited, and cursor-update event. When handling such an event you can obtain the dictionary by sending `userData` (page 1089) to the `NSEvent` object. (The dictionary is not available for mouse-moved events.) This parameter may be `nil`.

Return Value

The newly-initialized tracking area object.

Discussion

After creating and initializing an `NSTrackingArea` object with this method, you must add it to a target view using the `addTrackingArea:` (page 3142) method. When changes in the view require changes in the geometry of its tracking areas, the Application Kit invokes `updateTrackingAreas` (page 3239). The view should implement this method to replace the current `NSTrackingArea` object with one with a recomputed area.

Special Considerations

Beginning with Mac OS X v10.5, the `initWithRect:options:owner:userInfo:`, along with the `addTrackingArea:` (page 3142) method of `NSView`, replace the `NSView` method `addTrackingRect:owner:userData:assumeInside:` (page 3142).

Availability

Available in Mac OS X v10.5 and later.

See Also

- `options` (page 3042)
- `owner` (page 3042)

- `rect` (page 3042)
- `userInfo` (page 3043)

Related Sample Code
BasicCocoaAnimations
MenuItemView
PhotoSearch
TrackIt

Declared In
`NSTrackingArea.h`

options

Returns the options specified for the receiver.

```
- (NSTrackingAreaOptions)options
```

Discussion
The options for an `NSTrackingArea` object are specified when the object is created. To determine if a particular option is in effect, perform a bitwise-AND operation with an `NSTrackingAreaOptions` (page 3043) constant and the value returned from this method, for example:

```
if ([trackingAreaObj options] & NSTrackingInVisibleRect != 0) {
    // do something appropriate
}
```

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSTrackingArea.h`

owner

Returns the object owning the receiver, which is the recipient of mouse-tracking, mouse-movement, and cursor-update messages.

```
- (id)owner
```

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSTrackingArea.h`

rect

Returns the rectangle defining the area encompassed by the receiver.

```
- (NSRect)rect
```

Discussion
The rectangle is specified in the local coordinate system of the associated view. if the `NSTrackingInVisibleRect` (page 3045) option is specified, the receiver is automatically synchronized with changes in the view's visible area (`visibleRect` (page 3245)) and the value returned from this method is ignored.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSTrackingArea.h`

userInfo

Returns the dictionary containing the data associated with the receiver when it was created.

```
- (NSDictionary *)userInfo
```

Discussion
Returns `nil` if no data was specified when the receiver was initialized. You can obtain this dictionary per event in each `mouseEntered:` (page 2165) and `mouseExited:` (page 2165) method by querying the passed-in `NSEvent` object with [[event trackingArea] `userData` (page 1089)].

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSTrackingArea.h`

Constants

NSTrackingAreaOptions

The data type defined for the constants specified in the *`options`* parameter of `initWithRect:options:owner:userInfo:` (page 3041). These constants are described below; you may specify multiple constants by performing a bitwise-OR operation with them.

```
typedef NSUInteger NSTrackingAreaOptions;
```

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSTrackingArea.h`

The following constants specify the type of the tracking area defined by an `NSTrackingArea` object. They request the type of messages the owning object should receive.

Constant	Description
`NSTrackingMouseEnteredAndExited`	The owner of the tracking area receives `mouseEntered:` (page 2165) when the mouse cursor enters the area and `mouseExited:` (page 2165) events when the mouse leaves the area. Available in Mac OS X v10.5 and later. Declared in `NSTrackingArea.h`.
`NSTrackingMouseMoved`	The owner of the tracking area receives `mouseMoved:` (page 2166) messages while the mouse cursor is within the area. Available in Mac OS X v10.5 and later. Declared in `NSTrackingArea.h`.
`NSTrackingCursorUpdate`	The owner of the tracking area receives `cursorUpdate:` (page 2147) messages when the mouse cursor enters the area; when the mouse leaves the area, the cursor is appropriately reset. Available in Mac OS X v10.5 and later. Declared in `NSTrackingArea.h`.

The following constants specify when the tracking area defined by an `NSTrackingArea` object is active. The owner receives all requested messages—which can include `mouseEntered:` (page 2165), `mouseExited:` (page 2165), `mouseMoved:` (page 2166), and `cursorUpdate:` (page 2147)—unless otherwise noted.

Constant	Description
`NSTrackingActiveWhenFirstResponder`	The owner receives messages when the view is the first responder. Available in Mac OS X v10.5 and later. Declared in `NSTrackingArea.h`.
`NSTrackingActiveInKeyWindow`	The owner receives messages when the view is in the key window. Available in Mac OS X v10.5 and later. Declared in `NSTrackingArea.h`.
`NSTrackingActiveInActiveApp`	The owner receives messages when the application is active. Available in Mac OS X v10.5 and later. Declared in `NSTrackingArea.h`.
`NSTrackingActiveAlways`	The owner receives messages regardless of first-responder status, window status, or application status. The `cursorUpdate:` (page 2147) message is *not* sent when the `NSTrackingCursorUpdate` (page 3044) option is specified along with this constant. Available in Mac OS X v10.5 and later. Declared in `NSTrackingArea.h`.

The following constants specify various behaviors of the tracking defined by an `NSTrackingArea` object.

Constant	Description
`NSTrackingAssumeInside`	The first event is generated when the cursor leaves the tracking area, regardless if the cursor is inside the area when the `NSTrackingArea` is added to a view. If this option is not specified, the first event is generated when the cursor leaves the tracking area if the cursor is initially inside the area, or when the cursor enters the area if the cursor is initially outside it. Generally, you do not want to request this behavior. Available in Mac OS X v10.5 and later. Declared in `NSTrackingArea.h`.
`NSTrackingInVisibleRect`	Mouse tracking occurs only in the visible rectangle of the view—in other words, that region of the tracking rectangle that is unobscured. Otherwise, the entire tracking area is active regardless of overlapping views. The `NSTrackingArea` object is automatically synchronized with changes in the view's visible area (`visibleRect` (page 3245)) and the value returned from `rect` (page 3042) is ignored. Available in Mac OS X v10.5 and later. Declared in `NSTrackingArea.h`.
`NSTrackingEnabledDuringMouseDrag`	The owner receives `NSMouseEntered` (page 1094) events when the mouse cursor is dragged into the tracking area. If this option is not specified, the owner receives mouse-entered events when the mouse is moved (no buttons pressed) into the tracking area and on `NSLeftMouseUp` (page 1093) events after a mouse drag. `NSMouseExited` (page 1094) and `NSMouseEntered` (page 1094) events are paired so their delivery is indirectly affected. That is, if a `NSMouseEntered` event is generated and the mouse cursor subsequently moves out of the tracking area, a `NSMouseExited` event is generated regardless if the mouse is moved or dragged, independent of this constant. Available in Mac OS X v10.5 and later. Declared in `NSTrackingArea.h`.

NSTreeController Class Reference

Inherits from	NSObjectController : NSController : NSObject
Conforms to	NSCoding (NSController) NSObject (NSObject)
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.4 and later.
Declared in	AppKit/NSTreeController.h
Companion guide	Cocoa Bindings Programming Topics
Related sample code	AbstractTree CoreRecipes ImageApp QTMetadataEditor SourceView

Overview

The `NSTreeController` is a bindings compatible controller that manages a tree of objects. It provides selection and sort management. Its primary purpose is to act as the controller when binding NSOutlineView and NSBrowser instances to a hierarchical collection of objects. The root content object of the tree can be a single object, or an array of objects.

An `NSTreeController` requires that you describe how the tree of objects is traversed by specifying the key-path for child objects specified by `setChildrenKeyPath:` (page 3064). All child objects for the tree must be key-value coding compliant for the same child key-path. If necessary, you should implement accessor methods in your model classes, that map the child key name to the appropriate class-specific method name.

Child objects can implement a count method (specified to the tree controller using `setCountKeyPath:` (page 3065)) that, if provided, returns the number of child objects available. Your model objects are expected to update the value of the count key-path in a key-value observing compliant method. You can also, optionally, provide a leaf key-path using `setLeafKeyPath:` (page 3065) that specifies a key in your model object that returns `YES` if the object is a leaf node, and `NO` if it is not. Changes to the leaf node value of the child object should be made in a key-value observing compliant manner. Providing the leaf node key-path prevents the `NSTreeController` from having to determine if a child object is a leaf node by examining the child object and as a result improves performance.

Adopted Protocols

NSCoding
- `encodeWithCoder:`
- `initWithCoder:`

NSCopying
- `copyWithZone:`

Tasks

Managing Sort Descriptors

- `setSortDescriptors:` (page 3067)
  Sets the sort descriptors used to arrange the receiver's contents.
- `sortDescriptors` (page 3067)
  Returns an array containing the sort descriptors used to arrange the receiver's content.

Setting the Content

- `setContent:` (page 3064)
  Sets the receiver's content.
- `content` (page 3055)
  Returns the receiver's content object.

Arranging Objects

- `arrangedObjects` (page 3052)
  Returns the tree controller's sorted content objects.
- `rearrangeObjects` (page 3060)
  Use this method to trigger reordering of the receiver's content.

Getting the Current Selection

- `setSelectionIndexPath:` (page 3066)
  Sets the receiver's current selection.
- `selectionIndexPath` (page 3062)
  Returns the index path of the first selected object.
- `setSelectionIndexPaths:` (page 3066)
  Sets the receiver's current selection to the specified index paths.

- `selectionIndexPaths` (page 3062)
  Returns an array containing the index paths of the currently selected objects.
- `selectedObjects` (page 3062)
  Returns an array containing the currently selected objects.
- `selectedNodes` (page 3061)
  Returns an array of the receiver's selected tree nodes.

Managing Selections

- `setSelectsInsertedObjects:` (page 3067)
  Sets whether the receiver will automatically select objects as they are inserted.
- `selectsInsertedObjects` (page 3063)
  Returns whether the receiver selects inserted objects automatically.
- `addSelectionIndexPaths:` (page 3052)
  Adds the objects at the specified *`indexPaths`* in the receiver's content to the current selection.
- `removeSelectionIndexPaths:` (page 3061)
  Removes the objects at the specified indexPaths from the receiver's current selection, returning `YES` if the selection was changed.
- `setAvoidsEmptySelection:` (page 3064)
  Sets whether the receiver will attempt to avoid an empty selection.
- `avoidsEmptySelection` (page 3053)
  Returns whether the receiver requires that the content array attempt to maintain a selection at all times.
- `setPreservesSelection:` (page 3065)
  Sets whether the receiver will attempt to preserve selection when the content changes.
- `preservesSelection` (page 3059)
  Returns whether the receiver will attempt to preserve the current selection when the content changes.
- `setAlwaysUsesMultipleValuesMarker:` (page 3063)
  Sets whether the receiver always returns the multiple values marker when multiple objects are selected, even if they have the same value.
- `alwaysUsesMultipleValuesMarker` (page 3052)
  Returns whether the receiver always returns the multiple values marker when multiple objects are selected, even if the selected items have the same value.

Adding, Inserting and Removing Objects

- `add:` (page 3051)
  Adds an object to the receiver after the current selection.
- `addChild:` (page 3051)
  Adds a child object to the currently selected item.
- `canAddChild` (page 3053)
  Returns `YES` if a child object can be added to the receiver's content.
- `canInsert` (page 3054)
  Returns `YES` if an object can be inserted into the receiver's content.

- `canInsertChild` (page 3054)
  Returns `YES` if a child object can be inserted into the receiver's content.
- `insert:` (page 3056)
  Creates a new object of the class specified by `objectClass` and inserts it into the receiver's content.
- `insertChild:` (page 3057)
  Creates a new object of the class specified by `objectClass` and inserts it into the receiver's content as a child of the current selection.
- `insertObject:atArrangedObjectIndexPath:` (page 3057)
  Inserts *`object`* into the receiver's arranged objects array at the location specified by *`indexPath`*, and adds it to the receiver's content.
- `insertObjects:atArrangedObjectIndexPaths:` (page 3057)
  Inserts *`objects`* into the receiver's arranged objects array at the locations specified in *`indexPaths`*, and adds them to the receiver's content.
- `remove:` (page 3060)
  Removes the receiver's selected objects from the content.
- `removeObjectAtArrangedObjectIndexPath:` (page 3060)
  Removes the object at the specified *`indexPath`* in the receiver's arranged objects from the receiver's content.
- `removeObjectsAtArrangedObjectIndexPaths:` (page 3061)
  Removes the objects at the specified *`indexPaths`* in the receiver's arranged objects from the receiver's content.
- `moveNode:toIndexPath:` (page 3058)
  Moves the specified tree node to the new index path.
- `moveNodes:toIndexPath:` (page 3059)
  Moves the specified tree nodes to the new index path.

Specifying Model Attributes

- `setChildrenKeyPath:` (page 3064)
  Sets the key path used by the receiver to access child objects to *`key`*.
- `childrenKeyPath` (page 3054)
  Returns the key path used to find the children in the receiver's objects.
- `setCountKeyPath:` (page 3065)
  Sets the key path used by the receiver to determine the number of objects at a node to *`key`*.
- `childrenKeyPathForNode:` (page 3055)
  Returns the key path used to find the children in the specified tree node.
- `countKeyPath` (page 3055)
  Returns the key path used to find the number of children for a node.
- `countKeyPathForNode:` (page 3056)
  Returns the key path that provides the number of children for a specified node.
- `setLeafKeyPath:` (page 3065)
  Sets the key path used by the receiver to determine if an object is a leaf node to *`key`*.
- `leafKeyPath` (page 3058)
  Returns the key path used by the receiver to determine if a node is a leaf key.

- leafKeyPathForNode: (page 3058)
  Returns the key path that specifies whether the node is a leaf node.

Instance Methods

add:

Adds an object to the receiver after the current selection.

```
- (void)add:(id)sender
```

Discussion
The *sender* is typically the object that invoked this method.

If the receiver is in object mode `newObject` is called and the returned object is added to the collection. If the receiver is in entity mode a new object is created that is appropriate as specified by the entity, and `newObject` is not used.

Special Considerations

Beginning with Mac OS X v10.4 the result of this method is deferred until the next iteration of the runloop so that the error presentation mechanism can provide feedback as a sheet.

Availability
Available in Mac OS X v10.4 and later.

See Also
- remove: (page 3060)

Declared In
`NSTreeController.h`

addChild:

Adds a child object to the currently selected item.

```
- (void)addChild:(id)sender
```

Discussion
The *sender* is typically the object that invoked this method.

If the receiver is in object mode `newObject` is called and the returned object is added as a child. If the receiver is in entity mode a new object is created that is appropriate for the relationship as specified by the entity, and `newObject` is not used.

Special Considerations

Beginning with Mac OS X v10.4 the result of this method is deferred until the next iteration of the runloop so that the error presentation mechanism can provide feedback as a sheet.

Availability
Available in Mac OS X v10.4 and later.

See Also
- remove: (page 3060)

Declared In
NSTreeController.h

addSelectionIndexPaths:

Adds the objects at the specified *indexPaths* in the receiver's content to the current selection.

```
- (BOOL)addSelectionIndexPaths:(NSArray *)indexPaths
```

Discussion
Attempting to change the selection may cause a commitEditing message which fails, thus denying the selection change.

Availability
Available in Mac OS X v10.4 and later.

See Also
- removeSelectionIndexPaths: (page 3061)

Declared In
NSTreeController.h

alwaysUsesMultipleValuesMarker

Returns whether the receiver always returns the multiple values marker when multiple objects are selected, even if the selected items have the same value.

```
- (BOOL)alwaysUsesMultipleValuesMarker
```

Discussion
The default is NO.

This property is observable using key-value observing.

Availability
Available in Mac OS X v10.4 and later.

See Also
- setAlwaysUsesMultipleValuesMarker: (page 3063)

Declared In
NSTreeController.h

arrangedObjects

Returns the tree controller's sorted content objects.

```
- (id)arrangedObjects
```

Return Value
A proxy root tree note containing the receiver's sorted content objects. The proxy object responds to `childNodes` (page 3071) and `descendantNodeAtIndexPath:` (page 3071) messages.

Discussion
This property is observable using key-value observing.

Special Considerations

Prior to Mac OS X v10.5 this method returned an opaque root node object representing all the currently displayed objects. That return value was only suitable for use with Cocoa bindings, and no assumption should be made about what methods that opaque object supports.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- rearrangeObjects` (page 3060)

Declared In
`NSTreeController.h`

avoidsEmptySelection

Returns whether the receiver requires that the content array attempt to maintain a selection at all times.

```
- (BOOL)avoidsEmptySelection
```

Discussion
The default is `YES`.

This property is observable using key-value observing.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- setAvoidsEmptySelection:` (page 3064)

Declared In
`NSTreeController.h`

canAddChild

Returns `YES` if a child object can be added to the receiver's content.

```
- (BOOL)canAddChild
```

Discussion
This property is observable using key-value observing.

Availability
Available in Mac OS X v10.4 and later.

See Also
- canInsertChild (page 3054)

Declared In
NSTreeController.h

canInsert

Returns YES if an object can be inserted into the receiver's content.

```
- (BOOL)canInsert
```

Discussion
This property is observable using key-value observing.

Availability
Available in Mac OS X v10.4 and later.

See Also
- canInsertChild (page 3054)

Declared In
NSTreeController.h

canInsertChild

Returns YES if a child object can be inserted into the receiver's content.

```
- (BOOL)canInsertChild
```

Discussion
This property is observable using key-value observing.

Availability
Available in Mac OS X v10.4 and later.

See Also
- insertChild: (page 3057)

Declared In
NSTreeController.h

childrenKeyPath

Returns the key path used to find the children in the receiver's objects.

```
- (NSString *)childrenKeyPath
```

Availability
Available in Mac OS X v10.4 and later.

See Also
- setChildrenKeyPath: (page 3064)

Declared In
NSTreeController.h

childrenKeyPathForNode:

Returns the key path used to find the children in the specified tree node.

```
- (NSString *)childrenKeyPathForNode:(NSTreeNode *)node
```

Parameters

node

A tree node in the receiver.

Return Value
A string containing the key path in *node* that provides the child nodes.

Availability
Available in Mac OS X v10.5 and later.

Declared In
NSTreeController.h

content

Returns the receiver's content object.

```
- (id)content
```

Return Value
The receiver's content object.

Discussion
This property is observable using key-value observing.

Availability
Available in Mac OS X v10.4 and later.

See Also
- setContent: (page 3064)

Declared In
NSTreeController.h

countKeyPath

Returns the key path used to find the number of children for a node.

```
- (NSString *)countKeyPath
```

Availability
Available in Mac OS X v10.4 and later.

See Also
- `setCountKeyPath:` (page 3065)

Declared In
`NSTreeController.h`

countKeyPathForNode:

Returns the key path that provides the number of children for a specified node.

```
- (NSString *)countKeyPathForNode:(NSTreeNode *)node
```

Parameters

node

A tree node in the receiver.

Return Value
A string containing the key path in *node* that provides the number of children.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSTreeController.h`

insert:

Creates a new object of the class specified by `objectClass` and inserts it into the receiver's content.

```
- (void)insert:(id)sender
```

Discussion
The *sender* is typically the object that invoked this method.

If the receiver is in object mode `newObject` is called and the returned object is inserted into the collection. If the receiver is in entity mode a new object is created that is appropriate as specified by the entity, and `newObject` is not used.

Special Considerations

Beginning with Mac OS X v10.4 the result of this method is deferred until the next iteration of the runloop so that the error presentation mechanism can provide feedback as a sheet.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `add:` (page 3051)

Declared In
`NSTreeController.h`

insertChild:

Creates a new object of the class specified by `objectClass` and inserts it into the receiver's content as a child of the current selection.

```
- (void)insertChild:(id)sender
```

Discussion
The *sender* is typically the object that invoked this method.

If the receiver is in object mode `newObject` is called and the returned object is inserted as a child. If the receiver is in entity mode a new object is created that is appropriate for the relationship as specified by the entity, and `newObject` is not used.

Special Considerations

Beginning with Mac OS X v10.4 the result of this method is deferred until the next iteration of the runloop so that the error presentation mechanism can provide feedback as a sheet.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `add:` (page 3051)

Declared In
`NSTreeController.h`

insertObject:atArrangedObjectIndexPath:

Inserts *object* into the receiver's arranged objects array at the location specified by *indexPath*, and adds it to the receiver's content.

```
- (void)insertObject:(id)object atArrangedObjectIndexPath:(NSIndexPath *)indexPath
```

Availability
Available in Mac OS X v10.4 and later.

See Also
- `insertObjects:atArrangedObjectIndexPaths:` (page 3057)

Related Sample Code
SourceView

Declared In
`NSTreeController.h`

insertObjects:atArrangedObjectIndexPaths:

Inserts *objects* into the receiver's arranged objects array at the locations specified in *indexPaths*, and adds them to the receiver's content.

```
- (void)insertObjects:(NSArray *)objects atArrangedObjectIndexPaths:(NSArray
    *)indexPaths
```

Availability
Available in Mac OS X v10.4 and later.

See Also
- `removeObjectAtArrangedObjectIndexPath:` (page 3060)

Declared In
`NSTreeController.h`

leafKeyPath

Returns the key path used by the receiver to determine if a node is a leaf key.

```
- (NSString *)leafKeyPath
```

Availability
Available in Mac OS X v10.4 and later.

See Also
- `setLeafKeyPath:` (page 3065)

Declared In
`NSTreeController.h`

leafKeyPathForNode:

Returns the key path that specifies whether the node is a leaf node.

```
- (NSString *)leafKeyPathForNode:(NSTreeNode *)node
```

Parameters
node
A tree node in the receiver.

Return Value
A string containing the key path in *node* that specifies that the node is a leaf node.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSTreeController.h`

moveNode:toIndexPath:

Moves the specified tree node to the new index path.

```
- (void)moveNode:(NSTreeNode *)node toIndexPath:(NSIndexPath *)indexPath
```

Parameters
node
A tree node.

indexPath
An index path specifying the new position in the receiver's content.

Availability
Available in Mac OS X v10.5 and later.

Related Sample Code
SourceView

Declared In
NSTreeController.h

moveNodes:toIndexPath:

Moves the specified tree nodes to the new index path.

```
- (void)moveNodes:(NSArray *)nodes toIndexPath:(NSIndexPath *)startingIndexPath
```

Parameters
nodes
An array of tree nodes.

startingIndexPath
An index path specifying the starting position to move the tree nodes to in the receiver's content.

Availability
Available in Mac OS X v10.5 and later.

Declared In
NSTreeController.h

preservesSelection

Returns whether the receiver will attempt to preserve the current selection when the content changes.

```
- (BOOL)preservesSelection
```

Discussion
The default is YES.

This property is observable using key-value observing.

Availability
Available in Mac OS X v10.4 and later.

See Also
- setPreservesSelection: (page 3065)

Declared In
NSTreeController.h

rearrangeObjects

Use this method to trigger reordering of the receiver's content.

```
- (void)rearrangeObjects
```

Discussion
Subclasses should invoke this method if any parameter that affects the arranged objects changes.

Availability
Available in Mac OS X v10.4 and later.

See Also
- arrangedObjects (page 3052)

Declared In
NSTreeController.h

remove:

Removes the receiver's selected objects from the content.

```
- (void)remove:(id)sender
```

Discussion
The *sender* is typically the object that invoked this method.

Special Considerations

Beginning with Mac OS X v10.4 the result of this method is deferred until the next iteration of the runloop so that the error presentation mechanism can provide feedback as a sheet.

Availability
Available in Mac OS X v10.4 and later.

See Also
- add: (page 3051)

Related Sample Code

Declared In
NSTreeController.h

removeObjectAtArrangedObjectIndexPath:

Removes the object at the specified *indexPath* in the receiver's arranged objects from the receiver's content.

```
- (void)removeObjectAtArrangedObjectIndexPath:(NSIndexPath *)indexPath
```

Availability
Available in Mac OS X v10.4 and later.

See Also
- removeObjectsAtArrangedObjectIndexPaths: (page 3061)

Declared In
NSTreeController.h

removeObjectsAtArrangedObjectIndexPaths:

Removes the objects at the specified *indexPaths* in the receiver's arranged objects from the receiver's content.

```
- (void)removeObjectsAtArrangedObjectIndexPaths:(NSArray *)indexPaths
```

Availability
Available in Mac OS X v10.4 and later.

See Also
- removeObjectAtArrangedObjectIndexPath: (page 3060)

Declared In
NSTreeController.h

removeSelectionIndexPaths:

Removes the objects at the specified indexPaths from the receiver's current selection, returning YES if the selection was changed.

```
- (BOOL)removeSelectionIndexPaths:(NSArray *)indexPaths
```

Discussion
Attempting to change the selection may cause a commitEditing message which fails, thus denying the selection change.

Availability
Available in Mac OS X v10.4 and later.

See Also
- addSelectionIndexPaths: (page 3052)

Declared In
NSTreeController.h

selectedNodes

Returns an array of the receiver's selected tree nodes.

```
- (NSArray *)selectedNodes
```

Return Value
An array containing the receiver's selected tree nodes

Availability
Available in Mac OS X v10.5 and later.

Declared In
NSTreeController.h

selectedObjects

Returns an array containing the currently selected objects.

```
- (NSArray *)selectedObjects
```

Return Value
An array containing the currently selected objects in the tree controller content.

Discussion
This property is observable using key-value observing.

Availability
Available in Mac OS X v10.4 and later.

Related Sample Code
QTMetadataEditor

Declared In
NSTreeController.h

selectionIndexPath

Returns the index path of the first selected object.

```
- (NSIndexPath *)selectionIndexPath
```

Return Value
Returns an index path of the first object in the tree controller's selection. Returns `nil` if there is no selection.

Discussion
This property is observable using key-value observing.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `selectionIndexPaths` (page 3062)

Related Sample Code
SourceView

Declared In
NSTreeController.h

selectionIndexPaths

Returns an array containing the index paths of the currently selected objects.

```
- (NSArray *)selectionIndexPaths
```

Return Value
An array containing `NSIndexPath` objects for each of the selected objects in the tree controller's content.

Discussion
This property is observable using key-value observing.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- selectionIndexPath` (page 3062)

Declared In
`NSTreeController.h`

selectsInsertedObjects

Returns whether the receiver selects inserted objects automatically.

```
- (BOOL)selectsInsertedObjects
```

Discussion
The default is `YES`.

This property is observable using key-value observing.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- setSelectsInsertedObjects:` (page 3067)

Declared In
`NSTreeController.h`

setAlwaysUsesMultipleValuesMarker:

Sets whether the receiver always returns the multiple values marker when multiple objects are selected, even if they have the same value.

```
- (void)setAlwaysUsesMultipleValuesMarker:(BOOL)flag
```

Discussion
Setting *flag* to `YES` can increase performance if your application doesn't allow editing multiple values. The default is `NO`.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- alwaysUsesMultipleValuesMarker` (page 3052)

Declared In
NSTreeController.h

setAvoidsEmptySelection:

Sets whether the receiver will attempt to avoid an empty selection.

```
- (void)setAvoidsEmptySelection:(BOOL)flag
```

Discussion
If *flag* is YES then the receiver will maintain a selection unless there are no objects in the content. The default is YES.

Availability
Available in Mac OS X v10.4 and later.

See Also
- avoidsEmptySelection (page 3053)

Declared In
NSTreeController.h

setChildrenKeyPath:

Sets the key path used by the receiver to access child objects to *key*.

```
- (void)setChildrenKeyPath:(NSString *)key
```

Availability
Available in Mac OS X v10.4 and later.

See Also
- childrenKeyPath (page 3054)

Declared In
NSTreeController.h

setContent:

Sets the receiver's content.

```
- (void)setContent:(id)content
```

Parameters
content
The content. The content can be an array of objects, or a single root object.

Availability
Available in Mac OS X v10.4 and later.

See Also
- content (page 3055)

Related Sample Code
ImageApp

Declared In
`NSTreeController.h`

setCountKeyPath:

Sets the key path used by the receiver to determine the number of objects at a node to *key*.

```
- (void)setCountKeyPath:(NSString *)key
```

Discussion
Specifying this key path, if the data is available in the model object, can increase performance, but disables insert and remove functionality.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `countKeyPath` (page 3055)

Declared In
`NSTreeController.h`

setLeafKeyPath:

Sets the key path used by the receiver to determine if an object is a leaf node to *key*.

```
- (void)setLeafKeyPath:(NSString *)key
```

Discussion
Specifying this key path is optional. If the receiver is able to determine that a node is a leaf node, it can disable inserting or adding children to those nodes.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `leafKeyPath` (page 3058)

Declared In
`NSTreeController.h`

setPreservesSelection:

Sets whether the receiver will attempt to preserve selection when the content changes.

```
- (void)setPreservesSelection:(BOOL)flag
```

Discussion
If *flag* is `YES` then the selection will be preserved, if possible. The default is `YES`.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `preservesSelection` (page 3059)

Declared In
`NSTreeController.h`

setSelectionIndexPath:

Sets the receiver's current selection.

```
- (BOOL)setSelectionIndexPath:(NSIndexPath *)indexPath
```

Parameters
indexPath
The proposed new selection.

Return Value
Return `YES` if the selection has changed, otherwise `NO`.

Discussion
Attempting to change the selection may cause a `commitEditing` message which fails, thus denying the selection change.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `selectionIndexPaths` (page 3062)

Declared In
`NSTreeController.h`

setSelectionIndexPaths:

Sets the receiver's current selection to the specified index paths.

```
- (BOOL)setSelectionIndexPaths:(NSArray *)indexPaths
```

Parameters
indexPaths
An array of NSIndexpath objects specifying the selected objects.

Return Value
Return `YES` if the selection has changed, otherwise `NO`.

Discussion
Attempting to change the selection may cause a `commitEditing` message which fails, thus denying the selection change.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `setSelectionIndexPath:` (page 3066)

Declared In
`NSTreeController.h`

setSelectsInsertedObjects:

Sets whether the receiver will automatically select objects as they are inserted.

```
- (void)setSelectsInsertedObjects:(BOOL)flag
```

Discussion
If *flag* is `YES` then items will be selected upon insertion. The default is `YES`.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `selectsInsertedObjects` (page 3063)

Declared In
`NSTreeController.h`

setSortDescriptors:

Sets the sort descriptors used to arrange the receiver's contents.

```
- (void)setSortDescriptors:(NSArray *)sortDescriptors
```

Parameters

sortDescriptors
An array of `NSSortDescriptor` objects. Passing `nil` causes the contents to be arranged in their natural order.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `sortDescriptors` (page 3067)

Declared In
`NSTreeController.h`

sortDescriptors

Returns an array containing the sort descriptors used to arrange the receiver's content.

```
- (NSArray *)sortDescriptors
```

Return Value
Returns an array containing the tree controller's sort descriptors. Returns `nil` if the receiver has no sort descriptors configured.

Discussion
This property is observable using key-value observing.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- setSortDescriptors:` (page 3067)

Declared In
`NSTreeController.h`

NSTreeNode Class Reference

Overview

`NSTreeNode` simplifies the creation and management of trees of objects. Each tree node represents a model object. A tree node with `nil` as its parent node is considered the root of the tree.

Tasks

Creating Tree Nodes

`+ treeNodeWithRepresentedObject:` (page 3070)
Creates and returns a tree node that represents the specified object.

`- initWithRepresentedObject:` (page 3072)
Initializes a newly allocated tree node that represents the specified object.

Getting Information About a Node

`- representedObject` (page 3073)
Returns the object the tree node represents.

`- indexPath` (page 3071)
Returns the position of the receiver relative to its root parent.

- `isLeaf` (page 3072)
  Returns whether the receiver is a leaf node.
- `childNodes` (page 3071)
  Returns an array containing receiver's child nodes.
- `mutableChildNodes` (page 3072)
  Returns a mutable array that provides read-write access to the receiver's child nodes.
- `descendantNodeAtIndexPath:` (page 3071)
  Returns the receiver's descendent at the specified index path.
- `parentNode` (page 3073)
  Returns the receiver's parent node.

Sorting the Subtree

- `sortWithSortDescriptors:recursively:` (page 3074)
  Sorts the receiver's subtree using the values of the represented objects with the specified sort descriptors.

Class Methods

treeNodeWithRepresentedObject:

Creates and returns a tree node that represents the specified object.

```
+ (id)treeNodeWithRepresentedObject:(id)modelObject
```

Parameters

modelObject
  The object the tree node represents.

Return Value
An initialized tree node that represents *modelObject*.

Availability
Available in Mac OS X v10.5 and later.

Related Sample Code
DragNDropOutlineView

Declared In
`NSTreeNode.h`

Instance Methods

childNodes

Returns an array containing receiver's child nodes.

```
- (NSArray *)childNodes
```

Return Value
An array containing the receiver's child nodes.

Availability
Available in Mac OS X v10.5 and later.

Related Sample Code
DragNDropOutlineView

Declared In
`NSTreeNode.h`

descendantNodeAtIndexPath:

Returns the receiver's descendent at the specified index path.

```
- (NSTreeNode *)descendantNodeAtIndexPath:(NSIndexPath *)indexPath
```

Parameters

indexPath
An index path specifying a descendent of the receiver.

Return Value
A tree node, or `nil` if the node does not exist.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSTreeNode.h`

indexPath

Returns the position of the receiver relative to its root parent.

```
- (NSIndexPath *)indexPath
```

Return Value
An index path that represents the receiver's position relative to the tree's root node.

Availability
Available in Mac OS X v10.5 and later.

Related Sample Code
AbstractTree
SourceView

Declared In
`NSTreeNode.h`

initWithRepresentedObject:

Initializes a newly allocated tree node that represents the specified object.

```
- (id)initWithRepresentedObject:(id)modelObject
```

Parameters
modelObject
The object the tree node represents.

Return Value
An initialized tree node that represents *modelObject*.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSTreeNode.h`

isLeaf

Returns whether the receiver is a leaf node.

```
- (BOOL)isLeaf
```

Return Value
`YES` if the receiver is a leaf node (has no child nodes), otherwise `NO`.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSTreeNode.h`

mutableChildNodes

Returns a mutable array that provides read-write access to the receiver's child nodes.

```
- (NSMutableArray *)mutableChildNodes
```

Return Value
A mutable array that provides read-write access to the receiver's child nodes.

Discussion
Nodes that are inserted into this array have their parent nodes set to the receiver. Nodes that are removed from this array automatically have their parent node set to `nil`. The array that is returned is observable using key-value observing.

Availability
Available in Mac OS X v10.5 and later.

Related Sample Code
DragNDropOutlineView

Declared In
`NSTreeNode.h`

parentNode

Returns the receiver's parent node.

```
- (NSTreeNode *)parentNode
```

Return Value
The receiver's parent node.

Availability
Available in Mac OS X v10.5 and later.

Related Sample Code
AbstractTree
DragNDropOutlineView
SourceView

Declared In
`NSTreeNode.h`

representedObject

Returns the object the tree node represents.

```
- (id)representedObject
```

Return Value
The object the tree node represents.

Availability
Available in Mac OS X v10.5 and later.

Related Sample Code
DragNDropOutlineView

Declared In
`NSTreeNode.h`

sortWithSortDescriptors:recursively:

Sorts the receiver's subtree using the values of the represented objects with the specified sort descriptors.

```
- (void)sortWithSortDescriptors:(NSArray *)sortDescriptors
    recursively:(BOOL)recursively
```

Parameters

sortDescriptors

Array of sort descriptors specifying how to sort the represented objects.

recursively

A Boolean that specifies whether the child nodes should be sorted recursively.

Discussion

All the represented objects in the child nodes must be key-value coding compliant for the keys specified in the sort descriptors.

Availability

Available in Mac OS X v10.5 and later.

Availability	Available in Mac OS X v10.0 and later.
Declared in	AppKit/NSTypesetter.h
Companion guides	Text System Overview Text Layout Programming Guide

Overview

`NSLayoutManager` uses concrete subclasses of this abstract class, `NSTypesetter`, to perform line layout, which includes word wrapping, hyphenation, and line breaking in either vertical or horizontal rectangles. By default, the text system uses the concrete subclass `NSATSTypesetter`.

Subclassing Notes

`NSTypesetter` provides concrete subclasses with default implementation interfacing with the Cocoa text system. By subclassing `NSTypesetter`, an application can override the `layoutParagraphAtPoint:` (page 3094) method to integrate a custom typesetting engine into the Cocoa text system. On the other hand, an application can subclass `NSATSTypesetter` and override the glyph storage interface to integrate the concrete subclass into its own custom layout system.

`NSTypesetter` methods belong to three categories: glyph storage interface methods, layout phase interface methods, and core typesetter methods. The glyph storage interface methods map to `NSLayoutManager` methods. The typesetter itself calls these methods, and their default implementations call the Cocoa layout manager. An `NSTypesetter` subclass can override these methods to call its own glyph storage facility, in which case it should override all of them. (This does not preclude the overridden method calling its superclass implementation if appropriate.)

The layout phase interface provides control points similar to delegate methods; if implemented, the system invokes these methods to notify an `NSTypesetter` subclass of events in the layout process so it can intervene as needed.

The remainder of the `NSTypesetter` methods are primitive, core typesetter methods. The core typesetter methods correlate with typesetting state attributes; the layout manager calls these methods to store its values before starting the layout process. If you subclass `NSTypesetter` and override the glyph storage interface methods, you can call the core methods to control the typesetter directly.

Glyph Storage Interface

Override these methods to use `NSTypesetter`'s built-in concrete subclass, `NSATSTypesetter`, with a custom glyph storage and layout system other than the Cocoa layout manager and text container mechanism.

`characterRangeForGlyphRange:actualGlyphRange:` (page 3086)
`glyphRangeForCharacterRange:actualCharacterRange:` (page 3091)
`getGlyphsInRange:glyphs:characterIndexes:glyphInscriptions:elasticBits:bidiLevels:` (page 3088)
`getLineFragmentRect:usedRect:remainingRect:forStartingGlyphAtIndex:proposedRect:lineSpacing:paragraphSpacingBefore:paragraphSpacingAfter:` (page 3090)
`setLineFragmentRect:forGlyphRange:usedRect:baselineOffset:` (page 3102)
`substituteGlyphsInRange:withGlyphs:` (page 3107)
`insertGlyph:atGlyphIndex:characterIndex:` (page 3092)
`deleteGlyphsInRange:` (page 3087)
`setNotShownAttribute:forGlyphRange:` (page 3104)
`setDrawsOutsideLineFragment:forGlyphRange:` (page 3101)
`setLocation:withAdvancements:forStartOfGlyphRange:` (page 3103)
`setAttachmentSize:forGlyphRange:` (page 3099)
`setBidiLevels:forGlyphRange:` (page 3100)

Layout Phase Interface

Override these methods to customize the text layout process, including modifying line fragments, controlling line breaking and hyphenation, and controlling the behavior of tabs and other control glyphs.

`willSetLineFragmentRect:forGlyphRange:usedRect:baselineOffset:` (page 3109)
`shouldBreakLineByWordBeforeCharacterAtIndex:` (page 3106)
`shouldBreakLineByHyphenatingBeforeCharacterAtIndex:` (page 3105)
`hyphenationFactorForGlyphAtIndex:` (page 3091)
`hyphenCharacterForGlyphAtIndex:` (page 3092)
`boundingBoxForControlGlyphAtIndex:forTextContainer:proposedLineFragment:glyphPosition:characterIndex:` (page 3085)

Tasks

Getting a Typesetter

`+ sharedSystemTypesetter` (page 3082)
Returns a shared instance of a reentrant typesetter.

+ sharedSystemTypesetterForBehavior: (page 3082)
Returns a shared instance of a reentrant typesetter that implements typesetting with the specified behavior.

Getting Information About a Typesetter

+ defaultTypesetterBehavior (page 3081)
Returns the default typesetter behavior.

Getting Information About Glyphs

+ printingAdjustmentInLayoutManager:forNominallySpacedGlyphRange:packedGlyphs:count: (page 3081)
Returns the interglyph spacing in the specified range when sent to a printer.

- baselineOffsetInLayoutManager:glyphIndex: (page 3084)
Returns the distance from the bottom of the bounding box of a specified glyph to its baseline.

Managing the Layout Manager

- layoutManager (page 3094)
Returns the layout manager for the text being typeset.

- setUsesFontLeading: (page 3105)
Sets whether the typesetter uses the leading (or line gap) value specified in the font metric information.

- usesFontLeading (page 3108)
Returns whether the typesetter uses the leading (or line gap) value specified in the font metric information of the current font.

- setTypesetterBehavior: (page 3104)
Sets the default typesetter behavior, which affects glyph spacing and line height.

- typesetterBehavior (page 3108)
Returns the current typesetter behavior.

- setHyphenationFactor: (page 3101)
Sets the threshold controlling when hyphenation is attempted.

- hyphenationFactor (page 3091)
Returns the current hyphenation factor.

Managing Text Containers

- currentTextContainer (page 3087)
Returns the text container for the text being typeset.

- textContainers (page 3107)
Returns an array containing the text containers belonging to the current layout manager.

- setLineFragmentPadding: (page 3102)
Sets the amount (in points) by which text is inset within line fragment rectangles.

- `lineFragmentPadding` (page 3095)
  Returns the current line fragment padding, in points.

Mapping Screen and Printer Fonts

- `substituteFontForFont:` (page 3106)
  Returns a screen font suitable for use in place of a given font.

Handling Control Characters

- `textTabForGlyphLocation:writingDirection:maxLocation:` (page 3108)
  Returns the text tab next closest to a given glyph location within the given parameters.
- `actionForControlCharacterAtIndex:` (page 3083)
  Returns the action associated with a control character.

Bidirectional Text Processing

- `setBidiProcessingEnabled:` (page 3100)
  Controls whether the typesetter performs bidirectional text processing.
- `bidiProcessingEnabled` (page 3085)
  Returns whether bidirectional text processing is enabled.

Accessing Paragraph Typesetting Information

- `currentParagraphStyle` (page 3087)
  Returns the paragraph style object for the text being typeset.
- `setAttributedString:` (page 3099)
  Sets the text backing store on which this typesetter operates.
- `attributedString` (page 3083)
  Returns the text backing store, usually an instance of `NSTextStorage`.
- `setParagraphGlyphRange:separatorGlyphRange:` (page 3104)
  Sets the current glyph range being processed.
- `paragraphGlyphRange` (page 3096)
  Returns the glyph range currently being processed.
- `paragraphSeparatorGlyphRange` (page 3097)
  Returns the current paragraph separator range.
- `paragraphCharacterRange` (page 3096)
  Returns the character range currently being processed.
- `paragraphSeparatorCharacterRange` (page 3097)
  Returns the current paragraph separator character range.
- `attributesForExtraLineFragment` (page 3083)
  Returns the attributes used to lay out the extra line fragment.

Paragraph Layout

- `layoutParagraphAtPoint:` (page 3094)
  Lays out glyphs in the current glyph range until the next paragraph separator is reached.
- `beginParagraph` (page 3085)
  Sets up layout parameters at the beginning of a paragraph.
- `endParagraph` (page 3088)
  Sets up layout parameters at the end of a paragraph.
- `beginLineWithGlyphAtIndex:` (page 3084)
  Sets up layout parameters at the beginning of a line during typesetting.
- `endLineWithGlyphRange:` (page 3088)
  Sets up layout parameters at the end of a line during typesetting.

Character Layout

- `layoutCharactersInRange:forLayoutManager:maximumNumberOfLineFragments:` (page 3093)
  Lays out characters in the given character range for the specified layout manager.

Line and Paragraph Spacing

- `lineSpacingAfterGlyphAtIndex:withProposedLineFragmentRect:` (page 3095)
  Returns the line spacing in effect following the specified glyph.
- `paragraphSpacingAfterGlyphAtIndex:withProposedLineFragmentRect:` (page 3098)
  Returns the paragraph spacing that is in effect after the specified glyph.
- `paragraphSpacingBeforeGlyphAtIndex:withProposedLineFragmentRect:` (page 3098)
  Returns the number of points of space—added before a paragraph—that is in effect before the specified glyph.

Glyph Caching

- `setHardInvalidation:forGlyphRange:` (page 3101)
  Sets whether to force the layout manager to invalidate the specified portion of the glyph cache when invalidating layout.

Laying out Glyphs

- `layoutGlyphsInLayoutManager:startingAtGlyphIndex:maxNumberOfLineFragments:nextGlyphIndex:` (page 3094)
  Lays out glyphs in the specified layout manager starting at a specified glyph.
- `boundingBoxForControlGlyphAtIndex:forTextContainer:proposedLineFragment:glyphPosition:characterIndex:` (page 3085)
  Returns the bounding rectangle for the specified control glyph with the specified parameters.

- getLineFragmentRect:usedRect:forParagraphSeparatorGlyphRange:atProposedOrigin: (page 3089)
  Calculates the line fragment rectangle and line fragment used rectangle for blank lines.
- getLineFragmentRect:usedRect:remainingRect:forStartingGlyphAtIndex:proposedRect:lineSpacing:paragraphSpacingBefore:paragraphSpacingAfter: (page 3090)
  Calculates line fragment rectangle, line fragment used rectangle, and remaining rectangle for a line fragment.
- hyphenCharacterForGlyphAtIndex: (page 3092)
  Returns the hyphen character to be inserted after the specified glyph.
- hyphenationFactorForGlyphAtIndex: (page 3091)
  Returns the hyphenation factor in effect at a specified location.
- shouldBreakLineByHyphenatingBeforeCharacterAtIndex: (page 3105)
  Returns whether the line being laid out should be broken by hyphenating at the specified character.
- shouldBreakLineByWordBeforeCharacterAtIndex: (page 3106)
  Returns whether the line being laid out should be broken by a word break at the specified character.
- willSetLineFragmentRect:forGlyphRange:usedRect:baselineOffset: (page 3109)
  Called by the typesetter just prior to storing the actual line fragment rectangle location in the layout manager.

Interfacing with Glyph Storage

- characterRangeForGlyphRange:actualGlyphRange: (page 3086)
  Returns the range for the characters in the receiver's text store that are mapped to the specified glyphs.
- deleteGlyphsInRange: (page 3087)
  Deletes the specified glyphs from the glyph cache maintained by the layout manager.
- substituteGlyphsInRange:withGlyphs: (page 3107)
  Replaces the specified glyphs with specified replacement glyphs.
- getGlyphsInRange:glyphs:characterIndexes:glyphInscriptions:elasticBits:bidiLevels: (page 3088)
  Extracts the information needed to lay out the provided glyphs from the provided range.
- glyphRangeForCharacterRange:actualCharacterRange: (page 3091)
  Returns the range for the glyphs mapped to the characters of the text store in the specified range.
- setAttachmentSize:forGlyphRange: (page 3099)
  Sets the size the specified glyphs (assumed to be attachments) will be asked to draw themselves at.
- setBidiLevels:forGlyphRange: (page 3100)
  Sets the direction of the specified glyphs for bidirectional text.
- setDrawsOutsideLineFragment:forGlyphRange: (page 3101)
  Sets whether the specified glyphs exceed the bounds of the line fragment in which they are laid out.
- setLineFragmentRect:forGlyphRange:usedRect:baselineOffset: (page 3102)
  Sets the line fragment rectangle where the specified glyphs are laid out.
- setLocation:withAdvancements:forStartOfGlyphRange: (page 3103)
  Sets the location where the specified glyphs are laid out.
- setNotShownAttribute:forGlyphRange: (page 3104)
  Sets whether the specified glyphs are not shown.

`- insertGlyph:atGlyphIndex:characterIndex:` (page 3092) Available in Mac OS X v10.3 through Mac OS X v10.3

Enables the typesetter to insert a new glyph into the stream.

Class Methods

defaultTypesetterBehavior

Returns the default typesetter behavior.

```
+ (NSTypesetterBehavior)defaultTypesetterBehavior
```

Return Value
The default typesetter behavior.

Discussion
Possible return values are described in the `NSTypesetterBehavior` (page 1527) section for `NSLayoutManager`.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`NSTypesetter.h`

printingAdjustmentInLayoutManager:forNominallySpacedGlyphRange:packedGlyphs:count:

Returns the interglyph spacing in the specified range when sent to a printer.

```
+ (NSSize)printingAdjustmentInLayoutManager:(NSLayoutManager *)layoutMgr
    forNominallySpacedGlyphRange:(NSRange)nominallySpacedGlyphsRange
    packedGlyphs:(const unsigned char *)packedGlyphs
    count:(NSUInteger)packedGlyphsCount
```

Parameters

layoutMgr
The layout manager that will do the drawing.

nominallySpacedGlyphsRange
The range of the glyphs whose spacing is desired.

packedGlyphs
The glyphs as they are packed for sending to be drawn in *layoutMgr*.

packedGlyphsCount
The number of glyphs in *packedGlyphs*.

Return Value
The interglyph spacing in the specified range when sent to a printer. If the font metrics of the font used for displaying text on the screen is different from the font metrics of the font used in printing, then this interglyph spacing may need to be adjusted slightly to match that used on the screen.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSTypesetter.h

sharedSystemTypesetter

Returns a shared instance of a reentrant typesetter.

```
+ (id)sharedSystemTypesetter
```

Return Value
The shared system typesetter. This typesetter is reentrant.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSTypesetter.h

sharedSystemTypesetterForBehavior:

Returns a shared instance of a reentrant typesetter that implements typesetting with the specified behavior.

```
+ (id)sharedSystemTypesetterForBehavior:(NSTypesetterBehavior)theBehavior
```

Parameters
theBehavior
The desired behavior.

Return Value
A shared instance of a reentrant typesetter that implements typesetting with the specified behavior.

Discussion
Possible return values are described in the `NSTypesetterBehavior` (page 1527) section for `NSLayoutManager`.

Availability
Available in Mac OS X v10.2 and later.

See Also
- `setTypesetterBehavior:` (page 3104)
- `typesetterBehavior` (page 3108)

Declared In
NSTypesetter.h

Instance Methods

actionForControlCharacterAtIndex:

Returns the action associated with a control character.

```
- (NSTypesetterControlCharacterAction)actionForControlCharacterAtIndex:(NSUInteger)charIndex
```

Parameters

charIndex
The index of the control character.

Return Value
The action associated with the control character at *charIndex*.

Availability
Available in Mac OS X v10.4 and later.

Declared In
NSTypesetter.h

attributedString

Returns the text backing store, usually an instance of NSTextStorage.

```
- (NSAttributedString *)attributedString
```

Return Value
The text backing store.

Availability
Available in Mac OS X v10.4 and later.

See Also
- setAttributedString: (page 3099)

Declared In
NSTypesetter.h

attributesForExtraLineFragment

Returns the attributes used to lay out the extra line fragment.

```
- (NSDictionary *)attributesForExtraLineFragment
```

Return Value
A dictionary of attributes used to lay out the extra line fragment.

Discussion
The default implementation tries to use the NSTextView method typingAttributes (page 2963) if possible; otherwise, it uses the attributes for the last character.

Availability
Available in Mac OS X v10.4 and later.

Declared In
NSTypesetter.h

baselineOffsetInLayoutManager:glyphIndex:

Returns the distance from the bottom of the bounding box of a specified glyph to its baseline.

```
- (CGFloat)baselineOffsetInLayoutManager:(NSLayoutManager *)layoutMgr
    glyphIndex:(NSUInteger)glyphIndex
```

Parameters

layoutMgr
The layout manager used for the drawing.

glyphIndex
The index of the glyph in question.

Return Value
The distance from the bottom of the bounding box of the glyph in *layoutMgr* specified by *glyphIndex* to its baseline.

Discussion
The text system uses this value to calculate the vertical position of underlines.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSTypesetter.h

beginLineWithGlyphAtIndex:

Sets up layout parameters at the beginning of a line during typesetting.

```
- (void)beginLineWithGlyphAtIndex:(NSUInteger)glyphIndex
```

Parameters

glyphIndex
The index of the first glyph to be laid out in the line.

Discussion
Concrete subclass implementations of `layoutParagraphAtPoint:` (page 3094) should invoke this method at the beginning of each line.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- endLineWithGlyphRange:` (page 3088)

Declared In
NSTypesetter.h

beginParagraph

Sets up layout parameters at the beginning of a paragraph.

```
- (void)beginParagraph
```

Discussion
Concrete subclasses should invoke this method at the beginning of their `layoutParagraphAtPoint:` (page 3094) implementation.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- endParagraph` (page 3088)

Declared In
`NSTypesetter.h`

bidiProcessingEnabled

Returns whether bidirectional text processing is enabled.

```
- (BOOL)bidiProcessingEnabled
```

Return Value
`YES` if bidirectional text processing is enabled, `NO` otherwise.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- setBidiProcessingEnabled:` (page 3100)

Declared In
`NSTypesetter.h`

boundingBoxForControlGlyphAtIndex:forTextContainer:proposedLineFragment:glyphPosition:characterIndex:

Returns the bounding rectangle for the specified control glyph with the specified parameters.

```
- (NSRect)boundingBoxForControlGlyphAtIndex:(NSUInteger)glyphIndex
    forTextContainer:(NSTextContainer *)textContainer
    proposedLineFragment:(NSRect)proposedRect glyphPosition:(NSPoint)glyphPosition
     characterIndex:(NSUInteger)charIndex
```

Parameters

glyphIndex
The index of the control glyph in question.

textContainer
The text container to use to calculate the position.

proposedRect
The proposed line fragment rectangle.

glyphPosition
The position of the glyph in *textContainer*.

charIndex
The character index in *textContainer*.

Return Value
The bounding rectangle of the control glyph at *glyphIndex*, at the given *glyphPosition* and character index *charIndex*, in *textContainer*.

Discussion
The typesetter calls this method when it encounters a control glyph. The default behavior is to return zero width for control glyphs. A subclass can override this method to do something different, such as implement a way to display control characters.

`NSGlyphGenerator` can choose whether or not to map control characters to `NSControlGlyph`. Tab characters, for example, do not use this facility.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`NSTypesetter.h`

characterRangeForGlyphRange:actualGlyphRange:

Returns the range for the characters in the receiver's text store that are mapped to the specified glyphs.

```
- (NSRange)characterRangeForGlyphRange:(NSRange)glyphRange
    actualGlyphRange:(NSRangePointer)actualGlyphRange
```

Parameters

glyphRange
The range of glyphs.

actualGlyphRange
On return, the range of all glyphs mapped to the characters in the receiver's text store. May be `NULL`.

Return Value
The range for the characters in the receiver's text store that are mapped to the glyphs in *glyphRange*.

Discussion
A subclass can override this method to interact with custom glyph storage.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- glyphRangeForCharacterRange:actualCharacterRange:` (page 3091)

Declared In
`NSTypesetter.h`

currentParagraphStyle

Returns the paragraph style object for the text being typeset.

```
- (NSParagraphStyle *)currentParagraphStyle
```

Return Value
The paragraph style object for the text being typeset. This value is valid only while the typesetter is performing layout. More specifically, it's valid only when called inside `layoutGlyphsInLayoutManager:startingAtGlyphIndex:maxNumberOfLineFragments:nextGlyphIndex:` (page 3094).

Availability
Available in Mac OS X v10.4 and later.

Declared In
`NSTypesetter.h`

currentTextContainer

Returns the text container for the text being typeset.

```
- (NSTextContainer *)currentTextContainer
```

Return Value
The text container for the text being typeset. This value is valid only while the typesetter is performing layout. More specifically, it's valid only when called inside `layoutGlyphsInLayoutManager:startingAtGlyphIndex:maxNumberOfLineFragments:nextGlyphIndex:` (page 3094).

Availability
Available in Mac OS X v10.4 and later.

See Also
`- textContainers` (page 3107)

Declared In
`NSTypesetter.h`

deleteGlyphsInRange:

Deletes the specified glyphs from the glyph cache maintained by the layout manager.

```
- (void)deleteGlyphsInRange:(NSRange)glyphRange
```

Parameters
glyphRange
The range of glyphs to be deleted.

Discussion
A subclass can override this method to interact with custom glyph storage.

Availability
Available in Mac OS X v10.4 and later.

See Also
`insertGlyph:atGlyphIndex:characterIndex:` (page 3092)

Declared In
`NSTypesetter.h`

endLineWithGlyphRange:

Sets up layout parameters at the end of a line during typesetting.

```
- (void)endLineWithGlyphRange:(NSRange)lineGlyphRange
```

Parameters

lineGlyphRange
The range of glyphs laid out in the line.

Discussion
Concrete subclass implementations of `layoutParagraphAtPoint:` (page 3094) should invoke this method at the end of each line.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- beginLineWithGlyphAtIndex:` (page 3084)

Declared In
`NSTypesetter.h`

endParagraph

Sets up layout parameters at the end of a paragraph.

```
- (void)endParagraph
```

Discussion
Concrete subclasses should invoke this method at the end of their `layoutParagraphAtPoint:` (page 3094) implementation.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- beginParagraph` (page 3085)

Declared In
`NSTypesetter.h`

getGlyphsInRange:glyphs:characterIndexes:glyphInscriptions:elasticBits:bidiLevels:

Extracts the information needed to lay out the provided glyphs from the provided range.

```
- (NSUInteger)getGlyphsInRange:(NSRange)glyphsRange glyphs:(NSGlyph *)glyphBuffer
    characterIndexes:(NSUInteger *)charIndexBuffer
   glyphInscriptions:(NSGlyphInscription *)inscribeBuffer elasticBits:(BOOL
   *)elasticBuffer bidiLevels:(unsigned char *)bidiLevelBuffer
```

Parameters

glyphsRange

The range of glyphs.

glyphBuffer

The glyphs to lay out.

charIndexBuffer

The original characters for the glyphs. Note that a glyph at index 1 is not necessarily mapped to the character at index 1, because a glyph may be for a ligature or accent.

inscribeBuffer

The inscription attributes for each glyph, which are used to layout characters that are combined together.

elasticBuffer

Contains a Boolean value indicating whether a glyph is elastic for each glyph. An elastic glyph can be made longer at the end of a line or when needed for justification.

bidiLevelBuffer

Contains the bidirectional level value generated by `NSGlyphGenerator`, in case a subclass chooses to use this value.

Discussion

A subclass can override this method to interact with custom glyph storage.

Availability

Available in Mac OS X v10.4 and later.

Declared In

`NSTypesetter.h`

getLineFragmentRect:usedRect:forParagraphSeparatorGlyphRange:atProposedOrigin:

Calculates the line fragment rectangle and line fragment used rectangle for blank lines.

```
- (void)getLineFragmentRect:(NSRectPointer)lineFragmentRect
    usedRect:(NSRectPointer)lineFragmentUsedRect
    forParagraphSeparatorGlyphRange:(NSRange)paragraphSeparatorGlyphRange
    atProposedOrigin:(NSPoint)lineOrigin
```

Parameters

lineFragmentRect

On return, the calculated line fragment rectangle.

lineFragmentUsedRect

On return, the used rectangle (the portion of the line fragment rectangle that actually contains marks).

paragraphSeparatorGlyphRange

The range of glyphs under consideration. A *paragraphSeparatorGlyphRange* with length 0 indicates an extra line fragment (which occurs if the last character in the paragraph is a line separator).

lineOrigin
The origin point of the line fragment rectangle.

Availability
Available in Mac OS X v10.4 and later.

Declared In
NSTypesetter.h

getLineFragmentRect:usedRect:remainingRect:forStartingGlyphAtIndex:proposedRect:lineSpacing:paragraphSpacingBefore:paragraphSpacingAfter:

Calculates line fragment rectangle, line fragment used rectangle, and remaining rectangle for a line fragment.

```
- (void)getLineFragmentRect:(NSRectPointer)lineFragmentRect
    usedRect:(NSRectPointer)lineFragmentUsedRect
    remainingRect:(NSRectPointer)remainingRect
    forStartingGlyphAtIndex:(NSUInteger)startingGlyphIndex
    proposedRect:(NSRect)proposedRect lineSpacing:(CGFloat)lineSpacing
    paragraphSpacingBefore:(CGFloat)paragraphSpacingBefore
    paragraphSpacingAfter:(CGFloat)paragraphSpacingAfter
```

Parameters

lineFragmentRect
On return, the calculated line fragment rectangle.

lineFragmentUsedRect
On return, the used rectangle (the portion of the line fragment rectangle that actually contains marks).

remainingRect
On return, the remaining rectangle of *proposedRect*.

startingGlyphIndex
The glyph index where the line fragment starts.

proposedRect
The proposed rectangle of the line fragment.

lineSpacing
The line spacing.

paragraphSpacingBefore
The spacing before the paragraph.

paragraphSpacingAfter
The spacing after the paragraph.

Discussion
The height of the line fragment is determined using *lineSpacing*, *paragraphSpacingBefore*, and *paragraphSpacingAfter* as well as *proposedRect*. The width for *lineFragmentUsedRect* is set to the *lineFragmentRect* width. In the standard implementation, paragraph spacing is included in the line fragment rectangle but not the line fragment used rectangle; line spacing is included in both.

Availability
Available in Mac OS X v10.4 and later.

Declared In
NSTypesetter.h

glyphRangeForCharacterRange:actualCharacterRange:

Returns the range for the glyphs mapped to the characters of the text store in the specified range.

```
- (NSRange)glyphRangeForCharacterRange:(NSRange)charRange
    actualCharacterRange:(NSRangePointer)actualCharRange
```

Parameters

charRange

The range of the characters whose glyph range is desired.

actualCharRange

On return, all characters mapped to those glyphs; may be `NULL`.

Return Value
The range for the glyphs mapped to the characters of the text store in *charRange*.

Discussion
A subclass can override this method to interact with custom glyph storage.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `characterRangeForGlyphRange:actualGlyphRange:` (page 3086)

Declared In
`NSTypesetter.h`

hyphenationFactor

Returns the current hyphenation factor.

```
- (float)hyphenationFactor
```

Return Value
The hyphenation factor, a value ranging from 0.0 to 1.0 that controls when hyphenation is attempted. By default, the value is 0.0, meaning hyphenation is off. A factor of 1.0 causes hyphenation to be attempted always.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `setHyphenationFactor:` (page 3101)

Declared In
`NSTypesetter.h`

hyphenationFactorForGlyphAtIndex:

Returns the hyphenation factor in effect at a specified location.

```
- (float)hyphenationFactorForGlyphAtIndex:(NSUInteger)glyphIndex
```

Parameters

glyphIndex

The index of the glyph position to examine.

Return Value

The hyphenation factor in effect at *glyphIndex*. The hyphenation factor is a value ranging from 0.0 to 1.0 that controls when hyphenation is attempted. By default, the value is 0.0, meaning hyphenation is off. A factor of 1.0 causes hyphenation to be attempted always.

Discussion

The typesetter calls this method with a proposed hyphenation point for a line break to find the hyphenation factor in effect at that time. A subclass can override this method to customize the text layout process.

Availability

Available in Mac OS X v10.4 and later.

See Also

- hyphenCharacterForGlyphAtIndex: (page 3092)

Declared In

NSTypesetter.h

hyphenCharacterForGlyphAtIndex:

Returns the hyphen character to be inserted after the specified glyph.

```
- (UTF32Char)hyphenCharacterForGlyphAtIndex:(NSUInteger)glyphIndex
```

Parameters

glyphIndex

The index of the glyph in question.

Return Value

The hyphen character to be inserted after the glyph at *glyphIndex*.

Discussion

The typesetter calls this method before hyphenating. A subclass can override this method to return a different hyphen glyph.

Availability

Available in Mac OS X v10.4 and later.

See Also

- hyphenationFactorForGlyphAtIndex: (page 3091)

Declared In

NSTypesetter.h

insertGlyph:atGlyphIndex:characterIndex:

Enables the typesetter to insert a new glyph into the stream.

```
- (void)insertGlyph:(NSGlyph)glyph atGlyphIndex:(NSUInteger)glyphIndex
    characterIndex:(NSUInteger)charIndex
```

Parameters

glyph

The glyph to insert into the glyph cache.

glyphIndex

The index at which to insert *glyph*.

charIndex

The index of the character that *glyph* maps to. If the glyph is mapped to several characters, *charIndex* should indicate the first character to which it's mapped.

Discussion

The standard typesetter uses this method for inserting hyphenation glyphs. Because this method keeps the glyph caches synchronized, subclasses should always use this method to insert glyphs instead of calling `layoutManager` (page 3094) directly.

A subclass can override this method to interact with custom glyph storage.

Availability

Available in Mac OS X v10.4 and later.

Declared In

`NSTypesetter.h`

layoutCharactersInRange:forLayoutManager:maximumNumberOfLineFragments:

Lays out characters in the given character range for the specified layout manager.

```
- (NSRange)layoutCharactersInRange:(NSRange)characterRange
    forLayoutManager:(NSLayoutManager *)layoutManager
    maximumNumberOfLineFragments:(NSUInteger)maxNumLines
```

Parameters

characterRange

The range of the characters to lay out.

layoutManager

The layout manager that does the drawing.

maxNumLines

The maximum number of line fragments to lay out. Specify `NSUIntegerMax` for unlimited number of line fragments.

Return Value

The method returns the actual character range that the receiving `NSTypesetter` processed.

Discussion

The layout process can be interrupted when the number of line fragments exceeds *maxNumLines*.

Availability

Available in Mac OS X v10.5 and later.

Declared In

`NSTypesetter.h`

layoutGlyphsInLayoutManager:startingAtGlyphIndex:maxNumberOfLineFragments:nextGlyphIndex:

Lays out glyphs in the specified layout manager starting at a specified glyph.

```
- (void)layoutGlyphsInLayoutManager:(NSLayoutManager *)layoutMgr
    startingAtGlyphIndex:(NSUInteger)startGlyphIndex
    maxNumberOfLineFragments:(NSUInteger)maxNumLines nextGlyphIndex:(NSUInteger
    *)nextGlyph
```

Parameters

layoutMgr

The layout manager in which to lay out glyphs.

startGlyphIndex

The index of the starting glyph.

maxNumLines

The maximum number of lines to generate. Fewer lines may be laid out if the glyph storage runs out of glyphs.

nextGlyph

On return, set to the index of the next glyph that needs to be laid out.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSTypesetter.h

layoutManager

Returns the layout manager for the text being typeset.

```
- (NSLayoutManager *)layoutManager
```

Return Value
The layout manager for the text being typeset. This value is valid only while the typesetter is performing layout. More specifically, it's valid only when called inside `layoutGlyphsInLayoutManager:startingAtGlyphIndex:maxNumberOfLineFragments:nextGlyphIndex:` (page 3094).

Availability
Available in Mac OS X v10.4 and later.

Declared In
NSTypesetter.h

layoutParagraphAtPoint:

Lays out glyphs in the current glyph range until the next paragraph separator is reached.

```
- (NSUInteger)layoutParagraphAtPoint:(NSPointPointer)lineFragmentOrigin
```

Parameters

lineFragmentOrigin

The upper-left corner of line fragment rectangle. On return, *lineFragmentOrigin* contains the next origin.

Return Value

The next glyph index; usually the index right after the paragraph separator, but it can be inside the paragraph range if, for example, the end of the text container is reached before the paragraph separator.

Discussion

Concrete subclasses must implement this method. A concrete implementation must invoke `beginParagraph` (page 3085), `beginLineWithGlyphAtIndex:` (page 3084), `endLineWithGlyphRange:` (page 3088), and `endParagraph` (page 3088).

Availability

Available in Mac OS X v10.4 and later.

Declared In

`NSTypesetter.h`

lineFragmentPadding

Returns the current line fragment padding, in points.

```
- (CGFloat)lineFragmentPadding
```

Return Value

The current line fragment padding, in points; that is, the portion on each end of the line fragment rectangle left blank.

Discussion

Text is inset within the line fragment rectangle by this amount.

Availability

Available in Mac OS X v10.4 and later.

See Also

`- setLineFragmentPadding:` (page 3102)

Declared In

`NSTypesetter.h`

lineSpacingAfterGlyphAtIndex:withProposedLineFragmentRect:

Returns the line spacing in effect following the specified glyph.

```
- (CGFloat)lineSpacingAfterGlyphAtIndex:(NSUInteger)glyphIndex
    withProposedLineFragmentRect:(NSRect)rect
```

Parameters

glyphIndex

The index of the glyph in question.

rect
The proposed line fragment rectangle.

Return Value
the line spacing in effect following the glyph at *glyphIndex*.

Discussion
The `NSATSTypesetter` calls this method to determine the number of points of space to include below the descenders in the used rectangle for the proposed line fragment rectangle *rect*.

Line spacing, also called leading, is an attribute of `NSParagraphStyle`, which you can set on an `NSMutableParagraphStyle` object. A font typically includes a default minimum line spacing metric used if none is set in the paragraph style.

If the typesetter behavior specified in the layout manager is `NSTypesetterOriginalBehavior`, the text system uses the original, private typesetter `NSSimpleHorizontalTypesetter`, which adds the line spacing above the ascender. Similarly, `NSATSTypesetter` adds the line spacing above the ascender if the value is negative.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`NSTypesetter.h`

paragraphCharacterRange

Returns the character range currently being processed.

```
- (NSRange)paragraphCharacterRange
```

Return Value
The character range currently being processed.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `paragraphSeparatorCharacterRange` (page 3097)
- `paragraphSeparatorGlyphRange` (page 3097)
- `paragraphGlyphRange` (page 3096)

Declared In
`NSTypesetter.h`

paragraphGlyphRange

Returns the glyph range currently being processed.

```
- (NSRange)paragraphGlyphRange
```

Return Value
The glyph range currently being processed.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `setParagraphGlyphRange:separatorGlyphRange:` (page 3104)
- `paragraphSeparatorGlyphRange` (page 3097)
- `paragraphCharacterRange` (page 3096)
- `paragraphSeparatorCharacterRange` (page 3097)

Declared In
`NSTypesetter.h`

paragraphSeparatorCharacterRange

Returns the current paragraph separator character range.

```
- (NSRange)paragraphSeparatorCharacterRange
```

Return Value
The current paragraph separator character range, which is the full range that contains the current character range and that extends from one paragraph separator character to the next.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `paragraphGlyphRange` (page 3096)
- `paragraphSeparatorGlyphRange` (page 3097)
- `paragraphCharacterRange` (page 3096)

Declared In
`NSTypesetter.h`

paragraphSeparatorGlyphRange

Returns the current paragraph separator range.

```
- (NSRange)paragraphSeparatorGlyphRange
```

Return Value
The current paragraph separator range, which is the full range that contains the current glyph range and that extends from one paragraph separator character to the next.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `setParagraphGlyphRange:separatorGlyphRange:` (page 3104)
- `paragraphGlyphRange` (page 3096)
- `paragraphSeparatorCharacterRange` (page 3097)
- `paragraphCharacterRange` (page 3096)

Declared In
NSTypesetter.h

paragraphSpacingAfterGlyphAtIndex:withProposedLineFragmentRect:

Returns the paragraph spacing that is in effect after the specified glyph.

```
- (CGFloat)paragraphSpacingAfterGlyphAtIndex:(NSUInteger)glyphIndex
    withProposedLineFragmentRect:(NSRect)rect
```

Parameters

glyphIndex
The index of the glyph in question.

rect
The line fragment rectangle of the last line in the paragraph.

Return Value
The paragraph spacing—that is, the number of points of space added following a paragraph—that is in effect after the glyph specified by *glyphIndex*.

Discussion
The typesetter adds the number of points specified in the return value to the bottom of the line fragment rectangle specified by *rect* (but not to the used line fragment rectangle for that line). Paragraph spacing added after a paragraph correlates to the value returned by the `paragraphSpacing` (page 1875) method of `NSParagraphStyle`, which you can set using the `setParagraphSpacing:` (page 1723) method of `NSMutableParagraphStyle`.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `paragraphSpacingBeforeGlyphAtIndex:withProposedLineFragmentRect:` (page 3098)

Declared In
NSTypesetter.h

paragraphSpacingBeforeGlyphAtIndex:withProposedLineFragmentRect:

Returns the number of points of space—added before a paragraph—that is in effect before the specified glyph.

```
- (CGFloat)paragraphSpacingBeforeGlyphAtIndex:(NSUInteger)glyphIndex
    withProposedLineFragmentRect:(NSRect)rect
```

Parameters

glyphIndex
The index of the glyph in question.

rect
The line fragment rectangle of the first line in the paragraph.

Return Value
The number of points of space—added before a paragraph—that is in effect before the glyph specified by *glyphIndex*.

Discussion
The typesetter adds the number of points specified in the return value to the top of the line fragment rectangle specified by *rect* (but not to the used line fragment rectangle for that line). Paragraph spacing added before a paragraph correlates to the value returned by the `paragraphSpacingBefore` (page 1876) method of `NSParagraphStyle`, which you can set using the `setParagraphSpacingBefore:` (page 1724) method of `NSMutableParagraphStyle`.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- paragraphSpacingAfterGlyphAtIndex:withProposedLineFragmentRect:` (page 3098)

Declared In
`NSTypesetter.h`

setAttachmentSize:forGlyphRange:

Sets the size the specified glyphs (assumed to be attachments) will be asked to draw themselves at.

```
- (void)setAttachmentSize:(NSSize)attachmentSize forGlyphRange:(NSRange)glyphRange
```

Parameters

attachmentSize
The size the glyphs in *glyphRange* (assumed to be attachments) will be asked to draw themselves at.

glyphRange
The range of glyphs the attachment size applies to.

Discussion
A subclass can override this method to interact with custom glyph storage.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`NSTypesetter.h`

setAttributedString:

Sets the text backing store on which this typesetter operates.

```
- (void)setAttributedString:(NSAttributedString *)attrString
```

Parameters

attrString
The text backing store on which the typesetter should operate.

Special Considerations

Typesetters do not retain the text backing store on which they are operating.

Availability
Available in Mac OS X v10.4 and later.

See Also
- attributedString (page 3083)

Declared In
NSTypesetter.h

setBidiLevels:forGlyphRange:

Sets the direction of the specified glyphs for bidirectional text.

```
- (void)setBidiLevels:(const uint8_t *)levels forGlyphRange:(NSRange)glyphRange
```

Parameters

levels

Values in *levels* can range from 0 to 61 as defined by Unicode Standard Annex #9.

glyphRange

The range of glyphs for which the bidirectional text levels are desired.

Discussion
A subclass can override this method to interact with custom glyph storage.

Availability
Available in Mac OS X v10.4 and later.

Declared In
NSTypesetter.h

setBidiProcessingEnabled:

Controls whether the typesetter performs bidirectional text processing.

```
- (void)setBidiProcessingEnabled:(BOOL)flag
```

Parameters

flag

YES to enable bidirectional text processing, NO to disable it.

Discussion
You can use this method to disable the bidirectional layout stage if you know the paragraph does not need this stage; that is, if the characters in the backing store are in display order.

Availability
Available in Mac OS X v10.4 and later.

See Also
- bidiProcessingEnabled (page 3085)

Declared In
NSTypesetter.h

setDrawsOutsideLineFragment:forGlyphRange:

Sets whether the specified glyphs exceed the bounds of the line fragment in which they are laid out.

```
- (void)setDrawsOutsideLineFragment:(BOOL)flag forGlyphRange:(NSRange)glyphRange
```

Parameters

flag

YES if the glyphs in *glyphRange* exceed the bounds of the line fragment in which they are laid out, NO otherwise.

glyphRange

The range of the glyphs in question.

Discussion

This can happen when text is set at a fixed line height. For example, if the user specifies a fixed line height of 12 points and sets the font size to 24 points, the glyphs will exceed their layout rectangles.

A subclass can override this method to interact with custom glyph storage.

Availability

Available in Mac OS X v10.4 and later.

Declared In

NSTypesetter.h

setHardInvalidation:forGlyphRange:

Sets whether to force the layout manager to invalidate the specified portion of the glyph cache when invalidating layout.

```
- (void)setHardInvalidation:(BOOL)flag forGlyphRange:(NSRange)glyphRange
```

Parameters

flag

YES if the layout manager should invalidate the specified portion of the glyph cache, NO otherwise.

glyphRange

The range of glyphs in the cache to be marked for hard invalidation.

Availability

Available in Mac OS X v10.4 and later.

Declared In

NSTypesetter.h

setHyphenationFactor:

Sets the threshold controlling when hyphenation is attempted.

```
- (void)setHyphenationFactor:(float)factor
```

Parameters

factor

A frequency factor in the range of 0.0 to 1.0. By default, the value is 0.0, meaning hyphenation is off. A *factor* of 1.0 causes hyphenation to be attempted always.

Availability
Available in Mac OS X v10.4 and later.

See Also
- hyphenationFactor (page 3091)

Declared In
NSTypesetter.h

setLineFragmentPadding:

Sets the amount (in points) by which text is inset within line fragment rectangles.

```
- (void)setLineFragmentPadding:(CGFloat)padding
```

Parameters

padding

The amount (in points) by which text is inset within line fragment rectangles.

Special Considerations

Line fragment padding isn't a suitable means for expressing margins; you should set the text view's position and size for document margins or the paragraph margin attributes for text margins.

Availability
Available in Mac OS X v10.4 and later.

See Also
- lineFragmentPadding (page 3095)

Declared In
NSTypesetter.h

setLineFragmentRect:forGlyphRange:usedRect:baselineOffset:

Sets the line fragment rectangle where the specified glyphs are laid out.

```
- (void)setLineFragmentRect:(NSRect)fragmentRect forGlyphRange:(NSRange)glyphRange
    usedRect:(NSRect)usedRect baselineOffset:(CGFloat)baselineOffset
```

Parameters

fragmentRect

The line fragment rectangle where the glyphs in *glyphRange* are laid out.

glyphRange

The range of the specified glyphs.

usedRect
The portion of *fragmentRect*, in the NSTextContainer object's coordinate system, that actually contains glyphs or other marks that are drawn (including the text container's line fragment padding). The *usedRect* must be equal to or contained within *fragmentRect*.

baselineOffset
The vertical distance in pixels from the line fragment origin to the baseline on which the glyphs align.

Discussion
The exact positions of the glyphs must be set after the line fragment rectangle with `setLocation:forStartOfGlyphRange:`.

A subclass can override this method to interact with custom glyph storage.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`NSTypesetter.h`

setLocation:withAdvancements:forStartOfGlyphRange:

Sets the location where the specified glyphs are laid out.

```
- (void)setLocation:(NSPoint)location withAdvancements:(const CGFloat *)advancements
    forStartOfGlyphRange:(NSRange)glyphRange
```

Parameters
location
The location where the glyphs in *glyphRange* are laid out. The x-coordinate of *location* is expressed relative to the line fragment rectangle origin, and the y-coordinate is expressed relative to the baseline previously specified by `setLineFragmentRect:forGlyphRange:usedRect:baselineOffset:` (page 3102).

advancements
The nominal glyph advance width specified in the font metric information.

glyphRange
The range of glyphs whose layout location is being set. This series of glyphs can be displayed with a single PostScript `show` operation (a nominal range).

Discussion
Setting the location for a series of glyphs implies that the glyphs preceding it can't be included in a single `show` operation.

Before setting the location for a glyph range, you must specify line fragment rectangle with `setLineFragmentRect:forGlyphRange:usedRect:baselineOffset:`.

A subclass can override this method to interact with custom glyph storage.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`NSTypesetter.h`

setNotShownAttribute:forGlyphRange:

Sets whether the specified glyphs are not shown.

```
- (void)setNotShownAttribute:(BOOL)flag forGlyphRange:(NSRange)glyphRange
```

Parameters

flag

YES if the glyphs in *glyphRange* are not shown, NO if they are shown.

glyphRange

The range of glyphs in question.

Discussion

For example, a tab or newline character doesn't leave any marks; it just indicates where following glyphs are laid out.

A subclass can override this method to interact with custom glyph storage.

Availability

Available in Mac OS X v10.4 and later.

Declared In

NSTypesetter.h

setParagraphGlyphRange:separatorGlyphRange:

Sets the current glyph range being processed.

```
- (void)setParagraphGlyphRange:(NSRange)paragraphRange
    separatorGlyphRange:(NSRange)paragraphSeparatorRange
```

Parameters

paragraphRange

The current glyph range being processed.

paragraphSeparatorRange

The range of the paragraph separator character or characters.

Availability

Available in Mac OS X v10.4 and later.

See Also

- paragraphGlyphRange (page 3096)
- paragraphSeparatorGlyphRange (page 3097)

Declared In

NSTypesetter.h

setTypesetterBehavior:

Sets the default typesetter behavior, which affects glyph spacing and line height.

```
- (void)setTypesetterBehavior:(NSTypesetterBehavior)behavior
```

Parameters

behavior

The new behavior.

Availability
Available in Mac OS X v10.4 and later.

See Also
- typesetterBehavior (page 3108)

Declared In
NSTypesetter.h

setUsesFontLeading:

Sets whether the typesetter uses the leading (or line gap) value specified in the font metric information.

```
- (void)setUsesFontLeading:(BOOL)flag
```

Parameters

flag

YES to use the information in the font metrics, NO to ignore it.

Availability
Available in Mac OS X v10.4 and later.

See Also
- usesFontLeading (page 3108)

Declared In
NSTypesetter.h

shouldBreakLineByHyphenatingBeforeCharacterAtIndex:

Returns whether the line being laid out should be broken by hyphenating at the specified character.

```
- (BOOL)shouldBreakLineByHyphenatingBeforeCharacterAtIndex:(NSUInteger)charIndex
```

Parameters

charIndex

The index of the character just after the proposed hyphenation would occur.

Return Value
YES if the line should be broken by hyphenating, NO otherwise.

Discussion
The typesetter calls this method, if implemented by a subclass, before breaking a line by hyphenating before the character at *charIndex*, enabling the subclass to control line breaking.

A subclass can override this method to customize the text layout process. If the method returns NO, the typesetter continues looking for a break point.

Availability
Available in Mac OS X v10.4 and later.

See Also
- shouldBreakLineByWordBeforeCharacterAtIndex: (page 3106)

Declared In
NSTypesetter.h

shouldBreakLineByWordBeforeCharacterAtIndex:

Returns whether the line being laid out should be broken by a word break at the specified character.

```
- (BOOL)shouldBreakLineByWordBeforeCharacterAtIndex:(NSUInteger)charIndex
```

Parameters
charIndex
The index of the character just after the proposed word break would occur.

Return Value
YES if the line should be broken by a word break, NO otherwise.

Discussion
The typesetter calls this method, if implemented by a subclass, before breaking a line by word wrapping before the character at *charIndex*, enabling the subclass to control line breaking.

A subclass can override this method to customize the text layout process. If the method returns NO, the typesetter continues looking for a break point.

Availability
Available in Mac OS X v10.4 and later.

See Also
- shouldBreakLineByHyphenatingBeforeCharacterAtIndex: (page 3105)

Declared In
NSTypesetter.h

substituteFontForFont:

Returns a screen font suitable for use in place of a given font.

```
- (NSFont *)substituteFontForFont:(NSFont *)originalFont
```

Parameters
originalFont
The original font.

Return Value
A screen font suitable for use in place of *originalFont*. This method returns *originalFont* if a screen font can't be used or isn't available.

Discussion
A screen font can only be substituted if the receiver is set to use screen fonts and if no text view associated with the receiver is scaled or rotated.

Availability
Available in Mac OS X v10.4 and later.

Declared In
NSTypesetter.h

substituteGlyphsInRange:withGlyphs:

Replaces the specified glyphs with specified replacement glyphs.

```
- (void)substituteGlyphsInRange:(NSRange)glyphRange withGlyphs:(NSGlyph *)glyphs
```

Parameters

glyphRange
The range of glyphs to be substituted.

glyphs
The glyphs to substitute for the glyphs in `glyphRange`.

Discussion
This method does not alter the glyph-to-character mapping or invalidate layout information.

A subclass can override this method to interact with custom glyph storage.

Availability
Available in Mac OS X v10.4 and later.

Declared In
NSTypesetter.h

textContainers

Returns an array containing the text containers belonging to the current layout manager.

```
- (NSArray *)textContainers
```

Return Value
An array containing the text containers belonging to the current layout manager. This value is valid only while the typesetter is performing layout. More specifically, it's valid only when called inside `layoutGlyphsInLayoutManager:startingAtGlyphIndex:maxNumberOfLineFragments:nextGlyphIndex:` (page 3094).

Availability
Available in Mac OS X v10.4 and later.

See Also
- `layoutManager` (page 3094)
- `currentTextContainer` (page 3087)

Declared In
NSTypesetter.h

textTabForGlyphLocation:writingDirection:maxLocation:

Returns the text tab next closest to a given glyph location within the given parameters.

```
- (NSTextTab *)textTabForGlyphLocation:(CGFloat)glyphLocation
    writingDirection:(NSWritingDirection)direction maxLocation:(CGFloat)maxLocation
```

Parameters

glyphLocation

The location at which to start searching.

direction

The direction in which to search.

maxLocation

The maximum location for the search.

Return Value

The text tab next closest to *glyphLocation*, indexing in *direction* but not beyond *maxLocation*.

Discussion

The typesetter calls this method whenever it finds a tab character. To determine the width to advance the next glyph, the typesetter examines the `NSParagraphStyle` object's tab array and the default tab interval.

Availability

Available in Mac OS X v10.4 and later.

Declared In

`NSTypesetter.h`

typesetterBehavior

Returns the current typesetter behavior.

```
- (NSTypesetterBehavior)typesetterBehavior
```

Return Value

The current typesetter behavior.

Availability

Available in Mac OS X v10.4 and later.

See Also

`- setTypesetterBehavior:` (page 3104)

Declared In

`NSTypesetter.h`

usesFontLeading

Returns whether the typesetter uses the leading (or line gap) value specified in the font metric information of the current font.

```
- (BOOL)usesFontLeading
```

Return Value
`YES` if it uses the information in the font metrics, `NO` otherwise.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- setUsesFontLeading:` (page 3105)

Declared In
`NSTypesetter.h`

willSetLineFragmentRect:forGlyphRange:usedRect:baselineOffset:

Called by the typesetter just prior to storing the actual line fragment rectangle location in the layout manager.

```
- (void)willSetLineFragmentRect:(NSRectPointer)lineRect
    forGlyphRange:(NSRange)glyphRange usedRect:(NSRectPointer)usedRect
    baselineOffset:(CGFloat *)baselineOffset
```

Parameters

lineRect
The rectangle in which the glyphs in *glyphRange* are laid out.

glyphRange
The range of the glyphs to lay out.

usedRect
The portion of *lineRect*, in the NSTextContainer object's coordinate system, that actually contains glyphs or other marks that are drawn (including the text container's line fragment padding). The *usedRect* must be equal to or contained within *lineRect*.

baselineOffset
The vertical distance in pixels from the line fragment origin to the baseline on which the glyphs align.

Discussion
Called by the typesetter just prior to calling `setLineFragmentRect:forGlyphRange:usedRect:baselineOffset:` (page 3102) which stores the actual line fragment rectangle location in the layout manager.

A subclass can override this method to customize the text layout process. For example, it could change the shape of the line fragment rectangle. The subclass is responsible for ensuring that the modified rectangle remains valid (for example, that it lies within the text container).

Availability
Available in Mac OS X v10.4 and later.

Declared In
`NSTypesetter.h`

Constants

NSTypesetterControlCharacterAction

The following constants are possible values returned by the `actionForControlCharacterAtIndex:` (page 3083) method to determine the action associated with a control character.

```
enum {
    NSTypesetterZeroAdvancementAction = (1 << 0),
    NSTypesetterWhitespaceAction = (1 << 1),
    NSTypesetterHorizontalTabAction = (1 << 2),
    NSTypesetterLineBreakAction = (1 << 3),
    NSTypesetterParagraphBreakAction = (1 << 4),
    NSTypesetterContainerBreakAction = (1 << 5)
};
typedef NSUInteger NSTypesetterControlCharacterAction;
```

Constants

`NSTypesetterZeroAdvancementAction`

Glyphs with this action are filtered out from layout `(notShownAttribute == YES)`.

Available in Mac OS X v10.4 and later.

Declared in `NSTypesetter.h`.

`NSTypesetterWhitespaceAction`

The width for glyphs with this action are determined by `boundingBoxForControlGlyphAtIndex:forTextContainer:proposedLineFragment:glyphPosition:characterIndex:` (page 3085), if the method is implemented; otherwise, same as `NSTypesetterZeroAdvancementAction`.

Available in Mac OS X v10.4 and later.

Declared in `NSTypesetter.h`.

`NSTypesetterHorizontalTabAction`

Treated as tab character.

Available in Mac OS X v10.4 and later.

Declared in `NSTypesetter.h`.

`NSTypesetterLineBreakAction`

Causes line break.

Available in Mac OS X v10.4 and later.

Declared in `NSTypesetter.h`.

`NSTypesetterParagraphBreakAction`

Causes paragraph break; the value returned by `firstLineHeadIndent` (page 1872) is the advancement used for the following glyph.

Available in Mac OS X v10.4 and later.

Declared in `NSTypesetter.h`.

`NSTypesetterContainerBreakAction`

Causes container break.

Available in Mac OS X v10.4 and later.

Declared in `NSTypesetter.h`.

NSURL Additions Reference

Inherits from	NSObject
Conforms to	NSObject (NSObject)
Framework	/System/Library/Frameworks/AppKit.framework
Declared in	AppKit/NSPasteboard.h

Overview

The Application Kit extends Foundation's NSURL class by adding support for pasteboards. NSWorkspace provides `openURL:` (page 3473) to open a location specified by a URL.

Tasks

Working with Pasteboards

`+ URLFromPasteboard:` (page 3111)
Reads an NSURL object off of *pasteboard*. Returns `nil` if *pasteboard* does not contain data of type `NSURLPboardType`.

`- writeToPasteboard:` (page 3112)
Writes the receiver to *pasteboard*. You must declare an `NSURLPboardType` data type for *pasteboard* before invoking this method; otherwise it returns without doing anything.

Class Methods

URLFromPasteboard:

Reads an NSURL object off of *pasteboard*. Returns `nil` if *pasteboard* does not contain data of type `NSURLPboardType`.

```
+ (NSURL *)URLFromPasteboard:(NSPasteboard *)pasteboard
```

Availability
Available in Mac OS X v10.0 and later.

Overview

NSUserDefaultsController is a Cocoa bindings compatible controller class. Properties of the shared instance of this class can be bound to user interface elements to access and modify values stored in NSUserDefaults.

Tasks

Obtaining the Shared Instance

`+ sharedUserDefaultsController` (page 3114)
Returns the shared instance of NSUserDefaultsController, creating it if necessary.

Initializing a User Defaults Controller

`- initWithDefaults:initialValues:` (page 3116)
Returns an initialized NSUserDefaultsController object using the NSUserDefaults instance specified in *defaults* and the initial default values contained in the *initialValues* dictionary.

Managing User Defaults Values

- `defaults` (page 3115)
  Returns the instance of NSUserDefaults in use by the receiver.
- `setInitialValues:` (page 3118)
  Sets the receiver's initial values to *initialValues*.
- `hasUnappliedChanges` (page 3115)
  Returns whether the receiver has user default values that have not been saved to NSUserDefaults.
- `initialValues` (page 3116)
  Returns a dictionary containing the receiver's initial default values.
- `setAppliesImmediately:` (page 3118)
  Sets whether any changes made to the receiver's user default properties are saved immediately.
- `appliesImmediately` (page 3115)
  Returns whether any changes made to bound user default properties are saved immediately.
- `values` (page 3119)
  Returns a key value coding compliant object that is used to access the user default properties.
- `revert:` (page 3117)
  Causes the receiver to discard any unsaved changes to bound user default properties, restoring their previous values.
- `revertToInitialValues:` (page 3117)
  Causes the receiver to discard all edits and replace the values of all the user default properties with any corresponding values in the `initialValues` (page 3116) dictionary.
- `save:` (page 3117)
  Saves the values of the receiver's user default properties.

Class Methods

sharedUserDefaultsController

Returns the shared instance of NSUserDefaultsController, creating it if necessary.

```
+ (id)sharedUserDefaultsController
```

Discussion
This instance has no initial values, and uses `[NSUserDefaults standardUserDefaults]` to create the defaults. An application can get this object when an application launches and configure it as required.

Availability
Available in Mac OS X v10.3 and later.

Related Sample Code
DemoMonkey
Dicey
ImageApp
Sketch+Accessibility

Declared In
NSUserDefaultsController.h

Instance Methods

appliesImmediately

Returns whether any changes made to bound user default properties are saved immediately.

```
- (BOOL)appliesImmediately
```

Discussion
Default is YES.

This property is observable using key-value observing.

Availability
Available in Mac OS X v10.3 and later.

See Also
- setAppliesImmediately: (page 3118)

Declared In
NSUserDefaultsController.h

defaults

Returns the instance of NSUserDefaults in use by the receiver.

```
- (NSUserDefaults *)defaults
```

Discussion
This property is observable using key-value observing.

Availability
Available in Mac OS X v10.3 and later.

Related Sample Code
ImageApp

Declared In
NSUserDefaultsController.h

hasUnappliedChanges

Returns whether the receiver has user default values that have not been saved to NSUserDefaults.

```
- (BOOL)hasUnappliedChanges
```

Discussion
This property is observable using key-value observing.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `appliesImmediately` (page 3115)
- `setAppliesImmediately:` (page 3118)

Declared In
`NSUserDefaultsController.h`

initialValues

Returns a dictionary containing the receiver's initial default values.

```
- (NSDictionary *)initialValues
```

Discussion
These values are used when is no value found for the bound property in `defaults` (page 3115).

This property is observable using key-value observing.

Availability
Available in Mac OS X v10.3 and later.

See Also
- `setInitialValues:` (page 3118)
- `revertToInitialValues:` (page 3117)

Declared In
`NSUserDefaultsController.h`

initWithDefaults:initialValues:

Returns an initialized NSUserDefaultsController object using the NSUserDefaults instance specified in *defaults* and the initial default values contained in the *initialValues* dictionary.

```
- (id)initWithDefaults:(NSUserDefaults *)defaults initialValues:(NSDictionary
    *)initialValues
```

Discussion
If *defaults* is `nil`, the receiver uses `[NSUserDefaults standardUserDefaults]`.

This method is the designated initializer.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`NSUserDefaultsController.h`

revert:

Causes the receiver to discard any unsaved changes to bound user default properties, restoring their previous values.

```
- (void)revert:(id)sender
```

Discussion
The receiver invokes `discardEditing` (page 3679) on any currently registered editors. The *sender* is typically the object that invoked this method.

If `appliesImmediately` (page 3115) is `YES`, this method only causes any bound editors with uncommitted changes to discard their edits.

Availability
Available in Mac OS X v10.3 and later.

See Also
- `revertToInitialValues:` (page 3117)

Declared In
`NSUserDefaultsController.h`

revertToInitialValues:

Causes the receiver to discard all edits and replace the values of all the user default properties with any corresponding values in the `initialValues` (page 3116) dictionary.

```
- (void)revertToInitialValues:(id)sender
```

Discussion
This effectively sets the preferences that a user can change to their "out-of-the-box" values. This method has no effect if initial values were not specified. The *sender* is typically the object that invoked this method.

Availability
Available in Mac OS X v10.3 and later.

See Also
- `initialValues` (page 3116)
- `revert:` (page 3117)

Declared In
`NSUserDefaultsController.h`

save:

Saves the values of the receiver's user default properties.

```
- (void)save:(id)sender
```

Discussion
This method has no effect if `appliesImmediately` (page 3115) returns `YES`.

Availability
Available in Mac OS X v10.3 and later.

Declared In
NSUserDefaultsController.h

setAppliesImmediately:

Sets whether any changes made to the receiver's user default properties are saved immediately.

```
- (void)setAppliesImmediately:(BOOL)flag
```

Discussion
The default is YES.

Availability
Available in Mac OS X v10.3 and later.

See Also
- appliesImmediately (page 3115)

Declared In
NSUserDefaultsController.h

setInitialValues:

Sets the receiver's initial values to *initialValues*.

```
- (void)setInitialValues:(NSDictionary *)initialValues
```

Discussion
These values are used when a user default properties has no value in NSUserDefaults and by revertToInitialValues: (page 3117).

The initial values must be set before loading a nib that uses the receiver, as those values may be referenced at load time. It is good practice to set the initial values–along with registering any defaults for the applications–in the initialize class method of your preference dialog controller, or the application delegate.

Availability
Available in Mac OS X v10.3 and later.

See Also
- defaults (page 3115)
- initialValues (page 3116)

Related Sample Code
DemoMonkey
Sketch+Accessibility

Declared In
NSUserDefaultsController.h

values

Returns a key value coding compliant object that is used to access the user default properties.

```
- (id)values
```

Discussion
If present the value for the property in `defaults` (page 3115) is returned, otherwise a corresponding value in `initialValues` (page 3116) is returned.

This property is observable using key-value observing.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`NSUserDefaultsController.h`

NSView Class Reference

Inherits from	NSResponder : NSObject

Related sample code	MatrixMixerTest Quartz Composer WWDC 2005 TextEdit QuickLookSketch Sketch+Accessibility Sketch-112

Class at a Glance

`NSView` is a class that defines the basic drawing, event-handling, and printing architecture of an application. You typically don't interact with the `NSView` API directly; rather, your custom view classes inherit from `NSView` and override many of its methods, which are invoked automatically by the Application Kit. If you're not creating a custom view class, there are few methods you need to use.

Principal Attributes

- Event handling
- Integrated display to screen and printer
- Flexible coordinate systems
- Icon dragging

Commonly Used Methods

`frame` (page 3175)
Returns the location and size of the `NSView` object.

`bounds` (page 3150)
Returns the internal origin and size of the `NSView` object.

`setNeedsDisplay:` (page 3225)
Marks the `NSView` object as needing to be redrawn

`window` (page 3248)
Returns the `NSWindow` object that contains the `NSView` object.

`drawRect:` (page 3170)
Draws the `NSView` object. (All subclasses must implement this method, but it's rarely invoked explicitly.)

Overview

The `NSView` class that provides a structure for drawing, printing, and handling events.

`NSView` objects (also know, simply, as view objects or views) are arranged within an `NSWindow` object, in a nested hierarchy of subviews. A view object claims a rectangular region of its enclosing superview, is responsible for all drawing within that region, and is eligible to receive mouse events occurring in it as well. In addition to these major responsibilities, `NSView` handles dragging of icons and works with the `NSScrollView` class to support efficient scrolling.

Most of the functionality of `NSView` either is automatically invoked by the Application Kit, or is available in Interface Builder. Unless you're implementing a concrete subclass of `NSView` or working intimately with the content of the view hierarchy at runtime, you don't need to know much about this class's interface. See "Commonly Used Methods" (page 3122) for methods you might use regardless.

For more information on how `NSView` instances handle event and action messages, see *Cocoa Event-Handling Guide*. For more information on displaying tooltips and contextual menus, see "Displaying Contextual Menus" (page 1605) and "Managing Tooltips" (page 3286).

Subclassing Notes

`NSView` is perhaps the most important class in the Application Kit when it comes to subclassing and inheritance. Most user-interface objects you see in a Cocoa application are objects that inherit from `NSView`. If you want to create an object that draws itself in a special way, or that responds to mouse clicks in a special way, you would create a custom subclass of `NSView` (or of a class that inherits from `NSView`). Subclassing `NSView` is such a common and important procedure that several technical documents describe how to both draw in custom subclasses and respond to events in custom subclasses. See *Cocoa Drawing Guide* and *Cocoa Event-Handling Guide* (especially ""Handling Mouse Events"" and ""Mouse Events" in *Cocoa Event-Handling Guide*").

Tasks

Creating Instances

- `initWithFrame:` (page 3179)
  Initializes and returns a newly allocated `NSView` object with a specified frame rectangle.

Managing the View Hierarchy

- `superview` (page 3235)
  Returns the receiver's superview, or `nil` if it has none.
- `setSubviews:` (page 3228)
  Sets the receiver's subviews to the specified subviews.
- `subviews` (page 3235)
  Return the receiver's immediate subviews.
- `window` (page 3248)
  Returns the receiver's window object, or `nil` if it has none.
- `addSubview:` (page 3139)
  Adds a view to the receiver's subviews so it's displayed above its siblings.
- `addSubview:positioned:relativeTo:` (page 3140)
  Inserts a view among the receiver's subviews so it's displayed immediately above or below another view.
- `didAddSubview:` (page 3163)
  Overridden by subclasses to perform additional actions when subviews are added to the receiver.
- `removeFromSuperview` (page 3202)
  Unlinks the receiver from its superview and its window, removes it from the responder chain, and invalidates its cursor rectangles.
- `removeFromSuperviewWithoutNeedingDisplay` (page 3203)
  Unlinks the receiver from its superview and its window and removes it from the responder chain, but does not invalidate its cursor rectangles to cause redrawing.
- `replaceSubview:with:` (page 3205)
  Replaces one of the receiver's subviews with another view.
- `isDescendantOf:` (page 3181)
  Returns `YES` if the receiver is a subview of a given view or if it's identical to that view; otherwise, it returns `NO`.
- `opaqueAncestor` (page 3193)
  Returns the receiver's closest opaque ancestor (including the receiver itself).
- `ancestorSharedWithView:` (page 3147)
  Returns the closest ancestor shared by the receiver and a given view.
- `sortSubviewsUsingFunction:context:` (page 3234)
  Orders the receiver's immediate subviews using the specified comparator function.
- `viewDidMoveToSuperview` (page 3241)
  Informs the receiver that its superview has changed (possibly to `nil`).

- `viewDidMoveToWindow` (page 3241)
  Informs the receiver that it has been added to a new view hierarchy.
- `viewWillMoveToSuperview:` (page 3243)
  Informs the receiver that its superview is about to change to the specified superview (which may be `nil`).
- `viewWillMoveToWindow:` (page 3243)
  Informs the receiver that it's being added to the view hierarchy of the specified window object (which may be `nil`).
- `willRemoveSubview:` (page 3247)
  Overridden by subclasses to perform additional actions before subviews are removed from the receiver.
- `enclosingMenuItem` (page 3172)
  Returns the menu item containing the receiver or any of its superviews in the view hierarchy.

Searching by Tag

- `viewWithTag:` (page 3245)
  Returns the receiver's nearest descendant (including itself) with a specific tag, or `nil` if no subview has that tag.
- `tag` (page 3236)
  Returns the receiver's tag, an integer that you can use to identify view objects in your application.

Modifying the Frame Rectangle

- `setFrame:` (page 3218)
  Sets the receiver's frame rectangle to the specified rectangle.
- `frame` (page 3175)
  Returns the receiver's frame rectangle, which defines its position in its superview.
- `setFrameOrigin:` (page 3220)
  Sets the origin of the receiver's frame rectangle to the specified point, effectively repositioning it within its superview.
- `setFrameSize:` (page 3221)
  Sets the size of the receiver's frame rectangle to the specified dimensions, resizing it within its superview without affecting its coordinate system.
- `setFrameRotation:` (page 3221)
  Sets the rotation of the receiver's frame rectangle to a specified degree value, rotating it within its superview without affecting its coordinate system.
- `frameRotation` (page 3176)
  Returns the angle, in degrees, of the receiver's frame relative to its superview's coordinate system.

Modifying the Bounds Rectangle

- `setBounds:` (page 3214)
  Sets the receiver's bounds rectangle.

- `bounds` (page 3150)
  Returns the receiver's bounds rectangle, which expresses its location and size in its own coordinate system.
- `setBoundsOrigin:` (page 3214)
  Sets the origin of the receiver's bounds rectangle to a specified point,
- `setBoundsSize:` (page 3216)
  Sets the size of the receiver's bounds rectangle to specified dimensions, inversely scaling its coordinate system relative to its frame rectangle.
- `setBoundsRotation:` (page 3215)
  Sets the rotation of the receiver's bounds rectangle to a specific degree value.
- `boundsRotation` (page 3151)
  Returns the angle, in degrees, of the receiver's bounds rectangle relative to its frame rectangle.

Modifying the Coordinate System

- `translateOriginToPoint:` (page 3237)
  Translates the receiver's coordinate system so that its origin moves to a new location.
- `scaleUnitSquareToSize:` (page 3208)
  Scales the receiver's coordinate system so that the unit square scales to the specified dimensions.
- `rotateByAngle:` (page 3208)
  Rotates the receiver's bounds rectangle by a specified degree value around the origin of the coordinate system, (0.0, 0.0).

Examining Coordinate System Modifications

- `isFlipped` (page 3181)
  Returns `YES` if the receiver uses flipped drawing coordinates or `NO` if it uses native coordinates.
- `isRotatedFromBase` (page 3184)
  Returns `YES` if the receiver or any of its ancestors has ever received a `setFrameRotation:` (page 3221) or `setBoundsRotation:` (page 3215) message; otherwise returns `NO`.
- `isRotatedOrScaledFromBase` (page 3184)
  Returns `YES` if the receiver or any of its ancestors has ever had a nonzero frame or bounds rotation, or has been scaled from the window's base coordinate system; otherwise returns `NO`.

Base Coordinate Conversion

- `convertPointToBase:` (page 3157)
  Converts the point from the receiver's coordinate system to the base coordinate system.
- `convertPointFromBase:` (page 3156)
  Converts the point from the base coordinate system to the receiver's coordinate system.
- `convertSizeToBase:` (page 3161)
  Converts the size from the receiver's coordinate system to the base coordinate system.
- `convertSizeFromBase:` (page 3161)
  Converts the size from the base coordinate system to the receiver's coordinate system.

- `convertRectToBase:` (page 3159)
  Converts the rectangle from the receiver's coordinate system to the base coordinate system.
- `convertRectFromBase:` (page 3158)
  Converts the rectangle from the base coordinate system to the receiver's coordinate system.

Converting Coordinates

- `convertPoint:fromView:` (page 3155)
  Converts a point from the coordinate system of a given view to that of the receiver.
- `convertPoint:toView:` (page 3155)
  Converts a point from the receiver's coordinate system to that of a given view.
- `convertSize:fromView:` (page 3159)
  Converts a size from another view's coordinate system to that of the receiver.
- `convertSize:toView:` (page 3160)
  Converts a size from the receiver's coordinate system to that of another view.
- `convertRect:fromView:` (page 3157)
  Converts a rectangle from the coordinate system of another view to that of the receiver.
- `convertRect:toView:` (page 3158)
  Converts a rectangle from the receiver's coordinate system to that of another view.
- `centerScanRect:` (page 3153)
  Converts the corners of a specified rectangle to lie on the center of device pixels, which is useful in compensating for rendering overscanning when the coordinate system has been scaled.

Controlling Notifications

- `setPostsFrameChangedNotifications:` (page 3227)
  Controls whether the receiver informs observers when its frame rectangle changes.
- `postsFrameChangedNotifications` (page 3196)
  Returns `YES` if the receiver posts notifications to the default notification center whenever its frame rectangle changes; returns `NO` otherwise.
- `setPostsBoundsChangedNotifications:` (page 3226)
  Controls whether the receiver informs observers when its bounds rectangle changes.
- `postsBoundsChangedNotifications` (page 3196)
  Returns `YES` if the receiver posts notifications to the default notification center whenever its bounds rectangle changes; returns `NO` otherwise.

Resizing Subviews

- `resizeSubviewsWithOldSize:` (page 3206)
  Informs the receiver's subviews that the receiver's bounds rectangle size has changed.
- `resizeWithOldSuperviewSize:` (page 3207)
  Informs the receiver that the bounds size of its superview has changed.

- `setAutoresizesSubviews:` (page 3212)
  Determines whether the receiver automatically resizes its subviews when its frame size changes.
- `autoresizesSubviews` (page 3147)
  Returns `YES` if the receiver automatically resizes its subviews using `resizeSubviewsWithOldSize:` (page 3206) whenever its frame size changes, `NO` otherwise.
- `setAutoresizingMask:` (page 3212)
  Determines how the receiver's `resizeWithOldSuperviewSize:` (page 3207) method changes its frame rectangle.
- `autoresizingMask` (page 3147)
  Returns the receiver's autoresizing mask, which determines how it's resized by the `resizeWithOldSuperviewSize:` (page 3207) method.

Focusing

- `lockFocus` (page 3187)
  Locks the focus on the receiver, so subsequent commands take effect in the receiver's window and coordinate system.
- `lockFocusIfCanDraw` (page 3188)
  Locks the focus to the receiver atomically if the `canDraw` method returns `YES` and returns the value of `canDraw`.
- `lockFocusIfCanDrawInContext:` (page 3188)
  Locks the focus to the receiver atomically if drawing can occur in the specified graphics context.
- `unlockFocus` (page 3239)
  Balances an earlier `lockFocus` (page 3187) or `lockFocusIfCanDraw` (page 3188) message; restoring the focus to the previously focused view is necessary.
- `+ focusView` (page 3137)
  Returns the currently focused `NSView` object, or `nil` if there is none.

Displaying

- `setNeedsDisplay:` (page 3225)
  Controls whether the receiver's entire bounds is marked as needing display.
- `setNeedsDisplayInRect:` (page 3225)
  Marks the region of the receiver within the specified rectangle as needing display, increasing the receiver's existing invalid region to include it.
- `needsDisplay` (page 3191)
  Returns `YES` if the receiver needs to be displayed, as indicated using `setNeedsDisplay:` (page 3225) and `setNeedsDisplayInRect:` (page 3225); returns `NO` otherwise.
- `display` (page 3163)
  Displays the receiver and all its subviews if possible, invoking each the `NSView` methods `lockFocus` (page 3187), `drawRect:` (page 3170), and `unlockFocus` (page 3239) as necessary.
- `displayRect:` (page 3166)
  Acts as `display` (page 3163), but confining drawing to a rectangular region of the receiver.

- `displayRectIgnoringOpacity:` (page 3166)
  Displays the receiver but confines drawing to a specified region and does not back up to the first opaque ancestor—it simply causes the receiver and its descendants to execute their drawing code.
- `displayRectIgnoringOpacity:inContext:` (page 3166)
  Causes the receiver and its descendants to be redrawn to the specified graphics context.
- `displayIfNeeded` (page 3164)
  Displays the receiver and all its subviews if any part of the receiver has been marked as needing display with a `setNeedsDisplay:` (page 3225) or `setNeedsDisplayInRect:` (page 3225) message.
- `displayIfNeededInRect:` (page 3165)
  Acts as `displayIfNeeded` (page 3164), confining drawing to a specified region of the receiver..
- `displayIfNeededIgnoringOpacity` (page 3165)
  Acts as `displayIfNeeded` (page 3164), except that this method doesn't back up to the first opaque ancestor—it simply causes the receiver and its descendants to execute their drawing code.
- `displayIfNeededInRectIgnoringOpacity:` (page 3165)
  Acts as `displayIfNeeded` (page 3164), but confining drawing to *aRect* and not backing up to the first opaque ancestor—it simply causes the receiver and its descendants to execute their drawing code.
- `translateRectsNeedingDisplayInRect:by:` (page 3238)
  Translates the display rectangles by the specified delta.
- `isOpaque` (page 3183)
  Overridden by subclasses to return `YES` if the receiver is opaque, `NO` otherwise.
- `viewWillDraw` (page 3242)
  Informs the receiver that it will be required to draw content.

Focus Ring Drawing

- `setKeyboardFocusRingNeedsDisplayInRect:` (page 3223)
  Invalidates the area around the focus ring.
+ `defaultFocusRingType` (page 3137)
  Returns the default focus ring type.
- `setFocusRingType:` (page 3218)
  Sets the type of focus ring to be drawn around the receiver.
- `focusRingType` (page 3175)
  Returns the type of focus ring drawn around the receiver.

Fullscreen Mode

- `enterFullScreenMode:withOptions:` (page 3173)
  Sets the receiver to full screen mode.
- `exitFullScreenModeWithOptions:` (page 3174)
  Instructs the receiver to exit full screen mode.
- `isInFullScreenMode` (page 3183)
  Returns whether the view is in full screen mode.

Hiding Views

- `setHidden:` (page 3222)
  Sets whether the view is hidden.
- `isHidden` (page 3182)
  Returns whether the receiver is marked as hidden.
- `isHiddenOrHasHiddenAncestor` (page 3182)
  Returns `YES` if the receiver is marked as hidden or has an ancestor in the view hierarchy that is marked as hidden; returns `NO` otherwise.
- `viewDidHide` (page 3240)
  Invoked when the receiver is hidden, either directly, or in response to an ancestor being hidden.
- `viewDidUnhide` (page 3242)
  Invoked when the receiver is unhidden, either directly, or in response to an ancestor being unhidden

Drawing

- `canDrawConcurrently` (page 3153)
  Returns whether the view's `drawRect:` method can be invoked on a background thread.
- `setCanDrawConcurrently:` (page 3217)
  Sets whether the view's `drawRect:` method can be invoked on a background thread.
- `drawRect:` (page 3170)
  Overridden by subclasses to draw the receiver's image within the passed-in rectangle.
- `visibleRect` (page 3245)
  Returns the portion of the receiver not clipped by its superviews.
- `canDraw` (page 3152)
  Returns `YES` if drawing commands will produce any result, `NO` otherwise.
- `shouldDrawColor` (page 3232)
  Returns `NO` if the receiver is being drawn in an `NSWindow` object (as opposed, for example, to being printed) and the window object can't store color; otherwise returns `YES`.
- `getRectsBeingDrawn:count:` (page 3176)
  Returns by indirection a list of non-overlapping rectangles that define the area the receiver is being asked to draw in `drawRect:` (page 3170).
- `needsToDrawRect:` (page 3192)
  Returns whether the specified rectangle intersects any part of the area that the receiver is being asked to draw.
- `wantsDefaultClipping` (page 3246)
  Returns whether the Application Kit's default clipping provided to `drawRect:` (page 3170) implementations is in effect.
- `bitmapImageRepForCachingDisplayInRect:` (page 3150)
  Returns a bitmap-representation object suitable for caching the specified portion of the receiver.
- `cacheDisplayInRect:toBitmapImageRep:` (page 3151)
  Draws the specified area of the receiver, and its descendants, into a provided bitmap-representation object.

Managing Live Resize

- `inLiveResize` (page 3180)
  A convenience method, expected to be called from `drawRect:` (page 3170), to assist in decisions about optimized drawing.
- `preservesContentDuringLiveResize` (page 3196)
  Returns `YES` if the view supports the optimization of live-resize operations by preserving content that has not moved; otherwise, returns `NO`.
- `getRectsExposedDuringLiveResize:count:` (page 3177)
  Returns a list of rectangles indicating the newly exposed areas of the receiver.
- `rectPreservedDuringLiveResize` (page 3199)
  Returns the rectangle identifying the portion of your view that did not change during a live resize operation.
- `viewWillStartLiveResize` (page 3244)
  Informs the receiver of the start of a live resize.
- `viewDidEndLiveResize` (page 3240)
  Informs the receiver of the end of a live resize.

Managing the Graphics State

- `allocateGState` (page 3146)
  Causes the receiver to maintain a private graphics state object, which encapsulates all parameters of the graphics environment.
- `gState` (page 3178)
  Returns the identifier for the receiver's graphics state object, or 0 if the receiver doesn't have a graphics state object.
- `setUpGState` (page 3229)
  Overridden by subclasses to (re)initialize the receiver's graphics state object.
- `renewGState` (page 3205)
  Invalidates the receiver's graphics state object, if it has one.
- `releaseGState` (page 3201)
  Frees the receiver's graphics state object, if it has one.

Event Handling

- `acceptsFirstMouse:` (page 3138)
  Overridden by subclasses to return `YES` if the receiver should be sent a `mouseDown:` (page 2164) message for an initial mouse-down event, `NO` if not.
- `hitTest:` (page 3179)
  Returns the farthest descendant of the receiver in the view hierarchy (including itself) that contains a specified point, or `nil` if that point lies completely outside the receiver.
- `mouse:inRect:` (page 3189)
  Returns whether a region of the receiver contains a specified point, accounting for whether the receiver is flipped or not.

- `performKeyEquivalent:` (page 3195)
  Implemented by subclasses to respond to key equivalents (also known as keyboard shortcuts).
- `rightMouseDown:` (page 3207)
  Informs the receiver that the user has pressed the right mouse button.
- `performMnemonic:` (page 3195)
  Implemented by subclasses to respond to mnemonics.
- `mouseDownCanMoveWindow` (page 3190)
  Returns `YES` if the receiver does not need to handle a mouse down and can pass it through to superviews; `NO` if it needs to handle the mouse down.
- `inputContext` (page 3181)
  Returns the text input context object for the receiver.

Dragging Operations

- `dragImage:at:offset:event:pasteboard:source:slideBack:` (page 3168)
  Initiates a dragging operation from the receiver, allowing the user to drag arbitrary data with a specified icon into any application that has window or view objects that accept dragged data.
- `dragFile:fromRect:slideBack:event:` (page 3167)
  Initiates a dragging operation from the receiver, allowing the user to drag a file icon to any application that has window or view objects that accept files.
- `registerForDraggedTypes:` (page 3201)
  Registers the pasteboard types that the receiver will accept as the destination of an image-dragging session.
- `registeredDraggedTypes` (page 3200)
  Returns the array of pasteboard drag types that the view can accept.
- `unregisterDraggedTypes` (page 3239)
  Unregisters the receiver as a possible destination in a dragging session.
- `shouldDelayWindowOrderingForEvent:` (page 3231)
  Overridden by subclasses to allow the user to drag images from the receiver without its window moving forward and possibly obscuring the destination and without activating the application.
- `dragPromisedFilesOfTypes:fromRect:source:slideBack:event:` (page 3169)
  Initiates a dragging operation from the receiver, allowing the user to drag one or more promised files (or directories) into any application that has window or view objects that accept promised file data.

Tool Tips

- `addToolTipRect:owner:userData:` (page 3141)
  Creates a tool tip for a defined area the receiver and returns a tag that identifies the tool tip rectangle.
- `removeAllToolTips` (page 3201)
  Removes all tool tips assigned to the receiver.
- `removeToolTip:` (page 3203)
  Removes the tool tip identified by specified tag.
- `setToolTip:` (page 3229)
  Sets the tool tip text for the view to *`string`*.

- `toolTip` (page 3236)
  Returns the text for the view's tool tip.

Managing Tracking Rectangles

- `addTrackingRect:owner:userData:assumeInside:` (page 3142)
  Establishes an area for tracking mouse-entered and mouse-exited events within the receiver and returns a tag that identifies the tracking rectangle.
- `removeTrackingRect:` (page 3204)
  Removes the tracking rectangle identified by a tag.

Managing Tracking Areas

- `addTrackingArea:` (page 3142)
  Adds a given tracking area to the receiver.
- `removeTrackingArea:` (page 3204)
  Removes a given tracking area from the receiver.
- `trackingAreas` (page 3237)
  Returns an array of the receiver's tracking areas.
- `updateTrackingAreas` (page 3239)
  Invoked automatically when the view's geometry changes such that its tracking areas need to be recalculated.

Managing Cursor Tracking

- `addCursorRect:cursor:` (page 3139)
  Establishes the cursor to be used when the mouse pointer lies within a specified region.
- `removeCursorRect:cursor:` (page 3202)
  Completely removes a cursor rectangle from the receiver.
- `discardCursorRects` (page 3163)
  Invalidates all cursor rectangles set up using `addCursorRect:cursor:` (page 3139).
- `resetCursorRects` (page 3206)
  Overridden by subclasses to define their default cursor rectangles.

Scrolling

- `scrollPoint:` (page 3209)
  Scrolls the receiver's closest ancestor `NSClipView` object so a point in the receiver lies at the origin of the clip view's bounds rectangle.
- `scrollRectToVisible:` (page 3210)
  Scrolls the receiver's closest ancestor `NSClipView` object the minimum distance needed so a specified region of the receiver becomes visible in the clip view.

- `autoscroll:` (page 3148)
  Scrolls the receiver's closest ancestor `NSClipView` object proportionally to the distance of an event that occurs outside of it.
- `adjustScroll:` (page 3145)
  Overridden by subclasses to modify a given rectangle, returning the altered rectangle.
- `scrollRect:by:` (page 3210)
  Copies the visible portion of the receiver's rendered image within a region and lays that portion down again at a specified offset .
- `enclosingScrollView` (page 3172)
  Returns the nearest ancestor `NSScrollView` object containing the receiver (not including the receiver itself); otherwise returns `nil`.
- `scrollClipView:toPoint:` (page 3209)
  Notifies the superview of a clip view that the clip view needs to reset the origin of its bounds rectangle.
- `reflectScrolledClipView:` (page 3200)
  Notifies a clip view's superview that either the clip view's bounds rectangle or the document view's frame rectangle has changed, and that any indicators of the scroll position need to be adjusted.

Contextual Menus

- `menuForEvent:` (page 3189)
  Overridden by subclasses to return a context-sensitive pop-up menu for a given mouse-down event.
+ `defaultMenu` (page 3137)
  Overridden by subclasses to return the default pop-up menu for instances of the receiving class.

Key-view Loop Management

- `canBecomeKeyView` (page 3152)
  Returns whether the receiver can become key view.
- `needsPanelToBecomeKey` (page 3191)
  Overridden by subclasses to determine if the receiver requires its panel, which might otherwise avoid becoming key, to become the key window so that it can handle keyboard input and navigation.
- `setNextKeyView:` (page 3226)
  Inserts a specified view object after the receiver in the key view loop of the receiver's window.
- `nextKeyView` (page 3192)
  Returns the view object following the receiver in the key view loop.
- `nextValidKeyView` (page 3193)
  Returns the closest view object in the key view loop that follows the receiver and accepts first responder status.
- `previousKeyView` (page 3197)
  Returns the view object preceding the receiver in the key view loop.
- `previousValidKeyView` (page 3197)
  Returns the closest view object in the key view loop that precedes the receiver and accepts first responder status.

Printing

- `print:` (page 3198)
  This action method opens the Print panel, and if the user chooses an option other than canceling, prints the receiver and all its subviews to the device specified in the Print panel.
- `beginPageInRect:atPlacement:` (page 3149)
  Called at the beginning of each page, this method sets up the coordinate system so that a region inside the receiver's bounds is translated to a specified location..
- `dataWithEPSInsideRect:` (page 3162)
  Returns EPS data that draws the region of the receiver within a specified rectangle.
- `dataWithPDFInsideRect:` (page 3162)
  Returns PDF data that draws the region of the receiver within a specified rectangle.
- `printJobTitle` (page 3198)
  Returns the receiver's print job title.
- `pageFooter` (page 3194)
  Returns a default footer string that includes the current page number and page count.
- `pageHeader` (page 3194)
  Returns a default header string that includes the print job title and date.
- `writeEPSInsideRect:toPasteboard:` (page 3248)
  Writes EPS data that draws the region of the receiver within a specified rectangle onto a pasteboard.
- `writePDFInsideRect:toPasteboard:` (page 3249)
  Writes PDF data that draws the region of the receiver within a specified rectangle onto a pasteboard.
- `drawPageBorderWithSize:` (page 3170)
  Allows applications that use the Application Kit pagination facility to draw additional marks on each logical page.
- `drawSheetBorderWithSize:` (page 3171)
  Allows applications that use the Application Kit pagination facility to draw additional marks on each printed sheet.

Pagination

- `heightAdjustLimit` (page 3178)
  Returns the fraction (from 0.0 to 1.0) of the page that can be pushed onto the next page during automatic pagination to prevent items such as lines of text from being divided across pages.
- `widthAdjustLimit` (page 3247)
  Returns the fraction (from 0.0 to 1.0) of the page that can be pushed onto the next page during automatic pagination to prevent items such as small images or text columns from being divided across pages.
- `adjustPageWidthNew:left:right:limit:` (page 3144)
  Overridden by subclasses to adjust page width during automatic pagination.
- `adjustPageHeightNew:top:bottom:limit:` (page 3143)
  Overridden by subclasses to adjust page height during automatic pagination.
- `knowsPageRange:` (page 3185)
  Returns `YES` if the receiver handles page boundaries, `NO` otherwise.

- `rectForPage:` (page 3199)
  Implemented by subclasses to determine the portion of the receiver to be printed for the page number page.
- `locationOfPrintRect:` (page 3186)
  Invoked by `print:` (page 3198) to determine the location of the region of the receiver being printed on the physical page.

Writing Conforming Rendering Instructions

- `beginDocument` (page 3149)
  Invoked at the beginning of the printing session, this method sets up the current graphics context.
- `endDocument` (page 3173)
  This method is invoked at the end of the printing session.
- `endPage` (page 3173)
  Writes the end of a conforming page.

Core Animation Layer-Backing

- `layer` (page 3185)
  Returns the Core Animation layer that the receiver uses as its backing store.
- `setLayer:` (page 3223)
  Sets the Core Animation layer that the receiver uses for layer-backing to the specified layer.
- `wantsLayer` (page 3246)
  Returns a Boolean value that indicates whether the receiver is using a layer as its backing store.
- `setWantsLayer:` (page 3230)
  Specifies whether the receiver and its subviews use a Core Animation layer as a backing store.
- `makeBackingLayer` (page 3189)
  Creates the view's backing layer.
- `layerContentsPlacement` (page 3186)
  Returns the current layer contents placement policy.
- `setLayerContentsPlacement:` (page 3223)
  Sets the view's layer contents placement policy.
- `layerContentsRedrawPolicy` (page 3186)
  Returns the view's layer contents redraw policy.
- `setLayerContentsRedrawPolicy:` (page 3224)
  Sets the receiver layer contents redraw policy.

Core Animation Layer Properties

- `setFrameCenterRotation:` (page 3219)
  Rotates the frame of the receiver about the layer's position.
- `frameCenterRotation` (page 3176)
  Returns the receiver's rotation about the layer's position.

- `setAlphaValue:` (page 3211)
  Sets the opacity of the receiver.
- `alphaValue` (page 3146)
  Returns the opacity of the receiver
- `setBackgroundFilters:` (page 3213)
  An array of CoreImage filters that are applied to the receiver's background.
- `backgroundFilters` (page 3149)
  Returns the array of CoreImage filters that are applied to the receiver's background
- `setCompositingFilter:` (page 3217)
  Sets a CoreImage filter that is used to composite the receiver's contents with the background.
- `compositingFilter` (page 3154)
  Returns the CoreImage filter that is used to composite the receiver's contents with the background
- `setContentFilters:` (page 3218)
  Sets the array of CoreImage filters that are applied to the contents of the receiver and its sublayers.
- `contentFilters` (page 3154)
  Returns the array of CoreImage filters that are applied to the contents of the receiver and its sublayers.
- `setShadow:` (page 3228)
  Sets the shadow drawn by the receiver.
- `shadow` (page 3231)
  Returns the shadow drawn by the receiver

Displaying Definition Windows

- `showDefinitionForAttributedString:atPoint:` (page 3232)
  Shows a window displaying the definition of the of the attributed string at the specified point.
- `showDefinitionForAttributedString:range:options:baselineOriginProvider:` (page 3233)
  Shows a window displaying the definition of the specified range of the attributed string.

Touch Event Handling

- `acceptsTouchEvents` (page 3138)
  Returns whether the view will accept touch events.
- `setAcceptsTouchEvents:` (page 3211)
  Sets whether the view should accept touch events.
- `wantsRestingTouches` (page 3247)
  Returns whether the view wants resting touches.
- `setWantsRestingTouches:` (page 3230)
  Sets whether the view wants to receive resting touch events.

Class Methods

defaultFocusRingType

Returns the default focus ring type.

```
+ (NSFocusRingType)defaultFocusRingType
```

Return Value
The default type of focus ring for objects of the receiver's class. Possible return values are listed in `NSFocusRingType` (page 4009).

Discussion
If `NSFocusRingTypeDefault` is returned from the instance method `focusRingType` (page 3175), the receiver can invoke this class method to find out what type of focus ring is the default. The receiver is free to ignore the default setting.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`NSView.h`

defaultMenu

Overridden by subclasses to return the default pop-up menu for instances of the receiving class.

```
+ (NSMenu *)defaultMenu
```

Discussion
The default implementation returns `nil`.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- menuForEvent:` (page 3189)
`menu` (page 2163) (`NSResponder`)

Declared In
`NSView.h`

focusView

Returns the currently focused `NSView` object, or `nil` if there is none.

```
+ (NSView *)focusView
```

Availability
Available in Mac OS X v10.0 and later.

See Also
- `lockFocus` (page 3187)
- `unlockFocus` (page 3239)

Declared In
`NSView.h`

Instance Methods

acceptsFirstMouse:

Overridden by subclasses to return `YES` if the receiver should be sent a `mouseDown:` (page 2164) message for an initial mouse-down event, `NO` if not.

```
- (BOOL)acceptsFirstMouse:(NSEvent *)theEvent
```

Parameters
theEvent
The initial mouse-down event, which must be over the receiver in its window.

Discussion
The receiver can either return a value unconditionally or use the location of *theEvent* to determine whether or not it wants the event. The default implementation ignores *theEvent* and returns `NO`.

Override this method in a subclass to allow instances to respond to click-through. This allows the user to click on a view in an inactive window, activating the view with one click, instead of clicking first to make the window active and then clicking the view. Most view objects refuse a click-through attempt, so the event simply activates the window. Many control objects, however, such as instances of `NSButton` and `NSSlider`, do accept them, so the user can immediately manipulate the control without having to release the mouse button.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `hitTest:` (page 3179)

Declared In
`NSView.h`

acceptsTouchEvents

Returns whether the view will accept touch events.

```
- (BOOL)acceptsTouchEvents
```

Return Value
`YES` if the view accepts touch events, otherwise `NO`.

Discussion
The default is `NO`.

Availability
Available in Mac OS X v10.6 and later.

See Also
- `setAcceptsTouchEvents:` (page 3211)

Declared In
`NSView.h`

addCursorRect:cursor:

Establishes the cursor to be used when the mouse pointer lies within a specified region.

```
- (void)addCursorRect:(NSRect)aRect
    cursor:(NSCursor *)aCursor
```

Parameters

aRect
A rectangle defining a region of the receiver.

aCursor
An object representing a cursor.

Discussion
Cursor rectangles aren't subject to clipping by superviews, nor are they intended for use with rotated views. You should explicitly confine a cursor rectangle to the view's visible rectangle to prevent improper behavior.

This method is intended to be invoked only by the `resetCursorRects` (page 3206) method. If invoked in any other way, the resulting cursor rectangle will be discarded the next time the view's cursor rectangles are rebuilt.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `removeCursorRect:cursor:` (page 3202)
- `discardCursorRects` (page 3163)
- `resetCursorRects` (page 3206)
- `visibleRect` (page 3245)

Related Sample Code
DragItemAround

Declared In
`NSView.h`

addSubview:

Adds a view to the receiver's subviews so it's displayed above its siblings.

```
- (void)addSubview:(NSView *)aView
```

Parameters

aView

The view to add to the receiver as a subview.

Discussion

This method also sets the receiver as the next responder of *aView*.

The receiver retains *aView*. If you use `removeFromSuperview` (page 3202) to remove *aView* from the view hierarchy, *aView* is released. If you want to keep using *aView* after removing it from the view hierarchy (if, for example, you are swapping through a number of views), you must retain it before invoking `removeFromSuperview` (page 3202).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSView.h`

addSubview:positioned:relativeTo:

Inserts a view among the receiver's subviews so it's displayed immediately above or below another view.

```
- (void)addSubview:(NSView *)aView
    positioned:(NSWindowOrderingMode)place
    relativeTo:(NSView *)otherView
```

Parameters

aView

The view object to add to the receiver as a subview.

place

An `enum` constant specifying the position of the `aView` relative to `otherView`. Valid values are `NSWindowAbove` or `NSWindowBelow`.

otherView

The other view `aView` is to be positioned relative to. If *otherView* is `nil` (or isn't a subview of the receiver), *aView* is added above or below all of its new siblings.

Discussion
This method also sets the receiver as the next responder of *aView*.

The receiver retains *aView*. If you use `removeFromSuperview` (page 3202) to remove *aView* from the view hierarchy, *aView* is released. If you want to keep using *aView* after removing it from the view hierarchy (if, for example, you are swapping through a number of views), you must retain it before invoking `removeFromSuperview` (page 3202).

Availability
Available in Mac OS X v10.0 and later.

See Also
- `addSubview:` (page 3139)
- `subviews` (page 3235)
- `removeFromSuperview` (page 3202)

`setNextResponder:` (page 2197) (`NSResponder`)

Related Sample Code
GLUT

Declared In
`NSView.h`

addToolTipRect:owner:userData:

Creates a tool tip for a defined area the receiver and returns a tag that identifies the tool tip rectangle.

```
- (NSToolTipTag)addToolTipRect:(NSRect)aRect
    owner:(id)anObject
    userData:(void *)userData
```

Parameters

aRect

A rectangle defining the region of the receiver to associate the tool tip with.

anObject

An object from which to obtain the tool tip string. The object should either implement `view:stringForToolTip:point:userData:` (page 3921), or return a suitable string from its `description` method. (It can therefore simply be an `NSString` object.)

Important: The receiver maintains a weak reference to *anObject*. You are responsible for ensuring that *anObject* remains valid for as long as it may be needed.

userData

Any additional information you want to pass to `view:stringForToolTip:point:userData:` (page 3921); it is not used if *anObject* does not implement this method.

Return Value
An integer tag identifying the tool tip; you can use this tag to remove the tool tip.

Discussion
The tool tip string is obtained dynamically from *anObject* by invoking either the `NSToolTipOwner` informal protocol method `view:stringForToolTip:point:userData:` (page 3921), if implemented, or the `NSObject` protocol method `description`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `removeToolTip:` (page 3203)
- `removeAllToolTips` (page 3201)

Declared In
`NSView.h`

addTrackingArea:

Adds a given tracking area to the receiver.

```
- (void)addTrackingArea:(NSTrackingArea *)trackingArea
```

Parameters
trackingArea
The tracking area to add to the receiver.

Availability
Available in Mac OS X v10.5 and later.

Related Sample Code
BasicCocoaAnimations
MenuItemView
PhotoSearch
TrackIt

Declared In
`NSView.h`

addTrackingRect:owner:userData:assumeInside:

Establishes an area for tracking mouse-entered and mouse-exited events within the receiver and returns a tag that identifies the tracking rectangle.

```
- (NSTrackingRectTag)addTrackingRect:(NSRect)aRect
    owner:(id)userObject
    userData:(void *)userData
    assumeInside:(BOOL)flag
```

Parameters
aRect
A rectangle that defines a region of the receiver for tracking mouse-entered and mouse-exited events.

userObject

The object that gets sent the event messages. It can be the receiver itself or some other object (such as an NSCursor or a custom drawing tool object), as long as it responds to both `mouseEntered:` (page 2165) and `mouseExited:` (page 2165).

userData

Data stored in the `NSEvent` object for each tracking event.

flag

If `YES`, the first event will be generated when the cursor leaves *aRect*, regardless if the cursor is inside *aRect* when the tracking rectangle is added. If `NO` the first event will be generated when the cursor leaves *aRect* if the cursor is initially inside *aRect*, or when the cursor enters *aRect* if the cursor is initially outside *aRect*. You usually want to set this flag to `NO`.

Return Value
A tag that identifies the tracking rectangle. It is stored in the associated `NSEvent` objects and can be used to remove the tracking rectangle.

Discussion
Tracking rectangles provide a general mechanism that can be used to trigger actions based on the cursor location (for example, a status bar or hint field that provides information on the item the cursor lies over). To simply change the cursor over a particular area, use `addCursorRect:cursor:` (page 3139). If you must use tracking rectangles to change the cursor, the `NSCursor` class specification describes the additional methods that must be invoked to change cursors by using tracking rectangles.

On Mac OS X v10.5 and later, tracking areas provide a greater range of functionality (see `addTrackingArea:` (page 3142)).

Availability
Available in Mac OS X v10.0 and later.

See Also

GLUT

Declared In
`NSView.h`

adjustPageHeightNew:top:bottom:limit:

Overridden by subclasses to adjust page height during automatic pagination.

```
- (void)adjustPageHeightNew:(CGFloat *)newBottom
    top:(CGFloat)top
    bottom:(CGFloat)proposedBottom
    limit:(CGFloat)bottomLimit
```

Parameters

newBottom

Returns by indirection a new `float` value for the bottom edge of the pending page rectangle in the receiver's coordinate system.

top

A `float` value that sets the top edge of the pending page rectangle in the receiver's coordinate system.

proposedBottom

A `float` value that sets the bottom edge of the pending page rectangle in the receiver's coordinate system.

bottomLimit

The topmost float value *newBottom* can be set to, as calculated using the return value of `heightAdjustLimit` (page 3178).

Discussion

This method is invoked by `print:` (page 3198). The receiver can raise the bottom edge and return the new value in *newBottom*, allowing it to prevent items such as lines of text from being divided across pages. If *bottomLimit* is exceeded, the pagination mechanism simply uses *bottomLimit* for the bottom edge.

The default implementation of this method propagates the message to its subviews, allowing nested views to adjust page height for their drawing as well. An `NSButton` object or other small view, for example, will nudge the bottom edge up if necessary to prevent itself from being cut in two (thereby pushing it onto an adjacent page). Subclasses should invoke `super`'s implementation, if desired, after first making their own adjustments.

Availability

Available in Mac OS X v10.0 and later.

See Also

`- adjustPageWidthNew:left:right:limit:` (page 3144)

Declared In

`NSView.h`

adjustPageWidthNew:left:right:limit:

Overridden by subclasses to adjust page width during automatic pagination.

```
- (void)adjustPageWidthNew:(CGFloat *)newRight
    left:(CGFloat)left
    right:(CGFloat)proposedRight
    limit:(CGFloat)rightLimit
```

Parameters

newRight

Returns by indirection a new `float` value for the right edge of the pending page rectangle in the receiver's coordinate system.

left

A `float` value that sets the left edge of the pending page rectangle in the receiver's coordinate system.

proposedRight

A `float` value that sets the right edge of the pending page rectangle in the receiver's coordinate system.

rightLimit

The leftmost `float` value *newRight* can be set to, as calculated using the return value of `widthAdjustLimit` (page 3247).

Discussion
This method is invoked by `print:` (page 3198). The receiver can pull in the right edge and return the new value in *newRight*, allowing it to prevent items such as small images or text columns from being divided across pages. If *rightLimit* is exceeded, the pagination mechanism simply uses *rightLimit* for the right edge.

The default implementation of this method propagates the message to its subviews, allowing nested views to adjust page width for their drawing as well. An `NSButton` object or other small view, for example, will nudge the right edge out if necessary to prevent itself from being cut in two (thereby pushing it onto an adjacent page). Subclasses should invoke `super`'s implementation, if desired, after first making their own adjustments.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- adjustPageHeightNew:top:bottom:limit:` (page 3143)

Declared In
`NSView.h`

adjustScroll:

Overridden by subclasses to modify a given rectangle, returning the altered rectangle.

```
- (NSRect)adjustScroll:(NSRect)proposedVisibleRect
```

Parameters

proposedVisibleRect

A rectangle defining a region of the receiver.

Discussion
`NSClipView` invokes this method to allow its document view to adjust its position during scrolling. For example, a custom view object that displays a table of data can adjust the origin of *proposedVisibleRect* so rows or columns aren't cut off by the edge of the enclosing `NSClipView`. `NSView`'s implementation simply returns *proposedVisibleRect*.

`NSClipView` only invokes this method during automatic or user controlled scrolling. Its `scrollToPoint:` (page 635) method doesn't invoke this method, so you can still force a scroll to an arbitrary point.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSView.h`

allocateGState

Causes the receiver to maintain a private graphics state object, which encapsulates all parameters of the graphics environment.

```
- (void)allocateGState
```

Discussion
If you do not invoke `allocateGState`, a graphics state object is constructed from scratch each time the NSView is focused.

The receiver builds the graphics state parameters using `setUpGState` (page 3229), then automatically establishes this graphics state each time the focus is locked on it. A graphics state may improve performance for view objects that are focused often and need to set many parameters, but use of standard rendering operators is normally efficient enough.

Because graphics states occupy a fair amount of memory, they can actually degrade performance. Be sure to test application performance with and without the private graphics state before committing to its use.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setUpGState` (page 3229)
- `gState` (page 3178)
- `renewGState` (page 3205)

Related Sample Code
GLUT

Declared In
`NSView.h`

alphaValue

Returns the opacity of the receiver

```
- (CGFloat)alphaValue
```

Return Value
The current opacity of the receiver

Discussion
This method returns the value of the `opacity` property of the receiver's layer. Possible values are between 0.0 (transparent) and 1.0 (opaque). The default is 1.0.

Sending this message to a view that is not managing a Core Animation layer causes an exception.

Availability
Available in Mac OS X v10.5 and later.

Related Sample Code
RoundTransparentWindow

Declared In
NSView.h

ancestorSharedWithView:

Returns the closest ancestor shared by the receiver and a given view.

```
- (NSView *)ancestorSharedWithView:(NSView *)aView
```

Parameters

aView

The view to test (along with the receiver) for closest shared ancestor.

Return Value
The closest ancestor or `nil` if there's no such object. Returns `self` if *aView* is identical to the receiver.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `isDescendantOf:` (page 3181)

Declared In
NSView.h

autoresizesSubviews

Returns `YES` if the receiver automatically resizes its subviews using `resizeSubviewsWithOldSize:` (page 3206) whenever its frame size changes, `NO` otherwise.

```
- (BOOL)autoresizesSubviews
```

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setAutoresizesSubviews:` (page 3212)

Declared In
NSView.h

autoresizingMask

Returns the receiver's autoresizing mask, which determines how it's resized by the `resizeWithOldSuperviewSize:` (page 3207) method.

```
- (NSUInteger)autoresizingMask
```

Return Value
An integer bit mask specified by combining using the C bitwise OR operator any of the options described in "Resizing masks" (page 3250).

Discussion
If the autoresizing mask is equal to `NSViewNotSizable` (that is, if none of the options are set), then the receiver doesn't resize at all in `resizeWithOldSuperviewSize:` (page 3207).

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
PhotoSearch
PredicateEditorSample

Declared In
`NSView.h`

autoscroll:

Scrolls the receiver's closest ancestor `NSClipView` object proportionally to the distance of an event that occurs outside of it.

```
- (BOOL)autoscroll:(NSEvent *)theEvent
```

Parameters
theEvent
An event object whose location should be expressed in the window's base coordinate system (which it normally is), not the receiving view's.

Return Value
Returns `YES` if any scrolling is performed; otherwise returns `NO`.

Discussion
View objects that track mouse-dragged events can use this method to scroll automatically when the cursor is dragged outside of the `NSClipView` object. Repeated invocations of this method (with an appropriate delay) result in continual scrolling, even when the mouse doesn't move.

Availability
Available in Mac OS X v10.0 and later.

See Also
`autoscroll:` (page 632) (NSClipView)
`- scrollPoint:` (page 3209)
`- isDescendantOf:` (page 3181)

Rulers

Declared In
`NSView.h`

backgroundFilters

Returns the array of CoreImage filters that are applied to the receiver's background

```
- (NSArray *)backgroundFilters
```

Return Value
An array of CoreImage filters.

Discussion
This method returns the value of the `backgroundFilters` property of the receiver's layer.

Sending this message to a view that is not managing a Core Animation layer causes an exception.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSView.h`

beginDocument

Invoked at the beginning of the printing session, this method sets up the current graphics context.

```
- (void)beginDocument
```

Discussion
Note that this method may be invoked in a subthread.

Override it to configure printing related settings. You should store your settings in the object returned by `NSPrintInfo`'s `sharedPrintInfo` (page 2048) class method, which is guaranteed to return an instance specific to the thread in which you invoke this method. If you override this method, call the superclass implementation.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSView.h`

beginPageInRect:atPlacement:

Called at the beginning of each page, this method sets up the coordinate system so that a region inside the receiver's bounds is translated to a specified location..

```
- (void)beginPageInRect:(NSRect)aRect
    atPlacement:(NSPoint)location
```

Parameters

aRect
A rectangle defining the region to be translated.

location
A point that is the end-point of translation.

Discussion
If you override this method, be sure to call the superclass implementation.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSView.h`

bitmapImageRepForCachingDisplayInRect:

Returns a bitmap-representation object suitable for caching the specified portion of the receiver.

```
- (NSBitmapImageRep *)bitmapImageRepForCachingDisplayInRect:(NSRect)aRect
```

Parameters

aRect

A rectangle defining the area of the receiver to be cached.

Return Value
An autoreleased `NSBitmapImageRep` object or `nil` if the object could not be created.

Discussion
Passing the visible rectangle of the receiver (`[self visibleRect]`) returns a bitmap suitable for caching the current contents of the view, including all of its descendants.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- cacheDisplayInRect:toBitmapImageRep:` (page 3151)

Related Sample Code
AnimatedTableView
Reducer

Declared In
`NSView.h`

bounds

Returns the receiver's bounds rectangle, which expresses its location and size in its own coordinate system.

```
- (NSRect)bounds
```

Discussion
By default, the origin of the returned rectangle is (0, 0) and its size matches the size of the receiver's frame rectangle (measured in points). In Mac OS X v10.5 and later, if the receiver is being rendered into an OpenGL graphics context (using an `NSOpenGLContext` object), the default bounds origin is still (0, 0) but the default bounds size is measured in pixels instead of points. Thus, for user space scale factors other than 1.0, the default size of the bounds rectangle may be bigger or smaller than the default size of the frame rectangle when drawing with OpenGL.

Important: Developers of OpenGL applications should not rely on this method converting coordinates to pixels automatically in future releases. Instead, you should convert coordinates to device space explicitly using the `convertPointToBase:` (page 3157), `convertSizeToBase:` (page 3161), or `convertRectToBase:` (page 3159) methods or their earlier counterparts `convertPoint:toView:` (page 3155), `convertSize:toView:` (page 3160), or `convertRect:toView:` (page 3158).

If you explicitly change the origin or size of the bounds rectangle, this method does not return the default rectangle and instead returns the rectangle you set. If you add a rotation factor to the view, however, that factor is also reflected in the returned bounds rectangle. You can determine if a rotation factor is in effect by calling the `boundsRotation` (page 3151) method.

Availability
Available in Mac OS X v10.0 and later.

`NSView.h`

boundsRotation

Returns the angle, in degrees, of the receiver's bounds rectangle relative to its frame rectangle.

```
- (CGFloat)boundsRotation
```

Discussion
See the `setBoundsRotation:` (page 3215) method description for more information on bounds rotation.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `rotateByAngle:` (page 3208)
- `setBoundsRotation:` (page 3215)

Declared In
`NSView.h`

cacheDisplayInRect:toBitmapImageRep:

Draws the specified area of the receiver, and its descendants, into a provided bitmap-representation object.

```
- (void)cacheDisplayInRect:(NSRect)rect
    toBitmapImageRep:(NSBitmapImageRep *)bitmapImageRep
```

Parameters

rect

A rectangle defining the region to be drawn into *bimapImageRep*.

bitmapImageRep

An `NSBitmapImageRep` object. For pixel-format compatibility, *bitmapImageRep* should have been obtained from `bitmapImageRepForCachingDisplayInRect:` (page 3150).

Discussion

You are responsible for initializing the bitmap to the desired configuration before calling this method. However, once initialized, you can reuse the same bitmap multiple times to refresh the cached copy of your view's contents.

The bitmap produced by this method is transparent (that is, has an alpha value of 0) wherever the receiver and its descendants do not draw any content.

Availability

Available in Mac OS X v10.4 and later.

See Also

`- bitmapImageRepForCachingDisplayInRect:` (page 3150)

Related Sample Code

AnimatedTableView

Reducer

Declared In

`NSView.h`

canBecomeKeyView

Returns whether the receiver can become key view.

```
- (BOOL)canBecomeKeyView
```

Return Value

Returns `YES` if the receiver can become key view, `NO` otherwise.

Availability

Available in Mac OS X v10.3 and later.

Declared In

`NSView.h`

canDraw

Returns `YES` if drawing commands will produce any result, `NO` otherwise.

```
- (BOOL)canDraw
```

Discussion
Use this method when invoking a draw method directly along with `lockFocus` (page 3187) and `unlockFocus` (page 3239), bypassing the `display...` methods (which test drawing ability and perform locking for you). If this method returns `NO`, you shouldn't invoke `lockFocus` (page 3187) or perform any drawing.

A view object can draw on-screen if it is not hidden, it is attached to a view hierarchy in a window (`NSWindow`), and the window has a corresponding window device. A view object can draw during printing if it is a descendant of the view being printed.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setHidden:` (page 3222)

Declared In
`NSView.h`

canDrawConcurrently

Returns whether the view's `drawRect:` method can be invoked on a background thread.

```
- (BOOL)canDrawConcurrently
```

Return Value
`YES` if `drawRect:` (page 3170) can be invoked from a background thread, otherwise `NO`. The default is `NO`.

Availability
Available in Mac OS X v10.6 and later.

See Also
`- setCanDrawConcurrently:` (page 3217)

Declared In
`NSView.h`

centerScanRect:

Converts the corners of a specified rectangle to lie on the center of device pixels, which is useful in compensating for rendering overscanning when the coordinate system has been scaled.

```
- (NSRect)centerScanRect:(NSRect)aRect
```

Parameters
aRect
The rectangle whose corners are to be converted.

Return Value
The adjusted rectangle.

Discussion
This method converts the given rectangle to device coordinates, adjusts the rectangle to lie in the center of the pixels, and converts the resulting rectangle back to the receiver's coordinate system. Note that this method does not take into account any transformations performed using the `NSAffineTransform` class or Quartz 2D routines.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- isRotatedOrScaledFromBase` (page 3184)

compositingFilter

Returns the CoreImage filter that is used to composite the receiver's contents with the background

```
- (CIFilter *)compositingFilter
```

Return Value
The CoreImage filter.

Discussion
This method returns the value of the `filters` property of the receiver's layer.

Sending this message to a view that is not managing a Core Animation layer causes an exception.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSView.h`

contentFilters

Returns the array of CoreImage filters that are applied to the contents of the receiver and its sublayers.

```
- (NSArray *)contentFilters
```

Return Value
An array of CoreImage filters

Discussion
This method returns the value of the `filters` property of the receiver's layer.

Sending this message to a view that is not managing a Core Animation layer causes an exception.

Availability
Available in Mac OS X v10.5 and later.

Declared In
NSView.h

convertPoint:fromView:

Converts a point from the coordinate system of a given view to that of the receiver.

```
- (NSPoint)convertPoint:(NSPoint)aPoint
    fromView:(NSView *)aView
```

Parameters

aPoint

A point specifying a location in the coordinate system of aView.

aView

The view with aPoint in its coordinate system. If *aView* is nil, this method instead converts from window base coordinates. Otherwise, both *aView* and the receiver must belong to the same NSWindow object.

Return Value
The point converted to the coordinate system of the receiver.

Availability
Available in Mac OS X v10.0 and later.

See Also

- writeEPSInsideRect:toPasteboard: (page 3248)

Declared In
NSView.h

dataWithPDFInsideRect:

Returns PDF data that draws the region of the receiver within a specified rectangle.

```
- (NSData *)dataWithPDFInsideRect:(NSRect)aRect
```

Parameters

aRect

A rectangle defining the region.

Discussion
This data can be placed on an NSPasteboard object, written to a file, or used to create an NSImage object.

Availability
Available in Mac OS X v10.0 and later.

See Also
- writePDFInsideRect:toPasteboard: (page 3249)

Related Sample Code
QuickLookSketch

Sketch-112

Declared In
NSView.h

didAddSubview:

Overridden by subclasses to perform additional actions when subviews are added to the receiver.

```
- (void)didAddSubview:(NSView *)subview
```

Parameters

subview

The view that was added as a subview.

Discussion

This method is invoked by `addSubview:` (page 3139).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSView.h`

discardCursorRects

Invalidates all cursor rectangles set up using `addCursorRect:cursor:` (page 3139).

```
- (void)discardCursorRects
```

Discussion

You need never invoke this method directly; neither is it typically invoked during the invalidation of cursor rectangles. `NSWindow` automatically invalidates cursor rectangles in response to `invalidateCursorRectsForView:` (page 3335) and before the receiver's cursor rectangles are reestablished using `resetCursorRects` (page 3206). This method is invoked just before the receiver is removed from a window and when the receiver is deallocated.

Availability

Available in Mac OS X v10.0 and later.

See Also

`discardCursorRects` (page 3320) (NSWindow)

Related Sample Code

DragItemAround

Declared In

`NSView.h`

display

Displays the receiver and all its subviews if possible, invoking each the `NSView` methods `lockFocus` (page 3187), `drawRect:` (page 3170), and `unlockFocus` (page 3239) as necessary.

```
- (void)display
```

Discussion

If the receiver isn't opaque, this method backs up the view hierarchy to the first opaque ancestor, calculates the portion of the opaque ancestor covered by the receiver, and begins displaying from there.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `canDraw` (page 3152)
- `opaqueAncestor` (page 3193)

Declared In
`NSView.h`

displayIfNeeded

Displays the receiver and all its subviews if any part of the receiver has been marked as needing display with a `setNeedsDisplay:` (page 3225) or `setNeedsDisplayInRect:` (page 3225) message.

```
- (void)displayIfNeeded
```

Discussion
This method invokes the `NSView` methods `lockFocus` (page 3187), `drawRect:` (page 3170), and `unlockFocus` (page 3239) as necessary. If the receiver isn't opaque, this method backs up the view hierarchy to the first opaque ancestor, calculates the portion of the opaque ancestor covered by the receiver, and begins displaying from there.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSView.h`

displayIfNeededIgnoringOpacity

Acts as `displayIfNeeded` (page 3164), except that this method doesn't back up to the first opaque ancestor—it simply causes the receiver and its descendants to execute their drawing code.

```
- (void)displayIfNeededIgnoringOpacity
```

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
DispatchFractal

Declared In
`NSView.h`

displayIfNeededInRect:

Acts as `displayIfNeeded` (page 3164), confining drawing to a specified region of the receiver..

```
- (void)displayIfNeededInRect:(NSRect)aRect
```

Parameters

aRect

A rectangle defining the region to be redrawn. It should be specified in the coordinate system of the receiver.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSView.h`

displayIfNeededInRectIgnoringOpacity:

Acts as `displayIfNeeded` (page 3164), but confining drawing to *aRect* and not backing up to the first opaque ancestor—it simply causes the receiver and its descendants to execute their drawing code.

```
- (void)displayIfNeededInRectIgnoringOpacity:(NSRect)aRect
```

Parameters

aRect

A rectangle defining the region to be redrawn. It should be specified in the coordinate system of the receiver.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSView.h`

displayRect:

Acts as `display` (page 3163), but confining drawing to a rectangular region of the receiver.

```
- (void)displayRect:(NSRect)aRect
```

Parameters

aRect

A rectangle defining the region of the receiver to be redrawn; should be specified in the coordinate system of the receiver.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSView.h

displayRectIgnoringOpacity:

Displays the receiver but confines drawing to a specified region and does not back up to the first opaque ancestor—it simply causes the receiver and its descendants to execute their drawing code.

```
- (void)displayRectIgnoringOpacity:(NSRect)aRect
```

Parameters

aRect

A rectangle defining the region of the receiver to be redrawn; should be specified in the coordinate system of the receiver.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSView.h

displayRectIgnoringOpacity:inContext:

Causes the receiver and its descendants to be redrawn to the specified graphics context.

```
- (void)displayRectIgnoringOpacity:(NSRect)aRect
    inContext:(NSGraphicsContext *)context
```

Parameters

aRect

A rectangle defining the region of the receiver to be redrawn. It should be specified in the coordinate system of the receiver.

context

The graphics context in which drawing will occur. See the discussion below for more about this parameter.

Discussion
Acts as `display` (page 3163), but confines drawing to *aRect*. This method initiates drawing with the receiver, even if the receiver is not opaque. Appropriate scaling factors for the view are obtained from *context*.

If the *context* parameter represents the context for the window containing the view, then all of the necessary transformations are applied. This includes the application of the receiver's bounds and frame transforms along with any transforms it inherited from its ancestors. In this situation, the view is also marked as no longer needing an update for the specified rectangle.

If *context* specifies any other graphics context, then only the receiver's bounds transform is applied. This means that drawing is not constrained to the view's visible rectangle. It also means that any dirty rectangles are not cleared, since they are not being redrawn to the window.

Availability
Available in Mac OS X v10.4 and later.

Related Sample Code
QuickLookSketch

Declared In
NSView.h

dragFile:fromRect:slideBack:event:

Initiates a dragging operation from the receiver, allowing the user to drag a file icon to any application that has window or view objects that accept files.

```
- (BOOL)dragFile:(NSString *)fullPath fromRect:(NSRect)aRect
    slideBack:(BOOL)slideBack event:(NSEvent *)theEvent
```

Parameters

fullPath
A string that specifies the absolute path for the file that is dragged.

aRect
A rectangle that describes the position of the icon in the receiver's coordinate system.

slideBack
A Boolean that indicates whether the icon being dragged should slide back to its position in the receiver if the file isn't accepted. The icon slides back to *aRect* if *slideBack* is YES, the file is not accepted by the dragging destination, and the user has not disabled icon animation; otherwise it simply disappears.

theEvent
The mouse-down event object from which to initiate the drag operation. In particular, its mouse location is used for the offset of the icon being dragged.

Return Value
YES if the receiver successfully initiates the dragging operation (which doesn't necessarily mean the dragging operation concluded successfully). Otherwise returns NO.

Discussion
This method must be invoked only within an implementation of the mouseDown: (page 2164) method.

See the NSDraggingSource, NSDraggingInfo, and NSDraggingDestination protocol specifications for more information on dragging operations.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `dragImage:at:offset:event:pasteboard:source:slideBack:` (page 3168)
- `shouldDelayWindowOrderingForEvent:` (page 3231)

Declared In
`NSView.h`

dragImage:at:offset:event:pasteboard:source:slideBack:

Initiates a dragging operation from the receiver, allowing the user to drag arbitrary data with a specified icon into any application that has window or view objects that accept dragged data.

```
- (void)dragImage:(NSImage *)anImage at:(NSPoint)imageLoc offset:(NSSize)mouseOffset
    event:(NSEvent *)theEvent pasteboard:(NSPasteboard *)pboard
   source:(id)sourceObject slideBack:(BOOL)slideBack
```

Parameters

anImage
The `NSImage` object to be dragged.

imageLoc
The location of the image's lower-left corner, in the receiver's coordinate system. It determines the placement of the dragged image under the cursor. When determining the image location you should use the mouse down coordinate, provided in *theEvent*, rather than the current mouse location.

mouseOffset
This parameter is ignored.

theEvent
The left mouse-down event that triggered the dragging operation (see discussion below).

pboard
The pasteboard that holds the data to be transferred to the destination (see discussion below).

sourceObject
An object that serves as the controller of the dragging operation. It must conform to the `NSDraggingSource` informal protocol and is typically the receiver itself or its `NSWindow` object.

slideBack
A Boolean that determines whether the drag image should slide back if it's rejected. The image slides back to *imageLoc* if *slideBack* is `YES` and the image isn't accepted by the dragging destination. If `NO` the image doesn't slide back.

Discussion
This method must be invoked only within an implementation of the `mouseDown:` (page 2164) or `mouseDragged:` (page 2164) methods.

Before invoking this method, you must place the data to be transferred on *pboard*. To do this, get the drag pasteboard object (`NSDragPboard`), declare the types of the data, and then put the data on the pasteboard. This code fragment initiates a dragging operation on an image itself (that is, the image is the data to be transferred):

```
- (void)mouseDown:(NSEvent *)theEvent
{
    NSSize dragOffset = NSMakeSize(0.0, 0.0);
    NSPasteboard *pboard;
```

```
    pboard = [NSPasteboard pasteboardWithName:NSDragPboard];
    [pboard declareTypes:[NSArray arrayWithObject:NSTIFFPboardType]  owner:self];
    [pboard setData:[[self image] TIFFRepresentation] forType:NSTIFFPboardType];

    [self dragImage:[self image] at:[self imageLocation] offset:dragOffset
        event:theEvent pasteboard:pboard source:self slideBack:YES];

    return;
}
```

See the `NSDraggingSource`, `NSDraggingInfo`, and `NSDraggingDestination` protocol specifications for more information on dragging operations.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `dragFile:fromRect:slideBack:event:` (page 3167)
- `shouldDelayWindowOrderingForEvent:` (page 3231)

Declared In
`NSView.h`

dragPromisedFilesOfTypes:fromRect:source:slideBack:event:

Initiates a dragging operation from the receiver, allowing the user to drag one or more promised files (or directories) into any application that has window or view objects that accept promised file data.

```
- (BOOL)dragPromisedFilesOfTypes:(NSArray *)typeArray fromRect:(NSRect)aRect
    source:(id)sourceObject slideBack:(BOOL)slideBack event:(NSEvent *)theEvent
```

Parameters

typeArray
An array of file types being promised. The array elements can consist of file extensions and HFS types encoded with the `NSFileTypeForHFSTypeCode` function. If promising a directory of files, only include the top directory in the array.

aRect
A rectangle that describes the position of the icon in the receiver's coordinate system.

sourceObject
An object that serves as the controller of the dragging operation. It must conform to the `NSDraggingSource` informal protocol, and is typically the receiver itself or its `NSWindow` object.

slideBack
A Boolean that indicates whether the icon being dragged should slide back to its position in the receiver if the file isn't accepted. The icon slides back to *aRect* if *slideBack* is `YES`, the promised files are not accepted by the dragging destination, and the user has not disabled icon animation; otherwise it simply disappears.

theEvent
The mouse-down event object from which to initiate the drag operation. In particular, its mouse location is used for the offset of the icon being dragged.

Return Value
`YES` if the drag operation is initiated successfully, `NO` otherwise.

Discussion
This method must be invoked only within an implementation of the `mouseDown:` (page 2164) method. As part of its implementation, this method invokes `dragImage:at:offset:event:pasteboard:source:slideBack:` (page 3168).

Promised files are files that do not exist, yet, but that the drag source, *sourceObject*, promises to create at a file system location specified by the drag destination when the drag is successfully dropped.

See *Drag and Drop Programming Topics for Cocoa* for more information on dragging operations.

Availability
Available in Mac OS X v10.2 and later.

See Also

- `shouldDelayWindowOrderingForEvent:` (page 3231)

Declared In
`NSView.h`

drawPageBorderWithSize:

Allows applications that use the Application Kit pagination facility to draw additional marks on each logical page.

```
- (void)drawPageBorderWithSize:(NSSize)borderSize
```

Parameters
borderSize
An `NSSize` structure that defines a logical page.

Discussion
The marks can be such things as alignment marks or a virtual sheet border of size *borderSize*. The default implementation doesn't draw anything.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `drawSheetBorderWithSize:` (page 3171)

Declared In
`NSView.h`

drawRect:

Overridden by subclasses to draw the receiver's image within the passed-in rectangle.

```
- (void)drawRect:(NSRect)dirtyRect
```

Parameters
dirtyRect
A rectangle defining the dirty area of the view that requires redrawing.

Discussion
The receiver can assume the focus has been locked and the coordinate transformations of its frame and bounds rectangles have been applied; all it needs to do is invoke rendering client functions.

You can avoid unnecessary drawing by paying attention to the *dirtyRect* parameter which defines the area that must be redrawn. The bounds of the entire view, as opposed to the dirty region, is given by [self bounds].

On Mac OS X version 10.2 and earlier, the Application Kit automatically clips any drawing you perform in this method to this rectangle. On Mac OS X version 10.3 and later, the Application Kit automatically clips drawing to a list of non-overlapping rectangles that more rigorously specify the area needing drawing. You can invoke the `getRectsBeingDrawn:count:` (page 3176) method to retrieve this list of rectangles and use them to constrain your drawing more tightly, if you wish. Moreover, the `needsToDrawRect:` (page 3192) method gives you a convenient way to test individual objects for intersection with the rectangles in the list. See *Cocoa Drawing Guide* for information and references on drawing.

The default implementation does nothing. If your custom view is a direct `NSView` subclass you do not need to call `super`'s implementation.

Note: If a subclass returns `YES` upon receiving an `isOpaque` (page 3183) message, it must completely fill *dirtyRect* with opaque content.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `display` (page 3163)

Declared In
`NSView.h`

drawSheetBorderWithSize:

Allows applications that use the Application Kit pagination facility to draw additional marks on each printed sheet.

```
- (void)drawSheetBorderWithSize:(NSSize)borderSize
```

Parameters

borderSize

An `NSSize` structure that defines a printed sheet.

Discussion

The marks can be such things as crop marks or fold lines of size *borderSize*. This method has been deprecated.

Availability

Available in Mac OS X v10.0 and later.

See Also

`- drawPageBorderWithSize:` (page 3170)

Declared In

`NSView.h`

enclosingMenuItem

Returns the menu item containing the receiver or any of its superviews in the view hierarchy.

```
- (NSMenuItem *)enclosingMenuItem
```

Return Value

Returns the menu item containing the receiver or any of its superviews in the view hierarchy, or `nil` if the receiver's view hierarchy is not in a menu item

Availability

Available in Mac OS X v10.5 and later.

Declared In

`NSMenuItem.h`

enclosingScrollView

Returns the nearest ancestor `NSScrollView` object containing the receiver (not including the receiver itself); otherwise returns `nil`.

```
- (NSScrollView *)enclosingScrollView
```

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSView.h`

endDocument

This method is invoked at the end of the printing session.

```
- (void)endDocument
```

Discussion
If you override this method, call the superclass implementation.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSView.h`

endPage

Writes the end of a conforming page.

```
- (void)endPage
```

Discussion
This method is invoked after each page is printed. It invokes `unlockFocus` (page 3239). This method also generates comments for the bounding box and page fonts, if they were specified as being at the end of the page.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSView.h`

enterFullScreenMode:withOptions:

Sets the receiver to full screen mode.

```
- (BOOL)enterFullScreenMode:(NSScreen *)screen
    withOptions:(NSDictionary *)options
```

Parameters

screen
The screen the receiver should cover.

options
A dictionary of options for the mode. For possible keys, see "`Full Screen Mode Options`" (page 3252).

Return Value
`YES` if the receiver was able to enter full screen mode, otherwise `NO`.

Discussion
When the `NSFullScreenModeApplicationPresentationOptions` (page 3252) is contained in the options dictionary, the presentation options that were in effect when this method is invoked are not altered, and no displays are captured.

If you do not wish to capture the screen when going to full screen mode, you can add `NSFullScreenModeApplicationPresentationOptions` (page 3252) to the options dictionary with the value returned by the `presentationOptions` (page 158).

When the `NSFullScreenModeApplicationPresentationOptions` (page 3252) options is specified, exiting full screen mode using `exitFullScreenModeWithOptions:` (page 3174) will restore the previously active `presentationOptions` (page 158).

Special Considerations

On Mac OS X v 10.5 invoking this method when the receiver was not in a window would cause an exception. On Mac OS X v 10.6 and later, you can now send this message to a view not in a window. For applications that must also run on Mac OS X v 10.5, a simple workaround is to place the view in an offscreen dummy window.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSView.h`

focusRingType

Returns the type of focus ring drawn around the receiver.

```
- (NSFocusRingType)focusRingType
```

Return Value
An `enum` constant identifying a type of focus ring. Possible values are listed in `NSFocusRingType` (page 4009).

Discussion
You can disable a view's drawing of its focus ring by overriding this method to return `NSFocusRingTypeNone`, or by invoking `setFocusRingType:` (page 3218) with and argument of `NSFocusRingTypeNone`. You should only disable the default drawing of a view's focus ring if you want it to draw its own focus ring (for example, setting the background color of the view), or if the view does not have sufficient space to display a focus ring.

Availability
Available in Mac OS X v10.3 and later.

See Also
`- setFocusRingType:` (page 3218)

Declared In
`NSView.h`

frame

Returns the receiver's frame rectangle, which defines its position in its superview.

```
- (NSRect)frame
```

Discussion
The frame rectangle may be rotated; use the `frameRotation` (page 3176) method to check this.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSView.h`

frameCenterRotation

Returns the receiver's rotation about the layer's position.

```
- (CGFloat)frameCenterRotation
```

Return Value
The angle of rotation of the frame around the center of the receiver.

Discussion
If the application has altered the layer's `anchorPoint` property, the behavior is undefined. Sending this message to a view that is not managing a Core Animation layer causes an exception.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSView.h`

frameRotation

Returns the angle, in degrees, of the receiver's frame relative to its superview's coordinate system.

```
- (CGFloat)frameRotation
```

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setFrameRotation:` (page 3221)
- `boundsRotation` (page 3151)

Declared In
`NSView.h`

getRectsBeingDrawn:count:

Returns by indirection a list of non-overlapping rectangles that define the area the receiver is being asked to draw in `drawRect:` (page 3170).

```
- (void)getRectsBeingDrawn:(const NSRect **)rects
    count:(NSInteger *)count
```

Parameters

rects

On return, contains a list of non-overlapping rectangles defining areas to be drawn in. The rectangles returned in *rects* are in the coordinate space of the receiver.

count

On return, the number of rectangles in the `rects` list.

Discussion

An implementation of `drawRect:` can use this information to test whether objects or regions within the view intersect with the rectangles in the list, and thereby avoid unnecessary drawing that would be completely clipped away.

The `needsToDrawRect:` (page 3192) method gives you a convenient way to test individual objects for intersection with the area being drawn in `drawRect:` (page 3170). However, you may want to retrieve and directly inspect the rectangle list if this is a more efficient way to perform intersection testing.

You should send this message only from within a `drawRect:` (page 3170) implementation. The *aRect* parameter of `drawRect:` is the rectangle enclosing the returned list of rectangles; you can use it in an initial pass to reject objects that are clearly outside the area to be drawn.

Availability

Available in Mac OS X v10.3 and later.

See Also

`- wantsDefaultClipping` (page 3246)

Declared In

`NSView.h`

getRectsExposedDuringLiveResize:count:

Returns a list of rectangles indicating the newly exposed areas of the receiver.

```
- (void)getRectsExposedDuringLiveResize:(NSRect)exposedRects
    count:(NSInteger *)count
```

Parameters

exposedRects

On return, contains the list of rectangles. The returned rectangles are in the coordinate space of the receiver.

count

Contains the number of rectangles in *exposedRects*; this value may be 0 and is guaranteed to be no more than 4.

Discussion

If your view does not support content preservation during live resizing, the entire area of your view is returned in the *exposedRects* parameter. To support content preservation, override `preservesContentDuringLiveResize` (page 3196) in your view and have your implementation return `YES`.

Note: The window containing your view must also support content preservation. To enable support for this feature in your window, use the `setPreservesContentDuringLiveResize:` (page 3393) method of `NSWindow`.

If the view decreased in both height and width, the list of returned rectangles will be empty. If the view increased in both height and width and its upper-left corner stayed anchored in the same position, the list of returned rectangles will contain a vertical and horizontal component indicating the exposed area.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `preservesContentDuringLiveResize` (page 3196)
- `rectPreservedDuringLiveResize` (page 3199)

Declared In
`NSView.h`

gState

Returns the identifier for the receiver's graphics state object, or 0 if the receiver doesn't have a graphics state object.

```
- (NSInteger)gState
```

Discussion
A view object's graphics state object is recreated from scratch whenever the view is focused, unless the `allocateGState` (page 3146) method has been invoked. So if the receiver hasn't been focused or hasn't received the `allocateGState` (page 3146) message, this method returns 0.

Although applications rarely need to use the value returned by `gState` (page 3178), it can be passed to the few methods that take an object identifier as a parameter.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `allocateGState` (page 3146)
- `setUpGState` (page 3229)
- `renewGState` (page 3205)
- `releaseGState` (page 3201)
- `lockFocus` (page 3187)

Declared In
`NSView.h`

heightAdjustLimit

Returns the fraction (from 0.0 to 1.0) of the page that can be pushed onto the next page during automatic pagination to prevent items such as lines of text from being divided across pages.

```
- (CGFloat)heightAdjustLimit
```

Discussion
This fraction is used to calculate the bottom edge limit for an `adjustPageHeightNew:top:bottom:limit:` (page 3143) message.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- widthAdjustLimit` (page 3247)

Declared In
`NSView.h`

hitTest:

Returns the farthest descendant of the receiver in the view hierarchy (including itself) that contains a specified point, or `nil` if that point lies completely outside the receiver.

```
- (NSView *)hitTest:(NSPoint)aPoint
```

Parameters

aPoint

A point that is in the coordinate system of the receiver's superview, not of the receiver itself.

Return Value
A view object that is the farthest descendent of *aPoint*.

Discussion
This method is used primarily by an `NSWindow` object to determine which view should receive a mouse-down event. You'd rarely need to invoke this method, but you might want to override it to have a view object hide mouse-down events from its subviews. This method ignores hidden views.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- mouse:inRect:` (page 3189)
`- convertPoint:toView:` (page 3155)
`- setHidden:` (page 3222)

TargetGallery

Declared In
`NSView.h`

initWithFrame:

Initializes and returns a newly allocated `NSView` object with a specified frame rectangle.

```
- (id)initWithFrame:(NSRect)frameRect
```

Parameters

frameRect

The frame rectangle for the created view object.

Return Value

An initialized `NSView` object or nil if the object couldn't be created.

Discussion

The new view object must be inserted into the view hierarchy of a window before it can be used. This method is the designated initializer for the `NSView` class. Returns an initialized object.

Availability

Available in Mac OS X v10.0 and later.

Rulers

Declared In

`NSView.h`

inLiveResize

A convenience method, expected to be called from `drawRect:` (page 3170), to assist in decisions about optimized drawing.

```
- (BOOL)inLiveResize
```

Return Value

`YES` if the receiver is in a live-resize operation, `NO` otherwise.

Availability

Available in Mac OS X v10.1 and later.

See Also

- `viewDidEndLiveResize` (page 3240)
- `viewWillStartLiveResize` (page 3244)

Related Sample Code

Cocoa OpenGL

MatrixMixerTest

WhackedTV

Declared In

`NSView.h`

inputContext

Returns the text input context object for the receiver.

```
- (NSTextInputContext *)inputContext
```

Return Value
The text input context object, or `nil` the receiver doesn't conform to `NSTextInputClient` protocol.

Availability
Available in Mac OS X v10.6 and later.

Related Sample Code
TextInputView

Declared In
`NSView.h`

isDescendantOf:

Returns `YES` if the receiver is a subview of a given view or if it's identical to that view; otherwise, it returns `NO`.

```
- (BOOL)isDescendantOf:(NSView *)aView
```

Parameters

aView
The view to test for subview relationship within the view hierarchy.

Discussion
The method returns `YES` if the receiver is either an immediate or distant subview of `aView`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `superview` (page 3235)
- `subviews` (page 3235)
- `ancestorSharedWithView:` (page 3147)

Declared In
`NSView.h`

isFlipped

Returns `YES` if the receiver uses flipped drawing coordinates or `NO` if it uses native coordinates.

```
- (BOOL)isFlipped
```

Discussion
The default implementation returns `NO`; subclasses that use flipped coordinates should override this method to return `YES`.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
ImageMap
ImageMapExample
Quartz Composer WWDC 2005 TextEdit
Rulers
Sketch-112

Declared In
`NSView.h`

isHidden

Returns whether the receiver is marked as hidden.

```
- (BOOL)isHidden
```

Discussion
The return value reflects the state of the receiver only, as set in Interface Builder or through the most recent `setHidden:` (page 3222) message, and does not account for the state of the receiver's ancestors in the view hierarchy, Thus this method returns `NO` when the receiver is effectively hidden because it has a hidden ancestor. See `setHidden:` for a discussion of the mechanics and implications of hidden views.

If you want to determine whether a view is effectively hidden, for whatever reason, send the `isHiddenOrHasHiddenAncestor` (page 3182) to the view instead.

Availability
Available in Mac OS X v10.3 and later.

Related Sample Code
GLSLShowpiece

Declared In
`NSView.h`

isHiddenOrHasHiddenAncestor

Returns `YES` if the receiver is marked as hidden or has an ancestor in the view hierarchy that is marked as hidden; returns `NO` otherwise.

```
- (BOOL)isHiddenOrHasHiddenAncestor
```

Discussion
The return value reflects state set through the `setHidden:` (page 3222) method in the receiver of one of its ancestors in the view hierarchy. It does not account for other reasons why a view might be considered hidden, such as being positioned outside its superview's bounds, not having a window, or residing in a window that is offscreen or overlapped by another window.

Availability
Available in Mac OS X v10.3 and later.

See Also
- `isHidden` (page 3182)

Declared In
`NSView.h`

isInFullScreenMode

Returns whether the view is in full screen mode.

```
- (BOOL)isInFullScreenMode
```

Return Value
`YES` if the receiver is in full screen mode, otherwise `NO`.

Availability
Available in Mac OS X v10.5 and later.

See Also
- `enterFullScreenMode:withOptions:` (page 3173)
- `exitFullScreenModeWithOptions:` (page 3174)

Related Sample Code

From A View to A Movie
GeekGameBoard
OpenCL NBody Simulation Example
QTCoreVideo201

Declared In
`NSView.h`

isOpaque

Overridden by subclasses to return `YES` if the receiver is opaque, `NO` otherwise.

```
- (BOOL)isOpaque
```

Discussion
A view object is opaque if it completely covers its frame rectangle when drawing itself. The default implementation performs no drawing at all and so returns `NO`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `opaqueAncestor` (page 3193)
- `displayRectIgnoringOpacity:` (page 3166)
- `displayIfNeededIgnoringOpacity` (page 3165)
- `displayIfNeededInRectIgnoringOpacity:` (page 3165)

Related Sample Code
ImageApp
Quartz Composer WWDC 2005 TextEdit
Sketch+Accessibility
Sketch-112
WhackedTV

Declared In
`NSView.h`

isRotatedFromBase

Returns `YES` if the receiver or any of its ancestors has ever received a `setFrameRotation:` (page 3221) or `setBoundsRotation:` (page 3215) message; otherwise returns `NO`.

```
- (BOOL)isRotatedFromBase
```

Discussion
The intent of this information is to optimize drawing and coordinate calculation, not necessarily to reflect the exact state of the receiver's coordinate system, so it may not reflect the actual rotation. For example, if an `NSView` object is rotated to 45 degrees and later back to 0, this method still returns `YES`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `frameRotation` (page 3176)
- `boundsRotation` (page 3151)

Declared In
`NSView.h`

isRotatedOrScaledFromBase

Returns `YES` if the receiver or any of its ancestors has ever had a nonzero frame or bounds rotation, or has been scaled from the window's base coordinate system; otherwise returns `NO`.

```
- (BOOL)isRotatedOrScaledFromBase
```

Discussion
The intent of this information is to optimize drawing and coordinate calculation, not necessarily to reflect the exact state of the receiver's coordinate system, so it may not reflect the actual rotation or scaling. For example, if an `NSView` object is rotated to 45 degrees and later back to 0, this method still returns `YES`.

Availability
Available in Mac OS X v10.0 and later.

See Also

- scaleUnitSquareToSize: (page 3208)

Declared In
NSView.h

knowsPageRange:

Returns YES if the receiver handles page boundaries, NO otherwise.

```
- (BOOL)knowsPageRange:(NSRangePointer)aRange
```

Parameters

aRange

On return, holds the page range if YES is returned directly. Page numbers are one-based—that is pages run from one to *N*.

Discussion
Returns NO if the receiver uses the default auto-pagination mechanism. The default implementation returns NO. Override this method if your class handles page boundaries.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSView.h

layer

Returns the Core Animation layer that the receiver uses as its backing store.

```
- (CALayer *)layer
```

Return Value
The Core Animation layer the receiver is using as its backing store.

Availability
Available in Mac OS X v10.5 and later.

Related Sample Code
AnimatedTableView
CALayerEssentials
FunHouse
GeekGameBoard
Quartz2DBasics

Declared In
NSView.h

layerContentsPlacement

Returns the current layer contents placement policy.

```
- (NSViewLayerContentsPlacement)layerContentsPlacement
```

Return Value
The placement policy. See "NSViewLayerContentsPlacement" (page 3253) for supported values.

Availability
Available in Mac OS X v10.6 and later.

See Also
`- setLayerContentsPlacement:` (page 3223)

Declared In
`NSView.h`

layerContentsRedrawPolicy

Returns the view's layer contents redraw policy.

```
- (NSViewLayerContentsRedrawPolicy)layerContentsRedrawPolicy
```

Return Value
The current redraw policy. See "NSViewLayerContentsRedrawPolicy" (page 3252) for supported values.

Discussion
The `layerContentsRedrawPolicy` (page 3186) and `layerContentsPlacement` (page 3186) settings can have significant impacts on performance. See `setLayerContentsRedrawPolicy:` (page 3224) and `setLayerContentsPlacement:` (page 3223) for more information.

Availability
Available in Mac OS X v10.6 and later.

See Also
`- setLayerContentsRedrawPolicy:` (page 3224)

Declared In
`NSView.h`

locationOfPrintRect:

Invoked by `print:` (page 3198) to determine the location of the region of the receiver being printed on the physical page.

```
- (NSPoint)locationOfPrintRect:(NSRect)aRect
```

Parameters

aRect

A rectangle defining a region of the receiver; it is expressed in the default coordinate system of the page.

Return Value
A point to be used for setting the origin for *aRect*, whose size the receiver can examine in order to properly place it. It is expressed in the default coordinate system of the page.

Discussion
The default implementation places *aRect* according to the status of the `NSPrintInfo` object for the print job. By default it places the image in the upper-left corner of the page, but if the `NSPrintInfo` methods `isHorizontallyCentered` (page 2051) or `isVerticallyCentered` (page 2052) return `YES`, it centers a single-page image along the appropriate axis. A multiple-page document, however, is always placed so the divided pieces can be assembled at their edges.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSView.h`

lockFocus

Locks the focus on the receiver, so subsequent commands take effect in the receiver's window and coordinate system.

```
- (void)lockFocus
```

Discussion
If you don't use a `display...` method to draw an `NSView` object, you must invoke `lockFocus` before invoking methods that send commands to the window server, and must balance it with an `unlockFocus` (page 3239) message when finished.

Hiding or miniaturizing a one-shot window causes the backing store for that window to be released. If you don't use the standard display mechanism to draw, you should use `lockFocusIfCanDraw` (page 3188) rather than `lockFocus` if there is a chance of drawing while the window is either miniaturized or hidden.

Availability
Available in Mac OS X v10.0 and later.

See Also
`+ focusView` (page 3137)
`- display` (page 3163)
`- drawRect:` (page 3170)
`- lockFocusIfCanDraw` (page 3188)

GLUT
QTKitFrameStepper
VideoViewer

Declared In
`NSView.h`

lockFocusIfCanDraw

Locks the focus to the receiver atomically if the `canDraw` method returns `YES` and returns the value of `canDraw`.

```
- (BOOL)lockFocusIfCanDraw
```

Discussion
Your thread will not be preempted by other threads between the `canDraw` method and the lock. This method fails to lock focus and returns `NO`, when the receiver is hidden and the current context is drawing to the screen (as opposed to a printing context).

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
GLUT
VideoViewer

Declared In
`NSView.h`

lockFocusIfCanDrawInContext:

Locks the focus to the receiver atomically if drawing can occur in the specified graphics context.

```
- (BOOL)lockFocusIfCanDrawInContext:(NSGraphicsContext *)context
```

Parameters
context
The graphics context in which drawing might occur. See the discussion for the implications of the type of context.

Return Value
`YES` if successful; otherwise, returns `NO`.

Discussion
Your thread will not be preempted by other threads between the `canDraw` method and the lock.

If the *context* parameter represents the context for the window containing the view, then all of the necessary transformations are applied. This includes the application of the receiver's bounds and frame transforms along with any transforms it inherited from its ancestors. If *context* specifies any other graphics context, then only the receiver's bounds transform is applied.

Special Considerations

Important: This method was declared in Mac OS X v10.4, but is not used in that release. It currently does nothing and returns `NO`. However, it might be implemented in a future release.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `lockFocus` (page 3187)

- lockFocusIfCanDraw (page 3188)

Declared In
NSView.h

makeBackingLayer

Creates the view's backing layer.

```
- (CALayer *)makeBackingLayer
```

Return Value
A layer to use as the view's backing layer.

Availability
Available in Mac OS X v10.6 and later.

Declared In
NSView.h

menuForEvent:

Overridden by subclasses to return a context-sensitive pop-up menu for a given mouse-down event.

```
- (NSMenu *)menuForEvent:(NSEvent *)theEvent
```

Parameters
theEvent
An object representing a mouse-down event.

Discussion
The receiver can use information in the mouse event, such as its location over a particular element of the receiver, to determine what kind of menu to return. For example, a text object might display a text-editing menu when the cursor lies over text and a menu for changing graphics attributes when the cursor lies over an embedded image.

The default implementation returns the receiver's normal menu.

Availability
Available in Mac OS X v10.0 and later.

See Also
+ defaultMenu (page 3137)
menu (page 2163) (NSResponder)

Declared In
NSView.h

mouse:inRect:

Returns whether a region of the receiver contains a specified point, accounting for whether the receiver is flipped or not.

```
- (BOOL)mouse:(NSPoint)aPoint
    inRect:(NSRect)aRect
```

Parameters

aPoint

A point that is expressed in the receiver's coordinate system. This point generally represents the hot spot of the mouse cursor.

aRect

A rectangle that is expressed in the receiver's coordinate system.

Return Value

`YES` if `aRect` contains `aPoint`, `NO` otherwise.

Discussion

Point-in-rectangle functions generally assume that the bottom edge of a rectangle is outside of the rectangle boundaries, while the upper edge is inside the boundaries. This method views *aRect* from the point of view of the user—that is, this method always treats the bottom edge of the rectangle as the one closest to the bottom edge of the user's screen. By making this adjustment, this function ensures consistent mouse-detection behavior from the user's perspective.

Never use the Foundation's `NSPointInRect` function as a substitute for this method. It doesn't account for flipped coordinate systems.

Availability

Available in Mac OS X v10.0 and later.

See Also

`- hitTest:` (page 3179)

`- isFlipped` (page 3181)

`NSMouseInRect` (Foundation functions)

`- convertPoint:fromView:` (page 3155)

Declared In

`NSView.h`

mouseDownCanMoveWindow

Returns `YES` if the receiver does not need to handle a mouse down and can pass it through to superviews; `NO` if it needs to handle the mouse down.

```
- (BOOL)mouseDownCanMoveWindow
```

Discussion

This allows iApp-type applications to determine the region by which a window can be moved. By default, this method returns `NO` if the view is opaque; otherwise, it returns `YES`. Subclasses can override this method to return a different value.

Availability

Available in Mac OS X v10.2 and later.

Related Sample Code

DockTile

SpeedometerView

WebKitPluginStarter
WebKitPluginWithJavaScript

Declared In
NSView.h

needsDisplay

Returns YES if the receiver needs to be displayed, as indicated using setNeedsDisplay: (page 3225) and setNeedsDisplayInRect: (page 3225); returns NO otherwise.

```
- (BOOL)needsDisplay
```

Discussion
The displayIfNeeded... methods check this status to avoid unnecessary drawing, and all display methods clear this status to indicate that the view object is up to date.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSView.h

needsPanelToBecomeKey

Overridden by subclasses to determine if the receiver requires its panel, which might otherwise avoid becoming key, to become the key window so that it can handle keyboard input and navigation.

```
- (BOOL)needsPanelToBecomeKey
```

Return Value
Returns YES if it should be come key, NO otherwise.

Discussion
Such a subclass should also override acceptsFirstResponder (page 2143) to return YES.

This method is also used in keyboard navigation. It determines if a mouse click should give focus to a view (make it first responder). Some views will want to get keyboard focus when you click in them, for example text fields. Other views should only get focus if you tab to them, for example, buttons. You wouldn't want focus to shift from a textfield that has editing in progress simply because you clicked on a check box.

The default implementation returns NO.

Availability
Available in Mac OS X v10.0 and later.

becomesKeyOnlyIfNeeded (page 1860) (NSPanel)

Related Sample Code
ClockControl

Declared In
NSView.h

needsToDrawRect:

Returns whether the specified rectangle intersects any part of the area that the receiver is being asked to draw.

```
- (BOOL)needsToDrawRect:(NSRect)aRect
```

Parameters

aRect

A rectangle defining a region of the receiver.

Discussion
You typically send this message from within a `drawRect:` (page 3170) implementation. It gives you a convenient way to determine whether any part of a given graphical entity might need to be drawn. It is optimized to efficiently reject any rectangle that lies outside the bounding box of the area the receiver is being asked to draw in `drawRect:`.

Availability
Available in Mac OS X v10.3 and later.

Declared In
NSView.h

nextKeyView

Returns the view object following the receiver in the key view loop.

```
- (NSView *)nextKeyView
```

Return Value
Returns the view object following the receiver in the key view loop, or `nil` if there is none.

Discussion
This view should, if possible, be made first responder when the user navigates forward from the receiver using keyboard interface control.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- nextValidKeyView` (page 3193)

Dicey

Declared In
`NSView.h`

opaqueAncestor

Returns the receiver's closest opaque ancestor (including the receiver itself).

```
- (NSView *)opaqueAncestor
```

Availability
Available in Mac OS X v10.0 and later.

See Also
- `isOpaque` (page 3183)

- displayRectIgnoringOpacity: (page 3166)
- displayIfNeededIgnoringOpacity (page 3165)
- displayIfNeededInRectIgnoringOpacity: (page 3165)

Declared In
NSView.h

pageFooter

Returns a default footer string that includes the current page number and page count.

```
- (NSAttributedString *)pageFooter
```

Discussion
A printable view class can override this method to substitute its own content in place of the default value. You should not need to call this method directly. The printing system calls it once per page during printing.

Footers are generated only if the user defaults contain the key `NSPrintHeaderAndFooter` with the value `YES`.

Availability
Available in Mac OS X v10.4 and later.

See Also
- pageHeader (page 3194)

Declared In
NSView.h

pageHeader

Returns a default header string that includes the print job title and date.

```
- (NSAttributedString *)pageHeader
```

Discussion
Typically, the print job title is the same as the window title. A printable view class can override this method to substitute its own content in place of the default value. You should not need to call this method directly. The printing system calls it once per page during printing.

Headers are generated only if the user defaults contain the key `NSPrintHeaderAndFooter` with the value `YES`.

Availability
Available in Mac OS X v10.4 and later.

See Also
- pageFooter (page 3194)

Declared In
NSView.h

performKeyEquivalent:

Implemented by subclasses to respond to key equivalents (also known as keyboard shortcuts).

```
- (BOOL)performKeyEquivalent:(NSEvent *)theEvent
```

Parameters

theEvent

The key-down event object representing a key equivalent.

Return Value

YES if *theEvent* is a key equivalent that the receiver handled, NO if it is not a key equivalent that it should handle.

Discussion

If the receiver's key equivalent is the same as the characters of the key-down event *theEvent*, as returned by charactersIgnoringModifiers (page 1074), the receiver should take the appropriate action and return YES. Otherwise, it should return the result of invoking super's implementation. The default implementation of this method simply passes the message down the view hierarchy (from superviews to subviews) and returns NO if none of the receiver's subviews responds YES.

Availability

Available in Mac OS X v10.0 and later.

See Also

- performMnemonic: (page 3195)

keyDown: (page 3343) (NSWindow)

Declared In

NSView.h

performMnemonic:

Implemented by subclasses to respond to mnemonics.

```
- (BOOL)performMnemonic:(NSString *)aString
```

Parameters

aString

A string representing the mnemonic to handle.

Discussion

If the receiver's mnemonic is the same as the characters of the string *aString*, the receiver should take the appropriate action and return YES. Otherwise, it should return the result of invoking super's implementation. The default implementation of this method simply passes the message down the view hierarchy (from superviews to subviews) and returns NO if none of the receiver's subviews responds YES. Mnemonics are not supported in Mac OS X.

Availability

Available in Mac OS X v10.0 and later.

See Also

- performKeyEquivalent: (page 3195)

keyDown: (page 3343) (NSWindow)

Declared In
NSView.h

postsBoundsChangedNotifications

Returns YES if the receiver posts notifications to the default notification center whenever its bounds rectangle changes; returns NO otherwise.

```
- (BOOL)postsBoundsChangedNotifications
```

Discussion
See setPostsBoundsChangedNotifications: (page 3226) for a list of methods that result in notifications.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSView.h

postsFrameChangedNotifications

Returns YES if the receiver posts notifications to the default notification center whenever its frame rectangle changes; returns NO otherwise.

```
- (BOOL)postsFrameChangedNotifications
```

Discussion
See setPostsBoundsChangedNotifications: (page 3226) for a list of methods that result in notifications.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSView.h

preservesContentDuringLiveResize

Returns YES if the view supports the optimization of live-resize operations by preserving content that has not moved; otherwise, returns NO.

```
- (BOOL)preservesContentDuringLiveResize
```

Discussion
The default is NO. If your view supports the content preservation feature, you should override this method and have your implementation return YES.

Content preservation lets your view decide what to redraw during a live resize operation. If your view supports this feature, you should also provide a custom implementation of setFrameSize: (page 3221) that invalidates the portions of your view that actually need to be redrawn.

For information on how to implement this feature in your views, see *Cocoa Performance Guidelines*.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `setFrameSize:` (page 3221)

Declared In
`NSView.h`

previousKeyView

Returns the view object preceding the receiver in the key view loop.

```
- (NSView *)previousKeyView
```

Return Value
The view object preceding the receiver in the key view loop, or `nil` if there is none.

Discussion
This view should, if possible, be made first responder when the user navigates backward from the receiver using keyboard interface control.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `previousValidKeyView` (page 3197)
- `nextKeyView` (page 3192)
- `nextValidKeyView` (page 3193)

`selectKeyViewFollowingView:` (page 3364) (`NSWindow`)
`selectPreviousKeyView:` (page 3365) (`NSWindow`)
`selectKeyViewPrecedingView:` (page 3364) (`NSWindow`)
- `setHidden:` (page 3222)

Declared In
`NSView.h`

print:

This action method opens the Print panel, and if the user chooses an option other than canceling, prints the receiver and all its subviews to the device specified in the Print panel.

```
- (void)print:(id)sender
```

Parameters
sender
The object that sent the message.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `dataWithEPSInsideRect:` (page 3162)
- `writeEPSInsideRect:toPasteboard:` (page 3248)

Declared In
`NSView.h`

printJobTitle

Returns the receiver's print job title.

```
- (NSString *)printJobTitle
```

Discussion
The default implementation first tries the window's `NSDocument` display name (`displayName` (page 945)), then the window's title.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
ImageApp

Declared In
NSView.h

rectForPage:

Implemented by subclasses to determine the portion of the receiver to be printed for the page number page.

```
- (NSRect)rectForPage:(NSInteger)pageNumber
```

Parameters

pageNumber

An integer indicating a page number. Page numbers are one-based—that is pages run from one to *N*.

Return Value
A rectangle defining the region of the receiver to be printed for *pageNumber*. This method returns NSZeroRect if *pageNumber* is outside the receiver's bounds.

Discussion
If the receiver responded YES to an earlier knowsPageRange: (page 3185) message, this method is invoked for each page it specified in the out parameters of that message. The receiver is later made to display this rectangle in order to generate the image for this page.

If an NSView object responds NO to knowsPageRange: (page 3185), this method isn't invoked by the printing mechanism.

Availability
Available in Mac OS X v10.0 and later.

See Also
- adjustPageHeightNew:top:bottom:limit: (page 3143)
- adjustPageWidthNew:left:right:limit: (page 3144)

Declared In
NSView.h

rectPreservedDuringLiveResize

Returns the rectangle identifying the portion of your view that did not change during a live resize operation.

```
- (NSRect)rectPreservedDuringLiveResize
```

Discussion
The returned rectangle is in the coordinate system of your view and reflects the space your view previously occupied. This rectangle may be smaller or the same size as your view's current bounds, depending on whether the view grew or shrunk.

If your view does not support content preservation during live resizing, the returned rectangle will be empty. To support content preservation, override preservesContentDuringLiveResize (page 3196) in your view and have your implementation return YES.

Note: The window containing your view must also support content preservation. To enable support for this feature in your window, use the `setPreservesContentDuringLiveResize:` (page 3393) method of `NSWindow`.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `getRectsExposedDuringLiveResize:count:` (page 3177)
- `preservesContentDuringLiveResize` (page 3196)

Declared In
`NSView.h`

reflectScrolledClipView:

Notifies a clip view's superview that either the clip view's bounds rectangle or the document view's frame rectangle has changed, and that any indicators of the scroll position need to be adjusted.

```
- (void)reflectScrolledClipView:(NSClipView *)aClipView
```

Parameters
aClipView
The `NSClipView` object whose superview is to be notified.

Discussion
`NSScrollView` implements this method to update its `NSScroller` objects.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSClipView.h`

registeredDraggedTypes

Returns the array of pasteboard drag types that the view can accept.

```
- (NSArray *)registeredDraggedTypes
```

Discussion
This method returns the types registered by calling `registerForDraggedTypes:` (page 3201). Each element of the array is a uniform type identifier. The returned elements are in no particular order, but the array is guaranteed not to contain duplicate entries.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`NSView.h`

registerForDraggedTypes:

Registers the pasteboard types that the receiver will accept as the destination of an image-dragging session.

```
- (void)registerForDraggedTypes:(NSArray *)newTypes
```

Parameters

newTypes

An array of uniform type identifiers. See `Types for Standard Data (Mac OS X 10.6 and later)` (page 1904) for descriptions of the pasteboard type identifiers.

Discussion

Registering an `NSView` object for dragged types automatically makes it a candidate destination object for a dragging session. As such, it must properly implement some or all of the `NSDraggingDestination` protocol methods. As a convenience, `NSView` provides default implementations of these methods. See the `NSDraggingDestination` protocol specification for details.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `registeredDraggedTypes` (page 3200)
- `unregisterDraggedTypes` (page 3239)

Related Sample Code

CocoaDragAndDrop

CompositeLab

Declared In

`NSView.h`

releaseGState

Frees the receiver's graphics state object, if it has one.

```
- (void)releaseGState
```

Availability

Available in Mac OS X v10.0 and later.

See Also

- `allocateGState` (page 3146)

Declared In

`NSView.h`

removeAllToolTips

Removes all tool tips assigned to the receiver.

```
- (void)removeAllToolTips
```

Discussion
This method operates on tool tips created using either `addToolTipRect:owner:userData:` (page 3141) or `setToolTip:` (page 3229).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSView.h`

removeCursorRect:cursor:

Completely removes a cursor rectangle from the receiver.

```
- (void)removeCursorRect:(NSRect)aRect
    cursor:(NSCursor *)aCursor
```

Parameters

aRect

A rectangle defining a region of the receiver. Must match a value previously specified using `addCursorRect:cursor:` (page 3139).

aCursor

An object representing a cursor. Must match a value previously specified using `addCursorRect:cursor:` (page 3139).

Discussion
You should rarely need to use this method. `resetCursorRects` (page 3206), which is invoked any time cursor rectangles need to be rebuilt, should establish only the cursor rectangles needed. If you implement `resetCursorRects` (page 3206) in this way, you can then simply modify the state that `resetCursorRects` (page 3206) uses to build its cursor rectangles and then invoke the `NSWindow` method `invalidateCursorRectsForView:` (page 3335).

Availability
Available in Mac OS X v10.0 and later.

See Also
`- discardCursorRects` (page 3163)

Declared In
`NSView.h`

removeFromSuperview

Unlinks the receiver from its superview and its window, removes it from the responder chain, and invalidates its cursor rectangles.

```
- (void)removeFromSuperview
```

Discussion
The receiver is also released; if you plan to reuse it, be sure to retain it before sending this message and to release it as appropriate when adding it as a subview of another `NSView`.

Never invoke this method during display.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `addSubview:` (page 3139)
- `addSubview:positioned:relativeTo:` (page 3140)
- `removeFromSuperviewWithoutNeedingDisplay` (page 3203)

Related Sample Code

Sketch-112
SourceView

Declared In
`NSView.h`

removeFromSuperviewWithoutNeedingDisplay

Unlinks the receiver from its superview and its window and removes it from the responder chain, but does not invalidate its cursor rectangles to cause redrawing.

```
- (void)removeFromSuperviewWithoutNeedingDisplay
```

Discussion
The receiver is also released; if you plan to reuse it, be sure to retain it before sending this message and to release it as appropriate when adding it as a subview of another view.

Unlike its counterpart, `removeFromSuperview` (page 3202), this method can be safely invoked during display.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `addSubview:` (page 3139)
- `addSubview:positioned:relativeTo:` (page 3140)

Related Sample Code
CoreRecipes

Declared In
`NSView.h`

removeToolTip:

Removes the tool tip identified by specified tag.

```
- (void)removeToolTip:(NSToolTipTag)tag
```

Parameters

tag

An integer tag that is the value returned by a previous `addToolTipRect:owner:userData:` (page 3141) message.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSView.h`

removeTrackingArea:

Removes a given tracking area from the receiver.

```
- (void)removeTrackingArea:(NSTrackingArea *)trackingArea
```

Parameters

trackingArea

The tracking area to remove from the receiver.

Availability
Available in Mac OS X v10.5 and later.

Related Sample Code
TrackIt

Declared In
`NSView.h`

removeTrackingRect:

Removes the tracking rectangle identified by a tag.

```
- (void)removeTrackingRect:(NSTrackingRectTag)aTag
```

Parameters

aTag

An integer value identifying a tracking rectangle. It was returned by a previously sent `addTrackingRect:owner:userData:assumeInside:` (page 3142) message.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `addTrackingRect:owner:userData:assumeInside:` (page 3142)

Declared In
NSView.h

renewGState

Invalidates the receiver's graphics state object, if it has one.

```
- (void)renewGState
```

Discussion
The receiver's graphics state object will be regenerated using `setUpGState` (page 3229) the next time the receiver is focused for drawing

Availability
Available in Mac OS X v10.0 and later.

See Also
- `lockFocus` (page 3187)

Related Sample Code
GLSLShowpiece
VideoViewer

Declared In
NSView.h

replaceSubview:with:

Replaces one of the receiver's subviews with another view.

```
- (void)replaceSubview:(NSView *)oldView
    with:(NSView *)newView
```

Parameters
oldView
The view to be replaced by `newView`. May not be `nil`.

newView
The view to replace `oldView`. May not be `nil`.

Discussion
This method does nothing if *oldView* is not a subview of the receiver.

Neither *oldView* nor *newView* may be `nil`, and the behavior is undefined if either of these parameters is `nil`.

This method causes *oldView* to be released; if you plan to reuse it, be sure to retain it before sending this message and to release it as appropriate when adding it as a subview of another NSView.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `addSubview:` (page 3139)

`- addSubview:positioned:relativeTo:` (page 3140)

Related Sample Code
BasicCocoaAnimations
CocoaSlides

Declared In
`NSView.h`

resetCursorRects

Overridden by subclasses to define their default cursor rectangles.

```
- (void)resetCursorRects
```

Discussion
A subclass's implementation must invoke `addCursorRect:cursor:` (page 3139) for each cursor rectangle it wants to establish. The default implementation does nothing.

Application code should never invoke this method directly; it's invoked automatically as described in ""Responding to User Events and Actions" in *View Programming Guide*." Use the `invalidateCursorRectsForView:` (page 3335) method instead to explicitly rebuild cursor rectangles.

Availability
Available in Mac OS X v10.0 and later.

`- visibleRect` (page 3245)

Related Sample Code
GeekGameBoard
GLUT
TextLinks

Declared In
`NSView.h`

resizeSubviewsWithOldSize:

Informs the receiver's subviews that the receiver's bounds rectangle size has changed.

```
- (void)resizeSubviewsWithOldSize:(NSSize)oldBoundsSize
```

Parameters
oldBoundsSize
The previous size of the receiver's bounds rectangle.

Discussion
If the receiver is configured to autoresize its subviews, this method is automatically invoked by any method that changes the receiver's frame size.

The default implementation sends `resizeWithOldSuperviewSize:` (page 3207) to the receiver's subviews with *oldBoundsSize* as the argument. You shouldn't invoke this method directly, but you can override it to define a specific retiling behavior.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setAutoresizesSubviews:` (page 3212)

Declared In
`NSView.h`

resizeWithOldSuperviewSize:

Informs the receiver that the bounds size of its superview has changed.

```
- (void)resizeWithOldSuperviewSize:(NSSize)oldBoundsSize
```

Parameters

oldBoundsSize
The previous size of the superview's bounds rectangle.

Discussion
This method is normally invoked automatically from `resizeSubviewsWithOldSize:` (page 3206).

The default implementation resizes the receiver according to the autoresizing options listed under the `setAutoresizingMask:` (page 3212) method description. You shouldn't invoke this method directly, but you can override it to define a specific resizing behavior.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSView.h`

rightMouseDown:

Informs the receiver that the user has pressed the right mouse button.

```
- (void)rightMouseDown:(NSEvent *)theEvent
```

Parameters

theEvent
An object encapsulating information about the mouse-down event.

Discussion
The default implementation calls `menuForEvent:` (page 3189) and, if non `nil`, presents the contextual menu.

This behavior differs from other mouse events as the event is not passed up the responder chain.

See Also
- `rightMouseDown:` (page 2189) (NSResponder)

rotateByAngle:

Rotates the receiver's bounds rectangle by a specified degree value around the origin of the coordinate system, (0.0, 0.0).

```
- (void)rotateByAngle:(CGFloat)angle
```

Parameters

angle

A `float` value specifying the angle of rotation, in degrees.

Discussion

See the `setBoundsRotation:` (page 3215) method description for more information. This method neither redisplays the receiver nor marks it as needing display. You must do this yourself with `display` (page 3163) or `setNeedsDisplay:` (page 3225).

This method posts an `NSViewBoundsDidChangeNotification` (page 3256) to the default notification center if the receiver is configured to do so.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `setFrameRotation:` (page 3221)
- `setPostsBoundsChangedNotifications:` (page 3226)

Declared In

`NSView.h`

scaleUnitSquareToSize:

Scales the receiver's coordinate system so that the unit square scales to the specified dimensions.

```
- (void)scaleUnitSquareToSize:(NSSize)newUnitSize
```

Parameters

newUnitSize

An `NSSize` structure specifying the new unit size.

Discussion

For example, a *newUnitSize* of (0.5, 1.0) causes the receiver's horizontal coordinates to be halved, in turn doubling the width of its bounds rectangle. Note that scaling is performed from the origin of the coordinate system, (0.0, 0.0), not the origin of the bounds rectangle; as a result, both the origin and size of the bounds rectangle are changed. The frame rectangle remains unchanged.

This method neither redisplays the receiver nor marks it as needing display. You must do this yourself with `display` (page 3163) or `setNeedsDisplay:` (page 3225).

This method posts an `NSViewBoundsDidChangeNotification` (page 3256) to the default notification center if the receiver is configured to do so.

Availability

Available in Mac OS X v10.0 and later.

See Also
- `setBoundsSize:` (page 3216)
- `setPostsBoundsChangedNotifications:` (page 3226)

Declared In
`NSView.h`

scrollClipView:toPoint:

Notifies the superview of a clip view that the clip view needs to reset the origin of its bounds rectangle.

```
- (void)scrollClipView:(NSClipView *)aClipView
    toPoint:(NSPoint)newOrigin
```

Parameters

aClipView
The `NSClipView` object whose superview is to be notified.

newOrigin
A point that specifies the new origin of the clip view's bounds rectangle.

Discussion
The superview of *aClipView* should then send a `scrollToPoint:` (page 635) message to *aClipView* with *newOrigin* as the argument. This mechanism is provided so the `NSClipView` object's superview can coordinate scrolling of multiple tiled clip views.

Availability
Available in Mac OS X v10.0 and later.

See Also
`scrollToPoint:` (page 635) (NSClipView)

Declared In
`NSClipView.h`

scrollPoint:

Scrolls the receiver's closest ancestor `NSClipView` object so a point in the receiver lies at the origin of the clip view's bounds rectangle.

```
- (void)scrollPoint:(NSPoint)aPoint
```

Parameters

aPoint
The point in the receiver to scroll to.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `autoscroll:` (page 3148)

`scrollToPoint:` (page 635) (`NSClipView`)
- `isDescendantOf:` (page 3181)

Related Sample Code
GLUT

Declared In
`NSView.h`

scrollRect:by:

Copies the visible portion of the receiver's rendered image within a region and lays that portion down again at a specified offset .

```
- (void)scrollRect:(NSRect)aRect
    by:(NSSize)offset
```

Parameters

aRect

A rectangle defining a region of the receiver.

offset

A `NSSize` structure that specifies an offset from from *aRect*'s origin.

Discussion
This method is useful during scrolling or translation of the coordinate system to efficiently move as much of the receiver's rendered image as possible without requiring it to be redrawn, following these steps:

1. Invoke `scrollRect:by:` (page 3210) to copy the rendered image.
2. Move the view object's origin or scroll it within its superview.
3. Calculate the newly exposed rectangles and invoke either `setNeedsDisplay:` (page 3225) or `setNeedsDisplayInRect:` (page 3225) to draw them.

You should rarely need to use this method, however. The `scrollPoint:` (page 3209), `scrollRectToVisible:` (page 3210), and `autoscroll:` (page 3148) methods automatically perform optimized scrolling.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setBoundsOrigin:` (page 3214)
- `translateOriginToPoint:` (page 3237)

Declared In
`NSView.h`

scrollRectToVisible:

Scrolls the receiver's closest ancestor `NSClipView` object the minimum distance needed so a specified region of the receiver becomes visible in the clip view.

```
- (BOOL)scrollRectToVisible:(NSRect)aRect
```

Parameters

aRect

The rectangle to be made visible in the clip view.

Discussion

YES if any scrolling is performed; otherwise returns NO.

Availability

Available in Mac OS X v10.0 and later.

See Also

- autoscroll: (page 3148)
scrollToPoint: (page 635) (NSClipView)
- isDescendantOf: (page 3181)

Quartz Composer WWDC 2005 TextEdit

Declared In

NSView.h

setAcceptsTouchEvents:

Sets whether the view should accept touch events.

```
- (void)setAcceptsTouchEvents:(BOOL)flag
```

Parameters

flag

YES if the view should accept touch events, otherwise NO.

Discussion

By default views do not accept touch events.

Availability

Available in Mac OS X v10.6 and later.

See Also

- acceptsTouchEvents (page 3138)

Declared In

NSView.h

setAlphaValue:

Sets the opacity of the receiver.

```
- (void)setAlphaValue:(CGFloat)viewAlpha
```

Parameters

viewAlpha

The desired opacity of the receiver.

Discussion
This method sets the value of the `opacity` property of the receiver's layer. Possible values are between 0.0 (transparent) and 1.0 (opaque). The default is 1.0.

Sending this message to a view that is not managing a Core Animation layer causes an exception.

Availability
Available in Mac OS X v10.5 and later.

Related Sample Code
LayerBackedOpenGLView

Declared In
`NSView.h`

setAutoresizesSubviews:

Determines whether the receiver automatically resizes its subviews when its frame size changes.

```
- (void)setAutoresizesSubviews:(BOOL)flag
```

Parameters

flag

If `YES`, the receiver invokes `resizeSubviewsWithOldSize:` (page 3206) whenever its frame size changes; if `NO`, it doesn't.

Discussion
View objects do autoresize their subviews by default.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- autoresizesSubviews` (page 3147)

Related Sample Code
FunHouse
GLUT
Sproing
TextSizingExample

Declared In
`NSView.h`

setAutoresizingMask:

Determines how the receiver's `resizeWithOldSuperviewSize:` (page 3207) method changes its frame rectangle.

```
- (void)setAutoresizingMask:(NSUInteger)mask
```

Parameters

mask

An integer bit mask. *mask* can be specified by combining using the C bitwise OR operator any of the options described in "Resizing masks" (page 3250).

Discussion

Where more than one option along an axis is set, `resizeWithOldSuperviewSize:` (page 3207) by default distributes the size difference as evenly as possible among the flexible portions. For example, if `NSViewWidthSizable` and `NSViewMaxXMargin` are set and the superview's width has increased by 10.0 units, the receiver's frame and right margin are each widened by 5.0 units.

Availability

Available in Mac OS X v10.0 and later.

setBackgroundFilters:

An array of CoreImage filters that are applied to the receiver's background.

```
- (void)setBackgroundFilters:(NSArray *)filters
```

Parameters

filters

An array of CoreImage filters.

Discussion

This method sets the value of the `backgroundFilters` property of the receiver's layer.

Sending this message to a view that is not managing a Core Animation layer causes an exception.

Availability

Available in Mac OS X v10.5 and later.

Related Sample Code

LayerBackedOpenGLView

Declared In

`NSView.h`

setBounds:

Sets the receiver's bounds rectangle.

```
- (void)setBounds:(NSRect)boundsRect
```

Parameters

boundsRect

A rectangle defining the new bounds of the receiver.

Discussion

The bounds rectangle determines the origin and scale of the receiver's coordinate system within its frame rectangle. This method neither redisplays the receiver nor marks it as needing display. You must do this yourself with `display` (page 3163) or `setNeedsDisplay:` (page 3225).

This method posts an `NSViewBoundsDidChangeNotification` (page 3256) to the default notification center if the receiver is configured to do so.

After calling this method, `NSView` creates an internal transform (or appends these changes to an existing internal transform) to convert from frame coordinates to bounds coordinates in your view. As long as the width-to-height ratio of the two coordinate systems remains the same, your content appears normal. If the ratios differ, your content may appear skewed.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `bounds` (page 3150)
- `setBoundsRotation:` (page 3215)

CIAnnotation

Declared In

`NSView.h`

setBoundsOrigin:

Sets the origin of the receiver's bounds rectangle to a specified point,

```
- (void)setBoundsOrigin:(NSPoint)newOrigin
```

Parameters

newOrigin

A point specifying the new bounds origin of the receiver.

Discussion

In setting the new bounds origin, this method effectively shifts the receiver's coordinate system so *newOrigin* lies at the origin of the receiver's frame rectangle. It neither redisplays the receiver nor marks it as needing display. You must do this yourself with `display` or `setNeedsDisplay:` (page 3225).

This method posts an `NSViewBoundsDidChangeNotification` (page 3256) to the default notification center if the receiver is configured to do so.

After calling this method, `NSView` creates an internal transform (or appends these changes to an existing internal transform) to convert from frame coordinates to bounds coordinates in your view. As long as the width-to-height ratio of the two coordinate systems remains the same, your content appears normal. If the ratios differ, your content may appear skewed.

Availability
Available in Mac OS X v10.0 and later.

Rulers

Declared In
`NSView.h`

setBoundsRotation:

Sets the rotation of the receiver's bounds rectangle to a specific degree value.

```
- (void)setBoundsRotation:(CGFloat)angle
```

Parameters

angle
A `float` value specifying the angle of rotation, in degrees.

Discussion
Positive values indicate counterclockwise rotation, negative clockwise. Rotation is performed around the coordinate system origin, (0.0, 0.0), which need not coincide with that of the frame rectangle or the bounds rectangle. This method neither redisplays the receiver nor marks it as needing display. You must do this yourself with `display` (page 3163) or `setNeedsDisplay:` (page 3225).

This method posts an `NSViewBoundsDidChangeNotification` (page 3256) to the default notification center if the receiver is configured to do so.

Bounds rotation affects the orientation of the drawing within the view object's frame rectangle, but not the orientation of the frame rectangle itself. Also, for a rotated bounds rectangle to enclose all the visible areas of its view object—that is, to guarantee coverage over the frame rectangle—it must also contain some areas that aren't visible. This can cause unnecessary drawing to be requested, which may affect performance. It may be better in many cases to rotate the coordinate system in the `drawRect:` (page 3170) method rather than use this method.

After calling this method, NSView creates an internal transform (or appends these changes to an existing internal transform) to convert from frame coordinates to bounds coordinates in your view. As long as the width-to-height ratio of the two coordinate systems remains the same, your content appears normal. If the ratios differ, your content may appear skewed.

Availability
Available in Mac OS X v10.0 and later.

TrackIt

Declared In
NSView.h

setBoundsSize:

Sets the size of the receiver's bounds rectangle to specified dimensions, inversely scaling its coordinate system relative to its frame rectangle.

```
- (void)setBoundsSize:(NSSize)newSize
```

Parameters

newSize
An NSSize structure specifying the new width and height of the receiver's bounds rectangle.

Discussion
For example, a view object with a frame size of (100.0, 100.0) and a bounds size of (200.0, 100.0) draws half as wide along the x axis. This method neither redisplays the receiver nor marks it as needing display. You must do this yourself with display (page 3163) or setNeedsDisplay: (page 3225).

This method posts an NSViewBoundsDidChangeNotification (page 3256) to the default notification center if the receiver is configured to do so.

After calling this method, NSView creates an internal transform (or appends these changes to an existing internal transform) to convert from frame coordinates to bounds coordinates in your view. As long as the width-to-height ratio of the two coordinate systems remains the same, your content appears normal. If the ratios differ, your content may appear skewed.

Declared In
`NSView.h`

setCanDrawConcurrently:

Sets whether the view's `drawRect:` method can be invoked on a background thread.

```
- (void)setCanDrawConcurrently:(BOOL)flag
```

Parameters

flag

`YES` if `drawRect:` (page 3170) can be invoked from a background thread, otherwise `NO`. The default is `NO` for most types of views..

Discussion
The view's window must also have its `allowsConcurrentViewDrawing` (page 3298) property set to `YES` (the default) for threading of view drawing to actually take place.

Availability
Available in Mac OS X v10.6 and later.

See Also
`- setCanDrawConcurrently:` (page 3217)
`allowsConcurrentViewDrawing` (page 3298) (NSWindow)

Declared In
`NSView.h`

setCompositingFilter:

Sets a CoreImage filter that is used to composite the receiver's contents with the background.

```
- (void)setCompositingFilter:(CIFilter *)filter
```

Parameters

filter

A CoreImage filter.

Discussion
This method sets the value of the `compositingFilter` (page 3154) property of the receiver's layer.

Sending this message to a view that is not managing a Core Animation layer causes an exception.

Availability
Available in Mac OS X v10.5 and later.

Declared In
NSView.h

setContentFilters:

Sets the array of CoreImage filters that are applied to the contents of the receiver and its sublayers.

```
- (void)setContentFilters:(NSArray *)filters
```

Parameters

filters

An array of CoreImage filters.

Discussion
This method sets the value of the `filters` property of the receiver's layer.

Sending this message to a view that is not managing a Core Animation layer causes an exception.

Availability
Available in Mac OS X v10.5 and later.

Declared In
NSView.h

setFocusRingType:

Sets the type of focus ring to be drawn around the receiver.

```
- (void)setFocusRingType:(NSFocusRingType)focusRingType
```

Parameters

focusRingType

An `enum` constant identifying a type of focus ring. Possible values are listed in `NSFocusRingType` (page 4009). You can specify `NSFocusRingTypeNone` to indicate you do not want your view to have a focus ring.

Discussion
This method only sets the desired focus ring type and does not cause the view to draw the actual focus ring. You are responsible for drawing the focus ring in your view's drawRect: (page 3170) method whenever your view is made the first responder.

Availability
Available in Mac OS X v10.3 and later.

See Also
- `focusRingType` (page 3175)

Declared In
NSView.h

setFrame:

Sets the receiver's frame rectangle to the specified rectangle.

```
- (void)setFrame:(NSRect)frameRect
```

Parameters

frameRect

The new frame rectangle for the view.

Discussion

This method, in setting the frame rectangle, repositions and resizes the receiver within the coordinate system of its superview. It neither redisplays the receiver nor marks it as needing display. You must do this yourself with `display` (page 3163) or `setNeedsDisplay:` (page 3225).

This method posts an `NSViewFrameDidChangeNotification` (page 3257) to the default notification center if the receiver is configured to do so.

If your view does not use a custom bounds rectangle, this method also sets your view bounds to match the size of the new frame. You specify a custom bounds rectangle by calling `setBounds:` (page 3214), `setBoundsOrigin:` (page 3214), `setBoundsRotation:` (page 3215), or `setBoundsSize:` (page 3216)explicitly. Once set, NSView creates an internal transform to convert from frame coordinates to bounds coordinates. As long as the width-to-height ratio of the two coordinate systems remains the same, your content appears normal. If the ratios differ, your content may appear skewed.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `frame` (page 3175)
- `setFrameRotation:` (page 3221)
- `setFrameOrigin:` (page 3220)

Declared In

`NSView.h`

setFrameCenterRotation:

Rotates the frame of the receiver about the layer's position.

```
- (void)setFrameCenterRotation:(CGFloat)angle
```

Parameters

angle

The angle to rotate the frame around the center of the receiver.

Discussion
If the application has altered the layer's `anchorPoint` property, the behavior is undefined. Sending this message to a view that is not managing a Core Animation layer causes an exception.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSView.h`

setFrameOrigin:

Sets the origin of the receiver's frame rectangle to the specified point, effectively repositioning it within its superview.

```
- (void)setFrameOrigin:(NSPoint)newOrigin
```

Parameters

newOrigin
The point that is the new origin of the receiver's frame.

Discussion
This method neither redisplays the receiver nor marks it as needing display. You must do this yourself with `display` (page 3163) or `setNeedsDisplay:` (page 3225).

This method posts an `NSViewFrameDidChangeNotification` (page 3257) to the default notification center if the receiver is configured to do so.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `frame` (page 3175)

Declared In
`NSView.h`

setFrameRotation:

Sets the rotation of the receiver's frame rectangle to a specified degree value, rotating it within its superview without affecting its coordinate system.

```
- (void)setFrameRotation:(CGFloat)angle
```

Parameters

angle

A `float` value indicating the degree of rotation.

Discussion

Positive values indicate counterclockwise rotation, negative clockwise. Rotation is performed around the origin of the frame rectangle.

This method neither redisplays the receiver nor marks it as needing display. You must do this yourself with `display` (page 3163) or `setNeedsDisplay:` (page 3225).

This method posts an `NSViewFrameDidChangeNotification` (page 3257) to the default notification center if the receiver is configured to do so.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `frameRotation` (page 3176)
- `setBoundsRotation:` (page 3215)

Declared In

`NSView.h`

setFrameSize:

Sets the size of the receiver's frame rectangle to the specified dimensions, resizing it within its superview without affecting its coordinate system.

```
- (void)setFrameSize:(NSSize)newSize
```

Parameters

newSize

An `NSSize` structure specifying the new height and width of the frame rectangle.

Discussion

This method neither redisplays the receiver nor marks it as needing display. You must do this yourself with `display` (page 3163) or `setNeedsDisplay:` (page 3225).

This method posts an `NSViewFrameDidChangeNotification` (page 3257) to the default notification center if the receiver is configured to do so.

In Mac OS X version 10.4 and later, you can override this method to support content preservation during live resizing. In your overridden implementation, include some conditional code to be executed only during a live resize operation. Your code must invalidate any portions of your view that need to be redrawn.

Availability

Available in Mac OS X v10.0 and later.

See Also

Declared In
`NSView.h`

setHidden:

Sets whether the view is hidden.

```
- (void)setHidden:(BOOL)flag
```

Parameters
flag
`YES` if the receiver is to be hidden, `NO` otherwise.

Discussion
A hidden view disappears from its window and does not receive input events. It remains in its superview's list of subviews, however, and participates in autoresizing as usual. The Application Kit also disables any cursor rectangle, tool-tip rectangle, or tracking rectangle associated with a hidden view. Hiding a view with subviews has the effect of hiding those subviews and any view descendants they might have. This effect is implicit and does not alter the hidden state of the receiver's descendants as reported by `isHidden` (page 3182).

Hiding the view that is the window's current first responder causes the view's next valid key view (`nextValidKeyView` (page 3193)) to become the new first responder. A hidden view remains in the `nextKeyView` (page 3192) chain of views it was previously part of, but is ignored during keyboard navigation.

Availability
Available in Mac OS X v10.3 and later.

See Also
- `isHidden` (page 3182)
- `isHiddenOrHasHiddenAncestor` (page 3182)

Declared In
NSView.h

setKeyboardFocusRingNeedsDisplayInRect:

Invalidates the area around the focus ring.

```
- (void)setKeyboardFocusRingNeedsDisplayInRect:(NSRect)rect
```

Parameters

rect

The rectangle of the control or cell defining the area around the focus ring. *rect* will be expanded to include the focus ring for invalidation.

Availability
Available in Mac OS X v10.1 and later.

Declared In
NSView.h

setLayer:

Sets the Core Animation layer that the receiver uses for layer-backing to the specified layer.

```
- (void)setLayer:(CALayer *)newLayer
```

Parameters

newLayer

A Core Animation layer to use as the receiver's backing store.

Availability
Available in Mac OS X v10.5 and later.

Related Sample Code
CocoaSlides
CoreAnimationKioskStyleMenu

Declared In
NSView.h

setLayerContentsPlacement:

Sets the view's layer contents placement policy.

```
- (void)setLayerContentsPlacement:(NSViewLayerContentsPlacement)newPlacement
```

Parameters

newPlacement

The placement policy. See "NSViewLayerContentsPlacement" (page 3253) for supported values.

Discussion
The content placement determines how the backing layer's existing cached content image will be mapped into the layer as the layer is resized. It is analogous to, and underpinned by, the CALayer class `contentsGravity` property. See `setLayerContentsRedrawPolicy:` (page 3224) for more information.

Availability
Available in Mac OS X v10.6 and later.

See Also
`- layerContentsPlacement` (page 3186)

Declared In
`NSView.h`

setLayerContentsRedrawPolicy:

Sets the receiver layer contents redraw policy.

```
- (void)setLayerContentsRedrawPolicy:(NSViewLayerContentsRedrawPolicy)newPolicy
```

Parameters
newPolicy
The redraw policy. See "NSViewLayerContentsRedrawPolicy" (page 3252) for supported values.

Discussion
If you know that redrawing at each animation frame is not necessary to produce correctly rendered results for a particular view, or are willing to accept an approximation of the view's intermediate appearance during potentially brief animations in exchange for an animation performance and smoothness benefit, you can change the view's `layerContentsRedrawPolicy` (page 3186) to one of the modes that does not require constant redrawing.

When doing this, you must also specify the desired layer content placement for the view. The content placement determines how the backing layer's existing cached content image will be mapped into the layer as the layer is resized. It is analogous to, and underpinned by, the CALayer class `contentsGravity` property.

For a view that has no associated layer, or that has been assigned a developer-provided layer (a layer-hosting view) using the NSView `setLayer:` (page 3223) method, the default contents redraw policy is is `NSViewLayerContentsRedrawNever` (page 3253), with an accompanying `layerContentsPlacement` (page 3186) of `NSViewLayerContentsPlacementScaleAxesIndependently` (page 3254). This instructs AppKit that it is not allowed to replace the layer's content, and provides the same content placement as CALayer's default `contentsGravity` setting of `kCAGravityResize`. For a view that has acquired an AppKit-generated backing layer (a layer-backed view), AppKit sets the contents redraw policy to a default of `NSViewLayerContentsRedrawDuringViewResize` (page 3253), forcing the view's content to be continually redrawn into the view's backing layer during animated resizing of the view, which produces strictly correct but not optimally performance results.

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSView.h`

setNeedsDisplay:

Controls whether the receiver's entire bounds is marked as needing display.

```
- (void)setNeedsDisplay:(BOOL)flag
```

Parameters

flag

If YES, marks the receiver's entire bounds as needing display; if NO, marks it as not needing display.

Discussion

Whenever the data or state used for drawing a view object changes, the view should be sent a setNeedsDisplay: message. NSView objects marked as needing display are automatically redisplayed on each pass through the application's event loop. (View objects that need to redisplay before the event loop comes around can of course immediately be sent the appropriate display... method.)

Availability

Available in Mac OS X v10.0 and later.

See Also

- setNeedsDisplayInRect: (page 3225)
- needsDisplay (page 3191)

Related Sample Code

Declared In

NSView.h

setNeedsDisplayInRect:

Marks the region of the receiver within the specified rectangle as needing display, increasing the receiver's existing invalid region to include it.

```
- (void)setNeedsDisplayInRect:(NSRect)invalidRect
```

Parameters

invalidRect

The rectangular region of the receiver to mark as invalid; it should be specified in the coordinate system of the receiver.

Discussion

A later displayIfNeeded... method will then perform drawing only within the invalid region. View objects marked as needing display are automatically redisplayed on each pass through the application's event loop. (View objects that need to redisplay before the event loop comes around can of course immediately be sent the appropriate display... method.)

Availability

Available in Mac OS X v10.0 and later.

Declared In
`NSView.h`

setPostsBoundsChangedNotifications:

Controls whether the receiver informs observers when its bounds rectangle changes.

```
- (void)setPostsBoundsChangedNotifications:(BOOL)flag
```

Parameters

flag

If `YES`, the receiver will post notifications to the default notification center whenever its bounds rectangle changes; if *flag* is `NO` it won't.

Discussion
Note that if *flag* is `YES` and bounds notifications are suppressed, when the bounds change notification is reenabled the view will immediately post a single such notification if its bounds changed during this time. This will happen even if there has been no net change in the view's bounds.

The following methods can result in notification posting:

- `setBounds:` (page 3214)
- `setBoundsOrigin:` (page 3214)
- `setBoundsRotation:` (page 3215)
- `setBoundsSize:` (page 3216)
- `translateOriginToPoint:` (page 3237)
- `scaleUnitSquareToSize:` (page 3208)
- `rotateByAngle:` (page 3208)

Availability
Available in Mac OS X v10.0 and later.

See Also
- `postsBoundsChangedNotifications` (page 3196)

Related Sample Code
GLUT

Declared In
`NSView.h`

setPostsFrameChangedNotifications:

Controls whether the receiver informs observers when its frame rectangle changes.

```
- (void)setPostsFrameChangedNotifications:(BOOL)flag
```

Parameters

flag

If `YES`, the receiver will post notifications to the default notification center whenever its frame rectangle changes; if *flag* is `NO` it won't.

Discussion
Note that if *flag* is `YES` and frame notifications are suppressed, when the frame change notification is reenabled the view will immediately post a single such notification if its frame changed during this time. This will happen even if there has been no net change in the view's frame.

The following methods can result in notification posting:

- `setFrame:` (page 3218)
- `setFrameOrigin:` (page 3220)
- `setFrameRotation:` (page 3221)
- `setFrameSize:` (page 3221)

Availability
Available in Mac OS X v10.0 and later.

See Also
- `postsFrameChangedNotifications` (page 3196)

Related Sample Code
GLUT

Declared In
`NSView.h`

setShadow:

Sets the shadow drawn by the receiver.

```
- (void)setShadow:(NSShadow *)shadow
```

Parameters

shadow
An instance of `NSShadow`.

Discussion
This method sets the `shadowColor`,`shadowOffset`, `shadowOpacity` and `shadowRadius` properties of the receiver's layer.

Sending this message to a view that is not managing a Core Animation layer causes an exception.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSView.h`

setSubviews:

Sets the receiver's subviews to the specified subviews.

```
- (void)setSubviews:(NSArray *)newSubviews
```

Parameters

newSubviews
An array of subviews. The *newSubviews* array can consist of existing subviews of the receiver or other views that have `nil` as their superview. If *newSubviews* is `nil`, or contains duplicated views, or if any of its members have a superview other than `nil` or the receiver, an invalid argument exception is thrown.

Discussion
Using this method you can: reorder the receiver's existing subviews, add or remove subviews en masse, replace all of the receiver's subviews with a new set of subviews, or remove all the receiver's subviews.

Given a valid array of views in `newSubviews`, `setSubviews:` (page 3228) performs any required sorting of the subviews array, as well as sending any `addSubview:` (page 3139) and `removeFromSuperview` (page 3202) messages as necessary to leave the receiver with the requested new array of subviews. Any member of *newSubviews* that isn't already a subview of the receiver is added. Any member of the view's existing `subviews` array that isn't in *newSubviews* is removed. And any views that are in both `subviews` (page 3235) and *newSubviews* are moved in the subviews array as needed, without being removed and re-added.

This method marks the affected view and window areas as needing display.

Availability
Available in Mac OS X v10.5 and later.

Related Sample Code
CocoaSlides

Declared In
NSView.h

setToolTip:

Sets the tool tip text for the view to *string*.

```
- (void)setToolTip:(NSString *)string
```

Parameters

string
A string that contains the text to use for the tool tip. If nil, it cancels tool tip display for the view.

Availability
Available in Mac OS X v10.0 and later.

See Also
- toolTip (page 3236)

Related Sample Code
EnhancedAudioBurn

Declared In
NSView.h

setUpGState

Overridden by subclasses to (re)initialize the receiver's graphics state object.

```
- (void)setUpGState
```

Discussion
This method is automatically invoked when the graphics state object created using allocateGState (page 3146) needs to be initialized. The default implementation does nothing. Your subclass can override it to set the current font, line width, or any other graphics state parameter except coordinate transformations and the clipping path—these are established by the frame and bounds rectangles and by methods such as scaleUnitSquareToSize: (page 3208) and translateOriginToPoint: (page 3237). Note that drawRect: can further transform the coordinate system and clipping path for whatever temporary effects it needs.

Availability
Available in Mac OS X v10.0 and later.

See Also
- allocateGState (page 3146)
- renewGState (page 3205)

Declared In
NSView.h

setWantsLayer:

Specifies whether the receiver and its subviews use a Core Animation layer as a backing store.

```
- (void)setWantsLayer:(BOOL)flag
```

Parameters

flag

YES if the receiver and its subviews should use a Core Animation layer as its backing store, otherwise NO.

Discussion
The order that setWantsLayer: and setLayer: are called is important, it makes the distinction between a layer-backed view, and a layer-hosting view.

A layer-backed view is a view that is backed by a Core Animation layer. Any drawing done by the view is the cached in the backing layer. You configured a layer-backed view by simply invoking `setWantsLayer:` (page 3230) with a value of YES. The view class will automatically create the a backing layer for you, and you use the view class's drawing mechanisms. **When using layer-backed views you should never interact directly with the layer.**

A layer-hosting view is a view that contains a Core Animation layer that you intend to manipulate directly. You create a layer-hosting view by instantiating an instance of a Core Animation layer class and setting that layer using the view's `setLayer:` (page 3223) method. After doing so, you then invoke `setWantsLayer:` (page 3230) with a value of YES. **When using a layer-hosting view you should not rely on the view for drawing, nor should you add subviews to the layer-hosting view.**

Availability
Available in Mac OS X v10.5 and later.

AnimatedTableView
CocoaSlides
CoreAnimationKioskStyleMenu
LayerBackedOpenGLView

Declared In
NSView.h

setWantsRestingTouches:

Sets whether the view wants to receive resting touch events.

```
- (void)setWantsRestingTouches:(BOOL)flag
```

Parameters

flag

YES if the view wants resting touches, otherwise NO. The default is NO.

Discussion
A resting touch occurs when a user rests their thumb on a device (for example, the glass trackpad of a MacBook).

By default, these touches are not delivered and are not included in the event's set of touches. Touches may transition in and out of resting at any time. Unless the view wants restingTouches, began / ended events are simulated as touches transition from resting to active and vice versa.

In general resting touches should be ignored.

Availability
Available in Mac OS X v10.6 and later.

See Also
`- wantsRestingTouches` (page 3247)

Declared In
`NSView.h`

shadow

Returns the shadow drawn by the receiver

```
- (NSShadow *)shadow
```

Return Value
An instance of `NSShadow` that is created using the `shadowColor`,`shadowOffset`, `shadowOpacity` and `shadowRadius` properties of the receiver's layer.

Discussion
Sending this message to a view that is not managing a Core Animation layer causes an exception.

Availability
Available in Mac OS X v10.5 and later.

Related Sample Code
CocoaSlides

Declared In
`NSView.h`

shouldDelayWindowOrderingForEvent:

Overridden by subclasses to allow the user to drag images from the receiver without its window moving forward and possibly obscuring the destination and without activating the application.

```
- (BOOL)shouldDelayWindowOrderingForEvent:(NSEvent *)theEvent
```

Parameters
`theEvent`
An object representing an initial mouse-down event.

Return Value
If this method returns `YES`, the normal window-ordering and activation mechanism is delayed (not necessarily prevented) until the next mouse-up event. If it returns `NO`, then normal ordering and activation occur.

Discussion
Never invoke this method directly; it's invoked automatically for each mouse-down event directed at the NSView.

An `NSView` subclass that allows dragging should implement this method to return `YES` if *`theEvent`* is potentially the beginning of a dragging session or of some other context where window ordering isn't appropriate. This method is invoked before a `mouseDown:` (page 2164) message for *`theEvent`* is sent. The default implementation returns `NO`.

If, after delaying window ordering, the receiver actually initiates a dragging session or similar operation, it should also send a `preventWindowOrdering` (page 158) message to `NSApp`, which completely prevents the window from ordering forward and the activation from becoming active. `preventWindowOrdering` (page 158) is sent automatically by the `NSViewdragImage:...` and `dragFile:...` methods.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSView.h`

shouldDrawColor

Returns `NO` if the receiver is being drawn in an `NSWindow` object (as opposed, for example, to being printed) and the window object can't store color; otherwise returns `YES`.

```
- (BOOL)shouldDrawColor
```

Discussion
A view object can base its drawing behavior on the return value of this method to improve its appearance in grayscale windows.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- drawRect:` (page 3170)
`canStoreColor` (page 3306) (NSWindow)

Declared In
`NSView.h`

showDefinitionForAttributedString:atPoint:

Shows a window displaying the definition of the of the attributed string at the specified point.

```
- (void)showDefinitionForAttributedString:(NSAttributedString *)attrString
    atPoint:(NSPoint)textBaselineOrigin
```

Parameters

attrString

The attributed string for which to show the definition. If the receiver is an instance of NSTextView, the `attrString` can be `nil`, in which case the text view will automatically supply values suitable for displaying definitions for the specified range within its text content.

textBaselineOrigin

Specifies the baseline origin of *attrString* in the receiver's view coordinate system.

Discussion

Shows a window that displays the definition (or other subject depending on available dictionaries) of the specified attributed string.

This method can be used for implementing the same functionality as the `NSTextView` "Look Up in Dictionary" contextual menu on a custom view.

Availability

Available in Mac OS X v10.6 and later.

See Also

`- showDefinitionForAttributedString:range:options:baselineOriginProvider:` (page 3233)

Declared In

`NSView.h`

showDefinitionForAttributedString:range:options:baselineOriginProvider:

Shows a window displaying the definition of the specified range of the attributed string.

```
- (void)showDefinitionForAttributedString:(NSAttributedString *)attrString
    range:(NSRange)targetRange
    options:(NSDictionary *)options
    baselineOriginProvider:(NSPoint (^)(NSRange adjustedRange))originProvider
```

Parameters

attrString

The attributed string for which to show the definition. If the receiver is an instance of NSTextView, the `attrString` can be `nil`, in which case the text view will automatically supply values suitable for displaying definitions for the specified range within its text content.

range

The range of the attributed string to define. You can pass a zero-length range and the appropriate range will be auto-detected around the range's offset. That's the recommended approach when there is no selection.

options

An optional dictionary that specifies how the definition is displayed. See "NSDefinition Presentation Constants" (page 3255) for the key and it's possible values.

originProvider

The originProvider block object should return the baseline origin for the first character at the adjusted range.

If the receiver is an instance of NSTextView, the originProvider can be `NULL`, in which case the text view will automatically supply values suitable for displaying definitions for the specified range within its text content.

The block object takes a single argument:

adjustedRange

The adjusted range.

The block object returns an `NSPoint` to be used as the baseline origin of the first character, in the receiver view coordinate system.

Discussion
This method does not cause scrolling, so clients should perform any necessary scrolling before calling this method.

Availability
Available in Mac OS X v10.6 and later.

See Also
`- showDefinitionForAttributedString:atPoint:` (page 3232)

Declared In
`NSView.h`

sortSubviewsUsingFunction:context:

Orders the receiver's immediate subviews using the specified comparator function.

```
- (void)sortSubviewsUsingFunction:(NSComparisonResult (*)(id, id, void *))compare
    context:(void *)context
```

Parameters

compare

A pointer to the comparator function. This function must take as arguments two subviews to be ordered and contextual data (supplied in *context* which may be arbitrary data used to help in the comparison. The comparator function should return `NSOrderedAscending` if the first subview should be ordered lower, `NSOrderedDescending` if the second subview should be ordered lower, and `NSOrderedSame` if their ordering isn't important.

context

Arbitrary data that might help the comparator function `compare` in its decisions.

Availability
Available in Mac OS X v10.0 and later.

See Also
`sortedArrayUsingFunction:context:` (`NSArray`)

Declared In
`NSView.h`

subviews

Return the receiver's immediate subviews.

```
- (NSArray *)subviews
```

Return Value
Returns an array containing the receiver's subviews.

Discussion
The order of the subviews may be considered as being back-to-front, but this does not imply invalidation and drawing behavior. The order is based on the order of the receiver's subviews as specified in the nib file from which they were unarchived or the programmatic interface for modifying the receiver's subview list. This ordering is also the reverse of the order in which hit-testing is done.

Note: The contents of this array may change at any time. If you intend to manipulate this array you should copy it rather than simply retain.

Availability
Available in Mac OS X v10.0 and later.

toolTip

Returns the text for the view's tool tip.

```
- (NSString *)toolTip
```

Return Value
The tool tip text or nil if the view doesn't currently display tool tip text

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setToolTip:` (page 3229)

Declared In
`NSView.h`

trackingAreas

Returns an array of the receiver's tracking areas.

```
- (NSArray *)trackingAreas
```

Return Value
An array of the receiver's tracking areas (instances of `NSTrackingArea`). If the receiver has no tracking areas, returns an empty array.

Availability
Available in Mac OS X v10.5 and later.

Related Sample Code
MenuItemView
PhotoSearch

Declared In
`NSView.h`

translateOriginToPoint:

Translates the receiver's coordinate system so that its origin moves to a new location.

```
- (void)translateOriginToPoint:(NSPoint)newOrigin
```

Parameters
newOrigin
A point that specifies the new origin.

Discussion
In the process, the origin of the receiver's bounds rectangle is shifted by (*-newOrigin*.x, *-newOrigin*.y). This method neither redisplays the receiver nor marks it as needing display. You must do this yourself with `display` (page 3163) or `setNeedsDisplay:` (page 3225).

Note the difference between this method and setting the bounds origin. Translation effectively moves the image inside the bounds rectangle, while setting the bounds origin effectively moves the rectangle over the image. The two are in a sense inverse, although translation is cumulative, and setting the bounds origin is absolute.

This method posts an `NSViewBoundsDidChangeNotification` (page 3256) to the default notification center if the receiver is configured to do so.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSView.h`

translateRectsNeedingDisplayInRect:by:

Translates the display rectangles by the specified delta.

```
- (void)translateRectsNeedingDisplayInRect:(NSRect)clipRect
    by:(NSSize)delta
```

Parameters

clipRect
A rectangle defining the region of the receiver, typically the receiver's bounds.

delta
A NSSize structure that specifies an offset from from aRect's origin.

Discussion
This method performs the shifting of dirty rectangles that an equivalent `scrollRect:by:` (page 3210) operation would cause, without performing the actual scroll operation. It is only useful in very rare cases where a view implements its own low-level scrolling mechanics.

This method:

1. Collects the receiving view's dirty rectangles.
2. Clears all dirty rectangles in the intersection of *clipRect* and the view's bounds.
3. Shifts the retrieved rectangles by the *delta* offset.
4. Clips the result to the intersection of *clipRect* and the view's bounds
5. Marks the resultant rectangles as needing display.

The developer must ensure that *clipRect* and *delta* are pixel-aligned in order to guarantee correct drawing. See "The View Coordinate System" in *View Programming Guide* for a description of how to pixel-align view coordinates.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSView.h`

unlockFocus

Balances an earlier `lockFocus` (page 3187) or `lockFocusIfCanDraw` (page 3188) message; restoring the focus to the previously focused view is necessary.

```
- (void)unlockFocus
```

Discussion
Raises an `NSInvalidArgumentException` if invoked on the wrong view.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSView.h`

unregisterDraggedTypes

Unregisters the receiver as a possible destination in a dragging session.

```
- (void)unregisterDraggedTypes
```

Availability
Available in Mac OS X v10.0 and later.

See Also
`- registerForDraggedTypes:` (page 3201)

Declared In
`NSView.h`

updateTrackingAreas

Invoked automatically when the view's geometry changes such that its tracking areas need to be recalculated.

```
- (void)updateTrackingAreas
```

Discussion
You should override this method to remove out of date tracking areas and add recomputed tracking areas; your implementation should call `super`.

Availability
Available in Mac OS X v10.5 and later.

Related Sample Code
PhotoSearch

Declared In
`NSView.h`

viewDidEndLiveResize

Informs the receiver of the end of a live resize.

```
- (void)viewDidEndLiveResize
```

Discussion
In the simple case, a view is sent `viewWillStartLiveResize` (page 3244) before the first resize operation on the containing window and `viewDidEndLiveResize` after the last resize operation. A view that is repeatedly added and removed from a window during live resize will receive only one `viewWillStartLiveResize` (on the first time it is added to the window) and one `viewDidEndLiveResize` (when the window has completed the live resize operation). This allows a superview such as `NSBrowser` object to add and remove its `NSMatrix` subviews during live resize without the `NSMatrix` receiving multiple calls to these methods.

A view might allocate data structures to cache-drawing information in `viewWillStartLiveResize` (page 3244) and should clean up these data structures in `viewDidEndLiveResize`. In addition, a view that does optimized drawing during live resize might want to do full drawing after `viewDidEndLiveResize`, although a view should not assume that it has a drawing context in `viewDidEndLiveResize` (since it may have been removed from the window during live resize). A view that wants to redraw itself after live resize should call `[self setNeedsDisplay:YES]` in `viewDidEndLiveResize`.

A view subclass should call `super` from these methods.

Availability
Available in Mac OS X v10.1 and later.

Declared In
`NSView.h`

viewDidHide

Invoked when the receiver is hidden, either directly, or in response to an ancestor being hidden.

```
- (void)viewDidHide
```

Discussion
The receiver receives this message when its `isHiddenOrHasHiddenAncestor` (page 3182) state goes from `NO` to `YES`. This will happen when the view or an ancestor is marked as hidden, or when the view or an ancestor is inserted into a new view hierarchy.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSView.h`

viewDidMoveToSuperview

Informs the receiver that its superview has changed (possibly to `nil`).

```
- (void)viewDidMoveToSuperview
```

Discussion
The default implementation does nothing; subclasses can override this method to perform whatever actions are necessary.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `viewDidMoveToWindow` (page 3241)
- `viewWillMoveToSuperview:` (page 3243)
- `viewWillMoveToWindow:` (page 3243)

Declared In
`NSView.h`

viewDidMoveToWindow

Informs the receiver that it has been added to a new view hierarchy.

```
- (void)viewDidMoveToWindow
```

Discussion
The default implementation does nothing; subclasses can override this method to perform whatever actions are necessary.

`window` (page 3248) may return `nil` when this method is invoked, indicating that the receiver does not currently reside in any window. This occurs when the receiver has just been removed from its superview or when the receiver has just been added to a superview that does not itself have a window. Overrides of this method may choose to ignore such cases if they are not of interest.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSView.h

viewDidUnhide

Invoked when the receiver is unhidden, either directly, or in response to an ancestor being unhidden

```
- (void)viewDidUnhide
```

Discussion
The receiver receives this message when its isHiddenOrHasHiddenAncestor state goes from YES to NO. This can happen when the view or an ancestor is marked as not hidden, or when the view or an ancestor is removed from its containing view hierarchy.

Availability
Available in Mac OS X v10.5 and later.

Declared In
NSView.h

viewWillDraw

Informs the receiver that it will be required to draw content.

```
- (void)viewWillDraw
```

Discussion
In response to receiving one of the display... messages the receiver will recurse down the view hierarchy, sending this message to each of the views that may be involved in the display operation.

Subclasses can override this method to move or resize views, mark additional areas as requiring display, or other actions that can best be deferred until they are required for drawing. During the recursion, sending of setNeedsDisplay: (page 3225) and setNeedsDisplayInRect: (page 3225) messages to views in the hierarchy that's about to be drawn is valid and supported, and will affect the assessment of the total area to be rendered in that drawing pass.

A subclass's implementation of viewWillDraw can use the existing NSView getRectsBeingDrawn:count: (page 3176) method to obtain a list of rectangles that bound the affected area, enabling it to restrict its efforts to that area.

The following is an example of a generic subclass implementation:

```
- (void)viewWillDraw {
```

```
    // Perform some operations before recursing for descendants.

    // Now recurse to handle all our descendants.
    // Overrides must call up to super like this.
    [super viewWillDraw];

    // Perform some operations that might depend on descendants
    //  already having had a chance to update.
}
```

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSView.h`

viewWillStartLiveResize

Informs the receiver of the start of a live resize.

```
- (void)viewWillStartLiveResize
```

Discussion
In the simple case, a view is sent `viewWillStartLiveResize` before the first resize operation on the containing window and `viewDidEndLiveResize` (page 3240) after the last resize operation. A view that is repeatedly added and removed from a window during live resize will receive only one `viewWillStartLiveResize` (on the first time it is added to the window) and one `viewDidEndLiveResize` (when the window has completed the live resize operation). This allows a superview such as `NSBrowser` object to add and remove its `NSMatrix` subviews during live resize without the `NSMatrix` object receiving multiple calls to these methods.

A view might allocate data structures to cache-drawing information in `viewWillStartLiveResize` and should clean up these data structures in `viewDidEndLiveResize` (page 3240). In addition, a view that does optimized drawing during live resize might want to do full drawing after `viewDidEndLiveResize`, although a view should not assume that it has a drawing context in `viewDidEndLiveResize` (since it may have been removed from the window during live resize). A view that wants to redraw itself after live resize should call `[self setNeedsDisplay:YES]` in `viewDidEndLiveResize`.

A view subclass should call `super` from these methods.

Availability
Available in Mac OS X v10.1 and later.

Declared In
`NSView.h`

visibleRect

Returns the portion of the receiver not clipped by its superviews.

```
- (NSRect)visibleRect
```

Return Value
A rectangle defining the unclipped portion of the receiver.

Discussion
Visibility for this method is defined quite simply and doesn't account for whether other `NSView` objects (or windows) overlap the receiver or whether the receiver has a window at all. This method returns `NSZeroRect` if the receiver is effectively hidden.

During a printing operation the visible rectangle is further clipped to the page being imaged.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSView.h

wantsDefaultClipping

Returns whether the Application Kit's default clipping provided to `drawRect:` (page 3170) implementations is in effect.

```
- (BOOL)wantsDefaultClipping
```

Return Value
`YES` if the default clipping is in effect, `NO` otherwise. By default, this method returns `YES`.

Discussion
Subclasses may override this method to return `NO` if they want to suppress the default clipping. They may want to do this in situations where drawing performance is critical to avoid the cost of setting up, enforcing, and cleaning up the clip path

A view that overrides this method to refuse the default clipping must either set up whatever clipping it requires or constrain its drawing exactly to the list of rectangles returned by `getRectsBeingDrawn:count:` (page 3176). Failing to do so could result in corruption of other drawing in the view's window.

Availability
Available in Mac OS X v10.3 and later.

Related Sample Code
VideoViewer

Declared In
NSView.h

wantsLayer

Returns a Boolean value that indicates whether the receiver is using a layer as its backing store.

```
- (BOOL)wantsLayer
```

Return Value
`YES` if the receiver is using a Core Animation layer as its backing store, otherwise `NO`.

Availability
Available in Mac OS X v10.5 and later.

Declared In
NSView.h

wantsRestingTouches

Returns whether the view wants resting touches.

```
- (BOOL)wantsRestingTouches
```

Return Value
`YES` if the view wants resting touches, otherwise `NO`. The default is `NO`.

Discussion
A resting touch occurs when a user rests their thumb on a device (for example, the glass trackpad of a MacBook).

By default, these touches are not delivered and are not included in the event's set of touches. Touches may transition in and out of resting at any time. Unless the view wants restingTouches, began / ended events are simulated as touches transition from resting to active and vice versa.

In general resting touches should be ignored.

Availability
Available in Mac OS X v10.6 and later.

See Also
`- setWantsRestingTouches:` (page 3230)

Declared In
`NSView.h`

widthAdjustLimit

Returns the fraction (from 0.0 to 1.0) of the page that can be pushed onto the next page during automatic pagination to prevent items such as small images or text columns from being divided across pages.

```
- (CGFloat)widthAdjustLimit
```

Discussion
This fraction is used to calculate the right edge limit for a `adjustPageWidthNew:left:right:limit:` (page 3144) message.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- heightAdjustLimit` (page 3178)

Declared In
`NSView.h`

willRemoveSubview:

Overridden by subclasses to perform additional actions before subviews are removed from the receiver.

```
- (void)willRemoveSubview:(NSView *)subview
```

Parameters

subview

The subview that will be removed.

Discussion

This method is invoked when *subview* receives a `removeFromSuperview` (page 3202) message or *subview* is removed from the receiver due to it being added to another view with `addSubview:` (page 3139).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSView.h`

window

Returns the receiver's window object, or `nil` if it has none.

```
- (NSWindow *)window
```

Availability

Available in Mac OS X v10.0 and later.

Constants

NSBorderType

These constants specify the type of a view's border.

```
enum {
    NSNoBorder     = 0,
    NSLineBorder   = 1,
    NSBezelBorder  = 2,
    NSGrooveBorder = 3
};
typedef NSUInteger NSBorderType;
```

Constants
NSBezelBorder
A concave border that makes the view look sunken.

Available in Mac OS X v10.0 and later.

Declared in NSView.h.

`NSGrooveBorder`
A thin border that looks etched around the image.

Available in Mac OS X v10.0 and later.

Declared in `NSView.h`.

`NSLineBorder`
A black line border around the view.

Available in Mac OS X v10.0 and later.

Declared in `NSView.h`.

`NSNoBorder`
No border.

Available in Mac OS X v10.0 and later.

Declared in `NSView.h`.

Declared In
`NSView.h`

Resizing masks

These constants are used by `setAutoresizingMask:` (page 3212).

```
enum {
   NSViewNotSizable     = 0,
   NSViewMinXMargin     = 1,
   NSViewWidthSizable   = 2,
   NSViewMaxXMargin     = 4,
   NSViewMinYMargin     = 8,
   NSViewHeightSizable  = 16,
   NSViewMaxYMargin     = 32
};
```

Constants
`NSViewNotSizable`
The receiver cannot be resized.

Available in Mac OS X v10.0 and later.

Declared in `NSView.h`.

`NSViewMinXMargin`
The left margin between the receiver and its superview is flexible.

Available in Mac OS X v10.0 and later.

Declared in `NSView.h`.

`NSViewWidthSizable`
The receiver's width is flexible.

Available in Mac OS X v10.0 and later.

Declared in `NSView.h`.

`NSViewMaxXMargin`
The right margin between the receiver and its superview is flexible.

Available in Mac OS X v10.0 and later.

Declared in `NSView.h`.

`NSViewMinYMargin`
The bottom margin between the receiver and its superview is flexible.

Available in Mac OS X v10.0 and later.

Declared in `NSView.h`.

`NSViewHeightSizable`
The receiver's height is flexible.

Available in Mac OS X v10.0 and later.

Declared in `NSView.h`.

`NSViewMaxYMargin`
The top margin between the receiver and its superview is flexible.

Available in Mac OS X v10.0 and later.

Declared in `NSView.h`.

Declared In
`NSView.h`

NSToolTipTag

This type describes the rectangle used to identify a tool tip rectangle.

```
typedef NSInteger NSToolTipTag;
```

Discussion
See the methods `addToolTipRect:owner:userData:` (page 3141) and `removeToolTip:` (page 3203).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSView.h`

NSTrackingRectTag

This type describes the rectangle used to track the mouse.

```
typedef NSInteger NSTrackingRectTag;
```

Discussion
See the methods `addTrackingRect:owner:userData:assumeInside:` (page 3142) and `removeTrackingRect:` (page 3204).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSView.h`

Full Screen Mode Options

These constants are keys that you can use in the options dictionary in `enterFullScreenMode:withOptions:` (page 3173) and `exitFullScreenModeWithOptions:` (page 3174).

```
NSString * const NSFullScreenModeAllScreens;
NSString * const NSFullScreenModeSetting;
NSString * const NSFullScreenModeWindowLevel;
NSString * const NSFullScreenModeApplicationPresentationOptions;
```

Constants

`NSFullScreenModeAllScreens`

Key whose corresponding value specifies whether the view should take over all screens.

The corresponding value is an instance of `NSNumber` containing a Boolean value.

Available in Mac OS X v10.5 and later.

Declared in `NSView.h`.

`NSFullScreenModeSetting`

Key whose corresponding value specifies the the full screen mode setting.

The corresponding value is an instance of `NSDictionary` that contains keys specified in `Display Mode Standard Properties` and `Display Mode Optional Properties` in *Quartz Display Services Reference*.

When the `NSFullScreenModeApplicationPresentationOptions` (page 3252) is specified in the options dictionary specifying this option as well will cause an exception.

Available in Mac OS X v10.5 and later.

Declared in `NSView.h`.

`NSFullScreenModeWindowLevel`

Key whose corresponding value specifies the screen mode window level.

The corresponding value is an instance of `NSNumber` containing an integer value.

Available in Mac OS X v10.5 and later.

Declared in `NSView.h`.

`NSFullScreenModeApplicationPresentationOptions`

Key whose corresponding value specifies the application presentation options..

The corresponding value is an instance of `NSNumber` containing an unsigned integer value of `NSApplicationPresentationOptions` (page 187). Those options can be combined using the C bit-wise `OR` operator before created the `NSNumber` instance. See *NSApplication Class Reference* constants section `NSApplicationPresentationOptions` (page 187) for more information on these options.

Available in Mac OS X v10.6 and later.

Declared in `NSView.h`.

Declared In

`NSView.h`

NSViewLayerContentsRedrawPolicy

These constants specify how layer resizing is handled when a view is layer-backed or layer-hosting. See `layerContentsRedrawPolicy` (page 3186) and `setLayerContentsRedrawPolicy:` (page 3224) for more information.

```
enum {
    NSViewLayerContentsRedrawNever                  = 0,
    NSViewLayerContentsRedrawOnSetNeedsDisplay      = 1,
    NSViewLayerContentsRedrawDuringViewResize       = 2,
    NSViewLayerContentsRedrawBeforeViewResize       = 3
};
typedef NSInteger NSViewLayerContentsRedrawPolicy;
```

Constants

`NSViewLayerContentsRedrawNever`

Leave the layer's contents alone. Never mark the layer as needing display, or draw the view's contents to the layer. This is how developer created layers (layer-hosting views) are treated.

Available in Mac OS X v10.6 and later.

Declared in `NSView.h`.

`NSViewLayerContentsRedrawOnSetNeedsDisplay`

Any of the `setNeedsDisplay...` methods sent to the view will cause the view redraw the affected layer parts by invoking the view's `drawRect:` (page 3170), but neither the layer or the view are marked as needing display when the view's size changes.

Available in Mac OS X v10.6 and later.

Declared in `NSView.h`.

`NSViewLayerContentsRedrawDuringViewResize`

Resize the view's backing-layer and redraw the view to the layer when the view's size changes. If the resize is animated, AppKit will drive the resize animation itself and will do this resize and redraw at each step of the animation. Affected parts of the layer will also be redrawn when the view is marked as needing display. This mode is a superset of `NSViewLayerContentsRedrawOnSetNeedsDisplay` (page 3253). This is the way that layer-backed views are currently treated.

Available in Mac OS X v10.6 and later.

Declared in `NSView.h`.

`NSViewLayerContentsRedrawBeforeViewResize`

Resize the layer and redraw the view to the layer when the view's size changes. This will be done just once at the beginning of a resize animation, not at each frame of the animation. Affected parts of the layer will also be redrawn when the view is marked as needing display. This mode is a superset of `NSViewLayerContentsRedrawOnSetNeedsDisplay` (page 3253).

Available in Mac OS X v10.6 and later.

Declared in `NSView.h`.

NSViewLayerContentsPlacement

These constants specify the location of the layer content when the content is not re-rendered in response to view resizing. See `setLayerContentsPlacement:` (page 3223) for more information.

```
enum {
    NSViewLayerContentsPlacementScaleAxesIndependently      =  0,
    NSViewLayerContentsPlacementScaleProportionallyToFit    =  1,
    NSViewLayerContentsPlacementScaleProportionallyToFill   =  2,
    NSViewLayerContentsPlacementCenter                      =  3,
    NSViewLayerContentsPlacementTop                         =  4,
    NSViewLayerContentsPlacementTopRight                    =  5,
    NSViewLayerContentsPlacementRight                       =  6,
    NSViewLayerContentsPlacementBottomRight                 =  7,
    NSViewLayerContentsPlacementBottom                      =  8,
    NSViewLayerContentsPlacementBottomLeft                  =  9,
    NSViewLayerContentsPlacementLeft                        = 10,
    NSViewLayerContentsPlacementTopLeft                     = 11
};
typedef NSInteger NSViewLayerContentsPlacement;
```

Constants

`NSViewLayerContentsPlacementScaleAxesIndependently`

The content is resized to fit the entire bounds rectangle.

Available in Mac OS X v10.6 and later.

Declared in `NSView.h`.

`NSViewLayerContentsPlacementScaleProportionallyToFit`

The content is resized to fit the bounds rectangle, preserving the aspect of the content. If the content does not completely fill the bounds rectangle, the content is centered in the partial axis.

Available in Mac OS X v10.6 and later.

Declared in `NSView.h`.

`NSViewLayerContentsPlacementScaleProportionallyToFill`

The content is resized to completely fill the bounds rectangle, while still preserving the aspect of the content. The content is centered in the axis it exceeds.

Available in Mac OS X v10.6 and later.

Declared in `NSView.h`.

`NSViewLayerContentsPlacementCenter`

The content is horizontally and vertically centered in the bounds rectangle.

Available in Mac OS X v10.6 and later.

Declared in `NSView.h`.

`NSViewLayerContentsPlacementTop`

The content is horizontally centered at the top-edge of the bounds rectangle.

Available in Mac OS X v10.6 and later.

Declared in `NSView.h`.

`NSViewLayerContentsPlacementTopRight`

The content is positioned in the top-right corner of the bounds rectangle.

Available in Mac OS X v10.6 and later.

Declared in `NSView.h`.

`NSViewLayerContentsPlacementRight`

The content is vertically centered at the right-edge of the bounds rectangle.

Available in Mac OS X v10.6 and later.

Declared in `NSView.h`.

`NSViewLayerContentsPlacementBottomRight`
The content is positioned in the bottom-right corner of the bounds rectangle.

Available in Mac OS X v10.6 and later.

Declared in `NSView.h`.

`NSViewLayerContentsPlacementBottom`
The content is horizontally centered at the bottom-edge of the bounds rectangle.

Available in Mac OS X v10.6 and later.

Declared in `NSView.h`.

`NSViewLayerContentsPlacementBottomLeft`
The content is positioned in the bottom-left corner of the bounds rectangle.

Available in Mac OS X v10.6 and later.

Declared in `NSView.h`.

`NSViewLayerContentsPlacementLeft`
The content is vertically centered at the left-edge of the bounds rectangle.

Available in Mac OS X v10.6 and later.

Declared in `NSView.h`.

`NSViewLayerContentsPlacementTopLeft`
The content is positioned in the top-left corner of the bounds rectangle.

Available in Mac OS X v10.6 and later.

Declared in `NSView.h`.

NSDefinition Presentation Constants

These constants are used to control how definition windows are displayed by `showDefinitionForAttributedString:range:options:baselineOriginProvider:` (page 3233). If this option is unspecified, the definition will be shown in either of those presentation forms depending on the 'Contextual Menu:' setting in Dictionary application preferences.

```
NSString * const NSDefinitionPresentationTypeKey;
NSString * const NSDefinitionPresentationTypeOverlay;
NSString * const NSDefinitionPresentationTypeDictionaryApplication;
```

Constants

`NSDefinitionPresentationTypeKey`
An optional key in the options dictionary that specifies the presentation type of the definition display. It can have a value of `NSDefinitionPresentationTypeOverlay` (page 3255) or `NSDefinitionPresentationTypeDictionaryApplication` (page 3256).

Available in Mac OS X v10.6 and later.

Declared in `NSView.h`.

`NSDefinitionPresentationTypeOverlay`
A possible value of the `NSDefinitionPresentationTypeKey` (page 3255) dictionary key that produces a small overlay window at the string location,

Available in Mac OS X v10.6 and later.

Declared in `NSView.h`.

`NSDefinitionPresentationTypeDictionaryApplication`
A possible value of the `NSDefinitionPresentationTypeKey` (page 3255) dictionary key that invokes Dictionary application to display the definition.

Available in Mac OS X v10.6 and later.

Declared in `NSView.h`.

Notifications

NSViewBoundsDidChangeNotification

Posted whenever the `NSView`'s bounds rectangle changes independently of the frame rectangle, if the `NSView` is configured using `setPostsBoundsChangedNotifications:` (page 3226) to post such notifications.

The notification object is the `NSView` object whose bounds rectangle has changed. This notification does not contain a *`userInfo`* dictionary.

The following methods can result in notification posting:

`setBounds:` (page 3214)
`setBoundsOrigin:` (page 3214)
`setBoundsRotation:` (page 3215)
`setBoundsSize:` (page 3216)
`translateOriginToPoint:` (page 3237)
`scaleUnitSquareToSize:` (page 3208)
`rotateByAngle:` (page 3208)

Note that the bounds rectangle resizes automatically to track the frame rectangle. Because the primary change is that of the frame rectangle, however, `setFrame:` (page 3218) and `setFrameSize:` (page 3221) don't result in a bounds-changed notification.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSView.h`

NSViewFocusDidChangeNotification

Deprecated notification that was posted for an `NSView` object and each of its descendants (recursively) whenever the frame or bounds geometry of the view changed.

In Mac OS X v10.4 and later, this notification is no longer posted. In earlier version of Mac OS X, use `NSViewBoundsDidChangeNotification` and `NSViewFrameDidChangeNotification` instead to get the same information provided by this notification.

The notification object is the view whose geometry changed. This notification does not contain a *`userInfo`* dictionary.

Availability
Deprecated in Mac OS X v10.4 and later.

See Also
NSViewBoundsDidChangeNotification (page 3256)
NSViewFrameDidChangeNotification (page 3257)

Declared In
NSView.h

NSViewFrameDidChangeNotification

Posted whenever the view's frame rectangle changes, if the view is configured using setPostsFrameChangedNotifications: (page 3227) to post such notifications.

The notification object is the NSView object whose frame rectangle has changed. This notification does not contain a *userInfo* dictionary.

The following methods can result in notification posting:

- setFrame: (page 3218)
- setFrameOrigin: (page 3220)
- setFrameRotation: (page 3221)
- setFrameSize: (page 3221)

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSView.h

NSViewDidUpdateTrackingAreasNotification

Posted whenever an NSView object recalculates its tracking areas. It is sent after the view receives updateTrackingAreas (page 3239).

Availability
Available in Mac OS X v10.5 and later.

Declared In
NSView.h

NSViewGlobalFrameDidChangeNotification

Posted whenever an NSView object that has attached surfaces (that is, NSOpenGLContext objects) moves to a different screen, or other cases where the NSOpenGLContext object needs to be updated. The notification object is the surface's view. This notification does not contain a *userInfo* dictionary.

Availability
Available in Mac OS X v10.1 and later.

Declared In
NSView.h

Overview

The `NSViewAnimation` class, a public subclass of `NSAnimation`, offers a convenient way to animate multiple views and windows. The animation effects you can achieve are limited to changes in frame location and size, and to fade-in and fade-out effects.

An `NSViewAnimation` object takes an array of dictionaries from which it determines the objects to animate and the effects to apply to them. Each dictionary must have a target object and, optionally, properties that specify beginning and ending frame and whether to fade in or fade out. (See "View Animation Dictionary Keys" (page 3261) for further information.) Animations with `NSViewAnimation` are, by default, in non-blocking mode over a duration of 0.5 seconds using the ease in-out animation curve. But you can configure the animation to have any duration, curve, frame rate, and blocking mode. You may also set progress marks, assign a delegate, and implement delegation methods in order to animate view and windows concurrent with the ones specified as targets in the view-animation dictionary.

Invoking the `NSAnimation` `stopAnimation` (page 112) method on a running `NSViewAnimation` object moves the animation to the end frame.

Tasks

Initializing an NSViewAnimation Object

- `initWithViewAnimations:` (page 3260)
  Returns an `NSViewAnimation` object initialized with the supplied information.

Getting and Setting View-animation Dictionaries

- `setViewAnimations:` (page 3261)
  Sets the dictionaries defining the objects to animate.
- `viewAnimations` (page 3261)
  Returns the array of dictionaries defining the objects to animate.

Instance Methods

initWithViewAnimations:

Returns an `NSViewAnimation` object initialized with the supplied information.

```
- (id)initWithViewAnimations:(NSArray *)viewAnimations
```

Parameters

viewAnimations

An array of `NSDictionary` objects. Each dictionary specifies a view or window to animate and the effect to apply. *viewAnimations* can be `nil`, but you must later set the required array of dictionaries with `setViewAnimations:` (page 3261) if you want to use the capabilities of the `NSViewAnimation` class. See"View Animation Dictionary Keys" (page 3261) for a description of valid keys and values for dictionaries in *viewAnimations*.

Return Value

The created `NSViewAnimation` object or `nil` if there was a problem initializing the object.

Availability

Available in Mac OS X v10.4 and later.

setViewAnimations:

Sets the dictionaries defining the objects to animate.

```
- (void)setViewAnimations:(NSArray *)viewAnimations
```

Parameters

viewAnimations

An array of `NSDictionary` objects. Each dictionary specifies a view or window to animate and the effect to apply. Pass in `nil` to remove the current list of dictionaries. See "View Animation Dictionary Keys" (page 3261) for a description of valid keys and values for dictionaries in *viewAnimations*.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `viewAnimations` (page 3261)

Constants

View Animation Dictionary Keys

The following string constants are keys for the dictionaries in the array passed into `initWithViewAnimations:` (page 3260) and `setViewAnimations:` (page 3261).

```
NSString *NSViewAnimationTargetKey;
NSString *NSViewAnimationStartFrameKey;
NSString *NSViewAnimationEndFrameKey;
NSString *NSViewAnimationEffectKey;
```

Constants

`NSViewAnimationTargetKey`

The target of the animation.

The target can be either an `NSView` object or an `NSWindow` object. This property is required.

Available in Mac OS X v10.4 and later.

Declared in `NSAnimation.h`.

`NSViewAnimationStartFrameKey`

The size and location of the window or view at the start of the animation.

The size and location are specified by an `NSRect` structure encoded in an `NSValue` object. This property is optional. If it is not specified, `NSViewAnimation` uses the frame of the window or view at the start of the animation.

Available in Mac OS X v10.4 and later.

Declared in `NSAnimation.h`.

`NSViewAnimationEndFrameKey`

The size and location of the window or view at the end of the animation.

The size and location are specified by an `NSRect` structure encoded in an `NSValue` object. This property is optional. If it is not specified, `NSViewAnimation` uses the frame of the window or view at the start of the animation. If the target is a view and the end frame is empty, the view is hidden at the end.

Available in Mac OS X v10.4 and later.

Declared in `NSAnimation.h`.

`NSViewAnimationEffectKey`

An effect to apply to the animation.

Takes a string constant specifying fade-in or fade-out effects for the target: `NSViewAnimationFadeInEffect` and `NSViewAnimationFadeOutEffect`. If the target is a view and the effect is to fade out, the view is hidden at the end. If the effect is to fade in an initially hidden view and the end frame is non-empty, the view is unhidden at the end. If the target is a window, the window is ordered in or out as appropriate to the effect. This property is optional.

Available in Mac OS X v10.4 and later.

Declared in `NSAnimation.h`.

Declared In

`NSAnimation.h`

Values for NSViewAnimationEffectKey

The following constants specify the animation effect to apply and are used as values for the animation effect property of the animation view. See the description of `NSViewAnimationEffectKey` for usage details.

```
NSString *NSViewAnimationFadeInEffect;
NSString *NSViewAnimationFadeOutEffect;
```

Constants

`NSViewAnimationFadeInEffect`

Specifies a fade-in type of effect.

Available in Mac OS X v10.4 and later.

Declared in `NSAnimation.h`.

`NSViewAnimationFadeOutEffect`

Specifies a fade-out type of effect.

Available in Mac OS X v10.4 and later.

Declared in `NSAnimation.h`.

Availability

Available in Mac OS X v10.4 and later

Declared In

`NSAnimation.h`

Overview

An `NSViewController` object manages a view, typically loaded from a nib file.

This management includes:

- Memory management of top-level objects similar to that of the `NSWindowController` class, taking the same care to prevent reference cycles when controls are bound to the nib file's owner that `NSWindowController` began taking in Mac OS v 10.4.
- Declaring a generic `representedObject` (page 3271) property, to make it easy to establish bindings in the nib to an object that isn't yet known at nib-loading time or readily available to the code that's doing the nib loading.
- Implementing the key-value binding `NSEditor` informal protocol, so that applications using `NSViewController` can easily make bound controls in the views commit or discard the changes the user is making.

`NSViewController` is meant to be highly reusable. For example, the `NSPageLayout` and `NSPrintPanel` `addAccessoryController:` (page 1854) methods take an `NSViewController` instance as the argument, and set the `representedObject` (page 3271) to the `NSPrintInfo` that is to be shown to the user. This allows a developer to easily create new printing accessory views using bindings and the `NSPrintInfo` class' new key-value coding and key-value observing compliance. When the user dismisses a printing panel,

`NSPageLayout` and `NSPrintPanel` each send `NSEditor` messages to each accessory view controller to ensure that the user's changes have been committed or discarded properly. The titles of the accessories are retrieved from the view controllers and shown to the user in pulldown menus that the user can choose from. If your application needs to dynamically associate relatively complex views with the objects that they present to the user, you might be able to reuse `NSViewController` in similar ways.

Tasks

Creating A View Controller

- `initWithNibName:bundle:` (page 3269)
  Returns an `NSViewController` object initialized to the nib file in the specified bundle.
- `loadView` (page 3269)
  Instantiate the receiver's view and set it.

Represented Object

- `setRepresentedObject:` (page 3271)
  Sets the object whose value is being presented in the receiver's view.
- `representedObject` (page 3271)
  Returns the object whose value is being presented in the receiver's view.

Nib Properties

- `nibBundle` (page 3270)
  Return the name of the nib bundle to be loaded to instantiate the receivers view.
- `nibName` (page 3270)
  Return the name of the nib to be loaded to instantiate the receivers view

View Properties

- `view` (page 3273)
  Returns the receiver's view.
- `setView:` (page 3272)
  Sets the receivers view to the specified object.
- `title` (page 3272)
  Returns the localized title of the receiver's view.
- `setTitle:` (page 3271)
  Sets the localized title of the receiver's view to the specified string.

NSEditor Conformance

- `commitEditingWithDelegate:didCommitSelector:contextInfo:` (page 3267)
  Attempt to commit any currently edited results of the receiver.
- `commitEditing` (page 3267)
  Returns whether the receiver was able to commit any pending edits.
- `discardEditing` (page 3268)
  Causes the receiver to discard any changes, restoring the previous values.

Instance Methods

commitEditing

Returns whether the receiver was able to commit any pending edits.

```
- (BOOL)commitEditing
```

Return Value
Returns `YES` if the changes were successfully applied to the model, `NO` otherwise.

Discussion
A commit is denied if the receiver fails to apply the changes to the model object, perhaps due to a validation error.

Availability
Available in Mac OS X v10.5 and later.

See Also
- `commitEditingWithDelegate:didCommitSelector:contextInfo:` (page 3267)
- `discardEditing` (page 3268)

Declared In
`NSViewController.h`

commitEditingWithDelegate:didCommitSelector:contextInfo:

Attempt to commit any currently edited results of the receiver.

```
- (void)commitEditingWithDelegate:(id)delegate
    didCommitSelector:(SEL)didCommitSelector contextInfo:(void *)contextInfo
```

Parameters
delegate
An object that can serve as the receiver's delegate. It should implement the method specified by *didCommitSelector*.

didCommitSelector
A selector that is invoked on delegate.

contextInfo

Contextual information that is sent as the `contextInfo` argument to delegate when *didCommitSelector* is invoked.

Discussion
The receiver must have been registered as the editor of an object using `objectDidBeginEditing:` (page 3682), and has not yet been unregistered by a subsequent invocation of `objectDidEndEditing:` (page 3682). When the committing has either succeeded or failed, send the *delegate* the message specified by *didCommitSelector*.

The *didCommitSelector* method must have the following method signature:.

```
- (void)editor:(id)editor didCommit:(BOOL)didCommit contextInfo:(void
*)contextInfo
```

If an error occurs while attempting to commit, for example if key-value coding validation fails, an implementation of this method should typically send the receiver's view a`presentError:modalForWindow:delegate:didPresentSelector:contextInfo:` (page 2187) message, specifying the view's containing window.

You may find this method useful in some situations when you want to ensure that pending changes are applied before a change in user interface state. For example, you may need to ensure that changes pending in a text field are applied before a window is closed. See also `commitEditing` (page 3267) which performs a similar function but which allows you to handle any errors directly, although it provides no information beyond simple success/failure.

Availability
Available in Mac OS X v10.5 and later.

See Also
- `commitEditing` (page 3267)
- `discardEditing` (page 3268)

Declared In
`NSViewController.h`

discardEditing

Causes the receiver to discard any changes, restoring the previous values.

```
- (void)discardEditing
```

Availability
Available in Mac OS X v10.5 and later.

See Also
- `commitEditing` (page 3267)

Declared In
`NSViewController.h`

initWithNibName:bundle:

Returns an `NSViewController` object initialized to the nib file in the specified bundle.

```
- (id)initWithNibName:(NSString *)nibNameOrNil bundle:(NSBundle *)nibBundleOrNil
```

Parameters

nibNameOrNil

The name of the nib file, without any leading path information.

nibBundleOrNil

The bundle in which to search for the nib file. If you specify nil, this method looks for the nib file in the main bundle.

Return Value

The initialized `NSViewController` object or `nil` if there were errors during initialization or the nib file could not be located.

Discussion

The `NSViewController` object looks for the nib file in the bundle's language-specific project directories first, followed by the Resources directory.

The specified nib should typically have the class of the file's owner set to `NSViewController`, or a custom subclass, with the `view` outlet connected to a view.

If you pass in a `nil` for *nibNameOrNil* then `nibName` (page 3270) will return `nil` and `loadView` (page 3269) will throw an exception; in this case you must invoke `setView:` (page 3272) before `view` (page 3273) is invoked, or override `loadView` (page 3269).

Availability

Available in Mac OS X v10.5 and later.

Related Sample Code

ComplexBrowser

SourceView

ViewController

ZipBrowser

Declared In

`NSViewController.h`

loadView

Instantiate the receiver's view and set it.

```
- (void)loadView
```

Discussion

The default implementation of this method invokes `nibName` (page 3270) and `nibBundle` (page 3270) and then uses the `NSNib` class to load the nib with the receiver as the file's owner. If the `view` outlet of the file's owner in the nib is properly connected, the regular nib loading machinery will send the receiver a `setView:` (page 3272) message.

Availability
Available in Mac OS X v10.5 and later.

Related Sample Code
AnimatedTableView

Declared In
NSViewController.h

nibBundle

Return the name of the nib bundle to be loaded to instantiate the receivers view.

```
- (NSBundle *)nibBundle
```

Return Value
The name of the nib bundle.

Discussion
The default implementation returns whatever value was passed to the initializer.

Availability
Available in Mac OS X v10.5 and later.

See Also
- `initWithNibName:bundle:` (page 3269)
- `nibName` (page 3270)

Declared In
NSViewController.h

nibName

Return the name of the nib to be loaded to instantiate the receivers view

```
- (NSString *)nibName
```

Return Value
The name of the nib.

Discussion
The default implementation returns whatever value was passed to the initializer.

Availability
Available in Mac OS X v10.5 and later.

See Also
- `initWithNibName:bundle:` (page 3269)
- `nibBundle` (page 3270)

Declared In
NSViewController.h

representedObject

Returns the object whose value is being presented in the receiver's view.

```
- (id)representedObject
```

Return Value
The object whose value is presented in the receiver's view.

Discussion
This class is key-value coding and key-value observing compliant for `representedObject` (page 3271) so when you use it as the file's owner of a view's nib you can bind controls to the file's owner using key paths that start with `representedObject`.

Availability
Available in Mac OS X v10.5 and later.

See Also
`- setRepresentedObject:` (page 3271)

Declared In
`NSViewController.h`

setRepresentedObject:

Sets the object whose value is being presented in the receiver's view.

```
- (void)setRepresentedObject:(id)representedObject
```

Parameters
representedObject
The object whose value is presented in the receiver's view.

Discussion
The default implementation of this method doesn't copy the passed-in object, it retains it. In another words, *representedObject* is a to-one relationship, not an attribute.

This class is key-value coding and key-value observing compliant for `representedObject` (page 3271) so when you use it as the file's owner of a view's nib you can bind controls to the file's owner using key paths that start with `representedObject`.

Availability
Available in Mac OS X v10.5 and later.

See Also
`- representedObject` (page 3271)

Declared In
`NSViewController.h`

setTitle:

Sets the localized title of the receiver's view to the specified string.

```
- (void)setTitle:(NSString *)title
```

Parameters

title

The localized title of the receiver view.

Discussion

`NSViewController` does not use the title property directly. This property is here because so many anticipated uses of this class will involve letting the user choose among multiple named views using a pulldown menu or some other user interface.

This class is key value coding and key value compliant for this property.

Availability

Available in Mac OS X v10.5 and later.

See Also

`- title` (page 3272)

Declared In

`NSViewController.h`

setView:

Sets the receivers view to the specified object.

```
- (void)setView:(NSView *)view
```

Parameters

view

The view the receiver should manage.

Discussion

You can invoke this method immediately after creating the object to specify a view that's created in a different manner than the receiver's default implementation would provide.

Availability

Available in Mac OS X v10.5 and later.

See Also

`- view` (page 3273)

Declared In

`NSViewController.h`

title

Returns the localized title of the receiver's view.

```
- (NSString *)title
```

Return Value

The localized title of the receiver's view

Discussion
`NSViewController` does not use the title property directly. This property is here because so many anticipated uses of this class will involve letting the user choose among multiple named views using a pulldown menu or some other user interface.

This class is key value coding and key value compliant for this property.

Availability
Available in Mac OS X v10.5 and later.

Overview

The `NSWindow` class defines objects (known as **windows**) that manage and coordinate the windows an application displays on the screen. A single `NSWindow` object corresponds to at most one onscreen window. The two principal functions of a window are to provide an area in which views can be placed and to accept and distribute, to the appropriate views, events the user instigates through actions with the mouse and keyboard.

Note: Although the `NSWindow` class inherits the `NSCoding` protocol from `NSResponder`, the class does not support coding. Legacy support for archivers exists but its use is deprecated and may not work. Any attempt to archive or unarchive an `NSWindow` object using a keyed coding object raises an `NSInvalidArgumentException` exception.

Tasks

Creating Windows

- `initWithContentRect:styleMask:backing:defer:` (page 3332)
  Initializes the window with the specified values.
- `initWithContentRect:styleMask:backing:defer:screen:` (page 3333)
  Initializes an allocated window with the specified values.

Configuring Windows

- `styleMask` (page 3402)
  Returns the window's style mask, indicating what kinds of control items it displays.
- `setStyleMask:` (page 3398)
  Sets the window's style mask to the given value.
- `worksWhenModal` (page 3409)
  Indicates whether the window is able to receive keyboard and mouse events even when some other window is being run modally.
- `alphaValue` (page 3298)
  Returns the window's alpha value.
- `setAlphaValue:` (page 3367)
  Applies a given alpha value to the entire window.
- `backgroundColor` (page 3301)
  Returns the color of the window's background.
- `setBackgroundColor:` (page 3370)
  Sets the window's background color to the given color.
- `colorSpace` (page 3309)
  Returns the window's color space.
- `setColorSpace:` (page 3373)
  Sets the window's color space.
- `contentView` (page 3313)
  Returns the window's content view, the highest accessible `NSView` object in the window's view hierarchy.
- `setContentView:` (page 3376)
  Makes a given view the window's content view.

- `canHide` (page 3306)
  Indicates whether the window can be hidden when its application becomes hidden (during execution of the `NSApplication hide:` (page 148) method).
- `setCanHide:` (page 3372)
  Specifies whether the window can be hidden when its application becomes hidden (during execution of the `NSApplication hide:` (page 148) method).
- `isOnActiveSpace` (page 3340)
  Indicates whether the window is on the currently active space.
- `hidesOnDeactivate` (page 3331)
  Indicates whether the window is removed from the screen when its application becomes inactive.
- `setHidesOnDeactivate:` (page 3386)
  Specifies whether the window is removed from the screen when the application is inactive.
- `collectionBehavior` (page 3309)
  Identifies the window's behavior in window collections.
- `setCollectionBehavior:` (page 3372)
  Specifies the window's behavior in window collections.
- `isOpaque` (page 3340)
  Indicates whether the window is opaque.
- `setOpaque:` (page 3392)
  Specifies whether the window is opaque.
- `hasShadow` (page 3331)
  Indicates whether the window has a shadow.
- `setHasShadow:` (page 3385)
  Specifies whether the window has a shadow.
- `invalidateShadow` (page 3336)
  Invalidates the window shadow so that it is recomputed based on the current window shape.
- `autorecalculatesContentBorderThicknessForEdge:` (page 3300)
  Indicates whether the window calculates the thickness of a given border automatically.
- `setAutorecalculatesContentBorderThickness:forEdge:` (page 3369)
  Specifies whether the window calculates the thickness of a given border automatically.
- `contentBorderThicknessForEdge:` (page 3310)
  Indicates the thickness of a given border of the window.
- `setContentBorderThickness:forEdge:` (page 3373)
  Specifies the thickness of a given border of the window.
- `delegate` (page 3316)
  Returns the window's delegate.
- `setDelegate:` (page 3377)
  Sets the window's delegate to a given object or removes an existing delegate.
- `preventsApplicationTerminationWhenModal` (page 3357)
  Indicates whether the window prevents application termination when modal.
- `setPreventsApplicationTerminationWhenModal:` (page 3394)
  Specifies whether the window prevents application termination when modal.

- `canBeVisibleOnAllSpaces` (page 3305) Deprecated in Mac OS X v10.5
  Indicates whether the window can be visible on all spaces or on only one space at a time. (Deprecated. Use `setCollectionBehavior:` (page 3372) instead.)
- `setCanBeVisibleOnAllSpaces:` (page 3371) Deprecated in Mac OS X v10.5
  Specifies whether the window can be visible on all spaces or on only one space at a time. (Deprecated. Use `collectionBehavior` (page 3309) instead.)

Accessing Window Information

+ `defaultDepthLimit` (page 3292)
  Returns the default depth limit for instances of `NSWindow`.
- `windowNumber` (page 3408)
  Provides the window number of the window's window device.
+ `windowNumbersWithOptions:` (page 3296)
  Returns the window numbers for all visible windows satisfying the specified options.
- `gState` (page 3330)
  Returns the window's graphics state object.
- `canStoreColor` (page 3306)
  Indicates whether the window has a depth limit that allows it to store color values.
- `deviceDescription` (page 3318)
  Returns a dictionary containing information about the window's resolution.
- `canBecomeVisibleWithoutLogin` (page 3305)
  Indicates whether the window can be displayed at the login window. Default: `NO`.
- `setCanBecomeVisibleWithoutLogin:` (page 3371)
  Specifies whether the window can be displayed at the login window.
- `sharingType` (page 3401)
  Indicates the level of access other processes have to the window's content.
- `setSharingType:` (page 3396)
  Specifies the level of access other processes have to the window's content.
- `backingType` (page 3302)
  Returns the window's backing store type.
- `setBackingType:` (page 3370)
  Sets the window's backing store type to a given type.
- `backingLocation` (page 3302)
  Indicates the window's backing store location.
- `preferredBackingLocation` (page 3356)
  Indicates the preferred location for the window's backing store.
- `setPreferredBackingLocation:` (page 3393)
  Specifies the preferred location for the window's backing store.
- `isOneShot` (page 3340)
  Indicates whether the window device the window manages is freed when it's removed from the screen list.

- `setOneShot:` (page 3391)
  Sets whether the window device that the window manages should be freed when it's removed from the screen list.
- `depthLimit` (page 3317)
  Returns the depth limit of the window.
- `setDepthLimit:` (page 3378)
  Sets the depth limit of the window to a given limit.
- `hasDynamicDepthLimit` (page 3330)
  Indicates whether the window's depth limit can change to match the depth of the screen it's on.
- `setDynamicDepthLimit:` (page 3380)
  Sets whether the window changes its depth to match the depth of the screen it's on, or the depth of the deepest screen when it spans multiple screens.

Getting Layout Information

+ `contentRectForFrameRect:styleMask:` (page 3292)
  Returns the content rectangle used by a window with a given frame rectangle and window style.
+ `frameRectForContentRect:styleMask:` (page 3293)
  Returns the frame rectangle used by a window with a given content rectangle and window style.
+ `minFrameWidthWithTitle:styleMask:` (page 3294)
  Returns the minimum width a window's frame rectangle must have for it to display a title, with a given window style.
- `contentRectForFrameRect:` (page 3312)
  Returns the window's content rectangle with a given frame rectangle.
- `frameRectForContentRect:` (page 3329)
  Returns the window's frame rectangle with a given content rectangle.

Managing Windows

- `drawers` (page 3324)
  Returns the collection of drawers associated with the window.
- `windowController` (page 3407)
  Returns the window's window controller.
- `setWindowController:` (page 3400)
  Sets the window's window controller.

Managing Sheets

- `attachedSheet` (page 3300)
  Returns the sheet attached to the window.
- `isSheet` (page 3341)
  Indicates whether the window has ever run as a modal sheet.

Sizing Windows

- `frame` (page 3328)
  Returns the window's frame rectangle.
- `setFrameOrigin:` (page 3383)
  Positions the bottom-left corner of the window's frame rectangle at a given point in screen coordinates.
- `setFrameTopLeftPoint:` (page 3384)
  Positions the top-left corner of the window's frame rectangle at a given point in screen coordinates.
- `constrainFrameRect:toScreen:` (page 3309)
  Modifies and returns a frame rectangle so that its top edge lies on a specific screen.
- `cascadeTopLeftFromPoint:` (page 3306)
  Positions the window's top left to a given point.
- `setFrame:display:` (page 3381)
  Sets the origin and size of the window's frame rectangle according to a given frame rectangle, thereby setting its position and size onscreen.
- `setFrame:display:animate:` (page 3381)
  Sets the origin and size of the window's frame rectangle, with optional animation, according to a given frame rectangle, thereby setting its position and size onscreen.
- `animationResizeTime:` (page 3299)
  Specifies the duration of a smooth frame-size change.
- `aspectRatio` (page 3300)
  Returns the window's aspect ratio, which constrains the size of its frame rectangle to integral multiples of this ratio when the user resizes it.
- `setAspectRatio:` (page 3368)
  Sets the window's aspect ratio, which constrains the size of its frame rectangle to integral multiples of this ratio when the user resizes it.
- `minSize` (page 3348)
  Returns the minimum size to which the window's frame (including its title bar) can be sized.
- `setMinSize:` (page 3390)
  Sets the minimum size to which the window's frame (including its title bar) can be sized to *aSize*.
- `maxSize` (page 3346)
  Returns the maximum size to which the window's frame (including its title bar) can be sized.
- `setMaxSize:` (page 3388)
  Sets the maximum size to which the window's frame (including its title bar) can be sized.
- `isZoomed` (page 3342)
  Returns a Boolean value that indicates whether the window is in a zoomed state.
- `performZoom:` (page 3355)
  This action method simulates the user clicking the zoom box by momentarily highlighting the button and then zooming the window.
- `zoom:` (page 3409)
  This action method toggles the size and location of the window between its standard state (provided by the application as the "best" size to display the window's data) and its user state (a new size and location the user may have set by moving or resizing the window).
- `resizeFlags` (page 3361)
  Returns the flags field of the event record for the mouse-down event that initiated the resizing session.

- `showsResizeIndicator` (page 3401)
  Returns a Boolean value that indicates whether the window's resize indicator is visible.
- `setShowsResizeIndicator:` (page 3397)
  Specifies whether the window's resize indicator is visible
- `resizeIncrements` (page 3361)
  Returns the window's resizing increments.
- `setResizeIncrements:` (page 3396)
  Restricts the user's ability to resize the window so the width and height change by multiples of width and height increments.
- `preservesContentDuringLiveResize` (page 3356)
  Returns whether the window tries to optimize user-initiated resize operations by preserving the content of views that have not changed.
- `setPreservesContentDuringLiveResize:` (page 3393)
  Specifies whether the window tries to optimize live resize operations by preserving the content of views that have not changed.
- `inLiveResize` (page 3335)
  Indicates whether the window is being resized by the user.

Sizing Content

- `contentAspectRatio` (page 3310)
  Returns the window's content aspect ratio.
- `setContentAspectRatio:` (page 3373)
  Sets the aspect ratio (height in relation to width) of the window's content view, constraining the dimensions of its content rectangle to integral multiples of that ratio when the user resizes it.
- `contentMinSize` (page 3311)
  Returns the minimum size of the window's content view.
- `setContentMinSize:` (page 3374)
  Sets the minimum size of the window's content view in the window's base coordinate system.
- `setContentSize:` (page 3375)
  Sets the size of the window's content view to a given size, which is expressed in the window's base coordinate system.
- `contentMaxSize` (page 3311)
  Returns the maximum size of the window's content view.
- `setContentMaxSize:` (page 3374)
  Sets the maximum size of the window's content view in the window's base coordinate system.
- `contentResizeIncrements` (page 3312)
  Returns the window's content-view resizing increments.
- `setContentResizeIncrements:` (page 3375)
  Restricts the user's ability to resize the window so the width and height of its content view change by multiples of width and height increments.

Managing Window Layers

- `isVisible` (page 3342)
  Indicates whether the window is visible onscreen (even when It's obscured by other windows).
- `orderOut:` (page 3352)
  Removes the window from the screen list, which hides the window.
- `orderBack:` (page 3350)
  Moves the window to the back of its level in the screen list, without changing either the key window or the main window.
- `orderFront:` (page 3351)
  Moves the window to the front of its level in the screen list, without changing either the key window or the main window.
- `orderFrontRegardless` (page 3351)
  Moves the window to the front of its level, even if its application isn't active, without changing either the key window or the main window.
- `orderWindow:relativeTo:` (page 3352)
  Repositions the window's window device in the window server's screen list.
- `level` (page 3343)
  Returns the window level of the window.
- `setLevel:` (page 3387)
  Sets the window's window level to a given level.

Managing Window Frames in User Defaults

+ `removeFrameUsingName:` (page 3294)
  Removes the frame data stored under a given name from the application's user defaults.
- `setFrameUsingName:` (page 3384)
  Sets the window's frame rectangle by reading the rectangle data stored under a given name from the defaults system.
- `setFrameUsingName:force:` (page 3385)
  Sets the window's frame rectangle by reading the rectangle data stored under a given name from the defaults system. Can operate on nonresizable windows.
- `saveFrameUsingName:` (page 3363)
  Saves the window's frame rectangle in the user defaults system under a given name.
- `frameAutosaveName` (page 3329)
  Returns the name used to automatically save the window's frame rectangle data in the defaults system, as set through `setFrameAutosaveName:` (page 3382).
- `setFrameAutosaveName:` (page 3382)
  Sets the name used to automatically save the window's frame rectangle in the defaults system to a given name.
- `stringWithSavedFrame` (page 3402)
  Returns a string representation of the window's frame rectangle.
- `setFrameFromString:` (page 3383)
  Sets the window's frame rectangle from a given string representation.

Managing Key Status

- `isKeyWindow` (page 3338)
  Indicates whether the window is the key window for the application.
- `canBecomeKeyWindow` (page 3304)
  Indicates whether the window can become the key window.
- `makeKeyWindow` (page 3345)
  Makes the window the key window.
- `makeKeyAndOrderFront:` (page 3345)
  Moves the window to the front of the screen list, within its level, and makes it the key window; that is, it shows the window.
- `becomeKeyWindow` (page 3302)
  Invoked automatically to inform the window that it has become the key window; never invoke this method directly.
- `resignKeyWindow` (page 3360)
  Invoked automatically when the window resigns key window status; never invoke this method directly.

Managing Main Status

- `isMainWindow` (page 3338)
  Indicates whether the window is the application's main window.
- `canBecomeMainWindow` (page 3304)
  Indicates whether the window can become the application's main window.
- `makeMainWindow` (page 3346)
  Makes the window the main window.
- `becomeMainWindow` (page 3303)
  Invoked automatically to inform the window that it has become the main window; never invoke this method directly.
- `resignMainWindow` (page 3361)
  Invoked automatically when the window resigns main window status; never invoke this method directly.

Managing Toolbars

- `toolbar` (page 3404)
  Returns the window's toolbar.
- `setToolbar:` (page 3399)
  Sets the window's toolbar.
- `toggleToolbarShown:` (page 3403)
  The action method for the "Hide Toolbar" menu item (which alternates with "Show Toolbar").
- `runToolbarCustomizationPalette:` (page 3362)
  The action method for the "Customize Toolbar…" menu item.

Managing Attached Windows

- `childWindows` (page 3308)
  Returns an array of the window's attached child windows.
- `addChildWindow:ordered:` (page 3297)
  Adds a given window as a child window of the window.
- `removeChildWindow:` (page 3358)
  Detaches a given child window from the window.
- `parentWindow` (page 3353)
  Returns the parent window to which the window is attached as a child.
- `setParentWindow:` (page 3392)
  Adds the window as a child of a given window. For use by subclasses when setting the parent window in the window.

Managing Window Buffers

- `isFlushWindowDisabled` (page 3337)
  Indicates whether the window's flushing ability is disabled.
- `enableFlushWindow` (page 3324)
  Reenables the `flushWindow` (page 3327) method for the window after it was disabled through a previous `disableFlushWindow` (page 3319) message.
- `disableFlushWindow` (page 3319)
  Disables the `flushWindow` (page 3327) method for the window.
- `flushWindow` (page 3327)
  Flushes the window's offscreen buffer to the screen if the window is buffered and flushing is enabled.
- `flushWindowIfNeeded` (page 3328)
  Flushes the window's offscreen buffer to the screen if flushing is enabled and if the last `flushWindow` (page 3327) message had no effect because flushing was disabled.

Managing Default Buttons

- `defaultButtonCell` (page 3316)
  Returns the button cell that performs as if clicked when the window receives a Return (or Enter) key event.
- `setDefaultButtonCell:` (page 3377)
  Makes the key equivalent of button cell the Return (or Enter) key, so when the user presses Return that button performs as if clicked.
- `enableKeyEquivalentForDefaultButtonCell` (page 3324)
  Reenables the default button cell's key equivalent, so it performs a click when the user presses Return (or Enter).
- `disableKeyEquivalentForDefaultButtonCell` (page 3319)
  Disables the default button cell's key equivalent, so it doesn't perform a click when the user presses Return (or Enter).

Managing Field Editors

- `fieldEditor:forObject:` (page 3325)
  Returns the window's field editor, creating it if requested.
- `endEditingFor:` (page 3325)
  Forces the field editor to give up its first responder status and prepares it for its next assignment.

Managing the Window Menu

- `isExcludedFromWindowsMenu` (page 3337)
  Indicates whether the window is excluded from the application's Windows menu.
- `setExcludedFromWindowsMenu:` (page 3380)
  Specifies whether the window's title is omitted from the application's Windows menu.

Managing Cursor Rectangles

- `areCursorRectsEnabled` (page 3299)
  Indicates whether the window's cursor rectangles are enabled.
- `enableCursorRects` (page 3324)
  Reenables cursor rectangle management within the window after a `disableCursorRects` (page 3318) message.
- `disableCursorRects` (page 3318)
  Disables all cursor rectangle management within the window.
- `discardCursorRects` (page 3320)
  Invalidates all cursor rectangles in the window.
- `invalidateCursorRectsForView:` (page 3335)
  Marks as invalid the cursor rectangles of a given `NSView` object in the window's view hierarchy, so they'll be set up again when the window becomes key (or immediately if the window is key).
- `resetCursorRects` (page 3360)
  Clears the window's cursor rectangles and the cursor rectangles of the `NSView` objects in its view hierarchy.

Managing Title Bars

+ `standardWindowButton:forStyleMask:` (page 3295)
  Returns a new instance of a given standard window button, sized appropriately for a given window style.
- `standardWindowButton:` (page 3402)
  Returns the window button of a given window button kind in the window's view hierarchy.
- `showsToolbarButton` (page 3401)
  Indicates whether the toolbar control button is currently displayed.
- `setShowsToolbarButton:` (page 3397)
  Specifies whether the window shows the toolbar control button.

Managing Tooltips

- `allowsToolTipsWhenApplicationIsInactive` (page 3298)
  Indicates whether the window can display tooltips even when the application is in the background.
- `setAllowsToolTipsWhenApplicationIsInactive:` (page 3367)
  Specifies whether the window can display tooltips even when the application is in the background.

Handling Events

+ `menuChanged:` (page 3294)
  This method does nothing; it is here for backward compatibility.
- `currentEvent` (page 3314)
  Returns the event currently being processed by the application, by invoking `NSApplication`'s `currentEvent` (page 142) method.
- `nextEventMatchingMask:` (page 3349)
  Returns the next event matching a given mask.
- `nextEventMatchingMask:untilDate:inMode:dequeue:` (page 3349)
  Forwards the message to the global `NSApplication` object, `NSApp`.
- `discardEventsMatchingMask:beforeEvent:` (page 3321)
  Forwards the message to the `NSApplication` object, `NSApp`.
- `postEvent:atStart:` (page 3355)
  Forwards the message to the global `NSApplication` object, `NSApp`.
- `sendEvent:` (page 3366)
  This action method dispatches mouse and keyboard events sent to the window by the `NSApplication` object.
- `tryToPerform:with:` (page 3404)
  Dispatches action messages with a given argument.

Managing Responders

- `initialFirstResponder` (page 3332)
  Returns view that's made first responder the first time the window is placed onscreen.
- `firstResponder` (page 3327)
  Returns the window's first responder.
- `setInitialFirstResponder:` (page 3387)
  Sets a given view as the one that's made first responder (also called the key view) the first time the window is placed onscreen.
- `makeFirstResponder:` (page 3344)
  Attempts to make a given responder the first responder for the window.

Managing the Key View Loop

- `selectKeyViewPrecedingView:` (page 3364)
  Makes key the view that precedes the given view.
- `selectKeyViewFollowingView:` (page 3364)
  Makes key the view that follows the given view.
- `selectPreviousKeyView:` (page 3365)
  This action method searches for a candidate previous key view and, if it finds one, invokes `makeFirstResponder:` (page 3344) to establish it as the first responder.
- `selectNextKeyView:` (page 3364)
  This action method searches for a candidate next key view and, if it finds one, invokes `makeFirstResponder:` (page 3344) to establish it as the first responder.
- `keyViewSelectionDirection` (page 3343)
  Returns the direction the window is currently using to change the key view.
- `autorecalculatesKeyViewLoop` (page 3301)
  Indicates whether the window automatically recalculates the key view loop when views are added.
- `recalculateKeyViewLoop` (page 3357)
  Marks the key view loop as dirty and in need of recalculation.
- `setAutorecalculatesKeyViewLoop:` (page 3370)
  Specifies whether to recalculate the key view loop automatically when views are added or removed.

Handling Keyboard Events

- `keyDown:` (page 3343)
  Handles a given keyboard event that may need to be interpreted as changing the key view or triggering a keyboard equivalent.

Handling Mouse Events

- `acceptsMouseMovedEvents` (page 3296)
  Indicates whether the window accepts mouse-moved events.
- `ignoresMouseEvents` (page 3331)
  Indicates whether the window is transparent to mouse events.
- `setIgnoresMouseEvents:` (page 3387)
  Specifies whether the window is transparent to mouse clicks and other mouse events, allowing overlay windows.
- `mouseLocationOutsideOfEventStream` (page 3348)
  Returns the current location of the pointer reckoned in the window's base coordinate system.
- `setAcceptsMouseMovedEvents:` (page 3366)
  Specifies whether the window is to accept mouse-moved events.
- `+ windowNumberAtPoint:belowWindowWithWindowNumber:` (page 3295)
  Returns the number of the frontmost window that would be hit by a mouse-down at the specified screen location.

Bracketing Drawing Operations

- `cacheImageInRect:` (page 3303)
  Stores the window's raster image from a given rectangle expressed in the window's base coordinate system.
- `restoreCachedImage` (page 3362)
  Splices the window's cached image rectangles, if any, back into its raster image (and buffer if it has one), undoing the effect of any drawing performed within those areas since they were established using `cacheImageInRect:` (page 3303).
- `discardCachedImage` (page 3320)
  Discards all of the window's cached image rectangles.

Drawing Windows

- `display` (page 3321)
  Passes a display message down the window's view hierarchy, thus redrawing all views within the window, including the frame view that draws the border, title bar, and other peripheral elements.
- `displayIfNeeded` (page 3321)
  Passes a `displayIfNeeded` message down the window's view hierarchy, thus redrawing all views that need to be displayed, including the frame view that draws the border, title bar, and other peripheral elements.
- `viewsNeedDisplay` (page 3407)
  Indicates whether any of the window's views need to be displayed.
- `setViewsNeedDisplay:` (page 3400)
  Specifies whether the window's views need to be displayed..
- `isAutodisplay` (page 3336)
  Indicates whether the window automatically displays views that need to be displayed.
- `setAutodisplay:` (page 3368)
  Specifies whether the window is to automatically display the views that are marked as needing it.
- `useOptimizedDrawing:` (page 3405)
  Specifies whether the window is to optimize focusing and drawing when displaying its views.
- `graphicsContext` (page 3330)
  Provides the graphics context associated with the window for the current thread.
- `allowsConcurrentViewDrawing` (page 3298)
  Indicates whether the window allows multithreaded view drawing.
- `setAllowsConcurrentViewDrawing:` (page 3366)
  Specifies whether the window allows its views to be drawn concurrently.

Updating Windows

- `disableScreenUpdatesUntilFlush` (page 3319)
  Disables the window's screen updates until the window is flushed.
- `update` (page 3405)
  Updates the window.

Dragging Items

- `dragImage:at:offset:event:pasteboard:source:slideBack:` (page 3323)
  Begins a dragging session.
- `registerForDraggedTypes:` (page 3358)
  Registers a give set of pasteboard types as the pasteboard types the window will accept as the destination of an image-dragging session.
- `unregisterDraggedTypes` (page 3405)
  Unregisters the window as a possible destination for dragging operations.

Converting Coordinates

- `convertBaseToScreen:` (page 3313)
  Converts a given point from the window's base coordinate system to the screen coordinate system.
- `convertScreenToBase:` (page 3314)
  Converts a given point from the screen coordinate system to the window's base coordinate system.
- `userSpaceScaleFactor` (page 3406)
  Returns the scale factor applied to the window.

Accessing Edited Status

- `isDocumentEdited` (page 3336)
  Indicates whether the window's document has been edited.
- `setDocumentEdited:` (page 3379)
  Specifies whether the window's document has been edited.

Managing Titles

- `title` (page 3403)
  Returns either the string that appears in the title bar of the window, or the path to the represented file.
- `setTitle:` (page 3398)
  Sets the string that appears in the window's title bar (if it has one) to a given string and displays the title.
- `setTitleWithRepresentedFilename:` (page 3399)
  Sets a given path as the window's title, formatting it as a file-system path, and records this path as the window's associated filename using `setRepresentedFilename:` (page 3395).
- `representedFilename` (page 3359)
  Returns the pathname of the file the window represents.
- `setRepresentedFilename:` (page 3395)
  Sets the pathname of the file the window represents.
- `representedURL` (page 3359)
  Provides the URL of the file the window represents.

- `setRepresentedURL:` (page 3395)
  Specifies the URL of the file the window represents.

Accessing Screen Information

- `screen` (page 3363)
  Returns the screen the window is on.
- `deepestScreen` (page 3315)
  Returns the deepest screen the window is on (it may be split over several screens).
- `displaysWhenScreenProfileChanges` (page 3322)
  Indicates whether the window context should be updated when the screen profile changes or when the window moves to a different screen.
- `setDisplaysWhenScreenProfileChanges:` (page 3378)
  Specifies whether the window context should be updated when the screen profile changes.

Moving Windows

- `isMovableByWindowBackground` (page 3339)
  Indicates whether the window is movable by clicking and dragging anywhere in its background.
- `setMovableByWindowBackground:` (page 3391)
  Sets whether the window is movable by clicking and dragging anywhere in its background.
- `isMovable` (page 3339)
  Indicates whether the window can be moved by clicking in its title bar or background.
- `setMovable:` (page 3391)
  Specifies whether the window can be dragged by clicking in its title bar or background.
- `center` (page 3307)
  Sets the window's location to the center of the screen.

Closing Windows

- `performClose:` (page 3354)
  This action method simulates the user clicking the close button by momentarily highlighting the button and then closing the window.
- `close` (page 3308)
  Removes the window from the screen.
- `isReleasedWhenClosed` (page 3341)
  Indicates whether the window is released when it receives the `close` message.
- `setReleasedWhenClosed:` (page 3394)
  Specifies whether the window is released when it receives the `close` message.

Minimizing Windows

- `isMiniaturized` (page 3338)
  Indicates whether the window is minimized.
- `performMiniaturize:` (page 3354)
  Simulates the user clicking the minimize button by momentarily highlighting the button, then minimizing the window.
- `miniaturize:` (page 3347)
  Removes the window from the screen list and displays the minimized window in the Dock.
- `deminiaturize:` (page 3317)
  Deminimizes the window.
- `miniwindowImage` (page 3347)
  Returns the custom miniaturized window image of the window.
- `setMiniwindowImage:` (page 3389)
  Sets the window's custom minimized window image to a given image.
- `miniwindowTitle` (page 3347)
  Returns the title displayed in the window's minimized window.
- `setMiniwindowTitle:` (page 3390)
  Sets the title of the window's miniaturized counterpart to a given string and redisplays it.

Getting the Dock Tile

- `dockTile` (page 3322)
  Provides the application's Dock tile.

Printing Windows

- `print:` (page 3357)
  This action method runs the Print panel, and if the user chooses an option other than canceling, prints the window (its frame view and all subviews).
- `dataWithEPSInsideRect:` (page 3314)
  Returns EPS data that draws the region of the window within a given rectangle.
- `dataWithPDFInsideRect:` (page 3315)
  Returns PDF data that draws the region of the window within a given rectangle.

Providing Services

- `validRequestorForSendType:returnType:` (page 3406)
  Searches for an object that responds to a Services request.

Working with Carbon

`- initWithWindowRef:` (page 3334)
Returns a Cocoa window created from a Carbon window.

`- windowRef` (page 3408)
Returns the Carbon `WindowRef` associated with the window, creating one if necessary.

Class Methods

contentRectForFrameRect:styleMask:

Returns the content rectangle used by a window with a given frame rectangle and window style.

```
+ (NSRect)contentRectForFrameRect:(NSRect)windowFrame
    styleMask:(NSUInteger)windowStyle
```

Parameters

windowFrame
The frame rectangle for the window expressed in screen coordinates.

windowStyle
The window style for the window. See "Constants" (page 3411) for a list of style mask values.

Return Value
The content rectangle, expressed in screen coordinates, used by the window with *windowFrame* and *windowStyle*.

Discussion
When a `NSWindow` instance is available, you should use `contentRectForFrameRect:` (page 3312) instead of this method.

Availability
Available in Mac OS X v10.0 and later.

See Also
`+ frameRectForContentRect:styleMask:` (page 3293)

Related Sample Code
GLUT

Declared In
`NSWindow.h`

defaultDepthLimit

Returns the default depth limit for instances of `NSWindow`.

```
+ (NSWindowDepth)defaultDepthLimit
```

Return Value
The default depth limit for instances of `NSWindow`, determined by the depth of the deepest screen level available to the window server.

Discussion
The value returned can be examined with the Application Kit functions `NSPlanarFromDepth` (page 3990), `NSColorSpaceFromDepth` (page 3966), `NSBitsPerSampleFromDepth` (page 3966), and `NSBitsPerPixelFromDepth` (page 3966).

Availability
Available in Mac OS X v10.0 and later.

See Also
- `- setDepthLimit:` (page 3378)
- `- setDynamicDepthLimit:` (page 3380)
- `- canStoreColor` (page 3306)

Declared In
`NSWindow.h`

frameRectForContentRect:styleMask:

Returns the frame rectangle used by a window with a given content rectangle and window style.

```
+ (NSRect)frameRectForContentRect:(NSRect)windowContentRect
    styleMask:(NSUInteger)windowStyle
```

Parameters

windowContentRect
The content rectangle for a window expressed in screen coordinates.

windowStyle
The window style for the window. See "Window Style Masks" (page 3411) for a list of style mask values.

Return Value
The frame rectangle, expressed in screen coordinates, used by the window with *windowContentRect* and *windowStyle*.

Discussion
When a `NSWindow` instance is available, you should use `frameRectForContentRect:` (page 3329) instead of this method.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `+ contentRectForFrameRect:styleMask:` (page 3292)

Declared In
NSWindow.h

menuChanged:

This method does nothing; it is here for backward compatibility.

```
+ (void)menuChanged:(NSMenu *)menu
```

Parameters

menu
The menu object that changed.

Availability
Available in Mac OS X v10.0 and later.

See Also
- menu (page 2163) (NSResponder)

Declared In
NSWindow.h

minFrameWidthWithTitle:styleMask:

Returns the minimum width a window's frame rectangle must have for it to display a title, with a given window style.

```
+ (CGFloat)minFrameWidthWithTitle:(NSString *)windowTitle
    styleMask:(NSUInteger)windowStyle
```

Parameters

windowTitle
The title for the window.

windowStyle
The window style for the window. See "Window Style Masks" (page 3411) for a list of style mask values.

Return Value
The minimum width of the window's frame, using windowStyle, in order to display windowTitle.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSWindow.h

removeFrameUsingName:

Removes the frame data stored under a given name from the application's user defaults.

```
+ (void)removeFrameUsingName:(NSString *)frameName
```

Parameters

frameName

The name of the frame to remove.

Availability

Available in Mac OS X v10.0 and later.

See Also

- setFrameUsingName: (page 3384)
- setFrameAutosaveName: (page 3382)

Declared In

NSWindow.h

standardWindowButton:forStyleMask:

Returns a new instance of a given standard window button, sized appropriately for a given window style.

```
+ (NSButton *)standardWindowButton:(NSWindowButton)windowButtonKind
    forStyleMask:(NSUInteger)windowStyle
```

Parameters

windowButtonKind

The kind of standard window button to return.

windowStyle

The window style for which *windowButtonKind* is to be sized. See "Window Style Masks" (page 3411) for the list of allowable values.

Return Value

The new window button of the kind identified by *windowButtonKind*; nil when no such button kind exists.

Discussion

The caller is responsible for adding the button to the view hierarchy and for setting the target to be the window.

Availability

Available in Mac OS X v10.2 and later.

See Also

- standardWindowButton: (page 3402)

Declared In

NSWindow.h

windowNumberAtPoint:belowWindowWithWindowNumber:

Returns the number of the frontmost window that would be hit by a mouse-down at the specified screen location.

```
+ (NSInteger)windowNumberAtPoint:(NSPoint)point
    belowWindowWithWindowNumber:(NSInteger)windowNumber
```

Parameters

point

The location of the mouse-down in screen coordinates.

windowNumber

If non-0, the search will start below *windowNumber* window in z-order.

Return Value

The window number of the window under the point. The window number returned may correspond to a window in another application.

Discussion

Because this method uses the same rules as mouse-down hit-testing, windows with transparency at the given point, and windows that ignore mouse events, will not be returned.

Availability

Available in Mac OS X v10.6 and later.

Declared In

NSWindow.h

windowNumbersWithOptions:

Returns the window numbers for all visible windows satisfying the specified options.

```
+ (NSArray *)windowNumbersWithOptions:(NSWindowNumberListOptions)options
```

Parameters

options

The possible options are specified in "NSWindowNumberListOptions" (page 3420).

Return Value

An array of window numbers for all visible windows satisfying the specified options.

Availability

Available in Mac OS X v10.6 and later.

Declared In

NSWindow.h

Instance Methods

acceptsMouseMovedEvents

Indicates whether the window accepts mouse-moved events.

```
- (BOOL)acceptsMouseMovedEvents
```

Return Value

YES when the window accepts (and distributes) mouse-moved events; otherwise, NO.

Discussion
The `NSWindow` default is `NO`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setAcceptsMouseMovedEvents:` (page 3366)

Declared In
`NSWindow.h`

addChildWindow:ordered:

Adds a given window as a child window of the window.

```
- (void)addChildWindow:(NSWindow *)childWindow
    ordered:(NSWindowOrderingMode)orderingMode
```

Parameters

childWindow
The child window to order.

orderingMode
`NSWindowAbove`: *childWindow* is ordered immediately in front of the window.
`NSWindowBelow`: *childWindow* is ordered immediately behind the window.

Discussion
After the *childWindow* is added as a child of the window, it is maintained in relative position indicated by *orderingMode* for subsequent ordering operations involving either window. While this attachment is active, moving *childWindow* will not cause the window to move (as in sliding a drawer in or out), but moving the window will cause *childWindow* to move.

Note that you should not create cycles between parent and child windows. For example, you should not add window B as child of window A, then add window A as a child of window B.

Availability
Available in Mac OS X v10.2 and later.

See Also
- `removeChildWindow:` (page 3358)
- `childWindows` (page 3308)
- `parentWindow` (page 3353)
- `setParentWindow:` (page 3392)

Declared In
`NSWindow.h`

allowsConcurrentViewDrawing

Indicates whether the window allows multithreaded view drawing.

```
- (BOOL)allowsConcurrentViewDrawing
```

Return Value
`YES` if the window allows multithreaded view drawing; otherwise, `NO`.

Discussion
The default value is `YES`.

Availability
Available in Mac OS X v10.6 and later.

See Also
`- setAllowsConcurrentViewDrawing:` (page 3366)

Declared In
`NSWindow.h`

allowsToolTipsWhenApplicationIsInactive

Indicates whether the window can display tooltips even when the application is in the background.

```
- (BOOL)allowsToolTipsWhenApplicationIsInactive
```

Return Value
`YES` if the window can display tooltips even when the application is in the background; otherwise, `NO`.

Discussion
The default is `NO`.

Availability
Available in Mac OS X v10.3 and later.

See Also
`- setAllowsToolTipsWhenApplicationIsInactive:` (page 3367)

Declared In
`NSWindow.h`

alphaValue

Returns the window's alpha value.

```
- (CGFloat)alphaValue
```

Return Value
The window's alpha value.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setAlphaValue:` (page 3367)

Related Sample Code
From A View to A Movie
FunkyOverlayWindow

Declared In
`NSWindow.h`

animationResizeTime:

Specifies the duration of a smooth frame-size change.

```
- (NSTimeInterval)animationResizeTime:(NSRect)newWindowFrame
```

Parameters
newWindowFrame
The frame rectangle specified in `setFrame:display:animate:` (page 3381).

Return Value
The duration of the frame size change.

Discussion
Subclasses can override this method to control the total time for the frame change.

The `NSWindow` implementation uses the value from the `NSWindowResizeTime` user default as the time in seconds to resize by 150 pixels. If this value is unspecified, `NSWindowResizeTime` is 0.20 seconds (this default value may be different in different releases of Mac OS X).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSWindow.h`

areCursorRectsEnabled

Indicates whether the window's cursor rectangles are enabled.

```
- (BOOL)areCursorRectsEnabled
```

Return Value
`YES` when cursor rectangles are enabled; otherwise, `NO`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `enableCursorRects` (page 3324)
- `addCursorRect:cursor:` (page 3139) (`NSView`)

Declared In
NSWindow.h

aspectRatio

Returns the window's aspect ratio, which constrains the size of its frame rectangle to integral multiples of this ratio when the user resizes it.

```
- (NSSize)aspectRatio
```

Return Value
The window's aspect ratio.

Discussion
The size of the window's frame rectangle is constrained to integral multiples of this ratio when the user resizes it. You can set an NSWindow object's size to any ratio programmatically.

Availability
Available in Mac OS X v10.0 and later.

See Also
- resizeIncrements (page 3361)
- setAspectRatio: (page 3368)
- setFrame:display: (page 3381)

Declared In
NSWindow.h

attachedSheet

Returns the sheet attached to the window.

```
- (NSWindow *)attachedSheet
```

Return Value
The sheet attached to the window; nil when the window doesn't have a sheet attached.

Availability
Available in Mac OS X v10.1 and later.

Declared In
NSWindow.h

autorecalculatesContentBorderThicknessForEdge:

Indicates whether the window calculates the thickness of a given border automatically.

```
- (BOOL)autorecalculatesContentBorderThicknessForEdge:(NSRectEdge)edge
```

Parameters

edge

Border whose thickness autorecalculation status to set:

- `NSMaxYEdge`: Top border.
- `NSMinYEdge`: Bottom border.

Return Value
`YES` when the window auto-recalculates the given border's thickness; otherwise, `NO`.

Availability
Available in Mac OS X v10.5 and later.

See Also
`- setAutorecalculatesContentBorderThickness:forEdge:` (page 3369)

Declared In
`NSWindow.h`

autorecalculatesKeyViewLoop

Indicates whether the window automatically recalculates the key view loop when views are added.

```
- (BOOL)autorecalculatesKeyViewLoop
```

Return Value
`YES` if the window automatically recalculates the key view loop when views are added; otherwise, `NO`.

Availability
Available in Mac OS X v10.4 and later.

See Also
`- recalculateKeyViewLoop` (page 3357)
`- setAutorecalculatesKeyViewLoop:` (page 3370)

Declared In
`NSWindow.h`

backgroundColor

Returns the color of the window's background.

```
- (NSColor *)backgroundColor
```

Return Value
The window's background color.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setBackgroundColor:` (page 3370)

Declared In
NSWindow.h

backingLocation

Indicates the window's backing store location.

```
- (NSWindowBackingLocation)backingLocation
```

Return Value
The location of the window's backing store. See "NSWindowBackingLocation" (page 3420) for possible values.

Availability
Available in Mac OS X v10.5 and later.

See Also
- preferredBackingLocation (page 3356)

Declared In
NSWindow.h

backingType

Returns the window's backing store type.

```
- (NSBackingStoreType)backingType
```

Return Value
The backing store type.

Discussion
The possible return values are described in "NSBackingStoreType—Buffered Window Drawing" (page 3417).

Availability
Available in Mac OS X v10.0 and later.

See Also
- setBackingType: (page 3370)

Related Sample Code
StickiesWithCoreData

Declared In
NSWindow.h

becomeKeyWindow

Invoked automatically to inform the window that it has become the key window; never invoke this method directly.

```
- (void)becomeKeyWindow
```

Discussion
This method reestablishes the window's first responder, sends the `becomeKeyWindow` message to that object if it responds, and posts an `NSWindowDidBecomeKeyNotification` (page 3422) to the default notification center.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `makeKeyWindow` (page 3345)
- `makeKeyAndOrderFront:` (page 3345)
- `becomeMainWindow` (page 3303)

Declared In
`NSWindow.h`

becomeMainWindow

Invoked automatically to inform the window that it has become the main window; never invoke this method directly.

```
- (void)becomeMainWindow
```

Discussion
This method posts an `NSWindowDidBecomeMainNotification` (page 3423) to the default notification center.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `makeMainWindow` (page 3346)
- `becomeKeyWindow` (page 3302)

Declared In
`NSWindow.h`

cacheImageInRect:

Stores the window's raster image from a given rectangle expressed in the window's base coordinate system.

```
- (void)cacheImageInRect:(NSRect)rectangle
```

Parameters
rectangle
The rectangle representing the image to cache.

Discussion
This method allows the window to perform temporary drawing, such as a band around the selection as the user drags the mouse, and to quickly restore the previous image by invoking `restoreCachedImage` (page 3362) and `flushWindowIfNeeded` (page 3328). The next time the window displays, it discards its cached image rectangles. You can also explicitly use `discardCachedImage` (page 3320) to free the memory occupied by cached image rectangles. *aRect* is made integral before caching the image to avoid antialiasing artifacts.

Only the last cached rectangle is remembered and can be restored.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `display` (page 3321)

Declared In
`NSWindow.h`

canBecomeKeyWindow

Indicates whether the window can become the key window.

```
- (BOOL)canBecomeKeyWindow
```

Return Value
`YES` if the window can become the key window, otherwise, `NO`.

Discussion
Attempts to make the window the key window are abandoned if this method returns `NO`. The `NSWindow` (page 3275) implementation returns `YES` if the window has a title bar or a resize bar, or `NO` otherwise.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `isKeyWindow` (page 3338)
- `makeKeyWindow` (page 3345)

Related Sample Code

canBecomeVisibleWithoutLogin

Indicates whether the window can be displayed at the login window. Default: `NO`.

```
- (BOOL)canBecomeVisibleWithoutLogin
```

Return Value
`YES` when the window can be displayed at the login window; otherwise, `NO`.

Availability
Available in Mac OS X v10.5 and later.

See Also
- `setCanBecomeVisibleWithoutLogin:` (page 3371)

Declared In
`NSWindow.h`

canBeVisibleOnAllSpaces

Indicates whether the window can be visible on all spaces or on only one space at a time. (Deprecated in Mac OS X v10.5. Use `setCollectionBehavior:` (page 3372) instead.)

```
- (BOOL)canBeVisibleOnAllSpaces
```

Return Value
`YES` when the window can be visible on all spaces; `NO` when it can be visible on only one space at a time.

Discussion
The default is `NO`.

Availability
Available in Mac OS X v10.5 and later.
Deprecated in Mac OS X v10.5.

Declared In
NSWindow.h

canHide

Indicates whether the window can be hidden when its application becomes hidden (during execution of the NSApplication hide: (page 148) method).

```
- (BOOL)canHide
```

Return Value
YES if the window can be hidden when its application becomes hidden; otherwise, NO.

Discussion
The default is YES.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setCanHide: (page 3372)

Declared In
NSWindow.h

canStoreColor

Indicates whether the window has a depth limit that allows it to store color values.

```
- (BOOL)canStoreColor
```

Return Value
YES when the window's depth limit allows it to store color values; otherwise, NO.

Availability
Available in Mac OS X v10.0 and later.

See Also
- depthLimit (page 3317)
- shouldDrawColor (page 3232) (NSView)

Declared In
NSWindow.h

cascadeTopLeftFromPoint:

Positions the window's top left to a given point.

```
- (NSPoint)cascadeTopLeftFromPoint:(NSPoint)topLeft
```

Parameters

topLeft

The new top-left point, in screen coordinates, for the window. When `NSZeroPoint`, the window is not moved, except as needed to constrain to the visible screen

Return Value
The point shifted from top left of the window in screen coordinates.

Discussion
The returned point can be passed to a subsequent invocation of `cascadeTopLeftFromPoint:` to position the next window so the title bars of both windows are fully visible.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setFrameTopLeftPoint:` (page 3384)

Related Sample Code
EnhancedDataBurn

Declared In
`NSWindow.h`

center

Sets the window's location to the center of the screen.

```
- (void)center
```

Discussion
The window is placed exactly in the center horizontally and somewhat above center vertically. Such a placement carries a certain visual immediacy and importance. This method doesn't put the window onscreen, however; use `makeKeyAndOrderFront:` (page 3345) to do that.

You typically use this method to place a window—most likely an alert dialog—where the user can't miss it. This method is invoked automatically when a panel is placed on the screen by the `runModalForWindow:` (page 163) method of the `NSApplication` class.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSWindow.h`

childWindows

Returns an array of the window's attached child windows.

```
- (NSArray *)childWindows
```

Return Value
An array containing the window's child windows.

Availability
Available in Mac OS X v10.2 and later.

See Also
- `removeChildWindow:` (page 3358)
- `addChildWindow:ordered:` (page 3297)
- `parentWindow` (page 3353)
- `setParentWindow:` (page 3392)

Declared In
`NSWindow.h`

close

Removes the window from the screen.

```
- (void)close
```

Discussion
If the window is set to be released when closed, a `release` message is sent to the object after the current event is completed. For an `NSWindow` object, the default is to be released on closing, while for an `NSPanel` object, the default is not to be released. You can use the `setReleasedWhenClosed:` (page 3394) method to change the default behavior.

A window doesn't have to be visible to receive the close message. For example, when the application terminates, it sends the close message to all windows in its window list, even those that are not currently visible.

The close method posts an `NSWindowWillCloseNotification` (page 3426) notification to the default notification center.

The close method differs in two important ways from the `performClose:` (page 3354) method:

- It does not attempt to send a `windowShouldClose:` (page 3937) message to the window or its delegate.
- It does not simulate the user clicking the close button by momentarily highlighting the button.

Use `performClose:` (page 3354) if you need these features.

Availability
Available in Mac OS X v10.0 and later.

collectionBehavior

Identifies the window's behavior in window collections.

```
- (NSWindowCollectionBehavior)collectionBehavior
```

Return Value
The collection behavior identifier.

Availability
Available in Mac OS X v10.5 and later.

See Also
- setCollectionBehavior: (page 3372)

Declared In
NSWindow.h

colorSpace

Returns the window's color space.

```
- (NSColorSpace *)colorSpace
```

Return Value
The color space. Will return nil If the window does not have a backing store, and is off-screen.

Availability
Available in Mac OS X v10.6 and later.

See Also
- setColorSpace: (page 3373)

Declared In
NSWindow.h

constrainFrameRect:toScreen:

Modifies and returns a frame rectangle so that its top edge lies on a specific screen.

```
- (NSRect)constrainFrameRect:(NSRect)frameRect toScreen:(NSScreen *)screen
```

Parameters

frameRect

The proposed frame rectangle to adjust.

screen

The screen on which the top edge of the window's frame is to lie.

Return Value
The adjusted frame rectangle.

Discussion
If the window is resizable and the window's height is greater than the screen height, the rectangle's height is adjusted to fit within the screen as well. The rectangle's width and horizontal location are unaffected. You shouldn't need to invoke this method yourself; it's invoked automatically (and the modified frame is used to locate and set the size of the window) whenever a titled `NSWindow` object is placed onscreen and whenever its size is changed.

Subclasses can override this method to prevent their instances from being constrained or to constrain them differently.

Availability
Available in Mac OS X v10.0 and later.

iSpend

Declared In
`NSWindow.h`

contentAspectRatio

Returns the window's content aspect ratio.

```
- (NSSize)contentAspectRatio
```

Return Value
The window's content aspect ratio.

Discussion
The default content aspect ratio is `(0, 0)`.

Availability
Available in Mac OS X v10.3 and later.

See Also
`- setContentAspectRatio:` (page 3373)

Declared In
`NSWindow.h`

contentBorderThicknessForEdge:

Indicates the thickness of a given border of the window.

```
- (CGFloat)contentBorderThicknessForEdge:(NSRectEdge)edge
```

Parameters

edge

The border whose thickness to get:

- `NSMaxYEdge`: Top border.
- `NSMinYEdge`: Bottom border.

Return Value
Thickness of the given border, in points.

Availability
Available in Mac OS X v10.5 and later.

See Also
`- setContentBorderThickness:forEdge:` (page 3373)

Declared In
`NSWindow.h`

contentMaxSize

Returns the maximum size of the window's content view.

```
- (NSSize)contentMaxSize
```

Return Value
The maximum size of the window's content view.

Availability
Available in Mac OS X v10.3 and later.

See Also
`- setContentMaxSize:` (page 3374)
`- contentMinSize` (page 3311)

Declared In
`NSWindow.h`

contentMinSize

Returns the minimum size of the window's content view.

```
- (NSSize)contentMinSize
```

Return Value
The minimum size of the window's content view.

Availability
Available in Mac OS X v10.3 and later.

See Also
- `setContentMinSize:` (page 3374)
- `contentMaxSize` (page 3311)

Declared In
`NSWindow.h`

contentRectForFrameRect:

Returns the window's content rectangle with a given frame rectangle.

```
- (NSRect)contentRectForFrameRect:(NSRect)windowFrame
```

Parameters
windowFrame
The frame rectangle for the window expressed in screen coordinates.

Return Value
The window's content rectangle, expressed in screen coordinates, with *windowFrame*.

Discussion
The window uses its current style mask in computing the content rectangle. See "Window Style Masks" (page 3411) for a list of style mask values. The main advantage of this instance-method counterpart to `contentRectForFrameRect:styleMask:` (page 3292) is that it allows you to take toolbars into account when converting between content and frame rectangles. (The toolbar is not included in the content rectangle.)

Availability
Available in Mac OS X v10.3 and later.

currentEvent

Returns the event currently being processed by the application, by invoking NSApplication's currentEvent (page 142) method.

```
- (NSEvent *)currentEvent
```

Return Value
The event being processed by the application.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSWindow.h

dataWithEPSInsideRect:

Returns EPS data that draws the region of the window within a given rectangle.

```
- (NSData *)dataWithEPSInsideRect:(NSRect)rect
```

Parameters

rect

A rectangle (expressed in the window's coordinate system) that identifies the region to be expressed as EPS data.

Return Value

The region in the window (identified by *rect*) as EPS data.

Discussion

This data can be placed on a pasteboard, written to a file, or used to create an `NSImage` object.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `dataWithEPSInsideRect:` (page 3162) (`NSView`)
- `writeEPSInsideRect:toPasteboard:` (page 3248) (`NSView`)

Declared In

`NSWindow.h`

dataWithPDFInsideRect:

Returns PDF data that draws the region of the window within a given rectangle.

```
- (NSData *)dataWithPDFInsideRect:(NSRect)rect
```

Parameters

rect

A rectangle (expressed in the window's coordinate system) that identifies the region to be expressed as PDF data.

Return Value

The region in the window (identified by *rect*) as PDF data.

Discussion

This data can be placed on a pasteboard, written to a file, or used to create an `NSImage` object.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `dataWithPDFInsideRect:` (page 3162) (`NSView`)
- `writePDFInsideRect:toPasteboard:` (page 3249) (`NSView`)

Declared In

`NSWindow.h`

deepestScreen

Returns the deepest screen the window is on (it may be split over several screens).

```
- (NSScreen *)deepestScreen
```

Return Value
The deepest screen the window is on; `nil` when the window is offscreen.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `screen` (page 3363)
+ `deepestScreen` (page 2314) (`NSScreen`)

Declared In
`NSWindow.h`

defaultButtonCell

Returns the button cell that performs as if clicked when the window receives a Return (or Enter) key event.

```
- (NSButtonCell *)defaultButtonCell
```

Return Value
The button cell.

Discussion
This cell draws itself as the focal element for keyboard interface control, unless another button cell is focused on, in which case the default button cell temporarily draws itself as normal and disables its key equivalent.

The window receives a Return key event if no responder in its responder chain claims it, or if the user presses the Control key along with the Return key.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setDefaultButtonCell:` (page 3377)
- `disableKeyEquivalentForDefaultButtonCell` (page 3319)
- `enableKeyEquivalentForDefaultButtonCell` (page 3324)

Declared In
`NSWindow.h`

delegate

Returns the window's delegate.

```
- (id < NSWindowDelegate >)delegate
```

Return Value
The window's delegate, or `nil` if it doesn't have a delegate.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setDelegate:` (page 3377)

Related Sample Code
FancyAbout
Quartz Composer WWDC 2005 TextEdit

Declared In
`NSWindow.h`

deminiaturize:

Deminimizes the window.

```
- (void)deminiaturize:(id)sender
```

Parameters
sender
The message's sender.

Discussion
Invoke this method to programmatically deminimize a minimized window in the Dock.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `miniaturize:` (page 3347)
- `styleMask` (page 3402)

Related Sample Code
GLUT

Declared In
`NSWindow.h`

depthLimit

Returns the depth limit of the window.

```
- (NSWindowDepth)depthLimit
```

Return Value
Depth limit of the window.

Discussion
The value returned can be examined with the Application Kit functions `NSPlanarFromDepth` (page 3990), `NSColorSpaceFromDepth` (page 3966), `NSBitsPerSampleFromDepth` (page 3966), and `NSBitsPerPixelFromDepth` (page 3966).

Availability
Available in Mac OS X v10.0 and later.

See Also
+ defaultDepthLimit (page 3292)
- setDepthLimit: (page 3378)
- setDynamicDepthLimit: (page 3380)

Declared In
NSWindow.h

deviceDescription

Returns a dictionary containing information about the window's resolution.

```
- (NSDictionary *)deviceDescription
```

Return Value
A dictionary containing resolution information about the window, such as color, depth, and so on.

Discussion
This information is useful for tuning images and colors to the window's display capabilities. The contents of the dictionary are described in "Display Device—Descriptions" (page 3413).

Availability
Available in Mac OS X v10.0 and later.

See Also
- deviceDescription (page 2317) (NSScreen)
- bestRepresentationForDevice: (page 1337) (NSImage)
- colorUsingColorSpaceName: (page 700) (NSColor)

Related Sample Code
CocoaDVDPlayer

Declared In
NSWindow.h

disableCursorRects

Disables all cursor rectangle management within the window.

```
- (void)disableCursorRects
```

Discussion
Use this method when you need to do some special cursor manipulation and you don't want the Application Kit interfering.

Availability
Available in Mac OS X v10.0 and later.

See Also
- enableCursorRects (page 3324)

Declared In
NSWindow.h

disableFlushWindow

Disables the flushWindow (page 3327) method for the window.

```
- (void)disableFlushWindow
```

Discussion
If the window is buffered, disabling flushWindow (page 3327) prevents drawing from being automatically flushed by the NSView display... methods from the window's backing store to the screen. This method permits several views to be drawn before the results are shown to the user.

Flushing should be disabled only temporarily, while the window's display is being updated. Each disableFlushWindow message must be paired with a subsequent enableFlushWindow (page 3324) message. Invocations of these methods can be nested; flushing isn't reenabled until the last (unnested) enableFlushWindow (page 3324) message is sent.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
CocoaDVDPlayer

Declared In
NSWindow.h

disableKeyEquivalentForDefaultButtonCell

Disables the default button cell's key equivalent, so it doesn't perform a click when the user presses Return (or Enter).

```
- (void)disableKeyEquivalentForDefaultButtonCell
```

Availability
Available in Mac OS X v10.0 and later.

See Also
- defaultButtonCell (page 3316)
- enableKeyEquivalentForDefaultButtonCell (page 3324)

Declared In
NSWindow.h

disableScreenUpdatesUntilFlush

Disables the window's screen updates until the window is flushed.

```
- (void)disableScreenUpdatesUntilFlush
```

Discussion
This method can be invoked to synchronize hardware surface flushes with the window's flushes. The window immediately disables screen updates using the `NSDisableScreenUpdates` (page 3969) function and reenables screen updates when the window flushes. Sending this message multiple times during a window update cycle has no effect.

Availability
Available in Mac OS X v10.4 and later.

Related Sample Code
CocoaSlides
GLSLShowpiece

Declared In
`NSWindow.h`

discardCachedImage

Discards all of the window's cached image rectangles.

```
- (void)discardCachedImage
```

Discussion
An `NSWindow` object automatically discards its cached image rectangles when it displays.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `cacheImageInRect:` (page 3303)
- `restoreCachedImage` (page 3362)
- `display` (page 3321)

Declared In
`NSWindow.h`

discardCursorRects

Invalidates all cursor rectangles in the window.

```
- (void)discardCursorRects
```

Discussion
This method is invoked by `resetCursorRects` (page 3360) to clear out existing cursor rectangles before resetting them. You shouldn't invoke it in the code you write, but you might want to override it to change its behavior.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSWindow.h`

discardEventsMatchingMask:beforeEvent:

Forwards the message to the `NSApplication` object, `NSApp`.

```
- (void)discardEventsMatchingMask:(NSUInteger)eventMask beforeEvent:(NSEvent
    *)lastEvent
```

Parameters

eventMask

The mask of the events to discard.

lastEvent

The event up to which queued events are discarded from the queue.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `discardEventsMatchingMask:beforeEvent:` (page 144) (`NSApplication`)

Declared In
`NSWindow.h`

display

Passes a display message down the window's view hierarchy, thus redrawing all views within the window, including the frame view that draws the border, title bar, and other peripheral elements.

```
- (void)display
```

Discussion
You rarely need to invoke this method. `NSWindow` objects normally record which of their views need display and display them automatically on each pass through the event loop.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `display` (page 3163) (`NSView`)
- `displayIfNeeded` (page 3321)
- `isAutodisplay` (page 3336)

Related Sample Code
GLUT

Declared In
`NSWindow.h`

displayIfNeeded

Passes a `displayIfNeeded` message down the window's view hierarchy, thus redrawing all views that need to be displayed, including the frame view that draws the border, title bar, and other peripheral elements.

```
- (void)displayIfNeeded
```

Discussion
This method is useful when you want to modify some number of views and then display only the ones that were modified.

You rarely need to invoke this method. `NSWindow` objects normally record which of their views need display and display them automatically on each pass through the event loop.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `- display` (page 3321)
- `- displayIfNeeded` (page 3164) (`NSView`)

Declared In
`NSWindow.h`

displaysWhenScreenProfileChanges

Indicates whether the window context should be updated when the screen profile changes or when the window moves to a different screen.

```
- (BOOL)displaysWhenScreenProfileChanges
```

Return Value
`YES` when the window context should be updated when the screen profile changes or when the window moves to a different screen; otherwise, `NO`.

Discussion
The default value is `NO`.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `- setDisplaysWhenScreenProfileChanges:` (page 3378)

Related Sample Code
VideoViewer

Declared In
`NSWindow.h`

dockTile

Provides the application's Dock tile.

```
- (NSDockTile *)dockTile
```

Return Value
The application's Dock tile.

Availability
Available in Mac OS X v10.5 and later.

Declared In
NSWindow.h

dragImage:at:offset:event:pasteboard:source:slideBack:

Begins a dragging session.

```
- (void)dragImage:(NSImage *)image at:(NSPoint)imageLocation
    offset:(NSSize)pointerOffset event:(NSEvent *)event pasteboard:(NSPasteboard
    *)pasteboard source:(id)sourceObject slideBack:(BOOL)slideBack
```

Parameters

image
The object to be dragged.

imageLocation
Location of the image's bottom-left corner in the window's coordinate system. It determines the placement of the dragged image under the pointer.

initialOffset
The pointer's location relative to the mouse-down location. Not used in Mac OS X v10.4 and later.

event
The left-mouse down event that triggered the dragging operation.

pasteboard
The pasteboard that holds the data to be transfered to the destination.

sourceObject
The object serving as the controller of the dragging operation. It must conform to the NSDraggingSource informal protocol.

slideBack
Specifies whether the drag image should slide back to *imageLocation* if it's rejected by the drag destination. Pass YES to specify slideback behavior or NO to specify that it should not.

Discussion
This method should be invoked only from within a view's implementation of the mouseDown: (page 2164) or mouseDragged: (page 2164) methods (which overrides the version defined in NSResponder class). Essentially the same as the NSView method of the same name, except that *imageLocation* is given in the NSWindow object's base coordinate system.

Availability
Available in Mac OS X v10.0 and later.

See Also
- dragImage:at:offset:event:pasteboard:source:slideBack: (page 3168) (NSView)

Declared In
NSWindow.h

drawers

Returns the collection of drawers associated with the window.

```
- (NSArray *)drawers
```

Return Value
The collection of drawers associated with the window.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSDrawer.h

enableCursorRects

Reenables cursor rectangle management within the window after a `disableCursorRects` (page 3318) message.

```
- (void)enableCursorRects
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSWindow.h

enableFlushWindow

Reenables the `flushWindow` (page 3327) method for the window after it was disabled through a previous `disableFlushWindow` (page 3319) message.

```
- (void)enableFlushWindow
```

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
CocoaDVDPlayer

Declared In
NSWindow.h

enableKeyEquivalentForDefaultButtonCell

Reenables the default button cell's key equivalent, so it performs a click when the user presses Return (or Enter).

```
- (void)enableKeyEquivalentForDefaultButtonCell
```

Availability
Available in Mac OS X v10.0 and later.

See Also
- `defaultButtonCell` (page 3316)
- `disableKeyEquivalentForDefaultButtonCell` (page 3319)

Declared In
`NSWindow.h`

endEditingFor:

Forces the field editor to give up its first responder status and prepares it for its next assignment.

```
- (void)endEditingFor:(id)object
```

Parameters

object

The object that is using the window's field editor.

Discussion

If the field editor is the first responder, it's made to resign that status even if its `resignFirstResponder` (page 2189) method returns `NO`. This registration forces the field editor to send a `textDidEndEditing:` message to its delegate. The field editor is then removed from the view hierarchy, its delegate is set to `nil`, and it's emptied of any text it may contain.

This method is typically invoked by the object using the field editor when it's finished. Other objects normally change the first responder by simply using `makeFirstResponder:` (page 3344), which allows a field editor or other object to retain its first responder status if, for example, the user has entered an invalid value. The `endEditingFor:` (page 3325) method should be used only as a last resort if the field editor refuses to resign first responder status. Even in this case, you should always allow the field editor a chance to validate its text and take whatever other action it needs first. You can do this by first trying to make the `NSWindow` object the first responder:

```
if ([myWindow makeFirstResponder:myWindow]) {
    /* All fields are now valid; it's safe to use fieldEditor:forObject:
        to claim the field editor. */
}
else {
    /* Force first responder to resign. */
    [myWindow endEditingFor:nil];
}
```

Availability

Available in Mac OS X v10.0 and later.

See Also
- `fieldEditor:forObject:` (page 3325)
- `windowWillReturnFieldEditor:toObject:` (page 3940) (`NSWindowDelegate`)

Declared In
`NSWindow.h`

fieldEditor:forObject:

Returns the window's field editor, creating it if requested.

```
- (NSText *)fieldEditor:(BOOL)createWhenNeeded forObject:(id)anObject
```

Parameters

createWhenNeeded

If YES, creates a field editor if one doesn't exist; if NO, does not create a field editor.

A freshly created NSWindow object doesn't have a field editor. After a field editor has been created for a window, the *createWhenNeeded* argument is ignored. By passing NO for *createWhenNeeded* and testing the return value, however, you can predicate an action on the existence of the field editor.

anObject

A text-displaying object for which the delegate (in windowWillReturnFieldEditor:toObject: (page 3940)) assigns a custom field editor. Pass nil to get the default field editor, which can be the NSWindow field editor or a custom field editor returned by the delegate.

Return Value

Returns the field editor for the designated object (*anObject*) or, if *anObject* is nil, the default field editor. Returns nil if *createFlag* is NO and if the field editor doesn't exist.

Discussion

The field editor is a single NSTextView object that is shared among all the controls in a window for light text-editing needs. It is automatically instantiated when needed, and it can be used however your application sees fit. Typically, the field editor is used by simple text-bearing objects—for example, an NSTextField object uses its window's field editor to display and manipulate text. The field editor can be shared by any number of objects, and so its state may be constantly changing. Therefore, it shouldn't be used to display text that demands sophisticated layout (for this you should create a dedicated NSTextView object).

The field editor may be in use by some view object, so be sure to properly dissociate it from that object before actually using it yourself (the appropriate way to do this is illustrated in the description of endEditingFor: (page 3325)). Once you retrieve the field editor, you can insert it in the view hierarchy, set a delegate to interpret text events, and have it perform whatever editing is needed. Then, when it sends a textDidEndEditing: message to the delegate, you can get its text to display or store and remove the field editor using endEditingFor: (page 3325).

The window's delegate can substitute a custom field editor in place of the window's field editor by implementing windowWillReturnFieldEditor:toObject: (page 3940). The custom field editor can become the default editor (common to all text-displaying objects) or specific to a particular text-displaying object (*anObject*). The window sends this message to its delegate with itself and *anObject* as the arguments; if the delegate returns a non-nil value, the window returns that object instead of its field editor in fieldEditor:forObject:. However, note the following:

- If the window's delegate is identical to *anObject*, windowWillReturnFieldEditor:toObject: (page 3940) isn't sent to the delegate.
- The object returned by the delegate method, though it may become first responder, does not become the window's default field editor. Other objects continue to use the window's default field editor.

Availability

Available in Mac OS X v10.0 and later.

Declared In

NSWindow.h

firstResponder

Returns the window's first responder.

```
- (NSResponder *)firstResponder
```

Return Value
The first responder.

Discussion
The first responder is usually the first object in a responder chain to receive an event or action message. In most cases, the first responder is a view object in that the user selects or activates with the mouse or keyboard.

You can use the `firstResponder` method in custom subclasses of responder classes (`NSWindow`, `NSApplication`, `NSView`, and subclasses) to determine if an instance of the subclass is currently the first responder. You can also use it to help locate a text field that currently has first-responder status. For more on this subject, see "Event Handling Basics."

In Mac OS X v10.6 and later, *`firstResponder`* is key-value observing compliant.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `makeFirstResponder:` (page 3344)
- `acceptsFirstResponder` (page 2143) (`NSResponder`)

Related Sample Code

Declared In
`NSWindow.h`

flushWindow

Flushes the window's offscreen buffer to the screen if the window is buffered and flushing is enabled.

```
- (void)flushWindow
```

Discussion
Does nothing for other display devices, such as a printer. This method is automatically invoked by the `NSWindow` `display` (page 3321) and `displayIfNeeded` (page 3321) methods and the corresponding `NSView` `display` (page 3163) and `displayIfNeeded` (page 3164) methods.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `flushWindowIfNeeded` (page 3328)
- `disableFlushWindow` (page 3319)
- `enableFlushWindow` (page 3324)

Related Sample Code
QTKitFrameStepper

Declared In
NSWindow.h

flushWindowIfNeeded

Flushes the window's offscreen buffer to the screen if flushing is enabled and if the last `flushWindow` (page 3327) message had no effect because flushing was disabled.

```
- (void)flushWindowIfNeeded
```

Discussion
To avoid unnecessary flushing, use this method rather than `flushWindow` (page 3327) to flush an `NSWindow` object after flushing has been reenabled.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `disableFlushWindow` (page 3319)
- `enableFlushWindow` (page 3324)

Declared In
NSWindow.h

frame

Returns the window's frame rectangle.

```
- (NSRect)frame
```

Return Value
The frame rectangle of the window in screen coordinates, including the title bar.

Availability
Available in Mac OS X v10.0 and later.

frameAutosaveName

Returns the name used to automatically save the window's frame rectangle data in the defaults system, as set through `setFrameAutosaveName:` (page 3382).

```
- (NSString *)frameAutosaveName
```

Return Value
The name used to save the window's frame rectangle automatically in the defaults system.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setFrameUsingName:` (page 3384)

Declared In
`NSWindow.h`

frameRectForContentRect:

Returns the window's frame rectangle with a given content rectangle.

```
- (NSRect)frameRectForContentRect:(NSRect)windowContent
```

Parameters
windowContent
The content rectangle for the window expressed in screen coordinates.

Return Value
The window's frame rectangle, expressed in screen coordinates, with *windowContent*.

Discussion
The window uses its current style mask in computing the frame rectangle. See "Window Style Masks" (page 3411) for a list of style mask values. The major advantage of this instance-method counterpart to `frameRectForContentRect:styleMask:` (page 3293) is that it allows you to take toolbars into account when converting between content and frame rectangles. (The toolbar is included in the frame rectangle but not the content rectangle.)

Availability
Available in Mac OS X v10.3 and later.

See Also
`- contentRectForFrameRect:` (page 3312)
`+ frameRectForContentRect:styleMask:` (page 3293)

FunHouse

Declared In
NSWindow.h

gState

Returns the window's graphics state object.

```
- (NSInteger)gState
```

Return Value
The graphics state object associated with the window.

Discussion
This graphics state is used by default for all `NSView` objects in the window's view hierarchy, but individual views can be made to use their own with the `NSView` method `allocateGState` (page 3146).

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSWindow.h

hasDynamicDepthLimit

Indicates whether the window's depth limit can change to match the depth of the screen it's on.

```
- (BOOL)hasDynamicDepthLimit
```

Return Value
`YES` when the window has a dynamic depth limit; otherwise, `NO`.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setDynamicDepthLimit:` (page 3380)

Declared In
NSWindow.h

hasShadow

Indicates whether the window has a shadow.

```
- (BOOL)hasShadow
```

Return Value
YES when the window has a shadow; otherwise, NO.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setHasShadow: (page 3385)
- invalidateShadow (page 3336)

Declared In
NSWindow.h

hidesOnDeactivate

Indicates whether the window is removed from the screen when its application becomes inactive.

```
- (BOOL)hidesOnDeactivate
```

Return Value
YES if the window is removed from the screen when its application is deactivated; NO if it remains onscreen.

Discussion
The default for NSWindow is NO; the default for NSPanel is YES.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setHidesOnDeactivate: (page 3386)

Declared In
NSWindow.h

ignoresMouseEvents

Indicates whether the window is transparent to mouse events.

```
- (BOOL)ignoresMouseEvents
```

Return Value
YES when the window is transparent to mouse events; otherwise, NO.

Availability
Available in Mac OS X v10.2 and later.

See Also
- `setIgnoresMouseEvents:` (page 3387)

Declared In
`NSWindow.h`

initialFirstResponder

Returns view that's made first responder the first time the window is placed onscreen.

```
- (NSView *)initialFirstResponder
```

Return Value
The view that's made first responder the first time the window is placed onscreen.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setInitialFirstResponder:` (page 3387)
- `setNextKeyView:` (page 3226) (`NSView`)

Declared In
`NSWindow.h`

initWithContentRect:styleMask:backing:defer:

Initializes the window with the specified values.

```
- (id)initWithContentRect:(NSRect)contentRect styleMask:(NSUInteger)windowStyle
    backing:(NSBackingStoreType)bufferingType defer:(BOOL)deferCreation
```

Parameters

contentRect
Location and size of the window's content area in screen coordinates. Note that the window server limits window position coordinates to ±16,000 and sizes to 10,000.

windowStyle
The window's style. It can be `NSBorderlessWindowMask`, or it can contain any of the options described in "Window Style Masks" (page 3411), combined using the C bitwise OR operator. Borderless windows display none of the usual peripheral elements and are generally useful only for display or caching purposes; you should normally not need to create them. Also, note that a window's style mask should include `NSTitledWindowMask` if it includes any of the others.

bufferingType
Specifies how the drawing done in the window is buffered by the window device, and possible values are described in "NSBackingStoreType—Buffered Window Drawing" (page 3417).

deferCreation

Specifies whether the window server creates a window device for the window immediately. When `YES`, the window server defers creating the window device until the window is moved onscreen. All display messages sent to the window or its views are postponed until the window is created, just before it's moved onscreen.

Return Value
The initialized window.

Discussion
This method is the designated initializer for the `NSWindow` class.

Deferring the creation of the window improves launch time and minimizes the virtual memory load on the window server.

The new window creates a view to be its default content view. You can replace it with your own object by using the `setContentView:` (page 3376) method.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSWindow.h`

initWithContentRect:styleMask:backing:defer:screen:

Initializes an allocated window with the specified values.

```
- (id)initWithContentRect:(NSRect)contentRect styleMask:(NSUInteger)windowStyle
    backing:(NSBackingStoreType)bufferingType defer:(BOOL)deferCreation
    screen:(NSScreen *)screen
```

Parameters

contentRect

Location and size of the window's content area in screen coordinates. Note that the window server limits window position coordinates to ±16,000 and sizes to 10,000.

windowStyle

The window's style. It can be either `NSBorderlessWindowMask`, or it can contain any of the options described in "Window Style Masks" (page 3411), combined using the C bitwise OR operator. Borderless windows display none of the usual peripheral elements and are generally useful only for display or caching purposes; you should normally not need to create them. Also, note that a window's style mask should include `NSTitledWindowMask` if it includes any of the others.

bufferingType

Specifies how the drawing done in the window is buffered by the window device; possible values are described in "NSBackingStoreType—Buffered Window Drawing" (page 3417).

deferCreation

Specifies whether the window server creates a window device for the window immediately. When `YES`, the window server defers creating the window device until the window is moved onscreen. All display messages sent to the window or its views are postponed until the window is created, just before it's moved onscreen.

screen

Specifies where the window's content rectangle is drawn if the window is to be drawn in a screen other than the main screen. The content rectangle is drawn relative to the bottom-left corner of `screen`. When `nil`, the content rectangle is drawn on the main screen.

Return Value
The initialized window.

Discussion
The main screen is the one that contains the current key window or, if there is no key window, the one that contains the main menu. If there's neither a key window nor a main menu (if there's no active application), the main screen is the one where the origin of the screen coordinate system is located.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSWindow.h`

initWithWindowRef:

Returns a Cocoa window created from a Carbon window.

```
- (NSWindow *)initWithWindowRef:(void *)carbonWindowRef
```

Parameters

carbonWindowRef

The Carbon `WindowRef` object to use to create the Cocoa window.

Return Value
A Cocoa window created from *carbonWindowRef*.

Discussion
For more information on Carbon-Cocoa integration, see Using a Carbon User Interface in a Cocoa Application in *Carbon-Cocoa Integration Guide*.

Special Considerations

For historical reasons, contrary to normal memory management policy `initWithWindowRef:` does *not* retain *`windowRef`*. It is therefore recommended that you make sure you retain *`windowRef`* before calling this method. If *`windowRef`* is still valid when the Cocoa window is deallocated, the Cocoa window will release it.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `windowRef` (page 3408)

Related Sample Code
CarbonCocoaTempConverter

Declared In
`NSWindow.h`

inLiveResize

Indicates whether the window is being resized by the user.

```
- (BOOL)inLiveResize
```

Return Value
`YES` if the window is being live resized; otherwise, `NO`.

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSWindow.h`

invalidateCursorRectsForView:

Marks as invalid the cursor rectangles of a given `NSView` object in the window's view hierarchy, so they'll be set up again when the window becomes key (or immediately if the window is key).

```
- (void)invalidateCursorRectsForView:(NSView *)view
```

Parameters

`view`
The view in the window's view hierarchy.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `resetCursorRects` (page 3360)

- resetCursorRects (page 3206) (NSView)

Related Sample Code
DragItemAround

Declared In
NSWindow.h

invalidateShadow

Invalidates the window shadow so that it is recomputed based on the current window shape.

```
- (void)invalidateShadow
```

Availability
Available in Mac OS X v10.2 and later.

See Also
- hasShadow (page 3331)
- setHasShadow: (page 3385)

Declared In
NSWindow.h

isAutodisplay

Indicates whether the window automatically displays views that need to be displayed.

```
- (BOOL)isAutodisplay
```

Return Value
YES when the window automatically displays views that need to be displayed; otherwise, NO.

Discussion
Automatic display typically occurs on each pass through the event loop.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setAutodisplay: (page 3368)
- displayIfNeeded (page 3321)
- setNeedsDisplay: (page 3225) (NSView)

Declared In
NSWindow.h

isDocumentEdited

Indicates whether the window's document has been edited.

```
- (BOOL)isDocumentEdited
```

Return Value
`YES` when the window's document has been edited; otherwise, `NO`.

Discussion
Initially, by default, `NSWindow` objects are in the "not edited" state.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSWindow.h`

isExcludedFromWindowsMenu

Indicates whether the window is excluded from the application's Windows menu.

```
- (BOOL)isExcludedFromWindowsMenu
```

Return Value
`YES` when the window is excluded from the Windows menu; otherwise, `NO`.

Discussion
The default initial setting is `NO`.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setExcludedFromWindowsMenu:` (page 3380)

Declared In
`NSWindow.h`

isFlushWindowDisabled

Indicates whether the window's flushing ability is disabled.

```
- (BOOL)isFlushWindowDisabled
```

Return Value
`YES` when the window's flushing ability has been disabled; otherwise, `NO`.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- disableFlushWindow` (page 3319)
`- enableFlushWindow` (page 3324)

Declared In
`NSWindow.h`

isKeyWindow

Indicates whether the window is the key window for the application.

```
- (BOOL)isKeyWindow
```

Return Value
`YES` if the window is the key window for the application; otherwise, `NO`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `isMainWindow` (page 3338)
- `makeKeyWindow` (page 3345)

Related Sample Code
AnimatedTableView

Declared In
`NSWindow.h`

isMainWindow

Indicates whether the window is the application's main window.

```
- (BOOL)isMainWindow
```

Return Value
`YES` when the window is the main window for the application; otherwise, `NO`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `isKeyWindow` (page 3338)
- `makeMainWindow` (page 3346)

Declared In
`NSWindow.h`

isMiniaturized

Indicates whether the window is minimized.

```
- (BOOL)isMiniaturized
```

Return Value
`YES` if the window is minimized; otherwise, `NO`.

Discussion
A minimized window is removed from the screen and replaced by a image, icon, or button that represents it, called the counterpart.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `miniaturize:` (page 3347)

Declared In
`NSWindow.h`

isMovable

Indicates whether the window can be moved by clicking in its title bar or background.

```
- (BOOL)isMovable
```

Return Value
`YES` if the window can be moved by the user; otherwise, `NO`.

Discussion
`setMovableByWindowBackground:` (page 3391), called with the argument `YES`, is ignored by a window that returns `NO` from `isMovable`. If a window returns `NO`, that means it can only be dragged between spaces in F8 mode, and its relative screen position is always preserved. Note that a resizable window may still be resized, and the window frame may be changed programmatically. A non-movable window will not be moved or resized by the system in response to a display reconfiguration. Applications may choose to enable application-controlled window dragging after disabling user-initiating dragging by handling the `mouseDown:` (page 2164)/`mouseDragged:` (page 2164)/`mouseUp:` (page 2166) sequence in `sendEvent:` (page 3366) in an `NSWindow` subclass.

Availability
Available in Mac OS X v10.6 and later.

See Also
- `setMovable:` (page 3391)

Declared In
`NSWindow.h`

isMovableByWindowBackground

Indicates whether the window is movable by clicking and dragging anywhere in its background.

```
- (BOOL)isMovableByWindowBackground
```

Return Value
`YES` when the window is movable by clicking and dragging anywhere in its background; otherwise, `NO`.

Discussion
A window with a style mask of `NSTexturedBackgroundWindowMask` is movable by background by default. Sheets and drawers cannot be movable by window background.

Availability
Available in Mac OS X v10.2 and later.

See Also
- setMovableByWindowBackground: (page 3391)

Declared In
NSWindow.h

isOnActiveSpace

Indicates whether the window is on the currently active space.

```
- (BOOL)isOnActiveSpace
```

Return Value
YES if the window is on the currently active space; otherwise, NO.

Discussion
For visible windows, this method indicates whether the window is currently visible on the active space. For offscreen windows, it indicates whether ordering the window onscreen would cause it to be on the active space.

Availability
Available in Mac OS X v10.6 and later.

Declared In
NSWindow.h

isOneShot

Indicates whether the window device the window manages is freed when it's removed from the screen list.

```
- (BOOL)isOneShot
```

Return Value
YES when the window's window device is freed when it's removed from the screen list; otherwise, NO.

Discussion
The default is NO.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setOneShot: (page 3391)

Declared In
NSWindow.h

isOpaque

Indicates whether the window is opaque.

```
- (BOOL)isOpaque
```

Return Value
YES when the window is opaque; otherwise, NO.

Discussion
The default is YES.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setOpaque: (page 3392)

Declared In
NSWindow.h

isReleasedWhenClosed

Indicates whether the window is released when it receives the close message.

```
- (BOOL)isReleasedWhenClosed
```

Return Value
YES if the window is automatically released after being closed; NO if it's simply removed from the screen.

Discussion
The default for NSWindow is YES; the default for NSPanel is NO. Release when closed, however, is ignored for windows owned by window controllers.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setReleasedWhenClosed: (page 3394)

Declared In
NSWindow.h

isSheet

Indicates whether the window has ever run as a modal sheet.

```
- (BOOL)isSheet
```

Return Value
YES if the window has ever run as a modal sheet; otherwise, NO.

Discussion
Sheets are created using the NSPanel subclass.

Availability
Available in Mac OS X v10.1 and later.

Declared In
NSWindow.h

isVisible

Indicates whether the window is visible onscreen (even when It's obscured by other windows).

```
- (BOOL)isVisible
```

Return Value
`YES` when the window is onscreen (even if it's obscured by other windows); otherwise, `NO`.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- visibleRect` (page 3245) (`NSView`)

Related Sample Code
AnimatedTableView
GLUT
QTAudioExtractionPanel
Sketch+Accessibility

Declared In
`NSWindow.h`

isZoomed

Returns a Boolean value that indicates whether the window is in a zoomed state.

```
- (BOOL)isZoomed
```

Return Value
`YES` if the window is in a zoomed state; otherwise, `NO`.

Discussion
The zoomed state of the window is determined using the following steps:

1. If the delegate or the window class implements `windowWillUseStandardFrame:defaultFrame:` (page 3942), it is invoked to obtain the zoomed frame of the window. The result of `isZoomed` is then determined by whether or not the current window frame is equal to the zoomed frame.

2. If the neither the delegate nor the window class implements `windowWillUseStandardFrame:defaultFrame:`, a default frame that nearly fits the screen is chosen. If the delegate or window class implements , it is invoked to validate the proposed zoomed frame. Once the zoomed frame is validated, the result of `isZoomed` is determined by whether or not the current window frame is equal to the zoomed frame.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- zoom:` (page 3409)

Declared In
NSWindow.h

keyDown:

Handles a given keyboard event that may need to be interpreted as changing the key view or triggering a keyboard equivalent.

```
- (void)keyDown:(NSEvent *)event
```

Parameters

event
The keyboard event to process.

Availability
Available in Mac OS X v10.0 and later.

See Also
- selectNextKeyView: (page 3364)
- nextKeyView (page 3192) (NSView)

Declared In
NSWindow.h

keyViewSelectionDirection

Returns the direction the window is currently using to change the key view.

```
- (NSSelectionDirection)keyViewSelectionDirection
```

Return Value
The direction the window is using to change the key view.

Discussion
This direction can be one of the values described in "NSSelectionDirection—Direction of Key View Change" (page 3415).

Availability
Available in Mac OS X v10.0 and later.

See Also
- selectNextKeyView: (page 3364)
- selectPreviousKeyView: (page 3365)

Declared In
NSWindow.h

level

Returns the window level of the window.

```
- (NSInteger)level
```

Return Value
The window level.

Discussion
See "Window Levels" (page 3412) for a list of possible values.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setLevel:` (page 3387)

Declared In
`NSWindow.h`

makeFirstResponder:

Attempts to make a given responder the first responder for the window.

```
- (BOOL)makeFirstResponder:(NSResponder *)responder
```

Parameters

responder
The responder to set as the window's first responder. `nil` makes the window its first responder.

Return Value
`YES` when the operation is successful; otherwise, `NO`.

Discussion
If *responder* isn't already the first responder, this method first sends a `resignFirstResponder` (page 2189) message to the object that is the first responder. If that object refuses to resign, it remains the first responder, and this method immediately returns `NO`. If the current first responder resigns, this method sends a `becomeFirstResponder` (page 2144) message to *responder*. If *responder* does not accept first responder status, the `NSWindow` object becomes first responder; in this case, the method returns `YES` even if *responder* refuses first responder status.

If *responder* is `nil`, this method still sends `resignFirstResponder` (page 2189) to the current first responder. If the current first responder refuses to resign, it remains the first responder and this method immediately returns `NO`. If the current first responder returns `YES` from `resignFirstResponder`, the window is made its own first responder and this method returns `YES`.

The Application Kit framework uses this method to alter the first responder in response to mouse-down events; you can also use it to explicitly set the first responder from within your program. The *responder* object is typically an `NSView` object in the window's view hierarchy. If this method is called explicitly, first send `acceptsFirstResponder` (page 2143) to *responder*, and do not call `makeFirstResponder:` if `acceptsFirstResponder` returns `NO`.

Use `setInitialFirstResponder:` (page 3387) to the set the first responder to be used when the window is brought onscreen for the first time.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `becomeFirstResponder` (page 2144) (`NSResponder`)
- `resignFirstResponder` (page 2189) (`NSResponder`)

`NSWindow.h`

miniaturize:

Removes the window from the screen list and displays the minimized window in the Dock.

```
- (void)miniaturize:(id)sender
```

Parameters

sender

The message's sender.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `deminiaturize:` (page 3317)

Related Sample Code
GLUT
StickiesWithCoreData

Declared In
`NSWindow.h`

miniwindowImage

Returns the custom miniaturized window image of the window.

```
- (NSImage *)miniwindowImage
```

Return Value
The custom miniaturized window image.

Discussion
The miniaturized window image is the image displayed in the Dock when the window is minimized. If you did not assign a custom image to the window, this method returns `nil`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setMiniwindowImage:` (page 3389)
- `miniwindowTitle` (page 3347)

Declared In
`NSWindow.h`

miniwindowTitle

Returns the title displayed in the window's minimized window.

```
- (NSString *)miniwindowTitle
```

Return Value
The title displayed in the window's minimized window.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setMiniwindowTitle:` (page 3390)
- `miniwindowImage` (page 3347)

Declared In
`NSWindow.h`

mouseLocationOutsideOfEventStream

Returns the current location of the pointer reckoned in the window's base coordinate system.

```
- (NSPoint)mouseLocationOutsideOfEventStream
```

Return Value
The current location of the pointer reckoned in the window's base coordinate system, regardless of the current event being handled or of any events pending.

Discussion
For the same information in screen coordinates, use `NSEvent`'s `mouseLocation` (page 1067).

Availability
Available in Mac OS X v10.0 and later.

See Also
- currentEvent (page 142) (NSApplication)

Related Sample Code
GLUT

Declared In
NSWindow.h

nextEventMatchingMask:

Returns the next event matching a given mask.

```
- (NSEvent *)nextEventMatchingMask:(NSUInteger)eventMask
```

Parameters

eventMask

The mask that the event to return must match. Events with nonmatching masks are removed from the queue. See discardEventsMatchingMask:beforeEvent: (page 144) in NSApplication for the list of mask values.

Return Value
The next event whose mask matches *eventMask*; nil when no matching event was found.

Discussion
This method sends the message nextEventMatchingMask:eventMask untilDate:[NSDate distantFuture] inMode:NSEventTrackingRunLoopMode dequeue:YES to the application (NSApp).

Availability
Available in Mac OS X v10.0 and later.

See Also
- nextEventMatchingMask:untilDate:inMode:dequeue: (page 153) (NSApplication)

Related Sample Code
PhotoSearch
Sketch-112

Declared In

nextEventMatchingMask:untilDate:inMode:dequeue:

Forwards the message to the global NSApplication object, NSApp.

```
- (NSEvent *)nextEventMatchingMask:(NSUInteger)eventMask untilDate:(NSDate
    *)expirationDate inMode:(NSString *)runLoopMode dequeue:(BOOL)dequeue
```

Parameters

eventMask

The mask that the event to return must match.

expirationDate
The date until which to wait for events.

runLoopMode
The run loop mode to use while waiting for events

dequeue
YES to remove the returned event from the event queue; NO to leave the returned event in the queue.

Return Value
The next event whose mask matches *eventMask*; nil when no matching event was found.

Availability
Available in Mac OS X v10.0 and later.

Declared In

`NSWindow.h`

orderFrontRegardless

Moves the window to the front of its level, even if its application isn't active, without changing either the key window or the main window.

```
- (void)orderFrontRegardless
```

Parameters

sender

The message's sender.

Discussion

Normally an `NSWindow` object can't be moved in front of the key window unless it and the key window are in the same application. You should rarely need to invoke this method; it's designed to be used when applications are cooperating in such a way that an active application (with the key window) is using another application to display data.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `orderFront:` (page 3351)

- level (page 3343)

Related Sample Code
PreLoginAgents

Declared In
NSWindow.h

orderOut:

Removes the window from the screen list, which hides the window.

```
- (void)orderOut:(id)sender
```

Parameters

sender

The message's sender.

Discussion
If the window is the key or main window, the NSWindow object immediately behind it is made key or main in its place. Calling the orderOut: (page 3352) method causes the window to be removed from the screen, but does not cause it to be released. See the close (page 3308) method for information on when a window is released.

Availability
Available in Mac OS X v10.0 and later.

See Also

NSWindow.h

orderWindow:relativeTo:

Repositions the window's window device in the window server's screen list.

```
- (void)orderWindow:(NSWindowOrderingMode)orderingMode
    relativeTo:(NSInteger)otherWindowNumber
```

Parameters

orderingMode

`NSWindowOut` (page 3419): The window is removed from the screen list and *otherWindowNumber* is ignored.

`NSWindowAbove` (page 3419): The window is ordered immediately in front of the window whose window number is *otherWindowNumber*

`NSWindowBelow` (page 3419): The window is placed immediately behind the window represented by *otherWindowNumber*.

otherWindowNumber

The number of the window the window is to be placed in front of or behind. Pass `0` to place the window in front of (when *orderingMode* is `NSWindowAbove`) or behind (when *orderingMode* is `NSWindowBelow`) all other windows in its level.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `orderFront:` (page 3351)

FunkyOverlayWindow

Declared In
NSWindow.h

performClose:

This action method simulates the user clicking the close button by momentarily highlighting the button and then closing the window.

```
- (void)performClose:(id)sender
```

Parameters

sender
The message's sender.

Discussion
If the window's delegate or the window itself implements `windowShouldClose:` (page 3937), that message is sent with the window as the argument. (Only one such message is sent; if both the delegate and the `NSWindow` object implement the method, only the delegate receives the message.) If the `windowShouldClose:` (page 3937) method returns `NO`, the window isn't closed. If it returns `YES`, or if it isn't implemented, `performClose:` (page 3354) invokes the `close` (page 3308) method to close the window.

If the window doesn't have a close button or can't be closed (for example, if the delegate replies `NO` to a `windowShouldClose:` (page 3937) message), the system emits the alert sound.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `styleMask` (page 3402)

- `performClose:` (page 3354)

Declared In
`NSWindow.h`

performZoom:

This action method simulates the user clicking the zoom box by momentarily highlighting the button and then zooming the window.

```
- (void)performZoom:(id)sender
```

Parameters

sender
The object sending the message.

Discussion
If the window doesn't have a zoom box or can't be zoomed for some reason, the computer beeps.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `styleMask` (page 3402)
- `zoom:` (page 3409)

Declared In
`NSWindow.h`

postEvent:atStart:

Forwards the message to the global `NSApplication` object, `NSApp`.

```
- (void)postEvent:(NSEvent *)event atStart:(BOOL)atStart
```

Parameters

event
The event to add to the window's event queue.

atStart
`YES` to place the event in the front of the queue; `NO` to place it in the back.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `postEvent:atStart:` (page 157)

Declared In
NSWindow.h

preferredBackingLocation

Indicates the preferred location for the window's backing store.

```
- (NSWindowBackingLocation)preferredBackingLocation
```

Return Value
The preferred location for the window's backing store. See "Constants" (page 3411) for possible values.

Availability
Available in Mac OS X v10.5 and later.

See Also
- setPreferredBackingLocation: (page 3393)
- backingLocation (page 3302)

Declared In
NSWindow.h

preservesContentDuringLiveResize

Returns whether the window tries to optimize user-initiated resize operations by preserving the content of views that have not changed.

```
- (BOOL)preservesContentDuringLiveResize
```

Return Value
YES if the window tries to optimize live resize operations by preserving the content of views that have not moved; otherwise, NO.

Discussion
When live-resize optimization is active, the window redraws only those views that moved (or do not support this optimization) during a live resize operation.

See preservesContentDuringLiveResize (page 3196) in NSView for additional information on how to support this optimization.

Availability
Available in Mac OS X v10.4 and later.

See Also
- setPreservesContentDuringLiveResize: (page 3393)
- preservesContentDuringLiveResize (page 3196) (NSView)

Declared In
NSWindow.h

preventsApplicationTerminationWhenModal

Indicates whether the window prevents application termination when modal.

```
- (BOOL)preventsApplicationTerminationWhenModal
```

Return Value
`YES` if the window prevents application termination when modal; otherwise, `NO`.

Discussion
The default value is `YES`.

Availability
Available in Mac OS X v10.6 and later.

See Also
`- setPreventsApplicationTerminationWhenModal:` (page 3394)

Declared In
`NSWindow.h`

print:

This action method runs the Print panel, and if the user chooses an option other than canceling, prints the window (its frame view and all subviews).

```
- (void)print:(id)sender
```

Parameters
sender
The message's sender.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSWindow.h`

recalculateKeyViewLoop

Marks the key view loop as dirty and in need of recalculation.

```
- (void)recalculateKeyViewLoop
```

Discussion
The key view loop is actually recalculated the next time someone requests the next or previous key view of the window. The recalculated loop is based on the geometric order of the views in the window.

If you do not want to maintain the key view loop of your window manually, you can use this method to do it for you. When it is first loaded, `NSWindow` calls this method automatically if your window does not have a key view loop already established. If you add or remove views later, you can call this method manually to update the window's key view loop. You can also call `setAutorecalculatesKeyViewLoop:` (page 3370) to have the window recalculate the loop automatically.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `selectKeyViewFollowingView:` (page 3364)
- `selectKeyViewPrecedingView:` (page 3364)
- `setAutorecalculatesKeyViewLoop:` (page 3370)

Declared In
`NSWindow.h`

registerForDraggedTypes:

Registers a give set of pasteboard types as the pasteboard types the window will accept as the destination of an image-dragging session.

```
- (void)registerForDraggedTypes:(NSArray *)pasteboardTypes
```

Parameters

pasteboardTypes
An array of the pasteboard types the window will accept as the destination of an image-dragging session.

Discussion
Registering an `NSWindow` object for dragged types automatically makes it a candidate destination object for a dragging session. `NSWindow` has a default implementation for many of the methods in the `NSDraggingDestination` informal protocol. The default implementation forwards each message to the delegate if the delegate responds to the selector of the message. The messages forwarded this way are `draggingEntered:` (page 3655), `draggingUpdated:` (page 3656), `draggingExited:` (page 3655), `prepareForDragOperation:` (page 3657), `performDragOperation:` (page 3657), and `concludeDragOperation:` (page 3654).

Availability
Available in Mac OS X v10.0 and later.

See Also
- `unregisterDraggedTypes` (page 3405)

Declared In
`NSWindow.h`

removeChildWindow:

Detaches a given child window from the window.

```
- (void)removeChildWindow:(NSWindow *)childWindow
```

Parameters

childWindow
The child window to detach.

Availability
Available in Mac OS X v10.2 and later.

See Also
- `addChildWindow:ordered:` (page 3297)
- `childWindows` (page 3308)
- `parentWindow` (page 3353)
- `setParentWindow:` (page 3392)

Declared In
`NSWindow.h`

representedFilename

Returns the pathname of the file the window represents.

```
- (NSString *)representedFilename
```

Return Value
The path to the file of the window's represented file.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setRepresentedFilename:` (page 3395)

Declared In
`NSWindow.h`

representedURL

Provides the URL of the file the window represents.

```
- (NSURL *)representedURL
```

Return Value
The URL for the file the window represents.

Discussion
When the URL specifies a path, the window shows an icon in its title bar, as described in Table 170-1.

Table 170-1 Title bar document icon display

Filepath	Document icon
Empty	None.
Specifies a nonexistent file	Generic.
Specifies an existent file	Specific for the file's type.

You can customize the file icon in the tile bar with the following code:

```
[[<window> standardWindowButton:NSWindowDocumentIconButton] setImage:<image>]
```

When the URL identifies an existing file, the window's title offers a pop-up menu showing the path components of the URL. (The user displays this menu by Command-clicking the title.) The behavior and contents of this menu can be controlled with `window:shouldPopUpDocumentPathMenu:` (page 3931).

Availability
Available in Mac OS X v10.5 and later.

See Also
- `setRepresentedURL:` (page 3395)
- `window:shouldDragDocumentWithEvent:from:withPasteboard:` (page 3930) (`NSWindowDelegate`)

Declared In
`NSWindow.h`

resetCursorRects

Clears the window's cursor rectangles and the cursor rectangles of the `NSView` objects in its view hierarchy.

```
- (void)resetCursorRects
```

Discussion
Invokes `discardCursorRects` (page 3320) to clear the window's cursor rectangles, then sends `resetCursorRects` (page 3360) to every `NSView` object in the window's view hierarchy.

This method is typically invoked by the NSApplication object when it detects that the key window's cursor rectangles are invalid. In program code, it's more efficient to invoke `invalidateCursorRectsForView:` (page 3335).

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
TextLinks

Declared In
`NSWindow.h`

resignKeyWindow

Invoked automatically when the window resigns key window status; never invoke this method directly.

```
- (void)resignKeyWindow
```

Discussion
This method sends `resignKeyWindow` (page 3360) to the window's first responder, sends `windowDidResignKey:` (page 3936) to the window's delegate, and posts an `NSWindowDidResignKeyNotification` (page 3425) to the default notification center.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `becomeKeyWindow` (page 3302)

- resignMainWindow (page 3361)

Declared In
NSWindow.h

resignMainWindow

Invoked automatically when the window resigns main window status; never invoke this method directly.

```
- (void)resignMainWindow
```

Discussion
This method sends windowDidResignMain: (page 3936) to the window's delegate and posts an NSWindowDidResignMainNotification (page 3425) to the default notification center.

Availability
Available in Mac OS X v10.0 and later.

See Also
- becomeMainWindow (page 3303)
- resignKeyWindow (page 3360)

Declared In
NSWindow.h

resizeFlags

Returns the flags field of the event record for the mouse-down event that initiated the resizing session.

```
- (NSInteger)resizeFlags
```

Return Value
A mask indicating which of the modifier keys was held down when the mouse-down event occurred. The flags are listed in NSEvent object's modifierFlags (page 1082) method description.

Discussion
This method is valid only while the window is being resized

You can use this method to constrain the direction or amount of resizing. Because of its limited validity, this method should only be invoked from within an implementation of the delegate method windowWillResize:toSize: (page 3940).

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSWindow.h

resizeIncrements

Returns the window's resizing increments.

```
- (NSSize)resizeIncrements
```

Return Value
The window's resizing increments.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setResizeIncrements:` (page 3396)
- `setAspectRatio:` (page 3368)
- `setFrame:display:` (page 3381)

Declared In
`NSWindow.h`

restoreCachedImage

Splices the window's cached image rectangles, if any, back into its raster image (and buffer if it has one), undoing the effect of any drawing performed within those areas since they were established using `cacheImageInRect:` (page 3303).

```
- (void)restoreCachedImage
```

Discussion
You must invoke `flushWindow` (page 3327) after this method to guarantee proper redisplay. An `NSWindow` object automatically discards its cached image rectangles when it displays.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `discardCachedImage` (page 3320)
- `display` (page 3321)

Declared In
`NSWindow.h`

runToolbarCustomizationPalette:

The action method for the "Customize Toolbar…" menu item.

```
- (void)runToolbarCustomizationPalette:(id)sender
```

Parameters
sender
The message's sender.

Discussion
See the `NSToolbar` class description for additional information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSWindow.h

saveFrameUsingName:

Saves the window's frame rectangle in the user defaults system under a given name.

```
- (void)saveFrameUsingName:(NSString *)frameName
```

Parameters

frameName
The name under which the frame is to be saved.

Discussion
With the companion method `setFrameUsingName:` (page 3384), you can save and reset an `NSWindow` object's frame over various launches of an application. The default is owned by the application and stored under the name `"NSWindow Frame frameName"`. See `NSUserDefaults` for more information.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- stringWithSavedFrame` (page 3402)

Declared In
NSWindow.h

screen

Returns the screen the window is on.

```
- (NSScreen *)screen
```

Return Value
The screen where most of the window is on; `nil` when the window is offscreen.

Discussion
When the window is partly on one screen and partly on another, the screen where most of it lies is returned.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- deepestScreen` (page 3315)

Related Sample Code
CocoaDVDPlayer
GLUT
iSpend
QTQuartzPlayer

Declared In
NSWindow.h

selectKeyViewFollowingView:

Makes key the view that follows the given view.

```
- (void)selectKeyViewFollowingView:(NSView *)referenceView
```

Parameters

referenceView

The view whose following view in the key view loop is sought.

Discussion

Sends the `nextValidKeyView` (page 3193) message to *referenceView* and, if that message returns an `NSView` object, invokes `makeFirstResponder:` (page 3344) with the returned object.

Availability

Available in Mac OS X v10.0 and later.

See Also

`- selectKeyViewPrecedingView:` (page 3364)

Declared In

`NSWindow.h`

selectKeyViewPrecedingView:

Makes key the view that precedes the given view.

```
- (void)selectKeyViewPrecedingView:(NSView *)referenceView
```

Parameters

referenceView

The view whose preceding view in the key view loop is sought.

Discussion

Sends the `previousValidKeyView` (page 3197) message to *referenceView* and, if that message returns an `NSView` object, invokes `makeFirstResponder:` (page 3344) with the returned object.

Availability

Available in Mac OS X v10.0 and later.

See Also

`- selectKeyViewFollowingView:` (page 3364)

Declared In

`NSWindow.h`

selectNextKeyView:

This action method searches for a candidate next key view and, if it finds one, invokes `makeFirstResponder:` (page 3344) to establish it as the first responder.

```
- (void)selectNextKeyView:(id)sender
```

Parameters

sender

The message's sender.

Discussion

The candidate is one of the following (searched for in this order):

- The current first responder's next valid key view, as returned by the `nextValidKeyView` (page 3193) method of `NSView`
- The object designated as the window's initial first responder (using `setInitialFirstResponder:` (page 3387)) if it returns `YES` to an `acceptsFirstResponder` (page 2143) message
- Otherwise, the initial first responder's next valid key view, which may end up being `nil`

Availability

Available in Mac OS X v10.0 and later.

See Also

`- selectPreviousKeyView:` (page 3365)

`- selectKeyViewFollowingView:` (page 3364)

Declared In

`NSWindow.h`

selectPreviousKeyView:

This action method searches for a candidate previous key view and, if it finds one, invokes `makeFirstResponder:` (page 3344) to establish it as the first responder.

```
- (void)selectPreviousKeyView:(id)sender
```

Parameters

sender

The message's sender.

Discussion

The candidate is one of the following (searched for in this order):

- The current first responder's previous valid key view, as returned by the `previousValidKeyView` (page 3197) method of `NSView`
- The object designated as the window's initial first responder (using `setInitialFirstResponder:` (page 3387)) if it returns `YES` to an `acceptsFirstResponder` (page 2143) message
- Otherwise, the initial first responder's previous valid key view, which may end up being `nil`

Availability

Available in Mac OS X v10.0 and later.

See Also

`- selectNextKeyView:` (page 3364)

`- selectKeyViewPrecedingView:` (page 3364)

Declared In
NSWindow.h

sendEvent:

This action method dispatches mouse and keyboard events sent to the window by the NSApplication object.

```
- (void)sendEvent:(NSEvent *)event
```

Parameters

event

The mouse or keyboard event to process.

Discussion
Never invoke this method directly. A right mouse-down event in a window of an inactive application is not delivered to the corresponding NSWindow object. It is instead delivered to the NSApplication object through a sendEvent: (page 167) message with a window number of 0.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSWindow.h

setAcceptsMouseMovedEvents:

Specifies whether the window is to accept mouse-moved events.

```
- (void)setAcceptsMouseMovedEvents:(BOOL)acceptMouseMovedEvents
```

Parameters

acceptMouseMovedEvents

YES to have the window accept mouse-moved events (and to distribute them to its responders); NO to not accept such events.

Availability
Available in Mac OS X v10.0 and later.

See Also
– acceptsMouseMovedEvents (page 3296)

Related Sample Code
GLUT

Declared In
NSWindow.h

setAllowsConcurrentViewDrawing:

Specifies whether the window allows its views to be drawn concurrently.

```
- (void)setAllowsConcurrentViewDrawing:(BOOL)flag
```

Parameters

flag

If YES, the window allows its views to be drawn concurrently; if NO, it does not.

Availability
Available in Mac OS X v10.6 and later.

See Also
- allowsConcurrentViewDrawing (page 3298)

Related Sample Code
DispatchFractal

Declared In
NSWindow.h

setAllowsToolTipsWhenApplicationIsInactive:

Specifies whether the window can display tooltips even when the application is in the background.

```
- (void)setAllowsToolTipsWhenApplicationIsInactive:(BOOL)allowTooltipsWhenAppInactive
```

Parameters

allowTooltipsWhenAppInactive

YES to have the window display tooltips even when its application is inactive; NO to suppress tooltip display when inactive.

Discussion
The message does not take effect until the window changes to an active state.

Note: Enabling tooltips in an inactive application will cause the application to do work any time the pointer passes over the window, thus degrading system performance.

Availability
Available in Mac OS X v10.3 and later.

See Also
- allowsToolTipsWhenApplicationIsInactive (page 3298)

Declared In
NSWindow.h

setAlphaValue:

Applies a given alpha value to the entire window.

```
- (void)setAlphaValue:(CGFloat)windowAlpha
```

Parameters

windowAlpha

The alpha value to apply.

Availability

Available in Mac OS X v10.0 and later.

See Also

- alphaValue (page 3298)

Related Sample Code

From A View to A Movie

FunkyOverlayWindow

MyMediaPlayer

UIElementInspector

Declared In

NSWindow.h

setAspectRatio:

Sets the window's aspect ratio, which constrains the size of its frame rectangle to integral multiples of this ratio when the user resizes it.

```
- (void)setAspectRatio:(NSSize)aspectRatio
```

Parameters

aspectRatio

The aspect ratio to be maintained during resizing actions.

Discussion

An NSWindow object's aspect ratio and its resize increments are mutually exclusive attributes. In fact, setting one attribute cancels the setting of the other. For example, to cancel an established aspect ratio setting for an NSWindow object, you send it a setResizeIncrements: (page 3396) message with the width and height set to 1.0:

```
[myWindow setResizeIncrements:NSMakeSize(1.0,1.0)];
```

The setContentAspectRatio: (page 3373) method takes precedence over this method.

Availability

Available in Mac OS X v10.0 and later.

See Also

- aspectRatio (page 3300)
- setFrame:display: (page 3381)

Declared In

NSWindow.h

setAutodisplay:

Specifies whether the window is to automatically display the views that are marked as needing it.

```
- (void)setAutodisplay:(BOOL)autodisplay
```

Parameters

autodisplay

If YES, the window will automatically display views that need to be displayed; if NO, it will not.

Discussion

If *autodisplay* is NO, the window or its views must be explicitly displayed.

Availability

Available in Mac OS X v10.0 and later.

See Also

- isAutodisplay (page 3336)
- displayIfNeeded (page 3321)
- displayIfNeeded (page 3164) (NSView)

Declared In

NSWindow.h

setAutorecalculatesContentBorderThickness:forEdge:

Specifies whether the window calculates the thickness of a given border automatically.

```
- (void)setAutorecalculatesContentBorderThickness:(BOOL)flag forEdge:(NSRectEdge)edge
```

Parameters

autorecalculateContentBorderThickness

If YES, the window calculates the thickness of the edge automatically; if NO, it does not.

edge

The border whose thickness auto-recalculation status to set:

- NSMaxYEdge: Top border.
- NSMinYEdge: Bottom border.

Special Considerations

Turning off a border's auto-recalculation status sets its border thickness to 0.0.

In a non-textured window calling setAutorecalculatesContentBorderThickness:forEdge: passing NSMaxYEdge will raise an exception. It is only valid to set the content border thickness of the top edge in a textured window.

Availability

Available in Mac OS X v10.5 and later.

See Also

- autorecalculatesContentBorderThicknessForEdge: (page 3300)
- contentBorderThicknessForEdge: (page 3310)

Declared In

NSWindow.h

setAutorecalculatesKeyViewLoop:

Specifies whether to recalculate the key view loop automatically when views are added or removed.

```
- (void)setAutorecalculatesKeyViewLoop:(BOOL)autorecalculateKeyViewLoop
```

Parameters

autorecalculateKeyViewLoop

If YES,the window recalculates the key view loop automatically; if NO, it does not.

Discussion

If *autorecalculateKeyViewLoop* is NO, the client code must update the key view loop manually or call recalculateKeyViewLoop (page 3357) to have the window recalculate it.

Availability

Available in Mac OS X v10.4 and later.

See Also

- autorecalculatesKeyViewLoop (page 3301)
- recalculateKeyViewLoop (page 3357)

Declared In

NSWindow.h

setBackgroundColor:

Sets the window's background color to the given color.

```
- (void)setBackgroundColor:(NSColor *)color
```

Parameters

color

Color to set as the window's background color.

Availability

Available in Mac OS X v10.0 and later.

See Also

- backgroundColor (page 3301)

Related Sample Code

CIAnnotation

MyMediaPlayer

UIElementInspector

Declared In

NSWindow.h

setBackingType:

Sets the window's backing store type to a given type.

```
- (void)setBackingType:(NSBackingStoreType)backingType
```

Parameters

backingType

The backing store type to set.

Discussion

The valid backing store types are described in "Constants" (page 3411).

This method can be used only to switch a buffered window to retained or vice versa; you can't change the backing type to or from nonretained after initializing an `NSWindow` object (an error is generated if you attempt to do so).

Availability

Available in Mac OS X v10.0 and later.

See Also

- `backingType` (page 3302)
- `initWithContentRect:styleMask:backing:defer:` (page 3332)
- `initWithContentRect:styleMask:backing:defer:screen:` (page 3333)

Declared In

`NSWindow.h`

setCanBecomeVisibleWithoutLogin:

Specifies whether the window can be displayed at the login window.

```
- (void)setCanBecomeVisibleWithoutLogin:(BOOL)flag
```

Parameters

flag

`YES` to allow the window to be displayed at the login window; `NO` to prevent this behavior.

Availability

Available in Mac OS X v10.5 and later.

See Also

- `canBecomeVisibleWithoutLogin` (page 3305)

Related Sample Code

PreLoginAgents

Declared In

`NSWindow.h`

setCanBeVisibleOnAllSpaces:

Specifies whether the window can be visible on all spaces or on only one space at a time. (Deprecated in Mac OS X v10.5. Use `collectionBehavior` (page 3309) instead.)

```
- (void)setCanBeVisibleOnAllSpaces:(BOOL)flag
```

Parameters

flag

YES specifies that the window can be visible on all spaces; NO specifies that the window can be visible on only one space at a time.

Availability
Available in Mac OS X v10.5 and later.
Deprecated in Mac OS X v10.5.

Declared In
NSWindow.h

setCanHide:

Specifies whether the window can be hidden when its application becomes hidden (during execution of the NSApplication hide: (page 148) method).

```
- (void)setCanHide:(BOOL)canHide
```

Parameters

canHide

If YES, the window can be hidden when its application becomes hidden; if NO, it cannot.

Availability
Available in Mac OS X v10.0 and later.

See Also
- canHide (page 3306)

Declared In
NSWindow.h

setCollectionBehavior:

Specifies the window's behavior in window collections.

```
- (void)setCollectionBehavior:(NSWindowCollectionBehavior)behavior
```

Parameters

collectionBehavior

The collection behavior identifier to set.

Availability
Available in Mac OS X v10.5 and later.

See Also
- collectionBehavior (page 3309)

Declared In
NSWindow.h

setColorSpace:

Sets the window's color space.

```
- (void)setColorSpace:(NSColorSpace *)colorSpace
```

Parameters

colorSpace

The color space to set.

Availability
Available in Mac OS X v10.6 and later.

See Also
- colorSpace (page 3309)

Declared In
NSWindow.h

setContentAspectRatio:

Sets the aspect ratio (height in relation to width) of the window's content view, constraining the dimensions of its content rectangle to integral multiples of that ratio when the user resizes it.

```
- (void)setContentAspectRatio:(NSSize)contentAspectRatio
```

Parameters

contentAspectRatio

The aspect ratio of the window's content view.

Discussion
You can set a window's content view to any size programmatically, regardless of its aspect ratio. This method takes precedence over setAspectRatio: (page 3368).

Availability
Available in Mac OS X v10.3 and later.

See Also
- contentAspectRatio (page 3310)

Declared In
NSWindow.h

setContentBorderThickness:forEdge:

Specifies the thickness of a given border of the window.

```
- (void)setContentBorderThickness:(CGFloat)thickness forEdge:(NSRectEdge)edge
```

Parameters

borderThickness

The thickness for *edge*, in points.

edge

The border whose thickness to set:

- `NSMaxYEdge`: Top border.
- `NSMinYEdge`: Bottom border.

Discussion
In a non-textured window calling `setContentBorderThickness:forEdge:` passing `NSMaxYEdge` will raise an exception. It is only valid to set the content border thickness of the top edge in a textured window.

The `contentBorder` does not include the titlebar or toolbar, so a textured window that just wants the gradient in the titlebar and toolbar should have a `contentBorderThickness` of `0` for `NSMaxYEdge`.

Availability
Available in Mac OS X v10.5 and later.

See Also
- `contentBorderThicknessForEdge:` (page 3310)

Declared In
`NSWindow.h`

setContentMaxSize:

Sets the maximum size of the window's content view in the window's base coordinate system.

```
- (void)setContentMaxSize:(NSSize)contentMaxSize
```

Parameters
contentMaxSize

The maximum size of the window's content view in the window's base coordinate system.

Discussion
The maximum size constraint is enforced for resizing by the user as well as for the `setContentSize:` (page 3375) method and the `setFrame...` methods other than `setFrame:display:` (page 3381) and `setFrame:display:animate:` (page 3381). This method takes precedence over `setMaxSize:` (page 3388).

Availability
Available in Mac OS X v10.3 and later.

See Also
- `contentMaxSize` (page 3311)
- `setContentMinSize:` (page 3374)

Declared In
`NSWindow.h`

setContentMinSize:

Sets the minimum size of the window's content view in the window's base coordinate system.

```
- (void)setContentMinSize:(NSSize)contentMinSize
```

Parameters

contentMinSize

The minimum size of the window's content view in the window's base coordinate system.

Discussion

The minimum size constraint is enforced for resizing by the user as well as for the `setContentSize:` (page 3375) method and the `setFrame...` methods other than `setFrame:display:` (page 3381) and `setFrame:display:animate:` (page 3381). This method takes precedence over `setMinSize:` (page 3390).

Availability

Available in Mac OS X v10.3 and later.

See Also

- `contentMinSize` (page 3311)
- `setContentMaxSize:` (page 3374)

Declared In

`NSWindow.h`

setContentResizeIncrements:

Restricts the user's ability to resize the window so the width and height of its content view change by multiples of width and height increments.

```
- (void)setContentResizeIncrements:(NSSize)contentResizeIncrements
```

Parameters

contentResizeIncrements

The content-view resizing increments to set.

Discussion

As the user resizes the window, the size of its content view changes by integral multiples of *contentResizeIncrements*`.width` and *contentResizeIncrements*`.height`. However, you can set a window's size to any width and height programmatically. This method takes precedence over `setResizeIncrements:` (page 3396).

Availability

Available in Mac OS X v10.3 and later.

See Also

- `contentResizeIncrements` (page 3312)

Declared In

`NSWindow.h`

setContentSize:

Sets the size of the window's content view to a given size, which is expressed in the window's base coordinate system.

```
- (void)setContentSize:(NSSize)size
```

Parameters

size

The new size of the window's content view in the window's base coordinate system.

Discussion

This size in turn alters the size of the `NSWindow` object itself. Note that the window server limits window sizes to 10,000; if necessary, be sure to limit *aSize* relative to the frame rectangle.

Availability

Available in Mac OS X v10.0 and later.

See Also

VideoViewer

Declared In

`NSWindow.h`

setContentView:

Makes a given view the window's content view.

```
- (void)setContentView:(NSView *)view
```

Parameters

view

View that is to become the window's content view.

Discussion

The window retains the new content view and owns it thereafter. The *view* object is resized to fit precisely within the content area of the window. You can modify the content view's coordinate system through its bounds rectangle, but can't alter its frame rectangle (that is, its size or location) directly.

This method causes the old content view to be released; if you plan to reuse it, be sure to retain it before sending this message and to release it as appropriate when adding it to another `NSWindow` object or `NSView`.

Availability

Available in Mac OS X v10.0 and later.

setDelegate:

Sets the window's delegate to a given object or removes an existing delegate.

```
- (void)setDelegate:(id < NSWindowDelegate >)delegate
```

Parameters

delegate
The delegate for the window. Pass nil to remove an existing delegate.

Discussion
An NSWindow object's delegate is inserted in the responder chain after the window itself and is informed of various actions by the window through delegation messages.

Availability
Available in Mac OS X v10.0 and later.

Verification

Declared In
NSWindow.h

setDepthLimit:

Sets the depth limit of the window to a given limit.

```
- (void)setDepthLimit:(NSWindowDepth)depthLimit
```

Parameters
depthLimit
The depth limit to set.

Discussion
The NSBestDepth (page 3965) function provides the best depth limit based on a set of parameters.

Passing a value of 0 for *depthLimit* sets the depth limit to the window's default depth limit. A depth limit of 0 can be useful for reverting an NSWindow object to its initial depth.

On Mac OS X 10.6 and later, you can pass one of the explicit bit depths defined in "Explicit Window Depth Limits" (page 3417)NSWindowDepthTwentyfourBitRGB (page 3417) is the default.

Availability
Available in Mac OS X v10.0 and later.

See Also
- depthLimit (page 3317)
+ defaultDepthLimit (page 3292)
- setDynamicDepthLimit: (page 3380)

Declared In
NSWindow.h

setDisplaysWhenScreenProfileChanges:

Specifies whether the window context should be updated when the screen profile changes.

```
- (void)setDisplaysWhenScreenProfileChanges:(BOOL)displaysWhenScreenProfileChanges
```

Parameters

displaysWhenScreenProfileChanges

- YES specifies that the window context should be changed in these situations:
  - A majority of the window is moved to a different screen whose profile is different than the previous screen.
  - The ColorSync profile of the current screen changes.
- NO specifies that the screen profile information for the window context doesn't change.

Discussion

After the window context is updated, the window is told to display itself. If you need to update offscreen caches for the window, you should register to receive the NSWindowDidChangeScreenProfileNotification (page 3423) notification.

Availability

Available in Mac OS X v10.4 and later.

See Also

- displaysWhenScreenProfileChanges (page 3322)

Related Sample Code

ImageApp

Declared In

NSWindow.h

setDocumentEdited:

Specifies whether the window's document has been edited.

```
- (void)setDocumentEdited:(BOOL)documentEdited
```

Parameters

documentEdited

If YES, the window's document is marked as having been edited; if NO, it is marked as not having been edited.

Discussion

You should send setDocumentEdited:YES to an NSWindow object every time the window's document changes in such a way that it needs to be saved. Conversely, when the document is saved, you should send setDocumentEdited:NO. Then, before closing the window you can use isDocumentEdited (page 3336) to determine whether to allow the user a chance to save the document.

Availability

Available in Mac OS X v10.0 and later.

Related Sample Code

Quartz Composer WWDC 2005 TextEdit

Declared In
NSWindow.h

setDynamicDepthLimit:

Sets whether the window changes its depth to match the depth of the screen it's on, or the depth of the deepest screen when it spans multiple screens.

```
- (void)setDynamicDepthLimit:(BOOL)dynamicDepthLimit
```

Parameters

dynamicDepthLimit

If YES, the window has a dynamic depth limit; if NO, it does not.

Discussion
When *dynamicDepthLimit* is NO, the window uses either its preset depth limit or the default depth limit. A different, and nondynamic, depth limit can be set with the setDepthLimit: (page 3378) method.

Availability
Available in Mac OS X v10.0 and later.

See Also

setFrame:display:

Sets the origin and size of the window's frame rectangle according to a given frame rectangle, thereby setting its position and size onscreen.

```
- (void)setFrame:(NSRect)windowFrame display:(BOOL)displayViews
```

Parameters

windowFrame

The frame rectangle for the window, including the title bar.

displayViews

Specifies whether the window redraws the views that need to be displayed. When `YES` the window sends a `displayIfNeeded` (page 3321) message down its view hierarchy, thus redrawing all views.

Discussion

Note that the window server limits window position coordinates to ±16,000 and sizes to 10,000.

Availability

Available in Mac OS X v10.0 and later.

Declared In
`NSWindow.h`

setFrameAutosaveName:

Sets the name used to automatically save the window's frame rectangle in the defaults system to a given name.

```
- (BOOL)setFrameAutosaveName:(NSString *)frameName
```

Parameters

frameName

The name under which the frame is to be saved.

Return Value
`YES` when the frame name is set successfully; `NO` when frameName is being used as an autosave name by another `NSWindow` object in the application (in which case the window's old name remains in effect).

Discussion
If *frameName* isn't the empty string (@""), the window's frame is saved as a user default (as described in `saveFrameUsingName:` (page 3363)) each time the frame changes.

When the window has an autosave name, its frame data is written whenever the frame rectangle changes.

If there is a frame rectangle previously stored for *frameName* in the user defaults, the window's frame is set to this frame rectangle. That is, when you call this method with a previously used *frameName*, the window picks up the previously saved setting. For example, if you call `setFrameAutosaveName:` for a window that is already onscreen, this method could cause the window to move to a different screen location. For this reason, it is generally better to call this method before the window is visible on screen.

Keep in mind that a window controller may change the window's position when it displays it if window cascading is turned on. To preclude the window controller from changing a window's position from the one saved in the defaults system, you must send `setShouldCascadeWindows:NO` to the window controller.

Availability
Available in Mac OS X v10.0 and later.

setFrameFromString:

Sets the window's frame rectangle from a given string representation.

```
- (void)setFrameFromString:(NSString *)frameString
```

Parameters
frameString
A string representation of a frame rectangle, previously creating using stringWithSavedFrame (page 3402).

Discussion
If the window is not resizable, this method will not resize the window. The frame is constrained according to the window's minimum and maximum size settings. This method causes a windowWillResize:toSize: (page 3940) message to be sent to the delegate.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSWindow.h

setFrameOrigin:

Positions the bottom-left corner of the window's frame rectangle at a given point in screen coordinates.

```
- (void)setFrameOrigin:(NSPoint)point
```

Parameters
point
The new position of the window's bottom-left corner in screen coordinates.

Discussion
Note that the window server limits window position coordinates to ±16,000.

Availability
Available in Mac OS X v10.0 and later.

setFrameUsingName:force:

Sets the window's frame rectangle by reading the rectangle data stored under a given name from the defaults system. Can operate on nonresizable windows.

```
- (BOOL)setFrameUsingName:(NSString *)frameName force:(BOOL)force
```

Parameters

frameName

The name of the frame to read.

force

YES to use setFrameUsingName: (page 3384) on a nonresizable window; NO to fail on a nonresizable window.

Return Value

YES when *frameName* is read and the frame is set successfully; otherwise,NO.

Availability

Available in Mac OS X v10.0 and later.

Declared In

NSWindow.h

setHasShadow:

Specifies whether the window has a shadow.

```
- (void)setHasShadow:(BOOL)hasShadow
```

Parameters

hasShadow

If YES, the window has a shadow; if NO, it does not.

Discussion

If the shadow setting changes, the window shadow is invalidated, forcing the window shadow to be recomputed.

Availability

Available in Mac OS X v10.0 and later.

See Also

Declared In
NSWindow.h

setLevel:

Sets the window's window level to a given level.

```
- (void)setLevel:(NSInteger)windowLevel
```

Parameters

windowLevel

The window level to set.

Discussion

Some useful predefined values, ordered from lowest to highest, are described in "Window Levels" (page 3412).

Each level in the list groups windows within it in front of those in all preceding groups. Floating windows, for example, appear in front of all normal-level windows. When a window enters a new level, it's ordered in front of all its peers in that level.

The constant `NSTornOffMenuWindowLevel` is preferable to its synonym, `NSSubmenuWindowLevel`.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSWindow.h`

setMaxSize:

Sets the maximum size to which the window's frame (including its title bar) can be sized.

```
- (void)setMaxSize:(NSSize)maxFrameSize
```

Parameters

maxFrameSize

The maximum size of the window's frame.

Discussion

The maximum size constraint is enforced for resizing by the user as well as for the `setFrame...` methods other than `setFrame:display:` (page 3381) and `setFrame:display:animate:` (page 3381). Note that the window server limits window sizes to 10,000.

The default maximum size of a window is `{FLT_MAX, FLT_MAX}` (`FLT_MAX` is defined in `/usr/include/float.h`). Once the maximum size of a window has been set, there is no way to reset it other than specifying this default maximum size.

The setContentMaxSize: (page 3374) method takes precedence over this method.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `maxSize` (page 3346)
- `setMinSize:` (page 3390)
- `setAspectRatio:` (page 3368)
- `setResizeIncrements:` (page 3396)

CIAnnotation

Declared In
`NSWindow.h`

setMiniwindowImage:

Sets the window's custom minimized window image to a given image.

```
- (void)setMiniwindowImage:(NSImage *)miniwindowImage
```

Parameters

miniwindowImage
Image to set as the window's minimized window image.

Discussion
When the user minimizes the window, the Dock displays *miniwindowImage* in the corresponding Dock tile, scaling it as needed to fit in the tile. If you do not specify a custom image using this method, the Dock creates one for you automatically.

You can also call this method as needed to change the minimized window image. Typically, you would specify a custom image immediately prior to a window being minimized—when the system posts an `NSWindowWillMiniaturizeNotification` (page 3427). You can call this method while the window is minimized to update the current image in the Dock. However, this method is not recommended for creating complex animations in the Dock.

Support for custom images is disabled by default. To enable support, set the `AppleDockIconEnabled` key to `YES` when first registering your application's user defaults. You must set this key prior to calling the `init` method of `NSApplication`, which reads the current value of the key.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `miniwindowImage` (page 3347)
- `isMiniaturized` (page 3338)

Declared In
`NSWindow.h`

setMiniwindowTitle:

Sets the title of the window's miniaturized counterpart to a given string and redisplays it.

```
- (void)setMiniwindowTitle:(NSString *)miniwindowTitle
```

Parameters

miniwindowTitle

The string to set as the title of the minimized window.

Discussion

A minimized window's title normally reflects that of its full-size counterpart, abbreviated to fit if necessary. Although this method allows you to set the minimized window's title explicitly, changing the full-size `NSWindow` object's title (through `setTitle:` (page 3398) or `setTitleWithRepresentedFilename:` (page 3399)) automatically changes the minimized window's title as well.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `miniwindowTitle` (page 3347)

MyMediaPlayer

Declared In
NSWindow.h

setOneShot:

Sets whether the window device that the window manages should be freed when it's removed from the screen list.

```
- (void)setOneShot:(BOOL)oneShot
```

Parameters

oneShot

YES to free the window's window device when it's removed from the screen list (hidden) and to create another one when it's returned to the screen; NO to reuse the window device.

Discussion
Freeing the window device when it's removed from the screen list can result in memory savings and performance improvement for `NSWindow` objects that don't take long to display. It's particularly appropriate for `NSWindow` objects the user might use once or twice but not display continually.

Availability
Available in Mac OS X v10.0 and later.

`NSWindow.h`

setPreferredBackingLocation:

Specifies the preferred location for the window's backing store.

```
- (void)setPreferredBackingLocation:(NSWindowBackingLocation)backingLocation
```

Parameters

preferredBackingLocation

The preferred location for the window's backing store. See "NSWindowBackingLocation" (page 3420) for possible values.

Discussion

Use only when optimizing for performance.

Availability

Available in Mac OS X v10.5 and later.

See Also

- `preferredBackingLocation` (page 3356)

Related Sample Code

DispatchFractal

Declared In

`NSWindow.h`

setPreservesContentDuringLiveResize:

Specifies whether the window tries to optimize live resize operations by preserving the content of views that have not changed.

```
- (void)setPreservesContentDuringLiveResize:(BOOL)preservesContentDuringLiveResize
```

Parameters

preservesContentDuringLiveResize

YES turns on live-resize optimization; NO turns it off for the window and all of its contained views.

Discussion

By default, live-resize optimization is turned on.

You might consider disabling this optimization for the window if none of the window's contained views can take advantage of it. Disabling the optimization for the window prevents it from checking each view to see if the optimization is supported.

Availability

Available in Mac OS X v10.4 and later.

See Also

- preservesContentDuringLiveResize (page 3356)

Declared In

NSWindow.h

setPreventsApplicationTerminationWhenModal:

Specifies whether the window prevents application termination when modal.

```
- (void)setPreventsApplicationTerminationWhenModal:(BOOL)flag
```

Parameters

flag

If YES, the window will prevent application termination when modal; if NO, it will not.

Discussion

Normally, application termination is prevented when a modal window or sheet is open, without consulting the application delegate. Some windows may wish not to prevent termination, however. Calling this method with an argument of NO overrides the default behavior and allows termination to proceed even if the window is open, either through the sudden termination path if enabled, or after consulting the application delegate.

Availability

Available in Mac OS X v10.6 and later.

See Also

- preventsApplicationTerminationWhenModal (page 3357)

Declared In

NSWindow.h

setReleasedWhenClosed:

Specifies whether the window is released when it receives the close message.

```
- (void)setReleasedWhenClosed:(BOOL)releasedWhenClosed
```

Parameters

releasedWhenClosed

YES to specify that the window is to be hidden and released when it receives a close message; NO to specify that the window is only hidden, not released.

Discussion

Another strategy for releasing an NSWindow object is to have its delegate autorelease it on receiving a windowShouldClose: (page 3937) message.

Availability

Available in Mac OS X v10.0 and later.

NSWindow.h

setResizeIncrements:

Restricts the user's ability to resize the window so the width and height change by multiples of width and height increments.

```
- (void)setResizeIncrements:(NSSize)resizeIncrements
```

Parameters

resizeIncrements

The resizing increments to set.

Discussion

As the user resizes the window, its size changes by multiples of *increments*.width and *increments*.height, which should be whole numbers, 1.0 or greater. Whatever the current resizing increments, you can set an NSWindow object's size to any height and width programmatically.

Resize increments and aspect ratio are mutually exclusive attributes. For more information, see setAspectRatio: (page 3368).

The setContentResizeIncrements: (page 3375) method takes precedence over this method.

Availability

Available in Mac OS X v10.0 and later.

See Also

- resizeIncrements (page 3361)
- setFrame:display: (page 3381)

Declared In

NSWindow.h

setSharingType:

Specifies the level of access other processes have to the window's content.

```
- (void)setSharingType:(NSWindowSharingType)type
```

Parameters

sharingType

The sharing level of the window's content. See "NSWindowSharingType" (page 3419) for possible values.

Availability
Available in Mac OS X v10.5 and later.

See Also
- `sharingType` (page 3401)

Declared In
`NSWindow.h`

setShowsResizeIndicator:

Specifies whether the window's resize indicator is visible

```
- (void)setShowsResizeIndicator:(BOOL)showResizeIndicator
```

Parameters

showResizeIndicator
Specifies the resize indicator state. `YES` to show it, `NO` to hide it.

Discussion
This method does not affect whether the window is resizable.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `showsResizeIndicator` (page 3401)

Related Sample Code
QTKitPlayer

Declared In
`NSWindow.h`

setShowsToolbarButton:

Specifies whether the window shows the toolbar control button.

```
- (void)setShowsToolbarButton:(BOOL)showsToolbarButton
```

Parameters

showsToolbarButton
`YES` to display the toolbar control button; `NO` to hide the button.

Discussion
If the window does not have a toolbar, this method has no effect.

Availability
Available in Mac OS X v10.4 and later.

See Also
- `showsToolbarButton` (page 3401)

Declared In
NSWindow.h

setStyleMask:

Sets the window's style mask to the given value.

```
- (void)setStyleMask:(NSUInteger)styleMask
```

Parameters

styleMask
The new style mask value.

Discussion
The valid style mask values are the same values acceptable for use in `initWithContentRect:styleMask:backing:defer:` (page 3332). Some style mask changes cause the view hierarchy to be rebuilt.

Availability
Available in Mac OS X v10.6 and later.

See Also
`- styleMask` (page 3402)

Related Sample Code
MyMediaPlayer

Declared In
NSWindow.h

setTitle:

Sets the string that appears in the window's title bar (if it has one) to a given string and displays the title.

```
- (void)setTitle:(NSString *)title
```

Parameters

title
The string to set as the window's title.

Discussion
Also sets the title of the window's miniaturized window.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- title` (page 3403)
`- setTitleWithRepresentedFilename:` (page 3399)
`- setMiniwindowTitle:` (page 3390)

Related Sample Code

WhackedTV

Declared In
NSWindow.h

setTitleWithRepresentedFilename:

Sets a given path as the window's title, formatting it as a file-system path, and records this path as the window's associated filename using `setRepresentedFilename:` (page 3395).

```
- (void)setTitleWithRepresentedFilename:(NSString *)filePath
```

Parameters
filePath
The file path to set as the window's title.

Discussion
The filename—not the pathname—is displayed in the window's title bar.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `title` (page 3403)
- `setTitle:` (page 3398)
- `setMiniwindowTitle:` (page 3390)

Declared In
NSWindow.h

setToolbar:

Sets the window's toolbar.

```
- (void)setToolbar:(NSToolbar *)toolbar
```

Parameters
toolbar
The toolbar for the window.

Discussion
See the `NSToolbar` class description for additional information.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `toolbar` (page 3404)

Related Sample Code

QTKitPlayer

Declared In
NSWindow.h

setViewsNeedDisplay:

Specifies whether the window's views need to be displayed..

```
- (void)setViewsNeedDisplay:(BOOL)viewsNeedDisplay
```

Parameters
viewsNeedDisplay
If YES, the window's views are set to need to be displayed; if NO, they are not.

Discussion
You should rarely need to invoke this method; the NSView method setNeedsDisplay: (page 3225) and similar methods invoke it automatically.

Availability
Available in Mac OS X v10.0 and later.

See Also
- viewsNeedDisplay (page 3407)

Declared In
NSWindow.h

setWindowController:

Sets the window's window controller.

```
- (void)setWindowController:(NSWindowController *)windowController
```

Parameters
windowController
Window controller to set.

Availability
Available in Mac OS X v10.0 and later.

See Also
- windowController (page 3407)

Declared In
NSWindow.h

sharingType

Indicates the level of access other processes have to the window's content.

```
- (NSWindowSharingType)sharingType
```

Return Value
The sharing level of the window's content. See "NSWindowSharingType" (page 3419) for possible values.

Availability
Available in Mac OS X v10.5 and later.

See Also
- setSharingType: (page 3396)

Declared In
NSWindow.h

showsResizeIndicator

Returns a Boolean value that indicates whether the window's resize indicator is visible.

```
- (BOOL)showsResizeIndicator
```

Return Value
YES when the window's resize indicator is visible; otherwise, NO.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setShowsResizeIndicator: (page 3397)

Declared In
NSWindow.h

showsToolbarButton

Indicates whether the toolbar control button is currently displayed.

```
- (BOOL)showsToolbarButton
```

Return Value
YES if the standard toolbar button is currently displayed; otherwise, NO.

Discussion
When clicked, the toolbar control button shows or hides a window's toolbar. The toolbar control button appears in a window's title bar.

Availability
Available in Mac OS X v10.4 and later.

See Also
- setShowsToolbarButton: (page 3397)

Declared In
NSWindow.h

standardWindowButton:

Returns the window button of a given window button kind in the window's view hierarchy.

```
- (NSButton *)standardWindowButton:(NSWindowButton)windowButtonKind
```

Parameters

windowButtonKind
The kind of standard window button to return.

Return Value
Window button in the window's view hierarchy of the kind identified by *windowButtonKind*; `nil` when such button is not in the window's view hierarchy.

Availability
Available in Mac OS X v10.2 and later.

See Also
`+ standardWindowButton:forStyleMask:` (page 3295)

Related Sample Code
GLUT

Declared In
NSWindow.h

stringWithSavedFrame

Returns a string representation of the window's frame rectangle.

```
- (NSString *)stringWithSavedFrame
```

Return Value
A string representation of the window's frame rectangle in a format that can be used with a later `setFrameFromString:` (page 3383) message.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSWindow.h

styleMask

Returns the window's style mask, indicating what kinds of control items it displays.

```
- (NSUInteger)styleMask
```

Return Value
The window's style mask.

Discussion
See the information about the style mask in "Window Style Masks" (page 3411).

Availability
Available in Mac OS X v10.0 and later.

See Also
- setStyleMask: (page 3398)

Related Sample Code

GLUT
Quartz Composer WWDC 2005 TextEdit
StickiesWithCoreData

Declared In
NSWindow.h

title

Returns either the string that appears in the title bar of the window, or the path to the represented file.

```
- (NSString *)title
```

Return Value
The window's title or the path to the represented file.

Discussion
If the title has been set using `setTitleWithRepresentedFilename:` (page 3399), this method returns the file's path.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setTitle: (page 3398)

Related Sample Code
QTAudioExtractionPanel

Declared In
NSWindow.h

toggleToolbarShown:

The action method for the "Hide Toolbar" menu item (which alternates with "Show Toolbar").

```
- (void)toggleToolbarShown:(id)sender
```

Parameters
sender
The message's sender.

Discussion
See the `NSToolbar` class description for additional information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSWindow.h`

toolbar

Returns the window's toolbar.

```
- (NSToolbar *)toolbar
```

Return Value
The window's toolbar.

Discussion
See the `NSToolbar` class description for additional information.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setToolbar:` (page 3399)

Declared In
`NSWindow.h`

tryToPerform:with:

Dispatches action messages with a given argument.

```
- (BOOL)tryToPerform:(SEL)selector with:(id)object
```

Parameters

selector
The selector to attempt to execute.

object
The message's argument.

Return Value
`YES` when the window or its delegate perform *selector* with *object*; otherwise, `NO`.

Discussion
The window tries to perform the method *selector* using its inherited `NSResponder` method `tryToPerform:with:` (page 2202). If the window doesn't perform *selector*, the delegate is given the opportunity to perform it using its inherited `NSObject` method `performSelector:withObject:`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSWindow.h

unregisterDraggedTypes

Unregisters the window as a possible destination for dragging operations.

```
- (void)unregisterDraggedTypes
```

Availability
Available in Mac OS X v10.0 and later.

See Also
- registerForDraggedTypes: (page 3358)

Declared In
NSWindow.h

update

Updates the window.

```
- (void)update
```

Discussion
The NSWindow implementation of this method does nothing more than post an NSWindowDidUpdateNotification (page 3426) notification to the default notification center. A subclass can override this method to perform specialized operations, but it should send an update message to super just before returning. For example, the NSMenu class implements this method to disable and enable menu commands.

An NSWindow object is automatically sent an update message on every pass through the event loop and before it's displayed onscreen. You can manually cause an update message to be sent to all visible NSWindow objects through the NSApplication updateWindows (page 179) method.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setWindowsNeedUpdate: (page 172) (NSApplication)

Related Sample Code
FunHouse

Declared In
NSWindow.h

useOptimizedDrawing:

Specifies whether the window is to optimize focusing and drawing when displaying its views.

```
- (void)useOptimizedDrawing:(BOOL)optimizedDrawing
```

Parameters

optimizedDrawing

If YES, the window will optimize focusing and drawing for its views; if NO, it will not, in which case, the window does not preserve the Z-ordering of overlapping views when an object explicitly sends lockFocus (page 3187) to a view and draws directly to it, instead of using the AppKit standard display mechanism.

Discussion

The optimizations may prevent sibling subviews from being displayed in the correct order—which matters only if the subviews overlap. You should always set *optimizedDrawing* to YES when there are no overlapping subviews within the window. The default is NO.

Availability

Available in Mac OS X v10.0 and later.

Related Sample Code

DispatchFractal

Declared In

NSWindow.h

userSpaceScaleFactor

Returns the scale factor applied to the window.

```
- (CGFloat)userSpaceScaleFactor
```

Return Value

The scale factor applied to the window.

Discussion

Clients can multiply view coordinates by the returned scale factor to get a set of new coordinates that are scaled to the resolution of the target screen. For example, if the scale factor is 1.25 and the view frame size is 80 x 80, the actual size of the view frame is 100 x 100 pixels on the target screen.

Availability

Available in Mac OS X v10.4 and later.

Related Sample Code

VideoViewer

Declared In

NSWindow.h

validRequestorForSendType:returnType:

Searches for an object that responds to a Services request.

```
- (id)validRequestorForSendType:(NSString *)sendType returnType:(NSString
    *)returnType
```

Parameters

sendType

The input type of the Services request.

returnType

The return type of the Services request.

Return Value

The object that responds to the services request; `nil` when none is found.

Discussion

Messages to perform this method are initiated by the Services menu. It's part of the mechanism that passes `validRequestorForSendType:returnType:` messages up the responder chain.

This method works by forwarding the message to the window's delegate if it responds (and provided it isn't an `NSResponder` object with its own next responder). If the delegate doesn't respond to the message or returns `nil` when sent it, this method forwards the message to the `NSApplication` object. If the `NSApplication` object returns `nil`, this method also returns `nil`. Otherwise this method returns the object returned by the delegate or the `NSApplication` object.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `validRequestorForSendType:returnType:` (page 2204) (`NSResponder`)
- `validRequestorForSendType:returnType:` (page 180) (`NSApplication`)

Declared In

`NSWindow.h`

viewsNeedDisplay

Indicates whether any of the window's views need to be displayed.

```
- (BOOL)viewsNeedDisplay
```

Return Value

`YES` when any of the window's views need to be displayed; otherwise, `NO`.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `setViewsNeedDisplay:` (page 3400)

Declared In

`NSWindow.h`

windowController

Returns the window's window controller.

```
- (id)windowController
```

Return Value
The window's window controller.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setWindowController:` (page 3400)

Related Sample Code
FunHouse
PDFKitLinker2
QTAudioContextInsert
Sketch-112

Declared In
`NSWindow.h`

windowNumber

Provides the window number of the window's window device.

```
- (NSInteger)windowNumber
```

Return Value
The window number of the window's window device.

Discussion
Each window device in an application is given a unique window number—note that this isn't the same as the global window number assigned by the window server. This number can be used to identify the window device with the `orderWindow:relativeTo:` (page 3352) method and in the Application Kit function `NSWindowList` (page 4003). .

If the window doesn't have a window device, the value returned will be equal to or less than 0.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- initWithContentRect:styleMask:backing:defer:` (page 3332)
`- setOneShot:` (page 3391)

Related Sample Code
CocoaDVDPlayer
Quartz Composer WWDC 2005 TextEdit

Declared In
`NSWindow.h`

windowRef

Returns the Carbon `WindowRef` associated with the window, creating one if necessary.

```
- (void *)windowRef
```

Discussion
This method can be used to create a `WindowRef` for a window containing a Carbon control. Subsequent calls to this method return the existing `WindowRef`. You use a `WindowRef` to create a Carbon window reference for a Cocoa window; this assists the integration of Carbon and Cocoa code and objects.

For more information see `MacWindows.h`. For more information on Carbon-Cocoa integration, see *Carbon-Cocoa Integration Guide*.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- initWithWindowRef:` (page 3334)

Declared In
`NSWindow.h`

worksWhenModal

Indicates whether the window is able to receive keyboard and mouse events even when some other window is being run modally.

```
- (BOOL)worksWhenModal
```

Return Value
`YES` if the window is able to receive keyboard and mouse events even when some other window is being run modally; otherwise, `NO`.

Discussion
The `NSWindow` implementation of this method returns `NO`. Only subclasses of `NSPanel` should override this default.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- setWorksWhenModal:` (page 1862) (`NSPanel`)

Declared In
`NSWindow.h`

zoom:

This action method toggles the size and location of the window between its standard state (provided by the application as the "best" size to display the window's data) and its user state (a new size and location the user may have set by moving or resizing the window).

```
- (void)zoom:(id)sender
```

Parameters

sender

The object sending the message.

Discussion

For more information on the standard and user states, see `windowWillUseStandardFrame:defaultFrame:` (page 3942).

The `zoom:` method is typically invoked after a user clicks the window's zoom box but may also be invoked programmatically from the `performZoom:` (page 3355) method. It performs the following steps:

1. Invokes the `windowWillUseStandardFrame:defaultFrame:` (page 3942) method, if the delegate or the window class implements it, to obtain a "best fit" frame for the window. If neither the delegate nor the window class implements the method, uses a default frame that nearly fills the current screen, which is defined to be the screen containing the largest part of the window's current frame.
2. Adjusts the resulting frame, if necessary, to fit on the current screen.
3. Compares the resulting frame to the current frame to determine whether the window's standard frame is currently displayed. If the current frame is within a few pixels of the standard frame in size and location, it is considered a match.
4. Determines a new frame. If the window is currently in the standard state, the new frame represents the user state, saved during a previous zoom. If the window is currently in the user state, the new frame represents the standard state, computed in step 1 above. If there is no saved user state because there has been no previous zoom, the size and location of the window do not change.
5. Determines whether the window currently allows zooming. By default, zooming is allowed. If the window's delegate implements the `windowShouldZoom:toFrame:` (page 3938) method, `zoom:` invokes that method. If the delegate doesn't implement the method but the window does, `zoom:` invokes the window's version. `windowShouldZoom:toFrame:` returns `NO` if zooming is not currently allowed.
6. If the window currently allows zooming, sets the new frame.

Availability

Available in Mac OS X v10.0 and later.

See Also

`- isZoomed` (page 3342)

CIAnnotation

Declared In

`NSWindow.h`

Constants

Window Style Masks

These constants specify the presence of a title and various buttons in a window's border. It can be `NSBorderlessWindowMask`, or it can contain any of the following options, combined using the C bitwise OR operator:

```
enum {
   NSBorderlessWindowMask = 0,
   NSTitledWindowMask = 1 << 0,
   NSClosableWindowMask = 1 << 1,
   NSMiniaturizableWindowMask = 1 << 2,
   NSResizableWindowMask = 1 << 3,
   NSTexturedBackgroundWindowMask = 1 << 8
};
```

Constants

`NSBorderlessWindowMask`

The window displays none of the usual peripheral elements. Useful only for display or caching purposes.

Available in Mac OS X v10.0 and later.

Declared in `NSWindow.h`.

`NSTitledWindowMask`

The window displays a title bar.

Available in Mac OS X v10.0 and later.

Declared in `NSWindow.h`.

`NSClosableWindowMask`

The window displays a close button.

Available in Mac OS X v10.0 and later.

Declared in `NSWindow.h`.

`NSMiniaturizableWindowMask`

The window displays a minimize button.

Available in Mac OS X v10.0 and later.

Declared in `NSWindow.h`.

`NSResizableWindowMask`

The window displays a resize control.

Available in Mac OS X v10.0 and later.

Declared in `NSWindow.h`.

`NSTexturedBackgroundWindowMask`

The window displays with a metal-textured background. Additionally, the window may be moved by clicking and dragging anywhere in the window background. A bordered window with this mask gets rounded bottom corners.

Available in Mac OS X v10.2 and later.

Declared in `NSWindow.h`.

Declared In

`NSWindow.h`

Window Levels

The standard window levels in Mac OS X.

```
#define NSNormalWindowLevel           kCGNormalWindowLevel
#define NSFloatingWindowLevel         kCGFloatingWindowLevel
#define NSSubmenuWindowLevel          kCGTornOffMenuWindowLevel
#define NSTornOffMenuWindowLevel      kCGTornOffMenuWindowLevel
#define NSMainMenuWindowLevel         kCGMainMenuWindowLevel
#define NSStatusWindowLevel           kCGStatusWindowLevel
#define NSModalPanelWindowLevel       kCGModalPanelWindowLevel
#define NSPopUpMenuWindowLevel        kCGPopUpMenuWindowLevel
#define NSScreenSaverWindowLevel      kCGScreenSaverWindowLevel
#define NSDockWindowLevel             kCGDockWindowLevel
```

Constants

`NSNormalWindowLevel`

The default level for `NSWindow` objects.

Available in Mac OS X v10.0 and later.

Declared in `NSWindow.h`.

`NSFloatingWindowLevel`

Useful for floating palettes.

Available in Mac OS X v10.0 and later.

Declared in `NSWindow.h`.

`NSSubmenuWindowLevel`

Reserved for submenus. Synonymous with `NSTornOffMenuWindowLevel`, which is preferred.

Available in Mac OS X v10.0 and later.

Declared in `NSWindow.h`.

`NSTornOffMenuWindowLevel`

The level for a torn-off menu. Synonymous with `NSSubmenuWindowLevel`.

Available in Mac OS X v10.0 and later.

Declared in `NSWindow.h`.

`NSModalPanelWindowLevel`

The level for a modal panel.

Available in Mac OS X v10.0 and later.

Declared in `NSWindow.h`.

`NSMainMenuWindowLevel`

Reserved for the application's main menu.

Available in Mac OS X v10.0 and later.

Declared in `NSWindow.h`.

`NSStatusWindowLevel`

The level for a status window.

Available in Mac OS X v10.0 and later.

Declared in `NSWindow.h`.

`NSPopUpMenuWindowLevel`
The level for a pop-up menu.

Available in Mac OS X v10.0 and later.

Declared in `NSWindow.h`.

`NSScreenSaverWindowLevel`
The level for a screen saver.

Available in Mac OS X v10.0 and later.

Declared in `NSWindow.h`.

`NSDockWindowLevel`

The level for the doc.. (Deprecated. Deprecated. There is no replacement.)

Available in Mac OS X v10.0 and later.

Declared in `NSWindow.h`.

Discussion
The stacking of levels takes precedence over the stacking of windows within each level. That is, even the bottom window in a level will obscure the top window of the next level down. Levels are listed in order from lowest to highest. These constants are mapped (using `#define` statements) to corresponding elements in `Window Level Keys`.

Display Device—Descriptions

These constants are the keys for device description dictionaries used by `deviceDescription` (page 3318).

```
NSString *NSDeviceResolution;
NSString *NSDeviceColorSpaceName;
NSString *NSDeviceBitsPerSample;
NSString *NSDeviceIsScreen;
NSString *NSDeviceIsPrinter;
NSString *NSDeviceSize;
```

Constants
`NSDeviceResolution`
The corresponding value is an `NSValue` object containing a value of type `NSSize` that describes the window's raster resolution in dots per inch (dpi).

Available in Mac OS X v10.0 and later.

Declared in `NSGraphics.h`.

`NSDeviceColorSpaceName`
The corresponding value is an `NSString` object giving the name of the window's color space.

See `Color_Space_Names` (page 4017) in *Application Kit Constants Reference* for a list of possible values.

Available in Mac OS X v10.0 and later.

Declared in `NSGraphics.h`.

`NSDeviceBitsPerSample`
The corresponding value is an `NSNumber` object containing an integer that gives the bit depth of the window's raster image (2-bit, 8-bit, and so forth).

Available in Mac OS X v10.0 and later.

Declared in `NSGraphics.h`.

`NSDeviceIsScreen`
If there is a corresponding value, this indicates that the display device is a screen.

Available in Mac OS X v10.0 and later.

Declared in `NSGraphics.h`.

`NSDeviceIsPrinter`
If there is a corresponding value, this indicates that the display device is a printer.

Available in Mac OS X v10.0 and later.

Declared in `NSGraphics.h`.

`NSDeviceSize`
The corresponding value is an `NSValue` object containing a value of type `NSSize` that gives the size of the window's frame rectangle.

Available in Mac OS X v10.0 and later.

Declared in `NSGraphics.h`.

Declared In
`NSGraphics.h`

Managing Scaling Factors

This constant provides a way to manage scaling factors:

```
enum {
    NSUnscaledWindowMask        = 1 << 11
};
```

Constants
`NSUnscaledWindowMask`
Specifies that the window is created without any scaling factors applied.

The client is responsible for all scaling operations in the window. Such a window returns `1.0` from its `userSpaceScaleFactor` method.

Currently restricted to borderless windows (`NSBorderlessWindowMask`).

Available in Mac OS X v10.4 and later.

Declared in `NSWindow.h`.

Controlling the Look of a Window and Its Toolbar

This constant controls the look of a window and its toolbar.

```
enum {
    NSUnifiedTitleAndToolbarWindowMask    = 1 << 12
};
```

Constants
`NSUnifiedTitleAndToolbarWindowMask`
Specifies a window whose toolbar and title bar are rendered on a single continuous background.

Available in Mac OS X v10.4 and later.

Declared in `NSWindow.h`.

NSSelectionDirection—Direction of Key View Change

These constants specify the direction a window is currently using to change the key view. They're used by `keyViewSelectionDirection` (page 3343).

```
enum {
    NSDirectSelection = 0,
    NSSelectingNext,
    NSSelectingPrevious
};
typedef NSUInteger NSSelectionDirection;
```

Constants

`NSDirectSelection`
The window isn't traversing the key view loop.
Available in Mac OS X v10.0 and later.
Declared in `NSWindow.h`.

`NSSelectingNext`
The window is proceeding to the next valid key view.
Available in Mac OS X v10.0 and later.
Declared in `NSWindow.h`.

`NSSelectingPrevious`
The window is proceeding to the previous valid key view.
Available in Mac OS X v10.0 and later.
Declared in `NSWindow.h`.

NSWindowButton—Accessing Standard Title Bar Buttons

These constants provide a way to access standard title bar buttons:

```
enum {
     NSWindowCloseButton,
     NSWindowMiniaturizeButton,
     NSWindowZoomButton,
     NSWindowToolbarButton,
     NSWindowDocumentIconButton
};
typedef NSUInteger NSWindowButton;
```

Constants

`NSWindowCloseButton`
The close button.
Available in Mac OS X v10.2 and later.
Declared in `NSWindow.h`.

`NSWindowMiniaturizeButton`
The minimize button.
Available in Mac OS X v10.2 and later.
Declared in `NSWindow.h`.

`NSWindowZoomButton`
The zoom button.

Available in Mac OS X v10.2 and later.

Declared in `NSWindow.h`.

`NSWindowToolbarButton`
The toolbar button.

Available in Mac OS X v10.2 and later.

Declared in `NSWindow.h`.

`NSWindowDocumentIconButton`
The document icon button.

Available in Mac OS X v10.2 and later.

Declared in `NSWindow.h`.

NSRunLoop—Ordering Modes for NSWindow

These constants are passed to `NSRunLoop`'s `performSelector:target:argument:order:modes:`.

```
enum {
   NSDisplayWindowRunLoopOrdering,
   NSResetCursorRectsRunLoopOrdering
};
```

Constants

`NSDisplayWindowRunLoopOrdering`
The priority at which windows are displayed.

Available in Mac OS X v10.0 and later.

Declared in `NSWindow.h`.

`NSResetCursorRectsRunLoopOrdering`
The priority at which cursor rects are reset.

Available in Mac OS X v10.0 and later.

Declared in `NSWindow.h`.

NSWindowDepth—Window Depth

This type represents the depth, or amount of memory, devoted to a single pixel in a window or screen. A depth of 0 indicates default depth. Window depths should not be made persistent as they will not be the same across systems.

```
typedef int NSWindowDepth;
```

Discussion

Use the functions `NSColorSpaceFromDepth` (page 3966), `NSBitsPerPixelFromDepth` (page 3966), and `NSPlanarFromDepth` (page 3990) to extract info from an `NSWindowDepth` value. Use `NSBestDepth` (page 3965) to compute window depths. `NSBestDepth` (page 3965) tries to accommodate all the parameters (match or better); if there are multiple matches, it gives the closest, with matching color space first, then bps, then planar, then `bpp`. `bpp` is "bits per pixel"; 0 indicates default (same as the number of bits per plane, either `bps` or `bps` * `NSNumberOfColorComponents` (page 3988)); other values maybe used as hints to provide backing stores of different configuration: for instance, 8-bit color.

On Mac OS X 10.6 and later, you can pass one of the explicit bit depths defined in "Explicit Window Depth Limits" (page 3417) to the NSWindow method `setDepthLimit:` (page 3378).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSGraphics.h`

Explicit Window Depth Limits

These constants define explicit window depths that can be used with `setDepthLimit:` (page 3378).

```
enum {
    NSWindowDepthTwentyfourBitRGB = 0x208,
    NSWindowDepthSixtyfourBitRGB = 0x210,
    NSWindowDepthOnehundredtwentyeightBitRGB = 0x220
};
```

Constants

`NSWindowDepthTwentyfourBitRGB`
Twenty four bit RGB depth limit.
Available in Mac OS X v10.6 and later.
Declared in `NSGraphics.h`.

`NSWindowDepthSixtyfourBitRGB`
Sixty four bit RGB depth limit.
Available in Mac OS X v10.6 and later.
Declared in `NSGraphics.h`.

`NSWindowDepthOnehundredtwentyeightBitRGB`
One hundred and twenty eight bit RGB depth limit.
Available in Mac OS X v10.6 and later.
Declared in `NSGraphics.h`.

NSBackingStoreType—Buffered Window Drawing

These constants specify how the drawing done in a window is buffered by the window device.

```
enum {
    NSBackingStoreRetained     = 0,
    NSBackingStoreNonretained  = 1,
    NSBackingStoreBuffered     = 2
};
typedef NSUInteger NSBackingStoreType;
```

Constants

`NSBackingStoreRetained`

The window uses a buffer, but draws directly to the screen where possible and to the buffer for obscured portions.

You should not use this mode. It combines the limitations of `NSBackingStoreNonretained` with the memory use of `NSBackingStoreBuffered`. The original NeXTSTEP implementation was an interesting compromise that worked well with fast memory mapped framebuffers on the CPU bus—something that hasn't been in general use since around 1994. These tend to have performance problems.

In Mac OS X 10.5 and later, requests for retained windows will result in the window system creating a buffered window, as that better matches actual use.

Available in Mac OS X v10.0 and later.

Declared in `NSGraphics.h`.

`NSBackingStoreNonretained`

The window draws directly to the screen without using any buffer.

You should not use this mode. It exists primarily for use in the original Classic Blue Box. It does not support Quartz drawing, alpha blending, or opacity. Moreover, it does not support hardware acceleration, and interferes with system-wide display acceleration. If you use this mode, your application must manage visibility region clipping itself, and manage repainting on visibility changes.

Available in Mac OS X v10.0 and later.

Declared in `NSGraphics.h`.

`NSBackingStoreBuffered`

The window renders all drawing into a display buffer and then flushes it to the screen.

You should use this mode. It supports hardware acceleration, Quartz drawing, and takes advantage of the GPU when possible. It also supports alpha channel drawing, opacity controls, using the compositor.

Available in Mac OS X v10.0 and later.

Declared in `NSGraphics.h`.

NSWindowOrderingMode

These constants let you specify how a window is ordered relative to another window. For more information, see `orderWindow:relativeTo:` (page 3352).

```
enum {
    NSWindowAbove          =  1,
    NSWindowBelow          = -1,
    NSWindowOut              =  0
};
typedef NSInteger NSWindowOrderingMode;
```

Constants

`NSWindowAbove`

Moves the window above the indicated window.

Available in Mac OS X v10.0 and later.

Declared in `NSGraphics.h`.

`NSWindowBelow`

Moves the window below the indicated window.

Available in Mac OS X v10.0 and later.

Declared in `NSGraphics.h`.

`NSWindowOut`

Moves the window off the screen.

Available in Mac OS X v10.0 and later.

Declared in `NSGraphics.h`.

NSWindowSharingType

The following constants and the related data type represent the access levels other processes can have to a window's content.

```
enum {
    NSWindowSharingNone = 0,
    NSWindowSharingReadOnly = 1,
    NSWindowSharingReadWrite = 2
};
typedef NSUInteger NSWindowSharingType;
```

Constants

`NSWindowSharingNone`

The window's contents cannot be read by another process.

Available in Mac OS X v10.5 and later.

Declared in `NSWindow.h`.

`NSWindowSharingReadOnly`

The window's contents can be read but not modified by another process.

Available in Mac OS X v10.5 and later.

Declared in `NSWindow.h`.

`NSWindowSharingReadWrite`

The window's contents can be read and modified by another process.

Available in Mac OS X v10.5 and later.

Declared in `NSWindow.h`.

NSWindowBackingLocation

The following constants and the related data type represent a window's possible backing locations.

```
enum {
    NSWindowBackingLocationDefault = 0,
    NSWindowBackingLocationVideoMemory = 1,
    NSWindowBackingLocationMainMemory = 2
};
typedef NSUInteger NSWindowBackingLocation;
```

Constants

`NSWindowBackingLocationDefault`

Determined by the operating system.

Available in Mac OS X v10.5 and later.

Declared in `NSWindow.h`.

`NSWindowBackingLocationVideoMemory`

Video memory.

Available in Mac OS X v10.5 and later.

Declared in `NSWindow.h`.

`NSWindowBackingLocationMainMemory`

Physical memory.

Available in Mac OS X v10.5 and later.

Declared in `NSWindow.h`.

NSWindowNumberListOptions

The options that may be passed to the `windowNumbersWithOptions:` (page 3296) method.

```
enum {
   NSWindowNumberListAllApplications = 1 << 0,
   NSWindowNumberListAllSpaces = 1 << 4
};
typedef NSUInteger NSWindowNumberListOptions;
```

Constants

`NSWindowNumberListAllApplications`

The window numbers of windows visible on any space and belonging to any application.

Available in Mac OS X v10.6 and later.

Declared in `NSWindow.h`.

`NSWindowNumberListAllSpaces`

The window numbers of windows visible on any space and belonging to the calling application.

Available in Mac OS X v10.6 and later.

Declared in `NSWindow.h`.

Discussion

If the value 0 is passed instead, then the list returned from the method contains window numbers for visible windows on the active space belonging to the calling application.

Managing Window Collections

Window collection behaviors related to Exposé and Spaces.

```
enum {
   NSWindowCollectionBehaviorDefault = 0,
   NSWindowCollectionBehaviorCanJoinAllSpaces = 1 << 0,
   NSWindowCollectionBehaviorMoveToActiveSpace = 1 << 1
};
enum {
   NSWindowCollectionBehaviorManaged = 1 << 2,
   NSWindowCollectionBehaviorTransient = 1 << 3,
   NSWindowCollectionBehaviorStationary = 1 << 4,
};
enum {
   NSWindowCollectionBehaviorParticipatesInCycle = 1 << 5,
   NSWindowCollectionBehaviorIgnoresCycle = 1 << 6
};
typedef NSUInteger NSWindowCollectionBehavior;
```

Constants

`NSWindowCollectionBehaviorDefault`

The window can be associated to one space at a time.

Available in Mac OS X v10.5 and later.

Declared in `NSWindow.h`.

`NSWindowCollectionBehaviorCanJoinAllSpaces`

The window appears in all spaces. The menu bar behaves this way.

Available in Mac OS X v10.5 and later.

Declared in `NSWindow.h`.

`NSWindowCollectionBehaviorMoveToActiveSpace`

Making the window active does not cause a space switch; the window switches to the active space.

Available in Mac OS X v10.5 and later.

Declared in `NSWindow.h`.

`NSWindowCollectionBehaviorManaged`

The window participates in Spaces and Exposé. This is the default behavior if `windowLevel` is equal to `NSNormalWindowLevel` (page 3412).

Available in Mac OS X v10.6 and later.

Declared in `NSWindow.h`.

`NSWindowCollectionBehaviorTransient`

The window floats in Spaces and is hidden by Exposé. This is the default behavior if `windowLevel` is not equal to `NSNormalWindowLevel` (page 3412).

Available in Mac OS X v10.6 and later.

Declared in `NSWindow.h`.

`NSWindowCollectionBehaviorStationary`

The window is unaffected by Exposé; it stays visible and stationary, like the desktop window.

Available in Mac OS X v10.6 and later.

Declared in `NSWindow.h`.

`NSWindowCollectionBehaviorParticipatesInCycle`
The window participates in the window cycle for use with the Cycle Through Windows Window menu item.

Available in Mac OS X v10.6 and later.

Declared in `NSWindow.h`.

`NSWindowCollectionBehaviorIgnoresCycle`
The window is not part of the window cycle for use with the Cycle Through Windows Window menu item.

Available in Mac OS X v10.6 and later.

Declared in `NSWindow.h`.

Application Kit Version for Deferred Window Display Support

The version of the AppKit.framework containing a specific bug fix or capability.

```
#define NSAppKitVersionNumberWithDeferredWindowDisplaySupport        1019.0
```

Constants

`NSAppKitVersionNumberWithDeferredWindowDisplaySupport`
The specific version of the AppKit framework that introduced for custom sheet positioning. Developers should not need to use this constant unless they are writing applications for Mac OS X v10.5 and earlier.

Available in Mac OS X v10.6 and later.

Declared in `NSWindow.h`.

Application Kit Version for Custom Sheet Position

The version of the AppKit.framework containing a specific bug fix or capability.

```
#define NSAppKitVersionNumberWithCustomSheetPosition 686.0
```

Constants

`NSAppKitVersionNumberWithCustomSheetPosition`
The specific version of the AppKit framework that introduced for custom sheet positioning. Developers should not need to use this constant unless they are writing applications for Mac OS X v10.2 and earlier.

Available in Mac OS X v10.3 and later.

Declared in `NSWindow.h`.

Notifications

NSWindowDidBecomeKeyNotification

Posted whenever an `NSWindow` object becomes the key window.

The notification object is the `NSWindow` object that has become key. This notification does not contain a *`userInfo`* dictionary.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSWindow.h`

NSWindowDidBecomeMainNotification

Posted whenever an `NSWindow` object becomes the main window.

The notification object is the `NSWindow` object that has become main. This notification does not contain a *`userInfo`* dictionary.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSWindow.h`

NSWindowDidChangeScreenNotification

Posted whenever a portion of an `NSWindow` object's frame moves onto or off of a screen.

The notification object is the `NSWindow` object that has changed screens. This notification does not contain a *`userInfo`* dictionary.

This notification is not sent in Mac OS X versions earlier than 10.4.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSWindow.h`

NSWindowDidChangeScreenProfileNotification

Posted whenever the display profile for the screen containing the window changes.

This notification is sent only if the window returns `YES` from `displaysWhenScreenProfileChanges` (page 3322). This notification may be sent when a majority of the window is moved to a different screen (whose profile is also different from the previous screen) or when the ColorSync profile for the current screen changes.

The notification object is the `NSWindow` object whose profile changed. This notification does not contain a *`userInfo`* dictionary.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`NSWindow.h`

NSWindowDidDeminiaturizeNotification

Posted whenever an `NSWindow` object is deminimized.

The notification object is the `NSWindow` object that has been deminimized. This notification does not contain a *`userInfo`* dictionary.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSWindow.h`

NSWindowDidEndSheetNotification

Posted whenever an `NSWindow` object closes an attached sheet.

The notification object is the `NSWindow` object that contained the sheet. This notification does not contain a *`userInfo`* dictionary.

Availability
Available in Mac OS X v10.1 and later.

Declared In
`NSWindow.h`

NSWindowDidEndLiveResizeNotification

Posted after the user resizes a window.

This notification is sent only once for a series of window resize operations.

The notification object is the `NSWindow` object that was resized. This notification does not contain a *`userInfo`* dictionary.

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSWindow.h`

NSWindowDidExposeNotification

Posted whenever a portion of a nonretained `NSWindow` object is exposed, whether by being ordered in front of other windows or by other windows being removed from in front of it.

The notification object is the `NSWindow` object that has been exposed. The *`userInfo`* dictionary contains the following information:

Key	Value
`@"NSExposedRect"`	The rectangle that has been exposed (an `NSValue` object containing an NSRect).

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSWindow.h

NSWindowDidMiniaturizeNotification

Posted whenever an NSWindow object is minimized.

The notification object is the NSWindow object that has been minimized. This notification does not contain a *userInfo* dictionary.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSWindow.h

NSWindowDidMoveNotification

Posted whenever an NSWindow object is moved.

The notification object is the NSWindow object that has moved. This notification does not contain a *userInfo* dictionary.

Note: This notification is sent when the window that moved didn't also change size. See NSWindowDidResizeNotification (page 3426) for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSWindow.h

NSWindowDidResignKeyNotification

Posted whenever an NSWindow object resigns its status as key window.

The notification object is the NSWindow object that has resigned its key window status. This notification does not contain a *userInfo* dictionary.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSWindow.h

NSWindowDidResignMainNotification

Posted whenever an NSWindow object resigns its status as main window.

The notification object is the NSWindow object that has resigned its main window status. This notification does not contain a *userInfo* dictionary.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSWindow.h`

NSWindowDidResizeNotification

Posted whenever an `NSWindow` object's size changes.

The notification object is the `NSWindow` object whose size has changed. This notification does not contain a *`userInfo`* dictionary.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSWindow.h`

NSWindowDidUpdateNotification

Posted whenever an `NSWindow` object receives an `update` (page 3405) message.

The notification object is the `NSWindow` object that received the `update` (page 3405) message. This notification does not contain a *`userInfo`* dictionary.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSWindow.h`

NSWindowWillBeginSheetNotification

Posted whenever an `NSWindow` object is about to open a sheet.

The notification object is the `NSWindow` object that is about to open the sheet. This notification does not contain a *`userInfo`* dictionary.

Availability
Available in Mac OS X v10.1 and later.

Declared In
`NSWindow.h`

NSWindowWillCloseNotification

Posted whenever an `NSWindow` object is about to close.

The notification object is the `NSWindow` object that is about to close. This notification does not contain a *`userInfo`* dictionary.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSWindow.h

NSWindowWillMiniaturizeNotification

Posted whenever an NSWindow object is about to be minimized.

The notification object is the NSWindow object that is about to be minimized. This notification does not contain a *userInfo* dictionary.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSWindow.h

NSWindowWillMoveNotification

Posted whenever an NSWindow object is about to move.

The notification object is the NSWindow object that is about to move. This notification does not contain a *userInfo* dictionary.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSWindow.h

NSWindowWillStartLiveResizeNotification

Posted before the user resizes a window.

This notification is sent only once for a series of window resize operations.

The notification object is the NSWindow object that is about to be live resized. This notification does not contain a *userInfo* dictionary.

Availability
Available in Mac OS X v10.6 and later.

Declared In
NSWindow.h

NSWindowController Class Reference

Inherits from	NSResponder : NSObject
Conforms to	NSCoding NSCoding (NSResponder) NSObject (NSObject)
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.0 and later.
Declared in	AppKit/NSWindowController.h
Companion guide	Document-Based Applications Overview
Related sample code	BundleLoader ImageKitDemo QTAudioContextInsert Sketch+Accessibility Sketch-112

Overview

An `NSWindowController` object manages a window, usually a window stored in a nib file.

This management entails:

- Loading and displaying the window
- Closing the window when appropriate
- Customizing the window's title
- Storing the window's frame (size and location) in the defaults database
- Cascading the window in relation to other document windows of the application

A window controller can manage a window by itself or as a role player in the Application Kit's document-based architecture, which also includes `NSDocument` and `NSDocumentController` objects. In this architecture, a window controller is created and managed by a "document" (an instance of an `NSDocument` subclass) and, in turn, keeps a reference to the document.

The relationship between a window controller and a nib file is important. Although a window controller can manage a programmatically created window, it usually manages a window in a nib file. The nib file can contain other top-level objects, including other windows, but the window controller's responsibility is this

primary window. The window controller is usually the owner of the nib file, even when it is part of a document-based application. Regardless of who is the file's owner, the window controller is responsible for freeing all top-level objects in the nib file it loads.

For simple documents—that is, documents with only one nib file containing a window—you need do little directly with `NSWindowController`. The Application Kit will create one for you. However, if the default window controller is not sufficient, you can create a custom subclass of `NSWindowController`. For documents with multiple windows or panels, your document must create separate instances of `NSWindowController` (or of custom subclasses of `NSWindowController`), one for each window or panel. An example is a CAD application that has different windows for side, top, and front views of drawn objects. What you do in your `NSDocument` subclass determines whether the default `NSWindowController` or separately created and configured `NSWindowController` objects are used.

Subclassing NSWindowController

You should create a subclass of `NSWindowController` when you want to augment the default behavior, such as to give the window a custom title or to perform some setup tasks before the window is loaded. In your class's initialization method, be sure to invoke on `super` either one of the `initWithWindowNibName:...` initializers or the `initWithWindow:` (page 3434) initializer. Which one depends on whether the window object originates in a nib file or is programmatically created.

Three `NSWindowController` methods are most commonly overridden:

Method Name	Description
`windowWillLoad` (page 3444)	Override to perform tasks before the window nib file is loaded.
`windowDidLoad` (page 3442)	Override to perform tasks after the window nib file is loaded.
`windowTitleForDocumentDisplayName:` (page 3444)	Override to customize the window title.

You can also override `loadWindow` (page 3436) to get different nib-searching or nib-loading behavior, although there is usually no need to do this.

Adopted Protocols

NSCoding
- `encodeWithCoder:`
- `initWithCoder:`

Tasks

Initializing NSWindowControllers

- `initWithWindow:` (page 3434)
  Returns a window controller initialized with a given window.
- `initWithWindowNibName:` (page 3434)
  Returns a window controller initialized with a nib file.
- `initWithWindowNibName:owner:` (page 3435)
  Returns a window controller initialized with a nib file and a specified owner for that nib file.
- `initWithWindowNibPath:owner:` (page 3435)
  Returns a window controller initialized with a nib file at an absolute path and a specified owner.

Loading and Display the Window

- `loadWindow` (page 3436)
  Loads the receiver's window from the nib file.
- `showWindow:` (page 3441)
  Displays the window associated with the receiver.
- `isWindowLoaded` (page 3436)
  Returns whether the nib file containing the receiver's window has been loaded.
- `window` (page 3441)
  Returns the window owned by the receiver.
- `setWindow:` (page 3439)
  Sets the window controller's window.
- `windowDidLoad` (page 3442)
  Sent after the window owned by the receiver has been loaded.
- `windowWillLoad` (page 3444)
  Sent before the window owned by the receiver is loaded.

Setting and Getting the Document

- `setDocument:` (page 3437)
  Sets the document associated with the window managed by the receiver.
- `document` (page 3433)
  Returns the document associated with the receiver.
- `setDocumentEdited:` (page 3437)
  Sets the document edited flag for the window controller.

Closing the Window

- `close` (page 3432)
  Closes the window if it was loaded.
- `shouldCloseDocument` (page 3440)
  Returns whether the receiver necessarily closes the associated document when the window it manages is closed.
- `setShouldCloseDocument:` (page 3438)
  Sets whether the receiver should necessarily close the associated document when the window it manages is closed.

Getting Nib File Information

- `owner` (page 3437)
  Returns the owner of the nib file containing the window managed by the receiver.
- `windowNibName` (page 3443)
  Returns the name of the nib file that stores the window associated with the receiver.
- `windowNibPath` (page 3444)
  Returns the full path of the nib file that stores the window associated with the receiver.

Setting and Getting Window Attributes

- `setShouldCascadeWindows:` (page 3438)
  Sets whether the window should cascade in relation to other document windows.
- `shouldCascadeWindows` (page 3440)
  Returns whether the window will cascade in relation to other document windows when it is displayed.
- `setWindowFrameAutosaveName:` (page 3439)
  Sets the name under which the window's frame is saved in the defaults database.
- `windowFrameAutosaveName` (page 3443)
  Returns the name under which the frame rectangle of the window owned by the receiver is stored in the defaults database.
- `synchronizeWindowTitleWithDocumentName` (page 3441)
  Synchronizes the displayed window title and the represented filename with the information in the associated document.
- `windowTitleForDocumentDisplayName:` (page 3444)
  Returns the window title to be used for a given document display name.

Instance Methods

close

Closes the window if it was loaded.

```
- (void)close
```

Discussion
Because this method closes the window without asking the user for confirmation, you usually do not invoke it when the Close menu command is chosen. Instead invoke NSWindow's `performClose:` (page 3354) on the receiver's window. See "Window Closing Behavior" for an overview of deallocation behavior when a window is closed.

Availability
Available in Mac OS X v10.0 and later.

- `shouldCloseDocument` (page 3440)
- `setShouldCloseDocument:` (page 3438)

Related Sample Code
FunHouse
GLUT
QTCompressionOptionsWindow
UIElementInspector

Declared In
`NSWindowController.h`

document

Returns the document associated with the receiver.

```
- (id)document
```

Return Value
The document associated with the receiver or `nil` if there is none.

Discussion
When a window controller is added to a document's list of window controllers, the document sets the window controller's document with `setDocument:`. The Application Kit uses this outlet to access the document for relevant next-responder messages.

Availability
Available in Mac OS X v10.0 and later.

Sketch-112

Declared In
`NSWindowController.h`

initWithWindow:

Returns a window controller initialized with a given window.

```
- (id)initWithWindow:(NSWindow *)window
```

Parameters

window

The window object to manage; can be `nil`.

Return Value

A newly initialized window controller.

Discussion

This method is the designated initializer for `NSWindowController`.

This initializer is useful when a window has been loaded but no window controller is assigned. The default initialization turns on cascading, sets the `shouldCloseDocument` (page 3440) flag to `NO`, and sets the window frame autosave name to an empty string. As a side effect, the created window controller is added as an observer of the `NSWindowWillCloseNotification` (page 3426)s posted by that window object (which is handled by a private method). If you make the window controller a delegate of the window, you can implement NSWindow's `windowShouldClose:` delegate method.

Availability

Available in Mac OS X v10.0 and later.

Related Sample Code

FunHouse

MyMediaPlayer

UIElementInspector

Declared In

`NSWindowController.h`

initWithWindowNibName:

Returns a window controller initialized with a nib file.

```
- (id)initWithWindowNibName:(NSString *)windowNibName
```

Parameters

windowNibName

The name of the nib file (minus the "`.nib`" extension) that archives the receiver's window; cannot be `nil`.

Discussion

Sets the owner of the nib file to the receiver. The default initialization turns on cascading, sets the `shouldCloseDocument` (page 3440) flag to `NO`, and sets the autosave name for the window's frame to an empty string.

Availability

Available in Mac OS X v10.0 and later.

UIElementInspector

Declared In
NSWindowController.h

initWithWindowNibName:owner:

Returns a window controller initialized with a nib file and a specified owner for that nib file.

```
- (id)initWithWindowNibName:(NSString *)windowNibName owner:(id)owner
```

Parameters

windowNibName
The name of the nib file (minus the ".nib" extension) that archives the receiver's window; cannot be nil.

owner
The nib file's owner; cannot be nil.

Discussion
The default initialization turns on cascading, sets the shouldCloseDocument (page 3440) flag to NO, and sets the autosave name for the window's frame to an empty string.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSWindowController.h

initWithWindowNibPath:owner:

Returns a window controller initialized with a nib file at an absolute path and a specified owner.

```
- (id)initWithWindowNibPath:(NSString *)windowNibPath owner:(id)owner
```

Parameters

windowNibPath
The full path to the nib file that archives the receiver's window; cannot be nil.

owner
The nib file's owner; cannot be nil.

Discussion
Use this method if your nib file is at a fixed location (which is not inside either the file's owner's class's bundle or in the application's main bundle). The default initialization turns on cascading, sets the shouldCloseDocument (page 3440) flag to NO, and sets the autosave name for the window's frame to an empty string.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSWindowController.h

isWindowLoaded

Returns whether the nib file containing the receiver's window has been loaded.

```
- (BOOL)isWindowLoaded
```

Return Value
YES if the nib file containing the receiver's window has been loaded, NO otherwise.

Availability
Available in Mac OS X v10.0 and later.

loadWindow

Loads the receiver's window from the nib file.

```
- (void)loadWindow
```

Discussion
You should never directly invoke this method. Instead, invoke window (page 3441) so the windowDidLoad (page 3442) and windowWillLoad (page 3444) methods are invoked. Subclasses can override this method if the way it finds and loads the window is not adequate. It uses NSBundle's bundleForClass: method to get the bundle, using the class of the nib file owner as argument. It then locates the nib file within the bundle and, if successful, loads it; if unsuccessful, it tries to find the nib file in the main bundle.

Availability
Available in Mac OS X v10.0 and later.

See Also
- isWindowLoaded (page 3436)

Declared In
NSWindowController.h

owner

Returns the owner of the nib file containing the window managed by the receiver.

```
- (id)owner
```

Return Value
The owner of the nib file containing the window managed by the receiver; usually `self`, but can be the receiver's document or some other object.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- windowNibName` (page 3443)

Related Sample Code
ImageKitDemo

Declared In
`NSWindowController.h`

setDocument:

Sets the document associated with the window managed by the receiver.

```
- (void)setDocument:(NSDocument *)document
```

Parameters
document
The new document.

Discussion
Documents automatically call this method when they add a window controller to their list of window controllers; you should not call it directly.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- document` (page 3433)

Declared In
`NSWindowController.h`

setDocumentEdited:

Sets the document edited flag for the window controller.

```
- (void)setDocumentEdited:(BOOL)flag
```

Parameters
flag
`YES` if the document has been edited since its last save, `NO` if it hasn't.

Discussion
The window controller uses this flag to control whether its associated window shows up as dirty. You should not call this method directly for window controllers with an associated document; the document calls this method on its window controllers as needed.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSWindowController.h

setShouldCascadeWindows:

Sets whether the window should cascade in relation to other document windows.

```
- (void)setShouldCascadeWindows:(BOOL)flag
```

Parameters

flag

YES if the window should cascade in relation to other document windows, NO otherwise.

Discussion
Cascading in relation to other document windows means having a slightly offset location so that the title bars of previously displayed windows are still visible.

The default is YES.

Availability
Available in Mac OS X v10.0 and later.

See Also
- shouldCascadeWindows (page 3440)

Related Sample Code
Sketch+Accessibility

Declared In
NSWindowController.h

setShouldCloseDocument:

Sets whether the receiver should necessarily close the associated document when the window it manages is closed.

```
- (void)setShouldCloseDocument:(BOOL)flag
```

Parameters

flag

YES if the receiver necessarily closes the associated document when the window it manages is closed, NO otherwise.

Discussion
If NO, the document is closed only when the last remaining window of the document is closed.

The default is NO.

Availability
Available in Mac OS X v10.0 and later.

See Also
- shouldCloseDocument (page 3440)

Related Sample Code
DemoMonkey

Declared In
NSWindowController.h

setWindow:

Sets the window controller's window.

```
- (void)setWindow:(NSWindow *)aWindow
```

Parameters

aWindow
The new window.

Discussion
This method releases the old window and any associated top-level objects in its nib file and assumes ownership of the new window. You should generally create a new window controller for a new window and release the old window controller instead of using this method.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSWindowController.h

setWindowFrameAutosaveName:

Sets the name under which the window's frame is saved in the defaults database.

```
- (void)setWindowFrameAutosaveName:(NSString *)name
```

Parameters

name
The name under which the window's frame is saved in the defaults database.

Discussion
By default, *name* is an empty string, causing no information to be stored in the defaults database.

Availability
Available in Mac OS X v10.0 and later.

See Also
- windowFrameAutosaveName (page 3443)
- setFrameAutosaveName: (page 3382) (NSWindow)

Related Sample Code
Sketch+Accessibility

Declared In
NSWindowController.h

shouldCascadeWindows

Returns whether the window will cascade in relation to other document windows when it is displayed.

```
- (BOOL)shouldCascadeWindows
```

Return Value
YES if the window will cascade in relation to other document windows, NO otherwise.

Discussion
The default is YES.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setShouldCascadeWindows: (page 3438)

Declared In
NSWindowController.h

shouldCloseDocument

Returns whether the receiver necessarily closes the associated document when the window it manages is closed.

```
- (BOOL)shouldCloseDocument
```

Return Value
YES if the receiver necessarily closes the associated document when the window it manages is closed, NO otherwise.

Discussion
If NO, the document is closed only when the last remaining window of the document is closed.

The default is NO.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setShouldCloseDocument: (page 3438)

Declared In
NSWindowController.h

showWindow:

Displays the window associated with the receiver.

```
- (IBAction)showWindow:(id)sender
```

Parameters

sender

The control sending the message; can be nil.

Discussion

If the window is an `NSPanel` object and has its `becomesKeyOnlyIfNeeded` (page 1860) flag set to `YES`, the window is displayed in front of all other windows but is not made key; otherwise it is displayed in front and is made key. This method is useful for menu actions.

Availability

Available in Mac OS X v10.0 and later.

See Also

`- makeKeyAndOrderFront:` (page 3345) (NSWindow)

`- orderFront:` (page 3351) (NSWindow)

BasicCocoaAnimations

FunHouse

QTAudioContextInsert

Sketch+Accessibility

Sketch-112

Declared In

`NSWindowController.h`

synchronizeWindowTitleWithDocumentName

Synchronizes the displayed window title and the represented filename with the information in the associated document.

```
- (void)synchronizeWindowTitleWithDocumentName
```

Discussion

Does nothing if the window controller has no associated document or loaded window. This method queries the window controller's document to get the document's display name and full filename path, then calls `windowTitleForDocumentDisplayName:` (page 3444) to get the display name to show in the window title.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSWindowController.h`

window

Returns the window owned by the receiver.

```
- (NSWindow *)window
```

Return Value
The window owned by the receiver or `nil` if there isn't one.

Discussion
If the window has not yet been loaded, this method attempts to load the window's nib file using `loadWindow` (page 3436). Before it loads the window, it invokes `windowWillLoad` (page 3444), and if the window controller has a document, it invokes the document's corresponding method `windowControllerWillLoadNib:` (page 991) (if implemented). After loading the window, this method invokes `windowDidLoad` (page 3442) and, if there is a document, the NSDocument method `windowControllerDidLoadNib:` (page 990) (if implemented).

Availability
Available in Mac OS X v10.0 and later.

See Also
- `windowControllerWillLoadNib:` (page 991) (NSDocument)

Sketch-112

Declared In
NSWindowController.h

windowFrameAutosaveName

Returns the name under which the frame rectangle of the window owned by the receiver is stored in the defaults database.

```
- (NSString *)windowFrameAutosaveName
```

Return Value
The name under which the frame rectangle of the window owned by the receiver is stored in the defaults database.

Availability
Available in Mac OS X v10.0 and later.

See Also
- setWindowFrameAutosaveName: (page 3439)

Declared In
NSWindowController.h

windowNibName

Returns the name of the nib file that stores the window associated with the receiver.

```
- (NSString *)windowNibName
```

Return Value
The name of the nib file that stores the window associated with the receiver.

Discussion
If initWithWindowNibPath:owner: (page 3435) was used to initialize the instance, windowNibName returns the last path component with the ".nib" extension stripped off. If initWithWindowNibName: (page 3434) or initWithWindowNibName:owner: (page 3435) was used, windowNibName returns the name without the ".nib" extension.

Availability
Available in Mac OS X v10.0 and later.

See Also
- owner (page 3437)

Related Sample Code
ObjectPath
QTCompressionOptionsWindow
SourceView

Declared In
NSWindowController.h

windowNibPath

Returns the full path of the nib file that stores the window associated with the receiver.

```
- (NSString *)windowNibPath
```

Return Value
The full path of the nib file that stores the window associated with the receiver; `nil` if it cannot be located.

Discussion
If `initWithWindowNibPath:owner:` (page 3435) was used to initialize the instance, the path is just returned. If `initWithWindowNibName:` (page 3434) or `initWithWindowNibName:owner:` (page 3435) was used, `windowNibPath` locates the nib in the file's owner's class' bundle or in the application's main bundle and returns the full path (or `nil` if it cannot be located). Subclasses can override this to augment the search behavior, but probably ought to call `super` first.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSWindowController.h`

windowTitleForDocumentDisplayName:

Returns the window title to be used for a given document display name.

```
- (NSString *)windowTitleForDocumentDisplayName:(NSString *)displayName
```

Parameters

displayName
The display name for the document. This is the last path component under which the document file is saved.

Discussion
The default implementation returns *displayName*. Subclasses can override this method to customize the window title. For example, a CAD application could append "-Top" or "-Side," depending on the view displayed by the window.

Availability
Available in Mac OS X v10.0 and later.

See Also
`synchronizeWindowTitleWithDocumentName` (page 3441)

Declared In
`NSWindowController.h`

windowWillLoad

Sent before the window owned by the receiver is loaded.

```
- (void)windowWillLoad
```

Discussion
The default implementation does nothing.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `loadWindow` (page 3436)
- `window` (page 3441)
- `windowDidLoad` (page 3442)

NSWorkspace Class Reference

Inherits from	NSObject
Conforms to	NSObject (NSObject)
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.0 and later.
Declared in	AppKit/NSWorkspace.h AppKit/NSRunningApplication.h
Companion guide	Workspace Services Programming Topics
Related sample code	AppList DesktopImage iChatStatusFromApplication Quartz Composer WWDC 2005 TextEdit SourceView

Overview

An `NSWorkspace` object responds to application requests to perform a variety of services:

- Opening, manipulating, and obtaining information about files and devices
- Tracking changes to the file system, devices, and the user database
- Getting and setting Finder information for files.
- Launching applications

There is one shared `NSWorkspace` object per application. You use the class method `sharedWorkspace` (page 3452) to access it. For example, the following statement uses an `NSWorkspace` object to request that a file be opened in the TextEdit application:

```
[[NSWorkspace sharedWorkspace] openFile:@"/Myfiles/README"
    withApplication:@"TextEdit"];
```

Tasks

Accessing the Shared NSWorkspace Instance

`+ sharedWorkspace` (page 3452)
Returns the shared `NSWorkspace` instance.

Accessing the NSWorkspace Notification Center

`- notificationCenter` (page 3469)
Returns the notification center for workspace notifications.

Opening Files

`- openFile:` (page 3469)
Opens the specified file specified using the default application associated with its type.

`- openFile:withApplication:` (page 3471)
Opens a file using the specified application.

`- openFile:fromImage:at:inView:` (page 3470)
Opens a file using the default application for its type and animates the action using a custom icon.

`- openFile:withApplication:andDeactivate:` (page 3471)
Opens the specified file and optionally deactivates the sending application.

`- openURL:` (page 3473)
Opens the location at the specified URL.

`- openTempFile:` (page 3472) Deprecated in Mac OS X v10.6
Opens the specified temporary file using the default application for its type.

Manipulating Applications

`- launchApplication:` (page 3463)
Launches the specified application.

`- launchApplication:showIcon:autolaunch:` (page 3463)
Launches the specified application using additional options.

`- launchApplicationAtURL:options:configuration:error:` (page 3464)
Launches the app at the specified URL.

`- hideOtherApplications` (page 3460)
Hides all applications other than the sender.

Manipulating Files

- `duplicateURLs:completionHandler:` (page 3455)
  Duplicates the specified URLS asynchronously in the same manner as the Finder..
- `recycleURLs:completionHandler:` (page 3475)
  Moves the specified URLs to the trash in the same manner a the Finder.
- `performFileOperation:source:destination:files:tag:` (page 3474)
  Performs a file operation on a set of files in a particular directory.
- `activateFileViewerSelectingURLs:` (page 3453)
  Activates the Finder, and opens one or more windows selecting the specified files.
- `selectFile:inFileViewerRootedAtPath:` (page 3477)
  Selects the file specified by *fullPath*.

Manipulating Uniform Type Identifier Information

- `typeOfFile:error:` (page 3480)
  Returns the uniform type identifier of the specified file, if it can be determined..
- `localizedDescriptionForType:` (page 3466)
  Returns the localized description for the specified Uniform Type Identifier
- `preferredFilenameExtensionForType:` (page 3475)
  Returns the preferred filename extension for the specified Uniform Type Identifier.
- `filenameExtension:isValidForType:` (page 3457)
  Returns whether the specified filename extension is appropriate for the Uniform Type Identifier.
- `type:conformsToType:` (page 3480)
  Returns a Boolean indicating that the first Uniform Type Identifier conforms to the second Uniform Type Identifier.
- `URLForApplicationWithBundleIdentifier:` (page 3482)
  Returns the URL for the application with the specified identifier.

Requesting Information

- `iconForFile:` (page 3460)
  Returns an image containing the icon for the specified file.
- `iconForFileType:` (page 3462)
  Returns an image containing the icon for files of the specified type.
- `iconForFiles:` (page 3461)
  Returns an image containing the icon for the specified files.
- `getInfoForFile:application:type:` (page 3460)
  Retrieves information about the specified file.
- `URLForApplicationToOpenURL:` (page 3482)
  Returns the URL to the default application that would be used to open the given URL.
- `fullPathForApplication:` (page 3458)
  Returns the full path for the specified application.

- `getFileSystemInfoForPath:isRemovable:isWritable:isUnmountable:description:type:` (page 3459)
  Describes the file system at *fullPath*.
- `isFilePackageAtPath:` (page 3462)
  Determines whether the specified path is a file package.
- `activeApplication` (page 3453)
  Returns a dictionary with information about the current active application.
- `launchedApplications` (page 3465)
  Returns an array of dictionaries, one entry for each running application.

Image Animation

- `slideImage:from:to:` (page 3479)
  Animates a sliding image from one point to another.

Requesting Additional Time Before Logout

- `extendPowerOffBy:` (page 3456)
  Requests the system wait for the specified amount of time before turning off the power or logging out the user.

Tracking Changes to the File System

- `noteFileSystemChanged:` (page 3468)
  Informs the `NSWorkspace` object that the file system changed at the specified path.
- `fileSystemChanged` (page 3458) Deprecated in Mac OS X v10.6
  Returns a Boolean value indicating whether a change to the file system has been registered with a `noteFileSystemChanged` (page 3468) message since the last `fileSystemChanged` (page 3458) message.
- `noteFileSystemChanged` (page 3468) Deprecated in Mac OS X v10.6
  Informs the `NSWorkspace` object that the file system has changed.

Updating Registered Services and File Types

- `findApplications` (page 3458) Deprecated in Mac OS X v10.6
  Examines all applications and updates the records of registered services and file types.

Tracking Changes to the Defaults Database

- `noteUserDefaultsChanged` (page 3468) Deprecated in Mac OS X v10.6
  Informs the `NSWorkspace` object that the defaults database has changed.

- `userDefaultsChanged` (page 3483) Deprecated in Mac OS X v10.6
  Returns a Boolean value indicating whether a change to the defaults database has been registered with a `noteUserDefaultsChanged` (page 3468) message since the last `userDefaultsChanged` (page 3483) message.

Tracking Status Changes for Applications and Devices

- `mountedRemovableMedia` (page 3466)
  Returns the full pathnames of all currently mounted removable disks.
- `mountedLocalVolumePaths` (page 3466)
  Returns the mount points of all local volumes, not just the removable ones returned by `mountedRemovableMedia` (page 3466).
- `runningApplications` (page 3476)
  Returns an array of `NSRunningApplication` representing the running applications.
- `checkForRemovableMedia` (page 3454) Deprecated in Mac OS X v10.6
  Polls the system's drives for any disks that have been inserted but not yet mounted.
- `mountNewRemovableMedia` (page 3467) Deprecated in Mac OS X v10.6
  Returns the full pathnames of any newly mounted disks.

Providing Custom Icons

- `setIcon:forFile:options:` (page 3478)
  Sets the icon for the file or directory at the specified path.

Unmounting a Device

- `unmountAndEjectDeviceAtPath:` (page 3481)
  Unmounts and ejects the device at the specified path.
- `unmountAndEjectDeviceAtURL:error:` (page 3481)
  Attempts to eject the volume mounted at the given path.

Working with Bundles

- `absolutePathForAppBundleWithIdentifier:` (page 3453)
  Returns the absolute file-system path of an application bundle.
- `launchAppWithBundleIdentifier:options:additionalEventParamDescriptor:launchIdentifier:` (page 3464)
  Launches the application corresponding to the specified *`bundleIdentifier`*.
- `openURLs:withAppBundleIdentifier:options:additionalEventParamDescriptor:launchIdentifiers:` (page 3473)
  Opens one or more files from an array of URLs.

Managing the Desktop Image

- `desktopImageURLForScreen:` (page 3455)
  Returns the URL for the desktop image for the given screen.
- `setDesktopImageURL:forScreen:options:error:` (page 3477)
  Sets the desktop image for the given screen to the image at the specified URL.
- `desktopImageOptionsForScreen:` (page 3454)
  Returns the desktop image options for the given screen.

Performing Finder Spotlight Searches

- `showSearchResultsForQueryString:` (page 3479)
  Displays a Spotlight search results window in Finder for the specified query string.

Finder File Labels

- `fileLabelColors` (page 3457)
  Returns the corresponding array of file label colors for the file labels.
- `fileLabels` (page 3457)
  Returns the array of file labels as strings.

Class Methods

sharedWorkspace

Returns the shared `NSWorkspace` instance.

```
+ (NSWorkspace *)sharedWorkspace
```

Return Value
The `NSWorkspace` object associated with the process.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
CocoaDVDPlayer
DesktopImage
iChatStatusFromApplication
Quartz Composer WWDC 2005 TextEdit
SourceView

Declared In
`NSWorkspace.h`

Instance Methods

absolutePathForAppBundleWithIdentifier:

Returns the absolute file-system path of an application bundle.

```
- (NSString *)absolutePathForAppBundleWithIdentifier:(NSString *)bundleIdentifier
```

Parameters

bundleIdentifier

The bundle identifier string. This value corresponds to the value in the `CFBundleIdentifier` key of the application's `Info.plist` file. For example, the bundle identifier of the TextEdit application is `com.apple.TextEdit`.

Return Value

The file system path to the application bundle identified by *bundleIdentifier*, or `nil` if the bundle cannot be found.

Availability

Available in Mac OS X v10.3 and later.

Related Sample Code

Quartz Composer WWDC 2005 TextEdit

Declared In

`NSWorkspace.h`

activateFileViewerSelectingURLs:

Activates the Finder, and opens one or more windows selecting the specified files.

```
- (void)activateFileViewerSelectingURLs:(NSArray *)fileURLs
```

Parameters

fileURLs

The files to select and display in the Finder.

Availability

Available in Mac OS X v10.6 and later.

Declared In

`NSWorkspace.h`

activeApplication

Returns a dictionary with information about the current active application.

```
- (NSDictionary *)activeApplication
```

Return Value

A dictionary with information about the application. The dictionary contains as many of the keys described in Table 172-1 (page 3483) as are available.

Special Considerations

It is strongly suggested that you use the `NSRunningApplication` classes' `currentApplication` (page 2275) or `active`methods to retrieve this information in applications targeted for Mac OS X v10.6 and later.

Availability

Available in Mac OS X v10.2 and later.

See Also

- `runningApplications` (page 3476)
- `launchedApplications` (page 3465)

Related Sample Code

iChatStatusFromApplication

Declared In

`NSWorkspace.h`

checkForRemovableMedia

Polls the system's drives for any disks that have been inserted but not yet mounted. (Deprecated in Mac OS X v10.6.)

```
- (void)checkForRemovableMedia
```

Discussion

This method doesn't wait until such disks are mounted; instead, it requests that the disk be mounted asynchronously and returns immediately. Currently has no effect.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.6.

See Also

- `mountNewRemovableMedia` (page 3467)
- `mountedRemovableMedia` (page 3466)

Declared In

`NSWorkspace.h`

desktopImageOptionsForScreen:

Returns the desktop image options for the given screen.

```
- (NSDictionary *)desktopImageOptionsForScreen:(NSScreen *)screen
```

Parameters

screen

The screen for which to get the desktop image options.

Return Value

A dictionary containing key-value pairs specified in "Desktop Image Dictionary Keys" (page 3487).

Availability
Available in Mac OS X v10.6 and later.

See Also
- `desktopImageURLForScreen:` (page 3455)
- `setDesktopImageURL:forScreen:options:error:` (page 3477)

Related Sample Code
DesktopImage

Declared In

Declared In
`NSWorkspace.h`

duplicateURLs:completionHandler:

Duplicates the specified URLS asynchronously in the same manner as the Finder..

```
- (void)duplicateURLs:(NSArray *)URLs completionHandler:(void (^)(NSDictionary
    *newURLs, NSError *error))handler
```

Parameters

URLs
The array of URLs to duplicate.

handler

The completion handler block object. If completionHandler is not `nil`, it will be called when the operation is complete, on the same dispatch queue that was used for the `duplicateURLs:completionHandler:` call. The completionHandler may be nil if you are not interested in the results.

The block takes two arguments:

newURLs

A dictionary parameter that maps the given URLs to their new URLs locations. Files that could not be duplicated will not be present in the dictionary.

error

If the operation succeeded for every file, the error parameter will be nil. If it failed for one or more files, the error parameter will describe the overall result of the operation in a manner suitable for presentation to the user.

Discussion
This methods may show a progress indicator, or other user interface elements, at AppKit's discretion.

In Mac OS X 10.6, this method require that the main run loop be run in a common mode.

Availability
Available in Mac OS X v10.6 and later.

See Also
`- recycleURLs:completionHandler:` (page 3475)

Declared In
`NSWorkspace.h`

extendPowerOffBy:

Requests the system wait for the specified amount of time before turning off the power or logging out the user.

```
- (NSInteger)extendPowerOffBy:(NSInteger)requested
```

Parameters

requested

The number of milliseconds to wait before turning off the power or logging off the user.

Return Value
The number of milliseconds granted by the system.

Discussion
Currently unimplemented.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSWorkspace.h`

fileLabelColors

Returns the corresponding array of file label colors for the file labels.

```
- (NSArray *)fileLabelColors
```

Return Value
An array of `NSColor` objects.

Discussion
This array has the same number of elements as `fileLabels` (page 3457), and the color at a given index corresponds to the label at the same index.

You can listen for notifications named `NSWorkspaceDidChangeFileLabelsNotification` (page 3495) to be notified when file labels change which may result in changes to the order of the `fileLabelColors`.

Availability
Available in Mac OS X v10.6 and later.

See Also
`- fileLabels` (page 3457)

Declared In
`NSWorkspace.h`

fileLabels

Returns the array of file labels as strings.

```
- (NSArray *)fileLabels
```

Return Value
An array of strings.

Discussion
You can listen for notifications named `NSWorkspaceDidChangeFileLabelsNotification` (page 3495) to be notified when file labels change.

Availability
Available in Mac OS X v10.6 and later.

See Also
`- fileLabelColors` (page 3457)

Declared In
`NSWorkspace.h`

filenameExtension:isValidForType:

Returns whether the specified filename extension is appropriate for the Uniform Type Identifier.

```
- (BOOL)filenameExtension:(NSString *)filenameExtension isValidForType:(NSString
    *)typeName
```

Parameters

filenameExtension

A string containing the filename extension.

typeName

A string containing the Uniform Type Identifier.

Return Value

YES if *fileNameExtension* is a valid extension for *typeName*, NO otherwise

Availability

Available in Mac OS X v10.5 and later.

Declared In

NSWorkspace.h

fileSystemChanged

Returns a Boolean value indicating whether a change to the file system has been registered with a noteFileSystemChanged (page 3468) message since the last fileSystemChanged (page 3458) message. (Deprecated in Mac OS X v10.6.)

```
- (BOOL)fileSystemChanged
```

Return Value

Currently, this method always returns NO.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.6.

Declared In

NSWorkspace.h

findApplications

Examines all applications and updates the records of registered services and file types. (Deprecated in Mac OS X v10.6.)

```
- (void)findApplications
```

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.6.

Declared In

NSWorkspace.h

fullPathForApplication:

Returns the full path for the specified application.

```
- (NSString *)fullPathForApplication:(NSString *)appName
```

Parameters

appName

The name of the application.

Return Value

The full path for the application, or `nil` if the specified application was not found.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSWorkspace.h`

getFileSystemInfoForPath:isRemovable:isWritable:isUnmountable:description:type:

Describes the file system at *fullPath*.

```
- (BOOL)getFileSystemInfoForPath:(NSString *)fullPath isRemovable:(BOOL
    *)removableFlag isWritable:(BOOL *)writableFlag isUnmountable:(BOOL
    *)unmountableFlag description:(NSString **)description type:(NSString
    **)fileSystemType
```

Parameters

fullPath

The path to the file-system mount point.

removableFlag

On input, a boolean variable; on return, this variable contains `YES` if the file system is on removable media.

writableFlag

On input, a boolean variable; on return, this variable contains `YES` if the file system writable.

unmountableFlag

On input, a boolean variable; on return, this variable contains `YES` if the file system is unmountable.

description

On input, a pointer to a string object variable; on return, if the method was successful, this variable contains a string object that describes the file system. You should not rely on this description for program logic but can use it in message strings. Values can include “hard,” “nfs,” and “foreign."

fileSystemType

On input, a pointer to a string object variable; on return, if the method was successful, this variable contains the file-system type. Values can include “HFS,” “UFS,” or other values.

Return Value

`YES` if the information was successfully returned, otherwise `NO`.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSWorkspace.h`

getInfoForFile:application:type:

Retrieves information about the specified file.

```
- (BOOL)getInfoForFile:(NSString *)fullPath application:(NSString **)appName
    type:(NSString **)type
```

Parameters

fullPath

The full path to the desired file.

appName

The application the system would use to open the file.

type

On input, a pointer to a string object variable; on return, if the method is successful, this variable contains a string object with the filename extension or encoded HFS file type of the file.

Return Value

`YES` if the information was retrieved successfully; otherwise, `NO` if the file could not be found or the application was not associated with the file.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `iconForFile:` (page 3460)
- `iconForFiles:` (page 3461)

Declared In

`NSWorkspace.h`

hideOtherApplications

Hides all applications other than the sender.

```
- (void)hideOtherApplications
```

Discussion

The user can hide all applications except the current one by Command-Option-clicking on an application's Dock icon.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSWorkspace.h`

iconForFile:

Returns an image containing the icon for the specified file.

```
- (NSImage *)iconForFile:(NSString *)fullPath
```

Parameters

fullPath

The full path to the file.

Return Value

The icon associated with the file.

Discussion

The returned image has an initial size of 32 pixels by 32 pixels.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `getInfoForFile:application:type:` (page 3460)
- `iconForFileType:` (page 3462)
- `iconForFiles:` (page 3461)

Spotlighter

Declared In

`NSWorkspace.h`

iconForFiles:

Returns an image containing the icon for the specified files.

```
- (NSImage *)iconForFiles:(NSArray *)fullPaths
```

Parameters

fullPaths

An array of `NSString` objects, each of which contains the full path to a file.

Return Value

The icon associated with the group of files.

Discussion

If *fullPaths* specifies one file, that file's icon is returned. If *fullPaths* specifies more than one file, an icon representing the multiple selection is returned.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `iconForFile:` (page 3460)
- `iconForFileType:` (page 3462)

Declared In

`NSWorkspace.h`

iconForFileType:

Returns an image containing the icon for files of the specified type.

```
- (NSImage *)iconForFileType:(NSString *)fileType
```

Parameters

fileType

The file type, which may be either a filename extension or an encoded HFS file type.

Return Value

The icon associated with files of the given type.

Discussion

The returned image has an initial size of 32 pixels by 32 pixels.

Availability

Available in Mac OS X v10.0 and later.

Declared In

NSWorkspace.h

isFilePackageAtPath:

Determines whether the specified path is a file package.

```
- (BOOL)isFilePackageAtPath:(NSString *)fullPath
```

Parameters

fullPath

The full path to examine.

Return Value

YES if the path identifies a file package; otherwise, NO if the path does not exist, is not a directory, or is not a file package.

Availability

Available in Mac OS X v10.0 and later.

Declared In

NSWorkspace.h

launchApplication:

Launches the specified application.

```
- (BOOL)launchApplication:(NSString *)appName
```

Parameters

appName

The name of the application to open.

Return Value

YES if the application was successfully launched or was already running; otherwise, NO.

Discussion

The *appName* parameter need not be specified with a full path and, in the case of an application wrapper, may be specified with or without the .app extension, as described in "Use of .app Extension".

Before this method begins, it posts an NSWorkspaceWillLaunchApplicationNotification (page 3491) to the NSWorkspace object's notification center. When the operation is complete, it posts an NSWorkspaceDidLaunchApplicationNotification (page 3491).

Availability

Available in Mac OS X v10.0 and later.

See Also

- launchApplication:showIcon:autolaunch: (page 3463)

Related Sample Code

QTAudioExtractionPanel

Declared In

NSWorkspace.h

launchApplication:showIcon:autolaunch:

Launches the specified application using additional options.

```
- (BOOL)launchApplication:(NSString *)appName showIcon:(BOOL)showIcon
    autolaunch:(BOOL)autolaunch
```

Parameters

appName

The name of the application to open.

showIcon

If NO, the application's icon is not placed on the screen. (The icon still exists, though.)

autolaunch

If YES, the autolaunch default is set as though the specified application were autolaunched at startup.

Return Value

YES if the application was successfully launched or was already running; otherwise, NO.

Discussion

This method is provided to enable daemon-like applications that lack a normal user interface. Its use is not generally encouraged.

Returns `YES` if the application is successfully launched or already running, and `NO` if it can't be launched.

Before this method begins, it posts an `NSWorkspaceWillLaunchApplicationNotification` (page 3491) to the `NSWorkspace` object's notification center. When the operation is complete, it posts an `NSWorkspaceDidLaunchApplicationNotification` (page 3491).

Availability
Available in Mac OS X v10.0 and later.

See Also
`- launchApplication:` (page 3463)

Declared In
`NSWorkspace.h`

launchApplicationAtURL:options:configuration:error:

Launches the app at the specified URL.

```
- (NSRunningApplication *)launchApplicationAtURL:(NSURL
    *)url options:(NSWorkspaceLaunchOptions)options configuration:(NSDictionary
    *)configuration error:(NSError **)error
```

Parameters

url

The application URL.

options

Options to use when launching the application. See "NSWorkspaceLaunchOptions" (page 3487) for possible values.

configuration

A dictionary containing the configuration options. Possible key-value pairs are described in "Workspace Launch Configuration Options" (page 3484)

error

Return Value

Discussion

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSWorkspace.h`

launchAppWithBundleIdentifier:options:additionalEventParamDescriptor:launchIdentifier:

Launches the application corresponding to the specified *bundleIdentifier*.

```
- (BOOL)launchAppWithBundleIdentifier:(NSString *)bundleIdentifier
    options:(NSWorkspaceLaunchOptions)options
    additionalEventParamDescriptor:(NSAppleEventDescriptor *)descriptor
    launchIdentifier:(NSNumber **)identifier
```

Parameters

bundleIdentifier

A bundle identifier string. This value corresponds to the value in the `CFBundleIdentifier` key of the application's `Info.plist` file. For example, the bundle identifier of the TextEdit application is `com.apple.TextEdit`.

options

Options to use when launching the application. Values for this parameter are described in "NSWorkspaceLaunchOptions" (page 3487).

descriptor

Additional options specified in an AppleEvent-style descriptor. For example, you could use this parameter to specify additional documents to open when the application is launched.

identifier

The *launchIdentifiers* are currently unused, and you should pass `NULL`.

Return Value

`YES` if the application was found and launched; otherwise, `NO`.

Availability

Available in Mac OS X v10.3 and later.

See Also

`- openURLs:withAppBundleIdentifier:options:additionalEventParamDescriptor:launchIdentifiers:` (page 3473)

Declared In

`NSWorkspace.h`

launchedApplications

Returns an array of dictionaries, one entry for each running application.

```
- (NSArray *)launchedApplications
```

Return Value

An array of `NSDictionary` objects. Each dictionary contains as many of the keys described in Table 172-1 (page 3483) as are available.

Special Considerations

It is strongly suggested that you use the `NSWorkspace runningApplications` (page 3476) method and the `NSRunningApplication` class to retrieve this information in applications targeted for Mac OS X v10.6 and later.

Availability

Available in Mac OS X v10.2 and later.

See Also

`- runningApplications` (page 3476)

`- activeApplication` (page 3453)

Declared In
NSWorkspace.h

localizedDescriptionForType:

Returns the localized description for the specified Uniform Type Identifier

```
- (NSString *)localizedDescriptionForType:(NSString *)typeName
```

Parameters

typeName
A string containing the Uniform Type Identifier.

Return Value
An NSString containing the localized description of *typeName*.

Discussion
The localized description is suitable for displaying to the user.

Availability
Available in Mac OS X v10.5 and later.

Related Sample Code
CocoaSlides

Declared In
NSWorkspace.h

mountedLocalVolumePaths

Returns the mount points of all local volumes, not just the removable ones returned by `mountedRemovableMedia` (page 3466).

```
- (NSArray *)mountedLocalVolumePaths
```

Return Value
An array of `NSString` objects, each of which contains the full pathname of the mount point for any local volumes.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
SourceView

Declared In
NSWorkspace.h

mountedRemovableMedia

Returns the full pathnames of all currently mounted removable disks.

```
- (NSArray *)mountedRemovableMedia
```

Return Value
An array of `NSString` objects, each of which contains the full pathname of a mounted removable disk.

Discussion
If the computer provides an interrupt or other notification when the user inserts a disk into a drive, the Finder will mount the disk immediately. However, if no notification is given, the Finder won't be aware that a disk needs to be mounted. On such systems, an application should invoke either `mountNewRemovableMedia` (page 3467) or `checkForRemovableMedia` (page 3454) before invoking `mountedRemovableMedia` (page 3466). Either of these methods cause the Finder to poll the drives to see if a disk is present. If a disk has been inserted but not yet mounted, these methods will cause the Finder to mount it.

The Disk button in an Open or Save panel invokes `mountedRemovableMedia` (page 3466) and `mountNewRemovableMedia` (page 3467) as part of its operation, so most applications won't need to invoke these methods directly.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `checkForRemovableMedia` (page 3454)
- `mountNewRemovableMedia` (page 3467)

Related Sample Code
CocoaDVDPlayer

Declared In
`NSWorkspace.h`

mountNewRemovableMedia

Returns the full pathnames of any newly mounted disks. (Deprecated in Mac OS X v10.6.)

```
- (NSArray *)mountNewRemovableMedia
```

Return Value
An array of NSString objects, each of which contains the full pathname to a newly mounted disk.

Discussion
This method polls the system's drives for any disks that have been inserted but not yet mounted and waits until the new disks have been mounted. This method posts an `NSWorkspaceDidMountNotification` (page 3494) to the `NSWorkspace` object's notification center when it is finished. Currently provides the same functionality as `mountedRemovableMedia` (page 3466).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.6.

See Also
- `checkForRemovableMedia` (page 3454)
- `mountedRemovableMedia` (page 3466)

Declared In
`NSWorkspace.h`

noteFileSystemChanged

Informs the `NSWorkspace` object that the file system has changed. (Deprecated in Mac OS X v10.6.)

```
- (void)noteFileSystemChanged
```

Discussion
The `NSWorkspace` object then gets the status of all the files and directories it is interested in and updates itself appropriately. This method is used by many objects that write or delete files.

The `NSDocument` and `NSSavePanel` objects use this method when saving a file. If you create a file directly, you should call `noteFileSystemChanged` (page 3468) so that the Finder can update the folder if it is open.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.6.

See Also
`- fileSystemChanged` (page 3458)

Declared In
`NSWorkspace.h`

noteFileSystemChanged:

Informs the `NSWorkspace` object that the file system changed at the specified path.

```
- (void)noteFileSystemChanged:(NSString *)path
```

Parameters
path
The full path that changed.

Discussion
The `NSWorkspace` object then gets the status of all the files and directories it is interested in and updates itself appropriately. This method is used by many objects that write or delete files.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- fileSystemChanged` (page 3458)

Related Sample Code
Quartz Composer WWDC 2005 TextEdit

Declared In
`NSWorkspace.h`

noteUserDefaultsChanged

Informs the `NSWorkspace` object that the defaults database has changed. (Deprecated in Mac OS X v10.6.)

```
- (void)noteUserDefaultsChanged
```

Discussion
The `NSWorkspace` object then reads all the defaults it is interested in and reconfigures itself appropriately. For example, this method is used by the Preferences application to notify the Finder whether the user prefers to see hidden files. Currently has no effect.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.6.

See Also
`- userDefaultsChanged` (page 3483)

Declared In
`NSWorkspace.h`

notificationCenter

Returns the notification center for workspace notifications.

```
- (NSNotificationCenter *)notificationCenter
```

Return Value
The notification center object.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
CocoaDVDPlayer
iChatStatusFromApplication

Declared In
`NSWorkspace.h`

openFile:

Opens the specified file specified using the default application associated with its type.

```
- (BOOL)openFile:(NSString *)fullPath
```

Parameters
fullPath
The full path to the file.

Return Value
`YES` if the file was successfully opened; otherwise, `NO`.

Discussion
The sending application is deactivated before the request is sent.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `- openFile:fromImage:at:inView:` (page 3470)
- `- openFile:withApplication:` (page 3471)

QTRecorder
Quartz Composer WWDC 2005 TextEdit
SourceView

Declared In
`NSWorkspace.h`

openFile:fromImage:at:inView:

Opens a file using the default application for its type and animates the action using a custom icon.

```
- (BOOL)openFile:(NSString *)fullPath fromImage:(NSImage *)anImage at:(NSPoint)point
    inView:(NSView *)aView
```

Parameters

fullPath
The full path to the file.

anImage
The icon for the file.

point
The point in `aView` at which to display the icon.

aView
The view in which to display the icon.

Return Value
`YES` if the file was successfully opened; otherwise, `NO`.

Discussion
The Finder provides an animation before opening the file to give the user feedback that the file is to be opened. To provide this animation, *anImage* should contain an icon for the file, and its image should be displayed at *point*, specified in the coordinates of *aView*. Currently provides the same functionality as `openFile:` (page 3469).

The sending application is deactivated before the request is sent.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `- openFile:` (page 3469)
- `- openFile:withApplication:` (page 3471)
- `- openFile:withApplication:andDeactivate:` (page 3471)

- openTempFile: (page 3472)

Declared In
NSWorkspace.h

openFile:withApplication:

Opens a file using the specified application.

```
- (BOOL)openFile:(NSString *)fullPath withApplication:(NSString *)appName
```

Parameters

fullPath
The full path to the file.

appName
The name of the application to use when opening the file.

Return Value
YES if the file was successfully opened; otherwise, NO.

Discussion
The *appName* parameter need not be specified with a full path and, in the case of an application wrapper, may be specified with or without the .app extension, as described in "Use of .app Extension". The sending application is deactivated before the request is sent.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSWorkspace.h

openFile:withApplication:andDeactivate:

Opens the specified file and optionally deactivates the sending application.

```
- (BOOL)openFile:(NSString *)fullPath withApplication:(NSString *)appName
    andDeactivate:(BOOL)flag
```

Parameters

fullPath
The full path to the file.

appName
The name of the application to use when opening the file.

flag
If YES, the sending application is deactivated before the request is sent, allowing the opening application to become the active application.

Return Value
YES if the file was successfully opened; otherwise, NO.

Discussion
The *appName* parameter need not be specified with a full path and, in the case of an application wrapper, may be specified with or without the .app extension, as described in "Use of .app Extension". If *appName* is nil, the default application for the file's type is used.

Availability
Available in Mac OS X v10.0 and later.

See Also
- openFile: (page 3469)
- openFile:withApplication: (page 3471)
application:openFile: (page 3566) (NSApplicationDelegate)

Related Sample Code

Declared In
NSWorkspace.h

openTempFile:

Opens the specified temporary file using the default application for its type. (Deprecated in Mac OS X v10.6.)

```
- (BOOL)openTempFile:(NSString *)fullPath
```

Parameters
fullPath
The full path to the temporary file.

Return Value
YES if the file was successfully opened; otherwise, NO.

Discussion
The sending application is deactivated before the request is sent. Using this method instead of one of the openFile:... methods lets the receiving application know that it should delete the file when it no longer needs it. Currently provides the same functionality as openFile: (page 3469).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.6.

See Also
- openFile: (page 3469)

Declared In
NSWorkspace.h

openURLs:withAppBundleIdentifier:options:additionalEventParamDescriptor:launchIdentifiers:

Opens one or more files from an array of URLs.

```
- (BOOL)openURLs:(NSArray *)urls withAppBundleIdentifier:(NSString *)bundleIdentifier
    options:(NSWorkspaceLaunchOptions)options
   additionalEventParamDescriptor:(NSAppleEventDescriptor *)descriptor
   launchIdentifiers:(NSArray **)identifiers
```

Parameters

urls

An array of NSURL objects, each one identifying a URL for the application to open.

bundleIdentifier

A bundle identifier string or nil to use the default system bindings. This value corresponds to the value in the CFBundleIdentifier key of the application's Info.plist file. For example, the bundle identifier of the TextEdit application is com.apple.TextEdit.

options

Options to use when launching the application. Values for this parameter are described in "NSWorkspaceLaunchOptions" (page 3487).

descriptor

Additional options specified in an AppleEvent-style descriptor. For example, you could use this parameter to specify additional documents to open when the application is launched.

identifiers

The *launchIdentifiers* are currently unused, and you should pass `NULL`.

Return Value
`YES` if the application was found and launched; otherwise, `NO`.

Availability
Available in Mac OS X v10.3 and later.

See Also
`- launchAppWithBundleIdentifier:options:additionalEventParamDescriptor:launchIdentifier:` (page 3464)

Related Sample Code
NewsReader

Declared In
`NSWorkspace.h`

performFileOperation:source:destination:files:tag:

Performs a file operation on a set of files in a particular directory.

```
- (BOOL)performFileOperation:(NSString *)operation source:(NSString *)source
    destination:(NSString *)destination files:(NSArray *)files tag:(NSInteger *)tag
```

Parameters

operation

The file operation to perform. The possible values for this parameter are described in "File Operations" (page 3485).

source

The full path to the directory containing the files on which to operate.

destination

The full path to the destination directory of the operation.

files

An array of `NSString` objects specifying the names of the files and directories to be manipulated. Each string must not contain any path information other than the name of the file or directory. In other words, all of the files and directories must be located in the source directory and not in one if its subdirectories.

tag

On input, a integer variable; on return, this variable contains a negative integer if the operation fails, 0 if the operation was performed synchronously and succeeded, or a positive integer if the operation was performed asynchronously. If the value is a positive integer, the value is a tag that identifies the requested file operation.

Return Value
`YES` if the operation succeeded; otherwise, `NO`.

Discussion
Some operations—such as moving, copying, and linking files—require a destination directory to be specified. If not, *`destination`* should be the empty string (`@""`). Before this method returns, it posts an `NSWorkspaceDidPerformFileOperationNotification` (page 3494) to the `NSWorkspace` object's notification center.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
Quartz Composer WWDC 2005 TextEdit

Declared In
`NSWorkspace.h`

preferredFilenameExtensionForType:

Returns the preferred filename extension for the specified Uniform Type Identifier.

```
- (NSString *)preferredFilenameExtensionForType:(NSString *)typeName
```

Parameters
`typeName`
A string containing the Uniform Type Identifier.

Return Value
The appropriate filename extension for typeName, or `nil` if no extension could be determined.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSWorkspace.h`

recycleURLs:completionHandler:

Moves the specified URLs to the trash in the same manner a the Finder.

```
- (void)recycleURLs:(NSArray *)URLs completionHandler:(void (^)(NSDictionary
    *newURLs, NSError *error))handler
```

Parameters
`URLs`
The array of URLs to move to the trash.

handler

The completion handler block object. If completionHandler is not `nil`, it will be called when the operation is complete, on the same dispatch queue that was used for the `recycleURLs:completionHandler:` call. The completionHandler may be nil if you are not interested in the results.

The block takes two arguments:

newURLs

A dictionary parameter that maps the given URLs to their new URLs locations in the trash. Files that could not be moved to the trash will not be present in the dictionary.

error

If the operation succeeded for every file, the error parameter will be nil. If it failed for one or more files, the error parameter will describe the overall result of the operation in a manner suitable for presentation to the user.

Discussion
This methods may show a progress indicator, or other user interface elements, at AppKit's discretion.

In Mac OS X 10.6, this method require that the main run loop be run in a common mode.

Availability
Available in Mac OS X v10.6 and later.

See Also
`- duplicateURLs:completionHandler:` (page 3455)

Declared In
`NSWorkspace.h`

runningApplications

Returns an array of `NSRunningApplication` representing the running applications.

```
- (NSArray *)runningApplications
```

Return Value
An array of `NSRunningApplication` instances.

Discussion
The order of the array is unspecified, but it is stable, meaning that the relative order of particular applications will not change across multiple calls to `runningApplications`. See *NSRunningApplication Class Reference* for more information on `NSRunningApplication`.

Similar to the `NSRunningApplication` class's properties, this property will only change when the main run loop is run in a common mode. Instead of polling, use key-value observing to be notified of changes to this array property.

This property is thread safe, in that it may be called from background threads and the result is returned atomically.

This property is observable using key-value observing.

Availability
Available in Mac OS X v10.6 and later.

Declared In
NSRunningApplication.h

selectFile:inFileViewerRootedAtPath:

Selects the file specified by *fullPath*.

```
- (BOOL)selectFile:(NSString *)fullPath inFileViewerRootedAtPath:(NSString
    *)rootFullPath
```

Parameters

fullPath
The full path of the file to select.

rootFullPath
If a path is specified, a new file viewer is opened. If you specify an empty string (@"") for this parameter, the file is selected in the main viewer.

Return Value
YES if the file was successfully selected; otherwise, NO.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
EnhancedAudioBurn

Declared In
NSWorkspace.h

setDesktopImageURL:forScreen:options:error:

Sets the desktop image for the given screen to the image at the specified URL.

```
- (BOOL)setDesktopImageURL:(NSURL *)url forScreen:(NSScreen *)screen
    options:(NSDictionary *)options error:(NSError **)error
```

Parameters

url
A file URL to the image. The URL must not be nil.

screen
The screen to set the desktop image on.

options
The options dictionary may contain any of the "Desktop Image Dictionary Keys" (page 3487) keys, which control how the image is scaled on the screen.

error
A error that is returned by-reference if setting the image fails.

Return Value
`YES` if the image was set as the desktop, otherwise `NO`. If `NO` is returned, the *`error`* parameter provides additional information.

Discussion
You should not present a user interface for picking the options. Instead, choose appropriate defaults and allow the user to adjust them in the System Preference Pane.

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSWorkspace.h`

setIcon:forFile:options:

Sets the icon for the file or directory at the specified path.

```
- (BOOL)setIcon:(NSImage *)image forFile:(NSString *)fullPath
    options:(NSWorkspaceIconCreationOptions)options
```

Parameters

`image`
The image to use as the icon for the file or directory.

`fullPath`
The full path of the file or directory.

`options`
The icon representations to generate from the image. You specify this value by combining the appropriate "Workspace icon creation options" (page 3490) constants, using the C bitwise `OR` operator. Specify `0` if you want to generate icons in all available icon representation formats.

Return Value
`YES` if the icon was set; otherwise, `NO`.

Discussion
The *`image`* can be an arbitrary image, with or without transparency. This image is automatically scaled (as needed) to generate the icon representations. The file or folder must exist and be writable by the user.

It is recommended that applications include the `NSExclude10_4ElementsIconCreationOption` option for compatibility with pre-Mac OS X v10.3 Finder. Icons that include the high resolution elements prevent custom icons from being displayed on earlier systems.

Availability
Available in Mac OS X v10.4 and later.

Declared In
NSWorkspace.h

showSearchResultsForQueryString:

Displays a Spotlight search results window in Finder for the specified query string.

```
- (BOOL)showSearchResultsForQueryString:(NSString *)queryString
```

Parameters

queryString
The string to search for.

Return Value
YES if the communication with Finder was successful, otherwise NO.

Discussion
Finder becomes the active application, if possible. The user can further refine the search via the Finder user interface.

Availability
Available in Mac OS X v10.6 and later.

Declared In
NSWorkspace.h

slideImage:from:to:

Animates a sliding image from one point to another. (Deprecated in Mac OS X v10.6.)

```
- (void)slideImage:(NSImage *)image from:(NSPoint)fromPoint to:(NSPoint)toPoint
```

Parameters

image
The image to animate.

fromPoint
The starting point, in screen coordinates.

toPoint
The ending point, in screen coordinates.

Discussion
Currently unimplemented.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.6.

Declared In
NSWorkspace.h

type:conformsToType:

Returns a Boolean indicating that the first Uniform Type Identifier conforms to the second Uniform Type Identifier.

```
- (BOOL)type:(NSString *)firstTypeName conformsToType:(NSString *)secondTypeName
```

Parameters

firstTypeName

A string containing the Uniform Type Identifier that should conform to *secondTypeName*.

secondTypeName

A string containing a Uniform Type Identifier.

Return Value

YES if *firstTypeName* conforms to the uniform type identifier hierarchy of *secondTypeName*, NO otherwise.

Discussion

Use this method instead of comparing Uniform Identifier Types for equality. See *Uniform Type Identifiers Overview* for information about Uniform Type Identifier conformance.

This method will always return YES if the two strings are equal. It is appropriate to use this method with other type names, including those declared in CFBundleTypeName Info.plist entries.

Availability

Available in Mac OS X v10.5 and later.

Declared In

NSWorkspace.h

typeOfFile:error:

Returns the uniform type identifier of the specified file, if it can be determined..

```
- (NSString *)typeOfFile:(NSString *)absoluteFilePath error:(NSError **)outError
```

Parameters

absoluteFilePath

The absolute path of the file.

outError

If the Uniform Type Identifier of the file at absolutePath can't be determined, *outError* contains an NSError object that describes why.

Return Value

An NSString containing the uniform type identifier of the file at absoluteFilePath. If no UTI can be determined the return value is nil.

Discussion

If the file at the specified path is a symbolic link, the type of the symbolic link is returned.

Availability

Available in Mac OS X v10.5 and later.

Related Sample Code

CocoaSlides

Quartz 2D Transformer

Declared In
NSWorkspace.h

unmountAndEjectDeviceAtPath:

Unmounts and ejects the device at the specified path.

```
- (BOOL)unmountAndEjectDeviceAtPath:(NSString *)path
```

Parameters

path
The path to the device.

Return Value
YES if the device was unmounted; otherwise, NO.

Discussion
When this method begins, it posts an NSWorkspaceWillUnmountNotification (page 3494) to the NSWorkspace object's notification center. When it is finished, it posts an NSWorkspaceDidUnmountNotification (page 3494).

The unmountAndEjectDeviceAtURL:error: (page 3481) is preferable as it will provide more detailed error information.

Availability
Available in Mac OS X v10.0 and later.

See Also
- unmountAndEjectDeviceAtURL:error: (page 3481)

Related Sample Code
CocoaDVDPlayer

Declared In
NSWorkspace.h

unmountAndEjectDeviceAtURL:error:

Attempts to eject the volume mounted at the given path.

```
- (BOOL)unmountAndEjectDeviceAtURL:(NSURL *)url error:(NSError **)error
```

Parameters

url
The URL of the volume to eject.

error
If the operation fails, this error contains more information about the failure.

Return Value
YES if the volume was unmounted and ejected successfully, otherwise NO, for example, if the volume is not ejectable.

Availability
Available in Mac OS X v10.6 and later.

See Also
`- unmountAndEjectDeviceAtPath:` (page 3481)

Declared In
`NSWorkspace.h`

URLForApplicationToOpenURL:

Returns the URL to the default application that would be used to open the given URL.

```
- (NSURL *)URLForApplicationToOpenURL:(NSURL *)url
```

Parameters

url
The URL of the file to open.

Return Value
The URL of the default application that would open the specified *url*. Returns nil if no application is able to open the url, or if the file url does not exist.

Discussion
This is the programmatic equivalent of double clicking a document in the Finder.

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSWorkspace.h`

URLForApplicationWithBundleIdentifier:

Returns the URL for the application with the specified identifier.

```
- (NSURL *)URLForApplicationWithBundleIdentifier:(NSString *)bundleIdentifier
```

Parameters

bundleIdentifier
A bundle identifier specifying an application.

Return Value
The URL of the application, or `nil` if no application has the bundle identifier.

Discussion
This uses various (currently unspecified) heuristics in case multiple apps have the same bundle ID.

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSWorkspace.h`

userDefaultsChanged

Returns a Boolean value indicating whether a change to the defaults database has been registered with a `noteUserDefaultsChanged` (page 3468) message since the last `userDefaultsChanged` (page 3483) message. (Deprecated in Mac OS X v10.6.)

```
- (BOOL)userDefaultsChanged
```

Return Value
Currently, this method always returns `NO`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.6.

Declared In
`NSWorkspace.h`

Constants

The following table describes keys for an `NSDictionary` object containing information about an application. This dictionary is returned by `activeApplication` (page 3453) and `launchedApplications` (page 3465), and is also provided in the *`userInfo`* of `NSWorkspace` notifications for application launch and termination.

Note that these constants are considered legacy.

Note: It is strongly suggested that you use the `NSWorkspace`class's `runningApplications` (page 3476) method and the `NSRunningApplication` class to retrieve this information in applications targeted to Mac OS X v10.6 and later, rather than the `activeApplication` (page 3453) and `launchedApplications` (page 3465) methods.

Table 172-1 `userInfo` dictionary keys for `activeApplication` and `launchedApplications` and notifications for application launch and termination.

Key	Value
`@"NSApplicationPath"`	The full path to the application, as a `NSString` object.
`@"NSApplicationName"`	The application's name, as an `NSString` object.
`@"NSApplicationBundleIdentifier"`	The application's bundle identifier, as an `NSString` object.
`@"NSApplicationProcessIdentifier"`	The application's process id, as an `NSNumber` object.
`@"NSApplicationProcessSerialNumberHigh"`	The high long of the process serial number (PSN), as an `NSNumber` object.
`@"NSApplicationProcessSerialNumberLow"`	The low long of the process serial number (PSN), as an `NSNumber` object.

File Types

These constants specify different types of files returned by the `getInfoForFile:application:type:` (page 3460) method.

```
NSString *NSPlainFileType;
NSString *NSDirectoryFileType;
NSString *NSApplicationFileType;
NSString *NSFilesystemFileType;
NSString *NSShellCommandFileType;
```

Constants

`NSPlainFileType`
Plain (untyped) file
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.6.
Declared in `NSWorkspace.h`.

`NSDirectoryFileType`
Directory
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.6.
Declared in `NSWorkspace.h`.

`NSApplicationFileType`
Cocoa application
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.6.
Declared in `NSWorkspace.h`.

`NSFilesystemFileType`
File-system mount point
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.6.
Declared in `NSWorkspace.h`.

`NSShellCommandFileType`
Executable shell command
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.6.
Declared in `NSWorkspace.h`.

Declared In
`NSWorkspace.h`

Workspace Launch Configuration Options

The following keys can be used in the configuration dictionary of the `launchApplicationAtURL:options:configuration:error:` (page 3464) method. Each key is optional, and if omitted, default behavior is applied.

```
NSString * const NSWorkspaceLaunchConfigurationAppleEvent;
NSString * const NSWorkspaceLaunchConfigurationArguments;
NSString * const NSWorkspaceLaunchConfigurationEnvironment;
NSString * const NSWorkspaceLaunchConfigurationArchitecture;
```

Constants

`NSWorkspaceLaunchConfigurationAppleEvent`

The value is the first `NSAppleEventDescriptor` to send to the new application. If an instance of the application is already running, this is sent to that application.

Available in Mac OS X v10.6 and later.

Declared in `NSWorkspace.h`.

`NSWorkspaceLaunchConfigurationArguments`

The value is an `NSArray` of `NSStrings`, passed to the new application in the `argv` parameter. Ignored if a new instance of the application is not launched.

Available in Mac OS X v10.6 and later.

Declared in `NSWorkspace.h`.

`NSWorkspaceLaunchConfigurationEnvironment`

The value is an `NSDictionary`, mapping `NSStrings` to `NSStrings`, containing environment variables to set for the new app. Ignored if a new instance of the application is not launched.

Available in Mac OS X v10.6 and later.

Declared in `NSWorkspace.h`.

`NSWorkspaceLaunchConfigurationArchitecture`

The value is an NSNumber containing an `Mach-O Architecture` constant. Ignored if a new instance of the application is not launched.

Available in Mac OS X v10.6 and later.

Declared in `NSWorkspace.h`.

File Operations

These constants specify different types of file operations used by `performFileOperation:source:destination:files:tag:` (page 3474).

```
NSString *NSWorkspaceMoveOperation;
NSString *NSWorkspaceCopyOperation;
NSString *NSWorkspaceLinkOperation;
NSString *NSWorkspaceCompressOperation;
NSString *NSWorkspaceDecompressOperation;
NSString *NSWorkspaceEncryptOperation;
NSString *NSWorkspaceDecryptOperation;
NSString *NSWorkspaceDestroyOperation;
NSString *NSWorkspaceRecycleOperation;
NSString *NSWorkspaceDuplicateOperation;
```

Constants

`NSWorkspaceMoveOperation`

Move file to destination. Behaves the same as `movePath:toPath:handler:`.

Available in Mac OS X v10.0 and later.

Declared in `NSWorkspace.h`.

`NSWorkspaceCopyOperation`
Copy file to destination. Behaves the same as `copyPath:toPath:handler:`.

Available in Mac OS X v10.0 and later.

Declared in `NSWorkspace.h`.

`NSWorkspaceLinkOperation`
Create hard link to file in destination. Behaves the same as `linkPath:toPath:handler:`.

Available in Mac OS X v10.0 and later.

Declared in `NSWorkspace.h`.

`NSWorkspaceCompressOperation`
Compress file. This operation always returns an error.

Available in Mac OS X v10.0 and later.

Declared in `NSWorkspace.h`.

`NSWorkspaceDecompressOperation`
Decompress file. This operation always returns an error.

Available in Mac OS X v10.0 and later.

Declared in `NSWorkspace.h`.

`NSWorkspaceEncryptOperation`
Encrypt file. This operation always returns an error.

Available in Mac OS X v10.0 and later.

Declared in `NSWorkspace.h`.

`NSWorkspaceDecryptOperation`
Decrypt file. This operation always returns an error.

Available in Mac OS X v10.0 and later.

Declared in `NSWorkspace.h`.

`NSWorkspaceDestroyOperation`
Destroy file. Behaves the same as `removeFileAtPath:handler:`.

Available in Mac OS X v10.0 and later.

Declared in `NSWorkspace.h`.

`NSWorkspaceRecycleOperation`
Move file to trash. The file is moved to the trash folder on the volume containing the file using the same semantics as `NSWorkspaceMoveOperation`. If a file with the same name currently exists in the trash folder, the new file is renamed. If no trash folder exists on the volume containing the file, the operation fails.

Available in Mac OS X v10.0 and later.

Declared in `NSWorkspace.h`.

`NSWorkspaceDuplicateOperation`
Duplicate file in source directory.

Available in Mac OS X v10.0 and later.

Declared in `NSWorkspace.h`.

Declared In
`NSWorkspace.h`

Desktop Image Dictionary Keys

The following keys may be specified or returned in the options dictionary for `setDesktopImageURL:forScreen:options:error:` (page 3477).

```
NSString * const NSWorkspaceDesktopImageScalingKey;
NSString * const NSWorkspaceDesktopImageAllowClippingKey;
NSString * const NSWorkspaceDesktopImageFillColorKey;
```

Constants

`NSWorkspaceDesktopImageScalingKey`

The value is an `NSNumber` containing an `NSImageScaling` (page 617) constant as declared in `NSCell`. If this is not specified, `NSImageScaleProportionallyUpOrDown` (page 617) is used. `NSImageScaleProportionallyDown` (page 617) is not currently supported.

Available in Mac OS X v10.6 and later.

Declared in `NSWorkspace.h`.

`NSWorkspaceDesktopImageAllowClippingKey`

The value is an `NSNumber` containing a `BOOL`, which affects the interpretation of Proportional scaling types. A `NO` value will make the image fully visible, but there may be empty space on the sides or top and bottom. A `YES` value will cause the image to fill the entire screen, but the image may be clipped. If this is not specified, `NO` is assumed. Non-proportional scaling types ignore this value.

Available in Mac OS X v10.6 and later.

Declared in `NSWorkspace.h`.

`NSWorkspaceDesktopImageFillColorKey`

The value is an `NSColor`, which is used to fill any empty space around the image. If not specified, a default value is used. Currently, only colors that use or can be converted to use `NSCalibratedRGBColorSpace` are supported, and any alpha value is ignored.

Available in Mac OS X v10.6 and later.

Declared in `NSWorkspace.h`.

NSWorkspaceLaunchOptions

These constants define launch options you can pass to `launchAppWithBundleIdentifier:options:additionalEventParamDescriptor:launchIdentifier:` (page 3464) and `openURLs:withAppBundleIdentifier:options:additionalEventParamDescriptor:launchIdentifiers:` (page 3473).

```
enum {
     NSWorkspaceLaunchAndPrint = 0x00000002,
     NSWorkspaceLaunchInhibitingBackgroundOnly = 0x00000080,
     NSWorkspaceLaunchWithoutAddingToRecents = 0x00000100,
     NSWorkspaceLaunchWithoutActivation = 0x00000200,
     NSWorkspaceLaunchAsync = 0x00010000,
     NSWorkspaceLaunchAllowingClassicStartup = 0x00020000,
     NSWorkspaceLaunchPreferringClassic = 0x00040000,
     NSWorkspaceLaunchNewInstance = 0x00080000,
     NSWorkspaceLaunchAndHide = 0x00100000,
     NSWorkspaceLaunchAndHideOthers = 0x00200000,
     NSWorkspaceLaunchDefault = NSWorkspaceLaunchAsync |
NSWorkspaceLaunchAllowingClassicStartup
};
typedef NSUInteger NSWorkspaceLaunchOptions;
```

Constants

`NSWorkspaceLaunchAndPrint`
Print items instead of opening them.
Available in Mac OS X v10.3 and later.
Declared in `NSWorkspace.h`.

`NSWorkspaceLaunchInhibitingBackgroundOnly`
Causes launch to fail if the target is background-only.
Available in Mac OS X v10.3 and later.
Declared in `NSWorkspace.h`.

`NSWorkspaceLaunchWithoutAddingToRecents`
Do not add the application or documents to the Recents menu.
Available in Mac OS X v10.3 and later.
Declared in `NSWorkspace.h`.

`NSWorkspaceLaunchWithoutActivation`
Launch the application but do not bring it into the foreground.
Available in Mac OS X v10.3 and later.
Declared in `NSWorkspace.h`.

`NSWorkspaceLaunchAsync`
Launch the application and return the results asynchronously.
Available in Mac OS X v10.3 and later.
Declared in `NSWorkspace.h`.

`NSWorkspaceLaunchAllowingClassicStartup`
Start up the Classic compatibility environment, if it is required by the application.
Available in Mac OS X v10.3 and later.
Declared in `NSWorkspace.h`.

`NSWorkspaceLaunchPreferringClassic`
Force the application to launch in the Classic compatibility environment.
Available in Mac OS X v10.3 and later.
Declared in `NSWorkspace.h`.

`NSWorkspaceLaunchNewInstance`
Create a new instance of the application, even if one is already running.

Available in Mac OS X v10.3 and later.

Declared in `NSWorkspace.h`.

`NSWorkspaceLaunchAndHide`
Tell the application to hide itself as soon as it has finished launching.

Available in Mac OS X v10.3 and later.

Declared in `NSWorkspace.h`.

`NSWorkspaceLaunchAndHideOthers`
Hide all applications except the newly launched one.

Available in Mac OS X v10.3 and later.

Declared in `NSWorkspace.h`.

`NSWorkspaceLaunchDefault`
Launch the application asynchronously and launch it in the Classic environment, if required.

Available in Mac OS X v10.3 and later.

Declared in `NSWorkspace.h`.

Volume Mounting Notification User Info Keys

The following keys are available in the `userInfo` parameter of the notification named `NSWorkspaceDidRenameVolumeNotification` (page 3493).

```
NSString * const NSWorkspaceVolumeLocalizedNameKey;
NSString * const NSWorkspaceVolumeURLKey;
```

Constants

`NSWorkspaceVolumeLocalizedNameKey`
NSString containing the user-visible name of the volume.

Available in Mac OS X v10.6 and later.

Declared in `NSWorkspace.h`.

`NSWorkspaceVolumeURLKey`
`NSURL` containing the mount path of the volume.

Available in Mac OS X v10.6 and later.

Declared in `NSWorkspace.h`.

NSWorkspaceDidRenameVolumeNotification User Info Keys

The following keys are available in the `userInfo` parameter of the notification named `NSWorkspaceDidRenameVolumeNotification` (page 3493).

```
NSString * const NSWorkspaceVolumeOldLocalizedNameKey;
NSString * const NSWorkspaceVolumeOldURLKey;
```

Constants

`NSWorkspaceVolumeOldLocalizedNameKey`
`NSString` containing the old user-visible name of the volume

Available in Mac OS X v10.6 and later.

Declared in `NSWorkspace.h`.

`NSWorkspaceVolumeOldURLKey`
`NSURL` containing the old mount path of the volume

Available in Mac OS X v10.6 and later.

Declared in `NSWorkspace.h`.

NSWorkspaceApplicationKey User Info Key

This constant is supplied in the userInfo dictionary of various notifications.

```
NSString * const NSWorkspaceApplicationKey;
```

Constants

`NSWorkspaceApplicationKey`
The value corresponding to this key is an instance of `NSRunningApplication` that reflects the affected application.

Available in Mac OS X v10.6 and later.

Declared in `NSWorkspace.h`.

Workspace icon creation options

These constants describe the `NSWorkspaceIconCreationOptions` values used by `setIcon:forFile:options:` (page 3478). You can combine these using the C bitwise OR operator.

```
enum {
    NSExcludeQuickDrawElementsIconCreationOption    = 1 << 1,
    NSExclude10_4ElementsIconCreationOption        = 1 << 2
};
typedef NSUInteger NSWorkspaceIconCreationOptions;
```

Constants

`NSExcludeQuickDrawElementsIconCreationOption`
Suppress generation of the QuickDraw format icon representations that are used in Mac OS X v10.0 through Mac OS X v10.4.

Available in Mac OS X v10.4 and later.

Declared in `NSWorkspace.h`.

`NSExclude10_4ElementsIconCreationOption`
Suppress generation of the new higher resolution icon representations that are supported in Mac OS X v10.4.

Available in Mac OS X v10.4 and later.

Declared in `NSWorkspace.h`.

Notifications

All `NSWorkspace` notifications are posted to the `NSWorkspace` object's own notification center, not the application's default notification center. Access this center using the `NSWorkspace` object's `notificationCenter` (page 3469) method.

NSWorkspaceWillLaunchApplicationNotification

Posted when the Finder is about to launch an application.

The notification object is the shared `NSWorkspace` instance. In Mac OS X v10.6 and later the *`userInfo`* dictionary contains the `NSWorkspaceApplicationKey` (page 3490) key with a corresponding instance of `NSRunningApplication` that represents the affected application.

In Mac OS X v10.5 and earlier the *`userInfo`* dictionary contains the keys and values described in Table 172-1 (page 3483).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSWorkspace.h`

NSWorkspaceDidLaunchApplicationNotification

Posted when a new application has started up.

The notification object is the shared `NSWorkspace` instance. In Mac OS X v10.6 and later the *`userInfo`* dictionary contains the `NSWorkspaceApplicationKey` (page 3490) key with a corresponding instance of `NSRunningApplication` that represents the affected application.

In Mac OS X v10.5 and earlier the *`userInfo`* dictionary contains the keys and values described in Table 172-1 (page 3483).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSWorkspace.h`

NSWorkspaceDidTerminateApplicationNotification

Posted when an application finishes executing.

The notification object is the shared `NSWorkspace` instance. In Mac OS X v10.6 and later the *`userInfo`* dictionary contains the `NSWorkspaceApplicationKey` (page 3490) key with a corresponding instance of `NSRunningApplication` that represents the affected application.

In Mac OS X v10.5 and earlier the *`userInfo`* dictionary contains the keys and values described in Table 172-1 (page 3483).

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSWorkspace.h

NSWorkspaceSessionDidBecomeActiveNotification

Posted after a user session is switched in. This allows an application to re-enable some processing when a switched out session gets switched back in, for example.

The notification object is the shared NSWorkspace instance. The notification does not contain a *userInfo* dictionary.

Availability
Available in Mac OS X v10.3 and later.

Declared In
NSWorkspace.h

NSWorkspaceSessionDidResignActiveNotification

Posted before a user session is switched out. This allows an application to disable some processing when its user session is switched out, and re-enable when that session gets switched back in, for example.

The notification object is the shared NSWorkspace instance. The notification does not contain a *userInfo* dictionary.

If an application is launched in an inactive session, NSWorkspaceSessionDidResignActiveNotification is sent after NSApplicationWillFinishLaunchingNotification (page 195) and before sending NSApplicationDidFinishLaunchingNotification (page 194).

Availability
Available in Mac OS X v10.3 and later.

Declared In
NSWorkspace.h

NSWorkspaceDidHideApplicationNotification

Posted when the Finder hid an application.

The notification object is the shared NSWorkspace instance. In Mac OS X v10.6 and later the *userInfo* dictionary contains the NSWorkspaceApplicationKey (page 3490) key with a corresponding instance of NSRunningApplication that represents the affected application.

Availability
Available in Mac OS X v10.6 and later.

Declared In
NSWorkspace.h

NSWorkspaceDidUnhideApplicationNotification

Posted when the Finder unhid an application.

The notification object is the shared `NSWorkspace` instance. In Mac OS X v10.6 and later the *`userInfo`* dictionary contains the `NSWorkspaceApplicationKey` (page 3490) key with a corresponding instance of `NSRunningApplication` that represents the affected application.

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSWorkspace.h`

NSWorkspaceDidActivateApplicationNotification

Posted when the Finder is about to activate an application.

The notification object is the shared `NSWorkspace` instance. In Mac OS X v10.6 and later the *`userInfo`* dictionary contains the `NSWorkspaceApplicationKey` (page 3490) key with a corresponding instance of `NSRunningApplication` that represents the affected application.

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSWorkspace.h`

NSWorkspaceDidDeactivateApplicationNotification

Posted when the Finder deactivated an application.

The notification object is the shared `NSWorkspace` instance. In Mac OS X v10.6 and later the *`userInfo`* dictionary contains the `NSWorkspaceApplicationKey` (page 3490) key with a corresponding instance of `NSRunningApplication` that represents the affected application.

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSWorkspace.h`

NSWorkspaceDidRenameVolumeNotification

Posted when a volume changes its name and/or mount path. These typically change simultaneously, in which case only one notification is posted.

The notification object is the shared `NSWorkspace` instance. The `userInfo` dictionary contains keys in "NSWorkspaceDidRenameVolumeNotification User Info Keys" (page 3489) and "Volume Mounting Notification User Info Keys" (page 3489).

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSWorkspace.h`

NSWorkspaceDidMountNotification

Posted when a new device has been mounted.

The notification object is the shared `NSWorkspace` instance.

In Mac OS X v10.5 and earlier the *`userInfo`* dictionary contains a key `@"NSDevicePath"` that returns the path where the device was mounted, as a string.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSWorkspace.h`

NSWorkspaceWillUnmountNotification

Posted when the Finder is about to unmount a device.

This notification will not be delivered if a volume was forcibly and immediately made unavailable, such as when a FireWire drive is simply unplugged, because there is no chance to deliver it before the volume becomes unavailable.

The notification object is the shared `NSWorkspace` instance. The *`userInfo`* dictionary contains a key `@"NSDevicePath"` that returns the path where the device was mounted, as a string.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSWorkspace.h`

NSWorkspaceDidUnmountNotification

Posted when the Finder did unmount a device.

This notification is delivered even if a volume was forcibly and immediately made unavailable, such as when a drive is simply unplugged.

The notification object is the shared `NSWorkspace` instance. The *`userInfo`* dictionary contains a key `@"NSDevicePath"` that returns the path where the device was mounted, as a string.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSWorkspace.h`

NSWorkspaceDidPerformFileOperationNotification

Posted when a file operation has been performed in the receiving application.

The notification object is the shared `NSWorkspace` instance. The *`userInfo`* dictionary contains a key `@"NSOperationNumber"` with a `NSNumber` object containing an integer indicating the type of file operation

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSWorkspace.h`

NSWorkspaceDidChangeFileLabelsNotification

Posted when the Finder file labels or colors change.

The notification object is the shared `NSWorkspace` instance. The notification does not contain a *`userInfo`* dictionary.

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSWorkspace.h`

NSWorkspaceActiveSpaceDidChangeNotification

Posted when a Spaces change has occurred.

The notification object is the shared `NSWorkspace` instance. The notification does not contain a *`userInfo`* dictionary.

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSWorkspace.h`

NSWorkspaceDidWakeNotification

Posted when the machine wakes from sleep.

The notification object is the shared `NSWorkspace` instance. The notification does not contain a *`userInfo`* dictionary.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`NSWorkspace.h`

NSWorkspaceWillPowerOffNotification

Posted when the user has requested a logout or that the machine be powered off.

The notification object is the shared `NSWorkspace` instance. This notification does not contain a *`userInfo`* dictionary.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSWorkspace.h

NSWorkspaceWillSleepNotification

Posted before the machine goes to sleep. An observer of this message can delay sleep for up to 30 seconds while handling this notification.

The notification object is the shared `NSWorkspace` instance. The notification does not contain a *`userInfo`* dictionary.

Availability
Available in Mac OS X v10.3 and later.

Declared In
NSWorkspace.h

NSWorkspaceScreensDidSleepNotification

Posted when the machine's screen goes to sleep.

The notification object is the shared `NSWorkspace` instance. The notification does not contain a *`userInfo`* dictionary.

Few applications are likely to be interested in this notification, but they may be useful for certain hardware-based drawing decisions, for example when using OpenGL.

Availability
Available in Mac OS X v10.6 and later.

Declared In
NSWorkspace.h

NSWorkspaceScreensDidWakeNotification

Posted when the machine's screens wake.

The notification object is the shared `NSWorkspace` instance. The notification does not contain a *`userInfo`* dictionary.

Few applications are likely to be interested in this notification, but they may be useful for certain hardware-based drawing decisions, for example when using OpenGL.

Availability
Available in Mac OS X v10.6 and later.

Declared In
NSWorkspace.h

Protocols

NSAccessibility Protocol Reference

(informal protocol)

Adopted by	NSObject
Framework	/System/Library/Frameworks/AppKit.framework
Declared in	AppKit/NSAccessibility.h AppKit/NSErrors.h
Companion guide	Accessibility Programming Guidelines for Cocoa

Overview

The `NSAccessibility` informal protocol defines methods that Cocoa classes must implement to make themselves available to an external assistive application. An assistive application interacts with your application to allow persons with disabilities to use your application. For example, a person with a visual impairment could use an application to convert menu items and button labels into speech and then perform actions by verbal command.

Because many Cocoa user interface classes already implement the `NSAccessibility` protocol, providing reasonable default behavior in most cases, Cocoa applications built with standard objects are automatically accessible. In general, you need to explicitly implement the `NSAccessibility` protocol methods only if you subclass one of them, adding new behavior.

The Cocoa implementations of these methods raise an `NSAccessibilityException` when errors occur, such as requesting the value of an unsupported attribute. In most cases, subclasses do not need to raise or catch these exceptions, because overridden methods should invoke their inherited methods for unrecognized attribute and action names.

An accessible object is described by a set of attributes that define characteristics such as the object type, its value, its size and position on the screen, and its place in the accessibility hierarchy. For some objects, the set of attributes can include parameterized attributes. Parameterized attributes behave similar to a function by allowing you to pass a parameter when requesting an attribute value.

See "Accessibility" (page 3951) in *Application Kit Functions Reference* for functions related to accessibility.

Tasks

Accessing Attributes

- `accessibilityAttributeNames` (page 3503)
  Returns an array of attribute names supported by the receiver.
- `accessibilityAttributeValue:` (page 3503)
  Returns the value of the specified attribute in the receiver.
- `accessibilityIsAttributeSettable:` (page 3506)
  Returns a Boolean value that indicates whether the value for the specified attribute in the receiver can be set.
- `accessibilitySetValue:forAttribute:` (page 3508)
  Sets the value of the specified attribute in the receiver to the specified value.
- `accessibilitySetOverrideValue:forAttribute:` (page 3508)
  Overrides the specified attribute in the receiver, or adds it if it does not exist, and sets its value to the specified value.
- `accessibilityArrayAttributeCount:` (page 3502)
  Returns the count of the specified accessibility array attribute.
- `accessibilityArrayAttributeValues:index:maxCount:` (page 3502)
  Returns a subarray of values of an accessibility array attribute.
- `accessibilityIndexOfChild:` (page 3505)
  Returns the index of the specified accessibility child in the parent.

Accessing Parameterized Attributes

- `accessibilityParameterizedAttributeNames` (page 3507)
  Returns a list of parameterized attribute names supported by the receiver.
- `accessibilityAttributeValue:forParameter:` (page 3504)
  Returns the value of the receiver's parameterized attribute corresponding to the specified attribute name and parameter.

Accessing Actions

- `accessibilityActionNames` (page 3501)
  Returns an array of action names supported by the receiver.
- `accessibilityActionDescription:` (page 3501)
  Returns a localized description of the specified action.
- `accessibilityPerformAction:` (page 3507)
  Performs the action associated with the specified action.

Querying Elements

- `accessibilityIsIgnored` (page 3506)
  Returns a Boolean value indicating whether the receiver should be ignored in the parent-child accessibility hierarchy.
- `accessibilityHitTest:` (page 3505)
  Returns the deepest descendant of the accessibility hierarchy that contains the specified point.
- `accessibilityFocusedUIElement` (page 3504)
  Returns the deepest descendant of the accessibility hierarchy that has the focus.

Instance Methods

accessibilityActionDescription:

Returns a localized description of the specified action.

```
- (NSString *)accessibilityActionDescription:(NSString *)action
```

Parameters

action
The action attribute.

Return Value
The description of the specified action, in a localized string.

Discussion
User interface classes must implement this method to return descriptions for all actions returned from `accessibilityActionNames` (page 3501). A button, for example, might return the string "press" for the `NSAccessibilityPressAction` action. Subclasses should invoke the superclass's implementation, if it exists, to obtain the descriptions of any inherited actions.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`NSAccessibility.h`

accessibilityActionNames

Returns an array of action names supported by the receiver.

```
- (NSArray *)accessibilityActionNames
```

Return Value
An array of action names.

Discussion
User interface classes must implement this method. Subclasses should invoke the superclass's implementation, if it exists, and append additional action names or remove unsupported actions. See "Constants" (page 3509) for some common action names.

Availability
Available in Mac OS X v10.2 and later.

ImageMap
ImageMapExample
Sketch+Accessibility
ZipBrowser

Declared In
`NSAccessibility.h`

accessibilityArrayAttributeCount:

Returns the count of the specified accessibility array attribute.

```
- (NSUInteger)accessibilityArrayAttributeCount:(NSString *)attribute
```

Parameters

attribute
The accessibility array attribute.

Return Value
The number of items in the specified array attribute.

Discussion
If `attribute` is not an array an exception is raised.

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSAccessibility.h`

accessibilityArrayAttributeValues:index:maxCount:

Returns a subarray of values of an accessibility array attribute.

```
- (NSArray *)accessibilityArrayAttributeValues:(NSString *)attribute
    index:(NSUInteger)index maxCount:(NSUInteger)maxCount
```

Parameters

attribute
The accessibility array attribute.

index
The starting index.

maxCount
The maximum desired number of items requested.

Return Value
An array of values within the specified index and count.

Discussion
Note that this method does not take a range. The max count is the maximum desired number of items requested by an accessibility client. This number may be beyond the bounds of your array.

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSAccessibility.h`

accessibilityAttributeNames

Returns an array of attribute names supported by the receiver.

```
- (NSArray *)accessibilityAttributeNames
```

Return Value
An array containing the attributes supported by the receiver.

Discussion
User interface classes must implement this method. Subclasses should invoke the superclass's implementation, if it exists, and append additional attributes or remove unsupported attributes. See "Constants" (page 3509) for lists of attribute names.

Availability
Available in Mac OS X v10.2 and later.

Related Sample Code
ImageMap
ImageMapExample
Sketch+Accessibility
TrackBall
ZipBrowser

Declared In
`NSAccessibility.h`

accessibilityAttributeValue:

Returns the value of the specified attribute in the receiver.

```
- (id)accessibilityAttributeValue:(NSString *)attribute
```

Parameters
attribute
The name of the attribute. See "Constants" (page 3509) for lists of attribute names.

Discussion
User interface classes must implement this method. Subclasses should invoke the superclass's implementation, if it exists, if *attribute* is not implemented in the subclass.

Availability
Available in Mac OS X v10.2 and later.

Related Sample Code
ZipBrowser

Declared In
`NSAccessibility.h`

accessibilityAttributeValue:forParameter:

Returns the value of the receiver's parameterized attribute corresponding to the specified attribute name and parameter.

```
- (id)accessibilityAttributeValue:(NSString *)attribute forParameter:(id)parameter
```

Parameters

attribute
The name of the attribute. See "Constants" (page 3509) for lists of attribute names.

parameter
The parameter.

Discussion
If you implement this method you should also implement `accessibilityParameterizedAttributeNames` (page 3507).

Availability
Available in Mac OS X v10.3 and later.

Declared In
`NSAccessibility.h`

accessibilityFocusedUIElement

Returns the deepest descendant of the accessibility hierarchy that has the focus.

```
- (id)accessibilityFocusedUIElement
```

Return Value
The deepest accessibility object in the accessibility hierarchy that has focus.

Discussion
You can assume that the search for the focus has already been narrowed down to the receiver. Override this method to do deeper searching by identifying which child element, if any, may have the focus. If a child element does not have the focus, either return `self` or, if available, invoke the superclass's implementation. The default `NSView` and `NSCell` implementations test whether the receiver is an ignored element and, if so, return the receiver's first unignored parent; otherwise they return `self`.

Availability
Available in Mac OS X v10.2 and later.

ImageMapExample
Sketch+Accessibility

TrackBall
ZipBrowser

Declared In
`NSAccessibility.h`

accessibilityHitTest:

Returns the deepest descendant of the accessibility hierarchy that contains the specified point.

```
- (id)accessibilityHitTest:(NSPoint)point
```

Parameters

point

The point being hit-tested, in lower-left relative screen coordinates.

Return Value
The deepest accessibility element in the accessibility hierarchy that contains the specified point.

Discussion
You can assume that the specified point has already been determined to lie within the receiver. Override this method to do deeper hit-testing by identifying which child element, if any, contains the point. `NSMatrix`, for example, identifies which of its cells contains the point and propagates the hit-test to it.

If the specified point is not contained within one of the receiver's children, either return `self` or, if available, invoke the superclass's implementation. The default `NSView` and `NSCell` implementations test whether the receiver is an ignored element and, if it is, return the receiver's first unignored parent; otherwise they return `self`.

Availability
Available in Mac OS X v10.2 and later.

Related Sample Code
Dicey
ImageMap
ImageMapExample
Sketch+Accessibility

Declared In
`NSAccessibility.h`

accessibilityIndexOfChild:

Returns the index of the specified accessibility child in the parent.

```
- (NSUInteger)accessibilityIndexOfChild:(id)child
```

Parameters

child

The accessibility child of an object.

Return Value
The index of the accessibility child object in the parent. Returns `NSNotFound` if the child does not exist.

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSAccessibility.h`

accessibilityIsAttributeSettable:

Returns a Boolean value that indicates whether the value for the specified attribute in the receiver can be set.

```
- (BOOL)accessibilityIsAttributeSettable:(NSString *)attribute
```

Parameters

attribute
The name of the attribute. See "Constants" (page 3509) for lists of attribute names.

Return Value
`YES` if the specified attribute can be set; otherwise, `NO`.

Discussion
User interface classes must implement this method. Subclasses should invoke the superclass's implementation, if it exists, if *attribute* is not implemented in the subclass.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`NSAccessibility.h`

accessibilityIsIgnored

Returns a Boolean value indicating whether the receiver should be ignored in the parent-child accessibility hierarchy.

```
- (BOOL)accessibilityIsIgnored
```

Return Value
`YES` if the receiver should be ignored; otherwise, `NO`.

Discussion
When asking for an object's children, ignored children should not be included; instead, the ignored children should be replaced by their own unignored children. The same applies when asking for an object's parent: an ignored parent should be skipped and the first unignored ancestor treated as the real parent. Likewise, when a hit-test or focus test is satisfied by an ignored element, the element's first unignored ancestor (or descendant in certain cases, such as single-celled controls) should be used instead.

Ignored elements allow the accessibility hierarchy to be a simplified version of the view and object ownership hierarchies. Intermediate objects can be bypassed and the real user interface objects accessed more quickly. For example, `NSControl` objects are ignored when they are single-celled; the visible parent-child relationship is between the control's parent (or a higher ancestor if the parent is ignored, too) and the control's cell.

Availability
Available in Mac OS X v10.2 and later.

ImageMap
ImageMapExample
Sketch+Accessibility
TrackBall

Declared In
`NSAccessibility.h`

accessibilityParameterizedAttributeNames

Returns a list of parameterized attribute names supported by the receiver.

```
- (NSArray *)accessibilityParameterizedAttributeNames
```

Return Value
An array of parameterized attributes in the receiver.

Discussion
If you implement this method you should also implement `accessibilityAttributeValue:forParameter:` (page 3504).

Availability
Available in Mac OS X v10.3 and later.

Related Sample Code
Sketch+Accessibility

Declared In
`NSAccessibility.h`

accessibilityPerformAction:

Performs the action associated with the specified action.

```
- (void)accessibilityPerformAction:(NSString *)action
```

Parameters
action
The action to perform.

Discussion
User interface classes must implement this method to handle all the actions returned from `accessibilityActionNames` (page 3501). Subclasses should invoke the superclass's implementation, if it exists, if *action* is not implemented in the subclass.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`NSAccessibility.h`

accessibilitySetOverrideValue:forAttribute:

Overrides the specified attribute in the receiver, or adds it if it does not exist, and sets its value to the specified value.

```
- (BOOL)accessibilitySetOverrideValue:(id)value forAttribute:(NSString *)attribute
```

Parameters

value

The attribute value to set.

attribute

The name of the attribute. See "Constants" (page 3509) for lists of attribute names.

Return Value

`YES` if the override was successful; otherwise, `NO`.

Discussion

This method is for changing the set of attributes on an instance, as an alternative to subclassing.

This method only works on objects whose class already implements the `NSAccessibility` protocol. If the specified attribute is already supported by the object, the value specified by this method wins.

If the specified attribute does not exist, it is created. This is done outside the `NSAccessibility` protocol, so `accessibilityAttributeNames` still returns the old list which does not contain the new attribute. Likewise, `accessibilityAttributeValue` does not return attributes created by the override process nor does it return their overridden values.

The values of overridden attributes are not settable by assistive applications.

If you need to undo the effect of using this method, call it again passing `nil` for the value.

Ensure that you invoke this method on the actual object that represents the user interface element. For example, in the case of `NSButton`, use the underlying `NSButtonCell`. The `NSButton` itself is ignored by accessibility.

This method works only on an object representing a single user interface element. So, for example, you cannot use it when a single object represents multiple user interface elements, as with `NSSegmentedCell`, which has only a single object but provides user interface elements for each segment.

Availability

Available in Mac OS X v10.4 and later.

Related Sample Code

Dicey

Declared In

`NSAccessibility.h`

accessibilitySetValue:forAttribute:

Sets the value of the specified attribute in the receiver to the specified value.

```
- (void)accessibilitySetValue:(id)value forAttribute:(NSString *)attribute
```

Parameters

value

The attribute value to set.

attribute

The name of the attribute. See "Constants" (page 3509) for lists of attribute names.

Discussion

User interface classes must implement this method if any of its attributes are settable. Subclasses should invoke the superclass's implementation, if it exists, if *attribute* is not implemented in the subclass.

Availability

Available in Mac OS X v10.2 and later.

Declared In

NSAccessibility.h

Constants

Standard attributes

Standard attributes that can be adopted by any accessibility object.

```
NSString *const NSAccessibilityChildrenAttribute;
NSString *const NSAccessibilityContentsAttribute;
NSString *const NSAccessibilityDescriptionAttribute;
NSString *const NSAccessibilityEnabledAttribute;
NSString *const NSAccessibilityFocusedAttribute;
NSString *const NSAccessibilityHelpAttribute;
NSString *const NSAccessibilityMaxValueAttribute;
NSString *const NSAccessibilityMinValueAttribute;
NSString *const NSAccessibilityParentAttribute;
NSString *const NSAccessibilityPositionAttribute;

NSString *const NSAccessibilityRoleDescriptionAttribute;
NSString *const NSAccessibilitySelectedChildrenAttribute;
NSString *const NSAccessibilityShownMenuAttribute;
NSString *const NSAccessibilitySizeAttribute;
NSString *const NSAccessibilitySubroleAttribute;
NSString *const NSAccessibilityTitleAttribute;
NSString *const NSAccessibilityTopLevelUIElementAttribute;
NSString *const NSAccessibilityValueAttribute;
NSString *const NSAccessibilityValueDescriptionAttribute;
NSString *const NSAccessibilityVisibleChildrenAttribute;
NSString *const NSAccessibilityWindowAttribute;
```

Constants

NSAccessibilityChildrenAttribute

The element's child elements in the accessibility hierarchy (NSArray).

Available in Mac OS X v10.2 and later.

Declared in NSAccessibility.h.

`NSAccessibilityContentsAttribute`
Elements that represent the contents in the current element, such as the document view of a scroll view (`NSArray`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityDescriptionAttribute`
The purpose of the element, not including the role (`NSString`).

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityEnabledAttribute`
A flag that indicates the enabled state of the element (`NSNumber`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityFocusedAttribute`
A flag that indicates the presence of keyboard focus (`NSNumber`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityHelpAttribute`
The help text for the element (`NSString`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityMaxValueAttribute`
The element's maximum value (`id`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityMinValueAttribute`
The element's minimum value (`id`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityParentAttribute`
The element's parent element in the accessibility hierarchy (`id`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityPositionAttribute`
The screen position of the element's lower-left corner in lower-left relative screen coordinates (`NSValue`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityRoleAttribute`
The element's type, such as `NSAccessibilityRadioButtonRole` (`NSString`). See "Roles" (page 3533) for a list of available roles.

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityRoleDescriptionAttribute`
A localized, human-intelligible description of the element's role, such as "radio button" (`NSString`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilitySelectedChildrenAttribute`
The currently selected children of the element (`NSArray`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityShownMenuAttribute`
The menu currently being displayed (`id`).

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilitySizeAttribute`
The element's size (`NSValue`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilitySubroleAttribute`
The element's subrole, such as `NSAccessibilityTableRowSubrole` (`NSString`). See "Subroles" (page 3540) for a list of available subroles.

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityTitleAttribute`
The title of the element, such as a button's visible text (`NSString`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityTopLevelUIElementAttribute`
The top-level element that contains this element (`id`).

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityValueAttribute`
The element's value (`id`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityValueDescriptionAttribute`
The description of the element's value (`NSString`).

Available in Mac OS X v10.5 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityVisibleChildrenAttribute`
The element's child elements that are visible (`NSArray`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityWindowAttribute`
The window containing the current element (`id`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

Declared In
`NSAccessibility.h`

Text-specific attributes

Attributes that are specific to text.

```
NSString *const NSAccessibilityInsertionPointLineNumberAttribute;
NSString *const NSAccessibilityNumberOfCharactersAttribute;
NSString *const NSAccessibilitySelectedTextAttribute;
NSString *const NSAccessibilitySelectedTextRangeAttribute;
NSString *const NSAccessibilitySelectedTextRangesAttribute;
NSString *const NSAccessibilitySharedCharacterRangeAttribute;
NSString *const NSAccessibilitySharedTextUIElementsAttribute;
NSString *const NSAccessibilityVisibleCharacterRangeAttribute;
```

Constants
`NSAccessibilityInsertionPointLineNumberAttribute`
The line number containing the insertion point (`NSNumber`).

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityNumberOfCharactersAttribute`
The number of characters in the text (`NSNumber`).

Available in Mac OS X v10.3 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilitySelectedTextAttribute`
The currently selected text (`NSString`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilitySelectedTextRangeAttribute`
The range of selected text (`NSValue`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilitySelectedTextRangesAttribute`
An array of `NSValue` (`rangeValue`) ranges of selected text (`NSArray`).

Available in Mac OS X v10.5 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilitySharedCharacterRangeAttribute`
The (`rangeValue`) part of shared text in this view (`NSValue`).

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilitySharedTextUIElementsAttribute`
The elements with which the text of this element is shared (`NSArray`).

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityVisibleCharacterRangeAttribute`
The range of visible text (`NSValue`). Returns ranges for entire lines. For example, characters that are horizontally clipped will be reported in the visible range.

Available in Mac OS X v10.3 and later.

Declared in `NSAccessibility.h`.

Declared In
`NSAccessibility.h`

Text-specific parameterized attributes

Parameterized attributes specific to text.

```
NSString *const NSAccessibilityAttributedStringForRangeParameterizedAttribute;
NSString *const NSAccessibilityBoundsForRangeParameterizedAttribute;
NSString *const NSAccessibilityLineForIndexParameterizedAttribute;
NSString *const NSAccessibilityRTFForRangeParameterizedAttribute;
NSString *const NSAccessibilityRangeForIndexParameterizedAttribute;
NSString *const NSAccessibilityRangeForLineParameterizedAttribute;
NSString *const NSAccessibilityRangeForPositionParameterizedAttribute;
NSString *const NSAccessibilityStringForRangeParameterizedAttribute;
NSString *const NSAccessibilityStyleRangeForIndexParameterizedAttribute;
```

Constants
`NSAccessibilityLineForIndexParameterizedAttribute`
The line number (`NSNumber`) of the specified character (`NSNumber`).

Available in Mac OS X v10.3 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityRangeForLineParameterizedAttribute`
The range of characters (`NSValue` containing an `NSRange`) corresponding to the specified line number (`NSNumber`).

Available in Mac OS X v10.3 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityStringForRangeParameterizedAttribute`
The substring (`NSString`) specified by the range (`NSValue` containing an `NSRange`).

Available in Mac OS X v10.3 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityRangeForPositionParameterizedAttribute`
The range of characters (`NSValue` containing an `NSRange`) composing the glyph at the specified point (`NSValue` containing `NSPoint`).

Available in Mac OS X v10.3 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityRangeForIndexParameterizedAttribute`
: The full range of characters (`NSValue` containing an `NSRange`), including the specified character, which compose a single glyph (`NSNumber`).

  Available in Mac OS X v10.3 and later.

  Declared in `NSAccessibility.h`.

`NSAccessibilityBoundsForRangeParameterizedAttribute`
: The rectangle (`NSValue` containing an `NSRect`) enclosing the specified range of characters (`NSValue` containing an `NSRange`). If the range crosses a line boundary, the returned rectangle will fully enclose all the lines of characters.

  Available in Mac OS X v10.3 and later.

  Declared in `NSAccessibility.h`.

`NSAccessibilityRTFForRangeParameterizedAttribute`
: The RTF data (`NSData`) describing the specified range of characters (`NSValue` containing an `NSRange`).

  Available in Mac OS X v10.3 and later.

  Declared in `NSAccessibility.h`.

`NSAccessibilityStyleRangeForIndexParameterizedAttribute`
: The full range of characters (`NSValue` containing an `NSRange`), including the specified character (`NSNumber`), which have the same style.

  Available in Mac OS X v10.3 and later.

  Declared in `NSAccessibility.h`.

`NSAccessibilityAttributedStringForRangeParameterizedAttribute`
: Does not use attributes from Appkit/AttributedString.h (`NSAttributedString`).

  Available in Mac OS X v10.4 and later.

  Declared in `NSAccessibility.h`.

Declared In
`NSAccessibility.h`

Text attributed string attributes and constants

Attributes and key constants used with attributed strings.

```
NSString *const NSAccessibilityAttachmentTextAttribute;
NSString *const NSAccessibilityBackgroundColorTextAttribute;
NSString *const NSAccessibilityFontFamilyKey;
NSString *const NSAccessibilityFontNameKey;
NSString *const NSAccessibilityFontSizeKey;
NSString *const NSAccessibilityFontTextAttribute;
NSString *const NSAccessibilityForegroundColorTextAttribute;
NSString *const NSAccessibilityLinkTextAttribute;
NSString *const NSAccessibilityMisspelledTextAttribute;
NSString *const NSAccessibilityShadowTextAttribute;
NSString *const NSAccessibilityStrikethroughColorTextAttribute;
NSString *const NSAccessibilityStrikethroughTextAttribute;
NSString *const NSAccessibilitySuperscriptTextAttribute;
NSString *const NSAccessibilityUnderlineColorTextAttribute;
NSString *const NSAccessibilityUnderlineTextAttribute;
NSString *const NSAccessibilityVisibleNameKey;
```

Constants

`NSAccessibilityForegroundColorTextAttribute`
Text foreground color (`CGColorRef`).

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityBackgroundColorTextAttribute`
Text background color (`CGColorRef`).

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityUnderlineColorTextAttribute`
Text underline color (`CGColorRef`).

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityStrikethroughColorTextAttribute`
Text strikethrough color (`CGColorRef`).

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityUnderlineTextAttribute`
Text underline style (`NSNumber`).

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilitySuperscriptTextAttribute`
Text superscript style (`NSNumber`). Values > 0 are superscript; values < 0 are subscript.

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityStrikethroughTextAttribute`
Text strikethrough (`NSNumber` as a Boolean value).

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityShadowTextAttribute`
Text shadow (`NSNumber` as a Boolean value).

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityAttachmentTextAttribute`
Text attachment (`id`).

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityLinkTextAttribute`
Text link (`id`).

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityMisspelledTextAttribute`
Misspelled text (`NSNumber` as a Boolean value).

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityFontTextAttribute`
Font keys (`NSDictionary`).

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityFontNameKey`
Required key for font name.

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityFontFamilyKey`
Optional key for font family.

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityVisibleNameKey`
Optional key for font visibility.

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityFontSizeKey`
Required key for font size.

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

Declared In
`NSAccessibility.h`

Window-specific attributes

Attributes specific to windows.

```
NSString *const NSAccessibilityCancelButtonAttribute;
NSString *const NSAccessibilityCloseButtonAttribute;
NSString *const NSAccessibilityDefaultButtonAttribute;
NSString *const NSAccessibilityGrowAreaAttribute;
NSString *const NSAccessibilityMainAttribute;
NSString *const NSAccessibilityMinimizeButtonAttribute;
NSString *const NSAccessibilityMinimizedAttribute;
NSString *const NSAccessibilityModalAttribute;
NSString *const NSAccessibilityProxyAttribute;
NSString *const NSAccessibilityToolbarButtonAttribute;
NSString *const NSAccessibilityZoomButtonAttribute;
```

Constants

`NSAccessibilityCloseButtonAttribute`

The element representing the close button (`id`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityGrowAreaAttribute`

The element representing the grow area (`id`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityModalAttribute`

A flag that indicates whether the window represented by this element is modal (`NSNumber`).

Available in Mac OS X v10.3 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityDefaultButtonAttribute`

The element that represents the default button (`id`).

Available in Mac OS X v10.3 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityCancelButtonAttribute`

The element that represents the cancel button (`id`).

Available in Mac OS X v10.3 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityMainAttribute`

A flag that indicates whether the window is the main window (`NSNumber`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityMinimizeButtonAttribute`

The element that represents the minimize button (`id`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityMinimizedAttribute`

A flag that indicates whether the window is minimized (`NSNumber`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityToolbarButtonAttribute`
The element that represents the toolbar button (`id`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityProxyAttribute`
The element that represents the window's document proxy (`id`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityZoomButtonAttribute`
The element that represents the zoom button (`id`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

Declared In
`NSAccessibility.h`

Orientations

Values that indicate the orientation of elements, such as scroll bars and split views. One of these values is returned as the value for an object's `NSAccessibilityOrientationAttribute` (page 3532).

```
NSString *const NSAccessibilityHorizontalOrientationValue;
NSString *const NSAccessibilityVerticalOrientationValue;
NSString *const NSAccessibilityUnknownOrientationValue;
```

Constants
`NSAccessibilityHorizontalOrientationValue`
The element is oriented horizontally.

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityVerticalOrientationValue`
The element is oriented vertically.

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityUnknownOrientationValue`
The element has unknown orientation.

Available in Mac OS X v10.6 and later.

Declared in `NSAccessibility.h`.

Application-specific attributes

Attributes that are specific to the application object.

```
NSString *const NSAccessibilityClearButtonAttribute;
NSString *const NSAccessibilityColumnTitlesAttribute;
NSString *const NSAccessibilityFocusedUIElementAttribute;
NSString *const NSAccessibilityFocusedWindowAttribute;
NSString *const NSAccessibilityFrontmostAttribute;
NSString *const NSAccessibilityHiddenAttribute;
NSString *const NSAccessibilityMainWindowAttribute;
NSString *const NSAccessibilityMenuBarAttribute;
NSString *const NSAccessibilityOrientationAttribute;
NSString *const NSAccessibilitySearchButtonAttribute;
NSString *const NSAccessibilitySearchMenuAttribute;
NSString *const NSAccessibilityWindowsAttribute;
```

Constants

`NSAccessibilityFocusedUIElementAttribute`

The element with the current focus (`id`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityFocusedWindowAttribute`

The application's window that has current focus (`id`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityFrontmostAttribute`

A flag that indicates whether the application is frontmost (`NSNumber`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityHiddenAttribute`

A flag that indicates whether the application is hidden (`NSNumber`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityMainWindowAttribute`

The application's main window (`id`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityMenuBarAttribute`

The application's menu bar (`id`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityWindowsAttribute`

The application's windows (`NSArray`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

Declared In

`NSAccessibility.h`

Grid view attributes

Attributes that are used with grid views, such as thumbnails and media browsers that present a grid of items. The children of a grid are ordered.

```
NSString *const NSAccessibilityColumnCountAttribute;
NSString *const NSAccessibilityOrderedByRowAttribute;
NSString *const NSAccessibilityRowCountAttribute;
```

Constants

`NSAccessibilityColumnCountAttribute`

The number of columns in the grid (`NSNumber` as `intValue`).

Available in Mac OS X v10.5 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityOrderedByRowAttribute`

A flag that indicates whether the grid is ordered row major (`YES`), or column major (`NO`) (`NSNumber` as `boolValue`).

Available in Mac OS X v10.5 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityRowCountAttribute`

The number of rows in the grid (`NSNumber` as `intValue`).

Available in Mac OS X v10.5 and later.

Declared in `NSAccessibility.h`.

Declared In

`NSAccessibility.h`

Table view and outline view attributes

Attributes that are specific to tables and outlines.

```
NSString *const NSAccessibilityColumnHeaderUIElementsAttribute;
NSString *const NSAccessibilityColumnsAttribute;
NSString *const NSAccessibilityRowHeaderUIElementsAttribute;
NSString *const NSAccessibilityRowsAttribute;
NSString *const NSAccessibilitySelectedColumnsAttribute;
NSString *const NSAccessibilitySelectedRowsAttribute;
NSString *const NSAccessibilitySortDirectionAttribute;
NSString *const NSAccessibilityVisibleColumnsAttribute;
NSString *const NSAccessibilityVisibleRowsAttribute;
```

Constants

`NSAccessibilityColumnHeaderUIElementsAttribute`

The table's column headers (`NSArray`).

Available in Mac OS X v10.6 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityColumnsAttribute`

The table's columns (`NSArray`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityRowHeaderUIElementsAttribute`
The table's row headers (`NSArray`).

Available in Mac OS X v10.6 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityRowsAttribute`
The table's rows (`NSArray`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilitySelectedColumnsAttribute`
The table's selected columns (`NSArray`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilitySelectedRowsAttribute`
The table's selected rows (`NSArray`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilitySortDirectionAttribute`
The column's sort direction (`NSString`). See "`Column sort direction`" (page 3523) for possible values.

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityVisibleColumnsAttribute`
The table's visible columns (`NSArray`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityVisibleRowsAttribute`
The table's visible rows (`NSArray`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

Declared In
`NSAccessibility.h`

Outline view attributes

Attributes that are used in outline views.

```
NSString *const NSAccessibilityDisclosedByRowAttribute;
NSString *const NSAccessibilityDisclosedRowsAttribute;
NSString *const NSAccessibilityDisclosingAttribute;
NSString *const NSAccessibilityDisclosureLevelAttribute;
```

Constants

`NSAccessibilityDisclosedByRowAttribute`

The row disclosing this row (`id`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityDisclosedRowsAttribute`

The rows disclosed by this row (`NSArray`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityDisclosingAttribute`

A flag that indicates whether a row is disclosing other rows (`NSNumber`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityDisclosureLevelAttribute`

The indentation level of this row (`NSNumber`).

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

Declared In

`NSAccessibility.h`

Cell-based table attributes

Attributes that are specific to cell-based tables.

```
NSString *const NSAccessibilitySelectedCellsAttribute;
NSString *const NSAccessibilityVisibleCellsAttribute;
```

Constants

`NSAccessibilitySelectedCellsAttribute`

The table's selected cells (`NSArray`). This attribute is required for cell-based tables.

Available in Mac OS X v10.6 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityVisibleCellsAttribute`

The table's visible cells (`NSArray`). This attribute is required for cell-based tables.

Available in Mac OS X v10.6 and later.

Declared in `NSAccessibility.h`.

Cell-based table parameterized attributes

Parameterized attributes specific to cell-based tables.

```
NSString *const NSAccessibilityCellForColumnAndRowParameterizedAttribute;
```

Constants

`NSAccessibilityCellForColumnAndRowParameterizedAttribute`

The cell at the specified row and column. The parameter is an `NSArray` that contains two `NSNumber` objects: the first number specifies the column index and the second number specifies the row index. This attribute is required for cell-based tables.

Available in Mac OS X v10.6 and later.

Declared in `NSAccessibility.h`.

Cell attributes

Attributes that are specific to individual table cells.

```
NSString *const NSAccessibilityRowIndexRangeAttribute;
NSString *const NSAccessibilityColumnIndexRangeAttribute;
```

Constants

`NSAccessibilityRowIndexRangeAttribute`

The row index range of the cell (an `NSValue` that contains the row's starting index and index span in the table).

Available in Mac OS X v10.6 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityColumnIndexRangeAttribute`

The column index range of the cell (an `NSValue` that contains the row's starting index and index span in the table).

Available in Mac OS X v10.6 and later.

Declared in `NSAccessibility.h`.

Column sort direction

Values that indicate the sort direction of a column (used with `NSAccessibilitySortDirectionAttribute` (page 3521)).

```
NSString *const NSAccessibilityAscendingSortDirectionValue;
NSString *const NSAccessibilityDescendingSortDirectionValue;
NSString *const NSAccessibilityUnknownSortDirectionValue;
```

Constants

`NSAccessibilityAscendingSortDirectionValue`

The column is sorted in ascending values.

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityDescendingSortDirectionValue`

The column is sorted in descending values.

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityUnknownSortDirectionValue`
The sort direction is unknown.

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

Declared In
`NSAccessibility.h`

Layout area attributes

Attributes that are specific to layout areas.

```
NSString *const NSAccessibilityHorizontalUnitsAttribute;
NSString *const NSAccessibilityVerticalUnitsAttribute;
NSString *const NSAccessibilityHorizontalUnitDescriptionAttribute;
NSString *const NSAccessibilityVerticalUnitDescriptionAttribute;
```

Constants
`NSAccessibilityHorizontalUnitsAttribute`
The units that the layout view uses for horizontal values (`NSString`). See "Ruler unit attributes" (page 3529) for possible values.

Available in Mac OS X v10.6 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityVerticalUnitsAttribute`
The units that the layout view uses for vertical values (`NSString`). See "Ruler unit attributes" (page 3529) for possible values.

Available in Mac OS X v10.6 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityHorizontalUnitDescriptionAttribute`
The description of the layout view's horizontal units (`NSString`).

Available in Mac OS X v10.6 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityVerticalUnitDescriptionAttribute`
The description of the layout view's vertical units (`NSString`).

Available in Mac OS X v10.6 and later.

Declared in `NSAccessibility.h`.

Layout area parameterized attributes

Parameterized attributes that are specific to layout areas.

```
NSString *const NSAccessibilityLayoutPointForScreenPointParameterizedAttribute;
NSString *const NSAccessibilityLayoutSizeForScreenSizeParameterizedAttribute;
NSString *const NSAccessibilityScreenPointForLayoutPointParameterizedAttribute;
NSString *const NSAccessibilityScreenSizeForLayoutSizeParameterizedAttribute;
```

Constants

`NSAccessibilityLayoutPointForScreenPointParameterizedAttribute`

The point in the layout area (`NSValue`) corresponding to the specified point on the screen (`NSValue`).

Available in Mac OS X v10.6 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityLayoutSizeForScreenSizeParameterizedAttribute`

The size of the layout area (`NSValue`) corresponding to the specified screen size (`NSValue`).

Available in Mac OS X v10.6 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityScreenPointForLayoutPointParameterizedAttribute`

The screen point (`NSValue`) corresponding to the specified point in the layout area (`NSValue`).

Available in Mac OS X v10.6 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityScreenSizeForLayoutSizeParameterizedAttribute`

The size of the screen (`NSValue`) corresponding to the specified size of the layout area (`NSValue`).

Available in Mac OS X v10.6 and later.

Declared in `NSAccessibility.h`.

Layout item attributes

Attributes that are specific to the items in a layout area.

```
NSString *const NSAccessibilityHandlesAttribute;
```

Constants

`NSAccessibilityHandlesAttribute`

The drag handles of the item (`NSArray`).

Available in Mac OS X v10.6 and later.

Declared in `NSAccessibility.h`.

Slider attributes

Attributes that are specific to sliders.

```
NSString *const NSAccessibilityAllowedValuesAttribute;
NSString *const NSAccessibilityLabelUIElementsAttribute;
NSString *const NSAccessibilityLabelValueAttribute;
```

Constants

`NSAccessibilityAllowedValuesAttribute`

The allowed values in the slider (`NSArray`).

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityLabelUIElementsAttribute`

The elements that represent the slider's labels (`NSArray`).

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityLabelValueAttribute`

The value of the label represented by this element (`NSNumber`).

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

Declared In

`NSAccessibility.h`

Screen matte attributes

Attributes that are specific to screen mattes.

```
NSString *const NSAccessibilityMatteContentUIElementAttribute;
NSString *const NSAccessibilityMatteHoleAttribute;
```

Constants

`NSAccessibilityMatteHoleAttribute`

The bounds of the matte hole, in screen coordinates (`NSValue` containing an `NSRect`).

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityMatteContentUIElementAttribute`

The element that is clipped by the matte (`id`).

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

Declared In

`NSAccessibility.h`

Ruler view attributes

Attributes that are specific to ruler views.

```
NSString *const NSAccessibilityMarkerGroupUIElementAttribute;
NSString *const NSAccessibilityMarkerTypeAttribute;
NSString *const NSAccessibilityMarkerTypeDescriptionAttribute;
NSString *const NSAccessibilityMarkerUIElementsAttribute;
NSString *const NSAccessibilityMarkerValuesAttribute;
NSString *const NSAccessibilityUnitDescriptionAttribute;
NSString *const NSAccessibilityUnitsAttribute;
```

Constants

`NSAccessibilityMarkerGroupUIElementAttribute`

Marker group user interface element (`id`).

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityMarkerTypeAttribute`

The type of the marker (`NSString`). See "Ruler marker type values" (page 3527) for possible values.

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityMarkerTypeDescriptionAttribute`

The description of the marker type (`NSString`).

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityMarkerUIElementsAttribute`

Array of marker user interface elements (`NSArray`)

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityMarkerValuesAttribute`

The marker values (`NSArray` of `NSNumber`).

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityUnitDescriptionAttribute`

The description of ruler units (`NSString`).

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityUnitsAttribute`

The ruler units (`NSString`). See "Ruler unit attributes" (page 3529) for possible values.

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

Declared In

`NSAccessibility.h`

Ruler marker type values

Values that indicate the marker type of an element.

```
NSString *const NSAccessibilityCenterTabStopMarkerTypeValue;
NSString *const NSAccessibilityDecimalTabStopMarkerTypeValue;
NSString *const NSAccessibilityFirstLineIndentMarkerTypeValue;
NSString *const NSAccessibilityHeadIndentMarkerTypeValue;
NSString *const NSAccessibilityLeftTabStopMarkerTypeValue;
NSString *const NSAccessibilityRightTabStopMarkerTypeValue;
NSString *const NSAccessibilityTailIndentMarkerTypeValue;
NSString *const NSAccessibilityUnknownMarkerTypeValue;
```

Constants

`NSAccessibilityLeftTabStopMarkerTypeValue`

Left tab stop.

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityRightTabStopMarkerTypeValue`

Right tab stop.

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityCenterTabStopMarkerTypeValue`

Center tab stop.

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityDecimalTabStopMarkerTypeValue`

Decimal tab stop.

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityHeadIndentMarkerTypeValue`

Head indent marker.

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityTailIndentMarkerTypeValue`

Tail indent marker.

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityFirstLineIndentMarkerTypeValue`

First line indent marker.

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityUnknownMarkerTypeValue`

Unknown marker type.

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

Declared In

`NSAccessibility.h`

Measurement unit attributes

Values that indicate the unit values of a ruler or layout area (used with `NSAccessibilityUnitsAttribute` (page 3527)).

```
NSString *const NSAccessibilityCentimetersUnitValue;
NSString *const NSAccessibilityInchesUnitValue;
NSString *const NSAccessibilityPicasUnitValue;
NSString *const NSAccessibilityPointsUnitValue;
NSString *const NSAccessibilityUnknownUnitValue;
```

Constants

`NSAccessibilityInchesUnitValue`
The units are inches.
Available in Mac OS X v10.4 and later.
Declared in `NSAccessibility.h`.

`NSAccessibilityCentimetersUnitValue`
The units are centimeters.
Available in Mac OS X v10.4 and later.
Declared in `NSAccessibility.h`.

`NSAccessibilityPointsUnitValue`
The units are points.
Available in Mac OS X v10.4 and later.
Declared in `NSAccessibility.h`.

`NSAccessibilityPicasUnitValue`
The units are picas.
Available in Mac OS X v10.4 and later.
Declared in `NSAccessibility.h`.

`NSAccessibilityUnknownUnitValue`
The units are unknown.
Available in Mac OS X v10.4 and later.
Declared in `NSAccessibility.h`.

Declared In

`NSAccessibility.h`

Linkage elements

Constants that specify links between accessibility elements.

```
NSString *const NSAccessibilityLinkedUIElementsAttribute;
NSString *const NSAccessibilityServesAsTitleForUIElementsAttribute;
NSString *const NSAccessibilityTitleUIElementAttribute;
```

Constants

`NSAccessibilityLinkedUIElementsAttribute`

The elements with which this element is related (`NSArray`). For example, the contents of a list item that are displayed in another pane or window.

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityTitleUIElementAttribute`

An element that represents another element's static text title (`id`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityServesAsTitleForUIElementsAttribute`

The elements for which this element serves as the title (`NSArray`).

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

Declared In

`NSAccessibility.h`

Miscellaneous attributes

Miscellaneous attributes that can apply to various types of elements.

```
NSString *const NSAccessibilityDecrementButtonAttribute;
NSString *const NSAccessibilityDocumentAttribute;
NSString *const NSAccessibilityEditedAttribute;
NSString *const NSAccessibilityExpandedAttribute;
NSString *const NSAccessibilityFilenameAttribute;
NSString *const NSAccessibilityHeaderAttribute;
NSString *const NSAccessibilityHorizontalScrollBarAttribute;
NSString *const NSAccessibilityIncrementButtonAttribute;
NSString *const NSAccessibilityIndexAttribute;
NSString *const NSAccessibilityNextContentsAttribute;
NSString *const NSAccessibilityOverflowButtonAttribute;
NSString *const NSAccessibilityPreviousContentsAttribute;
NSString *const NSAccessibilitySelectedAttribute;
NSString *const NSAccessibilitySplittersAttribute;
NSString *const NSAccessibilityTabsAttribute;
NSString *const NSAccessibilityURLAttribute;
NSString *const NSAccessibilityVerticalScrollBarAttribute;
NSString *const NSAccessibilityWarningValueAttribute;
NSString *const NSAccessibilityCriticalValueAttribute;
NSString *const NSAccessibilityPlaceholderValueAttribute;
```

Constants

`NSAccessibilityClearButtonAttribute`

The element that represents the clear button in a search field (`id`).

Available in Mac OS X v10.3 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityColumnTitlesAttribute`
The elements that represent column titles (`NSArray`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityDecrementButtonAttribute`
The element that represents a stepper's decrement button (`id`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityDocumentAttribute`
The URL for the file represented by the element (`NSString`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityEditedAttribute`
A flag that indicates whether the element has been modified (`NSNumber`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityExpandedAttribute`
A flag that indicates whether the element is expanded (`NSNumber`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityFilenameAttribute`
The filename associated with the element (`NSString`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityHeaderAttribute`
The element that represents a table view's header (`id`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityHorizontalScrollBarAttribute`
The element that represents a scroll view's horizontal scroll bar (`id`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityIncrementButtonAttribute`
The element that represents a stepper's increment button (`id`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityIndexAttribute`
The index of the row or column represented by the element (`NSValue`).

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityNextContentsAttribute`
The contents following the current divider element, such as a subview adjacent to a split view's splitter element (`NSArray`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityOrientationAttribute`
The element's orientation, which can have the value `NSAccessibilityHorizontalOrientationValue` (page 3518) or `NSAccessibilityVerticalOrientationValue` (page 3518).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityOverflowButtonAttribute`
The element that represents a toolbar's overflow button (`id`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityPreviousContentsAttribute`
The contents preceding the current divider element, such as a subview adjacent to a split view's splitter bar element (`NSArray`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilitySearchButtonAttribute`
The element that represents the search button in a search field (`id`).

Available in Mac OS X v10.3 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilitySearchMenuAttribute`
The element that represents the menu in a search field (`id`).

Available in Mac OS X v10.3 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilitySelectedAttribute`
A flag that indicates whether the element is selected (`NSNumber`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilitySplittersAttribute`
The views and splitter bar in a split view (`NSArray`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityTabsAttribute`
The tab elements in a tab view (`NSArray`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityURLAttribute`
The URL associated with the element (`NSURL`).

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityVerticalScrollBarAttribute`
The element that represents the vertical scroll bar in a scroll view (`id`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityWarningValueAttribute`
The warning value in a level indicator (typically, `NSNumber`).

Available in Mac OS X v10.6 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityCriticalValueAttribute`
The critical value in a level indicator (typically, `NSNumber`).

Available in Mac OS X v10.6 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityPlaceholderValueAttribute`
The placeholder value for a control, such as a text field (`NSString`).

Available in Mac OS X v10.6 and later.

Declared in `NSAccessibility.h`.

Declared In
`NSAccessibility.h`

Roles

Standard roles that identify the type of object an accessibility object represents. One of these values is returned as the value for an object's `NSAccessibilityRoleAttribute` (page 3510).

```
NSString *const NSAccessibilityApplicationRole;
NSString *const NSAccessibilityBrowserRole;
NSString *const NSAccessibilityBusyIndicatorRole;
NSString *const NSAccessibilityButtonRole;
NSString *const NSAccessibilityCellRole;
NSString *const NSAccessibilityCheckBoxRole;
NSString *const NSAccessibilityColorWellRole;
NSString *const NSAccessibilityColumnRole;
NSString *const NSAccessibilityComboBoxRole;
NSString *const NSAccessibilityDisclosureTriangleRole;
NSString *const NSAccessibilityDrawerRole;
NSString *const NSAccessibilityGridRole;
NSString *const NSAccessibilityGroupRole;
NSString *const NSAccessibilityGrowAreaRole;
NSString *const NSAccessibilityHandleRole;
NSString *const NSAccessibilityHelpTagRole;
NSString *const NSAccessibilityImageRole;
NSString *const NSAccessibilityIncrementorRole;
NSString *const NSAccessibilityLayoutAreaRole;
NSString *const NSAccessibilityLayoutItemRole;
NSString *const NSAccessibilityLinkRole;
NSString *const NSAccessibilityListRole;
NSString *const NSAccessibilityMatteRole;
NSString *const NSAccessibilityMenuBarRole;
NSString *const NSAccessibilityMenuButtonRole;
NSString *const NSAccessibilityMenuItemRole;
NSString *const NSAccessibilityMenuRole;
NSString *const NSAccessibilityOutlineRole;
NSString *const NSAccessibilityPopUpButtonRole;
NSString *const NSAccessibilityProgressIndicatorRole;
NSString *const NSAccessibilityRadioButtonRole;
NSString *const NSAccessibilityRadioGroupRole;
NSString *const NSAccessibilityRelevanceIndicatorRole;
NSString *const NSAccessibilityRowRole;
NSString *const NSAccessibilityRulerMarkerRole;
NSString *const NSAccessibilityRulerRole;
NSString *const NSAccessibilityScrollAreaRole;
NSString *const NSAccessibilityScrollBarRole;
NSString *const NSAccessibilitySheetRole;
NSString *const NSAccessibilitySliderRole;
NSString *const NSAccessibilitySortButtonRole;
NSString *const NSAccessibilitySplitGroupRole;
NSString *const NSAccessibilitySplitterRole;
NSString *const NSAccessibilityStaticTextRole;
NSString *const NSAccessibilitySystemWideRole;
NSString *const NSAccessibilityTabGroupRole;
NSString *const NSAccessibilityTableRole;
NSString *const NSAccessibilityTextAreaRole;
NSString *const NSAccessibilityTextFieldRole;
NSString *const NSAccessibilityToolbarRole;
NSString *const NSAccessibilityUnknownRole;
NSString *const NSAccessibilityValueIndicatorRole;
NSString *const NSAccessibilityWindowRole;
```

Constants

`NSAccessibilityApplicationRole`
Application.
Available in Mac OS X v10.2 and later.
Declared in `NSAccessibility.h`.

`NSAccessibilityBrowserRole`
Browser.
Available in Mac OS X v10.2 and later.
Declared in `NSAccessibility.h`.

`NSAccessibilityBusyIndicatorRole`
Busy indicator.
Available in Mac OS X v10.2 and later.
Declared in `NSAccessibility.h`.

`NSAccessibilityButtonRole`
Button.
Available in Mac OS X v10.2 and later.
Declared in `NSAccessibility.h`.

`NSAccessibilityCellRole`
Cell in a table or matrix.
Available in Mac OS X v10.6 and later.
Declared in `NSAccessibility.h`.

`NSAccessibilityCheckBoxRole`
Checkbox.
Available in Mac OS X v10.2 and later.
Declared in `NSAccessibility.h`.

`NSAccessibilityColorWellRole`
Color well.
Available in Mac OS X v10.2 and later.
Declared in `NSAccessibility.h`.

`NSAccessibilityColumnRole`
Column.
Available in Mac OS X v10.2 and later.
Declared in `NSAccessibility.h`.

`NSAccessibilityComboBoxRole`
Combo box.
Available in Mac OS X v10.2 and later.
Declared in `NSAccessibility.h`.

`NSAccessibilityDisclosureTriangleRole`
Disclosure triangle.
Available in Mac OS X v10.5 and later.
Declared in `NSAccessibility.h`.

`NSAccessibilityDrawerRole`
Drawer.

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityGridRole`
Grid.

Available in Mac OS X v10.5 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityGroupRole`
Group.

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityGrowAreaRole`
A window's grow (resize) area.

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityHandleRole`
Drag handle.

Available in Mac OS X v10.6 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityHelpTagRole`
Help tag.

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityImageRole`
Image.

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityIncrementorRole`
Stepper.

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityLayoutAreaRole`
Layout area (a view, such as a graphic view, that contains visual elements that may not have any accessibility representation).

Available in Mac OS X v10.6 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityLayoutItemRole`
An item in a layout area.

Available in Mac OS X v10.6 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityLinkRole`
Link.
Available in Mac OS X v10.4 and later.
Declared in `NSAccessibility.h`.

`NSAccessibilityListRole`
List.
Available in Mac OS X v10.2 and later.
Declared in `NSAccessibility.h`.

`NSAccessibilityMatteRole`
Matte.
Available in Mac OS X v10.4 and later.
Declared in `NSAccessibility.h`.

`NSAccessibilityMenuBarRole`
Menu bar.
Available in Mac OS X v10.2 and later.
Declared in `NSAccessibility.h`.

`NSAccessibilityMenuButtonRole`
Menu button.
Available in Mac OS X v10.2 and later.
Declared in `NSAccessibility.h`.

`NSAccessibilityMenuItemRole`
Menu item.
Available in Mac OS X v10.2 and later.
Declared in `NSAccessibility.h`.

`NSAccessibilityMenuRole`
Menu.
Available in Mac OS X v10.2 and later.
Declared in `NSAccessibility.h`.

`NSAccessibilityOutlineRole`
Outline.
Available in Mac OS X v10.2 and later.
Declared in `NSAccessibility.h`.

`NSAccessibilityPopUpButtonRole`
Pop-up button.
Available in Mac OS X v10.2 and later.
Declared in `NSAccessibility.h`.

`NSAccessibilityProgressIndicatorRole`
Progress indicator.
Available in Mac OS X v10.2 and later.
Declared in `NSAccessibility.h`.

`NSAccessibilityRadioButtonRole`
Radio button.
Available in Mac OS X v10.2 and later.
Declared in `NSAccessibility.h`.

`NSAccessibilityRadioGroupRole`
Radio button group.
Available in Mac OS X v10.2 and later.
Declared in `NSAccessibility.h`.

`NSAccessibilityRelevanceIndicatorRole`
Relevance indicator.
Available in Mac OS X v10.2 and later.
Declared in `NSAccessibility.h`.

`NSAccessibilityRowRole`
Row.
Available in Mac OS X v10.2 and later.
Declared in `NSAccessibility.h`.

`NSAccessibilityRulerRole`
Ruler.
Available in Mac OS X v10.4 and later.
Declared in `NSAccessibility.h`.

`NSAccessibilityRulerMarkerRole`
Ruler marker.
Available in Mac OS X v10.4 and later.
Declared in `NSAccessibility.h`.

`NSAccessibilityScrollAreaRole`
Scroll view.
Available in Mac OS X v10.2 and later.
Declared in `NSAccessibility.h`.

`NSAccessibilityScrollBarRole`
Scroll bar.
Available in Mac OS X v10.2 and later.
Declared in `NSAccessibility.h`.

`NSAccessibilitySheetRole`
Sheet.
Available in Mac OS X v10.2 and later.
Declared in `NSAccessibility.h`.

`NSAccessibilitySliderRole`
Slider.
Available in Mac OS X v10.2 and later.
Declared in `NSAccessibility.h`.

`NSAccessibilitySortButtonRole`
Sort button.
Available in Mac OS X v10.4 and later.
Deprecated in Mac OS X v10.6.
Declared in `NSAccessibility.h`.

`NSAccessibilitySplitGroupRole`
Split view.
Available in Mac OS X v10.2 and later.
Declared in `NSAccessibility.h`.

`NSAccessibilitySplitterRole`
Splitter bar of a split view.
Available in Mac OS X v10.2 and later.
Declared in `NSAccessibility.h`.

`NSAccessibilityStaticTextRole`
Uneditable text.
Available in Mac OS X v10.2 and later.
Declared in `NSAccessibility.h`.

`NSAccessibilitySystemWideRole`
The system-wide accessibility object.
Available in Mac OS X v10.2 and later.
Declared in `NSAccessibility.h`.

`NSAccessibilityTabGroupRole`
Tab group.
Available in Mac OS X v10.2 and later.
Declared in `NSAccessibility.h`.

`NSAccessibilityTableRole`
Table.
Available in Mac OS X v10.2 and later.
Declared in `NSAccessibility.h`.

`NSAccessibilityTextAreaRole`
Text view.
Available in Mac OS X v10.2 and later.
Declared in `NSAccessibility.h`.

`NSAccessibilityTextFieldRole`
Text field.
Available in Mac OS X v10.2 and later.
Declared in `NSAccessibility.h`.

`NSAccessibilityToolbarRole`
Toolbar.
Available in Mac OS X v10.2 and later.
Declared in `NSAccessibility.h`.

`NSAccessibilityUnknownRole`
Unknown object type.

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityValueIndicatorRole`
Value indicator.

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityWindowRole`
Window.

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

Declared In
`NSAccessibility.h`

Subroles

Subroles that identify a specialized type of object an accessibility object represents. One of these values is returned as the value for an object's `NSAccessibilitySubroleAttribute` (page 3511).

```
NSString *const NSAccessibilityCloseButtonSubrole;
NSString *const NSAccessibilityDecrementArrowSubrole;
NSString *const NSAccessibilityDecrementPageSubrole;
NSString *const NSAccessibilityDialogSubrole;
NSString *const NSAccessibilityFloatingWindowSubrole;
NSString *const NSAccessibilityIncrementArrowSubrole;
NSString *const NSAccessibilityIncrementPageSubrole;
NSString *const NSAccessibilityMinimizeButtonSubrole;
NSString *const NSAccessibilityOutlineRowSubrole;
NSString *const NSAccessibilitySearchFieldSubrole;
NSString *const NSAccessibilitySecureTextFieldSubrole;
NSString *const NSAccessibilityStandardWindowSubrole;
NSString *const NSAccessibilitySystemDialogSubrole;
NSString *const NSAccessibilitySystemFloatingWindowSubrole;
NSString *const NSAccessibilityTableRowSubrole;
NSString *const NSAccessibilityTextAttachmentSubrole;
NSString *const NSAccessibilityTextLinkSubrole;
NSString *const NSAccessibilityTimelineSubrole;
NSString *const NSAccessibilityToolbarButtonSubrole;
NSString *const NSAccessibilityUnknownSubrole;
NSString *const NSAccessibilityZoomButtonSubrole;
NSString *const NSAccessibilitySortButtonSubrole;
NSString *const NSAccessibilityRatingIndicatorSubrole;
NSString *const NSAccessibilityContentListSubrole;
NSString *const NSAccessibilityDefinitionListSubrole;
```

Constants
`NSAccessibilityCloseButtonSubrole`
A window's close button.

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityDecrementArrowSubrole`
Decrement arrow (the down arrow in a scroll bar).

Available in Mac OS X v10.3 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityDecrementPageSubrole`
Decrement page (the decrement area in the scroll track of a scroll bar).

Available in Mac OS X v10.3 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityDialogSubrole`
Dialog.

Available in Mac OS X v10.3 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityFloatingWindowSubrole`
Floating window.

Available in Mac OS X v10.3 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityIncrementArrowSubrole`
Increment arrow (the up arrow in a scroll bar).

Available in Mac OS X v10.3 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityIncrementPageSubrole`
Increment page (the increment area in the scroll track of a scroll bar).

Available in Mac OS X v10.3 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityMinimizeButtonSubrole`
A window's minimize button.

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityOutlineRowSubrole`
Outline row.

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilitySearchFieldSubrole`
Search field.

Available in Mac OS X v10.3 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilitySecureTextFieldSubrole`
Secure text field.

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityStandardWindowSubrole`
A standard window.

Available in Mac OS X v10.3 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilitySystemDialogSubrole`
System dialog (a system-generated dialog that floats on the top layer, regardless of which application is frontmost).

Available in Mac OS X v10.3 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilitySystemFloatingWindowSubrole`
System floating window (a system-generated panel).

Available in Mac OS X v10.3 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityTableRowSubrole`
Table row.

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityTextAttachmentSubrole`
Text attachment.

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityTextLinkSubrole`
Text link.

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityTimelineSubrole`
Timeline.

Available in Mac OS X v10.5 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityToolbarButtonSubrole`
A window's toolbar button.

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityUnknownSubrole`
Unknown subrole.

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityZoomButtonSubrole`
A window's zoom button.

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilitySortButtonSubrole`
Sort button in a table or outline view.

Available in Mac OS X v10.6 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityRatingIndicatorSubrole`
Rating indicator.

Available in Mac OS X v10.6 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityContentListSubrole`
Content that is organized in a list, but is not in a list control or table view.

Available in Mac OS X v10.6 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityDefinitionListSubrole`
A content list in a webpage.

Available in Mac OS X v10.6 and later.

Declared in `NSAccessibility.h`.

Declared In
`NSAccessibility.h`

Action values

Standard actions that accessibility objects can perform.

```
NSString *const NSAccessibilityCancelAction;
NSString *const NSAccessibilityConfirmAction;
NSString *const NSAccessibilityDecrementAction;
NSString *const NSAccessibilityDeleteAction;
NSString *const NSAccessibilityIncrementAction;
NSString *const NSAccessibilityPickAction;
NSString *const NSAccessibilityPressAction;
NSString *const NSAccessibilityRaiseAction;
NSString *const NSAccessibilityShowMenuAction;
```

Constants
`NSAccessibilityConfirmAction`
Simulates pressing Return in the object, such as a text field.

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityDecrementAction`
Decrements the value of the object.

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityDeleteAction`
Deletes the value of the object.

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityIncrementAction`
Increments the value of the object.

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityPickAction`
Selects the object, such as a menu item.

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityPressAction`
Simulates clicking an object, such as a button.

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityCancelAction`
Cancels the operation.

Available in Mac OS X v10.3 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityRaiseAction`
Simulates bringing a window forward by clicking on its title bar.

Available in Mac OS X v10.3 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityShowMenuAction`
Simulates showing a menu by clicking on it.

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

Declared In
`NSAccessibility.h`

Focus-change notifications

Notifications that are sent to observing assistive applications when focus-change events occur. The notifications are sent using the `NSAccessibilityPostNotification` (page 3956) function instead of an `NSNotificationCenter` object.

```
NSString *const NSAccessibilityMainWindowChangedNotification;
NSString *const NSAccessibilityFocusedWindowChangedNotification;
NSString *const NSAccessibilityFocusedUIElementChangedNotification;
```

Constants
`NSAccessibilityMainWindowChangedNotification`
Posted after the main window has changed.

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityFocusedWindowChangedNotification`
Posted after the key window has changed.

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityFocusedUIElementChangedNotification`
Posted after the element has gained focus.

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

Declared In
`NSAccessibility.h`

Window-change notifications

Notifications that are sent to observing assistive applications when window-change events occur. The notifications are sent using the `NSAccessibilityPostNotification` (page 3956) function instead of an `NSNotificationCenter` object.

```
NSString *const NSAccessibilityWindowCreatedNotification;
NSString *const NSAccessibilityWindowDeminiaturizedNotification;
NSString *const NSAccessibilityWindowMiniaturizedNotification;
NSString *const NSAccessibilityWindowMovedNotification;
NSString *const NSAccessibilityWindowResizedNotification;
```

Constants
`NSAccessibilityWindowCreatedNotification`
Posted after a new window has appeared.

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityWindowDeminiaturizedNotification`
Posted after the window has been restored to full size from the Dock.

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityWindowMiniaturizedNotification`
Posted after the window has been put in the Dock.

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityWindowMovedNotification`
Posted after the window has moved.

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityWindowResizedNotification`
Posted after the window has changed size.

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

Declared In
`NSAccessibility.h`

Application notifications

Notifications that are sent to observing assistive applications when application events occur. The notifications are sent using the `NSAccessibilityPostNotification` (page 3956) function instead of an `NSNotificationCenter` object.

```
NSString *const NSAccessibilityApplicationActivatedNotification;
NSString *const NSAccessibilityApplicationDeactivatedNotification;
NSString *const NSAccessibilityApplicationHiddenNotification;
NSString *const NSAccessibilityApplicationShownNotification;
```

Constants

`NSAccessibilityApplicationActivatedNotification`

Posted after the application has activated.

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityApplicationDeactivatedNotification`

Posted after the application has deactivated.

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityApplicationHiddenNotification`

Posted after the application has been hidden.

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityApplicationShownNotification`

Posted after the application has been shown.

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

Declared In

`NSAccessibility.h`

Drawer and sheet notifications

Notifications that are sent to observing assistive applications when drawer and sheet events occur. The notifications are sent using the `NSAccessibilityPostNotification` (page 3956) function instead of an `NSNotificationCenter` object.

```
NSString *const NSAccessibilityDrawerCreatedNotification;
NSString *const NSAccessibilitySheetCreatedNotification;
```

Constants

`NSAccessibilityDrawerCreatedNotification`

Posted after a drawer has appeared.

Available in Mac OS X v10.3 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilitySheetCreatedNotification`
Posted after a sheet has appeared.

Available in Mac OS X v10.3 and later.

Declared in `NSAccessibility.h`.

Declared In
`NSAccessibility.h`

Element notifications

Notifications that are sent to observing assistive applications when certain element-related events occur. Note that these notifications are not sent from every element. The notifications are sent using the `NSAccessibilityPostNotification` (page 3956) function instead of an `NSNotificationCenter` object.

```
NSString *const NSAccessibilityCreatedNotification;
NSString *const NSAccessibilityMovedNotification;
NSString *const NSAccessibilityResizedNotification;
NSString *const NSAccessibilityTitleChangedNotification;
NSString *const NSAccessibilityUIElementDestroyedNotification;
NSString *const NSAccessibilityValueChangedNotification;
```

Constants
`NSAccessibilityCreatedNotification`
Posted after the element has been created.

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityMovedNotification`
Posted after the element has been moved.

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityResizedNotification`
Posted after the element has been resized.

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityTitleChangedNotification`
Posted after the title has changed.

Available in Mac OS X v10.4 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityUIElementDestroyedNotification`
Posted after the element has been destroyed.

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityValueChangedNotification`
Posted after the element's value has changed.

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

Declared In
NSAccessibility.h

Miscellaneous notifications

Notifications that are sent to observing assistive applications when certain events occur. The notifications are sent using the NSAccessibilityPostNotification (page 3956) function instead of an NSNotificationCenter object.

```
NSString *const NSAccessibilityHelpTagCreatedNotification;
NSString *const NSAccessibilityRowCountChangedNotification;
NSString *const NSAccessibilitySelectedChildrenChangedNotification;
NSString *const NSAccessibilitySelectedColumnsChangedNotification;
NSString *const NSAccessibilitySelectedRowsChangedNotification;
NSString *const NSAccessibilitySelectedTextChangedNotification;
NSString *const NSAccessibilityRowExpandedNotification;
NSString *const NSAccessibilityRowCollapsedNotification;
NSString *const NSAccessibilitySelectedCellsChangedNotification;
NSString *const NSAccessibilityUnitsChangedNotification;
NSString *const NSAccessibilitySelectedChildrenMovedNotification;
```

Constants

NSAccessibilityHelpTagCreatedNotification
Posted after a help tag has appeared.
Available in Mac OS X v10.4 and later.
Declared in NSAccessibility.h.

NSAccessibilityRowCountChangedNotification
Posted after a row has been added or deleted.
Available in Mac OS X v10.4 and later.
Declared in NSAccessibility.h.

NSAccessibilitySelectedChildrenChangedNotification
Posted after selected child elements have changed.
Available in Mac OS X v10.4 and later.
Declared in NSAccessibility.h.

NSAccessibilitySelectedColumnsChangedNotification
Posted after selected columns have changed.
Available in Mac OS X v10.4 and later.
Declared in NSAccessibility.h.

NSAccessibilitySelectedRowsChangedNotification
Posted after selected rows have changed.
Available in Mac OS X v10.4 and later.
Declared in NSAccessibility.h.

NSAccessibilitySelectedTextChangedNotification
Posted after selected text has changed.
Available in Mac OS X v10.4 and later.
Declared in NSAccessibility.h.

`NSAccessibilityRowExpandedNotification`
Posted after the row has expanded.

Available in Mac OS X v10.6 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityRowCollapsedNotification`
Posted after the row has collapsed.

Available in Mac OS X v10.6 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilitySelectedCellsChangedNotification`
Posted after selected cells in a cell-based table have changed.

Available in Mac OS X v10.6 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilityUnitsChangedNotification`
Posted after the units in a layout area have changed.

Available in Mac OS X v10.6 and later.

Declared in `NSAccessibility.h`.

`NSAccessibilitySelectedChildrenMovedNotification`
Posted after selected items in a layout area have moved.

Available in Mac OS X v10.6 and later.

Declared in `NSAccessibility.h`.

Declared In
`NSAccessibility.h`

UserInfo key for error codes in accessibility exceptions

This is a key used by the `userInfo` dictionary of an `NSAccessibilityException`.

```
NSString *const NSAccessibilityErrorCodeExceptionInfo;
```

Constants
`NSAccessibilityErrorCodeExceptionInfo`
Integer error code used for debugging (as an `NSNumber`).

Available in Mac OS X v10.2 and later.

Declared in `NSAccessibility.h`.

Declared In
`NSAccessibility.h`

NSAlertDelegate Protocol Reference

Conforms to	NSObject
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.6 and later.
Declared in	AppKit/NSAlert.h
Companion guides	Dialogs and Special Panels Sheet Programming Topics

Overview

The `NSAlertDelegate` protocol defines the optional methods implemented by delegates of `NSAlert` objects.

Tasks

Displaying Help

`- alertShowHelp:` (page 3551)
Sent to the delegate when the user clicks the alert's help button. The delegate causes help to be displayed for an alert, directly or indirectly.

Instance Methods

alertShowHelp:

Sent to the delegate when the user clicks the alert's help button. The delegate causes help to be displayed for an alert, directly or indirectly.

```
- (BOOL)alertShowHelp:(NSAlert *)alert
```

Return Value
`YES` when the delegate displayed help directly, `NO` otherwise. When `NO` and the alert has a help anchor (`setHelpAnchor:` (page 90)), the application's help manager displays help using the help anchor.

Discussion
The delegate implements this method only to override the help-anchor lookup behavior.

Availability
Available in Mac OS X v10.3 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

`- setShowsHelp:` (page 92) (NSAlert)

Declared In
`NSAlert.h`

NSAnimatablePropertyContainer Protocol Reference

Adopted by	NSWindow NSView
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.5 and later.
Declared in	AppKit/NSAnimation.h

Overview

The NSAnimatablePropertyContainer protocol defines a way to add animation to an existing class with a minimum of API impact. It returns a proxy object for the receiver that can be used to initiate implied animation of property changes. An object's animator proxy should be treated as if it was the object itself, and may be passed to any code that accepts the object as a parameter. Sending of key-value-coding compliant "set" messages to the proxy will trigger animation for automatically animated properties of its target object.

An object's automatically animated properties are those for which `NSAnimatablePropertyContainer` (page 3553) finds and returns an CAAnimation instead of nil, often because `animator` (page 3556) specifies a default animation for the key.

It's perfectly valid to set a new value for a property for which an animation that is currently in progress; this simply sets a new target value for that property, with animation to the new target proceeding from whatever current value the property has reached. An in-flight property animation can be stopped by setting a new value for the property bracketed by an `NSAnimationContext` with 0.0 as the duration.

Tasks

Getting the Animator Proxy

- `animator` (page 3556) *required method*

  Returns a proxy object for the receiver that can be used to initiate implied animation for property changes. (required)

Managing Animations for Properties

- `animations` (page 3555) *required method*
  Returns the optional dictionary that maps event trigger keys to animation objects. (required)
- `setAnimations:` (page 3557) *required method*
  Sets the option dictionary that maps event trigger keys to animation objects. (required)
- `animationForKey:` (page 3555) *required method*
  Returns the animation that should be performed for the specified key. (required)
+ `defaultAnimationForKey:` (page 3554) *required method*
  Returns the default animation that should be performed for the specified key. (required)

Class Methods

defaultAnimationForKey:

Returns the default animation that should be performed for the specified key. (required)

```
+ (id)defaultAnimationForKey:(NSString *)key
```

Parameters

key

The action name or property specified as a string.

Return Value

The animation to perform. A subclass of `CAAnimation`.

Discussion

The `NSAnimatablePropertyContainer` (page 3553) method consults this class method when its search of the receivers `"Getting the Animator Proxy"` (page 3553) dictionary fails to return an animation for *key*.

An animatable property container should implement this method to return a default animation to be performed for each key that it wants to make auto-animatable, where *key* usually references a property of the receiver, but can also specify a special animation trigger (`NSAnimationTriggerOrderIn` (page 3557) or `NSAnimationTriggerOrderOut` (page 3557)).

A developer implementing a custom view subclass, can enable automatic animation for properties by overriding this method, and having it return the desired default `CAAnimation` subclass to use for each of the property keys of interest. The override should defer to super for any keys it doesn't specifically handle, facilitating inheritance of default animation specifications. The following is an example of such an implementation.

```
@implementation MyView
+ (id)defaultAnimationForKey:(NSString *)key {
    if ([key isEqualToString:@"borderColor"]) {
        // By default, animate border color changes with simple linear
interpolation to the new color value.
        return [CABasicAnimation animation];
    } else {
        // Defer to super's implementation for any keys we don't specifically
handle.
```

```
        return [super defaultAnimationForKey:key];
    }
}
@end
```

Availability
Available in Mac OS X v10.5 and later.

Declared In
NSAnimation.h

Instance Methods

animationForKey:

Returns the animation that should be performed for the specified key. (required)

```
- (id)animationForKey:(NSString *)key
```

Parameters

key
The action name or property specified as a string.

Return Value
The animation to perform. A subclass of `CAAnimation`.

Discussion
When the action specified by *key* is triggered for an object, this method is consulted to find the animation, if any, that should be performed in response.

Like its Core Animation `CALayer` counterpart, `actionForKey:`, this method is a funnel point that defines the order in which the search for an animation proceeds.It first checks the receiver's "Getting the Animator Proxy" (page 3553) dictionary for a value matching *key*, then falls back to `animator` (page 3556) for the receiver's class.

Subclasses should not typically need to override this method.

Availability
Available in Mac OS X v10.5 and later.

See Also
`- animator` (page 3556)
"Managing Animations for Properties" (page 3554)
"Getting the Animator Proxy" (page 3553)

Declared In
NSAnimation.h

animations

Returns the optional dictionary that maps event trigger keys to animation objects. (required)

```
- (NSDictionary *)animations
```

Return Value
The animations as a dictionary.

Discussion
When an action occurs that may trigger an animation the `NSAnimatablePropertyContainer` (page 3553) method first looks in this dictionary for an animation that matches the key. Typically, the key will name a property of the object whose value has just changed, but it may specify a special event trigger (`NSAnimationTriggerOrderIn` (page 3557) or `NSAnimationTriggerOrderOut` (page 3557)).

Availability
Available in Mac OS X v10.5 and later.

`- animator` (page 3556)
"Managing Animations for Properties" (page 3554)

Declared In
`NSAnimation.h`

animator

Returns a proxy object for the receiver that can be used to initiate implied animation for property changes. (required)

```
- (id)animator
```

Return Value
Returns a proxy object for the receiver that can initiate implied animations in response to property changes.

Discussion
The animator proxy object should be treated as if it was the receiver itself, and may be passed to any code that accepts the receiver as a parameter.

Sending key-value coding compliant "set" messages to the proxy will trigger animation for automatically animated properties of its target object, if the active `NSAnimationContext` in the current thread has a duration value greater than zero, and an animation for the property key is found by the `NSAnimatablePropertyContainer` (page 3553) search mechanism.

Availability
Available in Mac OS X v10.5 and later.

Constants

Transition Animation Keys

The following constants define the keys that reference the transitions used as views are made visible and hidden.

```
NSString *NSAnimationTriggerOrderIn;
NSString *NSAnimationTriggerOrderOut;
```

Constants

NSAnimationTriggerOrderIn

The key that references the transition animation used when a view becomes visible, either as a result of being inserted into the visible view hierarchy or as a result of the view no longer being set as hidden .

Available in Mac OS X v10.5 and later.

Declared in NSAnimation.h.

NSAnimationTriggerOrderOut

The key that references the transition animation used when a view is no longer visible, either as a result of being removed from the visible view hierarchy or as a result of the view set as hidden.

Available in Mac OS X v10.5 and later.

Declared in NSAnimation.h.

Overview

The `NSAnimationDelegate` protocol defines the optional methods implemented by delegates of `NSAnimation` objects.

Tasks

Controlling and Monitoring an Animation

- `animationDidEnd:` (page 3561)
  Sent to the delegate when the specified animation completes its run.
- `animationDidStop:` (page 3561)
  Sent to the delegate when the specified animation is stopped before it completes its run.
- `animationShouldStart:` (page 3562)
  Sent to the delegate just after an animation is started.
- `animation:valueForProgress:` (page 3560)
  Requests a custom curve value for the current progress value.

Managing Progress Marks

- `animation:didReachProgressMark:` (page 3560)
  Sent to the delegate when an animation reaches a specific progress mark.

Instance Methods

animation:didReachProgressMark:

Sent to the delegate when an animation reaches a specific progress mark.

```
- (void)animation:(NSAnimation *)animation
    didReachProgressMark:(NSAnimationProgress)progress
```

Parameters

animation

A running `NSAnimation` object that has reached a progress mark.

progress

A `float` value (typed as `NSAnimationProgress`) that indicates a progress mark of `animation`.

Discussion

The delegate typically implements this method to perform some animation effect for the time slice indicated by *progress*, such as redrawing objects in a view with new coordinates or changing the frame location or size of a window or view. As an alternative to this delegation message, you may choose to observe the `NSAnimationProgressMarkNotification` (page 116) notification.

Availability

Available in Mac OS X v10.4 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

`NSAnimation.h`

animation:valueForProgress:

Requests a custom curve value for the current progress value.

```
- (float)animation:(NSAnimation *)animation
    valueForProgress:(NSAnimationProgress)progress
```

Parameters

animation

An `NSAnimation` object that is running.

progress

A `float` value (typed as `NSAnimationProgress`) that indicates a progress mark of `animation`. This value is always between 0.0 and 1.0.

Return Value

A `float` value representing a custom curve.

Discussion

The delegate can compute and return a custom curve value for the given progress value. If the delegate does not implement this method, `NSAnimation` computes the current curve value.

The `animation:valueForProgress:` message is sent to the delegate when an `NSAnimation` object receives a `currentValue` (page 104) message. The value the delegate returns is used as the value of `currentValue` (page 104); if there is no delegate, or it doesn't implement `animation:valueForProgress:`, `NSAnimation` computes and returns the current value. `NSAnimation` does not invoke `currentValue` (page 104)itself, but subclasses might.

See the description of `currentValue` (page 104) for more information.

Availability
Available in Mac OS X v10.4 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
- `currentValue` (page 104) (NSAnimation)

Declared In
`NSAnimation.h`

animationDidEnd:

Sent to the delegate when the specified animation completes its run.

```
- (void)animationDidEnd:(NSAnimation *)animation
```

Parameters
animation
The `NSAnimation` instance that completed its run.

Discussion
When an `NSAnimation` object reaches the end of its planned duration, it has a progress value of 1.0.

Availability
Available in Mac OS X v10.4 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
- `animationDidStop:` (page 3561)
- `currentProgress` (page 104)

Declared In
`NSAnimation.h`

animationDidStop:

Sent to the delegate when the specified animation is stopped before it completes its run.

```
- (void)animationDidStop:(NSAnimation *)animation
```

Parameters
animation
The `NSAnimation` instance that was stopped.

Discussion
An `NSAnimation` object stops running when it receives a `stopAnimation` (page 112) message.

Availability
Available in Mac OS X v10.4 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
`- animationDidEnd:` (page 3561)

Declared In
`NSAnimation.h`

animationShouldStart:

Sent to the delegate just after an animation is started.

```
- (BOOL)animationShouldStart:(NSAnimation *)animation
```

Parameters

animation
The `NSAnimation` object that was just started.

Return Value
`NO` to cancel the animation, `YES` to have the animation proceed.

Discussion
The delegate is sent this message just after *animation* receives a `startAnimation` (page 111) message. The delegate can use this method to prepare objects and resources for the effect.

Availability
Available in Mac OS X v10.4 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Overview

The `NSApplicationDelegate` protocol defines the optional methods implemented by delegates of `NSApplication` objects.

Tasks

Launching Applications

`- applicationWillFinishLaunching:` (page 3578)
Sent by the default notification center immediately before the application object is initialized.

`- applicationDidFinishLaunching:` (page 3571)
Sent by the default notification center after the application has been launched and initialized but before it has received its first event.

Terminating Applications

- `applicationShouldTerminate:` (page 3576)
  Sent to notify the delegate that the application is about to terminate.
- `applicationShouldTerminateAfterLastWindowClosed:` (page 3577)
  Invoked when the user closes the last window the application has open.
- `applicationWillTerminate:` (page 3579)
  Sent by the default notification center immediately before the application terminates.

Managing Active Status

- `applicationWillBecomeActive:` (page 3577)
  Sent by the default notification center immediately before the application becomes active.
- `applicationDidBecomeActive:` (page 3570)
  Sent by the default notification center immediately after the application becomes active.
- `applicationWillResignActive:` (page 3578)
  Sent by the default notification center immediately before the application is deactivated.
- `applicationDidResignActive:` (page 3572)
  Sent by the default notification center immediately after the application is deactivated.

Hiding Applications

- `applicationWillHide:` (page 3578)
  Sent by the default notification center immediately before the application is hidden.
- `applicationDidHide:` (page 3572)
  Sent by the default notification center immediately after the application is hidden.
- `applicationWillUnhide:` (page 3579)
  Sent by the default notification center immediately after the application is unhidden.
- `applicationDidUnhide:` (page 3573)
  Sent by the default notification center immediately after the application is made visible.

Managing Windows

- `applicationWillUpdate:` (page 3580)
  Sent by the default notification center immediately before the application object updates its windows.
- `applicationDidUpdate:` (page 3573)
  Sent by the default notification center immediately after the application object updates its windows.
- `applicationShouldHandleReopen:hasVisibleWindows:` (page 3575)
  Sent by the application to the delegate prior to default behavior to reopen (`rapp`) AppleEvents.

Managing the Dock Menu

- `applicationDockMenu:` (page 3573)
  Allows the delegate to supply a dock menu for the application dynamically.

Displaying Errors

- `application:willPresentError:` (page 3570)
  Sent to the delegate before the specified application presents an error message to the user.

Managing the Screen

- `applicationDidChangeScreenParameters:` (page 3571)
  Sent by the default notification center when the configuration of the displays attached to the computer is changed (either programmatically or when the user changes settings in the Displays control panel).

Opening Files

- `application:openFile:` (page 3566)
  Tells the delegate to open a single file.
- `application:openFileWithoutUI:` (page 3567)
  Tells the delegate to open a file programmatically.
- `application:openTempFile:` (page 3567)
  Tells the delegate to open a temporary file.
- `application:openFiles:` (page 3566)
  Tells the delegate to open multiple files.
- `applicationOpenUntitledFile:` (page 3574)
  Tells the delegate to open an untitled file.
- `applicationShouldOpenUntitledFile:` (page 3575)
  Invoked immediately before opening an untitled file.

Printing

- `application:printFile:` (page 3568)
  Sent when the user starts up the application on the command line with the `-NSPrint` option.
- `application:printFiles:withSettings:showPrintPanels:` (page 3569)
  Prints a group of files.

Instance Methods

application:openFile:

Tells the delegate to open a single file.

```
- (BOOL)application:(NSApplication *)theApplication openFile:(NSString *)filename
```

Parameters

theApplication

The application object associated with the delegate.

filename

The name of the file to open.

Return Value

YES if the file was successfully opened or NO if it was not.

Discussion

Sent directly by *theApplication* to the delegate. The method should open the file *filename*, returning YES if the file is successfully opened, and NO otherwise. If the user started up the application by double-clicking a file, the delegate receives the application:openFile: (page 3566) message before receiving applicationDidFinishLaunching: (page 3571). (applicationWillFinishLaunching: (page 3578) is sent before application:openFile: (page 3566).)

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

See Also

- application:openFileWithoutUI: (page 3567)
- application:openTempFile: (page 3567)
- applicationOpenUntitledFile: (page 3574)

Related Sample Code

TextSizingExample

Declared In

NSApplication.h

application:openFiles:

Tells the delegate to open multiple files.

```
- (void)application:(NSApplication *)sender openFiles:(NSArray *)filenames
```

Parameters

sender

The application object associated with the delegate.

filenames

An array of NSString objects containing the names of the files to open..

Discussion
Identical to `application:openFile:` (page 3566) except that the receiver opens multiple files corresponding to the file names in the *filenames* array. Delegates should invoke the `replyToOpenOrPrint:` (page 161) method upon success or failure, or when the user cancels the operation.

Availability
Available in Mac OS X v10.3 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSApplication.h

application:openFileWithoutUI:

Tells the delegate to open a file programmatically.

```
- (BOOL)application:(id)sender openFileWithoutUI:(NSString *)filename
```

Parameters

sender
The object that sent the command.

filename
The name of the file to open.

Return Value
`YES` if the file was successfully opened or `NO` if it was not.

Discussion
Sent directly by *sender* to the delegate to request that the file *filename* be opened as a linked file. The method should open the file without bringing up its application's user interface—that is, work with the file is under programmatic control of *sender*, rather than under keyboard control of the user.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
- `application:openFile:` (page 3566)
- `application:openTempFile:` (page 3567)
- `applicationOpenUntitledFile:` (page 3574)
- `application:printFile:` (page 3568)

Declared In
NSApplication.h

application:openTempFile:

Tells the delegate to open a temporary file.

```
- (BOOL)application:(NSApplication *)theApplication openTempFile:(NSString *)filename
```

Parameters

theApplication

The application object associated with the delegate.

filename

The name of the temporary file to open.

Return Value

YES if the file was successfully opened or NO if it was not.

Discussion

Sent directly by *theApplication* to the delegate. The method should attempt to open the file *filename*, returning YES if the file is successfully opened, and NO otherwise.

By design, a file opened through this method is assumed to be temporary—it's the application's responsibility to remove the file at the appropriate time.

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

See Also

- application:openFile: (page 3566)
- application:openFileWithoutUI: (page 3567)
- applicationOpenUntitledFile: (page 3574)

Declared In

NSApplication.h

application:printFile:

Sent when the user starts up the application on the command line with the -NSPrint option.

```
- (BOOL)application:(NSApplication *)theApplication printFile:(NSString *)filename
```

Parameters

theApplication

The application object that is handling the printing.

filename

The name of the file to print.

Return Value

YES if the file was successfully printed or NO if it was not.

Discussion

This message is sent directly by *theApplication* to the delegate. The application terminates (using the terminate: (page 176) method) after this method returns.

If at all possible, this method should print the file without displaying the user interface. For example, if you pass the -NSPrint option to the TextEdit application, TextEdit assumes you want to print the entire contents of the specified file. However, if the application opens more complex documents, you may want to display a panel that lets the user choose exactly what they want to print.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
`- application:openFileWithoutUI:` (page 3567)

Declared In
`NSApplication.h`

application:printFiles:withSettings:showPrintPanels:

Prints a group of files.

```
- (NSApplicationPrintReply)application:(NSApplication *)application
    printFiles:(NSArray *)fileNames withSettings:(NSDictionary *)printSettings
    showPrintPanels:(BOOL)showPrintPanels
```

Parameters

application
The application object that is handling the printing.

fileNames
An array of `NSString` objects, each of which contains the name of a file to print.

printSettings
A dictionary containing `NSPrintInfo`-compatible print job attributes.

showPrintPanels
A Boolean that specifies whether the print panel should be displayed for each file printed. Print progress indicators will be presented even if this value is `NO`.

Return Value
A constant indicating whether printing was successful. For a list of possible values, see "NSApplicationPrintReply" (page 189).

Discussion
Return `NSPrintingReplyLater` if the result of printing cannot be returned immediately, for example, if printing will cause the presentation of a sheet. If your method returns `NSPrintingReplyLater` it must always invoke the `NSApplication` method `replyToOpenOrPrint:` (page 161)] when the entire print operation has been completed, successfully or not.

This delegate method replaces `application:printFiles:`, which is now deprecated. If your application delegate only implements the deprecated method, it is still invoked, and `NSApplication` uses private functionality to arrange for the print settings to take effect.

Availability
Available in Mac OS X v10.4 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSApplication.h`

application:willPresentError:

Sent to the delegate before the specified application presents an error message to the user.

```
- (NSError *)application:(NSApplication *)application willPresentError:(NSError
    *)error
```

Parameters

application

The application object associated with the delegate.

error

The error object that is used to construct the error message. Your implementation of this method can return a new `NSError` object or the same one in this parameter.

Return Value
The error object to display.

Discussion
You can implement this delegate method to customize the presentation of any error presented by your application, as long as no code in your application overrides either of the `NSResponder` methods `presentError:modalForWindow:delegate:didPresentSelector:contextInfo:` or `presentError:` in a way that prevents errors from being passed down the responder chain to the application object.

Your implementation of this delegate method can examine *error* and, if its localized description or recovery information is unhelpfully generic, return an error object with specific localized text that is more suitable for presentation in alert sheets and dialogs. If you do this, always use the domain and error code of the `NSError` object to distinguish between errors whose presentation you want to customize and those you do not. Don't make decisions based on the localized description, recovery suggestion, or recovery options because parsing localized text is problematic. If you decide not to customize the error presentation, just return the passed-in error object.

Availability
Available in Mac OS X v10.4 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSApplication.h`

applicationDidBecomeActive:

Sent by the default notification center immediately after the application becomes active.

```
- (void)applicationDidBecomeActive:(NSNotification *)aNotification
```

Parameters

aNotification

A notification named `NSApplicationDidBecomeActiveNotification` (page 193). Calling the `object` method of this notification returns the `NSApplication` object itself.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
- `applicationDidFinishLaunching:` (page 3571)
- `applicationDidResignActive:` (page 3572)
- `applicationWillBecomeActive:` (page 3577)

Declared In
`NSApplication.h`

applicationDidChangeScreenParameters:

Sent by the default notification center when the configuration of the displays attached to the computer is changed (either programmatically or when the user changes settings in the Displays control panel).

```
- (void)applicationDidChangeScreenParameters:(NSNotification *)aNotification
```

Parameters

aNotification

A notification named `NSApplicationDidChangeScreenParametersNotification` (page 194). Calling the `object` method of this notification returns the `NSApplication` object itself.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSApplication.h`

applicationDidFinishLaunching:

Sent by the default notification center after the application has been launched and initialized but before it has received its first event.

```
- (void)applicationDidFinishLaunching:(NSNotification *)aNotification
```

Parameters

aNotification

A notification named `NSApplicationDidFinishLaunchingNotification` (page 194). Calling the `object` method of this notification returns the `NSApplication` object itself.

Discussion
Delegates can implement this method to perform further initialization. This method is called after the application's main run loop has been started but before it has processed any events. If the application was launched by the user opening a file, the delegate's `application:openFile:` method is called before this method. If you want to perform initialization before any files are opened, implement the `applicationWillFinishLaunching:` (page 3578) method in your delegate, which is called before `application:openFile:`.)

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also

Declared In
`NSApplication.h`

applicationDidHide:

Sent by the default notification center immediately after the application is hidden.

```
- (void)applicationDidHide:(NSNotification *)aNotification
```

Parameters

aNotification

A notification named `NSApplicationDidHideNotification` (page 194). Calling the `object` method of this notification returns the `NSApplication` object itself.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
- `applicationWillHide:` (page 3578)

applicationDidResignActive:

Sent by the default notification center immediately after the application is deactivated.

```
- (void)applicationDidResignActive:(NSNotification *)aNotification
```

Parameters

aNotification

A notification named `NSApplicationDidResignActiveNotification` (page 194). Calling the `object` method of this notification returns the `NSApplication` object itself.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
- `applicationDidBecomeActive:` (page 3570)
- `applicationWillResignActive:` (page 3578)

Declared In
NSApplication.h

applicationDidUnhide:

Sent by the default notification center immediately after the application is made visible.

```
- (void)applicationDidUnhide:(NSNotification *)aNotification
```

Parameters

aNotification

A notification named `NSApplicationDidUnhideNotification` (page 195). Calling the `object` method of this notification returns the `NSApplication` object itself.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
- `applicationDidHide:` (page 3572)

Declared In
NSApplication.h

applicationDidUpdate:

Sent by the default notification center immediately after the application object updates its windows.

```
- (void)applicationDidUpdate:(NSNotification *)aNotification
```

Parameters

aNotification

A notification named `NSApplicationDidUpdateNotification` (page 195). Calling the `object` method of this notification returns the `NSApplication` object itself.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
- `applicationWillUpdate:` (page 3580)
- `updateWindows` (page 179) (NSApplication)

Declared In
NSApplication.h

applicationDockMenu:

Allows the delegate to supply a dock menu for the application dynamically.

```
- (NSMenu *)applicationDockMenu:(NSApplication *)sender
```

Parameters

sender

The application object associated with the delegate.

Return Value

The menu to display in the dock.

Discussion

You can also connect a menu in Interface Builder to the `dockMenu` outlet. A third way for your application to specify a dock menu is to provide an `NSMenu` in a nib.

If this method returns a menu, this menu takes precedence over the `dockMenu` in the nib.

The target and action for each menu item are passed to the dock. On selection of the menu item the dock messages your application, which should invoke `[NSApp sendAction:selector to:target from:nil]`.

To specify an `NSMenu` in a nib, you add the nib name to the `info.plist`, using the key `AppleDockMenu`. The nib name is specified without an extension. You then create a connection from the file's owner object (which by default is `NSApplication`) to the menu. Connect the menu to the `dockMenu` outlet of `NSApplication`. The menu is in its own nib file so it can be loaded lazily when the `dockMenu` is requested, rather than at launch time.

Availability

Available in Mac OS X v10.1 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

`NSApplication.h`

applicationOpenUntitledFile:

Tells the delegate to open an untitled file.

```
- (BOOL)applicationOpenUntitledFile:(NSApplication *)theApplication
```

Parameters

theApplication

The application object associated with the delegate.

Return Value

`YES` if the file was successfully opened or `NO` if it was not.

Discussion

Sent directly by *theApplication* to the delegate to request that a new, untitled file be opened.

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

See Also

- `application:openFile:` (page 3566)
- `application:openFileWithoutUI:` (page 3567)
- `application:openTempFile:` (page 3567)

Declared In
NSApplication.h

applicationShouldHandleReopen:hasVisibleWindows:

Sent by the application to the delegate prior to default behavior to reopen (rapp) AppleEvents.

```
- (BOOL)applicationShouldHandleReopen:(NSApplication *)theApplication
    hasVisibleWindows:(BOOL)flag
```

Parameters

theApplication
The application object.

flag
Indicates whether the NSApplication object found any visible windows in your application. You can use this value as an indication of whether the application would do anything if you return YES.

Return Value
YES if you want the application to perform its normal tasks or NO if you want the application to do nothing.

Discussion
These events are sent whenever the Finder reactivates an already running application because someone double-clicked it again or used the dock to activate it.

By default the Application Kit will handle this event by checking whether there are any visible NSWindow (not NSPanel) objects, and, if there are none, it goes through the standard untitled document creation (the same as it does if *theApplication* is launched without any document to open). For most document-based applications, an untitled document will be created.

The application delegate will also get a chance to respond to the normal untitled document delegate methods. If you implement this method in your application delegate, it will be called before any of the default behavior happens. If you return YES, then NSApplication will proceed as normal. If you return NO, then NSApplication will do nothing. So, you can either implement this method with a version that does nothing, and return NO if you do not want anything to happen at all (not recommended), or you can implement this method, handle the event yourself in some custom way, and return NO.

Miniaturized windows, windows in the Dock, are considered visible by this method, and cause *flag* to return YES, despite the fact that miniaturized windows return NO when sent an isVisible (page 3342) message.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSApplication.h

applicationShouldOpenUntitledFile:

Invoked immediately before opening an untitled file.

```
- (BOOL)applicationShouldOpenUntitledFile:(NSApplication *)sender
```

Parameters

sender

The application object associated with the delegate.

Return Value

YES if the application should open a new untitled file or NO if it should not.

Discussion

Use this method to decide whether the application should open a new, untitled file. Note that applicationOpenUntitledFile: (page 3574) is invoked if this method returns YES.

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

NSApplication.h

applicationShouldTerminate:

Sent to notify the delegate that the application is about to terminate.

```
- (NSApplicationTerminateReply)applicationShouldTerminate:(NSApplication *)sender
```

Parameters

sender

The application object that is about to be terminated.

Return Value

One of the values defined in NSApplicationTerminateReply (page 189) constants indicating whether the application should terminate. For compatibility reasons, a return value of NO is equivalent to NSTerminateCancel (page 189), and a return value of YES is equivalent to NSTerminateNow (page 189).

Discussion

This method is called after the application's Quit menu item has been selected, or after the terminate: (page 176) method has been called. Generally, you should return NSTerminateNow (page 189) to allow the termination to complete, but you can cancel the termination process or delay it somewhat as needed. For example, you might delay termination to finish processing some critical data but then terminate the application as soon as you are done by calling the replyToApplicationShouldTerminate: (page 160) method.

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

See Also

- terminate: (page 176) (NSApplication)
- applicationShouldTerminateAfterLastWindowClosed: (page 3577)
- applicationWillTerminate: (page 3579)

Declared In

NSApplication.h

applicationShouldTerminateAfterLastWindowClosed:

Invoked when the user closes the last window the application has open.

```
- (BOOL)applicationShouldTerminateAfterLastWindowClosed:(NSApplication
    *)theApplication
```

Parameters

theApplication

The application object whose last window was closed.

Return Value

`NO` if the application should not be terminated when its last window is closed; otherwise, `YES` to terminate the application.

Discussion

The application sends this message to your delegate when the application's last window is closed. It sends this message regardless of whether there are still panels open. (A panel in this case is defined as being an instance of `NSPanel` or one of its subclasses.)

If your implementation returns `NO`, control returns to the main event loop and the application is not terminated. If you return `YES`, your delegate's `applicationShouldTerminate:` method is subsequently invoked to confirm that the application should be terminated.

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

See Also

- `terminate:` (page 176)

Declared In

`NSApplication.h`

applicationWillBecomeActive:

Sent by the default notification center immediately before the application becomes active.

```
- (void)applicationWillBecomeActive:(NSNotification *)aNotification
```

Parameters

aNotification

A notification named `NSApplicationWillBecomeActiveNotification` (page 195). Calling the `object` method of this notification returns the `NSApplication` object itself.

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

See Also

- `applicationDidBecomeActive:` (page 3570)
- `applicationWillFinishLaunching:` (page 3578)
- `applicationWillResignActive:` (page 3578)

Declared In
NSApplication.h

applicationWillFinishLaunching:

Sent by the default notification center immediately before the application object is initialized.

```
- (void)applicationWillFinishLaunching:(NSNotification *)aNotification
```

Parameters

aNotification

A notification named NSApplicationWillFinishLaunchingNotification (page 195). Calling the object method of this notification returns the NSApplication object itself.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
- applicationDidFinishLaunching: (page 3571)
- applicationWillBecomeActive: (page 3577)
- finishLaunching (page 147) (NSApplication)

Declared In
NSApplication.h

applicationWillHide:

Sent by the default notification center immediately before the application is hidden.

```
- (void)applicationWillHide:(NSNotification *)aNotification
```

Parameters

aNotification

A notification named NSApplicationWillHideNotification (page 195). Calling the object method of this notification returns the NSApplication object itself.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
- applicationDidHide: (page 3572)
- hide: (page 148) (NSApplication)

Declared In
NSApplication.h

applicationWillResignActive:

Sent by the default notification center immediately before the application is deactivated.

```
- (void)applicationWillResignActive:(NSNotification *)aNotification
```

Parameters

aNotification

A notification named `NSApplicationWillResignActiveNotification` (page 196). Calling the `object` method of this notification returns the `NSApplication` object itself.

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

See Also

- `applicationWillBecomeActive:` (page 3577)
- `applicationDidResignActive:` (page 3572)

Declared In

`NSApplication.h`

applicationWillTerminate:

Sent by the default notification center immediately before the application terminates.

```
- (void)applicationWillTerminate:(NSNotification *)aNotification
```

Parameters

aNotification

A notification named `NSApplicationWillTerminateNotification` (page 196). Calling the `object` method of this notification returns the `NSApplication` object itself.

Discussion

Your delegate can use this method to perform any final cleanup before the application terminates.

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

See Also

- `applicationShouldTerminate:` (page 3576)
- `terminate:` (page 176) (NSApplication)

Declared In

`NSApplication.h`

applicationWillUnhide:

Sent by the default notification center immediately after the application is unhidden.

```
- (void)applicationWillUnhide:(NSNotification *)aNotification
```

Parameters

aNotification

A notification named `NSApplicationWillUnhideNotification` (page 196). Calling the `object` method of this notification returns the `NSApplication` object itself.

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

See Also

- `unhide:` (page 177) (NSApplication)
- `applicationDidUnhide:` (page 3573)
- `applicationWillHide:` (page 3578)

Declared In

`NSApplication.h`

applicationWillUpdate:

Sent by the default notification center immediately before the application object updates its windows.

```
- (void)applicationWillUpdate:(NSNotification *)aNotification
```

Parameters

aNotification

A notification named `NSApplicationWillUpdateNotification` (page 196). Calling the `object` method of this notification returns the `NSApplication` object itself.

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

See Also

- `applicationDidUpdate:` (page 3573)
- `updateWindows` (page 179) (NSApplication)

Declared In

`NSApplication.h`

Overview

The `NSBrowserDelegate` protocol defines the method that a delegate of `NSBrowser` should implement.

Tasks

Getting Browser Information

- `browser:isColumnValid:` (page 3589)
  Returns whether the contents of the specified column are valid.
- `browser:numberOfRowsInColumn:` (page 3591)
  Returns the number of rows of data in the specified column.
- `browser:numberOfChildrenOfItem:` (page 3591)
  Asks the delegate for the number of children the given item has.
- `browser:titleOfColumn:` (page 3598)
  Asks the delegate for the title to display above the specified column.

Managing Selection Behavior

- `browser:shouldTypeSelectForEvent:withCurrentSearchString:` (page 3597)
  Sent to the delegate to determine whether keyboard-based selection (type select) for a given event and search string should proceed.

- `browser:typeSelectStringForRow:inColumn:` (page 3599)
  Sent to the delegate to get the keyboard-based selection (type select) string for the specified row and column.
- `browser:nextTypeSelectMatchFromRow:toRow:inColumn:forString:` (page 3590)
  Sent to the delegate to customize a browser's keyboard-based selection (type select) behavior.

Managing Selection

- `browser:selectCellWithString:inColumn:` (page 3593)
  Asks the delegate to select the cell with the given title in the specified column.
- `browser:selectRow:inColumn:` (page 3594)
  Asks the delegate to select the cell at the specified row and column location.
- `browser:selectionIndexesForProposedSelection:inColumn:` (page 3594)
  Asks the delegate for a set of indexes to select when the user changes the selection in the browser with the keyboard or mouse.

Accessing Components

- `browser:child:ofItem:` (page 3585)
  Asks the delegate to return the child of the specified item at the specified index.
- `browser:isLeafItem:` (page 3589)
  Asks the delegate whether the specified item is a leaf item (an item that cannot be expanded).
- `browser:shouldEditItem:` (page 3595)
  Asks the delegate whether the browser may start an editing session for the specified item.
- `browser:objectValueForItem:` (page 3592)
  Returns the object that the specified item uses to draw its contents.
- `browser:setObjectValue:forItem:` (page 3595)
  Sets the object that the specified item uses to draw its contents to the specified object.
- `rootItemForBrowser:` (page 3603)
  Asks the delegate to return the root item of the browser.
- `browser:previewViewControllerForLeafItem:` (page 3592)
  Asks the delegate for a controller that provides a preview column for the specified leaf item.
- `browser:headerViewControllerForItem:` (page 3587)
  Asks the delegate for a controller that provides a header view for the specified column item.

Managing Columns

- `browser:createRowsForColumn:inMatrix:` (page 3586)
  Creates a row in the given matrix for each row of data in the specified column of the browser.
- `browser:willDisplayCell:atRow:column:` (page 3601)
  Gives the delegate the opportunity to modify the specified cell at the given row and column location before the browser displays it.

- `browser:didChangeLastColumn:toColumn:` (page 3586)
  Tells the delegate that the browser's last column changed.

Scrolling

- `browserWillScroll:` (page 3603)
  Notifies the delegate when the browser will scroll.
- `browserDidScroll:` (page 3603)
  Notifies the delegate when the browser has scrolled.

Dragging

- `browser:canDragRowsWithIndexes:inColumn:withEvent:` (page 3585)
  Sent to the delegate to determine whether the browser can attempt to initiate a drag of the specified rows for the specified event.
- `browser:draggingImageForRowsWithIndexes:inColumn:withEvent:offset:` (page 3587)
  Sent to the delegate to obtain an image to represent dragged rows during a drag operation on a browser.
- `browser:validateDrop:proposedRow:column:dropOperation:` (page 3600)
  Sent to the delegate during a dragging session to determine whether a drop should be accepted and to obtain the drop location. This method is required for a browser to be a drag destination.
- `browser:acceptDrop:atRow:column:dropOperation:` (page 3584)
  Sent to the delegate during a dragging session to determine whether to accept the drop.
- `browser:writeRowsWithIndexes:inColumn:toPasteboard:` (page 3602)
  Determines whether a drag operation can proceed. This method is required for a browser to be a drag source.
- `browser:namesOfPromisedFilesDroppedAtDestination:forDraggedRowsWithIndexes:inColumn:` (page 3589)
  Implements file promise drag operations.

Sizing

- `browser:shouldSizeColumn:forUserResize:toWidth:` (page 3596)
  Used to determine a column's initial size.
- `browser:sizeToFitWidthOfColumn:` (page 3598)
  Returns the ideal width for a column.
- `browserColumnConfigurationDidChange:` (page 3602)
  Used by clients to implement their own column width persistence.
- `browser:heightOfRow:inColumn:` (page 3588)
  Specifies the height of the specified row in the specified column.

Displaying Cell Content

`- browser:shouldShowCellExpansionForRow:column:` (page 3596)
Invoked to allow the delegate to control cell expansion for a specific row and column.

Instance Methods

browser:acceptDrop:atRow:column:dropOperation:

Sent to the delegate during a dragging session to determine whether to accept the drop.

```
- (BOOL)browser:(NSBrowser *)browser
    acceptDrop:(id <NSDraggingInfo>)info
    atRow:(NSInteger)row
    column:(NSInteger)column
    dropOperation:(NSBrowserDropOperation)dropOperation
```

Parameters

browser
The browser.

info
The drag session information.

row
The drop row.

column
The drop column.

dropOperation
The drop location relative to *row*.

Return Value
`YES` to accept the drop; `NO` to decline it.

Discussion
This method is required for a browser to be a drag destination. It is invoked after the `browser:validateDrop:proposedRow:column:dropOperation:` (page 3600) method allows the drop.

The delegate should incorporate the pasteboard data from the dragging session (*info*`.draggingPasteboard`).

Availability
Available in Mac OS X v10.5 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSBrowser.h`

browser:canDragRowsWithIndexes:inColumn:withEvent:

Sent to the delegate to determine whether the browser can attempt to initiate a drag of the specified rows for the specified event.

```
- (BOOL)browser:(NSBrowser *)browser
    canDragRowsWithIndexes:(NSIndexSet *)rowIndexes
    inColumn:(NSInteger)column
    withEvent:(NSEvent *)event
```

Parameters

browser
The browser.

rowIndexes
The rows the user is dragging.

column
The column containing the rows the user is dragging.

event
The drag event.

Return Value
`YES` to allow the drag operation; `NO` to disallow it.

Availability
Available in Mac OS X v10.5 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
`- canDragRowsWithIndexes:inColumn:withEvent:` (page 407) (`NSBrowser`)

Declared In
`NSBrowser.h`

browser:child:ofItem:

Asks the delegate to return the child of the specified item at the specified index.

```
- (id)browser:(NSBrowser *)browser
    child:(NSInteger)index
    ofItem:(id)item
```

Parameters

browser
The browser.

index
The child's index.

item
The item containing the child.

Return Value
The child at the specified index.

Availability
Available in Mac OS X v10.6 and later.

Declared In
NSBrowser.h

browser:createRowsForColumn:inMatrix:

Creates a row in the given matrix for each row of data in the specified column of the browser.

```
- (void)browser:(NSBrowser *)sender
    createRowsForColumn:(NSInteger)column
    inMatrix:(NSMatrix *)matrix
```

Parameters

sender
The browser.

column
The index of the column in which the rows are located.

matrix
The matrix in which the rows are created.

Discussion
Either this method or `browser:numberOfRowsInColumn:` (page 3591) must be implemented, but not both, or an `NSBrowserIllegalDelegateException` will be raised.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
`- browser:willDisplayCell:atRow:column:` (page 3601)

Declared In
NSBrowser.h

browser:didChangeLastColumn:toColumn:

Tells the delegate that the browser's last column changed.

```
- (void)browser:(NSBrowser *)browser
    didChangeLastColumn:(NSInteger)oldLastColumn
    toColumn:(NSInteger)column
```

Parameters

browser
The browser.

oldLastColumn
The index of the old last column.

column
The index of the new last column.

Availability
Available in Mac OS X v10.6 and later.

Declared In
NSBrowser.h

browser:draggingImageForRowsWithIndexes:inColumn:withEvent:offset:

Sent to the delegate to obtain an image to represent dragged rows during a drag operation on a browser.

```
- (NSImage *)browser:(NSBrowser *)browser
    draggingImageForRowsWithIndexes:(NSIndexSet *)rowIndexes
    inColumn:(NSInteger)column
    withEvent:(NSEvent *)event
    offset:(NSPointPointer)dragImageOffset
```

Parameters

browser
The browser.

rowIndexes
The indexes of the rows the user is dragging.

column
The column containing the rows the user is dragging.

event
The drag event.

dragImageOffset
The offset for the returned image:

- NSZeroPoint: Centers the image under the pointer.

Return Value
An image representing the visible rows identified by *rowIndexes*.

Availability
Available in Mac OS X v10.5 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
- draggingImageForRowsWithIndexes:inColumn:withEvent:offset: (page 413) (NSBrowser)

Declared In
NSBrowser.h

browser:headerViewControllerForItem:

Asks the delegate for a controller that provides a header view for the specified column item.

```
- (NSViewController *)browser:(NSBrowser *)browser
    headerViewControllerForItem:(id)item
```

Parameters

browser

The browser.

item

The column item.

Return Value

A view controller that provides a header view, or `nil` to omit the header view.

Discussion

The returned controller's represented object will be set to the column item. This method is called only if the delegate implements the item data source methods.

Availability

Available in Mac OS X v10.6 and later.

See Also

`- browser:previewViewControllerForLeafItem:` (page 3592)

Declared In

`NSBrowser.h`

browser:heightOfRow:inColumn:

Specifies the height of the specified row in the specified column.

```
- (CGFloat)browser:(NSBrowser *)browser
    heightOfRow:(NSInteger)row
    inColumn:(NSInteger)columnIndex
```

Parameters

browser

The browser.

row

The index of the row.

columnIndex

The index of the column.

Return Value

The height to set for the specified row, which must be greater than 0.

Discussion

The values returned for this method may be cached. Therefore, you should call `noteHeightOfRowsWithIndexesChanged:inColumn:` (page 423) to invalidate a row's height before changing it.

Availability

Available in Mac OS X v10.6 and later.

Declared In

`NSBrowser.h`

browser:isColumnValid:

Returns whether the contents of the specified column are valid.

```
- (BOOL)browser:(NSBrowser *)sender
    isColumnValid:(NSInteger)column
```

Parameters

sender

The browser containing the column to validate.

column

The index of the column to validate.

Return Value

`YES` if the column's contents are valid; otherwise, `NO`. If `NO` is returned, *sender* reloads the column.

Discussion

This method is invoked in response to the `validateVisibleColumns` (page 451)method of `NSBrowser` being sent to *sender*.

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

`NSBrowser.h`

browser:isLeafItem:

Asks the delegate whether the specified item is a leaf item (an item that cannot be expanded).

```
- (BOOL)browser:(NSBrowser *)browser
    isLeafItem:(id)item
```

Parameters

browser

The browser.

item

The item to be checked.

Return Value

`YES` if the specified item is a leaf item; otherwise, `NO`.

Availability

Available in Mac OS X v10.6 and later.

Declared In

`NSBrowser.h`

browser:namesOfPromisedFilesDroppedAtDestination:forDraggedRowsWithIndexes:inColumn:

Implements file promise drag operations.

```
- (NSArray *)browser:(NSBrowser *)browser
    namesOfPromisedFilesDroppedAtDestination:(NSURL *)dropDestination
    forDraggedRowsWithIndexes:(NSIndexSet *)rowIndexes
    inColumn:(NSInteger)column
```

Parameters

browser

The browser.

dropDestination

The drop filesystem location.

rowIndexes

The indexes of the rows the user is dropping.

column

The index of the column containing the rows the user is dropping.

Return Value

Filenames (not pathnames) for the actual files represented by the rows the user is dropping.

Discussion

Note that file promise drag operation support requires adding the data type `NSFilesPromisePboardType` to the pasteboard in the `browser:writeRowsWithIndexes:inColumn:toPasteboard:` (page 3602) method.

Availability

Available in Mac OS X v10.5 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

See Also

`- namesOfPromisedFilesDroppedAtDestination:` (page 423) (`NSBrowser`)

Related Sample Code

ZipBrowser

Declared In

`NSBrowser.h`

browser:nextTypeSelectMatchFromRow:toRow:inColumn:forString:

Sent to the delegate to customize a browser's keyboard-based selection (type select) behavior.

```
- (NSInteger)browser:(NSBrowser *)browser
    nextTypeSelectMatchFromRow:(NSInteger)startRow
    toRow:(NSInteger)endRow
    inColumn:(NSInteger)column
    forString:(NSString *)searchString
```

Parameters

browser

The browser.

startRow

The beginning of the row set to search.

endRow
The end of the row set to search. This value can be less than *startRowIndex* when the search wraps around to the beginning.

column
The column containing the rows being searched.

searchString
The keyboard-based selection string. It is `nil` when no keyboard-based selection has begun.

Return Value
The index of the first row that matches *searchString* between *startRowIndex* and *endRowIndex* - 1, or `-1` if there is no match.

Availability
Available in Mac OS X v10.5 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
- `browser:shouldTypeSelectForEvent:withCurrentSearchString:` (page 3597)
- `browser:typeSelectStringForRow:inColumn:` (page 3599)

Declared In
`NSBrowser.h`

browser:numberOfChildrenOfItem:

Asks the delegate for the number of children the given item has.

```
- (NSInteger)browser:(NSBrowser *)browser
    numberOfChildrenOfItem:(id)item
```

Parameters

browser
The browser.

item
The item that has some number of children.

Return Value
The number of children.

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSBrowser.h`

browser:numberOfRowsInColumn:

Returns the number of rows of data in the specified column.

```
- (NSInteger)browser:(NSBrowser *)sender
    numberOfRowsInColumn:(NSInteger)column
```

Parameters

sender

The browser.

column

The index of the column.

Return Value

The number of rows of data.

Discussion

Either this method or `browser:createRowsForColumn:inMatrix:` (page 3586) must be implemented, but not both.

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

See Also

`- browser:willDisplayCell:atRow:column:` (page 3601)

Declared In

`NSBrowser.h`

browser:objectValueForItem:

Returns the object that the specified item uses to draw its contents.

```
- (id)browser:(NSBrowser *)browser
    objectValueForItem:(id)item
```

Parameters

browser

The browser.

item

The item in question.

Return Value

The item's object.

Availability

Available in Mac OS X v10.6 and later.

See Also

`- browser:setObjectValue:forItem:` (page 3595)

Declared In

`NSBrowser.h`

browser:previewViewControllerForLeafItem:

Asks the delegate for a controller that provides a preview column for the specified leaf item.

```
- (NSViewController *)browser:(NSBrowser *)browser
    previewViewControllerForLeafItem:(id)item
```

Parameters

browser

The browser.

item

The leaf item.

Return Value

A view controller that provides a preview column, or `nil` to suppress the preview column.

Discussion

The returned controller's represented object is set to the specified leaf item. This method is called only if the delegate implements the item data source methods.

Availability

Available in Mac OS X v10.6 and later.

See Also

`- browser:headerViewControllerForItem:` (page 3587)

Declared In

`NSBrowser.h`

browser:selectCellWithString:inColumn:

Asks the delegate to select the cell with the given title in the specified column.

```
- (BOOL)browser:(NSBrowser *)sender
    selectCellWithString:(NSString *)title
    inColumn:(NSInteger)column
```

Parameters

sender

The browser.

title

The title of the cell to select.

column

The index of the column containing the cell to select.

Return Value

`YES` if the cell was successfully selected; otherwise, `NO`.

Discussion

Invoked in response to the `setPath:` (page 443) method of `NSBrowser` being received by *sender*.

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

See Also

`- selectedCellInColumn:` (page 430) (`NSBrowser`)

Declared In
NSBrowser.h

browser:selectionIndexesForProposedSelection:inColumn:

Asks the delegate for a set of indexes to select when the user changes the selection in the browser with the keyboard or mouse.

```
- (NSIndexSet *)browser:(NSBrowser *)browser
    selectionIndexesForProposedSelection:(NSIndexSet *)proposedSelectionIndexes
    inColumn:(NSInteger)column
```

Parameters

browser
The browser.

proposedSelectionIndexes
The set of indexes of the items in the proposed selection.

column
The column index of the column containing the selection.

Return Value
The set of indexes of the items that should be selected.

Discussion
This method may be called multiple times, with one new index added to the previous selection, to see whether a particular index can be selected when the user is extending the selection with the keyboard or mouse. The *proposedSelectionIndexes* parameter contains the entire selection, and you can return the existing selection if you do not want to change it. This method works only for item-based browsers.

Availability
Available in Mac OS X v10.6 and later.

Declared In
NSBrowser.h

browser:selectRow:inColumn:

Asks the delegate to select the cell at the specified row and column location.

```
- (BOOL)browser:(NSBrowser *)sender
    selectRow:(NSInteger)row
    inColumn:(NSInteger)column
```

Parameters

sender
The browser.

row
The index of the row containing the cell to select.

column
The index of the column containing the cell to select.

Return Value
`YES` if the cell was selected; otherwise, `NO`.

Discussion
Invoked in response to `selectRow:inColumn:` (page 433) of `NSBrowser` being received by *sender*.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
- `selectedRowInColumn:` (page 432) (`NSBrowser`)
- `selectRow:inColumn:` (page 433) (`NSBrowser`)

Declared In
`NSBrowser.h`

browser:setObjectValue:forItem:

Sets the object that the specified item uses to draw its contents to the specified object.

```
- (void)browser:(NSBrowser *)browser
    setObjectValue:(id)object
    forItem:(id)item
```

Parameters

browser
The browser.

object
The object to set.

item
The item whose object is set.

Availability
Available in Mac OS X v10.6 and later.

See Also
- `browser:objectValueForItem:` (page 3592)

Declared In
`NSBrowser.h`

browser:shouldEditItem:

Asks the delegate whether the browser may start an editing session for the specified item.

```
- (BOOL)browser:(NSBrowser *)browser
    shouldEditItem:(id)item
```

Parameters

browser
The browser.

item
The item to edit.

Return Value
YES to allow the editing session to begin; NO to disallow it.

Availability
Available in Mac OS X v10.6 and later.

Declared In
NSBrowser.h

browser:shouldShowCellExpansionForRow:column:

Invoked to allow the delegate to control cell expansion for a specific row and column.

```
- (BOOL)browser:(NSBrowser *)browser
    shouldShowCellExpansionForRow:(NSInteger)row
    column:(NSInteger)column
```

Parameters
browser
The browser.

row
The index of the row requesting an expansion tooltip.

column
The index of the column containing the requesting row.

Return Value
YES to allow the cell expansion tooltip; NO to disallow it.

Discussion
Cell expansion can occur when the mouse hovers over the specified cell and the cell contents are unable to be fully displayed within the cell. If this method returns YES, the full cell contents will be shown in a special floating tool tip view, otherwise the content is truncated.

Availability
Available in Mac OS X v10.5 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSBrowser.h

browser:shouldSizeColumn:forUserResize:toWidth:

Used to determine a column's initial size.

```
- (CGFloat)browser:(NSBrowser *)browser
    shouldSizeColumn:(NSInteger)columnIndex
    forUserResize:(BOOL)forUserResize
    toWidth:(CGFloat)suggestedWidth
```

Parameters

browser
The browser.

columnIndex
The index of the column to size.

forUserResize
Currently, this is always set to NO.

suggestedWidth
The suggested width for the column.

Return Value
The delegate's desired initial width for a newly added column. If you want to accept the suggested width, return *suggestedWidth*. If you return 0 or a size too small to display the resize handle and a portion of the column, the actual size used will be larger than the size you requested.

Discussion
This method applies only to browsers with resize type NSBrowserNoColumnResizing (page 452) or NSBrowserUserColumnResizing (page 452) (see NSBrowserColumnResizingType (page 451)).

Availability
Available in Mac OS X v10.3 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
- setWidth:ofColumn: (page 448) (NSBrowser)

Declared In
NSBrowser.h

browser:shouldTypeSelectForEvent:withCurrentSearchString:

Sent to the delegate to determine whether keyboard-based selection (type select) for a given event and search string should proceed.

```
- (BOOL)browser:(NSBrowser *)browser
    shouldTypeSelectForEvent:(NSEvent *)event
    withCurrentSearchString:(NSString *)searchString
```

Parameters

browser
The browser.

event
The keyboard event being processed.

searchString
The keyboard-based selection string. It is nil when no keyboard-based selection has begun.

Return Value
YES to allow the selection; NO to disallow it.

Availability
Available in Mac OS X v10.5 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
- `allowsTypeSelect` (page 405) (`NSBrowser`)

Declared In
`NSBrowser.h`

browser:sizeToFitWidthOfColumn:

Returns the ideal width for a column.

```
- (CGFloat)browser:(NSBrowser *)browser
    sizeToFitWidthOfColumn:(NSInteger)columnIndex
```

Parameters

browser
The browser.

columnIndex
The index of the column to size. If `-1`, the result is used to resize all columns.

Return Value
The ideal width of the column. This method is used when performing a "right-size" operation, that is, when sizing a column to the smallest width that contains all the content without clipping or truncating.

If *columnIndex* is `-1`, you should return a size that can be uniformly applied to all columns (that is, every column will be set to this size).

Returning a value of `-1` allows you to opt-out of providing a width for the requested column.

Discussion
This method applies only to browsers with resize type `NSBrowserUserColumnResizing`.

It is assumed that the implementation may be expensive, so it will be called only when necessary.

Availability
Available in Mac OS X v10.3 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSBrowser.h`

browser:titleOfColumn:

Asks the delegate for the title to display above the specified column.

```
- (NSString *)browser:(NSBrowser *)sender
    titleOfColumn:(NSInteger)column
```

Parameters

sender
The browser.

column
The index the column to be titled.

Return Value
The title of the specified column.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
- `setTitle:ofColumn:` (page 447)
- `titleOfColumn:` (page 450)

Declared In
`NSBrowser.h`

browser:typeSelectStringForRow:inColumn:

Sent to the delegate to get the keyboard-based selection (type select) string for the specified row and column.

```
- (NSString *)browser:(NSBrowser *)browser
    typeSelectStringForRow:(NSInteger)row
    inColumn:(NSInteger)column
```

Parameters
browser
The browser.

row
The row index.

column
The column index.

Return Value
The keyboard-based selection string.

Discussion
Returning the empty string or `nil` (for example, when the cell does not contain text) specifies that the [*column*, *row*] cell has no text to search.

If the delegate does not implement this method, all cells with text are searched, and the browser determines the keyboard-based selection text by sending `stringValue` (page 605) to the cell specified by *column* and *row*.

Availability
Available in Mac OS X v10.5 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
- `browser:shouldTypeSelectForEvent:withCurrentSearchString:` (page 3597)
- `browser:nextTypeSelectMatchFromRow:toRow:inColumn:forString:` (page 3590)

Declared In
NSBrowser.h

browser:validateDrop:proposedRow:column:dropOperation:

Sent to the delegate during a dragging session to determine whether a drop should be accepted and to obtain the drop location. This method is required for a browser to be a drag destination.

```
- (NSDragOperation)browser:(NSBrowser *)browser
    validateDrop:(id <NSDraggingInfo>)info
    proposedRow:(NSInteger *)row
    column:(NSInteger *)column
    dropOperation:(NSBrowserDropOperation *)dropOperation
```

Parameters

browser
The browser.

info
The drag session information.

row
On input, the proposed drop row. On output, the drop row.

column
On input, the proposed drop column. On output, the drop column.

dropOperation
On input, the proposed drop location. On output, the drop location.

Return Value
The drag operation that the data source is to perform. For the browser to accept the drop, it must not be NSDragOperationNone (page 3666).

Discussion
The browser proposes a drop column, row, and row-relative location for the drop based on the pointer position, as shown in this table:

Drop relative location	Description
NSBrowserDropOn (page 452)	Dragging location (*dragInfo*.draggingLocation) is closer to the middle of *row* than to either of its vertical sides.
NSBrowserDropAbove (page 452)	Dragging location is between two rows. Indicates a drop location above *row* and below *row* - 1.

These are a few examples of how to specify a drop location:

	Row index	Row-relative location
On row 2	2	NSBrowserDropOn (page 452)
Between rows 2 and 3	3	NSBrowserDropAbove (page 452)
Below the last row	[sender numberOfRows]	NSBrowserDropAbove (page 452)

	Row index	Row-relative location
All rows	-1	NSBrowserDropOn (page 452)

Availability
Available in Mac OS X v10.5 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
- registerForDraggedTypes: (page 3201) (NSView)

Declared In
NSBrowser.h

browser:willDisplayCell:atRow:column:

Gives the delegate the opportunity to modify the specified cell at the given row and column location before the browser displays it.

```
- (void)browser:(NSBrowser *)sender
    willDisplayCell:(id)cell
    atRow:(NSInteger)row
    column:(NSInteger)column
```

Parameters

sender
The browser.

cell
The cell to be displayed.

row
The row index of the cell to be displayed.

column
The column index of the cell to be displayed.

Discussion
The delegate should set any state necessary for the correct display of the cell.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

- browser:createRowsForColumn:inMatrix: (page 3586)
- browser:numberOfRowsInColumn: (page 3591)

Declared In
NSBrowser.h

browser:writeRowsWithIndexes:inColumn:toPasteboard:

Determines whether a drag operation can proceed. This method is required for a browser to be a drag source.

```
- (BOOL)browser:(NSBrowser *)browser
    writeRowsWithIndexes:(NSIndexSet *)rowIndexes
    inColumn:(NSInteger)column
    toPasteboard:(NSPasteboard *)pasteboard
```

Parameters

browser

The browser.

rowIndexes

The indexes of the rows the user is dragging.

column

The index of the column containing the dragged rows.

pasteboard

The pasteboard containing the content from the dragged rows.

Return Value

`YES` to allow the dragging operation to proceed (see discussion for further details); `NO` to disallow it.

Discussion

This method is called after a drag operation has been allowed to start (`browser:canDragRowsWithIndexes:inColumn:withEvent:` (page 3585) returns `YES`), but before it actually begins.

Availability

Available in Mac OS X v10.5 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

`NSBrowser.h`

browserColumnConfigurationDidChange:

Used by clients to implement their own column width persistence.

```
- (void)browserColumnConfigurationDidChange:(NSNotification *)notification
```

Parameters

notification

A notification named `NSBrowserColumnConfigurationDidChangeNotification` (page 453).

Discussion

This method applies only to browsers with resize type `NSBrowserUserColumnResizing` (page 452). It is invoked when the `setWidth:ofColumn:` (page 448) method of `NSBrowser` is used to change the width of any browser columns or when the user resizes any columns. If the user resizes more than one column, a single notification is posted when the user is finished resizing.

Availability

Available in Mac OS X v10.3 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
- `setWidth:ofColumn:` (page 448) (`NSBrowser`)

Declared In
`NSBrowser.h`

browserDidScroll:

Notifies the delegate when the browser has scrolled.

```
- (void)browserDidScroll:(NSBrowser *)sender
```

Parameters

sender
The browser sending the message.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSBrowser.h`

browserWillScroll:

Notifies the delegate when the browser will scroll.

```
- (void)browserWillScroll:(NSBrowser *)sender
```

Parameters

sender
The browser sending the message.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSBrowser.h`

rootItemForBrowser:

Asks the delegate to return the root item of the browser.

```
- (id)rootItemForBrowser:(NSBrowser *)browser
```

Parameters

browser
The browser.

Return Value
The browser's root item.

Discussion
By default, `nil` identifies the root item. This method can specify a different root item. To reload the previously set root item, call `loadColumnZero` (page 421), and `rootItemForBrowser:` will be called again.

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSBrowser.h`

NSChangeSpelling Protocol Reference

Adopted by	NSText
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.0 and later.
Declared in	AppKit/NSSpellProtocol.h
Companion guide	Spell Checking

Overview

This protocol is implemented by objects in the responder chain that can correct a misspelled word. See the NSSpellChecker class description for more information.

Tasks

Changing Spellings

`- changeSpelling:` (page 3605) *required method*

Replaces the selected word in the receiver with a corrected version from the Spelling panel. (required)

Instance Methods

changeSpelling:

Replaces the selected word in the receiver with a corrected version from the Spelling panel. (required)

```
- (void)changeSpelling:(id)sender
```

Discussion

This message is sent by the `NSSpellChecker` to the object whose text is being checked. To get the corrected spelling, ask *sender* for the string value of its selected cell (visible to the user as the text field in the Spelling panel). This method should replace the selected portion of the text with the string that it gets from the NSSpellChecker.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSSpellProtocol.h`

NSCollectionViewDelegate Protocol Reference

Conforms to	NSObject
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.6 and later.
Declared in	AppKit/NSCollectionView.h
Related sample code	IconCollection

Overview

The `NSCollectionViewDelegate` protocol defines the optional methods implemented by delegates of `NSCollectionView` objects.

The `NSCollectionViewDelegate` provides support for both drag and drop, and pasteboard support to collection views.

Tasks

Drag and Drop Support

`- collectionView:canDragItemsAtIndexes:withEvent:` (page 3608)
Returns whether the collection view can attempt to initiate a drag for the given event and items.

`- collectionView:validateDrop:proposedIndex:dropOperation:` (page 3610)
Invoked to determine a valid drop target.

`- collectionView:acceptDrop:index:dropOperation:` (page 3608)
Invoked when the mouse is released over a collection view that previously allowed a drop.

`- collectionView:draggingImageForItemsAtIndexes:withEvent:offset:` (page 3609)
Sent to the delegate to allow creation of a custom image to represent collection view items during a drag operation.

`- collectionView:namesOfPromisedFilesDroppedAtDestination:forDraggedItemsAtIndexes:` (page 3610)
Invoked to return an array of filenames that the receiver promises to create.

Writing to the Pasteboard

`- collectionView:writeItemsAtIndexes:toPasteboard:` (page 3611)
Invoked after it has been determined that a drag should begin, but before the drag has been started.

Instance Methods

collectionView:acceptDrop:index:dropOperation:

Invoked when the mouse is released over a collection view that previously allowed a drop.

```
- (BOOL)collectionView:(NSCollectionView *)collectionView acceptDrop:(id <
    NSDraggingInfo >)draggingInfo index:(NSInteger)index
    dropOperation:(NSCollectionViewDropOperation)dropOperation
```

Parameters

collectionView
The collection view that send the message.

draggingInfo
An object that contains more information about this dragging operation.

index
The index of the proposed drop item.

dropOperation
The type of dragging operation.

Return Value
`YES` if the drop operation should be accepted, otherwise `NO`.

Discussion
This method is called when the mouse is released over a collection view that previously decied to allow a drop via the `collectionView:validateDrop:proposedIndex:dropOperation:` (page 3610) method. At this time, the delegate should incorporate the data from the dragging pasteboard and update the collection view's contents.

You must implement this method for your collection view to be a drag destination

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSCollectionView.h`

collectionView:canDragItemsAtIndexes:withEvent:

Returns whether the collection view can attempt to initiate a drag for the given event and items.

```
- (BOOL)collectionView:(NSCollectionView *)collectionView
    canDragItemsAtIndexes:(NSIndexSet *)indexes withEvent:(NSEvent *)event
```

Parameters

collectionView

The collection view that send the message.

indexes

The indexes of the proposed dragging items.

event

The mouse down event that initiated the drag.

Return Value

YES if the items can attempt to initiate a drag for the specified items, otherwise NO.

Discussion

If the delegate does not implement this method, the collection view will act as if it returned YES.

Availability

Available in Mac OS X v10.6 and later.

Declared In

NSCollectionView.h

collectionView:draggingImageForItemsAtIndexes:withEvent:offset:

Sent to the delegate to allow creation of a custom image to represent collection view items during a drag operation.

```
- (NSImage *)collectionView:(NSCollectionView *)collectionView
    draggingImageForItemsAtIndexes:(NSIndexSet *)indexes withEvent:(NSEvent *)event
     offset:(NSPointPointer)dragImageOffset
```

Parameters

collectionView

The collection view that send the message.

indexes

The indexes of the dragging items.

event

The mouse down event that initiated the drag.

dragImageOffset

An in/out parameter that will initially be set to NSZeroPoint. it can be modified to reposition the returned image. A *dragImageOffset* of NSZeroPoint will cause the image to be centered under the mouse.

Return Value

An image containing a rendering of the visible portions of the views for each item.

Discussion

If the delegate does not implement this method, the collection view with return an image using draggingImageForItemsAtIndexes:withEvent:offset: (page 645). You can safely invoked draggingImageForItemsAtIndexes:withEvent:offset: (page 645) on *collectionView* from within this method.

You do not need to implement this method for your collection view to be a drag source.

Availability
Available in Mac OS X v10.6 and later.

Declared In
NSCollectionView.h

collectionView:namesOfPromisedFilesDroppedAtDestination: forDraggedItemsAtIndexes:

Invoked to return an array of filenames that the receiver promises to create.

```
- (NSArray *)collectionView:(NSCollectionView *)collectionView
    namesOfPromisedFilesDroppedAtDestination:(NSURL *)dropURL
    forDraggedItemsAtIndexes:(NSIndexSet *)indexes
```

Parameters

collectionView
The collection view that send the message.

dropURL
The drop location where the files are created.

indexes
The indexes of the dragging items.

Return Value
An array of filenames (not full paths) for the created files that the receiver promises to create.

Discussion
The delegate can support file promise drags by adding NSFilesPromisePboardType to the pasteboard in `collectionView:writeItemsAtIndexes:toPasteboard:` (page 3611).

For more information on file promise dragging, see documentation for the `NSDraggingSource` protocol and `namesOfPromisedFilesDroppedAtDestination:` (page 3663).

You do not need to implement this delegate method for your collection view to be a drag source.

Availability
Available in Mac OS X v10.6 and later.

Declared In
NSCollectionView.h

collectionView:validateDrop:proposedIndex:dropOperation:

Invoked to determine a valid drop target.

```
- (NSDragOperation)collectionView:(NSCollectionView *)collectionView validateDrop:(id
    < NSDraggingInfo >)draggingInfo proposedIndex:(NSInteger *)proposedDropIndex
    dropOperation:(NSCollectionViewDropOperation *)proposedDropOperation
```

Parameters

collectionView
The collection view that send the message.

draggingInfo
An object containing details about this dragging operation.

proposedDropIndex
The proposed drop index. This parameter is passed by-reference and can be modified retarget the drop operation.

proposedDropOperation
The proposed drop operation. This parameter is passed by-reference and can be modified to change the drop operation.

Return Value
A value that indicates which dragging operation the data source will perform. It must return something other than `NSDragOperationNone` (page 3666) to accept the drop

Discussion
Based on the mouse position, the collection view will suggest a proposed index and drop operation. These values are in/out parameters and can be changed by the delegate to retarget the drop operation.

The collection view will propose `NSCollectionViewDropOn` when the dragging location is closer to the middle of the item than either of its edges. Otherwise, it will propose `NSCollectionViewDropBefore`. You may override this default behavior by changing *proposedDropOperation* or *proposedDropIndex*.

To receive drag messages, you must first send `registerForDraggedTypes:` (page 3201) to the collection view with the drag types you want to support.

You must implement this method for your collection view to be a drag destination.

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSCollectionView.h`

collectionView:writeItemsAtIndexes:toPasteboard:

Invoked after it has been determined that a drag should begin, but before the drag has been started.

```
- (BOOL)collectionView:(NSCollectionView *)collectionView
    writeItemsAtIndexes:(NSIndexSet *)indexes toPasteboard:(NSPasteboard *)pasteboard
```

Parameters
collectionView
The collection view that send the message.

indexes
The indexes of the items to write to the pasteboard.

pasteboard
The pasteboard containing the content from the dragged items.

Return Value
`YES` to begin the drag, otherwise `NO`.

Discussion
To start the drag, you must first declare the pasteboard types that are supported by sending *pasteboard* a `declareTypes:owner:` (page 1893) method. You then place the data for the items at the specified indexes on *pasteboard*, and return `YES` from the method.

The drag image and other drag related information will be set up and provided by the view once this call returns `YES`.

You need to implement this method for your collection view to be a drag source.

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSCollectionView.h`

NSColorPickingCustom Protocol Reference

Adopted by	NSColorPicker
Conforms to	NSColorPickingDefault
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.0 and later.
Declared in	AppKit/NSColorPicking.h
Companion guide	Color Programming Topics
Related sample code	RadiantColorPicker

Overview

Together with the `NSColorPickingDefault` protocol, `NSColorPickingCustom` provides a way to add color pickers—custom user interfaces for color selection—to an application's `NSColorPanel` instance. The `NSColorPickingDefault` protocol provides basic behavior for a color picker. The `NSColorPicker` class adopts the `NSColorPickingDefault` protocol.

Note: This protocol must be implemented by a custom picker, or an error will occur.

Tasks

Configuring Color Pickers

`- setColor:` (page 3615) *required method*
Adjusts the receiver to make the specified color the currently selected color. (required)

Getting Color Picker Information

`- currentMode` (page 3614) *required method*
Returns the receiver's current mode (or submode, if applicable). (required)

- supportsMode: (page 3615) *required method*
  Returns a Boolean value indicating whether or not the receiver supports the specified picking mode. (required)

Displaying Color Pickers

- provideNewView: (page 3614) *required method*
  Returns the view containing the receiver's user interface. (required)

Instance Methods

currentMode

Returns the receiver's current mode (or submode, if applicable). (required)

```
- (NSColorPanelMode)currentMode
```

Return Value
The current color picker mode. The returned value should be unique to your color picker. See this protocol description's list of the unique values for the standard color pickers used by the Application Kit.

Availability
Available in Mac OS X v10.0 and later.

See Also
- supportsMode: (page 3615)

Related Sample Code
RadiantColorPicker

Declared In
NSColorPicking.h

provideNewView:

Returns the view containing the receiver's user interface. (required)

```
- (NSView *)provideNewView:(BOOL)initialRequest
```

Parameters
initialRequest
YES only when this method is first invoked for your color picker. If *initialRequest* is YES, the method should perform any initialization required (such as lazily loading a nib file, initializing the view, or performing any other custom initialization required for your picker).

Return Value
The view containing the color picker's user interface. The NSView returned by this method should be set to automatically resize both its width and height.

Discussion
This message is sent to the color picker whenever the color panel attempts to display it. This may be when the panel is first presented, when the user switches pickers, or when the picker is switched through an API.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSColorPicking.h`

setColor:

Adjusts the receiver to make the specified color the currently selected color. (required)

```
- (void)setColor:(NSColor *)color
```

Parameters

color

The color to set as the currently selected color.

Discussion
This method is invoked on the current color picker each time `NSColorPanel`'s `setColor:` (page 733) method is invoked. If *color* is actually different from the color picker's color (as it would be if, for example, the user dragged a color into `NSColorPanel`'s color well), this method could be used to update the color picker's color to reflect the change.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSColorPicking.h`

supportsMode:

Returns a Boolean value indicating whether or not the receiver supports the specified picking mode. (required)

```
- (BOOL)supportsMode:(NSColorPanelMode)mode
```

Parameters

mode

The color picking mode.

Return Value
`YES` if the color picker supports the specified color picking mode; otherwise `NO`.

Discussion
This method is invoked when the `NSColorPanel` is first initialized: It is used to attempt to restore the user's previously selected mode. It is also invoked by `NSColorPanel`'s `setMode:` (page 734) method to find the color picker that supports a particular mode. See this protocol description's list of the unique mode values for the standard color pickers used by the Application Kit.

Availability
Available in Mac OS X v10.0 and later.

See Also
- currentMode (page 3614)

Declared In
NSColorPicking.h

NSColorPickingDefault Protocol Reference

Adopted by	NSColorPicker
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.0 and later.
Declared in	AppKit/NSColorPicking.h
Companion guide	Color Programming Topics

Overview

The `NSColorPickingDefault` protocol, together with the `NSColorPickingCustom` protocol, provides an interface for adding color pickers—custom user interfaces for color selection—to an application's `NSColorPanel` instance. The `NSColorPickingDefault` protocol provides basic behavior for a color picker. The `NSColorPickingCustom` protocol provides implementation-specific behavior.

Tasks

Creating Color Pickers

- `initWithPickerMask:colorPanel:` (page 3620)
  Initializes the receiver with a given color panel and its mode.

Configuring Color Pickers

- `setMode:` (page 3622)
  Specifies the receiver's mode.
- `insertNewButtonImage:in:` (page 3621)
  Sets the image of a given button cell.
- `provideNewButtonImage` (page 3621)
  Provides the image of the button used to select the receiver in the color panel.
- `minContentSize` (page 3621)
  Indicates the receiver's minimum content size.

- `buttonToolTip` (page 3619)
  Provides the toolbar button help tag.

Handling Events

- `alphaControlAddedOrRemoved:` (page 3618)
  Sent when the color panel's opacity controls have been hidden or displayed.
- `viewSizeChanged:` (page 3622)
  Tells the recever when the color panel's view size changes in a way that might affect the color picker.

Managing Color Lists

- `attachColorList:` (page 3618)
  Tells the receiver to attach the given color list, if it isn't already displaying the list.
- `detachColorList:` (page 3619)
  Tells the receiver to detach the given color list, unless the receiver isn't displaying the list.

Instance Methods

alphaControlAddedOrRemoved:

Sent when the color panel's opacity controls have been hidden or displayed.

```
- (void)alphaControlAddedOrRemoved:(id)sender
```

Parameters

sender
  The color panel sending the message.

Discussion
This method is invoked automatically when the opacity slider of the `NSColorPanel` is added or removed; you never invoke this method directly.

If the color picker has its own opacity controls, it should hide or display them, depending on whether the sender's `showsAlpha` (page 736) method returns `NO` or `YES`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSColorPicking.h`

attachColorList:

Tells the receiver to attach the given color list, if it isn't already displaying the list.

```
- (void)attachColorList:(NSColorList *)colorList
```

Parameters

colorList

The color list to display.

Discussion

You never invoke this method; it's invoked automatically by the `NSColorPanel` object when its `attachColorList:` (page 730) method is invoked. Because the `NSColorPanel` list mode manages `NSColorList` objects, this method need only be implemented by a custom color picker that manages `NSColorList` objects itself.

Availability

Available in Mac OS X v10.0 and later.

See Also

`- detachColorList:` (page 3619)

Declared In

`NSColorPicking.h`

buttonToolTip

Provides the toolbar button help tag.

```
- (NSString *)buttonToolTip
```

Return Value

Help tag text.

Availability

Available in Mac OS X v10.5 and later.

Declared In

`NSColorPicking.h`

detachColorList:

Tells the receiver to detach the given color list, unless the receiver isn't displaying the list.

```
- (void)detachColorList:(NSColorList *)colorList
```

Parameters

colorList

The color list to detach.

Discussion

You never invoke this method; it's invoked automatically by the `NSColorPanel` object when its `detachColorList:` (page 731) method is invoked. Because the `NSColorPanel` list mode manages `NSColorList` objects, this method need only be implemented by a custom color picker that manages `NSColorList` objects itself.

Availability

Available in Mac OS X v10.0 and later.

See Also
- attachColorList: (page 3618)

Declared In
NSColorPicking.h

initWithPickerMask:colorPanel:

Initializes the receiver with a given color panel and its mode.

```
- (id)initWithPickerMask:(NSUInteger)panelModes colorPanel:(NSColorPanel
    *)owningColorPanel
```

Parameters

panelModes

A mask indicating the various color picker modes supported by the color panel. This is determined by the argument to the NSColorPanel method setPickerMask: (page 728). If it has not been set, *panelModes* is NSColorPanelAllModesMask. If your color picker supports any additional modes, you should invoke the setPickerMask: (page 728) method when your application initializes to notify the NSColorPanel class. The standard mode constants are defined in "Choosing the Color Pickers in a Color Panel".

owningColorPanel

The color panel than owns the receiver.

Return Value
If your color picker responds to any of the modes represented in *panelModes*, it should perform its initialization and return an initialized color picker. Color pickers that do so have their buttons inserted in the color panel and continue to receive messages from the panel as the user manipulates it. If the color picker doesn't respond to any of the modes represented in *panelModes*, it should do nothing and return nil.

Discussion
This method is sent by the NSColorPanel to all implementors of the color-picking protocols when the application's color panel is first initialized. In order for your color picker to receive this message, it must have a bundle in your application's "ColorPickers" directory (described in "Color Picker Bundles").

This method should examine the mask and determine whether it supports any of the modes included there. You may also check the value in *mask* to enable or disable any subpickers or optional controls implemented by your color picker. Your color picker may also retain *owningColorPanel* in an instance variable for future communication with the color panel.

This method is provided to initialize your color picker; however, much of a color picker's initialization may be done lazily through the NSColorPickingCustom protocol's provideNewView: (page 3614) method.

Availability
Available in Mac OS X v10.0 and later.

See Also
+ setPickerMask: (page 728) (NSColorPanel class)

Declared In
NSColorPicking.h

insertNewButtonImage:in:

Sets the image of a given button cell.

```
- (void)insertNewButtonImage:(NSImage *)newButtonImage in:(NSButtonCell *)buttonCell
```

Parameters

newButtonImage

The image to set for the button cell.

buttonCell

The `NSButtonCell` object that lets the user choose the picker from the color panel—the color picker's representation in the `NSMatrix` of the `NSColorPanel`.

Discussion
This method should perform application-specific manipulation of the image before it's inserted and displayed by the button cell.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- provideNewButtonImage` (page 3621)

Declared In
`NSColorPicking.h`

minContentSize

Indicates the receiver's minimum content size.

```
- (NSSize)minContentSize
```

Discussion
The receiver does not allow a size smaller than `minContentSize`.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSColorPicking.h`

provideNewButtonImage

Provides the image of the button used to select the receiver in the color panel.

```
- (NSImage *)provideNewButtonImage
```

Return Value
The image for the mode button the user uses to select this picker in the color panel; that is, the color picker's representation in the `NSMatrix` of the `NSColorPanel`.

This image is the same one the color panel uses as an argument when sending the `insertNewButtonImage:in:` (page 3621) message.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSColorPicking.h

setMode:

Specifies the receiver's mode.

```
- (void)setMode:(NSColorPanelMode)mode
```

Parameters

mode

The color picker mode. The available modes are described in "Choosing the Color Pickers in a Color Panel".

Discussion
This method is invoked by the NSColorPanel method setMode: (page 734) method to ensure the color picker reflects the current mode. For example, invoke this method during color picker initialization to ensure that all color pickers are restored to the mode the user left them in the last time an NSColorPanel was used.

Most color pickers have only one mode and thus don't need to do any work in this method. An example of a color picker that uses this method is the slider picker, which can choose from one of several submodes depending on the value of *mode*.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSColorPicking.h

viewSizeChanged:

Tells the recever when the color panel's view size changes in a way that might affect the color picker.

```
- (void)viewSizeChanged:(id)sender
```

Parameters

sender

The NSColorPanel that contains the color picker.

Discussion
Use this method to perform special preparation when resizing the color picker's view. Because this method is invoked only as appropriate, it's better to implement this method than to override the method superviewSizeChanged: for the NSView in which the color picker's user interface is contained.

Availability
Available in Mac OS X v10.0 and later.

Declared in	AppKit/NSComboBoxCell.h
Companion guide	Combo Box Programming Topics

Overview

The `NSComboBoxCellDataSource` protocol declares the methods that an `NSComboBoxCell` uses to access the contents of its data source object.

For more information, see *Combo Box Programming Topics*.

Tasks

Populating Combo Boxes

- `comboBoxCell:objectValueForItemAtIndex:` (page 3627)
  Returns the object that corresponds to the item at the given index in the combo box cell.
- `numberOfItemsInComboBoxCell:` (page 3627)
  Returns the number of items managed for the combo box cell by your data source object.

Entry Completion

- `comboBoxCell:completedString:` (page 3626)
  Returns the item from the combo box's pop-up list that matches the text entered by the user.
- `comboBoxCell:indexOfItemWithStringValue:` (page 3626)
  Invoked by an `NSComboBoxCell` object to synchronize the pop-up list's selected item with the text field's contents.

Instance Methods

comboBoxCell:completedString:

Returns the item from the combo box's pop-up list that matches the text entered by the user.

```
- (NSString *)comboBoxCell:(NSComboBoxCell *)aComboBoxCell completedString:(NSString
    *)uncompletedString
```

Parameters

aComboBoxCell

The combo box cell.

uncompletedString

The substring containing the text the user typed into the text field of the combo box cell.

Return Value

The completed string, from the items in the pop-up list, that matches the text entered by the user. Your implementation should return the first complete string that starts with *uncompletedString*.

Discussion

An `NSComboBoxCell` object uses this method to perform incremental—or "smart"—searches when the user types into the text field.

As the user types in the text field, the receiver uses this method to search for items from the pop-up list that start with what the user has typed. The receiver adds the new text to the end of the field and selects the new text, so when the user types another character, it replaces the new text.

If you don't implement this method, the receiver does not perform incremental searches.

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

`NSComboBoxCell.h`

comboBoxCell:indexOfItemWithStringValue:

Invoked by an `NSComboBoxCell` object to synchronize the pop-up list's selected item with the text field's contents.

```
- (NSUInteger)comboBoxCell:(NSComboBoxCell *)aComboBoxCell
    indexOfItemWithStringValue:(NSString *)aString
```

Parameters

aComboBoxCell

The combo box cell.

aString

The string to match. If `comboBoxCell:completedString:` (page 3626) is implemented, *aString* is the string returned by that method. Otherwise, *aString* is the text that the user has typed.

Return Value
The index for the pop-up list item matching *aString*, or NSNotFound if no item matches.

Discussion
If you don't implement this method, the receiver does not synchronize the pop-up list's selected item with the text field's contents.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSComboBoxCell.h

comboBoxCell:objectValueForItemAtIndex:

Returns the object that corresponds to the item at the given index in the combo box cell.

```
- (id)comboBoxCell:(NSComboBoxCell *)aComboBoxCell
    objectValueForItemAtIndex:(NSInteger)index
```

Parameters
aComboBoxCell
The combo box cell for which to return the item.
index
The index of the item to return.

Return Value
The object corresponding to the item at the specified index in the given combo box cell.

Discussion
An NSComboBoxCell object uses this method to populate the items displayed in its pop-up list.

Important: While this method is marked as @optional in the protocol, **you must implement this method if you are not providing the data for the combo box using using Cocoa bindings**.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSComboBoxCell.h

numberOfItemsInComboBoxCell:

Returns the number of items managed for the combo box cell by your data source object.

```
- (NSInteger)numberOfItemsInComboBoxCell:(NSComboBoxCell *)aComboBoxCell
```

Parameters

aComboBoxCell

The combo box cell for which your data source manages items.

Return Value

The number of items your data source object manages.

Discussion

An `NSComboBoxCell` object uses this method to determine how many items it should display in its pop-up list.

Important: While this method is marked as `@optional` in the protocol, **you must implement this method if you are not providing the data for the combo box using using Cocoa bindings**.

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Overview

The `NSComboBoxDataSource` informal protocol declares the methods that an `NSComboBox` object uses to access the contents of its data source object.

For more information, see *Combo Box Programming Topics*.

Tasks

Populating Combo Boxes

- `comboBox:objectValueForItemAtIndex:` (page 3631)
  Returns the object that corresponds to the item at the specified index in the combo box.
- `numberOfItemsInComboBox:` (page 3631)
  Returns the number of items that the data source manages for the combo box.

String Completion

- `comboBox:completedString:` (page 3630)
  Returns the first item from the pop-up list that starts with the text the user has typed.
- `comboBox:indexOfItemWithStringValue:` (page 3630)
  Returns the index of the combo box item matching the specified string.

Instance Methods

comboBox:completedString:

Returns the first item from the pop-up list that starts with the text the user has typed.

```
- (NSString *)comboBox:(NSComboBox *)aComboBox completedString:(NSString
    *)uncompletedString
```

Parameters

aComboBox

The combo box.

uncompletedString

The string to match against items in the combo box's pop-up list. This is text that the user has typed.

Return Value

The first complete string from the items in the combo box's pop-up list that starts with the string in *uncompletedString*.

Discussion

An `NSComboBox` object uses this method to perform incremental—or "smart"—searches when the user types into the text field. As the user types in the text field, the receiver uses this method to search for items from the pop-up list that start with what the user has typed. The receiver adds the new text to the end of the field and selects the new text, so when the user types another character, it replaces the new text.

This method is optional. If you don't implement it, the receiver does not perform incremental searches.

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

`NSComboBox.h`

comboBox:indexOfItemWithStringValue:

Returns the index of the combo box item matching the specified string.

```
- (NSUInteger)comboBox:(NSComboBox *)aComboBox indexOfItemWithStringValue:(NSString
    *)aString
```

Parameters

aComboBox

The combo box.

aString

The string to match against the items in the combo box. If the datasource implements`comboBox:completedString:` (page 3630), this is the string returned by that method. Otherwise, it is the text that the user has typed.

Return Value

The index for the item that matches the specified string, or `NSNotFound` if no item matches.

Discussion
An `NSComboBox` object uses this method to synchronize the pop-up list's selected item with the text field's contents. If you don't implement this method the receiver does not synchronize the pop-up list's selected item with the text field's contents.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSComboBox.h`

comboBox:objectValueForItemAtIndex:

Returns the object that corresponds to the item at the specified index in the combo box.

```
- (id)comboBox:(NSComboBox *)aComboBox objectValueForItemAtIndex:(NSInteger)index
```

Parameters

aComboBox
The combo box.

index
The index of the item to return.

Return Value
The object corresponding to the specified index number.

Discussion
An `NSComboBox` object uses this method to populate the items displayed in its pop-up list.

Important: While this method is marked as `@optional` in the protocol, you must implement this method if you are not providing the data for the combo box using Cocoa bindings.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSComboBox.h`

numberOfItemsInComboBox:

Returns the number of items that the data source manages for the combo box.

```
- (NSInteger)numberOfItemsInComboBox:(NSComboBox *)aComboBox
```

Parameters

aComboBox
The combo box.

Return Value
The number of items that the data source object manages for the specified combo box.

Discussion
An `NSComboBox` object uses this method to determine how many items it should display in its pop-up list.

Important: While this method is marked as `@optional` in the protocol, you must implement this method if you are not providing the data for the combo box using Cocoa bindings.

Companion guide	Combo Box Programming Topics

Overview

The `NSComboBoxDelegate` protocol defines the optional methods implemented by delegates of `NSComboBox` objects.

Tasks

Manipulating the Selection

- `comboBoxSelectionDidChange:` (page 3633)
  Informs the delegate that the pop-up list selection has finished changing.
- `comboBoxSelectionIsChanging:` (page 3634)
  Informs the delegate that the pop-up list selection is changing.
- `comboBoxWillDismiss:` (page 3634)
  Informs the delegate that the pop-up list is about to be dismissed.
- `comboBoxWillPopUp:` (page 3634)
  Informs the delegate that the pop-up list is about to be displayed.

Instance Methods

comboBoxSelectionDidChange:

Informs the delegate that the pop-up list selection has finished changing.

```
- (void)comboBoxSelectionDidChange:(NSNotification *)notification
```

Parameters

notification

A notification named `NSComboBoxSelectionDidChangeNotification` (page 786).

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

`NSComboBox.h`

comboBoxSelectionIsChanging:

Informs the delegate that the pop-up list selection is changing.

```
- (void)comboBoxSelectionIsChanging:(NSNotification *)notification
```

Parameters

notification

A notification named `NSComboBoxSelectionIsChangingNotification` (page 786).

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

`NSComboBox.h`

comboBoxWillDismiss:

Informs the delegate that the pop-up list is about to be dismissed.

```
- (void)comboBoxWillDismiss:(NSNotification *)notification
```

Parameters

notification

A notification named `NSComboBoxWillDismissNotification` (page 786).

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

`NSComboBox.h`

comboBoxWillPopUp:

Informs the delegate that the pop-up list is about to be displayed.

```
- (void)comboBoxWillPopUp:(NSNotification *)notification
```

Parameters

notification

A notification named `NSComboBoxWillPopUpNotification` (page 787).

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

`NSComboBox.h`

NSControlTextEditingDelegate Protocol Reference

Conforms to	NSObject
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.6 and later.
Declared in	AppKit/NSControl.h
Companion guide	Control and Cell Programming Topics for Cocoa
Related sample code	CoreAnimationText

Overview

The `NSControlTextEditingDelegate` protocol defines the optional methods implemented by delegates of objects that are subclasses of `NSControl`.

Tasks

Validating a Control's Value

`- control:isValidObject:` (page 3639)
Invoked when the insertion point leaves a cell belonging to the specified control, but before the value of the cell's object is displayed.

`- control:didFailToValidatePartialString:errorDescription:` (page 3639)
Invoked when the formatter for the cell belonging to *`control`* (or selected cell) rejects a partial string a user is typing into the cell.

Responding to Text Formatting

`- control:didFailToFormatString:errorDescription:` (page 3638)
Invoked when the formatter for the cell belonging to the specified control cannot convert a string to an underlying object.

Responding to Text Editing

- `control:textShouldBeginEditing:` (page 3640)
  Invoked when the user tries to enter a character in a cell of a control that allows editing of text (such as a text field or form field).
- `control:textShouldEndEditing:` (page 3640)
  Invoked when the insertion point tries to leave a cell of the control that has been edited.

Working with Text Completion

- `control:textView:completions:forPartialWordRange:indexOfSelectedItem:` (page 3641)
  Invoked to allow you to control the list of proposed text completions generated by text fields and other controls.

Working with Key Bindings

- `control:textView:doCommandBySelector:` (page 3642)
  Invoked when users press keys with predefined bindings in a cell of the specified control.

Instance Methods

control:didFailToFormatString:errorDescription:

Invoked when the formatter for the cell belonging to the specified control cannot convert a string to an underlying object.

```
- (BOOL)control:(NSControl *)control didFailToFormatString:(NSString *)string
    errorDescription:(NSString *)error
```

Parameters

control
The control whose cell could not convert the string.

string
The string that could not be converted.

error
A localized, user-presentable string that explains why the conversion failed.

Return Value
`YES` if the value in the string parameter should be accepted as is; otherwise, `NO` if the value in the parameter should be rejected.

Discussion
Your implementation of this method should evaluate the error or query the user an appropriate value indicating whether the string should be accepted or rejected.

Availability
Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
`getObjectValue:forString:errorDescription:` (`NSFormatter`)

Declared In
`NSControl.h`

control:didFailToValidatePartialString:errorDescription:

Invoked when the formatter for the cell belonging to *control* (or selected cell) rejects a partial string a user is typing into the cell.

```
- (void)control:(NSControl *)control didFailToValidatePartialString:(NSString
    *)string errorDescription:(NSString *)error
```

Parameters

control
The control whose cell rejected the string.

string
The string that includes the character that caused the rejection.

error
A localized, user-presentable string that explains why the string was rejected.

Discussion
You can implement this method to display a warning message or perform a similar action when the user enters improperly formatted text.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
`isPartialStringValid:newEditingString:errorDescription:` (`NSFormatter`)

Declared In
`NSControl.h`

control:isValidObject:

Invoked when the insertion point leaves a cell belonging to the specified control, but before the value of the cell's object is displayed.

```
- (BOOL)control:(NSControl *)control isValidObject:(id)object
```

Parameters

control
The control whose object value needs to be validated.

object
The object value to validate.

Return Value
`YES` if you want to allow the control to display the specified value; otherwise, `NO` to reject the value and return the cursor to the control's cell.

Discussion
This method gives the delegate the opportunity to validate the contents of the control's cell (or selected cell). In validating, the delegate should check the value in the *`object`* parameter and determine if it falls within a permissible range, has required attributes, accords with a given context, and so on. Examples of objects subject to such evaluations are an `NSDate` object that should not represent a future date or a monetary amount (represented by an `NSNumber` object) that exceeds a predetermined limit.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSControl.h`

control:textShouldBeginEditing:

Invoked when the user tries to enter a character in a cell of a control that allows editing of text (such as a text field or form field).

```
- (BOOL)control:(NSControl *)control textShouldBeginEditing:(NSText *)fieldEditor
```

Parameters
`control`
The control whose content is about to be edited.

`fieldEditor`
The field editor of the control.

Return Value
`YES` if the control's field editor should be allowed to start editing the text; otherwise, `NO`.

Discussion
You can use this method to allow or disallow editing in a control. This message is sent by the control directly to its delegate object.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSControl.h`

control:textShouldEndEditing:

Invoked when the insertion point tries to leave a cell of the control that has been edited.

```
- (BOOL)control:(NSControl *)control textShouldEndEditing:(NSText *)fieldEditor
```

Parameters

control

The control for which editing is about to end.

fieldEditor

The field editor of the control. You can use this parameter to get the edited text.

Return Value

YES if the insertion point should be allowed to end the editing session; otherwise, NO.

Discussion

This message is sent only by controls that allow editing of text (such as a text field or a form field). This message is sent by the control directly to its delegate object.

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

NSControl.h

control:textView:completions:forPartialWordRange:indexOfSelectedItem:

Invoked to allow you to control the list of proposed text completions generated by text fields and other controls.

```
- (NSArray *)control:(NSControl *)control textView:(NSTextView *)textView
    completions:(NSArray *)words forPartialWordRange:(NSRange)charRange
    indexOfSelectedItem:(NSInteger *)index
```

Parameters

control

The control whose cell initiated the message. If the control contains multiple cells, the one that initiated the message is usually the selected cell.

textView

The field editor of the control. You can use this parameter to get the typed text.

words

An array of NSString objects containing the potential completions. The completion strings are listed in their order of preference in the array.

charRange

The range of characters the user has already typed.

index

On input, an integer variable with the default value of 0. On output, you can set this value to an index in the returned array indicating which item should be selected initially. Set the value to -1 to indicate there should not be an initial selection.

Return Value

An array of NSString objects containing the list of completions to use in place of the array in the *words* parameter. The returned array should list the completions in their preferred order

Discussion
Each string you return should be a complete word that the user might be trying to type. The strings must be complete words rather than just the remainder of the word, in case completion requires some slight modification of what the user has already typed—for example, the addition of an accent, or a change in capitalization. You can also use this method to support abbreviations that complete into words that do not start with the characters of the abbreviation. The *index* argument allows you to return by reference an index specifying which of the completions should be selected initially.

The actual means of presentation of the potential completions is determined by the `complete:` method of `NSTextView`.

Availability
Available in Mac OS X v10.3 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
`- complete:` (page 2888) (`NSTextView`)

Declared In
`NSControl.h`

control:textView:doCommandBySelector:

Invoked when users press keys with predefined bindings in a cell of the specified control.

```
- (BOOL)control:(NSControl *)control textView:(NSTextView *)textView
    doCommandBySelector:(SEL)command
```

Parameters

control
The control whose cell initiated the message. If the control contains multiple cells, the one that initiated the message is usually the selected cell.

textView
The field editor of the control.

command
The selector that was associated with the binding.

Return Value
`YES` if the delegate object handles the key binding; otherwise, `NO`.

Discussion
These bindings are usually implemented as methods (*command*) defined in the `NSResponder` class; examples of such key bindings are arrow keys (for directional movement) and the Escape key (for name completion). By implementing this method, the delegate can override the default implementation of *command* and supply its own behavior.

For example, the default method for completing partially typed pathnames or symbols (usually when users press the Escape key) is `complete:` (page 2147). The default implementation of the `complete:` method (in `NSResponder`) does nothing. The delegate could evaluate the method in the *command* parameter and, if it's `complete:`, get the current string from the *textView* parameter and then expand it, or display a list of potential completions, or do whatever else is appropriate.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Availability	Available in Mac OS X v10.6 and later.
Declared in	AppKit/NSDatePickerCell.h
Related sample code	DatePicker

Overview

The `NSDatePickerCellDelegate` protocol defines the optional methods implemented by delegates of `NSDatePickerCell` objects.

Tasks

Content Validation

`- datePickerCell:validateProposedDateValue:timeInterval:` (page 3645)
The delegate receives this message each time the user attempts to change the receiver's value, allowing the delegate the opportunity to override the change.

Instance Methods

datePickerCell:validateProposedDateValue:timeInterval:

The delegate receives this message each time the user attempts to change the receiver's value, allowing the delegate the opportunity to override the change.

```
- (void)datePickerCell:(NSDatePickerCell *)aDatePickerCell
    validateProposedDateValue:(NSDate **)proposedDateValue
    timeInterval:(NSTimeInterval *)proposedTimeInterval
```

Parameters

aDatePickerCell

The cell cell that sent the message.

proposedDateValue

On input, contains the proposed new date. The delegate may change this value before returning.

proposedTimeInterval

On input, contains the proposed new time interval. The delegate may change this value before returning.

Discussion

When returning a new *proposedDateValue*, the `NSDate` instance should be autoreleased, and the *proposedDateValue* should not be released by the delegate.

The *proposedDateValue* and *proposedTimeInterval* are guaranteed to lie between the dates returned by `minDate` (page 899) and `maxDate` (page 898). If you modify these values, you should ensure that the new values are within the appropriate range.

Availability

Available in Mac OS X v10.4 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Companion guide	Cocoa Bindings Programming Topics

Overview

`NSDictionaryControllerKeyValuePair` is an informal protocol that is implemented by objects returned by the `NSDictionaryController` method `arrangedObjects`. See *NSDictionaryController Class Reference* for more information.

Tasks

Localizing the Display Key

- `setLocalizedKey:` (page 3649)
  Sets the localized key name for the receiver.
- `localizedKey` (page 3648)
  Returns the receiver's localized key name.

Key-Value Pair Settings

- `setKey:` (page 3649)
  Sets the key name for the receiver.
- `key` (page 3648)
  Returns the receiver's key name.
- `setValue:` (page 3649)
  Sets the receiver's value.
- `value` (page 3650)
  Returns the receiver's value.
- `isExplicitlyIncluded` (page 3648)
  Specifies whether the receiver's key name is an included key.

Instance Methods

isExplicitlyIncluded

Specifies whether the receiver's key name is an included key.

```
- (BOOL)isExplicitlyIncluded
```

Return Value
`YES` if the key name is specified as an included key, otherwise `NO`.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSDictionaryController.h`

key

Returns the receiver's key name.

```
- (NSString *)key
```

Return Value
The key name.

NSDockTilePlugIn Protocol Reference

Conforms to	NSObject
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.6 and later.
Declared in	AppKit/NSDockTile.h
Companion guide	Dock Tile Programming Guide

Overview

The `NSDockTilePlugIn` protocol defines the methods implemented by plug-ins that allow an application's Dock tile to be customized while the application is not running.

Customizing an application's Dock tile when the application itself is not running requires that you write a plug-in. The plug-in's principal class must implement the `NSDockTilePlugIn` protocol.

The name of the plugin is indicated by a `NSDockTilePlugIn` key in the application's Info.plist file.

The plugin is loaded in a system process at login time or when the application tile is added to the Dock. When the plugin is loaded, the principal class' implementation of `setDockTile:` (page 3652) is invoked, passing an `NSDockTile` for the plug-in to customize. If the principal class implements `dockMenu` (page 3652) it is invoked whenever the user causes the application's dock menu to be shown. When the dock tile is no longer valid (for example,. the application has been removed from the dock) -`setDockTile:` (page 3652) is invoked with `nil`.

Tasks

Setting the Dock Tile

- `setDockTile:` (page 3652) *required method*

  Invoked when the plug-in is first loaded and when the application is removed from the Dock. (required)

Getting the Dock Tile Menu

Instance Methods

dockMenu

Invoked when the user causes the application's dock menu to be shown.

```
- (NSMenu*)dockMenu
```

Return Value
The menu the dock tile displays.

Availability
Available in Mac OS X v10.6 and later.

Declared In
NSDockTile.h

setDockTile:

Invoked when the plug-in is first loaded and when the application is removed from the Dock. (required)

```
- (void)setDockTile:(NSDockTile*)dockTile
```

Parameters

dockTile
The dock tile associated with the application, or nil if the application has been removed from the Dock.

Discussion
The plugin is loaded in a system process at login time or when the application tile is added to the Dock.

The principal class of the plug-in must implement the NSDockTilePlugIn protocol.

Availability
Available in Mac OS X v10.6 and later.

Declared In
NSDockTile.h

NSDraggingDestination Protocol Reference

(informal protocol)

Framework	/System/Library/Frameworks/AppKit.framework
Declared in	AppKit/NSDragging.h
Companion guide	Drag and Drop Programming Topics for Cocoa

Overview

The `NSDraggingDestination` informal protocol declares methods that the destination object (or recipient) of a dragged image must implement. The destination automatically receives `NSDraggingDestination` messages for pasteboard data types it has registered for as an image enters, moves around inside, and then exits or is released within the destination's boundaries.

Tasks

Managing a Dragging Session Before an Image Is Released

- `draggingEntered:` (page 3655)
  Invoked when the dragged image enters destination bounds or frame; delegate returns dragging operation to perform.
- `wantsPeriodicDraggingUpdates` (page 3658)
  Asks the destination object whether it wants to receive periodic `draggingUpdated:` (page 3656) messages.
- `draggingUpdated:` (page 3656)
  Invoked periodically as the image is held within the destination area, allowing modification of the dragging operation or mouse-pointer position.
- `draggingEnded:` (page 3654)
  Implement this method to be notified when a drag operation ends in some other destination.
- `draggingExited:` (page 3655)
  Invoked when the dragged image exits the destination's bounds rectangle (in the case of a view object) or its frame rectangle (in the case of a window object).

Managing a Dragging Session After an Image Is Released

- `prepareForDragOperation:` (page 3657)
  Invoked when the image is released, allowing the receiver to agree to or refuse drag operation.

- `performDragOperation:` (page 3657)
  Invoked after the released image has been removed from the screen, signaling the receiver to import the pasteboard data.
- `concludeDragOperation:` (page 3654)
  Invoked when the dragging operation is complete, signaling the receiver to perform any necessary clean-up.

Instance Methods

concludeDragOperation:

Invoked when the dragging operation is complete, signaling the receiver to perform any necessary clean-up.

```
- (void)concludeDragOperation:(id < NSDraggingInfo >)sender
```

Parameters

sender
The object sending the message; use it to get details about the dragging operation.

Discussion
For this method to be invoked, the previous `performDragOperation:` (page 3657) must have returned `YES`. The destination implements this method to perform any tidying up that it needs to do, such as updating its visual representation now that it has incorporated the dragged data. This message is the last message sent from *sender* to the destination during a dragging session.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSDragging.h`

draggingEnded:

Implement this method to be notified when a drag operation ends in some other destination.

```
- (void)draggingEnded:(id < NSDraggingInfo >)sender
```

Parameters

sender
The object sending the message; use it to get details about the dragging operation.

Discussion
This method might be used by a destination doing auto-expansion in order to collapse any auto-expands.

Note: While this method has been implemented since Mac OS X V 10.0, it was non-functional until Mac OS X v10.5.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSDragging.h

draggingEntered:

Invoked when the dragged image enters destination bounds or frame; delegate returns dragging operation to perform.

```
- (NSDragOperation)draggingEntered:(id < NSDraggingInfo >)sender
```

Parameters

sender

The object sending the message; use it to get details about the dragging operation.

Return Value
One (and only one) of the dragging operation constants described in `Dragging operations` (page 3664) in the `NSDraggingInfo` reference. The default return value (if this method is not implemented by the destination) is the value returned by the previous `draggingEntered:` (page 3655) message.

Discussion
Invoked when a dragged image enters the destination but only if the destination has registered for the pasteboard data type involved in the drag operation. Specifically, this method is invoked when the mouse pointer enters the destination's bounds rectangle (if it is a view object) or its frame rectangle (if it is a window object).

This method must return a value that indicates which dragging operation the destination will perform when the image is released. In deciding which dragging operation to return, the method should evaluate the overlap between both the dragging operations allowed by the source (obtained from *sender* with the `draggingSourceOperationMask` (page 3663) method) and the dragging operations and pasteboard data types the destination itself supports.

If none of the operations is appropriate, this method should return `NSDragOperationNone` (this is the default response if the method is not implemented by the destination). A destination will still receive `draggingUpdated:` (page 3656) and `draggingExited:` (page 3655) even if `NSDragOperationNone` is returned by this method.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `draggingUpdated:` (page 3656)
- `draggingExited:` (page 3655)
- `prepareForDragOperation:` (page 3657)

Declared In
NSDragging.h

draggingExited:

Invoked when the dragged image exits the destination's bounds rectangle (in the case of a view object) or its frame rectangle (in the case of a window object).

```
- (void)draggingExited:(id < NSDraggingInfo >)sender
```

Parameters

sender

The object sending the message; use it to get details about the dragging operation.

Availability

Available in Mac OS X v10.0 and later.

Declared In

NSDragging.h

draggingUpdated:

Invoked periodically as the image is held within the destination area, allowing modification of the dragging operation or mouse-pointer position.

```
- (NSDragOperation)draggingUpdated:(id < NSDraggingInfo >)sender
```

Parameters

sender

The object sending the message; use it to get details about the dragging operation.

Return Value

One (and only one) of the dragging operation constants described in `Dragging operations` (page 3664) in the `NSDraggingInfo` reference. The default return value (if this method is not implemented by the destination) is the value returned by the previous `draggingEntered:` (page 3655) message.

Discussion

For this to be invoked, the destination must have registered for the pasteboard data type involved in the drag operation. The messages continue until the image is either released or dragged out of the window or view.

This method provides the destination with an opportunity to modify the dragging operation depending on the position of the mouse pointer inside of the destination view or window object. For example, you may have several graphics or areas of text contained within the same view and wish to tailor the dragging operation, or to ignore the drag event completely, depending upon which object is underneath the mouse pointer at the time when the user releases the dragged image and the `performDragOperation:` (page 3657) method is invoked.

You typically examine the contents of the pasteboard in the `draggingEntered:` (page 3655) method, where this examination is performed only once, rather than in the `draggingUpdated:` (page 3656) method, which is invoked multiple times.

Only one destination at a time receives a sequence of `draggingUpdated:` (page 3656) messages. If the mouse pointer is within the bounds of two overlapping views that are both valid destinations, the uppermost view receives these messages until the image is either released or dragged out.

Availability

Available in Mac OS X v10.0 and later.

See Also

- `draggingExited:` (page 3655)
- `prepareForDragOperation:` (page 3657)

Declared In
NSDragging.h

performDragOperation:

Invoked after the released image has been removed from the screen, signaling the receiver to import the pasteboard data.

```
- (BOOL)performDragOperation:(id < NSDraggingInfo >)sender
```

Parameters

sender
The object sending the message; use it to get details about the dragging operation.

Return Value
If the destination accepts the data, it returns YES; otherwise it returns NO. The default is to return NO.

Discussion
For this method to be invoked, the previous prepareForDragOperation: (page 3657) message must have returned YES. The destination should implement this method to do the real work of importing the pasteboard data represented by the image.

Availability
Available in Mac OS X v10.0 and later.

See Also
- concludeDragOperation: (page 3654)

Declared In
NSDragging.h

prepareForDragOperation:

Invoked when the image is released, allowing the receiver to agree to or refuse drag operation.

```
- (BOOL)prepareForDragOperation:(id < NSDraggingInfo >)sender
```

Parameters

sender
The object sending the message; use it to get details about the dragging operation.

Return Value
YES if the receiver agrees to perform the drag operation and NO if not.

Discussion
This method is invoked only if the most recent draggingEntered: (page 3655) or draggingUpdated: (page 3656) message returned an acceptable drag-operation value.

Availability
Available in Mac OS X v10.0 and later.

See Also
- performDragOperation: (page 3657)

Declared In
NSDragging.h

wantsPeriodicDraggingUpdates

Asks the destination object whether it wants to receive periodic `draggingUpdated:` (page 3656) messages.

```
- (BOOL)wantsPeriodicDraggingUpdates
```

Return Value
`YES` if the destination wants to receive periodic `draggingUpdated:` (page 3656) messages, `NO` otherwise.

Discussion
If the destination returns `NO`, these messages are sent only when the mouse moves or a modifier flag changes. Otherwise the destination gets the default behavior, where it receives periodic dragging-updated messages even if nothing changes.

Availability
Available in Mac OS X v10.4 and later.

Overview

The `NSDraggingInfo` protocol declares methods that supply information about a dragging session. `NSDraggingInfo` methods are designed to be invoked from within a class's implementation of `NSDraggingDestination` informal protocol methods. The Application Kit automatically passes an object that conforms to the `NSDraggingInfo` protocol as the argument to each of the methods defined by `NSDraggingDestination`. `NSDraggingInfo` messages should be sent to this object; you never need to create a class that implements the `NSDraggingInfo` protocol.

Tasks

Obtaining Information About the Dragging Session

- `draggingPasteboard` (page 3662)
  Returns the pasteboard object that holds the data being dragged.
- `draggingSequenceNumber` (page 3662)
  Returns a number that uniquely identifies the dragging session.
- `draggingSource` (page 3662)
  Returns the source, or owner, of the dragged data.
- `draggingSourceOperationMask` (page 3663)
  Returns the dragging operation mask of the dragging source.

- draggingLocation (page 3661)
  Returns the current location of the mouse pointer in the base coordinate system of the destination object's window.
- draggingDestinationWindow (page 3661)
  Returns the destination window for the dragging operation.
- namesOfPromisedFilesDroppedAtDestination: (page 3663)
  Sets the drop location for promised files and returns the names of the files that the receiver promises to create there.

Getting Image Information

- draggedImage (page 3660)
  Returns the image being dragged.
- draggedImageLocation (page 3661)
  Returns the current location of the dragged image's origin.

Sliding the Image

- slideDraggedImageTo: (page 3664)
  Slides the image to a specified location.

Instance Methods

draggedImage

Returns the image being dragged.

```
- (NSImage *)draggedImage
```

Return Value
The image being dragged.

Discussion
This image object visually represents the data put on the pasteboard during the drag operation; however, it is the pasteboard data and not this image that is ultimately utilized in the dragging operation.

Availability
Available in Mac OS X v10.0 and later.

See Also
- draggedImageLocation (page 3661)

Declared In
NSDragging.h

draggedImageLocation

Returns the current location of the dragged image's origin.

```
- (NSPoint)draggedImageLocation
```

Return Value
The dragged image's origin, in the base coordinate system of the destination object's window.

Discussion
The image moves along with the mouse pointer (the position of which is given by `draggingLocation` (page 3661)) but may be positioned at some offset.

Availability
Available in Mac OS X v10.0 and later.

See Also
`- draggedImage` (page 3660)

Declared In
`NSDragging.h`

draggingDestinationWindow

Returns the destination window for the dragging operation.

```
- (NSWindow *)draggingDestinationWindow
```

Return Value
The destination window for the dragging operation.

Discussion
Either this window is the destination itself, or it contains the view object that is the destination.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSDragging.h`

draggingLocation

Returns the current location of the mouse pointer in the base coordinate system of the destination object's window.

```
- (NSPoint)draggingLocation
```

Return Value
The current location of the mouse pointer in the base coordinate system of the destination object's window.

Availability
Available in Mac OS X v10.0 and later.

See Also
- draggedImageLocation (page 3661)

Declared In
NSDragging.h

draggingPasteboard

Returns the pasteboard object that holds the data being dragged.

```
- (NSPasteboard *)draggingPasteboard
```

Return Value
The pasteboard object that holds the data being dragged.

Discussion
The dragging operation that is ultimately performed utilizes this pasteboard data and not the image returned by the draggedImage (page 3660) method.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSDragging.h

draggingSequenceNumber

Returns a number that uniquely identifies the dragging session.

```
- (NSInteger)draggingSequenceNumber
```

Return Value
A number that uniquely identifies the dragging session.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSDragging.h

draggingSource

Returns the source, or owner, of the dragged data.

```
- (id)draggingSource
```

Return Value
The source, or owner, of the dragged data.

Discussion
This method returns nil if the source is not in the same application as the destination. The dragging source implements methods from the NSDraggingSource informal protocol.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSDragging.h

draggingSourceOperationMask

Returns the dragging operation mask of the dragging source.

```
- (NSDragOperation)draggingSourceOperationMask
```

Return Value
The dragging operation mask, which is declared by the dragging source through its `draggingSourceOperationMaskForLocal:` (page 3670) method. If the source does not permit any dragging operations, this method should return `NSDragOperationNone`.

Discussion
If the source permits dragging operations, the elements in the mask are one or more of the constants described in "Obtaining Information About the Dragging Session" (page 3659), combined using the C bitwise OR operator.

If the user is holding down a modifier key during the dragging session and the source does not prohibit modifier keys from affecting the drag operation (through its `ignoreModifierKeysWhileDragging` (page 3670) method), then the operating system combines the dragging operation value that corresponds to the modifier key (see the descriptions below) with the source's mask using the C bitwise AND operator.

The modifier keys are associated with the dragging operation options shown below:

Modifier Key	Dragging Operation
Control	`NSDragOperationLink`
Option	`NSDragOperationCopy`
Command	`NSDragOperationGeneric`

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSDragging.h

namesOfPromisedFilesDroppedAtDestination:

Sets the drop location for promised files and returns the names of the files that the receiver promises to create there.

```
- (NSArray *)namesOfPromisedFilesDroppedAtDestination:(NSURL *)dropDestination
```

Parameters

dropDestination

A URL object specifying the drop location for promised files.

Return Value

An array of file names, which are not full paths.

Discussion

Drag destinations should invoke this method within their `performDragOperation:` (page 3657) method. The source may or may not have created the files by the time this method returns.

Availability

Available in Mac OS X v10.2 and later.

Declared In

`NSDragging.h`

slideDraggedImageTo:

Slides the image to a specified location.

```
- (void)slideDraggedImageTo:(NSPoint)aPoint
```

Parameters

aPoint

A point that specifies a location in the screen coordinate system.

Discussion

This method can be used to adjust the location to which the dragged image will slide back if the drag is rejected.

It should only be invoked from within the destination's implementation of `prepareForDragOperation:` (page 3657), and will only have effect if the destination rejects the drag.

This method is invoked after the user has released the image but before it is removed from the screen.

Special Considerations

This method has been available since Mac OS X v 10.0, however it was not implemented until Mac OS X v 10.5. Previous to that version, it did nothing.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSDragging.h`

Constants

Dragging operations

These constants are used by `draggingSourceOperationMask` (page 3663).

```
enum {
   NSDragOperationNone    = 0,
   NSDragOperationCopy    = 1,
   NSDragOperationLink    = 2,
   NSDragOperationGeneric = 4,
   NSDragOperationPrivate = 8,
   NSDragOperationAll_Obsolete  = 15,
   NSDragOperationMove    = 16,
   NSDragOperationDelete  = 32,
   NSDragOperationEvery   = NSUIntegerMax
};
typedef NSUInteger NSDragOperation;
```

Constants

`NSDragOperationCopy`
The data represented by the image can be copied.
Available in Mac OS X v10.0 and later.
Declared in `NSDragging.h`.

`NSDragOperationLink`
The data can be shared.
Available in Mac OS X v10.0 and later.
Declared in `NSDragging.h`.

`NSDragOperationGeneric`
The operation can be defined by the destination.
Available in Mac OS X v10.0 and later.
Declared in `NSDragging.h`.

`NSDragOperationPrivate`
The operation is negotiated privately between the source and the destination.
Available in Mac OS X v10.0 and later.
Declared in `NSDragging.h`.

`NSDragOperationAll_Obsolete`
The `NSDragOperationAll` constant is deprecated. Use `NSDragOperationEvery` (page 3665) instead.
Available in Mac OS X v10.0 and later.
Declared in `NSDragging.h`.

`NSDragOperationMove`
The data can be moved.
Available in Mac OS X v10.0 and later.
Declared in `NSDragging.h`.

`NSDragOperationDelete`
The data can be deleted.
Available in Mac OS X v10.0 and later.
Declared in `NSDragging.h`.

`NSDragOperationEvery`
All of the above.
Available in Mac OS X v10.0 and later.
Declared in `NSDragging.h`.

`NSDragOperationNone`
No drag operations are allowed.

Available in Mac OS X v10.0 and later.

Declared in `NSDragging.h`.

NSDragOperationAll Deprecation

The NSDragOperationAll constant has been deprecated. Use `NSDragOperationEvery` (page 3665) instead.

```
#define NSDragOperationAll NSDragOperationAll_Obsolete
```

Constants

`NSDragOperationAll`
Use `NSDragOperationEvery` (page 3665) instead.

Available in Mac OS X v10.0 and later.

Declared in `NSDragging.h`.

NSDraggingSource Protocol Reference

(informal protocol)

Framework	/System/Library/Frameworks/AppKit.framework
Declared in	AppKit/NSDragging.h
Companion guide	Drag and Drop Programming Topics for Cocoa

Overview

The `NSDraggingSource` informal protocol declares methods that are implemented by the source object in a dragging session. The dragging source is specified as an argument to the `dragImage:at:offset:event:pasteboard:source:slideBack:` (page 3168) message, sent to a window or view object to initiate the dragging session.

The `NSDraggingSource` methods are invoked only if the dragging source implements them. All methods are invoked automatically during a dragging session—you never send an `NSDraggingSource` message directly to an object.

Tasks

Specifying Dragging Options

- `draggingSourceOperationMaskForLocal:` (page 3670)
  Returns an integer bit mask indicating the types of dragging operations the source object will allow to be performed on the dragged image's data.
- `ignoreModifierKeysWhileDragging` (page 3670)
  Sets whether the use of modifier keys should have an effect on the type of operation performed.

Responding to Messages During a Dragging Session

- `draggedImage:beganAt:` (page 3668)
  Gives the source object an opportunity to respond to the initiation of a dragging session.
- `draggedImage:movedTo:` (page 3669)
  Informs the dragging source when a dragged image moves to a new screen coordinate.
- `draggedImage:endedAt:operation:` (page 3669)
  Invoked after the dragging destination has been given a chance to operate on the data represented by the image,

- `namesOfPromisedFilesDroppedAtDestination:` (page 3671)
  Returns the names of the files that the receiver promises to create at a specified location.
- `draggedImage:endedAt:deposited:` (page 3668) *required method* Deprecated in Mac OS X v10.1
  Invoked after the dragging destination has been given a chance to operate on the data represented by the image. (required) (Deprecated. Use `draggedImage:endedAt:operation:` (page 3669) instead.)

Instance Methods

draggedImage:beganAt:

Gives the source object an opportunity to respond to the initiation of a dragging session.

```
- (void)draggedImage:(NSImage *)anImage beganAt:(NSPoint)aPoint
```

Parameters

anImage
The image of the dragged item.

aPoint
The origin of the image in screen coordinates.

Discussion
This method is invoked when *anImage* is displayed but before it starts following the mouse. For example, you might choose to have the source give a visual indication to the user that data is being dragged from the source.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `convertScreenToBase:` (page 3314) (NSWindow)
- `convertBaseToScreen:` (page 3313) (NSWindow)
- `convertPoint:fromView:` (page 3155) (NSView)
- `convertPoint:toView:` (page 3155) (NSView)

Declared In
`NSDragging.h`

draggedImage:endedAt:deposited:

Invoked after the dragging destination has been given a chance to operate on the data represented by the image. (required) (Deprecated in Mac OS X v10.1. Use `draggedImage:endedAt:operation:` (page 3669) instead.)

```
- (void)draggedImage:(NSImage *)anImage endedAt:(NSPoint)aPoint deposited:(BOOL)flag
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.1.

Declared In
NSDragging.h

draggedImage:endedAt:operation:

Invoked after the dragging destination has been given a chance to operate on the data represented by the image,

```
- (void)draggedImage:(NSImage *)anImage endedAt:(NSPoint)aPoint
    operation:(NSDragOperation)operation
```

Parameters

anImage
The dragged image.

aPoint
The point locating the image's origin in the screen coordinate system when it was released.

operation
An integer constant that indicates the operation performed by the destination.

Discussion
This method is invoked after the dragged image (*anImage*) has been released and the dragging destination has been given a chance to operate on the data it represents. This method provides the source object with an opportunity to respond to either a successful or a failed dragging session. For example, if you are moving data from one location to another, you could use this method to make the source data disappear from its previous location, if the dragging session is successful, or reset itself to its previous state, in the event of a failure.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSDragging.h

draggedImage:movedTo:

Informs the dragging source when a dragged image moves to a new screen coordinate.

```
- (void)draggedImage:(NSImage *)draggedImage movedTo:(NSPoint)screenPoint
```

Parameters

draggedImage
The dragged image.

screenPoint
The point specifying the new location of the image in screen coordinates.

Discussion
This message is similar to the dragging destination being sent `draggingUpdated:` (page 3656) messages.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSDragging.h

draggingSourceOperationMaskForLocal:

Returns an integer bit mask indicating the types of dragging operations the source object will allow to be performed on the dragged image's data.

```
- (NSDragOperation)draggingSourceOperationMaskForLocal:(BOOL)isLocal
```

Parameters

isLocal

YES indicates that the candidate destination object (the window or view over which the dragged image is currently poised) is in the same application as the source, while a NO value indicates that the destination object is in a different application.

Return Value
A mask, created by combining the dragging operations listed in the NSDragOperation (page 3664) section of NSDraggingInfo protocol reference using the C bitwise OR operator.If the source does not permit any dragging operations, it should return NSDragOperationNone (page 3666).

Discussion
If not implemented, the default value is NSDragOperationCopy (page 3665) | NSDragOperationLink (page 3665) | NSDragOperationGeneric (page 3665) | NSDragOperationPrivate (page 3665).

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSDragging.h

ignoreModifierKeysWhileDragging

Sets whether the use of modifier keys should have an effect on the type of operation performed.

```
- (BOOL)ignoreModifierKeysWhileDragging
```

Return Value
Return NO, if the user can tailor the drag operation by holding down a modifier key during the drag.

Discussion
If this method is not implemented the default behavior is equivalent to returning NO

The dragging option that corresponds to the modifier key is combined with the source's mask (as set with the draggingSourceOperationMaskForLocal: (page 3670) method) using the C bitwise OR operator. See the description for the draggingSourceOperationMask (page 3663) method in the NSDraggingInfo protocol specification for more information about dragging masks and modifier keys.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSDragging.h

namesOfPromisedFilesDroppedAtDestination:

Returns the names of the files that the receiver promises to create at a specified location.

```
- (NSArray *)namesOfPromisedFilesDroppedAtDestination:(NSURL *)dropDestination
```

Parameters

dropDestination

A URL object that identifies the location at which the promised files will be created.

Return Value

An array of the names of files (not full paths) that the receiver promises to create at `dropDestination`.

Discussion

This method is invoked when the drop has been accepted by the destination and the destination, in the case of another Cocoa application, invokes the NSDraggingInfo method `namesOfPromisedFilesDroppedAtDestination:` (page 3663). For long operations, you can cache *dropDestination* and defer the creation of the files until the `draggedImage:endedAt:operation:` (page 3669) method to avoid blocking the destination application.

Availability

Available in Mac OS X v10.2 and later.

Declared In

`NSDragging.h`

Overview

The `NSDrawerDelegate` protocol defines the messages sent to delegates of `NSDrawer`. All of the methods of this protocol are optional.

Tasks

Opening and Closing Drawers

- `drawerShouldOpen:` (page 3675)
  Asks the delegate if the specified drawer should open.
- `drawerWillOpen:` (page 3676)
  Notifies the delegate that the drawer will open.
- `drawerDidOpen:` (page 3674)
  Notifies the delegate that the drawer has opened.
- `drawerShouldClose:` (page 3674)
  Asks the delegate if the specified drawer should close.
- `drawerWillClose:` (page 3675)
  Notifies the delegate the the drawer will close.
- `drawerDidClose:` (page 3674)
  Notifies the delegate that the drawer has closed.

Managing Drawer Size

`- drawerWillResizeContents:toSize:` (page 3676)
Invoked when the user resizes the drawer or parent.

Instance Methods

drawerDidClose:

Notifies the delegate that the drawer has closed.

```
- (void)drawerDidClose:(NSNotification *)notification
```

Parameters

notification
An `NSDrawerDidCloseNotification` (page ?) notification sent by the default notification center immediately after the drawer has closed.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSDrawer.h`

drawerDidOpen:

Notifies the delegate that the drawer has opened.

```
- (void)drawerDidOpen:(NSNotification *)notification
```

Parameters

notification
An `NSDrawerDidOpenNotification` (page ?) notification, sent by the default notification center immediately after the drawer has opened.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSDrawer.h`

drawerShouldClose:

Asks the delegate if the specified drawer should close.

```
- (BOOL)drawerShouldClose:(NSDrawer *)sender
```

Parameters

sender

The drawer being closed.

Return Value

`YES` to allow the drawer to close; `NO` to prevent it from closing.

Discussion

This method is invoked on user-initiated attempts to close a drawer by dragging it or when the `close:` (page ?) method is called.

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

`NSDrawer.h`

drawerShouldOpen:

Asks the delegate if the specified drawer should open.

```
- (BOOL)drawerShouldOpen:(NSDrawer *)sender
```

Parameters

sender

The drawer requesting permission to open.

Return Value

`YES` if the drawer should open; `NO` to prevent the drawer from opening.

Discussion

This method is invoked on user-initiated attempts to open a drawer by dragging it or when the `open:` (page ?) method is called.

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

`NSDrawer.h`

drawerWillClose:

Notifies the delegate the the drawer will close.

```
- (void)drawerWillClose:(NSNotification *)notification
```

Parameters

notification

An `NSDrawerWillCloseNotification` (page ?) notification sent by the default notification center immediately before the drawer is closed.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSDrawer.h

drawerWillOpen:

Notifies the delegate that the drawer will open.

```
- (void)drawerWillOpen:(NSNotification *)notification
```

Parameters

notification
An NSDrawerWillOpenNotification (page ?) notification, sent by the default notification center immediately before the drawer is opened.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSDrawer.h

drawerWillResizeContents:toSize:

Invoked when the user resizes the drawer or parent.

```
- (NSSize)drawerWillResizeContents:(NSDrawer *)sender toSize:(NSSize)contentSize
```

Parameters

sender
The drawer being resized.

contentSize
The proposed new size of the drawer.

Return Value
The size that the drawer should be resized to. To resize to a different size, simply return the desired size from this method; to avoid resizing, return the current size.

Discussion
The receiver's minimum and maximum size constraints have already been applied when this method is invoked. While the user is resizing an NSDrawer or its parent, the delegate is sent a series of windowWillResize messages as the NSDrawer or parent window is dragged.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSDrawer.h

NSEditor Protocol Reference

(informal protocol)

Adopted by	NSController (informal protocol)
Framework	/System/Library/Frameworks/AppKit.framework
Declared in	AppKit/NSKeyValueBinding.h
Availability	Available in Mac OS X v10.3 and later.
Companion guide	Cocoa Bindings Programming Topics

Overview

The NSEditor informal protocol is implemented by controllers and user interface elements. It provides a means for requesting that the receiver commit or discard any pending edits.

These methods are typically invoked on user interface elements by a controller. They can also be sent to a controller in response to a user's attempt to save a document or quit an application.

NSController provides an implementation of this protocol, as do the Application Kit user interface elements that support binding.

Tasks

Managing Editing

- `discardEditing` (page 3679)
  Causes the receiver to discard any changes, restoring the previous values.
- `commitEditing` (page 3678)
  Returns whether the receiver was able to commit any pending edits.
- `commitEditingWithDelegate:didCommitSelector:contextInfo:` (page 3678)
  Attempt to commit any currently edited results of the receiver.

Instance Methods

commitEditing

Returns whether the receiver was able to commit any pending edits.

```
- (BOOL)commitEditing
```

Discussion
Returns `YES` if the changes were successfully applied to the model, `NO` otherwise. A commit is denied if the receiver fails to apply the changes to the model object, perhaps due to a validation error.

Availability
Available in Mac OS X v10.3 and later.

See Also
`- discardEditing` (page 3679)

Related Sample Code
AbstractTree
Core Data HTML Store
CoreRecipes
Image Kit with Core Data

Declared In
`NSKeyValueBinding.h`

commitEditingWithDelegate:didCommitSelector:contextInfo:

Attempt to commit any currently edited results of the receiver.

```
- (void)commitEditingWithDelegate:(id)delegate
    didCommitSelector:(SEL)didCommitSelector contextInfo:(void *)contextInfo
```

Discussion
The receiver must have been registered as the editor of an object using `objectDidBeginEditing:`, and has not yet been unregistered by a subsequent invocation of `objectDidEndEditing:`. When the committing has either succeeded or failed, send the following message to the specified object. The *`didCommitSelector`* method must have the following method signature:

```
- (void)editor:(id)editor didCommit:(BOOL)didCommit contextInfo:(void
*)contextInfo
```

If an error occurs while attempting to commit, for example if key-value coding validation fails, an implementation of this method should typically send the NSView in which editing is being done a `presentError:modalForWindow:delegate:didRecoverSelector:contextInfo:` message, specifying the view's containing window.

Availability
Available in Mac OS X v10.4 and later.

Related Sample Code
CoreRecipes

Declared In
`NSKeyValueBinding.h`

discardEditing

Causes the receiver to discard any changes, restoring the previous values.

```
- (void)discardEditing
```

Availability
Available in Mac OS X v10.3 and later.

NSEditorRegistration Protocol Reference

(informal protocol)

Adopted by	NSController (informal protocol)
Framework	/System/Library/Frameworks/AppKit.framework
Declared in	AppKit/NSKeyValueBinding.h
Availability	Available in Mac OS X v10.3 and later.
Companion guide	Cocoa Bindings Programming Topics

Overview

The `NSEditorRegistration` informal protocol is implemented by controllers to provide an interface for a view, the editor, to inform the controller when it has uncommitted changes.

An implementor is responsible for tracking which editors have uncommitted changes, and sending those editors `commitEditing` (page 3678) and `discardEditing` (page 3679) messages, as appropriate, to force the editor to submit, or discard, their values.

`NSController` provides an implementation of this informal protocol. You would implement this protocol if you wanted to provide your own controller class without subclassing `NSController`.

Tasks

Managing Editing

- `objectDidBeginEditing:` (page 3682)
  This message should be sent to the receiver when *`editor`* has uncommitted changes that can affect the receiver.
- `objectDidEndEditing:` (page 3682)
  This message should be sent to the receiver when *`editor`* has finished editing a property belonging to the receiver.

Instance Methods

objectDidBeginEditing:

This message should be sent to the receiver when *editor* has uncommitted changes that can affect the receiver.

```
- (void)objectDidBeginEditing:(id)editor
```

Availability
Available in Mac OS X v10.3 and later.

See Also

NSFontPanelValidation Protocol Reference

(informal protocol)

Framework	/System/Library/Frameworks/AppKit.framework
Declared in	AppKit/NSFontPanel.h
Companion guide	Font Panel

Overview

Informal protocol. The Font Panel can be explicitly ordered to display some or all of its elements by responding to the `validModesForFontPanel:` (page 3683) instance method.

Tasks

Validating Modes for a Font Panel

`- validModesForFontPanel:` (page 3683)
Returns the mode mask corresponding to the expected font panel mode.

Instance Methods

validModesForFontPanel:

Returns the mode mask corresponding to the expected font panel mode.

```
- (NSUInteger)validModesForFontPanel:(NSFontPanel *)fontPanel
```

Discussion
The mode masks are defined in `Mode Masks` (page 3684).

The Font Panel has the ability to hide elements that are not applicable for a given context by having the target respond to `validModesForFontPanel:`. If the target desires a font panel mode other than the standard mode mask, it must respond to this method.

This message is sent up the responder chain to the first responder implementing the method. Ideally that object should be the first responder found that also implements `changeFont:` (page 1239).

Availability
Available in Mac OS X v10.3 and later.

Declared In
`NSFontPanel.h`

Constants

Mode Masks

The following constants correspond to the available font panel mode masks returned by `validModesForFontPanel:` (page 3683).

```
enum {
    NSFontPanelFaceModeMask = 1 << 0,
    NSFontPanelSizeModeMask = 1 << 1,
    NSFontPanelCollectionModeMask = 1 << 2,
    NSFontPanelUnderlineEffectModeMask = 1<<8,
    NSFontPanelStrikethroughEffectModeMask = 1<<9,
    NSFontPanelTextColorEffectModeMask = 1<< 10,
    NSFontPanelDocumentColorEffectModeMask = 1<<11,
    NSFontPanelShadowEffectModeMask = 1<<12,
    NSFontPanelAllEffectsModeMask = 0XFFF00,
    NSFontPanelStandardModesMask = 0xFFFF,
    NSFontPanelAllModesMask = 0xFFFFFFFF
};
```

Constants

`NSFontPanelFaceModeMask`
Display the typeface column.
Available in Mac OS X v10.3 and later.
Declared in `NSFontPanel.h`.

`NSFontPanelSizeModeMask`
Display the font size column.
Available in Mac OS X v10.3 and later.
Declared in `NSFontPanel.h`.

`NSFontPanelCollectionModeMask`
Display the font collections column.
Available in Mac OS X v10.3 and later.
Declared in `NSFontPanel.h`.

`NSFontPanelUnderlineEffectModeMask`
Display the underline popup menu.
Available in Mac OS X v10.4 and later.
Declared in `NSFontPanel.h`.

`NSFontPanelStrikethroughEffectModeMask`
Display the strike-through popup menu.

Available in Mac OS X v10.4 and later.

Declared in `NSFontPanel.h`.

`NSFontPanelTextColorEffectModeMask`
Display the text color button.

Available in Mac OS X v10.4 and later.

Declared in `NSFontPanel.h`.

`NSFontPanelDocumentColorEffectModeMask`
Display the document color button.

Available in Mac OS X v10.4 and later.

Declared in `NSFontPanel.h`.

`NSFontPanelShadowEffectModeMask`
Display the shadow effects button.

Available in Mac OS X v10.4 and later.

Declared in `NSFontPanel.h`.

`NSFontPanelAllEffectsModeMask`
Display all the effects user interface items.

Available in Mac OS X v10.4 and later.

Declared in `NSFontPanel.h`.

`NSFontPanelStandardModesMask`
Display the standard default font panel—that is, including the collections, typeface, and size columns.

Available in Mac OS X v10.3 and later.

Declared in `NSFontPanel.h`.

`NSFontPanelAllModesMask`
Display all the available adornments.

Available in Mac OS X v10.3 and later.

Declared in `NSFontPanel.h`.

NSGlyphStorage Protocol Reference

Adopted by	NSLayoutManager
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.3 and later.
Declared in	AppKit/NSGlyphGenerator.h
Companion guides	Text System Overview Text Layout Programming Guide

Overview

The `NSGlyphStorage` protocol defines the methods that a glyph storage object must implement in order to interact properly with `NSGlyphGenerator`.

An example of a Cocoa class conforming to the `NSGlyphStorage` protocol is `NSLayoutManager`.

Tasks

Returning Text Storage

`- attributedString` (page 3688) *required method*
Returns the text storage object from which the `NSGlyphGenerator` object procures characters for glyph generation. (required)

Returning Glyph Display Options

`- layoutOptions` (page 3689) *required method*
Returns the current layout options. (required)

Modifying the Glyph Cache

`- insertGlyphs:length:forStartingGlyphAtIndex:characterIndex:` (page 3688) *required method*
Inserts the given glyphs into the glyph cache and maps them to the specified characters. (required)

Instance Methods

attributedString

Returns the text storage object from which the NSGlyphGenerator object procures characters for glyph generation. (required)

```
- (NSAttributedString *)attributedString
```

Return Value
The receiver's text storage object.

Availability
Available in Mac OS X v10.3 and later.

Declared In
NSGlyphGenerator.h

insertGlyphs:length:forStartingGlyphAtIndex:characterIndex:

Inserts the given glyphs into the glyph cache and maps them to the specified characters. (required)

```
- (void)insertGlyphs:(const NSGlyph *)glyphs length:(NSUInteger)length
    forStartingGlyphAtIndex:(NSUInteger)glyphIndex
    characterIndex:(NSUInteger)charIndex
```

Parameters

glyphs
The glyphs to insert.

glyphIndex
Location in the glyph cache to begin inserting glyphs.

length
Number of glyphs to insert.

charIndex
Index of first character to be mapped.

Discussion
This is a bulk insert method for the glyph cache.

Availability
Available in Mac OS X v10.3 and later.

Declared In
NSGlyphGenerator.h

layoutOptions

Returns the current layout options. (required)

```
- (NSUInteger)layoutOptions
```

Return Value
The layout options as a bit mask, as defined in "Constants" (page 3689).

Availability
Available in Mac OS X v10.3 and later.

Declared In
`NSGlyphGenerator.h`

setIntAttribute:value:forGlyphAtIndex:

Sets a custom attribute value for a given glyph. (required)

```
- (void)setIntAttribute:(NSInteger)attributeTag value:(NSInteger)val
    forGlyphAtIndex:(NSUInteger)glyphIndex
```

Parameters

attributeTag
The custom attribute.

val
The new attribute value.

glyphIndex
Index of the glyph whose attribute is set.

Discussion
Custom attributes are glyph attributes such as `NSGlyphInscription` or attributes defined by subclasses. Subclasses that define their own custom attributes must override this method and provide their own storage for the attribute values. Nonnegative tags are reserved; you can define your own attributes with negative tags and set values using this method.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`NSGlyphGenerator.h`

Constants

Layout Options

These constants describe layout options returned as a bit mask by the `layoutOptions` (page 3689) method.

```
enum {
    NSShowControlGlyphs = (1 << 0),
    NSShowInvisibleGlyphs = (1 << 1),
    NSWantsBidiLevels = (1 << 2)
};
```

Constants

`NSShowControlGlyphs`

Generates displayable glyphs for control characters.

Available in Mac OS X v10.3 and later.

Declared in `NSGlyphGenerator.h`.

`NSShowInvisibleGlyphs`

Generates displayable glyphs for invisible characters.

Available in Mac OS X v10.3 and later.

Declared in `NSGlyphGenerator.h`.

`NSWantsBidiLevels`

Generates directional formatting codes for bidirectional text.

Available in Mac OS X v10.3 and later.

Declared in `NSGlyphGenerator.h`.

Declared In

`NSGlyphGenerator.h`

NSIgnoreMisspelledWords Protocol Reference

Adopted by	NSText
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.0 and later.
Declared in	AppKit/NSSpellProtocol.h
Companion guide	Spell Checking

Overview

Implement this protocol to have the Ignore button in the Spelling panel function properly. The Ignore button allows the user to accept a word that the spelling checker believes is misspelled. In order for this action to update the "ignored words" list for the document being checked, the NSIgnoreMisspelledWords protocol must be implemented.

This protocol is necessary because a list of ignored words is useful only if it pertains to the entire document being checked, but the spelling checker (NSSpellChecker object) does not check the entire document for spelling at once. The spelling checker returns as soon as it finds a misspelled word. Thus, it checks only a subset of the document at any one time. The user usually wants to check the entire document, so usually several spelling checks are run in succession until no misspelled words are found. This protocol allows the list of ignored words to be maintained per document, even though the spelling checks are not run per document.

The NSIgnoreMisspelledWords protocol specifies a method, `ignoreSpelling:` (page 3692), which should be implemented like this:

```
- (void)ignoreSpelling:(id)sender {
    [[NSSpellChecker sharedSpellChecker] ignoreWord:[[sender selectedCell]
stringValue]
                                        inSpellDocumentWithTag: myDocumentTag];
}
```

The second argument to the NSSpellChecker method `ignoreWord:inSpellDocumentWithTag:` (page 2527) is a tag that the NSSpellChecker can use to distinguish the documents being checked. Once the NSSpellChecker has a way to distinguish the various documents, it can append new ignored words to the appropriate list.

To make the ignored words feature useful, the application must store a document's ignored words list with the document. See the NSSpellChecker class description for more information.

Tasks

Ignoring Spellings

- ignoreSpelling: (page 3692) *required method*

Instance Methods

ignoreSpelling:

- (void)**ignoreSpelling:**(id)*sender*

Discussion
Implement this action method to allow an application to ignore misspelled words on a document-by-document basis. This message is sent by the NSSpellChecker instance to the object whose text is being checked.

Implement this method by using the code shown in the protocol description.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSSpellProtocol.h

NSImageDelegate Protocol Reference

Conforms to	NSObject
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.6 and later.
Declared in	AppKit/NSImage.h
Companion guide	Cocoa Drawing Guide

Overview

The `NSImageDelegate` protocol defines the optional methods implemented by delegates of `NSImage` objects.

Tasks

Responding to Drawing Failure

`- imageDidNotDraw:inRect:` (page 3696)
Sent to the delegate when the image object is unable, for whatever reason, to lock focus on its image or draw in the specified rectangle.

Managing Incremental Loads

`- image:didLoadPartOfRepresentation:withValidRows:` (page 3694)
During incremental loading, this method is called repeatedly to inform the delegate that more of the image data is available.

`- image:didLoadRepresentation:withStatus:` (page 3694)
For incremental loading, this method is invoked when the specified image has been loaded and decompressed as fully as is possible.

`- image:didLoadRepresentationHeader:` (page 3695)
During incremental loading, this method is called once enough data has been read to determine the size of the image.

`- image:willLoadRepresentation:` (page 3695)
For incremental loading, this method is invoked when you first attempt to draw the image or otherwise access the bitmap data.

Instance Methods

image:didLoadPartOfRepresentation:withValidRows:

During incremental loading, this method is called repeatedly to inform the delegate that more of the image data is available.

```
- (void)image:(NSImage *)image didLoadPartOfRepresentation:(NSImageRep *)rep
    withValidRows:(NSInteger)rows
```

Parameters

image
The image object whose contents are being loaded.

rep
The image representation object that is receiving and processing the image data.

rows
The number of rows of data that have been decompressed.

Discussion
This method is optional; incremental loading will continue if the delegate does not implement it.

Availability
Available in Mac OS X v10.2 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSImage.h`

image:didLoadRepresentation:withStatus:

For incremental loading, this method is invoked when the specified image has been loaded and decompressed as fully as is possible.

```
- (void)image:(NSImage *)image didLoadRepresentation:(NSImageRep *)rep
    withStatus:(NSImageLoadStatus)status
```

Parameters

image
The image object whose contents are being loaded.

rep
The image representation object that loaded the image data.

status
The status of the load operation. For a list of possible values, see `NSImageLoadStatus` (page 1378) in *NSImage Class Reference*.

Discussion
The delegate must implement this method if it wants to support the incremental loading of images. In that case, you must also set up the image object to be loaded lazily, by initializing it using the `initByReferencingFile:` (page 1350) or `initByReferencingURL:` (page 1351) method.

If an error occurs during downloading or decompression, the *`status`* parameter is set to `NSImageLoadStatusInvalidData`, `NSImageLoadStatusUnexpectedEOF`, or `NSImageLoadStatusReadError`. If the download was cancelled, the *`status`* parameter is set to `NSImageLoadStatusCancelled`.

Availability
Available in Mac OS X v10.2 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSImage.h`

image:didLoadRepresentationHeader:

During incremental loading, this method is called once enough data has been read to determine the size of the image.

```
- (void)image:(NSImage *)image didLoadRepresentationHeader:(NSImageRep *)rep
```

Parameters
`image`
The image object whose contents are being loaded.
`rep`
The image representation object that is receiving and processing the image data.

Discussion
By the time this method is called, the `NSBitmapImageRep` object specified in the *`rep`* parameter is valid and has allocated the memory needed to store the bitmap. The bitmap itself is filled with the image's background color. This method is optional; incremental loading will continue if the delegate does not implement it.

Availability
Available in Mac OS X v10.2 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSImage.h`

image:willLoadRepresentation:

For incremental loading, this method is invoked when you first attempt to draw the image or otherwise access the bitmap data.

```
- (void)image:(NSImage *)image willLoadRepresentation:(NSImageRep *)rep
```

Parameters
`image`
The image object whose contents need to be loaded.

rep
The image representation object that was accessed.

Discussion
Downloading of the image begins immediately after this method returns. This method is optional; incremental loading will continue if the delegate does not implement it.

Availability
Available in Mac OS X v10.2 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSImage.h`

imageDidNotDraw:inRect:

Sent to the delegate when the image object is unable, for whatever reason, to lock focus on its image or draw in the specified rectangle.

```
- (NSImage *)imageDidNotDraw:(id)sender inRect:(NSRect)aRect
```

Parameters
sender
The `NSImage` object that encountered the problem.

aRect
The rectangle that the image object was attempting to draw.

Return Value
An `NSImage` to draw in place of the one in *sender*, or `nil` if the delegate wants to draw the image itself.

Discussion
The delegate can do one of the following:

- Return another `NSImage` object to draw in the sender's place.
- Draw the image itself and return `nil`,.
- Simply return `nil` to indicate that *sender* should give up on the attempt at drawing the image.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSImage.h`

NSKeyValueBindingCreation Protocol Reference

(informal protocol)

Framework	/System/Library/Frameworks/AppKit.framework
Declared in	AppKit/NSKeyValueBinding.h
Companion guides	Cocoa Bindings Programming Topics Cocoa Bindings Reference

Overview

The `NSKeyValueBindingCreation` informal protocol provides methods to create and remove bindings between view objects and controllers or controllers and model objects. In addition, it provides a means for a view subclass to advertise the bindings that it exposes. This informal protocol is implemented by `NSObject` and its methods can be overridden by view and controller subclasses.

When a new binding is created it relates the receiver's binding (for example, a property of the view object) to a property of the observable object specified by a key path. When the value of the specified property of the observable object changes, the receiver is notified using the key-value observing mechanism. A binding also specifies binding options that can further customize how the observing and the observed objects interact.

Bindings are considered to be a property of the object which is bound, and all information related to bindings should be retained by the object. All standard bindings on AppKit objects (views, cells, table columns, controllers) unbind their bindings automatically when they are released, but if you create key-value bindings for other kind of objects, you need to make sure that you remove those bindings when you release them (observed objects don't retain their observers, so controllers/model objects might continue referencing and messaging the objects that were bound to them).

Bindings between objects are typically established in Interface Builder using the Bindings inspector. However, there are times it must be done programmatically, such as when establishing a binding between objects in different nib files.

`NSView` subclasses can expose additional key-value-coding/key-value-observing compliant properties as bindings by calling the class method `exposeBinding:` (page 3698) for each of the properties. This is typically done in the class's `initialize` method. By exposing the bindings that an object supports and creating an Interface Builder palette, you can make instances of your own classes bindable in Interface Builder.

Tasks

Exposing Bindings

`+ exposeBinding:` (page 3698)
Exposes the specified *binding*, advertising its availability.

`- exposedBindings` (page 3699)
Returns an array containing the bindings exposed by the receiver.

Managing Bindings

`- valueClassForBinding:` (page 3701)
Returns the class of the value that will be returned for the specified binding.

`- bind:toObject:withKeyPath:options:` (page 3699)
Establishes a binding between a given property of the receiver and the property of a given object specified by a given key path.

`- optionDescriptionsForBinding:` (page 3700)
Returns an array describing the options for the specified binding.

`- infoForBinding:` (page 3700)
Returns a dictionary describing the receiver's *binding*.

`- unbind:` (page 3701)
Removes a given binding between the receiver and a controller.

Class Methods

exposeBinding:

Exposes the specified *binding*, advertising its availability.

```
+ (void)exposeBinding:(NSString *)binding
```

Parameters

binding
The key path for the property to be exposed.

Discussion
The bound property will be accessed using key-value-coding compliant methods. This method is typically invoked in the class's `initialize` implementation.

Bindings exposed using `exposeBinding` will be exposed automatically in exposedBindings (page 3699) unless that method explicitly filters them out, for example in subclasses.

Availability
Available in Mac OS X v10.3 and later.

Declared In
NSKeyValueBinding.h

Instance Methods

bind:toObject:withKeyPath:options:

Establishes a binding between a given property of the receiver and the property of a given object specified by a given key path.

```
- (void)bind:(NSString *)binding
    toObject:(id)observableController
    withKeyPath:(NSString *)keyPath
    options:(NSDictionary *)options
```

Parameters

binding

The key path for a property of the receiver previously exposed using the `exposeBinding:` (page 3698) method.

observableController

The bound-to object.

keyPath

A key path to a property reachable from *observableController*. The elements in the path must be key-value observing compliant (see *Key-Value Observing Programming Guide*).

options

A dictionary containing options for the binding, such as placeholder objects or an `NSValueTransformer` identifier as described in "Constants" (page 3702). This value is optional—pass `nil` to specify no options.

Availability
Available in Mac OS X v10.3 and later.

See Also
`- unbind:` (page 3701)

```
- (NSArray *)exposedBindings
```

Return Value
An array containing the bindings exposed by the receiver.

Discussion
A subclass can override this method to remove bindings that are exposed by a superclass that are not appropriate for the subclass.

Availability
Available in Mac OS X v10.3 and later.

See Also
`+ exposeBinding:` (page 3698)

Declared In
`NSKeyValueBinding.h`

infoForBinding:

Returns a dictionary describing the receiver's *binding*.

```
- (NSDictionary *)infoForBinding:(NSString *)binding
```

Parameters

binding

The name of a binding.

Return Value
A dictionary with information about *binding*, or `nil` if the binding is not bound. The dictionary contains three key/value pairs: `NSObservedObjectKey`: object bound, `NSObservedKeyPathKey`: key path bound, `NSOptionsKey`: dictionary with the options and their values for the bindings.

Discussion
This method is mostly for use by subclasses which want to analyze the existing bindings of an object.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`NSKeyValueBinding.h`

optionDescriptionsForBinding:

Returns an array describing the options for the specified binding.

```
- (NSArray *)optionDescriptionsForBinding:(NSString *)binding
```

Parameters

binding

The name of a binding

Return Value
Returns an array of `NSAttributeDescription` that describe the options for *binding*.

Discussion
The `NSAttributeDescription` instances in the array are used by Interface Builder to build the options editor user interface of the bindings inspector.

- The option name displayed for the option in the bindings inspector is based on the value of the `NSAttributeDescription` method `name`.
- The type of editor displayed for the option in the bindings inspector is based on the value of the `NSAttributeDescription` method `attributeType`.
- The default value displayed in the bindings inspector for the option is based on the value of the `NSAttributeDescription` method `defaultValue`.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSKeyValueBinding.h`

unbind:

Removes a given binding between the receiver and a controller.

```
- (void)unbind:(NSString *)binding
```

Parameters
binding
The name of a binding.

Availability
Available in Mac OS X v10.3 and later.

See Also
`- bind:toObject:withKeyPath:options:` (page 3699)

Declared In
`NSKeyValueBinding.h`

valueClassForBinding:

Returns the class of the value that will be returned for the specified binding.

```
- (Class)valueClassForBinding:(NSString *)binding
```

Parameters
binding
The name of a binding.

Return Value
The class of the value that will be returned for *binding*.

Discussion
This method is used by Interface Builder to determine the appropriate transformers for a binding.

Implementation of this method is optional.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`NSKeyValueBinding.h`

Constants

Binding Options

The following values are used as keys in the options dictionary passed to the `bind:toObject:withKeyPath:options:` (page 3699) method. These keys are also used in the dictionary returned as the `NSOptionsKey` value of `infoForBinding:` (page 3700). See the *Cocoa Bindings Reference* for more information.

```

Constants

`NSAllowsEditingMultipleValuesSelectionBindingOption`

An `NSNumber` object containing a Boolean value that determines if the binding allows editing when the value represents a multiple selection.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSAlwaysPresentsApplicationModalAlertsBindingOption`
An `NSNumber` object containing a Boolean value that determines if validation and error alert panels displayed as a result of this binding are displayed as application modal alerts. If `YES`, then the alerts are displayed application model, otherwise they are displayed as sheets.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSAllowsNullArgumentBindingOption`
An `NSNumber` object containing a Boolean value that determines if the argument bindings allows passing argument values of `nil`.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSConditionallySetsEditableBindingOption`
An `NSNumber` object containing a Boolean value that determines if the editable state of the user interface item is automatically configured based on the controller's selection.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSConditionallySetsEnabledBindingOption`
An `NSNumber` object containing a Boolean value that determines if the enabled state of the user interface item is automatically configured based on the controller's selection.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSConditionallySetsHiddenBindingOption`
An `NSNumber` object containing a Boolean value that determines if the hidden state of the user interface item is automatically configured based on the controller's selection.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSContentPlacementTagBindingOption`
An `NSNumber` object specifying the tag id of the popup menu item to replace with the content of the array. This allows you to use a popup menu that contains both static and bindings generated items.

Available in Mac OS X v10.5 and later.

Declared in `NSKeyValueBinding.h`.

`NSContinuouslyUpdatesValueBindingOption`
An `NSNumber` object containing a Boolean value that determines whether the value of the binding is updated as edits are made to the user interface item or is updated only when the user interface item resigns as the responder.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSCreatesSortDescriptorBindingOption`
An `NSNumber` object containing a Boolean value that determines if a sort descriptor is created for a table column.

If this value is `NO`, then the table column does not allow sorting.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSDeletesObjectsOnRemoveBindingsOption`
An `NSNumber` object containing a Boolean value that determines if an object is deleted from the managed context immediately upon being removed from a relationship.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSDisplayNameBindingOption`
An `NSString` object containing a human readable string to be displayed for a predicate.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSDisplayPatternBindingOption`
An `NSString` object that specifies a format string used to construct the final value of a string.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSHandlesContentAsCompoundValueBindingOption`
An `NSNumber` object containing a Boolean value that determines if the content is treated as a compound value.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSInsertsNullPlaceholderBindingOption`
An `NSNumber` object containing a Boolean value that determines if an additional item which represents `nil` is inserted into a matrix or pop-up menu before the items in the content array.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSInvokesSeparatelyWithArrayObjectsBindingOption`
An `NSNumber` object containing a Boolean value that determines whether the specified selector is invoked with the array as the argument or is invoked repeatedly with each array item as an argument.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSMultipleValuesPlaceholderBindingOption`
An object that is used as a placeholder when the key path of the bound controller returns the `NSMultipleValuesMarker` marker for a binding.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSNoSelectionPlaceholderBindingOption`
An object that is used as a placeholder when the key path of the bound controller returns the `NSNoSelectionMarker` marker for a binding.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSNotApplicablePlaceholderBindingOption`
An object that is used as a placeholder when the key path of the bound controller returns the `NSNotApplicableMarker` marker for a binding.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSNullPlaceholderBindingOption`
An object that is used as a placeholder when the key path of the bound controller returns `nil` for a binding.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSPredicateFormatBindingOption`
An `NSString` object containing the predicate pattern string for the predicate bindings. Use $value to refer to the value in the search field.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSRaisesForNotApplicableKeysBindingOption`
An `NSNumber` object containing a Boolean value that specifies if an exception is raised when the binding is bound to a key that is not applicable—for example when an object is not key-value coding compliant for a key.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSSelectorNameBindingOption`
An `NSString` object that specifies the method selector invoked by the target binding when the user interface item is clicked.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSSelectsAllWhenSettingContentBindingOption`
An `NSNumber` object containing a Boolean value that specifies if all the items in the array controller are selected when the content is set.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSValidatesImmediatelyBindingOption`
An `NSNumber` object containing a Boolean value that determines if the contents of the binding are validated immediately.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSValueTransformerNameBindingOption`
The value for this key is an identifier of a registered `NSValueTransformer` instance that is applied to the bound value.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSValueTransformerBindingOption`
An `NSValueTransformer` instance that is applied to the bound value.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

Binding Dictionary Keys

The following values are used as keys in the dictionary returned by `infoForBinding:` (page 3700)

```
NSString *NSObservedObjectKey;
NSString *NSObservedKeyPathKey;
NSString *NSOptionsKey;
```

Constants

`NSObservedObjectKey`

The object that is the observable controller of the binding.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSObservedKeyPathKey`

An `NSString` object containing the key path of the binding.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSOptionsKey`

An `NSDictionary` object containing key value pairs as specified in the options dictionary when the binding was created.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

Bindings

The following values are used to specify a binding to `bind:toObject:withKeyPath:options:` (page 3699), `infoForBinding:` (page 3700), `unbind:` (page 3701) and `valueClassForBinding:` (page 3701). See *Cocoa Bindings Reference* for more information.

Constants

`NSAlignmentBinding`

See *Cocoa Bindings Reference* for more information.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSAlternateImageBinding`

See *Cocoa Bindings Reference* for more information.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSAlternateTitleBinding`

See *Cocoa Bindings Reference* for more information.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSAnimateBinding`

See *Cocoa Bindings Reference* for more information.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSAnimationDelayBinding`

See *Cocoa Bindings Reference* for more information.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSArgumentBinding`

See *Cocoa Bindings Reference* for more information.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSAttributedStringBinding`

See *Cocoa Bindings Reference* for more information.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

See *Cocoa Bindings Reference* for more information.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSSelectedIdentifierBinding`

See *Cocoa Bindings Reference* for more information.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSSelectedIndexBinding`

See *Cocoa Bindings Reference* for more information.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSSelectedLabelBinding`

See *Cocoa Bindings Reference* for more information.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSSelectedObjectBinding`

See *Cocoa Bindings Reference* for more information.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSSelectedObjectsBinding`

See *Cocoa Bindings Reference* for more information.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSSelectedTagBinding`

See *Cocoa Bindings Reference* for more information.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSSelectedValueBinding`

See *Cocoa Bindings Reference* for more information.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSSelectedValuesBinding`

See *Cocoa Bindings Reference* for more information.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSSelectionIndexesBinding`

See *Cocoa Bindings Reference* for more information.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSSelectionIndexPathsBinding`

See *Cocoa Bindings Reference* for more information.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSSortDescriptorsBinding`

See *Cocoa Bindings Reference* for more information.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSTargetBinding`

See *Cocoa Bindings Reference* for more information.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSTextColorBinding`

See *Cocoa Bindings Reference* for more information.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSTitleBinding`

See *Cocoa Bindings Reference* for more information.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSToolTipBinding`

See *Cocoa Bindings Reference* for more information.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSTransparentBinding`

See *Cocoa Bindings Reference* for more information.

Available in Mac OS X v10.5 and later.

Declared in `NSKeyValueBinding.h`.

`NSValueBinding`

See *Cocoa Bindings Reference* for more information.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSValuePathBinding`

See *Cocoa Bindings Reference* for more information.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSValueURLBinding`

See *Cocoa Bindings Reference* for more information.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSVisibleBinding`

See *Cocoa Bindings Reference* for more information.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSWarningValueBinding`

See *Cocoa Bindings Reference* for more information.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

`NSWidthBinding`

See *Cocoa Bindings Reference* for more information.

Available in Mac OS X v10.4 and later.

Declared in `NSKeyValueBinding.h`.

NSLayoutManagerDelegate Protocol Reference

Conforms to	NSObject
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.6 and later.
Declared in	AppKit/NSLayoutManager.h
Companion guides	Text System Overview Text Layout Programming Guide

Overview

The `NSLayoutManagerDelegate` protocol defines the optional methods implemented by delegates of `NSLayoutManager` objects.

Tasks

Invalidating Glyphs and Layout

`- layoutManagerDidInvalidateLayout:` (page 3719)
Informs the delegate that the given layout manager has invalidated layout information (not glyph information).

Handling Layout for Text Containers

`- layoutManager:didCompleteLayoutForTextContainer:atEnd:` (page 3718)
Informs the delegate that the given layout manager has finished laying out text in the given text container.

Managing Temporary Attribute Support

`- layoutManager:shouldUseTemporaryAttributes:forDrawingToScreen:atCharacterIndex:effectiveRange:` (page 3718)

Sent when the layout manager is drawing and needs to decide whether or not to use temporary attributes.

Instance Methods

layoutManager:didCompleteLayoutForTextContainer:atEnd:

Informs the delegate that the given layout manager has finished laying out text in the given text container.

```
- (void)layoutManager:(NSLayoutManager *)aLayoutManager
    didCompleteLayoutForTextContainer:(NSTextContainer *)aTextContainer
    atEnd:(BOOL)flag
```

Parameters

aLayoutManager

The layout manager doing the layout.

aTextContainer

The text container in which layout is complete. If `nil`, if there aren't enough containers to hold all the text; the delegate can use this information as a cue to add another text container.

flag

If `YES`, *aLayoutManager* is finished laying out its text—this also means that *aTextContainer* is the final text container used by the layout manager. Delegates can use this information to show an indicator or background or to enable or disable a button that forces immediate layout of text.

Discussion

This message is sent whenever a text container has been filled. This method can be useful for paginating.

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

`NSLayoutManager.h`

layoutManager:shouldUseTemporaryAttributes:forDrawingToScreen:atCharacterIndex:effectiveRange:

Sent when the layout manager is drawing and needs to decide whether or not to use temporary attributes.

```
- (NSDictionary *)layoutManager:(NSLayoutManager *)layoutManager
    shouldUseTemporaryAttributes:(NSDictionary *)attrs
    forDrawingToScreen:(BOOL)toScreen atCharacterIndex:(NSUInteger)charIndex
    effectiveRange:(NSRangePointer)effectiveCharRange
```

Parameters

layoutManager

The layout manager sending the message.

attrs

The temporary attributes currently in effect for the given character range.

toScreen

YES if the layout manager is drawing to the screen; otherwise, NO.

charIndex

Index of the first character in the range being drawn.

effectiveCharRange

On input and output, the effective range to which the temporary attributes apply.

Return Value

The temporary attributes for the layout manager to use, or nil if no temporary attributes are to be used.

Discussion

The default behavior, if this method is not implemented, is to use temporary attributes only when drawing to the screen, so an implementation to match that behavior would return *attrs* if *toScreen* is YES and nil otherwise, without changing *effectiveCharRange*.

Availability

Available in Mac OS X v10.5 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

NSLayoutManager.h

layoutManagerDidInvalidateLayout:

Informs the delegate that the given layout manager has invalidated layout information (not glyph information).

```
- (void)layoutManagerDidInvalidateLayout:(NSLayoutManager *)sender
```

Parameters

sender

The layout manager that invalidated layout.

Discussion

This method is invoked only when layout was complete and then became invalidated for some reason. Delegates can use this information to show an indicator of background layout or to enable a button that forces immediate layout of text.

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

NSMatrixDelegate Protocol Reference

Conforms to	NSControlTextEditingDelegate
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.6 and later.
Declared in	AppKit/NSMatrix.h
Companion guide	Matrix Programming Guide

Overview

The `NSMatrixDelegate` protocol defines the optional methods implemented by delegates of `NSMatrix` objects.

This protocol simply adopts the `NSControlTextEditingDelegate` protocol, adding no additional methods. See *NSControlTextEditingDelegate Protocol Reference* for more information.

NSMenuDelegate Protocol Reference

Conforms to	NSObject
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.6 and later.
Declared in	AppKit/NSMenu.h
Companion guide	Application Menu and Pop-up List Programming Topics

Overview

The `NSMenuDelegate` protocol defines the optional methods implemented by delegates of `NSMenu` objects.

Tasks

Handling Keyboard Equivalents

`- menuHasKeyEquivalent:forEvent:target:action:` (page 3726)
Invoked to allow the delegate to return the target and action for a key-down event.

Updating Menu Layout

`- menu:updateItem:atIndex:shouldCancel:` (page 3725)
Invoked to let the delegate update a menu item before it is displayed.

`- confinementRectForMenu:onScreen:` (page 3724)
Invoked to allow the delegate to specify a display location for the menu.

Handling Highlighting

`- menu:willHighlightItem:` (page 3725)
Invoked to indicates that a menu is about to highlight a given item.

Handling Open and Close Events

- `menuWillOpen:` (page 3727)
  Invoked when a menu is about to open.
- `menuDidClose:` (page 3726)
  Invoked after a menu closed.

Handling Tracking

- `numberOfItemsInMenu:` (page 3728)
  Invoked when a menu is about to be displayed at the start of a tracking session so the delegate can specify the number of items in the menu.
- `menuNeedsUpdate:` (page 3727)
  Invoked when a menu is about to be displayed at the start of a tracking session so the delegate can modify the menu.

Instance Methods

confinementRectForMenu:onScreen:

Invoked to allow the delegate to specify a display location for the menu.

```
- (NSRect)confinementRectForMenu:(NSMenu *)menu onScreen:(NSScreen *)screen
```

Parameters

menu
The menu object.

screen
The screen the menu will open on.

Return Value
The rectangle, in screen coordinates, the menu should be displayed within.

Discussion
This method is sent to the delegate when a menu is about to be opened on the specified screen.

If you return `NSZeroRect`, or if the delegate does not implement this method, the menu will be confined to the bounds appropriate for the given screen. The returned rect may not be honored in all cases, for example, if it would force the menu to be too small.

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSMenu.h`

menu:updateItem:atIndex:shouldCancel:

Invoked to let the delegate update a menu item before it is displayed.

```
- (BOOL)menu:(NSMenu *)menu updateItem:(NSMenuItem *)item atIndex:(NSInteger)index
    shouldCancel:(BOOL)shouldCancel
```

Parameters

menu

The menu object that owns `item`.

item

The menu-item object that may be updated.

index

The integer index of the menu item.

shouldCancel

Set to `YES` if, due to some user action, the menu no longer needs to be displayed before all the menu items have been updated. You can ignore this flag, return `YES`, and continue; or you can save your work (to save time the next time your delegate is called) and return `NO` to stop the updating.

Return Value

`YES` to continue the process. If you return `NO`, your `menu:updateItem:atIndex:shouldCancel:` is not called again. In that case, it is your responsibility to trim any extra items from the menu.

Discussion

If your `numberOfItemsInMenu:` (page 3728) delegate method returns a positive value, then your `menu:updateItem:atIndex:shouldCancel:` method is called for each item in the menu. You can then update the menu title, image, and so forth for each menu item.

Availability

Available in Mac OS X v10.3 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

`NSMenu.h`

menu:willHighlightItem:

Invoked to indicates that a menu is about to highlight a given item.

```
- (void)menu:(NSMenu *)menu willHighlightItem:(NSMenuItem *)item
```

Parameters

menu

The menu object about to highlight an item.

item

The item about to be highlighted.

Discussion

Only one item per menu can be highlighted at a time. If *item* is `nil`, it means that all items in the menu are about to be unhighlighted

Availability

Available in Mac OS X v10.5 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
- `highlightedItem` (page 1614) (NSMenu)

Declared In
`NSMenu.h`

menuDidClose:

Invoked after a menu closed.

```
- (void)menuDidClose:(NSMenu *)menu
```

Parameters

menu
The menu that closed.

Special Considerations

Do not modify the structure of the menu or the menu items during this method.

Availability
Available in Mac OS X v10.5 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
- `menuWillOpen:` (page 3727)

Declared In
`NSMenu.h`

menuHasKeyEquivalent:forEvent:target:action:

Invoked to allow the delegate to return the target and action for a key-down event.

```
- (BOOL)menuHasKeyEquivalent:(NSMenu *)menu forEvent:(NSEvent *)event target:(id
    *)target action:(SEL *)action
```

Parameters

menu
The menu object sending the delegation message.

event
An `NSEvent` object representing a key-down event.

target
Return by reference the target object for the menu item that corresponds to the event. Specify `nil` to requests the menu's target.

action
Return by reference the action selector for the menu item that corresponds to the event.

Return Value
If there is a valid and enabled menu item that corresponds to this key-down even, return `YES` after specifying the target and action. Return `NO` if there are no items with that key equivalent or if the item is disabled.

Discussion
If the delegate does not define this method, the menu is populated to find out if any items have a matching key equivalent.

Availability
Available in Mac OS X v10.3 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
- `performKeyEquivalent:` (page 1625) (NSMenu)
- `performActionForItemAtIndex:` (page 1624) (NSMenu)

Declared In
`NSMenu.h`

menuNeedsUpdate:

Invoked when a menu is about to be displayed at the start of a tracking session so the delegate can modify the menu.

```
- (void)menuNeedsUpdate:(NSMenu *)menu
```

Parameters

menu
The menu object that is about to be displayed.

Discussion
You can change the menu by adding, removing or modifying menu items. Be sure to set the proper enable state for any new menu items. If populating the menu will take a long time, implement `numberOfItemsInMenu:` (page 3728) and `menu:updateItem:atIndex:shouldCancel:` (page 3725) instead.

Availability
Available in Mac OS X v10.3 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSMenu.h`

menuWillOpen:

Invoked when a menu is about to open.

```
- (void)menuWillOpen:(NSMenu *)menu
```

Parameters

menu
The menu that is about to open.

Special Considerations

Do not modify the structure of the menu or the menu items during this method.

Availability
Available in Mac OS X v10.5 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
- `menuDidClose:` (page 3726)

Declared In
`NSMenu.h`

numberOfItemsInMenu:

Invoked when a menu is about to be displayed at the start of a tracking session so the delegate can specify the number of items in the menu.

```
- (NSInteger)numberOfItemsInMenu:(NSMenu *)menu
```

Parameters

menu

The menu object about to be displayed.

Return Value
The number of menu items in the menu.

Discussion
If you return a positive value, the menu is resized by either removing or adding items. Newly created items are blank. After the menu is resized, your `menu:updateItem:atIndex:shouldCancel:` method is called for each item. If you return a negative value, the number of items is left unchanged and `menu:updateItem:atIndex:shouldCancel:` (page 3725) is not called. If you can populate the menu quickly, you can implement `menuNeedsUpdate:` (page 3727) instead of `numberOfItemsInMenu:` and `menu:updateItem:atIndex:shouldCancel:`.

Availability
Available in Mac OS X v10.3 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSMenu.h`

NSMenuValidation Protocol Reference

(informal protocol)

Framework	/System/Library/Frameworks/AppKit.framework
Declared in	AppKit/NSMenu.h
Companion guide	Application Menu and Pop-up List Programming Topics

Overview

This informal protocol allows your application to update the enabled or disabled status of an `NSMenuItem` object. It declares only one method, `validateMenuItem:` (page 3729).

Tasks

Validating Menu Items

`- validateMenuItem:` (page 3729)
Implemented to override the default action of enabling or disabling a specific menu item.

Instance Methods

validateMenuItem:

Implemented to override the default action of enabling or disabling a specific menu item.

```
- (BOOL)validateMenuItem:(NSMenuItem *)menuItem
```

Parameters

menuItem
An NSMenuItem object that represents the menu item.

Return Value
`YES` to enable *menuItem*, `NO` to disable it.

Discussion
The object implementing this method must be the target of *menuItem*. You can determine which menu item *menuItem* is by querying it for its tag or action.

The following example disables the menu item associated with the `nextRecord` action method when the selected line in a table view is the last one; conversely, it disables the menu item with `priorRecord` as its action method when the selected row is the first one in the table view. (The `countryKeys` array contains names that appear in the table view.)

```
- (BOOL)validateMenuItem:(NSMenuItem *)item {
    int row = [tableView selectedRow];
    if ([item action] == @selector(nextRecord) &&
        (row == [countryKeys indexOfObject:[countryKeys lastObject]])) {
        return NO;
    }
    if ([item action] == @selector(priorRecord) && row == 0) {
        return NO;
    }
    return YES;
}
```

Availability
Available in Mac OS X v10.0 and later.

NSNibAwaking Protocol Reference

(informal protocol)

Framework	/System/Library/Frameworks/AppKit.framework
Declared in	AppKit/NSNibLoading.h
Companion guide	Resource Programming Guide

Overview

This informal protocol consists of a single method, `awakeFromNib` (page 3731). Classes can implement this method to initialize state information after objects have been loaded from an Interface Builder archive (nib file).

Tasks

Responding to Being Loaded from a Nib File

- `awakeFromNib` (page 3731)
  Prepares the receiver for service after it has been loaded from an Interface Builder archive, or nib file.

Instance Methods

awakeFromNib

Prepares the receiver for service after it has been loaded from an Interface Builder archive, or nib file.

```
- (void)awakeFromNib
```

Discussion
An `awakeFromNib` message is sent to each object loaded from the archive, but only if it can respond to the message, and only after all the objects in the archive have been loaded and initialized. When an object receives an `awakeFromNib` message, it is guaranteed to have all its outlet instance variables set.

Note: During Interface Builder's test mode, this method is also sent to objects instantiated from loaded palettes, which include executable code for the objects. It is not sent to objects created using the Classes display of the nib file window in Interface Builder.

During the instantiation process, each object in the archive is unarchived and then initialized with the method befitting its type. Cocoa views (and custom views that can be customized using an associated Interface Builder palette) are initialized using their `initWithCoder:` method. Custom views are initialized using their `initWithFrame:` method. Custom classes that have been instantiated in the nib are initialized using their `init` method.

Once all objects have been instantiated and initialized from the archive, the nib loading code attempts to reestablish the connections between each object's outlets and the corresponding target objects. If your custom objects have outlets, an `NSNib` object attempts to reestablish any connections you created in Interface Builder. It starts by trying to establish the connections using your object's own methods first. For each outlet that needs a connection, the `NSNib` object looks for a method of the form `set`*OutletName*`:` in your object. If that method exists, the `NSNib` object calls it, passing the target object as a parameter. If you did not define a setter method with that exact name, the NSNib object searches the object for an instance variable (of type `IBOutlet id`) with the corresponding outlet name and tries to set its value directly. If an instance variable with the correct name cannot be found, initialization of that connection does not occur. Finally, after all the objects are fully initialized, each receives an `awakeFromNib` message.

Important: Because the order in which objects are instantiated from an archive is not guaranteed, your initialization methods should not send messages to other objects in the hierarchy. Messages to other objects can be sent safely from within `awakeFromNib`—by which time it's assured that all the objects are unarchived and initialized (though not necessarily awakened, of course).

Typically, you implement `awakeFromNib` for the class you associate with the "File's Owner" of the nib file. You might also want to implement this method for any other classes you instantiate directly in your nib file. The job of these objects is to give you a hook for connecting the nib file objects to other objects in your application. Once that job is finished, you can either dispose of the objects or use them as a controller for the nib file objects.

An example of how you might use `awakeFromNib` is shown below. Suppose your nib file has two custom views that must be positioned relative to each other at runtime. Trying to position them at initialization time might fail because the other view might not yet be unarchived and initialized yet. However, you can position both of them in the nib file owner's `awakeFromNib` method. In the code below, `firstView` and `secondView` are outlets of the file's owner:

```
- (void)awakeFromNib {
    NSRect viewFrame;

    viewFrame = [firstView frame];
    viewFrame.origin.x += viewFrame.size.width;
    [secondView setFrame:viewFrame];
    return;
}
```

It is recommended that you maintain a one-to-one correspondence between your File's Owner objects and their associated nib files. Loading two nib files with the same File's Owner object causes that object's `awakeFromNib` method being called twice, which could cause some data structures to be reinitialized in undesired ways. It is also recommended that you avoid loading other nib files from your `awakeFromNib` method implementation.

You should call the `super` implementation of `awakeFromNib` only if you know for certain that your superclass provides an implementation. Because the Application Kit does not provide a default implementation of the `awakeFromNib` method, calling `super` results in an exception if the parent class does not implement it. Classes whose immediate parent class is `NSObject` or `NSView` do not need to call the `super` implementation. For any other classes, you can use the `instancesRespondToSelector:` class method of `NSObject` to determine if the parent class responds to `awakeFromNib` and call the method if it does.

Overview

The `NSOpenSavePanelDelegate` protocol defines the methods that a delegate of `NSOpenPanel` or `NSSavePanel` should implement.

Tasks

Running Panels

- `panel:shouldEnableURL:` (page 3736)
  For `NSOpenPanel` delegates, asks the delegate whether the specified URL should be enabled in the panel. This method is not called for `NSSavePanel` delegates; all URLs are always disabled.
- `panel:validateURL:error:` (page 3737)
  For `NSSavePanel` delegates, asks the delegate for file URL validation when the user chooses the Save button. For `NSOpenPanel` delegates, asks the delegate for file URL validation once for each selected filename (or directory) when the user chooses the Open button.
- `panel:didChangeToDirectoryURL:` (page 3736)
  Informs the delegate that the user changed the selected directory to the directory located at the specified URL. The URL may be `nil` if the current URL can't be represented by an `NSURL` object.
- `panel:userEnteredFilename:confirmed:` (page 3737)
  Tells the delegate that the user confirmed a filename choice by clicking Save in a Save panel.

- `panel:willExpand:` (page 3738)
  Tells the delegate that the Save panel is about to expand or collapse because the user clicked the disclosure triangle that displays or hides the file browser.
- `panelSelectionDidChange:` (page 3738)
  Tells the delegate that the user changed the selection in the specified Save panel.

Instance Methods

panel:didChangeToDirectoryURL:

Informs the delegate that the user changed the selected directory to the directory located at the specified URL. The URL may be `nil` if the current URL can't be represented by an `NSURL` object.

```
- (void)panel:(id)sender
    didChangeToDirectoryURL:(NSURL *)url
```

Parameters

sender
The panel whose directory changed.

url
The URL of the new directory, or `nil` if it can't be represented by an `NSURL` object.

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSSavePanel.h`

panel:shouldEnableURL:

For `NSOpenPanel` delegates, asks the delegate whether the specified URL should be enabled in the panel. This method is not called for `NSSavePanel` delegates; all URLs are always disabled.

```
- (BOOL)panel:(id)sender
    shouldEnableURL:(NSURL *)url
```

Parameters

sender
The panel asking whether the URL should be enabled.

url
The URL to be checked.

Return Value
`YES` to allow the URL to be enabled in the panel; otherwise, `NO`.

Discussion
Implementations of this method should be fast to avoid stalling the user interface. Use `panel:validateURL:error:` (page 3737) instead if processing will take a long time.

Availability
Available in Mac OS X v10.6 and later.

Declared In
NSSavePanel.h

panel:userEnteredFilename:confirmed:

Tells the delegate that the user confirmed a filename choice by clicking Save in a Save panel.

```
- (NSString *)panel:(id)sender
    userEnteredFilename:(NSString *)filename
    confirmed:(BOOL)okFlag
```

Parameters

sender
The panel reporting the user's confirmation of a filename choice.

filename
The user's filename choice.

okFlag
If YES, the user clicked the Save button; if NO, the user did not.

Return Value
You can either leave the filename alone, return a new filename, or return nil to cancel the save (and leave the Save panel as is). This method is called before any required extension is appended to the filename and before the Save panel asks the user to replace an existing file, if applicable.

Note that in the future, this method may be called multiple times in the sessions as the user types. In those cases, *okFlag* will be NO until the user confirms the choice, in which case *okFlag* will become YES. If the delegate does extensive validation or puts up alerts, it should do so only when *okFlag* is YES.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
- panel:validateURL:error: (page 3737)

Declared In
NSSavePanel.h

panel:validateURL:error:

For NSSavePanel delegates, asks the delegate for file URL validation when the user chooses the Save button. For NSOpenPanel delegates, asks the delegate for file URL validation once for each selected filename (or directory) when the user chooses the Open button.

```
- (BOOL)panel:(id)sender
    validateURL:(NSURL *)url
    error:(NSError **)outError
```

Parameters

sender

The panel requesting URL validation.

url

The URL to be validated.

outError

If an error occurred during validation, the error that occurred.

Return Value

`YES` if the URL is an acceptable URL to save to or to open; otherwise, `NO`.

Availability

Available in Mac OS X v10.6 and later.

Declared In

`NSSavePanel.h`

panel:willExpand:

Tells the delegate that the Save panel is about to expand or collapse because the user clicked the disclosure triangle that displays or hides the file browser.

```
- (void)panel:(id)sender
    willExpand:(BOOL)expanding
```

Parameters

sender

The panel that is about to expand or collapse.

expanding

`YES` specifies that the panel is expanding; `NO` specifies that it is collapsing.

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

`NSSavePanel.h`

panelSelectionDidChange:

Tells the delegate that the user changed the selection in the specified Save panel.

```
- (void)panelSelectionDidChange:(id)sender
```

Parameters

sender

The panel whose selection changed.

Availability

Available in Mac OS X v10.3 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

`NSSavePanel.h`

NSOutlineViewDataSource Protocol Reference

Conforms to	NSObject
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.6 and later.
Declared in	AppKit/NSOutlineView.h
Companion guide	Outline View Programming Topics

Overview

`NSOutlineView` objects support a data source delegate in addition to the regular delegate object. The `NSOutlineViewDataSource` protocol defines methods that the outline view invokes as necessary to retrieve data and information about the data from the data source delegate, and—optionally—to update data values.

All the methods in the `NSOutlineViewDataSource` protocol are marked as `@optional`. While this is true, there are cases were you must implement some methods to achieve required functionality, specifically when working with conventional data sources rather that data that is provided by Cocoa bindings.

Required and Optional Methods Using Programmatic Conventions and Cocoa Bindings

If you are using conventional data sources for content you must implement the basic methods that provide the outline view with data: `outlineView:child:ofItem:` (page 3743), `outlineView:isItemExpandable:` (page 3744), `outlineView:numberOfChildrenOfItem:` (page 3746), and `outlineView:objectValueForTableColumn:byItem:` (page 3747). Applications that acquire their data using Cocoa bindings do not need to implement these methods.

Similarly, when using conventional data sources , if you want to allow the user to edit values, you must implement `outlineView:setObjectValue:forTableColumn:byItem:` (page 3748). When these methods are invoked by the outline view, `nil` as the *`item`* refers to the "root" item. `NSOutlineView` requires that each item in the outline view be unique. In order for the collapsed state of an outline view to remain consistent between reloads you must always return the same object for an item. When using Cocoa bindings to provide outline view content, there is no requirement to implement this method.

Note: Some of the methods in this `protocol`, such as `outlineView:child:ofItem:` (page 3743) and `outlineView:numberOfChildrenOfItem:` (page 3746) along with other methods that return data, are called very frequently, so they must be efficient.

Tasks

Working with Items in a View

- `outlineView:child:ofItem:` (page 3743)
  Returns the child item at the specified index of a given item.
- `outlineView:isItemExpandable:` (page 3744)
  Returns a Boolean value that indicates whether the a given item is expandable.
- `outlineView:numberOfChildrenOfItem:` (page 3746)
  Returns the number of child items encompassed by a given item.
- `outlineView:objectValueForTableColumn:byItem:` (page 3747)
  Invoked by *`outlineView`* to return the data object associated with the specified *`item`*.
- `outlineView:setObjectValue:forTableColumn:byItem:` (page 3748)
  Set the data object for a given item in a given column.

Supporting Drag and Drop

- `outlineView:acceptDrop:item:childIndex:` (page 3743)
  Returns a Boolean value that indicates whether a drop operation was successful.
- `outlineView:validateDrop:proposedItem:proposedChildIndex:` (page 3749)
  Used by an outline view to determine a valid drop target.
- `outlineView:namesOfPromisedFilesDroppedAtDestination:forDraggedItems:` (page 3745)
  Returns an array of filenames for the created files that the receiver promises to create.

Supporting Object Persistence

- `outlineView:itemForPersistentObject:` (page 3745)
  Invoked by *`outlineView`* to return the item for the archived *`object`*.
- `outlineView:persistentObjectForItem:` (page 3747)
  Invoked by *`outlineView`* to return an archived object for *`item`*.

Working with a Pasteboard

- `outlineView:writeItems:toPasteboard:` (page 3750)
  Returns a Boolean value that indicates whether a drag operation is allowed.

Sorting

`- outlineView:sortDescriptorsDidChange:` (page 3748)
Invoked by an outline view to notify the data source that the descriptors changed and the data may need to be resorted.

Instance Methods

outlineView:acceptDrop:item:childIndex:

Returns a Boolean value that indicates whether a drop operation was successful.

```
- (BOOL)outlineView:(NSOutlineView *)outlineView acceptDrop:(id < NSDraggingInfo
    >)info item:(id)item childIndex:(NSInteger)index
```

Parameters

outlineView
The outline view that sent the message. *outlineView* must have previously allowed a drop.

info
An object that contains more information about this dragging operation.

item
The parent of the item over which the cursor was placed when the mouse button was released.

index
The index of the child of *item* over which the cursor was placed when the mouse button was released.

Return Value
`YES` if the drop operation was successful, otherwise `NO`.

Discussion
The data source should incorporate the data from the dragging pasteboard in the implementation of this method. You can get the data for the drop operation from info using the `draggingPasteboard` (page 3662) method.

The return value indicates success or failure of the drag operation to the system.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
`- shouldCollapseAutoExpandedItemsForDeposited:` (page 1843) (NSOutlineView)

Declared In
`NSOutlineView.h`

outlineView:child:ofItem:

Returns the child item at the specified index of a given item.

```
- (id)outlineView:(NSOutlineView *)outlineView child:(NSInteger)index ofItem:(id)item
```

Parameters

outlineView

The outline view that sent the message.

index

The index of the child item from *item* to return.

item

An item in the data source.

Return Value

The child item at `index` of a *item*. If *item* is `nil`, returns the appropriate child item of the root object.

Discussion

Children of a given parent *item* are accessed sequentially. In order for the collapsed state of the outline view to remain consistent when it is reloaded you must always return the same object for a specified *child* and *item*.

Important: While this method is marked as `@optional` in the protocol, **you must implement this method if you are not providing the data for the outline view using Cocoa bindings.**

Special Considerations

`outlineView:child:ofItem:` (page 3743) is called very frequently, so it must be efficient.

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

See Also

`- outlineView:numberOfChildrenOfItem:` (page 3746)

Declared In

`NSOutlineView.h`

outlineView:isItemExpandable:

Returns a Boolean value that indicates whether the a given item is expandable.

```
- (BOOL)outlineView:(NSOutlineView *)outlineView isItemExpandable:(id)item
```

Parameters

outlineView

The outline view that sent the message.

item

An item in the data source.

Return Value

`YES` if *item* can be expanded to display its children, otherwise `NO`.

Discussion

This method may be called quite often and should be efficient.

Important: While this method is marked as `@optional` in the protocol, **you must implement this method if you are not providing the data for the outline view using Cocoa bindings.**

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSOutlineView.h`

outlineView:itemForPersistentObject:

Invoked by *outlineView* to return the item for the archived *object*.

```
- (id)outlineView:(NSOutlineView *)outlineView itemForPersistentObject:(id)object
```

Parameters

outlineView
The outline view that sent the message.

object
An archived representation of an item in *outlineView*'s data source.

Return Value
The unarchived item corresponding to *object*. If the item is an archived object, this method may return the object.

Discussion
When the outline view is restoring the saved expanded items, this method is called for each expanded item, to translate the archived object to an outline view item.

Special Considerations

You must implement this method if you are automatically saving expanded items (that is, if `autosaveExpandedItems` (page 1830) returns `YES`).

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSOutlineView.h`

outlineView:namesOfPromisedFilesDroppedAtDestination:forDraggedItems:

Returns an array of filenames for the created files that the receiver promises to create.

```
- (NSArray *)outlineView:(NSOutlineView *)outlineView
    namesOfPromisedFilesDroppedAtDestination:(NSURL *)dropDestination
    forDraggedItems:(NSArray *)items
```

Parameters

outlineView

The outline view that sent the message.

dropDestination

The drop location where the files are created.

items

The items being dragged.

Return Value

An array of filenames (not full paths) for the created files that the receiver promises to create.

Discussion

For more information on file promise dragging, see documentation on the `NSDraggingSource` protocol and `namesOfPromisedFilesDroppedAtDestination:` (page 3663).

Availability

Available in Mac OS X v10.4 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

`NSOutlineView.h`

outlineView:numberOfChildrenOfItem:

Returns the number of child items encompassed by a given item.

```
- (NSInteger)outlineView:(NSOutlineView *)outlineView numberOfChildrenOfItem:(id)item
```

Parameters

outlineView

The outline view that sent the message.

item

An item in the data source.

Return Value

The number of child items encompassed by *item*. If *item* is `nil`, this method should return the number of children for the top-level item.

Discussion

`outlineView:numberOfChildrenOfItem:` (page 3746) is called very frequently, so it must be efficient.

Important: While this method is marked as `@optional` in the protocol, **you must implement this method if you are not providing the data for the outline view using Cocoa bindings.**

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

`NSOutlineView.h`

outlineView:objectValueForTableColumn:byItem:

Invoked by *outlineView* to return the data object associated with the specified *item*.

```
- (id)outlineView:(NSOutlineView *)outlineView
    objectValueForTableColumn:(NSTableColumn *)tableColumn byItem:(id)item
```

Parameters

outlineView

The outline view that sent the message.

tableColumn

A column in *outlineView*.

item

An item in the data source in the specified *tableColumn* of the view.

Discussion

The item is located in the specified *tableColumn* of the view.

Important: While this method is marked as `@optional` in the protocol, **you must implement this method if you are not providing the data for the outline view using Cocoa bindings.**

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

`NSOutlineView.h`

outlineView:persistentObjectForItem:

Invoked by *outlineView* to return an archived object for *item*.

```
- (id)outlineView:(NSOutlineView *)outlineView persistentObjectForItem:(id)item
```

Parameters

outlineView

The outline view that sent the message.

item

The item for which to return an archived object.

Return Value

An archived representation of *item*. If the item is an archived object, this method may return the item.

Discussion

When the outline view is saving the expanded items, this method is called for each expanded item, to translate the outline view item to an archived object.

Special Considerations

You must implement this method if you are automatically saving expanded items (that is, if `autosaveExpandedItems` (page 1830) returns `YES`).

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSOutlineView.h

outlineView:setObjectValue:forTableColumn:byItem:

Set the data object for a given item in a given column.

```
- (void)outlineView:(NSOutlineView *)outlineView setObjectValue:(id)object
    forTableColumn:(NSTableColumn *)tableColumn byItem:(id)item
```

Parameters

outlineView
The outline view that sent the message.

object
The new value for the item.

tableColumn
A column in *outlineView*.

item
An item in the data source in the specified *tableColumn* of the view.

Discussion
The item is located in the specified *tableColumn* of the view.

Important: While this method is marked as `@optional` in the protocol, **you must implement this method if you are not providing the data for the outline view using Cocoa bindings.**

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSOutlineView.h

outlineView:sortDescriptorsDidChange:

Invoked by an outline view to notify the data source that the descriptors changed and the data may need to be resorted.

```
- (void)outlineView:(NSOutlineView *)outlineView sortDescriptorsDidChange:(NSArray
    *)oldDescriptors
```

Parameters

outlineView
The outline view that sent the message.

oldDescriptors
An array that contains the previous descriptors.

Discussion
The data source typically sorts and reloads the data, and adjusts the selections accordingly. If you need to know the current sort descriptors and the data source does not itself manage them, you can get *outlineView*'s current sort descriptors by sending it a `sortDescriptors` (page 2670) message.

Availability
Available in Mac OS X v10.3 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSOutlineView.h`

outlineView:validateDrop:proposedItem:proposedChildIndex:

Used by an outline view to determine a valid drop target.

```
- (NSDragOperation)outlineView:(NSOutlineView *)outlineView validateDrop:(id <
    NSDraggingInfo >)info proposedItem:(id)item proposedChildIndex:(NSInteger)index
```

Parameters
outlineView
The outline view that sent the message.

info
An object that contains more information about this dragging operation.

item
The proposed parent.

index
The proposed child location.

Return Value
A value that indicates which dragging operation the data source will perform.

Discussion
Based on the mouse position, the outline view will suggest a proposed drop location. The data source may "retarget" a drop if desired by calling `setDropItem:dropChildIndex:` (page 1841) and returning something other than `NSDragOperationNone`. You may choose to retarget for various reasons (for example, for better visual feedback when inserting into a sorted position).

Implementation of this method is optional.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSOutlineView.h`

outlineView:writeItems:toPasteboard:

Returns a Boolean value that indicates whether a drag operation is allowed.

```
- (BOOL)outlineView:(NSOutlineView *)outlineView writeItems:(NSArray *)items
    toPasteboard:(NSPasteboard *)pboard
```

Parameters

outlineView

The outline view that invoked the method.

items

An array of the items participating in the drag.

pboard

The pasteboard to which to write the drag data.

Return Value

`YES` if the drag operation is allowed, otherwise `NO`.

Discussion

Invoked by *outlineView* after it has been determined that a drag should begin, but before the drag has been started.

To refuse the drag, return `NO`. To start a drag, return `YES` and place the drag data onto the *pboard* (data, owner, and so on). The drag image and other drag-related information will be set up and provided by the outline view once this call returns with `YES`.

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

`NSOutlineView.h`

NSOutlineViewDelegate Protocol Reference

Conforms to	NSControlTextEditingDelegate
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.6 and later.
Declared in	AppKit/NSOutlineView.h
Companion guides	Outline View Programming Topics Drag and Drop Programming Topics for Cocoa

Overview

The `NSOutlineViewDelegate` protocol defines the optional methods implemented by delegates of `NSOutlineView` objects.

Some delegate methods have not yet migrated to the `NSOutlineViewDelegate` protocol, including:

- `outlineViewColumnDidMove:` (page 1844)
- `outlineViewColumnDidResize:` (page 1844)
- `outlineViewItemDidCollapse:` (page 1844)
- `outlineViewItemDidExpand:` (page 1845)
- `outlineViewItemWillCollapse:` (page 1845)
- `outlineViewItemWillExpand:` (page 1845)
- `outlineViewSelectionDidChange:` (page 1846)
- `outlineViewSelectionIsChanging:` (page 1846)

Tasks

Expanding and Collapsing the Outline

`- outlineView:shouldExpandItem:` (page 3759)
Returns a Boolean value that indicates whether the outline view should expand a given item.

- `outlineView:shouldCollapseItem:` (page 3757)
  Returns a Boolean value that indicates whether the outline view should collapse a given item.

Supporting Type Select

- `outlineView:typeSelectStringForTableColumn:item:` (page 3764)
  Returns the string that is used for type selection for a given column and item.
- `outlineView:nextTypeSelectMatchFromItem:toItem:forString:` (page 3756)
  Returns the first item that matches the searchString from within the range of startItem to endItem
- `outlineView:shouldTypeSelectForEvent:withCurrentSearchString:` (page 3762)
  Returns a Boolean value that indicates whether type select should proceed for a given event and search string.

Working with Tooltips

- `outlineView:toolTipForCell:rect:tableColumn:item:mouseLocation:` (page 3763)
  When the cursor pauses over a given cell, the value returned from this method is displayed in a tooltip.

Handling Selection

- `outlineView:shouldSelectTableColumn:` (page 3760)
  Returns a Boolean value that indicates whether the outline view should select a given table column.
- `outlineView:shouldSelectItem:` (page 3760)
  Returns a Boolean value that indicates whether the outline view should select a given item.
- `outlineView:selectionIndexesForProposedSelection:` (page 3757)
  Invoked to allow the delegate to modify the proposed selection.
- `selectionShouldChangeInOutlineView:` (page 3765)
  Returns a Boolean value that indicates whether the outline view should change its selection.

Displaying Cells

- `outlineView:willDisplayCell:forTableColumn:item:` (page 3765)
  Informs the delegate that *`outlineView`* is about to display the cell specified by *`tableColumn`* and *`item`*.
- `outlineView:willDisplayOutlineCell:forTableColumn:item:` (page 3765)
  Informs the delegate that an outline view is about to display a cell used to draw the expansion symbol.
- `outlineView:dataCellForTableColumn:item:` (page 3754)
  Returns the cell to use in a given column for a given item.
- `outlineView:shouldShowOutlineCellForItem:` (page 3761)
  Returns a whether the specified item should display the outline cell (the disclosure triangle).
- `outlineView:shouldShowCellExpansionForTableColumn:item:` (page 3760)
  Invoked to allow the delegate to control cell expansion for a specific column and item.

Moving and Resizing Columns

- `outlineView:shouldReorderColumn:toColumn:` (page 3759)
  Sent to the delegate to allow or prohibit the specified column to be dragged to a new location.

Editing Items

- `outlineView:shouldEditTableColumn:item:` (page 3758)
  Returns a Boolean value that indicates whether the outline view should allow editing of a given item in a given table column.

Working with Table Columns

- `outlineView:mouseDownInHeaderOfTableColumn:` (page 3756)
  Sent to the delegate whenever the mouse button is clicked in *outlineView* while the cursor is in a column header *tableColumn*.
- `outlineView:didClickTableColumn:` (page 3754)
  Sent at the time the mouse button subsequently goes up in *outlineView* and *tableColumn* has been "clicked" without having been dragged anywhere.
- `outlineView:didDragTableColumn:` (page 3755)
  Sent at the time the mouse button goes up in *outlineView* and *tableColumn* has been dragged during the time the mouse button was down.

Customizing Column and Row Sizes

- `outlineView:heightOfRowByItem:` (page 3755)
  Returns the height in points of the row containing *item*.
- `outlineView:sizeToFitWidthOfColumn:` (page 3763)
  Invoked to allow the delegate to provide custom sizing behavior when a column's resize divider is double clicked.

Customizing Tracking Support

- `outlineView:shouldTrackCell:forTableColumn:item:` (page 3762)
  Returns a Boolean value that indicates whether a given cell should be tracked.

Grouping Rows

- `outlineView:isGroupItem:` (page 3755)
  Returns a Boolean that indicates whether a given row should be drawn in the "group row" style.

Instance Methods

outlineView:dataCellForTableColumn:item:

Returns the cell to use in a given column for a given item.

```
- (NSCell *)outlineView:(NSOutlineView *)outlineView
    dataCellForTableColumn:(NSTableColumn *)tableColumn item:(id)item
```

Parameters

outlineView

The outline view that sent the message.

tableColumn

The table column for which the cell is required. This value may be `nil`.

item

The item for which the cell is required.

Return Value

The cell to use in column *tableColumn* for item *item*, or `nil` (see Discussion). The cell must properly implement `copyWithZone:` (since it may be copied by by the outline view).

Discussion

You can return a different data cell for any particular combination of table column and item, or a cell that will be used for the entire row (a full width cell). If *tableColumn* is non-`nil`, you should return a cell. Typically you should default to returning the result from `[tableColumn dataCellForRow:row]`.

When each row (identified by the item) is being drawn, this method is first called with a `nil` value for *tableColumn*. At this time, you can return a cell that will be used to draw the entire row, acting like a group. If you do return a cell for the 'nil' table column, your implementations of the other corresponding datasource and delegate methods must be prepared to be invoked with a `nil` value for *tableColumn*. If do not return a cell for the 'nil' table column, the method will be called once for each column in the outline view, as usual.

Availability

Available in Mac OS X v10.5 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

`NSOutlineView.h`

outlineView:didClickTableColumn:

Sent at the time the mouse button subsequently goes up in *outlineView* and *tableColumn* has been "clicked" without having been dragged anywhere.

```
- (void)outlineView:(NSOutlineView *)outlineView didClickTableColumn:(NSTableColumn
    *)tableColumn
```

Availability

Available in Mac OS X v10.3 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSOutlineView.h

outlineView:didDragTableColumn:

Sent at the time the mouse button goes up in *outlineView* and *tableColumn* has been dragged during the time the mouse button was down.

```
- (void)outlineView:(NSOutlineView *)outlineView didDragTableColumn:(NSTableColumn
    *)tableColumn
```

Availability
Available in Mac OS X v10.3 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSOutlineView.h

outlineView:heightOfRowByItem:

Returns the height in points of the row containing *item*.

```
- (CGFloat)outlineView:(NSOutlineView *)outlineView heightOfRowByItem:(id)item
```

Discussion
Values returned by this method should not include intercell spacing and must be greater than 0. Implement this method to support an outline view with varying row heights.

Special Considerations

For large tables in particular, you should make sure that this method is efficient. NSTableView may cache the values this method returns, so if you would like to change a row's height make sure to invalidate the row height by calling noteHeightOfRowsWithIndexesChanged: (page 2640). NSTableView automatically invalidates its entire row height cache in reloadData (page 2645) and noteNumberOfRowsChanged (page 2641).

Availability
Available in Mac OS X v10.4 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSOutlineView.h

outlineView:isGroupItem:

Returns a Boolean that indicates whether a given row should be drawn in the “group row” style.

```
- (BOOL)outlineView:(NSOutlineView *)outlineView isGroupItem:(id)item
```

Parameters

outlineView
The outline view that sent the message.

item
An item in the outline view.

Return Value
YES to indicate a particular row should have the "group row" style drawn for that row, otherwise NO.

Discussion
If the cell in that row is an instance of NSTextFieldCell and contains only a string value, the “group row” style attributes are automatically applied for that cell.

Availability
Available in Mac OS X v10.5 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSOutlineView.h

outlineView:mouseDownInHeaderOfTableColumn:

Sent to the delegate whenever the mouse button is clicked in *outlineView* while the cursor is in a column header *tableColumn*.

```
- (void)outlineView:(NSOutlineView *)outlineView
    mouseDownInHeaderOfTableColumn:(NSTableColumn *)tableColumn
```

Availability
Available in Mac OS X v10.3 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSOutlineView.h

outlineView:nextTypeSelectMatchFromItem:toItem:forString:

Returns the first item that matches the searchString from within the range of startItem to endItem

```
- (id)outlineView:(NSOutlineView *)outlineView
    nextTypeSelectMatchFromItem:(id)startItem toItem:(id)endItem forString:(NSString
     *)searchString
```

Parameters
outlineView
The outline view that sent the message.

startItem
The first item to search.

endItem
The item before which to stop searching. It is possible for endItem to be less than startItem if the search will wrap.

searchString
The string for which to search.

Return Value
The first item—from within the range of *startItem* to *endItem*—that matches the *searchString*, or `nil` if there is no match.

Discussion
Implement this method if you want to control how type selection works. You should include *startItem* as a possible match, but do not include *endItem*.

It is not necessary to implement this method in order to support type select.

Availability
Available in Mac OS X v10.5 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSOutlineView.h`

outlineView:selectionIndexesForProposedSelection:

Invoked to allow the delegate to modify the proposed selection.

```
- (NSIndexSet *)outlineView:(NSOutlineView *)outlineView
    selectionIndexesForProposedSelection:(NSIndexSet *)proposedSelectionIndexes
```

Parameters
outlineView
The outline view that sent the message.
proposedSelectionIndexes
An index set containing the indexes of the proposed selection.

Return Value
An `NSIndexSet` instance containing the indexes of the new selection. Return *proposedSelectionIndexes* if the proposed selection is acceptable, or the value of the table view's existing selection to avoid changing the selection.

Discussion
This method may be called multiple times with one new index added to the existing selection to find out if a particular index can be selected when the user is extending the selection with the keyboard or mouse.

Implementation of this method is optional. If implemented, this method will be called instead of `outlineView:willDisplayOutlineCell:forTableColumn:item:` (page 3765).

Availability
Available in Mac OS X v10.5 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSOutlineView.h`

outlineView:shouldCollapseItem:

Returns a Boolean value that indicates whether the outline view should collapse a given item.

```
- (BOOL)outlineView:(NSOutlineView *)outlineView shouldCollapseItem:(id)item
```

Parameters

outlineView

The outline view that sent the message.

item

The item that should collapse.

Return Value

YES to permit *outlineView* to collapse *item*, NO to deny permission.

Discussion

The delegate can implement this method to disallow collapsing of specific items. For example, if the first row of your outline view should not be collapsed, your delegate method could contain this line of code:

```
return [outlineView rowForItem:item]!=0;
```

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

NSOutlineView.h

outlineView:shouldEditTableColumn:item:

Returns a Boolean value that indicates whether the outline view should allow editing of a given item in a given table column.

```
- (BOOL)outlineView:(NSOutlineView *)outlineView shouldEditTableColumn:(NSTableColumn
    *)tableColumn item:(id)item
```

Return Value

YES to permit *outlineView* to edit the cell specified by *tableColumn* and *item*, NO to deny permission.

If this method returns YES, the cell may still not be editable—for example, if you have set up a custom NSTextFieldCell as a data cell, it must return YES for isEditable to allow editing.

Discussion

The delegate can implement this method to disallow editing of specific cells.

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

See Also

- outlineView:setObjectValue:forTableColumn:byItem:

Declared In

NSOutlineView.h

outlineView:shouldExpandItem:

Returns a Boolean value that indicates whether the outline view should expand a given item.

```
- (BOOL)outlineView:(NSOutlineView *)outlineView shouldExpandItem:(id)item
```

Parameters

outlineView

The outline view that sent the message.

item

The item that should expand.

Return Value

YES to permit *outlineView* to expand *item*, NO to deny permission.

Discussion

The delegate can implement this method to disallow expanding of specific items.

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

NSOutlineView.h

outlineView:shouldReorderColumn:toColumn:

Sent to the delegate to allow or prohibit the specified column to be dragged to a new location.

```
- (BOOL)outlineView:(NSOutlineView *)outlineView
    shouldReorderColumn:(NSInteger)columnIndex toColumn:(NSInteger)newColumnIndex
```

Parameters

outlineView

The outline view that sent the message.

columnIndex

The index of the column being dragged.

newColumnIndex

The proposed target index of the column.

Return Value

YES if the column reordering should be allowed, otherwise NO.

Discussion

When a column is initially dragged by the user, the delegate is first called with a *newColumnIndex* value of -1. Returning NO will disallow that column from being reordered at all. Returning YES allows it to be reordered, and the delegate will be called again when the column reaches a new location.

The actual NSTableColumn instance can be retrieved from the tableColumns (page 2670) array.

If this method is not implemented, all columns are considered reorderable.

Availability

Available in Mac OS X v10.6 and later.

Declared In
NSOutlineView.h

outlineView:shouldSelectItem:

Returns a Boolean value that indicates whether the outline view should select a given item.

```
- (BOOL)outlineView:(NSOutlineView *)outlineView shouldSelectItem:(id)item
```

Return Value
YES to permit *outlineView* to select *item*, NO to deny permission.

Discussion
The delegate can implement this method to disallow selection of particular items.

For better performance and finer grain control over the selection, use `outlineView:dataCellForTableColumn:item:` (page 3754).

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSOutlineView.h

outlineView:shouldSelectTableColumn:

Returns a Boolean value that indicates whether the outline view should select a given table column.

```
- (BOOL)outlineView:(NSOutlineView *)outlineView
    shouldSelectTableColumn:(NSTableColumn *)tableColumn
```

Return Value
YES to permit *outlineView* to select *tableColumn*, NO to deny permission.

Discussion
The delegate can implement this method to disallow selection of specific columns.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSOutlineView.h

outlineView:shouldShowCellExpansionForTableColumn:item:

Invoked to allow the delegate to control cell expansion for a specific column and item.

```
- (BOOL)outlineView:(NSOutlineView *)outlineView
    shouldShowCellExpansionForTableColumn:(NSTableColumn *)tableColumn item:(id)item
```

Parameters

outlineView
The outline view that sent the message.

tableColumn
A table column in the outline view.

item
An item in the outline view.

Return Value
YES to allow an expansion tooltip to appear in the column *tableColumn* for item *item*, otherwise NO.

Discussion
Cell expansion can occur when the mouse hovers over the specified cell and the cell contents are unable to be fully displayed within the cell. If this method returns YES, the full cell contents will be shown in a special floating tool tip view, otherwise the content is truncated.

Availability
Available in Mac OS X v10.5 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSOutlineView.h

outlineView:shouldShowOutlineCellForItem:

Returns a whether the specified item should display the outline cell (the disclosure triangle).

```
- (BOOL)outlineView:(NSOutlineView *)outlineView
    shouldShowOutlineCellForItem:(id)item
```

Parameters

outlineView
The outline view that sent the message.

item
An item in the outline view.

Return Value
YES if the outline cell should be displayed, otherwise NO.

Discussion
Returning NO causes frameOfOutlineCellAtRow: (page 1833) to return NSZeroRect, hiding the cell. In addition, the row will not be collapsable by keyboard shortcuts.

This method will only be called for expandable rows.

Availability
Available in Mac OS X v10.6 and later.

Declared In
NSOutlineView.h

outlineView:shouldTrackCell:forTableColumn:item:

Returns a Boolean value that indicates whether a given cell should be tracked.

```
- (BOOL)outlineView:(NSOutlineView *)outlineView shouldTrackCell:(NSCell *)cell
    forTableColumn:(NSTableColumn *)tableColumn item:(id)item
```

Parameters

outlineView

The outline view that sent the message.

cell

The cell used to display item *item* in column *tableColumn*

tableColumn

A table column in the outline view.

item

An item in the outline view.

Return Value

YES if the cell should be tracked for the item *item* in column *tableColumn*, otherwise NO.

Discussion

Normally, only selectable or selected cells can be tracked. If you implement this method, cells which are not selectable or selected can be tracked (and vice-versa). For example, this allows you to have a button cell in a table which does not change the selection, but can still be clicked on and tracked.

Availability

Available in Mac OS X v10.5 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

NSOutlineView.h

outlineView:shouldTypeSelectForEvent:withCurrentSearchString:

Returns a Boolean value that indicates whether type select should proceed for a given event and search string.

```
- (BOOL)outlineView:(NSOutlineView *)outlineView shouldTypeSelectForEvent:(NSEvent
    *)event withCurrentSearchString:(NSString *)searchString
```

Parameters

outlineView

The outline view that sent the message.

event

The event that caused the message to be sent.

searchString

The string for which searching is to proceed. The search string is nil if no type select has begun.

Return Value

YES if type select should proceed, otherwise NO.

Discussion

Generally, this method will be called from keyDown: (page 2159) and the event will be a key event.

Availability
Available in Mac OS X v10.5 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSOutlineView.h

outlineView:sizeToFitWidthOfColumn:

Invoked to allow the delegate to provide custom sizing behavior when a column's resize divider is double clicked.

```
- (CGFloat)outlineView:(NSOutlineView *)outlineView
    sizeToFitWidthOfColumn:(NSInteger)column
```

Parameters

outlineView
The outline view that sent the message.

column
The index of the column.

Return Value
The width of the specified column.

Discussion
By default, NSOutlineView iterates every row in the table, accesses a cell via preparedCellAtColumn:row: (page 2643), and requests the cellSize (page 549) to find the appropriate largest width to use.

For accurate results and performance, it is recommended that this method is implemented when using large tables. By default, large tables use a monte carlo simulation instead of interating every row.

Availability
Available in Mac OS X v10.6 and later.

Declared In
NSOutlineView.h

outlineView:toolTipForCell:rect:tableColumn:item:mouseLocation:

When the cursor pauses over a given cell, the value returned from this method is displayed in a tooltip.

```
- (NSString *)outlineView:(NSOutlineView *)outlineView toolTipForCell:(NSCell *)cell
    rect:(NSRectPointer)rect tableColumn:(NSTableColumn *)tc item:(id)item
   mouseLocation:(NSPoint)mouseLocation
```

Parameters

outlineView
The outline view that sent the message.

cell
The cell for which to generate a tooltip.

rect
The proposed active area of the tooltip. To control the default active area, you can modify the *rect* parameter. By default, *rect* is computed as `[cell drawingRectForBounds:cellFrame]`.

tc
The table column that contains *cell*.

item
The item for which to display a tooltip.

mouseLocation
The current mouse location in view coordinates.

Return Value
If you don't want a tooltip at that location, return `nil` or the empty string.

Availability
Available in Mac OS X v10.4 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSOutlineView.h`

outlineView:typeSelectStringForTableColumn:item:

Returns the string that is used for type selection for a given column and item.

```
- (NSString *)outlineView:(NSOutlineView *)outlineView
    typeSelectStringForTableColumn:(NSTableColumn *)tableColumn item:(id)item
```

Parameters
outlineView
The outline view that sent the message.

tableColumn
A table column in the outline view.

item
An item in the outline view.

Return Value
The string that is used for type selection. You may want to change what is searched for based on what is displayed, or simply return nil for that row and/or column to not be searched

Discussion
Implement this method if you want to control the string that is used for type selection. You may want to change what is searched for based on what is displayed, or simply return `nil` to specify that the given row and/or column should not be searched. By default, all cells with text in them are searched.

The default value when this delegate method is not implemented is:

```
[[outlineView preparedCellAtColumn:tableColumn row:[outlineView rowForItem:item]]
 stringValue]
```

and you can return this value from the delegate method if you wish.

Availability
Available in Mac OS X v10.5 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSOutlineView.h

outlineView:willDisplayCell:forTableColumn:item:

Informs the delegate that *outlineView* is about to display the cell specified by *tableColumn* and *item*.

```
- (void)outlineView:(NSOutlineView *)outlineView willDisplayCell:(id)cell
    forTableColumn:(NSTableColumn *)tableColumn item:(id)item
```

Discussion
The delegate can modify *cell* to alter its display attributes; for example, making uneditable values display in italic or gray text.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSOutlineView.h

outlineView:willDisplayOutlineCell:forTableColumn:item:

Informs the delegate that an outline view is about to display a cell used to draw the expansion symbol.

```
- (void)outlineView:(NSOutlineView *)outlineView willDisplayOutlineCell:(id)cell
    forTableColumn:(NSTableColumn *)tableColumn item:(id)item
```

Discussion
Informs the delegate that *outlineView* is about to display *cell*—an expandable cell (a cell that has the expansion symbol)—for the column and item specified by *tableColumn* and *item*. The delegate can modify cell to alter its display attributes.

This method is not invoked when *outlineView* is about to display a non-expandable cell.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSOutlineView.h

selectionShouldChangeInOutlineView:

Returns a Boolean value that indicates whether the outline view should change its selection.

```
- (BOOL)selectionShouldChangeInOutlineView:(NSOutlineView *)outlineView
```

Return Value
YES to permit *outlineView* to change its selection (typically a row being edited), NO to deny permission.

Discussion
For example, if the user is editing a cell and enters an improper value, the delegate can prevent the user from selecting or editing any other cells until a proper value has been entered into the original cell. The delegate can implement this method for complex validation of edited rows based on the values of any of their cells.

Availability
Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSOutlineView.h`

NSPasteboardItemDataProvider Protocol Reference

Conforms to	NSObject
Availability	Available in Mac OS X v10.6 and later.
Declared in	NSPasteboard.h
Companion guides	Pasteboard Programming Guide Drag and Drop Programming Topics for Cocoa Services Implementation Guide

Overview

This protocol is implemented by the data provider of a pasteboard item to provide the data for a particular UTI type.

You can specify an object as a pasteboard data provider for a pasteboard item using `NSPasteboardItem`'s `setDataProvider:forTypes:` (page 1914) method. The data provider must implement this protocol to provide data upon request.

Tasks

Providing Data

- `pasteboard:item:provideDataForType:` (page 3767) *required method*
  Asks the receiver to provide data for a specified type to a given pasteboard. (required)
- `pasteboardFinishedWithDataProvider:` (page 3768)
  Informs the receiver that the pasteboard no longer needs the data provider for any of its pasteboard items.

Instance Methods

pasteboard:item:provideDataForType:

Asks the receiver to provide data for a specified type to a given pasteboard. (required)

```
- (void)pasteboard:(NSPasteboard *)pasteboard
    item:(NSPasteboardItem *)item
    provideDataForType:(NSString *)type
```

Parameters

pasteboard

A pasteboard to which the receiver has promised to provide data.

item

A pasteboard item for which the receiver has promised to provide data

type

A UTI type string.

Discussion

The receiver was previously set as the provider using `setDataProvider:forTypes:` (page 1914).

Availability

Available in Mac OS X v10.6 and later.

Declared In

`NSPasteboardItem.h`

pasteboardFinishedWithDataProvider:

Informs the receiver that the pasteboard no longer needs the data provider for any of its pasteboard items.

```
- (void)pasteboardFinishedWithDataProvider:(NSPasteboard *)pasteboard
```

Parameters

pasteboard

A pasteboard.

Discussion

One data provider can provide data for more than one pasteboard item. This method is called when the pasteboard no longer needs the data provider for any of its pasteboard items. This can be either because the data provider has fulfilled all promises, or because ownership of the pasteboard has changed.

Availability

Available in Mac OS X v10.6 and later.

Declared In

`NSPasteboardItem.h`

NSPasteboardReading Protocol Reference

Conforms to	NSObject
Availability	Available in Mac OS X v10.6 and later.
Declared in	NSPasteboard.h
Companion guides	Pasteboard Programming Guide Drag and Drop Programming Topics for Cocoa Services Implementation Guide
Related sample code	DemoMonkey

Overview

The `NSPasteboardReading` protocol specifies the interface for initializing an object from a pasteboard. The Cocoa framework classes `NSString`, `NSAttributedString`, `NSURL`, `NSColor`, `NSSound`, `NSImage`, and `NSPasteboardItem` implement this protocol. You can make your custom class conform to this protocol so that you can read instances from a pasteboard using the `readObjectsForClasses:options:` (page 1897) method of `NSPasteboard`.

Tasks

Required Methods

`+ readableTypesForPasteboard:` (page 3770) *required method*

Returns an array of UTI strings of data types the receiver can read from the pasteboard and be initialized from. (required)

`+ readingOptionsForType:pasteboard:` (page 3770) *required method*

Returns options for reading data of a specified type from a given pasteboard. (required)

Optional Method

`- initWithPasteboardPropertyList:ofType:` (page 3771)

Initializes an instance with a property list object and a type string.

Class Methods

readableTypesForPasteboard:

Returns an array of UTI strings of data types the receiver can read from the pasteboard and be initialized from. (required)

```
+ (NSArray *)readableTypesForPasteboard:(NSPasteboard *)pasteboard
```

Parameters

pasteboard

A pasteboard.

You can use the pasteboard argument to provide different types based on the pasteboard name, should you need to do so.

Return Value

An array of UTI strings of data types instances of the receiver can read from the pasteboard and be initialized from.

Discussion

By default, the data for a type is provided to `initWithPasteboardPropertyList:ofType:` (page 3771) as an instance of `NSData`. If you implement `readingOptionsForType:pasteboard:` (page 3770) and specify a different option, the `NSData` object for a type can be converted to an `NSString` object or any other property list object.

Special Considerations

Do not perform other pasteboard operations in the method implementation.

Availability

Available in Mac OS X v10.6 and later.

Declared In

`NSPasteboard.h`

readingOptionsForType:pasteboard:

Returns options for reading data of a specified type from a given pasteboard. (required)

```
+ (NSPasteboardReadingOptions)readingOptionsForType:(NSString *)type
    pasteboard:(NSPasteboard *)pasteboard
```

Parameters

type

A UTI supported by instances of the receiver for reading (one of the types returned by `readableTypesForPasteboard:` (page 3770)).

pasteboard

A pasteboard.

You can use the pasteboard argument to provide return different based on the pasteboard name, should you need to do so.

Return Value
Options for reading data of *type* from *pasteboard*. For a list of valid values, see "Pasteboard Reading Options" (page 3772).

Special Considerations

Do not perform other pasteboard operations in the method implementation.

Availability
Available in Mac OS X v10.6 and later.

Declared In
NSPasteboard.h

Instance Methods

initWithPasteboardPropertyList:ofType:

Initializes an instance with a property list object and a type string.

```
- (id)initWithPasteboardPropertyList:(id)propertyList
    ofType:(NSString *)type
```

Parameters

propertyList

A property list containing data to initialize the receiver.

By default, the property list object is an instance of `NSData`. If you implement `readingOptionsForType:pasteboard:` (page 3770) and specify an option other than `NSPasteboardReadingAsData` (page 3772), the *propertyList* may be any other property list object.

type

A UTI supported by the receiver for reading (one of the types returned by `readableTypesForPasteboard:` (page 3770)).

Return Value
An object initialized using the data in *propertyList*.

Special Considerations

This method is considered optional because, if `readableTypesForPasteboard:` (page 3770) returns just a single type, and that type uses the `NSPasteboardReadingAsKeyedArchive` (page 3772) reading option, then instances are initialized using `initWithCoder:` instead of this method.

Availability
Available in Mac OS X v10.6 and later.

Declared In
NSPasteboard.h

Constants

Pasteboard Reading Options

Options to specify how data on the pasteboard should be interpreted to initialize an object in `initWithPasteboardPropertyList:ofType:` (page 3771).

```
enum {
    NSPasteboardReadingAsData         = 0,
    NSPasteboardReadingAsString       = 1 << 0,
    NSPasteboardReadingAsPropertyList = 1 << 1,
    NSPasteboardReadingAsKeyedArchive = 1 << 2
};
```

Constants

`NSPasteboardReadingAsData`

Reads data from the pasteboard as-is and returns it as an `NSData` object.

This is the default value.

Available in Mac OS X v10.6 and later.

Declared in `NSPasteboard.h`.

`NSPasteboardReadingAsString`

Reads data from the pasteboard and converts it to an `NSString` object.

Available in Mac OS X v10.6 and later.

Declared in `NSPasteboard.h`.

`NSPasteboardReadingAsPropertyList`

Reads data from the pasteboard and un-serializes it as a property list.

Available in Mac OS X v10.6 and later.

Declared in `NSPasteboard.h`.

`NSPasteboardReadingAsKeyedArchive`

Reads data from the pasteboard and uses `initWithCoder:` to initialize the object.

Available in Mac OS X v10.6 and later.

Declared in `NSPasteboard.h`.

Discussion

You can specify only one option from this list. If you do not specify an option, the default `NSPasteboardReadingAsData` (page 3772) is used.

NSPasteboardReadingOptions

A type to specify how data on the pasteboard should be interpreted to initialize an object in `initWithPasteboardPropertyList:ofType:` (page 3771).

```
typedef NSUInteger NSPasteboardReadingOptions;
```

Discussion

For valid values, see "Pasteboard Reading Options" (page 3772).

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSPasteboard.h`

NSPasteboardWriting Protocol Reference

Conforms to	NSObject
Availability	Available in Mac OS X v10.6 and later.
Declared in	NSPasteboard.h
Companion guides	Pasteboard Programming Guide Drag and Drop Programming Topics for Cocoa Services Implementation Guide
Related sample code	DemoMonkey

Overview

The `NSPasteboardWriting` protocol specifies the interface for retrieving a representation of an object that can be written to a pasteboard. The Cocoa framework classes `NSString`, `NSAttributedString`, `NSURL`, `NSColor`, `NSSound`, `NSImage`, and `NSPasteboardItem` implement this protocol. You can make your custom class conform to this protocol so that you can write instances of the class to a pasteboard using the `writeObjects:` (page 1903) method of `NSPasteboard`.

Tasks

Required Methods

`- writableTypesForPasteboard:` (page 3776) *required method*

Returns an array of UTI strings of data types the receiver can write to a given pasteboard. (required)

`- pasteboardPropertyListForType:` (page 3776) *required method*

Returns a property list object to represent the receiver on a pasteboard as an object of a specified type. (required)

Optional Method

`- writingOptionsForType:pasteboard:` (page 3777)

Returns options for writing data of a specified type to a given pasteboard.

Instance Methods

pasteboardPropertyListForType:

Returns a property list object to represent the receiver on a pasteboard as an object of a specified type. (required)

```
- (id)pasteboardPropertyListForType:(NSString *)type
```

Parameters

type

One of the types the receiver supports for writing (one of the UTIs returned by its implementation of `writableTypesForPasteboard:` (page 3776)).

Return Value

A property list object to represent the receiver on a pasteboard as an object of type *type*.

Discussion

The returned value will commonly be the `NSData` object for the specified data type. However, if this method returns either a string, or any other property-list type, the pasteboard will automatically convert these items to the correct data format required for the pasteboard.

Availability

Available in Mac OS X v10.6 and later.

Declared In

`NSPasteboard.h`

writableTypesForPasteboard:

Returns an array of UTI strings of data types the receiver can write to a given pasteboard. (required)

```
- (NSArray *)writableTypesForPasteboard:(NSPasteboard *)pasteboard
```

Parameters

pasteboard

A pasteboard.

You can use this argument to provide different options based on the pasteboard name, if you need to.

Return Value

An array of UTI strings of data types the receiver can write to *pasteboard*.

Discussion

By default, data for the first returned type is put onto the pasteboard immediately, with the remaining types being promised.

To change the default behavior, implement -writingOptionsForType:pasteboard: and return `NSPasteboardWritingPromised` (page 3778) to lazily provide data for types, return no option to provide the data for that type immediately. Use the pasteboard argument to provide different types based on the pasteboard name, if desired. Do not perform other pasteboard operations in the method implementation.

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSPasteboard.h`

writingOptionsForType:pasteboard:

Returns options for writing data of a specified type to a given pasteboard.

```
- (NSPasteboardWritingOptions)writingOptionsForType:(NSString *)type
    pasteboard:(NSPasteboard *)pasteboard
```

Parameters

type

One of the types the receiver supports for writing (one of the UTIs returned by its implementation of `writableTypesForPasteboard:` (page 3776)).

pasteboard

A pasteboard.

You can use this argument to provide different options based on the pasteboard name, if you need to.

Return Value
Options for writing data of type `type` to *pasteboard*. Return `0` for no options, or a value given in "Pasteboard Writing Options" (page 3777).

Special Considerations

Do not perform other pasteboard operations in the method implementation.

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSPasteboard.h`

Constants

Pasteboard Writing Options

Constant to specify options for writing to a pasteboard, used by `writingOptionsForType:pasteboard:` (page 3777).

```
enum {
    NSPasteboardWritingPromised = 1 << 9,
};
```

Constants

`NSPasteboardWritingPromised`

Data for a type with this option will be promised, not immediately written.

Available in Mac OS X v10.6 and later.

Declared in `NSPasteboard.h`.

NSPasteboardWritingOptions

Type to specify options for writing to a pasteboard.

```
typedef NSUInteger NSPasteboardWritingOptions;
```

Discussion

For possible values, see "Pasteboard Writing Options" (page 3777).

Availability

Available in Mac OS X v10.6 and later.

Declared In

`NSPasteboard.h`

NSPathCellDelegate Protocol Reference

Conforms to	NSObject
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.5 and later.
Declared in	AppKit/NSPathCell.h

Overview

The `NSPathCellDelegate` optional protocol enables the delegate of an `NSPathCell` object to customize the Open panel or pop-up menu of a path whose style is set to `NSPathStylePopUp` (page 1930).

Tasks

Customizing the Open Panel

`- pathCell:willDisplayOpenPanel:` (page 3779)
Implement this method to customize the Open panel shown by a pop-up–style path.

Customizing the Menu

`- pathCell:willPopUpMenu:` (page 3780)
Implement this method to customize the menu of a pop-up–style path.

Instance Methods

pathCell:willDisplayOpenPanel:

Implement this method to customize the Open panel shown by a pop-up–style path.

```
- (void)pathCell:(NSPathCell *)pathCell
    willDisplayOpenPanel:(NSOpenPanel *)openPanel
```

Parameters

pathCell

The path cell that sent the message.

openPanel

The Open panel to be displayed.

Discussion

This method is called before the Open panel is shown but after its allowed file types are set to the cell's allowed types. At this time, you can further customize the Open panel as required. This method is called only when the style is set to `NSPathStylePopUp`.

Implementation of this method is optional.

Availability

Available in Mac OS X v10.5 and later.

Declared In

`NSPathCell.h`

pathCell:willPopUpMenu:

Implement this method to customize the menu of a pop-up–style path.

```
- (void)pathCell:(NSPathCell *)pathCell
    willPopUpMenu:(NSMenu *)menu
```

Parameters

pathCell

The path cell that sent the message.

menu

The pop-up menu to be displayed.

Discussion

This method is called before the pop-up menu is shown. At this time, you can further customize the menu as required, adding and removing items. This method is called only when the style is set to `NSPathStylePopUp`.

Implementation of this method is optional.

Availability

Available in Mac OS X v10.5 and later.

Declared In

`NSPathCell.h`

NSPathControlDelegate Protocol Reference

Conforms to	NSObject
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.5 and later.
Declared in	AppKit/NSPathControl.h

Overview

The `NSPathControlDelegate` optional protocol is implemented by the delegate of an `NSPathControl` object to support dragging to and from the control.

Tasks

Dragging Support

- `pathControl:shouldDragPathComponentCell:withPasteboard:` (page 3782)
  Implement this method to enable dragging from the control.
- `pathControl:validateDrop:` (page 3783)
  Implement this method to enable dragging onto the control.
- `pathControl:acceptDrop:` (page 3782)
  Implement this method to accept previously validated contents dropped onto the control.

Customizing a Pop-Up–Style Path

- `pathControl:willDisplayOpenPanel:` (page 3783)
  Implement this method to customize the Open panel shown by a pop-up–style path.
- `pathControl:willPopUpMenu:` (page 3784)
  Implement this method to customize the menu of a pop-up–style path.

Instance Methods

pathControl:acceptDrop:

Implement this method to accept previously validated contents dropped onto the control.

```
- (BOOL)pathControl:(NSPathControl *)pathControl acceptDrop:(id < NSDraggingInfo
    >)info
```

Parameters

pathControl

The path control that sent the message.

info

An object containing details about this dragging operation.

Discussion

In order to accept the dropped contents previously accepted from `pathControl:validateDrop:` (page 3783), you must implement this method. This method is called from `performDragOperation:` (page 3657). You should change the URL value based on the dragged information.

If not implemented, and the control's cell is editable, the drop is accepted if it contains an `NSURLPboardType` or `NSFilenamesPboardType` that conforms to the cell's allowed types. The cell's URL value is automatically changed, and the action is invoked. Implementation of this method is optional.

Availability

Available in Mac OS X v10.5 and later.

Declared In

`NSPathControl.h`

pathControl:shouldDragPathComponentCell:withPasteboard:

Implement this method to enable dragging from the control.

```
- (BOOL)pathControl:(NSPathControl *)pathControl
    shouldDragPathComponentCell:(NSPathComponentCell *)pathComponentCell
    withPasteboard:(NSPasteboard *)pasteboard
```

Parameters

pathControl

The path control that sent the message.

pathComponentCell

The path component cell from which the drag is beginning.

pasteboard

The pasteboard.

Discussion
This method is called when a drag is about to begin. You can refuse to allow the drag to happen by returning `NO` and allow it by returning `YES`. By default, the pasteboard automatically has the following types on it: `NSStringPboardType`, `NSURLPboardType` (if there is a URL value for the cell being dragged), and `NSFilenamesPboardType` (if the URL value returns `YES` from `-isFileURL`). You can customize the types placed on the pasteboard at this time, if desired. Implementation of this method is optional.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSPathControl.h`

pathControl:validateDrop:

Implement this method to enable dragging onto the control.

```
- (NSDragOperation)pathControl:(NSPathControl *)pathControl validateDrop:(id <
    NSDraggingInfo >)info
```

Parameters

pathControl
The path control that sent the message.

info
An object containing details about this dragging operation.

Discussion
This method is called when something is dragged over the control. Return `NSDragOperationNone` to refuse the drop, or return anything else to accept it.

If not implemented, and the control's cell is editable, the drop is accepted if it contains an `NSURLPboardType` or `NSFilenamesPboardType` that conforms to the cell's allowed types. Implementation of this method is optional.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSPathControl.h`

pathControl:willDisplayOpenPanel:

Implement this method to customize the Open panel shown by a pop-up–style path.

```
- (void)pathControl:(NSPathControl *)pathControl willDisplayOpenPanel:(NSOpenPanel
    *)openPanel
```

Parameters

pathControl
The path control displaying the Open panel.

openPanel
The Open panel to be displayed.

Discussion
This method is called before the Open panel is shown but after its allowed file types are set to the cell's allowed types. At this time, you can further customize the Open panel as required. This method is called only when the style is set to `NSPathStylePopUp`. Implementation of this method is optional.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSPathControl.h`

pathControl:willPopUpMenu:

Implement this method to customize the menu of a pop-up–style path.

```
- (void)pathControl:(NSPathControl *)pathControl willPopUpMenu:(NSMenu *)menu
```

Parameters

pathControl
The path control displaying the pop-up menu.

menu
The pop-up menu to be displayed.

Discussion
This method is called before the pop-up menu is shown. At this time, you can further customize the menu as required, adding and removing items. This method is called only when the style is set to `NSPathStylePopUp`. Implementation of this method is optional.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSPathControl.h`

NSPlaceholders Protocol Reference

(informal protocol)

Framework	/System/Library/Frameworks/AppKit.framework
Declared in	AppKit/NSKeyValueBinding.h
Availability	Available in Mac OS X v10.3 and later.
Companion guide	Cocoa Bindings Programming Topics

Overview

The `NSPlaceholders` protocol provides an interface that allows an object to register default placeholders that will be displayed for a binding, when no other placeholder has been specified. Individual placeholder values can be specified for each of the marker objects (described in "`Selection Markers`" (page 3786)), as well as when the property is `nil`.

Placeholders are used when a property of an instance of the receiving class is accessed through a key value coding compliant method, and returns `nil` or a specialized marker.

Tasks

Managing Default Placeholders

`+ setDefaultPlaceholder:forMarker:withBinding:` (page 3786)

Sets *`placeholder`* as the default placeholder for the *`binding`*, when a key value coding compliant property of an instance of the receiving class returns the value specified by *`marker`*, and no other placeholder has been specified.

`+ defaultPlaceholderForMarker:withBinding:` (page 3786)

Returns an object that will be used as the placeholder for the *`binding`*, when a key value coding compliant property of an instance of the receiving class returns the value specified by *`marker`*, and no other placeholder has been specified.

Class Methods

defaultPlaceholderForMarker:withBinding:

Returns an object that will be used as the placeholder for the *binding*, when a key value coding compliant property of an instance of the receiving class returns the value specified by *marker*, and no other placeholder has been specified.

```
+ (id)defaultPlaceholderForMarker:(id)marker withBinding:(NSString *)binding
```

Discussion
The *marker* can be `nil` or one of the constants described in "Selection Markers" (page 3786).

Availability
Available in Mac OS X v10.3 and later.

See Also
`+ setDefaultPlaceholder:forMarker:withBinding:` (page 3786)

Declared In
`NSKeyValueBinding.h`

setDefaultPlaceholder:forMarker:withBinding:

Sets *placeholder* as the default placeholder for the *binding*, when a key value coding compliant property of an instance of the receiving class returns the value specified by *marker*, and no other placeholder has been specified.

```
+ (void)setDefaultPlaceholder:(id)placeholder forMarker:(id)marker
    withBinding:(NSString *)binding
```

Discussion
The *marker* can be `nil` or one of the constants described in "Selection Markers" (page 3786).

Availability
Available in Mac OS X v10.3 and later.

See Also
`+ defaultPlaceholderForMarker:withBinding:` (page 3786)

Declared In
`NSKeyValueBinding.h`

Constants

Selection Markers

The following constants are used to describe special cases for a controller's selection.

```
id NSMultipleValuesMarker;
id NSNoSelectionMarker;
id NSNotApplicableMarker;
```

Constants

`NSMultipleValuesMarker`

This marker indicates that a key's value contains multiple values that differ.

A binding can be configured to always return this marker for multiple items, even if the values are the same.

Available in Mac OS X v10.3 and later.

Declared in `NSKeyValueBinding.h`.

`NSNoSelectionMarker`

This marker indicates that the controller's selection is currently empty.

Available in Mac OS X v10.3 and later.

Declared in `NSKeyValueBinding.h`.

`NSNotApplicableMarker`

This marker indicates that an object is not key-value coding compliant for the requested key.

Available in Mac OS X v10.3 and later.

Declared in `NSKeyValueBinding.h`.

Availability

Available in Mac OS X v10.3 and later.

Declared In

`NSKeyValueBinding.h`

NSPrintPanelAccessorizing Protocol Reference

Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.5 and later.
Declared in	AppKit/NSPrintPanel.h

Overview

The `NSPrintPanelAccessorizing` protocol declares two methods that the `NSPrintPanel` class uses to get information from a printing accessory controller.

A printing accessory controller manages a custom print panel accessory view and used to coordinate print settings. If you are implementing a custom printing accessory view, your controller must support this protocol. Implementation of only one method in the protocol is actually required. The other method is considered optional and is used to support the print panel's built-in preview facilities.

Tasks

Responding to Being Loaded from a Nib File

- `localizedSummaryItems` (page 3790) *required method*
  Returns an array of dictionaries containing the localized user setting summary strings. (required)
- `keyPathsForValuesAffectingPreview` (page 3789)
  Returns a set of strings identifying the key paths for any properties that might affect the built-in print preview. (optional)

Instance Methods

keyPathsForValuesAffectingPreview

Returns a set of strings identifying the key paths for any properties that might affect the built-in print preview. (optional)

```
- (NSSet *)keyPathsForValuesAffectingPreview
```

Return Value
A set of `NSString` objects identifying one or more key paths. Only key paths for properties that might affect the contents of the print preview should be returned.

Discussion
If an accessory view modifies printing-related properties that are used by the print preview, you should implement this method to return the key paths for those properties. For example, if you write an accessory view that lets the user change the left and right document margins in the current `NSPrintInfo` object, you would return the following key paths: `representedObject.leftMargin`, `representedObject.rightMargin`. (The `NSPrintInfo` object is the represented object of the accessory controller.)

Implementation of this method is optional. You do not need to implement this method if you are not using the `NSPrintPanel` object's built-in preview facilities. If you do use these facilities, however, you should implement this method.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSPrintPanel.h`

localizedSummaryItems

Returns an array of dictionaries containing the localized user setting summary strings. (required)

```
- (NSArray *)localizedSummaryItems
```

Return Value
An array of `NSDictionary` objects, each of which contains a `NSPrintPanelAccessorySummaryItemNameKey` and `NSPrintPanelAccessorySummaryItemDescriptionKey` key. The values for the keys are both strings. This method must not return `nil`.

Discussion
Accessory panels must implement this method to return information about the panel's current settings. The returned array should contain a dictionary for each setting that is managed by the accessory panel and each dictionary should contain two key-value pairs identifying the name of the setting and its current value.

Your accessory view must be KVO-compliant for the `localizedSummaryItems` key path because `NSPrintPanel` object observes that key path and uses it to keep the contents of the summary view up to date. This means your view should manually send KVO notifications to observers for the `localizedSummaryItems` key path whenever the contents of the set of summary items changes. For more information on supporting key-value observing and manual notifications, see *Key-Value Observing Programming Guide*.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSPrintPanel.h`

Constants

Printing Summary Item Keys

These keys must be included in the dictionaries returned by the `localizedSummaryItems` (page 3790) method.

```
NSString *NSPrintPanelAccessorySummaryItemNameKey;
NSString *NSPrintPanelAccessorySummaryItemDescriptionKey;
```

Constants

`NSPrintPanelAccessorySummaryItemNameKey`

Used as a key to specify the name of the accessory panel setting. The corresponding value should be an `NSString` object.

Available in Mac OS X v10.5 and later.

Declared in `NSPrintPanel.h`.

`NSPrintPanelAccessorySummaryItemDescriptionKey`

Used as a key to identify the current value of the accessory panel setting. The corresponding value should be an `NSString` object.

Available in Mac OS X v10.5 and later.

Declared in `NSPrintPanel.h`.

Declared In

`NSPrintPanel.h`

NSRuleEditorDelegate Protocol Reference

Conforms to	NSObject
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.6 and later.
Declared in	AppKit/NSRuleEditor.h
Companion guides	Control and Cell Programming Topics for Cocoa Predicate Programming Guide

Overview

The `NSRuleEditorDelegate` protocol defines the optional methods implemented by delegates of `NSRuleEditor` objects.

Tasks

Providing Data

- `ruleEditor:child:forCriterion:withRowType:` (page 3794) *required method*
  Returns the child of a given item at a given index. (required)
- `ruleEditor:displayValueForCriterion:inRow:` (page 3794) *required method*
  Returns the value for a given criterion. (required)
- `ruleEditor:numberOfChildrenForCriterion:withRowType:` (page 3795) *required method*
  Returns the number of child items of a given criterion or row type. (required)
- `ruleEditor:predicatePartsForCriterion:withDisplayValue:inRow:` (page 3795)
  Returns a dictionary representing the parts of the predicate determined by the given criterion and value.

Monitoring Row Changes

- `ruleEditorRowsDidChange:` (page 3796)
  Notifies the receiver that a rule editor's rows changed.

Instance Methods

ruleEditor:child:forCriterion:withRowType:

Returns the child of a given item at a given index. (required)

```
- (id)ruleEditor:(NSRuleEditor *)editor child:(NSInteger)index
    forCriterion:(id)criterion withRowType:(NSRuleEditorRowType)rowType
```

Parameters

editor

The rule editor that sent the message.

index

The index of the requested child criterion. This value must be in the range from `0` up to (but not including) the number of children, as reported by the delegate in `ruleEditor:numberOfChildrenForCriterion:withRowType:` (page 3795).

criterion

The parent of the requested child, or `nil` if the rule editor is requesting a root criterion.

rowType

The type of the row.

Return Value

An object representing the requested child (or root) criterion. This object is used by the delegate to represent that position in the tree, and is passed as a parameter in subsequent calls to the delegate.

Special Considerations

The delegate must implement this method.

Availability

Available in Mac OS X v10.5 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

`NSRuleEditor.h`

ruleEditor:displayValueForCriterion:inRow:

Returns the value for a given criterion. (required)

```
- (id)ruleEditor:(NSRuleEditor *)editor displayValueForCriterion:(id)criterion
    inRow:(NSInteger)row
```

Parameters

editor

The rule editor that sent the message.

criterion

The criterion for which the value is required.

row

The row number of *criterion*.

Return Value
The value for *criterion*.

Discussion
The value should be an instance of `NSString`, `NSView`, or `NSMenuItem`. If the value is an `NSView` or `NSMenuItem`, you must ensure it is unique for every invocation of this method; that is, do not return a particular instance of `NSView` or `NSMenuItem` more than once.

Special Considerations

The delegate must implement this method.

Availability
Available in Mac OS X v10.5 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSRuleEditor.h`

ruleEditor:numberOfChildrenForCriterion:withRowType:

Returns the number of child items of a given criterion or row type. (required)

```
- (NSInteger)ruleEditor:(NSRuleEditor *)editor
    numberOfChildrenForCriterion:(id)criterion
    withRowType:(NSRuleEditorRowType)rowType
```

Parameters

editor

The rule editor that sent the message.

criterion

The criterion for which the number of children is required.

rowType

The type of row of *criterion*.

Return Value
The number of child items of *criterion*. If *criterion* is `nil`, return the number of root criteria for the row type *rowType*.

Special Considerations

The delegate must implement this method.

Availability
Available in Mac OS X v10.5 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSRuleEditor.h`

ruleEditor:predicatePartsForCriterion:withDisplayValue:inRow:

Returns a dictionary representing the parts of the predicate determined by the given criterion and value.

```
- (NSDictionary *)ruleEditor:(NSRuleEditor *)editor
    predicatePartsForCriterion:(id)criterion withDisplayValue:(id)value
    inRow:(NSInteger)row
```

Parameters

editor

The rule editor that sent the message.

criterion

The criterion for which the predicate parts are required.

value

The display value.

row

The row number of *criterion*.

Return Value

A dictionary representing the parts of the predicate determined by the given criterion and value. The keys of the dictionary should be the string constants specified in `Predicate Part Keys` (page 2230) with corresponding appropriate values.

Availability

Available in Mac OS X v10.5 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

`NSRuleEditor.h`

ruleEditorRowsDidChange:

Notifies the receiver that a rule editor's rows changed.

```
- (void)ruleEditorRowsDidChange:(NSNotification *)notification
```

Parameters

notification

A notification named`NSRuleEditorRowsDidChangeNotification` (page 2231).

Discussion

If the delegate implements this method, `NSRuleEditor` automatically registers its delegate to receive `NSRuleEditorRowsDidChangeNotification` (page 2231) notifications.

Availability

Available in Mac OS X v10.5 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

`NSRuleEditor.h`

NSServicesRequests Protocol Reference

(informal protocol)

Framework	/System/Library/Frameworks/AppKit.framework
Declared in	AppKit/NSApplication.h
Companion guide	Services Implementation Guide

Overview

This informal protocol consists of two methods, `writeSelectionToPasteboard:types:` (page 3798) and `readSelectionFromPasteboard:` (page 3797). The first method provides data to a remote service, and the second receives any data the remote service might send back. Both respond to messages that are generated when the user chooses a command from the Services menu.

Tasks

Working with Pasteboards

- `readSelectionFromPasteboard:` (page 3797)
  Reads data from the pasteboard and uses it to replace the current selection.
- `writeSelectionToPasteboard:types:` (page 3798)
  Writes the current selection to the pasteboard.

Instance Methods

readSelectionFromPasteboard:

Reads data from the pasteboard and uses it to replace the current selection.

```
- (BOOL)readSelectionFromPasteboard:(NSPasteboard *)pboard
```

Parameters

pboard
  The pasteboard containing the data to read.

Return Value

`YES` if your implementation was able to read the pasteboard data successfully; otherwise, `NO`.

Discussion
You implement this method to replace your application's current selection (that is, the text or objects that are currently selected) with the data on the pasteboard. The data would have been placed in the pasteboard by another application in response to a remote message from the Services menu. A `readSelectionFromPasteboard:` message is sent to the same object that previously received a `writeSelectionToPasteboard:types:` (page 3798) message.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSApplication.h`

writeSelectionToPasteboard:types:

Writes the current selection to the pasteboard.

```
- (BOOL)writeSelectionToPasteboard:(NSPasteboard *)pboard types:(NSArray *)types
```

Parameters

pboard
The pasteboard to receive your data.

types
An array of `NSString` objects listing the types of data that you should write to the pasteboard. You should write data to the pasteboard for as many of the types as you support.

Return Value
`YES` if your implementation was able to write one or more types to the pasteboard; otherwise, `NO`.

Discussion
A `writeSelectionToPasteboard:types:` message is sent to the first responder when the user chooses a command from the Services menu, but only if the receiver didn't return `nil` to a previous `validRequestorForSendType:returnType:` (page 2204) message.

After your method writes the data to the pasteboard, a remote message is sent to the application that provides the service the user requested. If the service provider supplies return data to replace the selection, the first responder will then receive a `readSelectionFromPasteboard:` (page 3797) message.

Availability
Available in Mac OS X v10.0 and later.

NSSoundDelegate Protocol Reference

Conforms to	NSObject
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.6 and later.
Declared in	AppKit/NSSound.h
Companion guide	Sound Programming Topics for Cocoa

Overview

The `NSSoundDelegate` protocol defines the optional methods implemented by delegates of `NSSound` objects.

Tasks

Playing Sounds

`- sound:didFinishPlaying:` (page 3799)
This delegate method is called when an `NSSound` instance has completed playback of its sound data.

Instance Methods

sound:didFinishPlaying:

This delegate method is called when an `NSSound` instance has completed playback of its sound data.

```
- (void)sound:(NSSound *)sound didFinishPlaying:(BOOL)finishedPlaying
```

Parameters

sound
The `NSSound` that has completed playback of its sound data.

finishedPlaying
`YES` when playback was successful; `NO` otherwise.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

`NSSound.h`

NSSpeechRecognizerDelegate Protocol Reference

Conforms to	NSObject
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.6 and later.
Declared in	AppKit/NSSpeechRecognizer.h
Companion guide	Speech

Overview

The `NSSpeechRecognizerDelegate` protocol defines the optional methods implemented by delegates of `NSSpeechRecognizer` objects.

Tasks

Recognizing Commands

`- speechRecognizer:didRecognizeCommand:` (page 3801)
Invoked when the recognition engine has recognized the application command *command*.

Instance Methods

speechRecognizer:didRecognizeCommand:

Invoked when the recognition engine has recognized the application command *command*.

```
- (void)speechRecognizer:(NSSpeechRecognizer *)sender didRecognizeCommand:(id)command
```

Discussion
command is one of the strings from the array passed to `setCommands:` (page 2483). The delegate typically evaluates which command was recognized and performs the related action.

Availability
Available in Mac OS X v10.3 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

`NSSpeechRecognizer.h`

NSSpeechSynthesizerDelegate Protocol Reference

Conforms to	NSObject
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.6 and later.
Declared in	AppKit/NSSpeechSynthesizer.h
Companion guide	Speech

Overview

The `NSSpeechSynthesizerDelegate` protocol defines the optional methods implemented by delegates of `NSSpeechSynthesizer` objects.

Tasks

Synthesizing Speech

- `speechSynthesizer:willSpeakWord:ofString:` (page 3806)
  Sent just before a synthesized word is spoken through the sound output device.
- `speechSynthesizer:willSpeakPhoneme:` (page 3805)
  Sent just before a synthesized phoneme is spoken through the sound output device.
- `speechSynthesizer:didEncounterErrorAtIndex:ofString:message:` (page 3804)
  Sent to the delegate when a speech synthesizer encounters an error in text being synthesized.
- `speechSynthesizer:didEncounterSyncMessage:` (page 3804)
  Sent to the delegate when a speech synthesizer encounters a synchronization error.
- `speechSynthesizer:didFinishSpeaking:` (page 3805)
  Sent when an `NSSpeechSynthesizer` object finishes speaking through the sound output device.

Instance Methods

speechSynthesizer:didEncounterErrorAtIndex:ofString:message:

Sent to the delegate when a speech synthesizer encounters an error in text being synthesized.

```
- (void)speechSynthesizer:(NSSpeechSynthesizer *)sender
    didEncounterErrorAtIndex:(NSUInteger)characterIndex ofString:(NSString *)string
     message:(NSString *)message
```

Parameters

sender

Speech synthesizer informing its delegate of an error.

characterIndex

Location in text where the receiver encountered the error.

text

Text the receiver was synthesizing when the error occurred.

errorMessage

Error message.

Discussion

The synthesizer sends an error delegate message whenever it encounters a syntax error within a command embedded in the string it is processing. This can be useful during application debugging, to detect problems with commands that you have embedded in strings that your application speaks. It can also be useful if your application allows users to embed commands within strings. Your application might display an alert indicating that the synthesizer encountered a problem in processing an embedded command.

If your application needs information about errors that occurred prior to calling your error delegate method, the application (including the error delegate method) can call the sender's `objectForProperty:error:` (page 2494) method with the `NSSpeechErrorsProperty` (page 2505) constant.

Availability

Available in Mac OS X v10.5 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

`NSSpeechSynthesizer.h`

speechSynthesizer:didEncounterSyncMessage:

Sent to the delegate when a speech synthesizer encounters a synchronization error.

```
- (void)speechSynthesizer:(NSSpeechSynthesizer *)sender
    didEncounterSyncMessage:(NSString *)message
```

Parameters

sender

Speech synthesizer informing its delegate of an error.

errorMessage

Error message.

Discussion
The synthesizer calls your synchronization delegate method whenever it encounters a synchronization command embedded in a string. You might use the synchronization delegate method to provide a callback not ordinarily provided.

For example, you might insert synchronization commands at the end of every sentence in a string, or you might enter synchronization commands after every numeric value in the text.

However, to synchronize your application with phonemes or words, it makes more sense to use the built-in phoneme and word delegate methods: `speechSynthesizer:willSpeakPhoneme:` (page 3805) and `speechSynthesizer:willSpeakWord:ofString:` (page 3806).

Availability
Available in Mac OS X v10.5 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSSpeechSynthesizer.h`

speechSynthesizer:didFinishSpeaking:

Sent when an `NSSpeechSynthesizer` object finishes speaking through the sound output device.

```
- (void)speechSynthesizer:(NSSpeechSynthesizer *)sender
    didFinishSpeaking:(BOOL)success
```

Parameters

sender
An `NSSpeechSynthesizer` object that has stopped speaking into the sound output device.

success
`YES` when speaking completed normally, `NO` if speaking is stopped prematurely for any reason.

Availability
Available in Mac OS X v10.3 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
- `startSpeakingString:` (page 2498) (NSSpeechSynthesizer)
- `stopSpeaking` (page 2500) (NSSpeechSynthesizer)

Declared In
`NSSpeechSynthesizer.h`

speechSynthesizer:willSpeakPhoneme:

Sent just before a synthesized phoneme is spoken through the sound output device.

```
- (void)speechSynthesizer:(NSSpeechSynthesizer *)sender
    willSpeakPhoneme:(short)phonemeOpcode
```

Parameters

sender

An `NSSpeechSynthesizer` object that's synthesizing text into speech.

phonemeOpcode

Phoneme that *sender* is about to speak into the sound output device.

Discussion

One use of this method might be to animate a mouth on screen to match the generated speech.

Important: In Mac OS X v10.4 and earlier, the delegate is not sent this message when the `NSSpeechSynthesizer` object is synthesizing speech to a file (`startSpeakingString:toURL:` (page 2499)).

Availability

Available in Mac OS X v10.3 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

See Also

`- startSpeakingString:` (page 2498) (NSSpeechSynthesizer)

Declared In

`NSSpeechSynthesizer.h`

speechSynthesizer:willSpeakWord:ofString:

Sent just before a synthesized word is spoken through the sound output device.

```
- (void)speechSynthesizer:(NSSpeechSynthesizer *)sender
    willSpeakWord:(NSRange)wordToSpeak ofString:(NSString *)text
```

Parameters

sender

An `NSSpeechSynthesizer` object that's synthesizing text into speech.

wordToSpeak

Word that *sender* is about to speak into the sound output device.

text

Text that is being synthesized by *sender*.

Discussion

One use of this method might be to visually highlight the word being spoken.

Important: In Mac OS X v10.4 and earlier, the delegate is not sent this message when the `NSSpeechSynthesizer` object is synthesizing speech to a file (`startSpeakingString:toURL:` (page 2499)).

Availability

Available in Mac OS X v10.3 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

`NSSpeechSynthesizer.h`

NSSplitViewDelegate Protocol Reference

Conforms to	NSObject
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.6 and later.
Declared in	AppKit/NSSplitView.h
Companion guides	Scroll View Programming Guide for Cocoa View Programming Guide
Related sample code	CoreAnimationText

Overview

The `NSSplitViewDelegate` protocol defines the optional methods implemented by delegates of `NSSplitView` objects.

Tasks

Managing Subviews

- `splitView:resizeSubviewsWithOldSize:` (page 3814)
  Allows the delegate to specify custom sizing behavior for the subviews of the NSSplitView *sender*.
- `splitViewWillResizeSubviews:` (page 3817)
  Invoked by the default notification center to notify the delegate that the splitview will resize its subviews.
- `splitViewDidResizeSubviews:` (page 3817)
  Invoked by the default notification center to notify the delegate that the splitview did resize its subviews.
- `splitView:canCollapseSubview:` (page 3811)
  Allows the delegate to determine whether the user can collapse and uncollapse *subview*.
- `splitView:shouldCollapseSubview:forDoubleClickOnDividerAtIndex:` (page 3815)
  Invoked to allow a delegate to determine if a subview should collapse in response to a double click.
- `splitView:shouldAdjustSizeOfSubview:` (page 3815)
  Allows the delegate to specify whether the subview should be resized.

Configuring and Drawing View Dividers

- `splitView:effectiveRect:forDrawnRect:ofDividerAtIndex:` (page 3813)
  Allows the delegate to modify the rectangle in which mouse clicks initiate divider dragging.
- `splitView:shouldHideDividerAtIndex:` (page 3816)
  Allows the delegate to determine whether a divider can be dragged or adjusted off the edge of the split view.
- `splitView:additionalEffectiveRectOfDividerAtIndex:` (page 3810)
  Allows the delegate to return an additional rectangle in which mouse clicks will initiate divider dragging.

Constraining Split Position

- `splitView:constrainMaxCoordinate:ofSubviewAt:` (page 3811)
  Allows the delegate for *sender* to constrain the maximum coordinate limit of a divider when the user drags it.
- `splitView:constrainMinCoordinate:ofSubviewAt:` (page 3812)
  Allows the delegate for *sender* to constrain the minimum coordinate limit of a divider when the user drags it.
- `splitView:constrainSplitPosition:ofSubviewAt:` (page 3813)
  Allows the delegate for *sender* to constrain the divider to certain positions.

Instance Methods

splitView:additionalEffectiveRectOfDividerAtIndex:

Allows the delegate to return an additional rectangle in which mouse clicks will initiate divider dragging.

```
- (NSRect)splitView:(NSSplitView *)splitView
    additionalEffectiveRectOfDividerAtIndex:(NSInteger)dividerIndex
```

Parameters

splitView
The split view that sent the message.

dividerIndex
The index of the divider.

Return Value
An additional rectangle in which mouse clicks should initiate divider dragging. The rectangle should be expressed in the coordinate system defined by *splitView*. Returning `NSZeroRect` indicates no additional dragging rectangle is desired.

Discussion
If a split view has no delegate, or if its delegate does not respond to this message, only mouse clicks within the effective frame of a divider initiate divider dragging.

Availability
Available in Mac OS X v10.5 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSSplitView.h

splitView:canCollapseSubview:

Allows the delegate to determine whether the user can collapse and uncollapse *subview*.

```
- (BOOL)splitView:(NSSplitView *)splitView canCollapseSubview:(NSView *)subview
```

Parameters

splitView
The split view that sent the message.

subview
The subview to collapse.

Return Value
YES if *subview* should collapse when the user drags a divider beyond the halfway mark between its minimum size and its edge, otherwise NO.

Discussion
The *subview* uncollapses when the user drags the divider back beyond the halfway mark between its minimum size and its edge.

To specify the minimum size, define the methods splitView:constrainMaxCoordinate:ofSubviewAt: (page 3811) and splitView:constrainMinCoordinate:ofSubviewAt: (page 3812). A subview can collapse only if you also define splitView:constrainMinCoordinate:ofSubviewAt: (page 3812).

A collapsed subview is hidden but retained by the split view object, with the same size it had before it was collapsed.

If the delegate does not implement this method the subviews can't be collapsed.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSSplitView.h

splitView:constrainMaxCoordinate:ofSubviewAt:

Allows the delegate for *sender* to constrain the maximum coordinate limit of a divider when the user drags it.

```
- (CGFloat)splitView:(NSSplitView *)splitView
    constrainMaxCoordinate:(CGFloat)proposedMax ofSubviewAt:(NSInteger)dividerIndex
```

Parameters

splitView
The split view that sent the message.

proposedMax
The proposed maximum coordinate limit of the subview, in the split view's flipped coordinate system.

dividerIndex
Specifies the divider the user is moving, with the first divider being 0 and increasing from top to bottom (or left to right).

Return Value
The maximum coordinate limit of the divider.

Discussion
This method is invoked before the split view begins tracking the mouse to position a divider. You may further constrain the limits that have been already set, but you cannot extend the divider limits.

If the split bars are horizontal (views are one on top of the other), *proposedMax* is the bottom limit. If the split bars are vertical (views are side by side), *proposedMax* is the right limit. The initial value of *proposedMax* is the bottom (or right side) of the subview after the divider.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
- isVertical (page 2545) (NSSplitView)

Declared In
NSSplitView.h

splitView:constrainMinCoordinate:ofSubviewAt:

Allows the delegate for *sender* to constrain the minimum coordinate limit of a divider when the user drags it.

```
- (CGFloat)splitView:(NSSplitView *)splitView
    constrainMinCoordinate:(CGFloat)proposedMin ofSubviewAt:(NSInteger)dividerIndex
```

Parameters

splitView
The split view that sent the message.

proposedMin
The proposed minimum coordinate limit of the subview, in the split view's flipped coordinate system.

dividerIndex
Specifies the divider the user is moving, with the first divider being 0 and increasing from top to bottom (or left to right).

Return Value
The minimum coordinate limit of the divider.

Discussion
This method is invoked before the split view begins tracking the cursor to position a divider. You may further constrain the limits that have been already set, but you cannot extend the divider limits.

If the split bars are horizontal (views are one on top of the other), *proposedMin* is the top limit. If the split bars are vertical (views are side by side), *proposedMin* is the left limit. The initial value of *proposedMin* is the top (or left side) of the subview before the divider.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
- `isVertical` (page 2545) (NSSplitView)

Declared In
`NSSplitView.h`

splitView:constrainSplitPosition:ofSubviewAt:

Allows the delegate for *sender* to constrain the divider to certain positions.

```
- (CGFloat)splitView:(NSSplitView *)splitView
    constrainSplitPosition:(CGFloat)proposedPosition
    ofSubviewAt:(NSInteger)dividerIndex
```

Parameters

splitView
The split view that sent the message.

proposedPosition
The cursor's current position, and the proposed position of the divider.

dividerIndex
Specifies the divider the user is moving, with the first divider being 0 and increasing from top to bottom (or left to right).

Return Value
The position at which to constrain the divider.

Discussion
If the delegate implements this method, the split view calls it repeatedly as the user moves the divider.

For example, if a subview's height must be a multiple of a certain number, use this method to return the multiple nearest to *proposedPosition*.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSSplitView.h`

splitView:effectiveRect:forDrawnRect:ofDividerAtIndex:

Allows the delegate to modify the rectangle in which mouse clicks initiate divider dragging.

```
- (NSRect)splitView:(NSSplitView *)splitView
    effectiveRect:(NSRect)proposedEffectiveRect forDrawnRect:(NSRect)drawnRect
    ofDividerAtIndex:(NSInteger)dividerIndex
```

Parameters

splitView

The split view that sent the message.

proposedEffectiveRect

The proposed rectangle in which mouse clicks should initiate divider dragging. The rectangle is expressed in the coordinate system defined by *splitView*.

drawnRect

The frame of the divider, expressed in the coordinate system defined by *splitView*.

dividerIndex

The index of the divider.

Return Value

The rectangle in which mouse clicks should initiate divider dragging. The rectangle should be expressed in the coordinate system defined by *splitView*.

Discussion

A split view with thick dividers proposes the drawn frame as the effective frame. A split view with thin dividers proposes an effective frame that's a little larger than the drawn frame, to make it easier for the user to actually grab the divider.

If a split view has no delegate, or if its delegate does not respond to this message, the split view behaves as if it has a delegate that returns *proposedEffectiveRect* when sent this message.

Availability

Available in Mac OS X v10.5 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

NSSplitView.h

splitView:resizeSubviewsWithOldSize:

Allows the delegate to specify custom sizing behavior for the subviews of the NSSplitView *sender*.

```
- (void)splitView:(NSSplitView *)splitView resizeSubviewsWithOldSize:(NSSize)oldSize
```

Parameters

splitView

The split view that sent the message.

oldSize

The size of the split view before the user resized it.

Discussion

If the delegate implements this method, `splitView:resizeSubviewsWithOldSize:` (page 3814) is invoked after the split view is resized.

The subviews should be resized such that the sum of the sizes of the subviews plus the sum of the thickness of the dividers equals the size of the NSSplitView's new frame. You can get the thickness of a divider through the `dividerThickness` (page 2543) method.

Note that if you implement this delegate method to resize subviews on your own, the NSSplitView does not perform any error checking for you. However, you can invoke `adjustSubviews` (page 2541) to perform the default sizing behavior.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
- `adjustSubviews` (page 2541) (NSSplitView)
- `setFrame:` (page 3218) (NSView)

Declared In
`NSSplitView.h`

splitView:shouldAdjustSizeOfSubview:

Allows the delegate to specify whether the subview should be resized.

```
- (BOOL)splitView:(NSSplitView *)splitView shouldAdjustSizeOfSubview:(NSView
    *)subview
```

Parameters

splitView
The split view that sent the message.

subview
The subview to resize.

Return Value
`YES` if adjustSubviews can change the size of the subview, otherwise `NO`. By returning `NO`, you lock the size of the split view *subview* while the split view is resized.

Discussion
Regardless of the value returned by this method, `adjustSubviews` (page 2541) may change the origin of the subview. Otherwise non-resizable subviews may also be resized in order to prevent an invalid subview layout.

If a split view has no delegate, or if its delegate does not respond to this message, the split view behaves as if this method returns `YES`.

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSSplitView.h`

splitView:shouldCollapseSubview:forDoubleClickOnDividerAtIndex:

Invoked to allow a delegate to determine if a subview should collapse in response to a double click.

```
- (BOOL)splitView:(NSSplitView *)splitView shouldCollapseSubview:(NSView *)subview
    forDoubleClickOnDividerAtIndex:(NSInteger)dividerIndex
```

Parameters

splitView
The split view that sent the message.

subview
The subview to collapse.

dividerIndex
The index of the divider.

Return Value
YES if the subview should collapse, NO otherwise.

Discussion
If implemented, the delegate will receive this message once for the subview before a divider when the user double-clicks on that divider, and again for the subview after the divider, but only if the delegate returned YES when sent splitView:canCollapseSubview: (page 3811) for the subview in question. When the delegate indicates that both subviews should be collapsed NSSplitView's behavior is undefined.

Availability
Available in Mac OS X v10.5 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSSplitView.h

splitView:shouldHideDividerAtIndex:

Allows the delegate to determine whether a divider can be dragged or adjusted off the edge of the split view.

```
- (BOOL)splitView:(NSSplitView *)splitView
    shouldHideDividerAtIndex:(NSInteger)dividerIndex
```

Parameters

splitView
The split view that sent the message.

dividerIndex
The zero-based index of the divider.

Return Value
YES if the divider should allow dragging off the edge of the split view, resulting in it not being visible.

Discussion
If a split view has no delegate, or if its delegate does not respond to this message, the split view behaves as if it has a delegate that returns NO when sent this message.

Availability
Available in Mac OS X v10.5 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSSplitView.h

splitViewDidResizeSubviews:

Invoked by the default notification center to notify the delegate that the splitview did resize its subviews.

```
- (void)splitViewDidResizeSubviews:(NSNotification *)aNotification
```

Parameters

aNotification

A notification named `NSSplitViewDidResizeSubviewsNotification` (page 2549).

Discussion

If the delegate implements this method, the delegate is automatically registered to receive this notification.

This method is invoked after the split view resizes two of its subviews in response to the repositioning of a divider.

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

`NSSplitView.h`

splitViewWillResizeSubviews:

Invoked by the default notification center to notify the delegate that the splitview will resize its subviews.

```
- (void)splitViewWillResizeSubviews:(NSNotification *)aNotification
```

Parameters

aNotification

A notification named `NSSplitViewWillResizeSubviewsNotification` (page 2550).

Discussion

If the delegate implements this method, the delegate is automatically registered to receive this notification.

This method is invoked before the split view resizes two of its subviews in response to the repositioning of a divider.

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Overview

The `NSTableViewDataSource` protocol declares the methods that an instance of `NSTableView` uses to provide and access the contents of its data source object.

Note: Some of the methods in this protocol, such as `tableView:objectValueForTableColumn:row:` (page 3822) and `numberOfRowsInTableView:` (page 3820) along with other methods that return data, are called very frequently, so they must be efficient.

Tasks

Getting Values

- `numberOfRowsInTableView:` (page 3820)
  Returns the number of records managed for *`aTableView`* by the data source object.
- `tableView:objectValueForTableColumn:row:` (page 3822)
  Invoked by the table view to return the data object associated with the specified row and column.

Setting Values

`- tableView:setObjectValue:forTableColumn:row:` (page 3823)
Sets the data object for an item in a given row in a given column.

Dragging

`- tableView:acceptDrop:row:dropOperation:` (page 3821)
Invoked by *aTableView* when the mouse button is released over a table view that previously decided to allow a drop.

`- tableView:namesOfPromisedFilesDroppedAtDestination:forDraggedRowsWithIndexes:` (page 3821)
Returns an array of filenames that represent the *indexSet* rows for a drag to *dropDestination*.

`- tableView:validateDrop:proposedRow:proposedDropOperation:` (page 3824)
Used by *aTableView* to determine a valid drop target.

`- tableView:writeRowsWithIndexes:toPasteboard:` (page 3825)
Returns a Boolean value that indicates whether a drag operation is allowed.

Sorting

`- tableView:sortDescriptorsDidChange:` (page 3823)
Invoked by *aTableView* to indicate that sorting may need to be done.

Instance Methods

numberOfRowsInTableView:

Returns the number of records managed for *aTableView* by the data source object.

```
- (NSInteger)numberOfRowsInTableView:(NSTableView *)aTableView
```

Parameters

aTableView
The table view that sent the message.

Return Value
The number of rows in *aTableView*.

Discussion
An instance of `NSTableView` uses this method to determine how many rows it should create and display. Your `numberOfRowsInTableView:` implementation is called very frequently, so it must be efficient.

Note: This method is optional if your application is using Cocoa bindings for providing data to the table view, otherwise it must be implemented.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSTableView.h`

tableView:acceptDrop:row:dropOperation:

Invoked by *aTableView* when the mouse button is released over a table view that previously decided to allow a drop.

```
- (BOOL)tableView:(NSTableView *)aTableView acceptDrop:(id < NSDraggingInfo >)info
    row:(NSInteger)row dropOperation:(NSTableViewDropOperation)operation
```

Parameters

aTableView
The table view that sent the message.

info
An object that contains more information about this dragging operation.

row
The index of the proposed target row.

operation
The type of dragging operation.

Return Value
`YES` if the drop operation was successful, otherwise `NO`.

Discussion
The data source should incorporate the data from the dragging pasteboard in the implementation of this method. You can get the data for the drop operation from info using the `draggingPasteboard` (page 3662) method.

To accept a drop on the second row, *row* would be 2 and *operation* would be `NSTableViewDropOn`. To accept a drop below the last row, *row* would be `[aTableView numberOfRows]` and *operation* would be `NSTableViewDropAbove`.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSTableView.h`

tableView:namesOfPromisedFilesDroppedAtDestination:forDraggedRowsWithIndexes:

Returns an array of filenames that represent the *indexSet* rows for a drag to *dropDestination*.

```
- (NSArray *)tableView:(NSTableView *)aTableView
    namesOfPromisedFilesDroppedAtDestination:(NSURL *)dropDestination
    forDraggedRowsWithIndexes:(NSIndexSet *)indexSet
```

Parameters

aTableView

The table view that sent the message.

dropDestination

The drop location where the files are created.

indexSet

The indexes of the items being dragged.

Return Value

An array of filenames (not full paths) for the created files that the receiver promises to create.

Discussion

This method is called when a destination has accepted a promise drag.

For more information on file promise dragging, see documentation on the `NSDraggingSource` protocol and `namesOfPromisedFilesDroppedAtDestination:` (page 3663).

Availability

Available in Mac OS X v10.4 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

`NSTableView.h`

tableView:objectValueForTableColumn:row:

Invoked by the table view to return the data object associated with the specified row and column.

```
- (id)tableView:(NSTableView *)aTableView objectValueForTableColumn:(NSTableColumn
    *)aTableColumn row:(NSInteger)rowIndex
```

Parameters

aTableView

The table view that sent the message.

aTableColumn

A column in in *aTableView*.

rowIndex

The row of the item in *aTableColumn*.

Return Value

An item in the data source in the specified tableColumn of the view.

Discussion

`tableView:objectValueForTableColumn:row:` is called each time the table cell needs to be redisplayed, so it must be efficient.

Note: This method is optional if your application is using Cocoa bindings for providing data to the table view, otherwise it must be implemented.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSTableView.h

tableView:setObjectValue:forTableColumn:row:

Sets the data object for an item in a given row in a given column.

```
- (void)tableView:(NSTableView *)aTableView setObjectValue:(id)anObject
    forTableColumn:(NSTableColumn *)aTableColumn row:(NSInteger)rowIndex
```

Parameters

aTableView
The table view that sent the message.

anObject
The new value for the item.

aTableColumn
A column in *aTableView*.

rowIndex
The row of the item in *aTableColumn*.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSTableView.h

tableView:sortDescriptorsDidChange:

Invoked by *aTableView* to indicate that sorting may need to be done.

```
- (void)tableView:(NSTableView *)aTableView sortDescriptorsDidChange:(NSArray
    *)oldDescriptors
```

Parameters

aTableView
The table view that sent the message.

oldDescriptors
An array that contains the previous descriptors.

Discussion
The data source typically sorts and reloads the data, and adjusts the selections accordingly. If you need to know the current sort descriptors and the data source does not manage them itself, you can get the current sort descriptors by sending *aTableView* a `sortDescriptors` (page 2670) message.

Availability
Available in Mac OS X v10.3 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSTableView.h`

tableView:validateDrop:proposedRow:proposedDropOperation:

Used by *aTableView* to determine a valid drop target.

```
- (NSDragOperation)tableView:(NSTableView *)aTableView validateDrop:(id <
    NSDraggingInfo >)info proposedRow:(NSInteger)row
    proposedDropOperation:(NSTableViewDropOperation)operation
```

Parameters

aTableView
The table view that sent the message.

info
An object that contains more information about this dragging operation.

row
The index of the proposed target row.

operation
The type of dragging operation proposed.

Return Value
The dragging operation the data source will perform.

Discussion
The data source may "retarget" a drop if desired by calling `setDropRow:dropOperation:` (page 2663) and returning something other than `NSDragOperationNone`. One may choose to retarget for various reasons (e.g. for better visual feedback when inserting into a sorted position).

To propose a drop on the second row, *row* would be 2 and *operation* would be `NSTableViewDropOn`. To propose a drop below the last row, *row* would be `[aTableView numberOfRows]` and *operation* would be `NSTableViewDropAbove`.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSTableView.h`

tableView:writeRowsWithIndexes:toPasteboard:

Returns a Boolean value that indicates whether a drag operation is allowed.

```
- (BOOL)tableView:(NSTableView *)aTableView writeRowsWithIndexes:(NSIndexSet
    *)rowIndexes toPasteboard:(NSPasteboard *)pboard
```

Parameters

aTableView

The table view that sent the message.

rowIndexes

An index set of row numbers that will be participating in the drag.

pboard

The pasteboard to which to write the drag data.

Return Value

YES if the drag operation is allowed, *NO* otherwise.

Discussion

Invoked by *aTableView* after it has been determined that a drag should begin, but before the drag has been started.

To refuse the drag, return `NO`. To start a drag, return `YES` and place the drag data onto *pboard* (data, owner, and so on). The drag image and other drag-related information will be set up and provided by the table view once this call returns with `YES`.

Availability

Available in Mac OS X v10.4 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Overview

The `NSTableViewDelegate` protocol defines the optional methods implemented by delegates of `NSTableView` objects.

Tasks

Displaying Cells

- `tableView:willDisplayCell:forTableColumn:row:` (page 3840)
  Informs the delegate that the tableview will display the specified cell at the row in the column.
- `tableView:dataCellForTableColumn:row:` (page 3829)
  Invoked to allow the delegate to return a custom data cell for a specified row and column.
- `tableView:shouldShowCellExpansionForTableColumn:row:` (page 3836)
  Invoked to allow the delegate to control cell expansion for a specific row and column.
- `tableView:isGroupRow:` (page 3832)
  Invoked to allow the delegate to indicate that a specified row is a group row.
- `tableView:toolTipForCell:rect:tableColumn:row:mouseLocation:` (page 3838)
  Returns a string that is displayed as a tooltip for the specified cell in the column and row.

Editing Cells

- `tableView:shouldEditTableColumn:row:` (page 3834)
  Returns whether the cell at the specified row and column can be edited.

Setting Row and Column Size

- `tableView:heightOfRow:` (page 3831)
  Returns the height of the specified row.
- `tableView:sizeToFitWidthOfColumn:` (page 3838)
  Invoked to allow the delegate to provide custom sizing behavior when a column's resize divider is double clicked.

Selecting in the Tableview

- `selectionShouldChangeInTableView:` (page 3829)
  Returns whether the selection should change.
- `tableView:shouldSelectRow:` (page 3835)
  Returns whether the table view should allow selection of the specified row.
- `tableView:selectionIndexesForProposedSelection:` (page 3833)
  Invoked to allow the delegate to modify the proposed selection.
- `tableView:shouldSelectTableColumn:` (page 3835)
  Returns whether the specified table column can be selected.
- `tableViewSelectionIsChanging:` (page 3841)
  Informs the delegate that the table view's selection is in the process of changing (typically because the user is dragging the mouse across a number of rows).
- `tableViewSelectionDidChange:` (page 3841)
  Informs the delegate that the table view's selection has changed.
- `tableView:shouldTypeSelectForEvent:withCurrentSearchString:` (page 3837)
  Invoked to allow the delegate to control type select for a specific event.
- `tableView:typeSelectStringForTableColumn:row:` (page 3839)
  Invoked to allow the delegate to provide an alternate text value used for type selection for a specified row and column.
- `tableView:nextTypeSelectMatchFromRow:toRow:forString:` (page 3833)
  Invoked to allow the delegate to allow the delegate to modify how type selection works.

Moving and Resizing Columns

- `tableView:shouldReorderColumn:toColumn:` (page 3834)
  Sent to the delegate to allow or prohibit the specified column to be dragged to a new location.
- `tableView:didDragTableColumn:` (page 3831)
  Sent at the time the mouse button goes up in *`tableView`* and *`tableColumn`* has been dragged during the time the mouse button was down.

- `tableViewColumnDidMove:` (page 3840)
  Informs the delegate that a column was moved by user action in the table view.
- `tableViewColumnDidResize:` (page 3841)
  Informs the delegate that a column was resized in the table view.

Responding to Mouse Events

- `tableView:didClickTableColumn:` (page 3830)
  Sent when the mouse button was clicked in a table column, but the column was not dragged.
- `tableView:mouseDownInHeaderOfTableColumn:` (page 3832)
  Sent to the delegate whenever the mouse button is clicked in the table view's header column.
- `tableView:shouldTrackCell:forTableColumn:row:` (page 3837)
  Invoked to allow the delegate to control the tracking behavior for a specific cell.

Instance Methods

selectionShouldChangeInTableView:

Returns whether the selection should change.

```
- (BOOL)selectionShouldChangeInTableView:(NSTableView *)aTableView
```

Parameters

aTableView
  The table view that sent the message.

Return Value
`YES` to allow the table view to change its selection (typically a row being edited), `NO` to deny selection change.

Discussion
The user can select and edit different cells within the same row, but can't select another row unless the delegate approves. The delegate can implement this method for complex validation of edited rows based on the values of any of their cells.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSTableView.h`

tableView:dataCellForTableColumn:row:

Invoked to allow the delegate to return a custom data cell for a specified row and column.

```
- (NSCell *)tableView:(NSTableView *)tableView dataCellForTableColumn:(NSTableColumn
    *)tableColumn row:(NSInteger)row
```

Parameters

tableView

The table view that sent the message.

tableColumn

The table column.

row

The row index.

Return Value

An `NSCell` subclass that is used for the specified *row* and *tableColumn*. The returned cell must properly implement `copyWithZone:`.

Discussion

A different data cell can be returned for any particular table column and row, or a cell that will be used for the entire row (a full width cell).

If the tableColumn is non-`nil`, you should return a cell, and generally that will be the result of sending *tableColumn* a `dataCellForRow:` (page 2590) message.

This method will be invoked with a *tableColumn* value of `nil` to allow you to return a group cell–a cell that will be used to draw the entire row, acting as a separator. If you return a cell when *tableColumn* is `nil`, any implemented datasource and delegate methods must be prepared to handle a `nil` table column value.

Availability

Available in Mac OS X v10.5 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

`NSTableView.h`

tableView:didClickTableColumn:

Sent when the mouse button was clicked in a table column, but the column was not dragged.

```
- (void)tableView:(NSTableView *)tableView didClickTableColumn:(NSTableColumn
    *)tableColumn
```

Parameters

tableView

The table view that sent the message.

tableColumn

The table column.

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

`NSTableView.h`

tableView:didDragTableColumn:

Sent at the time the mouse button goes up in *tableView* and *tableColumn* has been dragged during the time the mouse button was down.

```
- (void)tableView:(NSTableView *)tableView didDragTableColumn:(NSTableColumn
    *)tableColumn
```

Parameters

tableView

The table view that sent the message.

tableColumn

The table column.

Special Considerations

The behavior of this method on Mac OS X v10.5 is different from prior versions. On Mac OS X v 10.5 the dragged column is sent to the delegate. In earlier versions the table column that is currently located at the dragged column's original index is sent.

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

NSTableView.h

tableView:heightOfRow:

Returns the height of the specified row.

```
- (CGFloat)tableView:(NSTableView *)tableView heightOfRow:(NSInteger)row
```

Parameters

tableView

The table view that sent the message.

row

The row index.

Return Value

The height of the row. The height should not include intercell spacing and must be greater than zero.

Discussion

You should implement this method if your table supports varying row heights.

Although table views may cache the returned values, you should ensure that this method is efficient. When you change a row's height you must invalidate the existing row height by calling `noteHeightOfRowsWithIndexesChanged:` (page ?). `NSTableView` automatically invalidates its entire row height cache when `reloadData` (page ?) and `noteNumberOfRowsChanged` (page ?) are called.

Availability

Available in Mac OS X v10.4 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSTableView.h

tableView:isGroupRow:

Invoked to allow the delegate to indicate that a specified row is a group row.

```
- (BOOL)tableView:(NSTableView *)tableView isGroupRow:(NSInteger)row
```

Parameters

tableView
The table view that sent the message.

row
The row index.

Return Value
YES if the specified row should have the group row style drawn, NO otherwise.

Discussion
If the cell in *row* is an NSTextFieldCell and contains only a string, the group row style attributes will automatically be applied to the cell.

Availability
Available in Mac OS X v10.5 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSTableView.h

tableView:mouseDownInHeaderOfTableColumn:

Sent to the delegate whenever the mouse button is clicked in the table view's header column.

```
- (void)tableView:(NSTableView *)tableView
    mouseDownInHeaderOfTableColumn:(NSTableColumn *)tableColumn
```

Parameters

tableView
The table view that sent the message.

tableColumn
The table column.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSTableView.h

tableView:nextTypeSelectMatchFromRow:toRow:forString:

Invoked to allow the delegate to allow the delegate to modify how type selection works.

```
- (NSInteger)tableView:(NSTableView *)tableView
    nextTypeSelectMatchFromRow:(NSInteger)startRow toRow:(NSInteger)endRow
    forString:(NSString *)searchString
```

Parameters

tableView

The table view that sent the message.

startRow

The starting row of the search range.

endRow

The ending row of the search range.

searchString

A string containing the typed selection.

Return Value

The first row in the range of *startRow* through *endRow* (excluding *endRow* itself) that matches *selectionString*. Return -1 if no match is found.

Discussion

It is possible for `endRow` to be less than `startRow` if the search will wrap.

Availability

Available in Mac OS X v10.5 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

`NSTableView.h`

tableView:selectionIndexesForProposedSelection:

Invoked to allow the delegate to modify the proposed selection.

```
- (NSIndexSet *)tableView:(NSTableView *)tableView
    selectionIndexesForProposedSelection:(NSIndexSet *)proposedSelectionIndexes
```

Parameters

tableView

The table view that sent the message.

proposedSelectionIndexes

An index set containing the indexes of the proposed selection.

Return Value

An `NSIndexSet` instance containing the indexes of the new selection. Return *proposedSelectionIndexes* if the proposed selection is acceptable, or the value of the table view's existing selection to avoid changing the selection.

Discussion

This method may be called multiple times with one new index added to the existing selection to find out if a particular index can be selected when the user is extending the selection with the keyboard or mouse.

Implementation of this method is optional. If implemented, this method will be called instead of `tableView:shouldSelectRow:` (page ?).

Availability
Available in Mac OS X v10.5 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSTableView.h`

tableView:shouldEditTableColumn:row:

Returns whether the cell at the specified row and column can be edited.

```
- (BOOL)tableView:(NSTableView *)aTableView shouldEditTableColumn:(NSTableColumn
    *)aTableColumn row:(NSInteger)rowIndex
```

Parameters

aTableView
The table view that sent the message.

aTableColumn
The table column.

rowIndex
The row index.

Return Value
`YES` to allow editing the cell , `NO` to deny editing.

Discussion
The delegate can implement this method to disallow editing of specific cells.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSTableView.h`

tableView:shouldReorderColumn:toColumn:

Sent to the delegate to allow or prohibit the specified column to be dragged to a new location.

```
- (BOOL)tableView:(NSTableView *)tableView shouldReorderColumn:(NSInteger)columnIndex
    toColumn:(NSInteger)newColumnIndex
```

Parameters

tableView
The tableview that sent the message.

columnIndex
The index of the column being dragged.

newColumnIndex
The proposed target index of the column.

Return Value
YES if the column reordering should be allowed, otherwise NO.

Discussion
When a column is initially dragged by the user, the delegate is first called with a *newColumnIndex* value of -1. Returning NO will disallow that column from being reordered at all. Returning YES allows it to be reordered, and the delegate will be called again when the column reaches a new location.

The actual NSTableColumn instance can be retrieved from the tableColumns (page 2670) array.

If this method is not implemented, all columns are considered reorderable.

Availability
Available in Mac OS X v10.6 and later.

Declared In
NSTableView.h

tableView:shouldSelectRow:

Returns whether the table view should allow selection of the specified row.

```
- (BOOL)tableView:(NSTableView *)aTableView shouldSelectRow:(NSInteger)rowIndex
```

Parameters
aTableView
The table view that sent the message.

rowIndex
The row index.

Return Value
YES to permit selection of the row, NO to deny selection.

Discussion
The delegate can implement this method to disallow selection of particular rows.

For better performance and finer-grain control over the selection, use tableView:selectionIndexesForProposedSelection: (page 2643).

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSTableView.h

tableView:shouldSelectTableColumn:

Returns whether the specified table column can be selected.

```
- (BOOL)tableView:(NSTableView *)aTableView shouldSelectTableColumn:(NSTableColumn
    *)aTableColumn
```

Parameters

aTableView

The table view that sent the message.

aTableColumn

The table column.

Return Value

`YES` to permit selection, otherwise `NO`.

Discussion

The delegate can implement this method to disallow selection of particular columns.

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

`NSTableView.h`

tableView:shouldShowCellExpansionForTableColumn:row:

Invoked to allow the delegate to control cell expansion for a specific row and column.

```
- (BOOL)tableView:(NSTableView *)tableView
    shouldShowCellExpansionForTableColumn:(NSTableColumn *)tableColumn
    row:(NSInteger)row
```

Parameters

tableView

The table view that sent the message.

tableColumn

The table column.

row

The row index.

Return Value

`YES` if the tooltip cell should expand, `NO` otherwise.

Discussion

Cell expansion can occur when the mouse hovers over the specified cell and the cell contents are unable to be fully displayed within the cell. If this method returns `YES`, the full cell contents will be shown in a special floating tool tip view, otherwise the content is truncated.

Availability

Available in Mac OS X v10.5 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

`NSTableView.h`

tableView:shouldTrackCell:forTableColumn:row:

Invoked to allow the delegate to control the tracking behavior for a specific cell.

```
- (BOOL)tableView:(NSTableView *)tableView shouldTrackCell:(NSCell *)cell
    forTableColumn:(NSTableColumn *)tableColumn row:(NSInteger)row
```

Parameters

tableView

The table view that sent the message.

cell

The cell to track.

tableColumn

The table column.

row

A row in *tableView*.

Return Value

`YES` if the cell should track, `NO` otherwise.

Discussion

Normally, only selectable or selected cells can be tracked. If you implement this method, cells which are not selectable or selected can be tracked, and vice-versa.

For example, this allows you to have an `NSButtonCell` in a table which does not change the selection, but can still be clicked on and tracked.

Availability

Available in Mac OS X v10.5 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

`NSTableView.h`

tableView:shouldTypeSelectForEvent:withCurrentSearchString:

Invoked to allow the delegate to control type select for a specific event.

```
- (BOOL)tableView:(NSTableView *)tableView shouldTypeSelectForEvent:(NSEvent *)event
    withCurrentSearchString:(NSString *)searchString
```

Parameters

tableView

The table view that sent the message.

event

The event.

searchString

The search string or `nil` if no type select has began.

Return Value

YES to allow type select for event, NO otherwise.

Discussion
Typically, this is called from the table view `keyDown:` implementation and the event will be a key event.

Availability
Available in Mac OS X v10.5 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSTableView.h`

tableView:sizeToFitWidthOfColumn:

Invoked to allow the delegate to provide custom sizing behavior when a column's resize divider is double clicked.

```
- (CGFloat)tableView:(NSTableView *)tableView
    sizeToFitWidthOfColumn:(NSInteger)column
```

Parameters
tableView
The tableview that sent the message.

column
The index of the column.

Return Value
The width of the specified column.

Discussion
By default, `NSOutlineView` iterates every row in the table, accesses a cell via `preparedCellAtColumn:row:` (page 2643), and requests the `cellSize` (page 549) to find the appropriate largest width to use.

For accurate results and performance, it is recommended that this method is implemented when using large tables. By default, large tables use a monte carlo simulation instead of interating every row.

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSTableView.h`

tableView:toolTipForCell:rect:tableColumn:row:mouseLocation:

Returns a string that is displayed as a tooltip for the specified cell in the column and row.

```
- (NSString *)tableView:(NSTableView *)aTableView toolTipForCell:(NSCell *)aCell
    rect:(NSRectPointer)rect tableColumn:(NSTableColumn *)aTableColumn
    row:(NSInteger)row mouseLocation:(NSPoint)mouseLocation
```

Parameters
aTableView
The table view that sent the message.

aCell
The cell.

rect
The proposed active area of the tooltip. You can modify *rect* to provide an alternative active area.

aTableColumn
The table column.

row
The row index.

mouseLocation
The mouse location.

Return Value
A string containing the tooltip. Return `nil` or the empty string if no tooltip is desired.

Discussion
By default, *rect* is computed as `[cell drawingRectForBounds:cellFrame]`.

Availability
Available in Mac OS X v10.4 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSTableView.h`

tableView:typeSelectStringForTableColumn:row:

Invoked to allow the delegate to provide an alternate text value used for type selection for a specified row and column.

```
- (NSString *)tableView:(NSTableView *)tableView
    typeSelectStringForTableColumn:(NSTableColumn *)tableColumn row:(NSInteger)row
```

Parameters
tableView
The table view that sent the message.

tableColumn
The table column.

row
The row index.

Return Value
A string that is used in type select comparison for *row* and *tableColumn*. Return `nil` if the *row* or *tableColumn* should not be searched.

Discussion
Implement this method to change the string value that is searched for based on what is displayed. By default, all cells with text in them are searched.

If this delegate method is not implemented the string value is:

```
[[tableView preparedCellAtColumn:tableColumn row:row] stringValue]
```

This value can be returned from the delegate method if desired.

Implementation of this method is optional.

Availability
Available in Mac OS X v10.5 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSTableView.h

tableView:willDisplayCell:forTableColumn:row:

Informs the delegate that the tableview will display the specified cell at the row in the column.

```
- (void)tableView:(NSTableView *)aTableView willDisplayCell:(id)aCell
    forTableColumn:(NSTableColumn *)aTableColumn row:(NSInteger)rowIndex
```

Parameters

aTableView
The table view that sent the message.

aCell
The cell to be displayed.

aTableColumn
The table column.

rowIndex
The row index.

Discussion
The delegate can modify the display attributes of *aCell* to alter the appearance of the cell.

Because *aCell* is reused for every row in *aTableColumn*, the delegate must set the display attributes both when drawing special cells and when drawing normal cells.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSTableView.h

tableViewColumnDidMove:

Informs the delegate that a column was moved by user action in the table view.

```
- (void)tableViewColumnDidMove:(NSNotification *)aNotification
```

Parameters

aNotification
A notification named NSTableViewColumnDidMoveNotification (page ?).

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSTableView.h

tableViewColumnDidResize:

Informs the delegate that a column was resized in the table view.

```
- (void)tableViewColumnDidResize:(NSNotification *)aNotification
```

Parameters
aNotification
A notification named NSTableViewColumnDidResizeNotification (page ?).

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSTableView.h

tableViewSelectionDidChange:

Informs the delegate that the table view's selection has changed.

```
- (void)tableViewSelectionDidChange:(NSNotification *)aNotification
```

Parameters
aNotification
A notification named NSTableViewSelectionDidChangeNotification (page ?).

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSTableView.h

tableViewSelectionIsChanging:

Informs the delegate that the table view's selection is in the process of changing (typically because the user is dragging the mouse across a number of rows).

```
- (void)tableViewSelectionIsChanging:(NSNotification *)aNotification
```

Parameters
aNotification
A notification named NSTableViewSelectionIsChangingNotification (page ?).

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSTableView.h`

Declared in	AppKit/NSTabView.h
Companion guide	Tab Views

Overview

The `NSTabViewDelegate` protocol defines the optional methods implemented by delegates of `NSTabView` objects.

Tasks

Adding and Removing Tabs

- `tabViewDidChangeNumberOfTabViewItems:` (page 3845)
  Informs the delegate that the number of tab view items in *`tabView`* has changed.

Selecting a Tab

- `tabView:shouldSelectTabViewItem:` (page 3844)
  Invoked just before *`tabViewItem`* in *`tabView`* is selected.
- `tabView:willSelectTabViewItem:` (page 3844)
  Informs the delegate that *`tabView`* is about to select *`tabViewItem`*.
- `tabView:didSelectTabViewItem:` (page 3844)
  Informs the delegate that *`tabView`* has selected *`tabViewItem`*.

Instance Methods

tabView:didSelectTabViewItem:

Informs the delegate that *tabView* has selected *tabViewItem*.

```
- (void)tabView:(NSTabView *)tabView didSelectTabViewItem:(NSTabViewItem
    *)tabViewItem
```

Parameters

tabView

The tab view that sent the request.

tabViewItem

The tab view item that was selected.

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

NSTabView.h

tabView:shouldSelectTabViewItem:

Invoked just before *tabViewItem* in *tabView* is selected.

```
- (BOOL)tabView:(NSTabView *)tabView shouldSelectTabViewItem:(NSTabViewItem
    *)tabViewItem
```

Parameters

tabView

The tab view that sent the request.

tabViewItem

The tab view item to select.

Return Value

YES if the tab view item should be selected, otherwise NO.

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

NSTabView.h

tabView:willSelectTabViewItem:

Informs the delegate that *tabView* is about to select *tabViewItem*.

```
- (void)tabView:(NSTabView *)tabView willSelectTabViewItem:(NSTabViewItem
    *)tabViewItem
```

Parameters

tabView

The tab view that sent the request.

tabViewItem

The tab view item that is about to be selected.

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

NSTabView.h

tabViewDidChangeNumberOfTabViewItems:

Informs the delegate that the number of tab view items in *tabView* has changed.

```
- (void)tabViewDidChangeNumberOfTabViewItems:(NSTabView *)tabView
```

Parameters

tabView

The tab view that added or removed tabview items.

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

NSTextAttachmentCell Protocol Reference

Adopted by	NSTextAttachmentCell
Conforms to	NSObject
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.0 and later.
Declared in	AppKit/NSTextAttachment.h
Companion guides	Text System Overview Text Attachment Programming Topics

Overview

The NSTextAttachmentCell protocol declares the interface for objects that draw text attachment icons and handle mouse events on their icons. With the exceptions of `cellBaselineOffset` (page 3849), `setAttachment:` (page 3851), and `attachment` (page 3848), all of these methods are implemented by the NSCell class and described in that class specification.

See the NSAttributedString and NSTextView class specifications for general information on text attachments.

Tasks

Drawing

- `drawWithFrame:inView:` (page 3850) *required method*
  Draws the receiver's image within *cellFrame* in *aView*, which is the view currently focused. (required)
- `drawWithFrame:inView:characterIndex:` (page 3850) *required method*
  Draws the receiver's image within *cellFrame* in *aView*, which is the view currently focused. *charIndex* is the index of the attachment character within the text. (required)
- `drawWithFrame:inView:characterIndex:layoutManager:` (page 3850) *required method*
  Draws the receiver's image within *cellFrame* in *controlView*, which is the view currently focused. *charIndex* is the index of the attachment character within the text. *layoutManager* is the layout manager for the text. (required)

- highlight:withFrame:inView: (page 3851) *required method*
  Draws the receiver's image—with highlighting if *flag* is YES—within *cellFrame* in *aView*, which should be the focus view. (required)

Cell Size and Position

- cellSize (page 3849) *required method*
  Returns the size of the attachment's icon. (required)
- cellBaselineOffset (page 3849) *required method*
  Returns the position where the attachment cell's image should be drawn in text, relative to the current point established in the glyph layout. (required)
- cellFrameForTextContainer:proposedLineFragment:glyphPosition:characterIndex: (page 3849) *required method*
  Returns the frame of the cell as it would be drawn as the character at the given glyph *position*, and character index, *charIndex*, in *textContainer*. (required)

Event Handling

- wantsToTrackMouse (page 3853) *required method*
  Returns YES if the receiver will handle a mouse event occurring over its image (to support dragging, for example), NO otherwise. (required)
- wantsToTrackMouseForEvent:inRect:ofView:atCharacterIndex: (page 3853) *required method*
  Allows an attachment to specify what events it would want to track the mouse for. (required)
- trackMouse:inRect:ofView:untilMouseUp: (page 3852) *required method*
  Handles a mouse-down event on the receiver's image. (required)
- trackMouse:inRect:ofView:atCharacterIndex:untilMouseUp: (page 3851) *required method*
  Handles a mouse-down event on the receiver's image. (required)

Setting the Attachment

- setAttachment: (page 3851) *required method*
  Sets the text attachment object that owns the receiver to *anAttachment*, without retaining it (the text attachment, as the owner, retains the cell). (required)
- attachment (page 3848) *required method*
  Returns the text attachment object that owns the receiver. (required)

Instance Methods

attachment

Returns the text attachment object that owns the receiver. (required)

```
- (NSTextAttachment *)attachment
```

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setAttachment:` (page 3851)

Related Sample Code
Quartz Composer WWDC 2005 TextEdit

Declared In
`NSTextAttachment.h`

cellBaselineOffset

Returns the position where the attachment cell's image should be drawn in text, relative to the current point established in the glyph layout. (required)

```
- (NSPoint)cellBaselineOffset
```

Discussion
The image should be drawn so its lower-left corner lies on this point.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `icon` (NSFileWrapper)

Declared In
`NSTextAttachment.h`

cellFrameForTextContainer:proposedLineFragment:glyphPosition:characterIndex:

Returns the frame of the cell as it would be drawn as the character at the given glyph *position*, and character index, *charIndex*, in *textContainer*. (required)

```
- (NSRect)cellFrameForTextContainer:(NSTextContainer *)textContainer
    proposedLineFragment:(NSRect)lineFrag glyphPosition:(NSPoint)position
    characterIndex:(NSUInteger)charIndex
```

Discussion
The proposed line fragment is specified by *lineFrag*.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSTextAttachment.h`

cellSize

Returns the size of the attachment's icon. (required)

```
- (NSSize)cellSize
```

Availability
Available in Mac OS X v10.0 and later.

See Also
- `icon` (NSFileWrapper)
- `fileWrapper` (page 2757) (NSTextAttachment)

Declared In
`NSTextAttachment.h`

drawWithFrame:inView:

Draws the receiver's image within *cellFrame* in *aView*, which is the view currently focused. (required)

```
- (void)drawWithFrame:(NSRect)cellFrame inView:(NSView *)aView
```

Availability
Available in Mac OS X v10.0 and later.

See Also
- `drawWithFrame:inView:` (page 554) (NSCell)
- `lockFocus` (page 3187) (NSView)

Declared In
`NSTextAttachment.h`

drawWithFrame:inView:characterIndex:

Draws the receiver's image within *cellFrame* in *aView*, which is the view currently focused. *charIndex* is the index of the attachment character within the text. (required)

```
- (void)drawWithFrame:(NSRect)cellFrame inView:(NSView *)aView
    characterIndex:(NSUInteger)charIndex
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSTextAttachment.h`

drawWithFrame:inView:characterIndex:layoutManager:

Draws the receiver's image within *cellFrame* in *controlView*, which is the view currently focused. *charIndex* is the index of the attachment character within the text. *layoutManager* is the layout manager for the text. (required)

```
- (void)drawWithFrame:(NSRect)cellFrame inView:(NSView *)controlView
    characterIndex:(NSUInteger)charIndex layoutManager:(NSLayoutManager
    *)layoutManager
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSTextAttachment.h

highlight:withFrame:inView:

Draws the receiver's image—with highlighting if *flag* is YES—within *cellFrame* in *aView*, which should be the focus view. (required)

```
- (void)highlight:(BOOL)flag withFrame:(NSRect)cellFrame inView:(NSView *)aView
```

Availability
Available in Mac OS X v10.0 and later.

See Also
- highlight:withFrame:inView: (page 560) (NSCell)
- lockFocus (page 3187) (NSView)

Declared In
NSTextAttachment.h

setAttachment:

Sets the text attachment object that owns the receiver to *anAttachment*, without retaining it (the text attachment, as the owner, retains the cell). (required)

```
- (void)setAttachment:(NSTextAttachment *)anAttachment
```

Availability
Available in Mac OS X v10.0 and later.

See Also
- attachment (page 3848)
- setAttachmentCell: (page 2758) (NSTextAttachment)

Declared In
NSTextAttachment.h

trackMouse:inRect:ofView:atCharacterIndex:untilMouseUp:

Handles a mouse-down event on the receiver's image. (required)

```
- (BOOL)trackMouse:(NSEvent *)theEvent inRect:(NSRect)cellFrame ofView:(NSView
    *)aTextView atCharacterIndex:(NSUInteger)charIndex untilMouseUp:(BOOL)flag
```

Discussion
theEvent is the mouse-down event. *cellFrame* is the region of *aTextView* in which you should track further mouse events. *charIndex* is the position in the text at which this attachment appears. *aTextView* is the view that received the event. It's assumed to be an NSTextView, and should be the focus view. If *flag*

is YES, the receiver tracks the mouse until a mouse-up event occurs; if *flag* is NO, it stops tracking when a mouse-dragged event occurs outside of *cellFrame*. Returns YES if the receiver successfully finished tracking the mouse (typically through a mouse-up event), NO otherwise (such as when the mouse is dragged outside *cellFrame*).

NSTextAttachmentCell's implementation of this method calls upon *aTextView*'s delegate to handle the event. If *theEvent* is a mouse-up event for a double click, the text attachment cell sends the delegate a textView:doubleClickedOnCell:inRect: message and returns YES. Otherwise, depending on whether the user clicks or drags the cell, it sends the delegate a textView:clickedOnCell:inRect: or a textView:draggedCell:inRect:event: message and returns YES. NSTextAttachmentCell's implementation returns NO only if *flag* is NO and the mouse is dragged outside of *cellFrame*. The delegate methods are invoked only if the delegate responds.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSTextAttachment.h

trackMouse:inRect:ofView:untilMouseUp:

Handles a mouse-down event on the receiver's image. (required)

```
- (BOOL)trackMouse:(NSEvent *)theEvent inRect:(NSRect)cellFrame ofView:(NSView
    *)aTextView untilMouseUp:(BOOL)flag
```

Discussion
theEvent is the mouse-down event. *cellFrame* is the region of *aTextView* in which further mouse events should be tracked. *aTextView* is the view that received the event. It's assumed to be an NSTextView and should be the focus view. If *flag* is YES, the receiver tracks the mouse until a mouse-up event occurs; if *flag* is NO, it stops tracking when a mouse-dragged event occurs outside of *cellFrame*. Returns YES if the receiver successfully finished tracking the mouse (typically through a mouse-up event), NO otherwise (such as when the cursor is dragged outside *cellFrame*).

NSTextAttachmentCell's implementation of this method calls upon the delegate of *aTextView* to handle the event. If *theEvent* is a mouse-up event for a double click, the text attachment cell sends the delegate a textView:doubleClickedOnCell:inRect: message and returns YES. Otherwise, depending on whether the user clicks or drags the cell, it sends the delegate a textView:clickedOnCell:inRect: or a textView:draggedCell:inRect:event: message and returns YES. NSTextAttachmentCell's implementation returns NO only if *flag* is NO and the cursor is dragged outside of *cellFrame*. The delegate methods are invoked only if the delegate responds.

Availability
Available in Mac OS X v10.0 and later.

See Also
- wantsToTrackMouse (page 3853)
- trackMouse:inRect:ofView:untilMouseUp: (page 610) (NSCell)
- lockFocus (page 3187) (NSView)

Declared In
NSTextAttachment.h

wantsToTrackMouse

Returns `YES` if the receiver will handle a mouse event occurring over its image (to support dragging, for example), `NO` otherwise. (required)

```
- (BOOL)wantsToTrackMouse
```

Discussion
NSTextAttachmentCell's implementation of this method returns `YES`. The NSView containing the cell should invoke this method before sending a `trackMouse:inRect:ofView:untilMouseUp:` (page 3852) message.

For an attachment in an attributed string, if the attachment cell returns `NO` its attachment character should be selected rather than the cell being asked to track the mouse. This results in the attachment icon behaving as any regular glyph in text.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSTextAttachment.h`

wantsToTrackMouseForEvent:inRect:ofView:atCharacterIndex:

Allows an attachment to specify what events it would want to track the mouse for. (required)

```
- (BOOL)wantsToTrackMouseForEvent:(NSEvent *)theEvent inRect:(NSRect)cellFrame
    ofView:(NSView *)controlView atCharacterIndex:(NSUInteger)charIndex
```

Discussion
`theEvent` is the event in question that occurred in *`cellFrame`* inside *`controlView`*. *`charIndex`* is the index of the attachment character within the text. If `wantsToTrackMouse` (page 3853) returns `YES`, this method allows the attachment to decide whether it wishes to do so for particular events.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSTextAttachment.h`

Declared in	AppKit/NSText.h
Companion guide	Text System Overview

Overview

The `NSTextDelegate` protocol defines the optional methods implemented by delegates of `NSText` objects.

Tasks

Changing Text Formatting

- `textDidChange:` (page 3856)
  Informs the delegate that the text object has changed its characters or formatting attributes.

Editing Text

- `textShouldBeginEditing:` (page 3857)
  Invoked when a text object begins to change its text, this method requests permission for *`aTextObject`* to begin editing.
- `textDidBeginEditing:` (page 3856)
  Informs the delegate that the text object has begun editing (that the user has begun changing it).
- `textShouldEndEditing:` (page 3857)
  Invoked from a text object's implementation of `resignFirstResponder` (page 2189), this method requests permission for *`aTextObject`* to end editing.
- `textDidEndEditing:` (page 3856)
  Informs the delegate that the text object has finished editing (that it has resigned first responder status).

Instance Methods

textDidBeginEditing:

Informs the delegate that the text object has begun editing (that the user has begun changing it).

```
- (void)textDidBeginEditing:(NSNotification *)aNotification
```

Discussion
The name of *aNotification* is NSTextDidBeginEditingNotification (page 2752).

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSText.h

textDidChange:

Informs the delegate that the text object has changed its characters or formatting attributes.

```
- (void)textDidChange:(NSNotification *)aNotification
```

Discussion
The name of *aNotification* is NSTextDidChangeNotification (page 2752).

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSText.h

textDidEndEditing:

Informs the delegate that the text object has finished editing (that it has resigned first responder status).

```
- (void)textDidEndEditing:(NSNotification *)aNotification
```

Discussion
The name of *aNotification* is NSTextDidEndEditingNotification (page 2752).

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSText.h

textShouldBeginEditing:

Invoked when a text object begins to change its text, this method requests permission for *aTextObject* to begin editing.

```
- (BOOL)textShouldBeginEditing:(NSText *)aTextObject
```

Discussion
If the delegate returns YES, the text object proceeds to make changes. If the delegate returns NO, the text object abandons the editing operation. This method is also invoked when the user drags and drops a file onto the text object.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
- makeFirstResponder: (page 3344) (NSWindow)
- becomeFirstResponder (page 2144) (NSResponder)

Declared In
NSText.h

textShouldEndEditing:

Invoked from a text object's implementation of resignFirstResponder (page 2189), this method requests permission for *aTextObject* to end editing.

```
- (BOOL)textShouldEndEditing:(NSText *)aTextObject
```

Discussion
If the delegate returns YES, the text object proceeds to finish editing and resign first responder status. If the delegate returns NO, the text object selects all of its text and remains the first responder.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
- resignFirstResponder (page 2189) (NSResponder)

Availability	Available in Mac OS X v10.6 and later.
Declared in	AppKit/NSTextField.h
Companion guide	Text Fields

Overview

The `NSTextFieldDelegate` protocol adopts the `NSControlTextEditingDelegate` protocol and currently does not extend it further.

NSTextInput Protocol Reference

Adopted by	NSInputManager
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.0 and later.
Declared in	AppKit/NSInputManager.h
Companion guides	Text System Overview Text Input Management

Overview

The `NSTextInput` protocol defines the methods that Cocoa text views must implement in order to interact properly with the text input management system.

Important: `NSTextInput` protocol is slated for deprecation. Please use `NSTextInputClient` protocol, introduced in Mac OS X v10.5, as described in *NSTextInputClient Protocol Reference*.

`NSTextView` and its abstract superclass `NSText` are the only classes included in Cocoa that implement `NSTextInput`. To create another text view class, you can either subclass `NSTextView` (and not `NSText`, for historical reasons), or subclass `NSView` and implement the `NSTextInput` protocol.

Important: Methods specific to the `NSTextInput` protocol are intended for dealing with text input and generally are not suitable for other purposes.

Tasks

Marked Text

- `hasMarkedText` (page 3865) *required method*
  Returns a Boolean value indicating whether or not the receiver has marked text. (required)
- `markedRange` (page 3865) *required method*
  Returns the range of the marked text. (required)

- `selectedRange` (page 3866) *required method*
  Returns the range of selected text. (required)
- `setMarkedText:selectedRange:` (page 3866) *required method*
  Replaces currently marked text in the receiver's text storage with the given string and sets the selection to the given range, computed from the beginning of the marked text. (required)
- `unmarkText` (page 3867) *required method*
  Removes any marking from pending input text and disposes of the marked text as it wishes. The text view should accept the marked text as if it had been inserted normally. (required)
- `validAttributesForMarkedText` (page 3867) *required method*
  Returns an array of names for the attributes supported by the receiver. (required)

Text Storage

- `attributedSubstringFromRange:` (page 3862) *required method*
  Returns an attributed string derived from the given range in the receiver's text storage. (required)
- `insertText:` (page 3865) *required method*
  Inserts the given string into the receiver's text storage. (required)

Character Coordinates

- `characterIndexForPoint:` (page 3863) *required method*
  Returns the index of the character whose frame rectangle includes the given point. (required)
- `firstRectForCharacterRange:` (page 3864) *required method*
  Returns the first frame rectangle for characters in the given range, in screen coordinates. (required)

Key Bindings

- `doCommandBySelector:` (page 3864) *required method*
  Invokes the given selector if possible. (required)

Other

- `conversationIdentifier` (page 3863) *required method*
  Returns a number used to identify the receiver's context to the input server. (required)

Instance Methods

attributedSubstringFromRange:

Returns an attributed string derived from the given range in the receiver's text storage. (required)

```
- (NSAttributedString *)attributedSubstringFromRange:(NSRange)theRange
```

Parameters

theRange

The range in the text storage from which to create the returned string.

Return Value

The string created from the given range.

Discussion

This method allows input mangers to query any range in text storage.

An implementation of this method should be prepared for *theRange* to be out-of-bounds. For example, the InkWell text input service can ask for the contents of the text input client that extends beyond the document's range. In this case, you should return the intersection of the document's range and *theRange*. If the location of *theRange* is completely outside of the document's range, return `nil`.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSInputManager.h`

characterIndexForPoint:

Returns the index of the character whose frame rectangle includes the given point. (required)

```
- (NSUInteger)characterIndexForPoint:(NSPoint)thePoint
```

Parameters

thePoint

A point, in screen coordinates.

Return Value

The character index, measured from the start of the receiver's text storage, of the character containing the given point. Returns `NSNotFound` if the cursor is not within a character.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSInputManager.h`

conversationIdentifier

Returns a number used to identify the receiver's context to the input server. (required)

```
- (NSInteger)conversationIdentifier
```

Return Value

The identifying number of the receiver.

Discussion

Each text view within an application should return a unique identifier (typically its address). However, multiple text views sharing the same text storage must all return the same identifier.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSInputManager.h`

doCommandBySelector:

Invokes the given selector if possible. (required)

```
- (void)doCommandBySelector:(SEL)aSelector
```

Parameters

aSelector
The selector to be invoked.

Discussion
If *aSelector* cannot be invoked, then `doCommandBySelector:` should not pass this message up the responder chain. `NSResponder` also implements this method, and it does forward uninvokable commands up the responder chain, but a text view should not. A text view implementing the NSTextInput protocol inherits from `NSView`, which inherits from `NSResponder`, so your implementation of this method will override the one in `NSResponder`. It should not call `super`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `interpretKeyEvents:` (page 2158) (NSResponder)
- `doCommandBySelector:` (page 2152) (NSResponder)

Declared In
`NSInputManager.h`

firstRectForCharacterRange:

Returns the first frame rectangle for characters in the given range, in screen coordinates. (required)

```
- (NSRect)firstRectForCharacterRange:(NSRange)theRange
```

Parameters

theRange
The character range whose frame is returned.

Return Value
The frame rectangle for the given range of characters.

Discussion
If *theRange* spans multiple lines of text in the text view, the rectangle returned is the one for the characters in the first line. If the length of *theRange* is 0 (as it would be if there is nothing selected at the insertion point), the rectangle coincides with the insertion point, and its width is 0.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSInputManager.h

hasMarkedText

Returns a Boolean value indicating whether or not the receiver has marked text. (required)

```
- (BOOL)hasMarkedText
```

Return Value
YES if the receiver has marked text, NO if it doesn't.

Discussion
Unlike other methods in this protocol, this one is not called by an input server. The text view itself may call this method to determine whether there currently is marked text. NSTextView, for example, disables the Edit > Copy menu item when this method returns YES.

Availability
Available in Mac OS X v10.0 and later.

See Also
- markedRange (page 3865)

Declared In
NSInputManager.h

insertText:

Inserts the given string into the receiver's text storage. (required)

```
- (void)insertText:(id)aString
```

Parameters
aString
Either an NSString or an NSAttributedString object.

Discussion
This method is the entry point for inserting text typed by the user and is generally not suitable for other purposes. Programmatic modification of the text is best done by operating on the text storage directly. Because this method pertains to the actions of the user, the text view must be editable for the insertion to work.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSInputManager.h

markedRange

Returns the range of the marked text. (required)

```
- (NSRange)markedRange
```

Return Value
The range of marked text.

Discussion
The returned range measures from the start of the receiver's text storage. The return value's `location` is `NSNotFound`, and its `length` is 0 if and only if `hasMarkedText` (page 3865) returns `NO`.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setMarkedText:selectedRange:` (page 3866)
- `unmarkText` (page 3867)
- `hasMarkedText` (page 3865)

Declared In
`NSInputManager.h`

selectedRange

Returns the range of selected text. (required)

```
- (NSRange)selectedRange
```

Return Value
The range of selected text.

Discussion
The returned range measures from the start of the receiver's text storage. If there is no selection, the return value's `location` is `NSNotFound`, and its `length` is 0.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `setMarkedText:selectedRange:` (page 3866)

Declared In
`NSInputManager.h`

setMarkedText:selectedRange:

Replaces currently marked text in the receiver's text storage with the given string and sets the selection to the given range, computed from the beginning of the marked text. (required)

```
- (void)setMarkedText:(id)aString selectedRange:(NSRange)selRange
```

Parameters
aString
Either an `NSString` or an `NSAttributedString` object; must not be `nil`.

selRange
The range within *aString* to set as the selection.

Discussion
If there is no marked text, the current selection is replaced. If there is no selection, the string is inserted at the insertion point.

Availability
Available in Mac OS X v10.0 and later.

See Also
- `selectedRange` (page 3866)
- `unmarkText` (page 3867)

Declared In
`NSInputManager.h`

unmarkText

Removes any marking from pending input text and disposes of the marked text as it wishes. The text view should accept the marked text as if it had been inserted normally. (required)

```
- (void)unmarkText
```

Availability
Available in Mac OS X v10.0 and later.

See Also
- `selectedRange` (page 3866)
- `setMarkedText:selectedRange:` (page 3866)

Declared In
`NSInputManager.h`

validAttributesForMarkedText

Returns an array of names for the attributes supported by the receiver. (required)

```
- (NSArray *)validAttributesForMarkedText
```

Return Value
An array of `NSString` objects representing names for the supported attributes.

Discussion
The input server may choose to use some of these attributes in the text it inserts or in marked text. Returns an empty array if no attributes are supported. See NSAttributedString Additions (page 249) for the set of string constants that you could return in the array.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSInputManager.h`

NSTextInputClient Protocol Reference

Adopted by	NSTextView
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.5 and later.
Declared in	AppKit/NSTextInputClient.h
Related sample code	TextInputView

Overview

The `NSTextInputClient` protocol defines the methods that Cocoa text views must implement in order to interact properly with the text input management system. To create another text view class, you can either subclass `NSTextView` (and not `NSText`, for historical reasons), or subclass `NSView` and implement the `NSTextInputClient` protocol

Important: Methods specific to the `NSTextInputClient` protocol are intended for dealing with text input and generally are not suitable for other purposes.

Tasks

Handling Marked Text

- `hasMarkedText` (page 3875) *required method*
  Returns a Boolean value indicating whether the receiver has marked text. (required)
- `markedRange` (page 3875) *required method*
  Returns the range of the marked text. (required)
- `selectedRange` (page 3876) *required method*
  Returns the range of selected text. (required)
- `setMarkedText:selectedRange:replacementRange:` (page 3876) *required method*
  Replaces a specified range in the receiver's text storage with the given string and sets the selection. (required)
- `unmarkText` (page 3877) *required method*
  Unmarks the marked text. (required)

- `validAttributesForMarkedText` (page 3878) *required method* Available in Mac OS X v10.0 through Mac OS X v10.1
  Returns an array of attribute names recognized by the receiver. (required)

Storing Text

- `attributedSubstringForProposedRange:actualRange:` (page 3871) *required method*
  Returns an attributed string derived from the given range in the receiver's text storage. (required)
- `insertText:replacementRange:` (page 3875) *required method*
  Inserts the given string into the receiver, replacing the specified content. (required)

Getting Character Coordinates

- `characterIndexForPoint:` (page 3872) *required method*
  Returns the index of the character whose bounding rectangle includes the given point. (required)
- `firstRectForCharacterRange:actualRange:` (page 3873) *required method*
  Returns the first logical boundary rectangle for characters in the given range. (required)

Binding Keystrokes

- `doCommandBySelector:` (page 3872) *required method*
  Invokes the action specified by the given selector. (required)

Optional Methods

- `attributedString` (page 3871)
  Returns an attributed string representing the receiver's text storage.
- `fractionOfDistanceThroughGlyphForPoint:` (page 3874)
  Returns the fraction of the distance from the left side of the character to the right side that a given point lies.
- `baselineDeltaForCharacterAtIndex:` (page 3872)
  Returns the baseline position of a given character relative to the origin of rectangle returned by `firstRectForCharacterRange:actualRange:` (page 3873).
- `windowLevel` (page 3878)
  Returns the window level of the receiver.
- `drawsVerticallyForCharacterAtIndex:` (page 3873) *required method*
  Informs the text input management system whether the protocol-conforming client renders the character at the given index vertically. (required)

Instance Methods

attributedString

Returns an attributed string representing the receiver's text storage.

```
- (NSAttributedString *)attributedString
```

Return Value
The attributed string of the receiver's text storage.

Discussion
Implementation of this method is optional. A class adopting the `NSTextInputClient` protocol can implement this interface if it can be done efficiently to enable callers of this interface to access arbitrary portions of the receiver's content more efficiently.

Availability
Available in Mac OS X v10.5 and later.

Related Sample Code
TextInputView

Declared In
`NSTextInputClient.h`

attributedSubstringForProposedRange:actualRange:

Returns an attributed string derived from the given range in the receiver's text storage. (required)

```
- (NSAttributedString *)attributedSubstringForProposedRange:(NSRange)aRange
    actualRange:(NSRangePointer)actualRange
```

Parameters

aRange
The range in the text storage from which to create the returned string.

actualRange
The actual range of the returned string if it was adjusted, for example, to a grapheme cluster boundary or for performance or other reasons. `NULL` if range was not adjusted.

Return Value
The string created from the given range. May return `nil`.

Discussion
An implementation of this method should be prepared for *aRange* to be out of bounds. For example, the InkWell text input service can ask for the contents of the text input client that extends beyond the document's range. In this case, you should return the intersection of the document's range and *aRange*. If the location of *aRange* is completely outside of the document's range, return `nil`.

Availability
Available in Mac OS X v10.5 and later.

Declared In
NSTextInputClient.h

baselineDeltaForCharacterAtIndex:

Returns the baseline position of a given character relative to the origin of rectangle returned by `firstRectForCharacterRange:actualRange:` (page 3873).

```
- (CGFloat)baselineDeltaForCharacterAtIndex:(NSUInteger)anIndex
```

Parameters

anIndex

Index of the character whose baseline is tested.

Return Value
The vertical distance, in points, between the baseline of the character at *anIndex* and the rectangle origin.

Discussion
Implementation of this method is optional. This information allows the caller to determine finer-grained character positioning within the text storage of the text view adopting `NSTextInputClient`.

Availability
Available in Mac OS X v10.5 and later.

Declared In
NSTextInputClient.h

characterIndexForPoint:

Returns the index of the character whose bounding rectangle includes the given point. (required)

```
- (NSUInteger)characterIndexForPoint:(NSPoint)aPoint
```

Parameters

aPoint

The point to test, in screen coordinates.

Return Value
The character index, measured from the start of the receiver's text storage, of the character containing the given point. Returns `NSNotFound` if the cursor is not within a character's bounding rectangle.

Availability
Available in Mac OS X v10.5 and later.

Declared In
NSTextInputClient.h

doCommandBySelector:

Invokes the action specified by the given selector. (required)

```
- (void)doCommandBySelector:(SEL)aSelector
```

Parameters

aSelector

The selector to invoke.

Discussion

If *aSelector* cannot be invoked, then `doCommandBySelector:` should not pass this message up the responder chain. `NSResponder` also implements this method, and it does forward uninvokable commands up the responder chain, but a text view should not. A text view implementing the `NSTextInputClient` protocol inherits from `NSView`, which inherits from `NSResponder`, so your implementation of this method will override the one in `NSResponder`. It should not call `super`.

Availability

Available in Mac OS X v10.5 and later.

See Also

- `interpretKeyEvents:` (page 2158) (NSResponder)
- `doCommandBySelector:` (page 2152) (NSResponder)

Declared In

`NSTextInputClient.h`

drawsVerticallyForCharacterAtIndex:

Informs the text input management system whether the protocol-conforming client renders the character at the given index vertically. (required)

```
- (BOOL)drawsVerticallyForCharacterAtIndex:(NSUInteger)charIndex
```

Parameters

charIndex

The index of the character to test.

Return Value

`YES` if the character is rendered vertically; otherwise `NO`.

Availability

Available in Mac OS X v10.6 and later.

Declared In

`NSTextInputClient.h`

firstRectForCharacterRange:actualRange:

Returns the first logical boundary rectangle for characters in the given range. (required)

```
- (NSRect)firstRectForCharacterRange:(NSRange)aRange
    actualRange:(NSRangePointer)actualRange
```

Parameters

aRange

The character range whose boundary rectangle is returned.

actualRange

If non-NULL, contains the character range corresponding to the returned area if it was adjusted, for example, to a grapheme cluster boundary or characters in the first line fragment.

Return Value
The boundary rectangle for the given range of characters, in screen coordinates. The rectangle's size value can be negative if the text flows to the left.

Discussion
If *aRange* spans multiple lines of text in the text view, the rectangle returned is the one surrounding the characters in the first line. In that case *actualRange* contains the range covered by the first rect, so you can query all line fragments by invoking this method repeatedly. If the length of *aRange* is 0 (as it would be if there is nothing selected at the insertion point), the rectangle coincides with the insertion point, and its width is 0.

Availability
Available in Mac OS X v10.5 and later.

Declared In
NSTextInputClient.h

fractionOfDistanceThroughGlyphForPoint:

Returns the fraction of the distance from the left side of the character to the right side that a given point lies.

```
- (CGFloat)fractionOfDistanceThroughGlyphForPoint:(NSPoint)aPoint
```

Parameters
aPoint

The point to test.

Return Value
The fraction of the distance *aPoint* is through the glyph in which it lies. May be 0 or 1 if *aPoint* is not within the bounding rectangle of a glyph (0 if the point is to the left or above the glyph; 1 if it's to the right or below).

Discussion
Implementation of this method is optional. This allows caller to perform precise selection handling.

For purposes such as dragging out a selection or placing the insertion point, a partial percentage less than or equal to 0.5 indicates that *aPoint* should be considered as falling before the glyph; a partial percentage greater than 0.5 indicates that it should be considered as falling after the glyph. If the nearest glyph doesn't lie under *aPoint* at all (for example, if *aPoint* is beyond the beginning or end of a line), this ratio is 0 or 1.

For example, if the glyph stream contains the glyphs "A" and "b", with the width of "A" being 13 points, and *aPoint* is 8 points from the left side of "A", then the fraction of the distance is 8/13, or 0.615. In this case, the *aPoint* should be considered as falling between "A" and "b" for purposes such as dragging out a selection or placing the insertion point.

Availability
Available in Mac OS X v10.5 and later.

Declared In
NSTextInputClient.h

hasMarkedText

Returns a Boolean value indicating whether the receiver has marked text. (required)

```
- (BOOL)hasMarkedText
```

Return Value
`YES` if the receiver has marked text; otherwise `NO`.

Discussion
The text view itself may call this method to determine whether there currently is marked text. `NSTextView`, for example, disables the Edit > Copy menu item when this method returns `YES`.

Availability
Available in Mac OS X v10.5 and later.

See Also
- `markedRange` (page 3875)

Related Sample Code
TextInputView

Declared In
`NSTextInputClient.h`

insertText:replacementRange:

Inserts the given string into the receiver, replacing the specified content. (required)

```
- (void)insertText:(id)aString replacementRange:(NSRange)replacementRange
```

Parameters
`aString`
The text to insert, either an `NSString` or `NSAttributedString` instance.

`replacementRange`
The range of content to replace in the receiver's text storage.

Discussion
This method is the entry point for inserting text typed by the user and is generally not suitable for other purposes. Programmatic modification of the text is best done by operating on the text storage directly. Because this method pertains to the actions of the user, the text view must be editable for the insertion to work.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSTextInputClient.h`

markedRange

Returns the range of the marked text. (required)

```
- (NSRange)markedRange
```

Return Value
The range of marked text or `{NSNotFound, 0}` if there is no marked range.

Discussion
The returned range measures from the start of the receiver's text storage. The return value's `location` is `NSNotFound` and its `length` is 0 if and only if `hasMarkedText` (page 3875) returns `NO`.

Availability
Available in Mac OS X v10.5 and later.

TextInputView

Declared In
`NSTextInputClient.h`

selectedRange

Returns the range of selected text. (required)

```
- (NSRange)selectedRange
```

Return Value
The range of selected text or `{NSNotFound, 0}` if there is no selection.

Discussion
The returned range measures from the start of the receiver's text storage, that is, from 0 to the document length.

Availability
Available in Mac OS X v10.5 and later.

See Also
- `setMarkedText:selectedRange:replacementRange:` (page 3876)

Related Sample Code
TextInputView

Declared In
`NSTextInputClient.h`

setMarkedText:selectedRange:replacementRange:

Replaces a specified range in the receiver's text storage with the given string and sets the selection. (required)

```
- (void)setMarkedText:(id)aString selectedRange:(NSRange)selectedRange
    replacementRange:(NSRange)replacementRange
```

Parameters

aString

The string to insert. Can be either an `NSString` or `NSAttributedString` instance.

selectedRange

The range to set as the selection, computed from the beginning of the inserted string.

replacementRange

The range to replace, computed from the beginning of the marked text.

Discussion

If there is no marked text, the current selection is replaced. If there is no selection, the string is inserted at the insertion point.

When *aString* is an `NSString` object, the receiver is expected to render the marked text with distinguishing appearance (for example, `NSTextView` renders with `markedTextAttributes` (page 2906)).

Availability

Available in Mac OS X v10.5 and later.

See Also

- `selectedRange` (page 3876)
- `unmarkText` (page 3877)

Declared In

`NSTextInputClient.h`

unmarkText

Unmarks the marked text. (required)

```
- (void)unmarkText
```

Discussion

The receiver removes any marking from pending input text and disposes of the marked text as it wishes. The text view should accept the marked text as if it had been inserted normally. If there is no marked text, the invocation of this method has no effect.

Availability

Available in Mac OS X v10.5 and later.

See Also

- `selectedRange` (page 3876)
- `setMarkedText:selectedRange:replacementRange:` (page 3876)

Related Sample Code

TextInputView

Declared In

`NSTextInputClient.h`

validAttributesForMarkedText

Returns an array of attribute names recognized by the receiver. (required)

```
- (NSArray *)validAttributesForMarkedText
```

Return Value
An array of `NSString` objects representing names for the supported attributes.

Discussion
Returns an empty array if no attributes are supported. See *NSAttributedString Application Kit Additions Reference* for the set of string constants representing standard attributes.

Availability
Available in Mac OS X v10.5 and later.

Related Sample Code
TextInputView

Declared In
`NSTextInputClient.h`

windowLevel

Returns the window level of the receiver.

```
- (NSInteger)windowLevel
```

Return Value
The window level of the receiver.

Discussion
Implementation of this method is optional. A class adopting `NSTextInputClient` can implement this interface to specify its window level if it is higher than `NSFloatingWindowLevel`.

Availability
Available in Mac OS X v10.5 and later.

`NSTextInputClient.h`

NSTextViewDelegate Protocol Reference

Conforms to	NSTextDelegate
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.6 and later.
Declared in	AppKit/NSTextView.h
Companion guides	Text System Overview Text System User Interface Layer Programming Guide
Related sample code	FunHouse TextSizingExample

Overview

The `NSTextViewDelegate` protocol defines the optional methods implemented by delegates of `NSTextView` objects.

Tasks

Accessing Text System Objects

`- undoManagerForTextView:` (page 3896)
Returns the undo manager for the specified text view.

Controlling Display

`- textView:willDisplayToolTip:forCharacterAtIndex:` (page 3893)
Returns the actual tooltip to display.

Managing the Selection

`- textView:willChangeSelectionFromCharacterRange:toCharacterRange:` (page 3891)
Returns the actual range to select.

- `textView:willChangeSelectionFromCharacterRanges:toCharacterRanges:` (page 3892)
  Returns the actual character ranges to select.
- `textViewDidChangeSelection:` (page 3895)
  Sent when the selection changes in the text view.

Managing the Pasteboard

- `textView:writablePasteboardTypesForCell:atIndex:` (page 3894)
  Returns the writable pasteboard types for a given cell.
- `textView:writeCell:atIndex:toPasteboard:type:` (page 3895)
  Returns whether data of the specified type for the given cell could be written to the specified pasteboard.

Setting Text Attributes

- `textView:shouldChangeTextInRange:replacementString:` (page 3889)
  Sent when a text view needs to determine if text in a specified range should be changed.
- `textView:shouldChangeTextInRanges:replacementStrings:` (page 3889)
  Sent when a text view needs to determine if text in an array of specified ranges should be changed.
- `textView:shouldChangeTypingAttributes:toAttributes:` (page 3890)
  Sent when the typing attributes are changed.
- `textViewDidChangeTypingAttributes:` (page 3896)
  Sent when a text view's typing attributes change.

Clicking and Pasting

- `textView:clickedOnCell:inRect:atIndex:` (page 3882)
  Sent when the user clicks a cell.
- `textView:doubleClickedOnCell:inRect:atIndex:` (page 3886)
  Sent when the user double-clicks a cell.
- `textView:clickedOnLink:atIndex:` (page 3883)
  Sent after the user clicks a link.

Working With the Spelling Checker

- `textView:shouldSetSpellingState:range:` (page 3890)
  Sent when the spelling state is changed.
- `textView:willCheckTextInRange:options:types:` (page 3893)
  Invoked to allow the delegate to modify the text checking process before it occurs.
- `textView:didCheckTextInRange:types:options:results:orthography:wordCount:` (page 3884)
  Invoked to allow the delegate to modify the text checking results after checking has occurred.

Dragging

- `textView:draggedCell:inRect:event:atIndex:` (page 3888)
  Sent when the user attempts to drag a cell.

Text Completion

- `textView:completions:forPartialWordRange:indexOfSelectedItem:` (page 3884)
  Returns the actual completions for a partial word.

Performing Commands

- `textView:doCommandBySelector:` (page 3885)
  Sent to allow the delegate to perform the command for the text view.

Contextual Menu Management

- `textView:menu:forEvent:atIndex:` (page 3888)
  Allows delegate to control the context menu returned by the text view.

Deprecated Methods

- `textView:clickedOnLink:` (page 3883)
  Sent after the user clicks on a link. (Deprecated. Use `textView:clickedOnLink:atIndex:` instead.)
- `textView:draggedCell:inRect:event:` (page 3887)
  Sent when the user attempts to drag a cell. (Deprecated. Use `textView:draggedCell:inRect:event:atIndex:` instead.)
- `textView:clickedOnCell:inRect:` (page 3881)
  Sent when the user clicks a cell. (Deprecated. Use `textView:clickedOnCell:inRect:atIndex:` instead.)
- `textView:doubleClickedOnCell:inRect:` (page 3886)
  Sent when the user double-clicks a cell. (Deprecated. Use `textView:doubleClickedOnCell:inRect:atIndex:` instead.)

Instance Methods

textView:clickedOnCell:inRect:

Sent when the user clicks a cell. (Deprecated. Use `textView:clickedOnCell:inRect:atIndex:` instead.)

```
- (void)textView:(NSTextView *)aTextView clickedOnCell:(id < NSTextAttachmentCell
    >)attachmentCell inRect:(NSRect)cellFrame
```

Parameters

aTextView
The text view sending the message.

attachmentCell
The cell clicked by the user.

cellFrame
The frame of the clicked cell.

Discussion
This message is only sent if `textView:clickedOnCell:inRect:atIndex:` is not implemented. Implement this method in order to track the mouse after a mouse click on a cell.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSTextView.h`

textView:clickedOnCell:inRect:atIndex:

Sent when the user clicks a cell.

```
- (void)textView:(NSTextView *)aTextView clickedOnCell:(id < NSTextAttachmentCell
    >)cell inRect:(NSRect)cellFrame atIndex:(NSUInteger)charIndex
```

Parameters

aTextView
The text view sending the message.

cell
The cell clicked by the user.

cellFrame
The frame of the clicked cell.

charIndex
The character index of the clicked cell.

Discussion
The delegate can use this message as its cue to perform an action or select the attachment cell's character. *aTextView* is the first text view in a series shared by a layout manager, not necessarily the one that draws *cell*.

The delegate may subsequently receive a `textView:doubleClickedOnCell:inRect:atIndex:` (page 3886) message if the user continues to perform a double click.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
- `textView:doubleClickedOnCell:inRect:atIndex:` (page 3886)

Declared In
NSTextView.h

textView:clickedOnLink:

Sent after the user clicks on a link. (Deprecated. Use `textView:clickedOnLink:atIndex:` instead.)

```
- (BOOL)textView:(NSTextView *)aTextView clickedOnLink:(id)link
```

Parameters

aTextView
The text view sending the message.

link
The link that was clicked.

Discussion
This message is only sent if `textView:clickedOnLink:atIndex:` is not implemented.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
- `clickedOnLink:atIndex:` (page 2887) (NSTextView)
- `textView:clickedOnLink:atIndex:` (page 3883)

Declared In
NSTextView.h

textView:clickedOnLink:atIndex:

Sent after the user clicks a link.

```
- (BOOL)textView:(NSTextView *)aTextView clickedOnLink:(id)link
    atIndex:(NSUInteger)charIndex
```

Parameters

aTextView
The text view sending the message.

link
The link that was clicked; the value of `NSLinkAttributeName` (page 272).

charIndex
The character index where the click occurred, indexed within the text storage.

Return Value
`YES` if the click was handled; otherwise, `NO` to allow the next responder to handle it.

Discussion
The delegate can use this method to handle the click on the link. It is invoked by `clickedOnLink:atIndex:` (page 2887).

The *charIndex* parameter is a character index somewhere in the range of the link attribute. If the user actually physically clicked the link, then it should be the character that was originally clicked. In some cases a link may be opened indirectly or programmatically, in which case a character index somewhere in the range of the link attribute is supplied.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
- clickedOnLink:atIndex: (page 2887) (NSTextView)

Declared In
NSTextView.h

textView:completions:forPartialWordRange:indexOfSelectedItem:

Returns the actual completions for a partial word.

```
- (NSArray *)textView:(NSTextView *)textView completions:(NSArray *)words
    forPartialWordRange:(NSRange)charRange indexOfSelectedItem:(NSInteger *)index
```

Parameters

textView
The text view sending the message.

words
The proposed array of completions.

charRange
The range of characters to be completed.

index
On return, the index of the initially selected completion. The default is 0, and –1 indicates no selection.

Return Value
The actual array of completions that will be presented for the partial word at the given range. Returning nil or a zero-length array suppresses completion.

Availability
Available in Mac OS X v10.3 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSTextView.h

textView:didCheckTextInRange:types:options:results:orthography:wordCount:

Invoked to allow the delegate to modify the text checking results after checking has occurred.

```
- (NSArray *)textView:(NSTextView *)view didCheckTextInRange:(NSRange)range
    types:(NSTextCheckingTypes)checkingTypes options:(NSDictionary *)options
    results:(NSArray *)results orthography:(NSOrthography *)orthography
    wordCount:(NSInteger)wordCount
```

Parameters

view
The text view sending the message.

range
The range that was checked.

checkingTypes
The type of checking that was performed. The possible constants are listed in `NSTextCheckingTypes` and can be combined using the C bit-wise `OR` operator to perform multiple checks at the same time.

options
A dictionary of values used during the checking process to perform. See `Spell Checking Option Dictionary Keys` (page 2537) for the supported values.

results
An array of `NSTextCheckingResult` instances.

orthography
The orthography of the text.

wordCount
The number of words checked.

Return Value
An array of `NSTextCheckingResult` instances. You can return the results array as is, or an altered array of `NSTextCheckingResult` objects.

Discussion
Invoked by `handleTextCheckingResults:forRange:types:options:orthography:wordCount:` (page 2894), this method allows observation of text checking, or modification of the results

Availability
Available in Mac OS X v10.6 and later.

Declared In
`NSTextView.h`

textView:doCommandBySelector:

Sent to allow the delegate to perform the command for the text view.

```
- (BOOL)textView:(NSTextView *)aTextView doCommandBySelector:(SEL)aSelector
```

Parameters

aTextView
The text view sending the message. This is the first text view in a series shared by a layout manager.

aSelector
The selector.

Return Value
`YES` indicates that the delegate handled the command and the text view will not attempt to perform it; `NO` indicates that the delegate did not handle the command the text view will attempt to perform it.

Discussion
This method is invoked by `NSTextView`'s `doCommandBySelector:` (page 2152) method.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSTextView.h

textView:doubleClickedOnCell:inRect:

Sent when the user double-clicks a cell. (Deprecated. Use `textView:doubleClickedOnCell:inRect:atIndex:` instead.)

```
- (void)textView:(NSTextView *)aTextView doubleClickedOnCell:(id <
    NSTextAttachmentCell >)attachmentCell inRect:(NSRect)cellFrame
```

Parameters

aTextView
The text view sending the message.

cell
The cell double-clicked by the user.

cellFrame
The frame of the double-clicked cell.

Discussion
This message is only sent if `textView:doubleClickedOnCell:inRect:atIndex:` (page 3886) is not implemented. Implement this method in order to track the mouse after a mouse double-click on a cell.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
- `textView:doubleClickedOnCell:inRect:atIndex:` (page 3886)

Declared In
NSTextView.h

textView:doubleClickedOnCell:inRect:atIndex:

Sent when the user double-clicks a cell.

```
- (void)textView:(NSTextView *)aTextView doubleClickedOnCell:(id <
    NSTextAttachmentCell >)cell inRect:(NSRect)cellFrame
    atIndex:(NSUInteger)charIndex
```

Parameters

aTextView
The text view sending the message.

cell
The cell double-clicked by the user.

cellFrame
The frame of the double-clicked cell.

charIndex
The character index of the double-clicked cell.

Discussion
The delegate can use this message as its cue to perform an action, such as opening the file represented by the attachment. *aTextView* is the first text view in a series shared by a layout manager, not necessarily the one that draws *cell*.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSTextView.h

textView:draggedCell:inRect:event:

Sent when the user attempts to drag a cell. (Deprecated. Use `textView:draggedCell:inRect:event:atIndex:` instead.)

```
- (void)textView:(NSTextView *)aTextView draggedCell:(id < NSTextAttachmentCell
    >)cell inRect:(NSRect)aRect event:(NSEvent *)theEvent
```

Parameters
aTextView
The text view sending the message.

cell
The cell being dragged.

aRect
The rectangle from which the cell was dragged.

theEvent
The mouse-down event that preceded the mouse-dragged event.

Discussion
This method has been deprecated in favor of `textView:draggedCell:inRect:event:atIndex:` (page 3888).

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
`- dragImage:at:offset:event:pasteboard:source:slideBack:` (page 3168) (NSView)
`- dragFile:fromRect:slideBack:event:` (page 3167) (NSView)

Declared In
NSTextView.h

textView:draggedCell:inRect:event:atIndex:

Sent when the user attempts to drag a cell.

```
- (void)textView:(NSTextView *)aTextView draggedCell:(id < NSTextAttachmentCell
    >)cell inRect:(NSRect)rect event:(NSEvent *)event atIndex:(NSUInteger)charIndex
```

Parameters

aTextView

The text view sending the message.

cell

The cell being dragged.

aRect

The rectangle from which the cell was dragged.

theEvent

The mouse-down event that preceded the mouse-dragged event.

charIndex

The character position where the mouse button was clicked.

Discussion

The delegate can use this message as its cue to initiate a dragging operation.

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

See Also

- dragImage:at:offset:event:pasteboard:source:slideBack: (page 3168) (NSView)
- dragFile:fromRect:slideBack:event: (page 3167) (NSView)

Declared In

NSTextView.h

textView:menu:forEvent:atIndex:

Allows delegate to control the context menu returned by the text view.

```
- (NSMenu *)textView:(NSTextView *)view menu:(NSMenu *)menu forEvent:(NSEvent
    *)event atIndex:(NSUInteger)charIndex
```

Parameters

view

The text view sending the message.

menu

The proposed contextual menu.

event

The mouse-down event that initiated the contextual menu's display.

charIndex

The character position where the mouse button was clicked.

Return Value
A menu to use as the contextual menu. You can return *menu* unaltered, or you can return a customized menu.

Discussion
This method allows the delegate to control the context menu returned by `menuForEvent:` (page 3189).

Availability
Available in Mac OS X v10.5 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSTextView.h`

textView:shouldChangeTextInRange:replacementString:

Sent when a text view needs to determine if text in a specified range should be changed.

```
- (BOOL)textView:(NSTextView *)aTextView
    shouldChangeTextInRange:(NSRange)affectedCharRange replacementString:(NSString
     *)replacementString
```

Parameters

aTextView
The text view sending the message. This is the first text view in a series shared by a layout manager, not necessarily the text view displaying the selected text.

affectedCharRange
The range of characters to be replaced.

replacementString
The characters that will replace the characters in *affectedCharRange*; `nil` if only text attributes are being changed.

Return Value
`YES` to allow the replacement, or `NO` to reject the change.

Discussion
If a delegate implements this method and not its multiple-selection replacement, `textView:shouldChangeTextInRanges:replacementStrings:` (page 3889), it is called with an appropriate range and string. If a delegate implements the new method, then this one is ignored.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSTextView.h`

textView:shouldChangeTextInRanges:replacementStrings:

Sent when a text view needs to determine if text in an array of specified ranges should be changed.

```
- (BOOL)textView:(NSTextView *)textView shouldChangeTextInRanges:(NSArray
    *)affectedRanges replacementStrings:(NSArray *)replacementStrings
```

Parameters

textView

The text view sending the message. This is the first text view in a series shared by a layout manager, not necessarily the text view displaying the selected text.

affectedRanges

The array of ranges of characters to be replaced. This array must be a non-nil, non-empty array of objects responding to the NSValue `rangeValue` method, and in addition its elements must be sorted, non-overlapping, non-contiguous, and (except for the case of a single range) have non-zero-length.

replacementStrings

The array of strings that will replace the characters in *affectedRanges*, one string for each range; `nil` if only text attributes are being changed.

Return Value

`YES` to allow the replacement, or `NO` to reject the change.

Availability

Available in Mac OS X v10.4 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

`NSTextView.h`

textView:shouldChangeTypingAttributes:toAttributes:

Sent when the typing attributes are changed.

```
- (NSDictionary *)textView:(NSTextView *)textView
    shouldChangeTypingAttributes:(NSDictionary *)oldTypingAttributes
    toAttributes:(NSDictionary *)newTypingAttributes
```

Parameters

textView

The text view sending the message.

oldTypingAttributes

The old typing attributes.

newTypingAttributes

The proposed typing attributes.

Return Value

The actual new typing attributes.

Availability

Available in Mac OS X v10.4 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

`NSTextView.h`

textView:shouldSetSpellingState:range:

Sent when the spelling state is changed.

```
- (NSInteger)textView:(NSTextView *)textView shouldSetSpellingState:(NSInteger)value
    range:(NSRange)affectedCharRange
```

Parameters

textView

The text view sending the message.

value

The proposed spelling state value to set. Possible values, for the temporary attribute on the layout manager using the key `NSSpellingStateAttributeName`, are:

`NSSpellingStateSpellingFlag` (page 287) to highlight spelling issues.

`NSSpellingStateGrammarFlag` (page 287) to highlight grammar issues.

affectedCharRange

The character range over which to set the given spelling state.

Return Value
The actual spelling state to set.

Discussion
Delegate only. Allows delegate to control the setting of spelling and grammar indicators.

Availability
Available in Mac OS X v10.5 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
`- setSpellingState:range:` (page 2945) (NSTextView)

Declared In
`NSTextView.h`

textView:willChangeSelectionFromCharacterRange:toCharacterRange:

Returns the actual range to select.

```
- (NSRange)textView:(NSTextView *)aTextView
    willChangeSelectionFromCharacterRange:(NSRange)oldSelectedCharRange
    toCharacterRange:(NSRange)newSelectedCharRange
```

Parameters

aTextView

The text view sending the message. This is the first text view in a series shared by a layout manager, not necessarily the text view displaying the selected text.

oldSelectedCharRange

The original range of the selection.

newSelectedCharRange

The proposed character range for the new selection.

Return Value
The actual character range for the new selection.

Discussion
This method is invoked before a text view finishes changing the selection—that is, when the last argument to a `setSelectedRange:affinity:stillSelecting:` (page 2941) message is `NO`.

Special Considerations

In Mac OS X version 10.4 and later, if a delegate implements this delegate method and not its multiple-selection replacement, `textView:willChangeSelectionFromCharacterRanges:toCharacterRanges:` (page 3892), then multiple selection is effectively disallowed; attempts to set the selected ranges call the old delegate method with the first subrange, and afterwards only a single selected range is set.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
`- textView:willChangeSelectionFromCharacterRanges:toCharacterRanges:` (page 3892)

Declared In
`NSTextView.h`

textView:willChangeSelectionFromCharacterRanges:toCharacterRanges:

Returns the actual character ranges to select.

```
- (NSArray *)textView:(NSTextView *)aTextView
    willChangeSelectionFromCharacterRanges:(NSArray *)oldSelectedCharRanges
    toCharacterRanges:(NSArray *)newSelectedCharRanges
```

Parameters

aTextView
The text view sending the message. This is the first text view in a series shared by a layout manager, not necessarily the text view displaying the selected text.

oldSelectedCharRanges
An array containing the original ranges of the selection. This must be a non-`nil`, non-empty array of objects responding to the NSValue `rangeValue` method, and in addition its elements must be sorted, non-overlapping, non-contiguous, and (except for the case of a single range) have non-zero-length.

newSelectedCharRanges
An array containing the proposed character ranges for the new selection. This must be a non-`nil`, non-empty array of objects responding to the NSValue `rangeValue` method, and in addition its elements must be sorted, non-overlapping, non-contiguous, and (except for the case of a single range) have non-zero-length.

Return Value
An array containing the actual character ranges for the new selection.

Discussion
Invoked before an NSTextView finishes changing the selection—that is, when the last argument to a `setSelectedRange:affinity:stillSelecting:` (page 2941) or `setSelectedRanges:affinity:stillSelecting:` (page 2943) message is `NO`.

If a delegate implements both this method and `textView:willChangeSelectionFromCharacterRange:toCharacterRange:` (page 3891), then the latter is ignored.

Availability
Available in Mac OS X v10.4 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSTextView.h

textView:willCheckTextInRange:options:types:

Invoked to allow the delegate to modify the text checking process before it occurs.

```
- (NSDictionary *)textView:(NSTextView *)view willCheckTextInRange:(NSRange)range
    options:(NSDictionary *)options types:(NSTextCheckingTypes *)checkingTypes
```

Parameters

view
The text view sending the message.

range
The range to be checked.

options
A dictionary of values used during the checking process to perform. See Spell Checking Option Dictionary Keys (page 2537) for the supported values.

checkingTypes
The type of checking to be performed, passed by-reference. The possible constants are listed in NSTextCheckingTypes and can be combined using the C bit-wise OR operator to perform multiple checks at the same time.

You can change this parameter to alter the types of checking to be performed.

Return Value
A dictionary containing an alternative to the options *dictionary*.

Discussion
Invoked by checkTextInRange:types:options: (page 2886), this method allows control over text checking *options*s (via the return value) or types (by modifying the flags pointed to by the inout parameter *checkingTypes*)

Availability
Available in Mac OS X v10.6 and later.

Declared In
NSTextView.h

textView:willDisplayToolTip:forCharacterAtIndex:

Returns the actual tooltip to display.

```
- (NSString *)textView:(NSTextView *)textView willDisplayToolTip:(NSString *)tooltip
    forCharacterAtIndex:(NSUInteger)characterIndex
```

Parameters

textView
The text view sending the message.

tooltip
The proposed tooltip to display.

characterIndex
The location in *textView*.

Return Value
The actual tooltip to display, or `nil` to suppress display of the tooltip.

Discussion
The tooltip string is the value of the `NSToolTipAttributeName` (page 274) attribute at *characterIndex*.

Availability
Available in Mac OS X v10.3 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSTextView.h`

textView:writablePasteboardTypesForCell:atIndex:

Returns the writable pasteboard types for a given cell.

```
- (NSArray *)textView:(NSTextView *)aTextView writablePasteboardTypesForCell:(id
    < NSTextAttachmentCell >)cell atIndex:(NSUInteger)charIndex
```

Parameters

aTextView
The text view sending the message.

cell
The cell in question.

charIndex
The character index in the text view that was clicked.

Return Value
An array of types that can be written to the pasteboard for *cell*.

Discussion
This method is invoked after the user clicks *cell* at the specified *charIndex* location in *aTextView*. If the `textView:draggedCell:inRect:event:atIndex:` (page 3888) is not used, this method and `textView:writeCell:atIndex:toPasteboard:type:` (page 3895) allow *aTextView* to take care of attachment dragging and pasting, with the delegate responsible only for writing the attachment to the pasteboard.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSTextView.h`

textView:writeCell:atIndex:toPasteboard:type:

Returns whether data of the specified type for the given cell could be written to the specified pasteboard.

```
- (BOOL)textView:(NSTextView *)aTextView writeCell:(id < NSTextAttachmentCell >)cell
    atIndex:(NSUInteger)charIndex toPasteboard:(NSPasteboard *)pboard type:(NSString
    *)type
```

Parameters

aTextView
The text view sending the message.

cell
The cell whose contents should be written to the pasteboard.

charIndex
The index at which the cell was accessed.

pboard
The pasteboard to which the cell's contents should be written.

type
The type of data that should be written.

Return Value

`YES` if the write succeeded, `NO` otherwise.

Discussion

The receiver should attempt to write the *cell* to *pboard* with the given *type*, and return success or failure.

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

`NSTextView.h`

textViewDidChangeSelection:

Sent when the selection changes in the text view.

```
- (void)textViewDidChangeSelection:(NSNotification *)aNotification
```

Parameters

aNotification
A notification named `NSTextViewDidChangeSelectionNotification` (page 2974).

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

`NSTextView.h`

textViewDidChangeTypingAttributes:

Sent when a text view's typing attributes change.

```
- (void)textViewDidChangeTypingAttributes:(NSNotification *)aNotification
```

Parameters

aNotification

A notification named `NSTextViewDidChangeTypingAttributesNotification` (page 2975).

Availability

Available in Mac OS X v10.3 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

`NSTextView.h`

undoManagerForTextView:

Returns the undo manager for the specified text view.

```
- (NSUndoManager *)undoManagerForTextView:(NSTextView *)aTextView
```

Parameters

aTextView

The text view whose undo manager should be returned.

Return Value

The undo manager for *aTextView*.

Discussion

This method provides the flexibility to return a custom undo manager for the text view. Although `NSTextView` implements undo and redo for changes to text, applications may need a custom undo manager to handle interactions between changes to text and changes to other items in the application.

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

`NSTextView.h`

NSTokenFieldCellDelegate Protocol Reference

Conforms to	NSObject
Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.6 and later.
Declared in	AppKit/NSTokenFieldCell.h
Companion guide	Token Field Programming Guide

Overview

The `NSTokenFieldCellDelegate` protocol defines the optional methods implemented by delegates of `NSTokenFieldCell` objects.

Tasks

Displaying Tokenized Strings

`- tokenFieldCell:displayStringForRepresentedObject:` (page 3899) Available in Mac OS X v10.0 through Mac OS X v10.1 Available in Mac OS X v10.5 through Mac OS X v10.5

Allows the delegate to provide a string to be displayed as a proxy for the represented object.

`- tokenFieldCell:styleForRepresentedObject:` (page 3903) Available in Mac OS X v10.0 through Mac OS X v10.1 Available in Mac OS X v10.5 through Mac OS X v10.5

Allows the delegate to return the token style for editing the specified represented object.

Editing a Tokenized Strings

`- tokenFieldCell:editingStringForRepresentedObject:` (page 3899)

Allows the delegate to provide a string to be edited as a proxy for the represented object.

`- tokenFieldCell:representedObjectForEditingString:` (page 3901)

Allows the delegate to provide a represented object for the string being edited.

`- tokenFieldCell:shouldAddObjects:atIndex:` (page 3902) Available in Mac OS X v10.5 through Mac OS X v10.5

Allows the delegate to validate the tokens to be added to the receiver at a given index.

- tokenFieldCell:completionsForSubstring:indexOfToken:indexOfSelectedItem: (page 3898)
Available in Mac OS X v10.0 through Mac OS X v10.1 Available in Mac OS X v10.5 through Mac OS X v10.5
Allows the delegate to provide an array of appropriate completions for the contents of the receiver.

Reading To and Writing From the Pasteboard

- tokenFieldCell:readFromPasteboard: (page 3901)
Allows the delegate to return an array of objects representing the data read from *pboard*.
- tokenFieldCell:writeRepresentedObjects:toPasteboard: (page 3903)
Allows the delegate the opportunity to write custom pasteboard types to the pasteboard for the represented objects in *objects*.

Managing Menus for Represented Objects

- tokenFieldCell:hasMenuForRepresentedObject: (page 3900)
Allows the delegate to specify whether the represented object provides a menu.
- tokenFieldCell:menuForRepresentedObject: (page 3900)
Allows the delegate to provide a menu for the specified represented object.

Instance Methods

tokenFieldCell:completionsForSubstring:indexOfToken:indexOfSelectedItem:

Allows the delegate to provide an array of appropriate completions for the contents of the receiver.

```
- (NSArray *)tokenFieldCell:(NSTokenFieldCell *)tokenFieldCell
    completionsForSubstring:(NSString *)substring indexOfToken:(NSInteger)tokenIndex
     indexOfSelectedItem:(NSInteger *)selectedIndex
```

Parameters

tokenFieldCell
The token field cell that sent the message.

substring
The partial string that is to be completed.

tokenIndex
The index of the token being edited.

selectedIndex
Optionally, you can return by-reference an index into the returned array that specifies which of the completions should be initially selected. If none are to be selected, return by reference `-1`.

Return Value
An array of strings that are possible completions.

Discussion
If the delegate does not implement this method, no completions are provided.

Availability
Available in Mac OS X v10.4 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSTokenFieldCell.h

tokenFieldCell:displayStringForRepresentedObject:

Allows the delegate to provide a string to be displayed as a proxy for the represented object.

```
- (NSString *)tokenFieldCell:(NSTokenFieldCell *)tokenFieldCell
    displayStringForRepresentedObject:(id)representedObject
```

Parameters

tokenFieldCell
The token field cell that sent the message.

representedObject
A represented object of the token field cell.

Return Value
The string to be used as a proxy for `representedObject`. If you return `nil` or do not implement this method, then *representedObject* is displayed as the string.

Availability
Available in Mac OS X v10.4 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSTokenFieldCell.h

tokenFieldCell:editingStringForRepresentedObject:

Allows the delegate to provide a string to be edited as a proxy for the represented object.

```
- (NSString *)tokenFieldCell:(NSTokenFieldCell *)tokenFieldCell
    editingStringForRepresentedObject:(id)representedObject
```

Parameters

tokenFieldCell
The token field cell that sent the message.

representedObject
A represented object of the token field.

Return Value
A string that's an editable proxy of the represented object, or `nil` if the token should not be editable.

Availability
Available in Mac OS X v10.4 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
- tokenFieldCell:representedObjectForEditingString: (page 3901)

Declared In
NSTokenFieldCell.h

tokenFieldCell:hasMenuForRepresentedObject:

Allows the delegate to specify whether the represented object provides a menu.

```
- (BOOL)tokenFieldCell:(NSTokenFieldCell *)tokenFieldCell
    hasMenuForRepresentedObject:(id)representedObject
```

Parameters

tokenFieldCell
The token field cell that sent the message.

representedObject
A represented object of the token field.

Return Value
YES if the represented object has a menu, NO otherwise.

Discussion
By default tokens have no menus.

Availability
Available in Mac OS X v10.4 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
- tokenFieldCell:menuForRepresentedObject: (page 3900)

Declared In
NSTokenFieldCell.h

tokenFieldCell:menuForRepresentedObject:

Allows the delegate to provide a menu for the specified represented object.

```
- (NSMenu *)tokenFieldCell:(NSTokenFieldCell *)tokenFieldCell
    menuForRepresentedObject:(id)representedObject
```

Parameters

tokenFieldCell
The token field cell that sent the message.

representedObject
A represented object of the token field.

Return Value
The menu associated with the represented object.

Discussion
The returned menu should be autoreleased. By default tokens in a token field cell do not return menus.

Availability
Available in Mac OS X v10.4 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
- `tokenFieldCell:hasMenuForRepresentedObject:` (page 3900)

Declared In
`NSTokenFieldCell.h`

tokenFieldCell:readFromPasteboard:

Allows the delegate to return an array of objects representing the data read from *pboard*.

```
- (NSArray *)tokenFieldCell:(NSTokenFieldCell *)tokenFieldCell
    readFromPasteboard:(NSPasteboard *)pboard
```

Parameters

tokenFieldCell
The token field cell that sent the message.

pboard
The pasteboard from which to read the represented objects.

Return Value
An array of represented objects created from the pasteboard data.

Availability
Available in Mac OS X v10.4 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
- `tokenFieldCell:writeRepresentedObjects:toPasteboard:` (page 3903)

Declared In
`NSTokenFieldCell.h`

tokenFieldCell:representedObjectForEditingString:

Allows the delegate to provide a represented object for the string being edited.

```
- (id)tokenFieldCell:(NSTokenFieldCell *)tokenFieldCell
    representedObjectForEditingString:(NSString *)editingString
```

Parameters

tokenFieldCell
The token field cell that sent the message.

editingString
The edited string representation of a represented object.

Return Value
A represented object that is displayed rather than the editing string.

Discussion
If your application uses some object other than an `NSString` for their represented objects, you should return a new, autoreleased instance of that object from this method.

> **Note:** In Mac OS X v10.4, `NSTokenField` trims whitespace around tokens but it does not trim whitespace in Mac OS X versions 10.5.0 and 10.5.1. In Mac OS X v10.5.2, you get whitespace-trimming behavior by either linking against the v10.4 binary or linking against the v10.5 binary and *not* implementing the this method. If you do not want the whitespace-trimming behavior, link against the v10.5 binary and implement this method, returning the editing string if you have no represented object.

Availability
Available in Mac OS X v10.4 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
`- tokenFieldCell:editingStringForRepresentedObject:` (page 3899)

Declared In
`NSTokenFieldCell.h`

tokenFieldCell:shouldAddObjects:atIndex:

Allows the delegate to validate the tokens to be added to the receiver at a given index.

```
- (NSArray *)tokenFieldCell:(NSTokenFieldCell *)tokenFieldCell
    shouldAddObjects:(NSArray *)tokens atIndex:(NSUInteger)index
```

Parameters

`tokenFieldCell`
The token field cell that sent the message.

`tokens`
An array of tokens to be inserted in the receiver at `index`.

`index`
The index of the receiver in which the array of tokens to be validated (`tokens`) will be inserted.

Return Value
An array of validated tokens.

Discussion
The delegate can return the array unchanged or return a modified array of tokens. To reject the add completely, return an empty array. Returning `nil` causes an error.

Availability
Available in Mac OS X v10.4 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSTokenFieldCell.h`

tokenFieldCell:styleForRepresentedObject:

Allows the delegate to return the token style for editing the specified represented object.

```
- (NSTokenStyle)tokenFieldCell:(NSTokenFieldCell *)tokenFieldCell
    styleForRepresentedObject:(id)representedObject
```

Parameters

tokenFieldCell

The token field cell that sent the message.

representedObject

A represented object of the token field cell.

Return Value

The style that should be used to display the representedObject. Possible values are shown in `NSTokenStyle_Values`.

Discussion

If the delegate implements this method and returns an `NSTokenStyle` (page 2988) that differs from the style set by `setTokenStyle:` (page 2987), the value the delegate returns is preferred.

If the delegate does not implement this method, the token field cell's `tokenStyle` (page 2988) is used.

Availability

Available in Mac OS X v10.4 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

`NSTokenFieldCell.h`

tokenFieldCell:writeRepresentedObjects:toPasteboard:

Allows the delegate the opportunity to write custom pasteboard types to the pasteboard for the represented objects in *objects*.

```
- (BOOL)tokenFieldCell:(NSTokenFieldCell *)tokenFieldCell
    writeRepresentedObjects:(NSArray *)objects toPasteboard:(NSPasteboard *)pboard
```

Parameters

tokenFieldCell

The token field cell that sent the message.

objects

An array of represented objects associated with the token field cell.

pboard

The pasteboard to which to write the represented objects.

Return Value

`YES` if the delegate writes the represented objects to the pasteboard, `NO` otherwise. If `NO`, the token field writes the display strings to the `NSStringPboardType` (page 1909) pasteboard.

Availability

Available in Mac OS X v10.4 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Overview

The `NSTokenFieldDelegate` protocol defines the optional methods implemented by delegates of `NSTokenField` objects.

Tasks

Displaying Tokenized Strings

- `tokenField:displayStringForRepresentedObject:` (page 3907)
  Allows the delegate to provide a string to be displayed as a proxy for the given represented object.
- `tokenField:styleForRepresentedObject:` (page 3910)
  Allows the delegate to return the token style for editing the specified represented object.

Editing a Tokenized Strings

- `tokenField:completionsForSubstring:indexOfToken:indexOfSelectedItem:` (page 3906)
  Allows the delegate to provide an array of appropriate completions for the contents of the receiver.
- `tokenField:editingStringForRepresentedObject:` (page 3907)
  Allows the delegate to provide a string to be edited as a proxy for a represented object.
- `tokenField:representedObjectForEditingString:` (page 3909)
  Allows the delegate to provide a represented object for the given editing string.
- `tokenField:shouldAddObjects:atIndex:` (page 3910)
  Allows the delegate to validate the tokens to be added to the receiver at a particular location.

Reading To and Writing From the Pasteboard

- `tokenField:readFromPasteboard:` (page 3909)
  Allows the delegate to return an array of objects representing the data read from the specified pasteboard.
- `tokenField:writeRepresentedObjects:toPasteboard:` (page 3911)
  Sent so the delegate can write represented objects to the pasteboard corresponding to a given array of display strings.

Managing Menus for Represented Objects

- `tokenField:hasMenuForRepresentedObject:` (page 3908)
  Allows the delegate to specify whether the given represented object provides a menu.
- `tokenField:menuForRepresentedObject:` (page 3908)
  Allows the delegate to provide a menu for the specified represented object.

Instance Methods

tokenField:completionsForSubstring:indexOfToken:indexOfSelectedItem:

Allows the delegate to provide an array of appropriate completions for the contents of the receiver.

```
- (NSArray *)tokenField:(NSTokenField *)tokenField completionsForSubstring:(NSString
    *)substring indexOfToken:(NSInteger)tokenIndex indexOfSelectedItem:(NSInteger
    *)selectedIndex
```

Parameters

tokenField
The token field where editing is occurring.

substring
The partial string that is to be completed.

tokenIndex
The index of the token being edited.

selectedIndex
Optionally, you can return by-reference an index into the returned array that specifies which of the completions should be initially selected. If none are to be selected, return by reference `-1`.

Return Value
An array of strings that are possible completions.

Discussion
If the delegate does not implement this method, no completions are provided.

Availability
Available in Mac OS X v10.4 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSTokenField.h

tokenField:displayStringForRepresentedObject:

Allows the delegate to provide a string to be displayed as a proxy for the given represented object.

```
- (NSString *)tokenField:(NSTokenField *)tokenField
    displayStringForRepresentedObject:(id)representedObject
```

Parameters

tokenField
The token field that sent the message.

representedObject
A represented object of the token field.

Return Value
The string to be used as a proxy for `representedObject`. If you return `nil` or do not implement this method, then *representedObject* is displayed as the string.

Availability
Available in Mac OS X v10.4 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSTokenField.h

tokenField:editingStringForRepresentedObject:

Allows the delegate to provide a string to be edited as a proxy for a represented object.

```
- (NSString *)tokenField:(NSTokenField *)tokenField
    editingStringForRepresentedObject:(id)representedObject
```

Parameters

tokenField
The token field that sent the message.

representedObject
A represented object of the token field.

Return Value
A string that's an editable proxy of the represented object, or `nil` if the token should not be editable.

Availability
Available in Mac OS X v10.4 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
- `tokenField:representedObjectForEditingString:` (page 3909)

Declared In
NSTokenField.h

tokenField:hasMenuForRepresentedObject:

Allows the delegate to specify whether the given represented object provides a menu.

```
- (BOOL)tokenField:(NSTokenField *)tokenField
    hasMenuForRepresentedObject:(id)representedObject
```

Parameters

tokenField

The token field that sent the message.

representedObject

A represented object of the token field.

Return Value

`YES` if the represented object has a menu, `NO` otherwise.

Discussion

By default tokens in a token field have no menus.

Availability

Available in Mac OS X v10.4 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

See Also

`- tokenField:menuForRepresentedObject:` (page 3908)

Declared In

`NSTokenField.h`

tokenField:menuForRepresentedObject:

Allows the delegate to provide a menu for the specified represented object.

```
- (NSMenu *)tokenField:(NSTokenField *)tokenField
    menuForRepresentedObject:(id)representedObject
```

Parameters

tokenField

The token field that sent the message.

representedObject

A represented object of the token field.

Return Value

The menu associated with the represented object.

Discussion

The returned menu should be autoreleased. By default tokens in a token field do not return menus.

Availability

Available in Mac OS X v10.4 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

See Also

`- tokenField:hasMenuForRepresentedObject:` (page 3908)

Declared In
NSTokenField.h

tokenField:readFromPasteboard:

Allows the delegate to return an array of objects representing the data read from the specified pasteboard.

```
- (NSArray *)tokenField:(NSTokenField *)tokenField readFromPasteboard:(NSPasteboard
    *)pboard
```

Parameters

tokenField
The token field that sent the message.

pboard
The pasteboard from which to read the represented objects.

Return Value
An array of represented objects created from the pasteboard data.

Availability
Available in Mac OS X v10.4 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
- tokenField:writeRepresentedObjects:toPasteboard: (page 3911)

Declared In
NSTokenField.h

tokenField:representedObjectForEditingString:

Allows the delegate to provide a represented object for the given editing string.

```
- (id)tokenField:(NSTokenField *)tokenField
    representedObjectForEditingString:(NSString *)editingString
```

Parameters

tokenField
The token field that sent the message.

editingString
The edited string representation of a represented object.

Return Value
A represented object that is displayed rather than the editing string.

Discussion
If your application uses some object other than an NSString for their represented objects, you should return a new, autoreleased instance of that object from this method.

Note: In Mac OS X v10.4, `NSTokenField` trims whitespace around tokens but it does not trim whitespace in Mac OS X versions 10.5.0 and 10.5.1. In Mac OS X v10.5.2, you get whitespace-trimming behavior by either linking against the v10.4 binary or linking against the v10.5 binary and *not* implementing the this method. If you do not want the whitespace-trimming behavior, link against the v10.5 binary and implement this method, returning the editing string if you have no represented object.

Availability
Available in Mac OS X v10.4 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
`- tokenField:editingStringForRepresentedObject:` (page 3907)

Declared In
`NSTokenField.h`

tokenField:shouldAddObjects:atIndex:

Allows the delegate to validate the tokens to be added to the receiver at a particular location.

```
- (NSArray *)tokenField:(NSTokenField *)tokenField shouldAddObjects:(NSArray *)tokens
    atIndex:(NSUInteger)index
```

Parameters

tokenField
The token field that sent the message.

tokens
An array of tokens to be inserted in the receiver at `index`.

index
The index of the receiver in which the array of tokens to be validated (`tokens`) will be inserted.

Return Value
An array of validated tokens.

Discussion
The delegate can return the array unchanged or return a modified array of tokens. To reject the add completely, return an empty array. Returning `nil` causes an error.

Availability
Available in Mac OS X v10.4 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSTokenField.h`

tokenField:styleForRepresentedObject:

Allows the delegate to return the token style for editing the specified represented object.

```
- (NSTokenStyle)tokenField:(NSTokenField *)tokenField
    styleForRepresentedObject:(id)representedObject
```

Parameters

tokenField

The token field that sent the message.

representedObject

A represented object of the token field.

Return Value

The style that should be used to display the representedObject. Possible values are shown in `NSTokenStyle Values`.

Discussion

If the delegate implements this method and returns an `NSTokenStyle` (page 2988) that differs from the style set by `setTokenStyle:` (page 2981), the value the delegate returns is preferred.

If the delegate does not implement this method, the token field's `tokenStyle` (page 2982) is used.

Availability

Available in Mac OS X v10.4 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

`NSTokenField.h`

tokenField:writeRepresentedObjects:toPasteboard:

Sent so the delegate can write represented objects to the pasteboard corresponding to a given array of display strings.

```
- (BOOL)tokenField:(NSTokenField *)tokenField writeRepresentedObjects:(NSArray
    *)objects toPasteboard:(NSPasteboard *)pboard
```

Parameters

tokenField

The token field that sent the message.

objects

An array of represented objects associated with the token field.

pboard

The pasteboard to which to write the represented objects.

Return Value

`YES` if the delegate writes the represented objects to the pasteboard, `NO` otherwise. If `NO`, the token field writes the display strings to the `NSStringPboardType` (page 1909) pasteboard.

Availability

Available in Mac OS X v10.4 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Overview

The `NSToolbarDelegate` protocol defines the optional methods implemented by delegates of `NSToolbar` objects.

Tasks

Configuring a Toolbar

- `toolbar:itemForItemIdentifier:willBeInsertedIntoToolbar:` (page 3914)
  Sent to request a new toolbar item; returns a toolbar item of the identified kind for the specified toolbar.
- `toolbarAllowedItemIdentifiers:` (page 3915)
  Sent to discover the allowed item identifiers for a toolbar.
- `toolbarDefaultItemIdentifiers:` (page 3915)
  Sent to discover the default item identifiers for a toolbar.
- `toolbarSelectableItemIdentifiers:` (page 3916)
  Sent to discover the selectable item identifiers for a toolbar.

Responding to Additions and Deletions in the Toolbar

- `toolbarWillAddItem:` (page 3917)
  Sent just before a new item is added to a toolbar.
- `toolbarDidRemoveItem:` (page 3916)
  Sent just after an item has been removed from a toolbar.

Instance Methods

toolbar:itemForItemIdentifier:willBeInsertedIntoToolbar:

Sent to request a new toolbar item; returns a toolbar item of the identified kind for the specified toolbar.

```
- (NSToolbarItem *)toolbar:(NSToolbar *)toolbar itemForItemIdentifier:(NSString
    *)itemIdentifier willBeInsertedIntoToolbar:(BOOL)flag
```

Parameters

toolbar
  The toolbar for which the item is being requested.

itemIdentifier
  The identifier for the requested item.

flag
  `YES` if the item will be immediately inserted into the toolbar. If *flag* is `NO` the toolbar item is being requested for display in the toolbar customization sheet and should always be enabled or provide some other canonical representation. If you ignore this parameter the same toolbar item will be used in the toolbar and in the customization sheet.

Return Value
The toolbar item for the specified toolbar and identifier. Return `nil` to indicate that the identified kind of toolbar item is not supported. When an item is requested again, you may return the same `NSToolbarItem` object returned earlier or a different instance.

Discussion
Implement this method to create new toolbar item instances. This method is called lazily on behalf of a toolbar instance, which must be the sole owner of the toolbar item. A toolbar may ask again for a kind of toolbar item already supplied to it, in which case this method may return the same toolbar item it returned before or a different one. If your delegate services multiple toolbars, each attached to a different window, it is best to return a different item for each toolbar—an `NSToolbarItem` object can only be in one toolbar at a time.

If the item is a custom view item, the `NSView` object must be fully formed when the item is returned. Do not assume that the returned item is going to be added as an active item in the toolbar, as it could be that it will be used only in the customization palette. (The customization palette makes a copy of the returned item.)

Important: While this method is marked as `@optional` in the `NSToolbarDelegate` protocol , it must be implemented if the associated toolbar is created programatically. Toolbars created in Interface Builder can implement this method to augment functionality.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSToolbar.h`

toolbarAllowedItemIdentifiers:

Sent to discover the allowed item identifiers for a toolbar.

```
- (NSArray *)toolbarAllowedItemIdentifiers:(NSToolbar *)toolbar
```

Parameters
toolbar
The toolbar whose allowed item identifiers are to be returned.

Return Value
An array of toolbar item identifiers for *toolbar*, specifying the contents and the order of the items in the configuration palette.

Discussion
Every allowed item must be explicitly listed, even the standard ones. The identifiers returned should include all of those returned by `toolbarDefaultItemIdentifiers:` (page 3915).

Important: While this method is marked as `@optional` in the `NSToolbarDelegate` protocol , it must be implemented if the associated toolbar is created programatically. Toolbars created in Interface Builder can implement this method to augment functionality.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSToolbar.h`

toolbarDefaultItemIdentifiers:

Sent to discover the default item identifiers for a toolbar.

```
- (NSArray *)toolbarDefaultItemIdentifiers:(NSToolbar *)toolbar
```

Parameters
toolbar
The toolbar whose default item identifiers are to be returned.

Return Value
An array of toolbar item identifiers for *toolbar*, specifying the contents and the order of the items in the default toolbar configuration.

Discussion
During initialization of *toolbar*, this method is called only if a toolbar configuration for the identifier of *toolbar* is not found in the user preferences. This method is called during initialization of the toolbar customization palette.

Important: While this method is marked as `@optional` in the `NSToolbarDelegate` protocol , it must be implemented if the associated toolbar is created programatically. Toolbars created in Interface Builder can implement this method to augment functionality.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSToolbar.h`

toolbarDidRemoveItem:

Sent just after an item has been removed from a toolbar.

```
- (void)toolbarDidRemoveItem:(NSNotification *)notification
```

Parameters
notification
A notification named `NSToolbarDidRemoveItemNotification` (page 3005).

Discussion
This method allows you to remove information related to the item that may have been cached.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSToolbar.h`

toolbarSelectableItemIdentifiers:

Sent to discover the selectable item identifiers for a toolbar.

```
- (NSArray *)toolbarSelectableItemIdentifiers:(NSToolbar *)toolbar
```

Parameters
toolbar
The toolbar whose selectable item identifiers are to be returned.

Return Value
An array of item identifiers that should indicate selection in the specified *toolbar*.

Discussion
Toolbars that need to indicate item selection should return an array containing the identifiers of the selectable toolbar items.

If implemented, *toolbar* will display the currently selected item with a visual highlight. Clicking on an item whose identifier is selectable will automatically update the toolbar's selected item identifier, when possible. Clicking an item whose identifier is not selectable will not update the toolbar's selected item identifier.

Availability
Available in Mac OS X v10.3 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
- `setSelectedItemIdentifier:` (page 3000) (NSToolbar)

Declared In
`NSToolbar.h`

toolbarWillAddItem:

Sent just before a new item is added to a toolbar.

```
- (void)toolbarWillAddItem:(NSNotification *)notification
```

Parameters
notification
A notification named `NSToolbarWillAddItemNotification` (page 3005).

Discussion
If you need to cache a reference to a toolbar item or need to set up some initial state before a toolbar item is added, this is where to do it.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

`NSToolbar.h`

NSToolbarItemValidation Protocol Reference

(informal protocol)

Framework	/System/Library/Frameworks/AppKit.framework
Declared in	AppKit/NSToolbarItem.h
Companion guide	Toolbar Programming Topics for Cocoa

Overview

A toolbar item with a valid target and action is enabled by default. To allow a toolbar item to be disabled in certain situations, a toolbar item's target can implement the `validateToolbarItem:` (page 3919) method.

Note: NSToolbarItem's `validate` (page 3024) method calls this method only if the item's target has a valid action defined on its target and if the item is not a custom view item. If you want to validate a custom view item, then you have to subclass NSToolbarItem and override `validate` (page 3024).

Tasks

Validating Toolbar Items

`- validateToolbarItem:` (page 3919)
If this method is implemented and returns `NO`, NSToolbar will disable *`theItem`*; returning `YES` causes *`theItem`* to be enabled.

Instance Methods

validateToolbarItem:

If this method is implemented and returns `NO`, NSToolbar will disable *`theItem`*; returning `YES` causes *`theItem`* to be enabled.

```
- (BOOL)validateToolbarItem:(NSToolbarItem *)theItem
```

Discussion
NSToolbar only calls this method for image items.

Note: `validateToolbarItem:` is called very frequently, so it must be efficient.

If the receiver is the `target` for the actions of multiple toolbar items, it's necessary to determine which toolbar item *`theItem`* refers to by testing the `itemIdentifier`.

```
-(BOOL)validateToolbarItem:(NSToolbarItem *)toolbarItem
{
    BOOL enable = NO;
    if ([[toolbarItem itemIdentifier] isEqual:SaveDocToolbarItemIdentifier]) {
        // We will return YES (enable the save item)
        // only when the document is dirty and needs saving
        enable = [self isDocumentEdited];
    } else if ([[toolbarItem itemIdentifier]
isEqual:NSToolbarPrintItemIdentifier]) {
        // always enable print for this window
        enable = YES;
    }
    return enable;
}
```

Availability
Available in Mac OS X v10.0 and later.

NSToolTipOwner Protocol Reference

(informal protocol)

Framework	/System/Library/Frameworks/AppKit.framework
Declared in	AppKit/NSView.h
Companion guide	Online Help

Overview

The NSToolTipOwner informal protocol declares a method that allows an object to dynamically provide the text to a tool tip. If the tool tip object does not implement this method, the NSObject protocol `description` method is invoked instead.

Tasks

Obtaining Tool Tip Strings

`- view:stringForToolTip:point:userData:` (page 3921)
Returns the tool tip string to be displayed due to the cursor pausing at location *point* within the tool tip rectangle identified by *tag* in the view *view*.

Instance Methods

view:stringForToolTip:point:userData:

Returns the tool tip string to be displayed due to the cursor pausing at location *point* within the tool tip rectangle identified by *tag* in the view *view*.

```
- (NSString *)view:(NSView *)view stringForToolTip:(NSToolTipTag)tag
    point:(NSPoint)point userData:(void *)userData
```

Discussion
userData is additional information provided by the creator of the tool tip rectangle.

Availability
Available in Mac OS X v10.0 and later.

NSUserInterfaceValidations Protocol Reference

Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.0 and later.
Declared in	AppKit/NSUserInterfaceValidation.h
Companion guide	User Interface Validation

Overview

The `NSUserInterfaceValidations` protocol works with the `NSValidatedUserInterfaceItem` protocol to allow the target of a user interface element such as a menu item or a toolbar item to decide whether or not the user interface element should be enabled.

Your custom classes should adopt this protocol if an instance may be the target of a user interface element and need to conditionally enable or disable the element based on the current state of the instance. For more details, read *User Interface Validation*.

Tasks

Validating User Interface Items

`- validateUserInterfaceItem:` (page 3923) *required method*
Returns a Boolean value that indicates whether the sender should be enabled. (required)

Instance Methods

validateUserInterfaceItem:

Returns a Boolean value that indicates whether the sender should be enabled. (required)

```
- (BOOL)validateUserInterfaceItem:(id < NSValidatedUserInterfaceItem >)anItem
```

Parameters

anItem

The user interface item to validate. You can send *anItem* the `action` (page 3925) and `tag` (page 3926) messages.

Return Value

`YES` if the user interface item should be enabled, otherwise `NO`.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSUserInterfaceValidation.h`

NSValidatedUserInterfaceItem Protocol Reference

Framework	/System/Library/Frameworks/AppKit.framework
Availability	Available in Mac OS X v10.0 and later.
Declared in	AppKit/NSUserInterfaceValidation.h
Companion guide	User Interface Validation

Overview

The `NSValidatedUserInterfaceItem` protocol works with the `NSUserInterfaceValidations` protocol to enable or disable a control automatically, depending on whether any responder in the responder chain can handle the control's action method. The `NSMenuItem` and `NSToolbarItem` classes implement this protocol.

By conforming to this protocol, your control can participate in this validation mechanism. To validate a control, the application calls `validateUserInterfaceItem:` for each item in the responder chain, starting with the first responder. If no responder returns `YES`, the item is disabled. For example, a menu item that sends the `copy:` action message would disable itself if no responder in the responder chain can be copied.

Tasks

Getting Information About a User Interface Item

- `action` (page 3925) *required method*
  Returns the selector of the receiver's action method. (required)
- `tag` (page 3926) *required method*
  Returns the receiver's tag integer. (required)

Instance Methods

action

Returns the selector of the receiver's action method. (required)

```
- (SEL)action
```

Return Value
The selector of the receiver's action method.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSUserInterfaceValidation.h`

tag

Returns the receiver’s tag integer. (required)

```
- (NSInteger)tag
```

Return Value
The receiver's tag.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSUserInterfaceValidation.h`

NSWindowDelegate Protocol Reference

Conforms to	NSObject
Framework	/System/Library/Frameworks/AppKit.framework

Overview

The `NSWindowDelegate` protocol defines the methods that a delegate of `NSWindow` should implement. All methods in this protocol are optional.

By implementing these methods, the delegate may respond to window resizing, moving, exposing, minimizing, and a number of other window events.

Tasks

Managing Sheets

- `window:willPositionSheet:usingRect:` (page 3931)
  Tells the delegate that the window is about to show a sheet at the specified location, giving it the opportunity to return a custom location for the attachment of the sheet to the window.
- `windowWillBeginSheet:` (page 3938)
  Notifies the delegate that the window is about to open a sheet.
- `windowDidEndSheet:` (page 3934)
  Tells the delegate that the window has closed a sheet.

Sizing Windows

- `windowWillUseStandardFrame:defaultFrame:` (page 3942)
  Invoked by `NSWindow`'s `zoom:` (page 3409) method while determining the frame a window may be zoomed to.
- `windowShouldZoom:toFrame:` (page 3938)
  Asks the delegate whether the specified window should zoom to the specified frame.
- `windowWillResize:toSize:` (page 3940)
  Tells the delegate that the window is being resized (whether by the user or through one of the `setFrame...` methods other than `setFrame:display:` (page 3381)).
- `windowDidResize:` (page 3936)
  Informs the delegate that the window has been resized.
- `windowWillStartLiveResize:` (page 3941)
  Informs the delegate that the window is about to be live resized.
- `windowDidEndLiveResize:` (page 3934)
  Informs the delegate that a live resize operation on the window has ended.

Managing Key Status

- `windowDidBecomeKey:` (page 3932)
  Informs the delegate that the window has become the key window.
- `windowDidResignKey:` (page 3936)
  Informs the delegate that the window has resigned key window status.

Managing Main Status

- `windowDidBecomeMain:` (page 3932)
  Informs the delegate that the window has become main.
- `windowDidResignMain:` (page 3936)
  Informs the delegate that the window has resigned main window status.

Managing Field Editors

- `windowWillReturnFieldEditor:toObject:` (page 3940)
  Tells the delegate that the field editor for a text-displaying object has been requested.

Updating Windows

- `windowDidUpdate:` (page 3937)
  Tells the delegate that the window received an `update` (page 3405) message.

Exposing Windows

- `windowDidExpose:` (page 3935)
  Tells the delegate that the window has been exposed.

Dragging Windows

- `window:shouldDragDocumentWithEvent:from:withPasteboard:` (page 3930)
  Asks the delegate whether a user can drag the document icon from the window's title bar.

Getting the Undo Manager

- `windowWillReturnUndoManager:` (page 3941)
  Tells the delegate that the window's undo manager has been requested. Returns the appropriate undo manager for the window.

Managing Titles

- `window:shouldPopUpDocumentPathMenu:` (page 3931)
  Asks the delegate whether the window displays the title pop-up menu in response to a Command-click or Control-click on its title.

Moving Windows

- `windowWillMove:` (page 3939)
  Tells the delegate that the window is about to move.
- `windowDidMove:` (page 3935)
  Tells the delegate that the window has moved.
- `windowDidChangeScreen:` (page 3933)
  Tells the delegate that the window has changed screens.
- `windowDidChangeScreenProfile:` (page 3933)
  Tells the delegate that the window has changed screen display profiles.

Closing Windows

- `windowShouldClose:` (page 3937)
  Tells the delegate that the user has attempted to close a window or the window has received a `performClose:` (page 3354) message.
- `windowWillClose:` (page 3939)
  Tells the delegate that the window is about to close.

Minimizing Windows

- `windowWillMiniaturize:` (page 3939)
  Tells the delegate that the window is about to be minimized.
- `windowDidMiniaturize:` (page 3935)
  Tells the delegate that the window has been minimized.
- `windowDidDeminiaturize:` (page 3933)
  Tells the delegate that the window has been deminimized.

Instance Methods

window:shouldDragDocumentWithEvent:from:withPasteboard:

Asks the delegate whether a user can drag the document icon from the window's title bar.

```
- (BOOL)window:(NSWindow *)window
    shouldDragDocumentWithEvent:(NSEvent *)event
    from:(NSPoint)dragImageLocation
    withPasteboard:(NSPasteboard *)pasteboard
```

Parameters

window
The window containing the document icon the user wants to drag.

event
The left-mouse down event that triggered the dragging operation.

dragImageLocation
The location at which the user started the dragging operation.

pasteboard
The pasteboard containing the contents of the document, which the delegate can modify.

Return Value
`YES` to allow the drag to proceed; `NO` to prevent it.

Discussion
To implement its own dragging process, the delegate can perform the dragging operation and return `NO`.

Availability
Available in Mac OS X v10.5 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSWindow.h`

window:shouldPopUpDocumentPathMenu:

Asks the delegate whether the window displays the title pop-up menu in response to a Command-click or Control-click on its title.

```
- (BOOL)window:(NSWindow *)window
    shouldPopUpDocumentPathMenu:(NSMenu *)menu
```

Parameters

window

The window whose title the user Command-clicked or Control-clicked.

menu

The menu the window will display, if allowed. By default, its items are the path components of the file represented by *window*.

Return Value

`YES` to allow the display of the title pop-up menu; `NO` to prevent it.

Availability

Available in Mac OS X v10.5 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

- representedURL (page 3359)

Declared In

NSWindow.h

window:willPositionSheet:usingRect:

Tells the delegate that the window is about to show a sheet at the specified location, giving it the opportunity to return a custom location for the attachment of the sheet to the window.

```
- (NSRect)window:(NSWindow *)window
    willPositionSheet:(NSWindow *)sheet
    usingRect:(NSRect)rect
```

Parameters

window

The window containing the sheet to be animated.

sheet

The sheet to be shown.

rect

The default sheet location, just under the title bar of the window, aligned with the left and right edges of the window.

Return Value

The custom location specified.

Discussion

This method is also invoked whenever the user resizes *window* while *sheet* is attached.

This method is useful in many situations. If your window has a toolbar, for example, you can specify a location for the sheet that is just below it. If you want the sheet associated with a certain control or view, you could position the sheet so that it appears to originate from the object (through animation) or is positioned next to it.

Neither the *rect* parameter nor the returned `NSRect` value define the boundary of the sheet. They indicate where the top-left edge of the sheet is attached to the window. The origin is expressed in window coordinates; the default `origin.y` value is the height of the content view and the default `origin.x` value is 0. The `size.width` value indicates the width and behavior of the initial animation; if `size.width` is narrower than the sheet, the sheet genies out from the specified location, and if `size.width` is wider than the sheet, the sheet slides out. You cannot affect the size of the sheet through the `size.width` and `size.height` fields. It is recommended that you specify zero for the `size.height` value as this field may have additional meaning in a future release.

Availability
Available in Mac OS X v10.3 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSWindow.h`

windowDidBecomeKey:

Informs the delegate that the window has become the key window.

```
- (void)windowDidBecomeKey:(NSNotification *)notification
```

Parameters
notification
A notification named `NSWindowDidBecomeKeyNotification` (page 3422).

Discussion
You can retrieve the window object in question by sending `object` to *notification*.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSWindow.h`

windowDidBecomeMain:

Informs the delegate that the window has become main.

```
- (void)windowDidBecomeMain:(NSNotification *)notification
```

Parameters
notification
A notification named `NSWindowDidBecomeMainNotification` (page 3423).

Discussion
You can retrieve the window object in question by sending `object` to *notification*.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSWindow.h

windowDidChangeScreen:

Tells the delegate that the window has changed screens.

```
- (void)windowDidChangeScreen:(NSNotification *)notification
```

Parameters
notification
A notification named NSWindowDidChangeScreenNotification (page 3423).

Discussion
You can retrieve the NSWindow object in question by sending object to *notification*.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSWindow.h

windowDidChangeScreenProfile:

Tells the delegate that the window has changed screen display profiles.

```
- (void)windowDidChangeScreenProfile:(NSNotification *)notification
```

Parameters
notification
A notification named NSWindowDidChangeScreenProfileNotification (page 3423).

Discussion
You can retrieve the NSWindow object in question by sending object to *notification*.

Availability
Available in Mac OS X v10.4 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSWindow.h

windowDidDeminiaturize:

Tells the delegate that the window has been deminimized.

```
- (void)windowDidDeminiaturize:(NSNotification *)notification
```

Parameters

notification

A notification named `NSWindowDidDeminiaturizeNotification` (page 3423)

Discussion

You can retrieve the `NSWindow` object in question by sending `object` to *notification*.

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

`NSWindow.h`

windowDidEndLiveResize:

Informs the delegate that a live resize operation on the window has ended.

```
- (void)windowDidEndLiveResize:(NSNotification *)notification
```

Parameters

notification

A notification named `NSWindowDidEndLiveResizeNotification` (page 3424).

Discussion

You can retrieve the window object in question by sending `object` to *notification*.

Availability

Available in Mac OS X v10.6 and later.

Declared In

`NSWindow.h`

windowDidEndSheet:

Tells the delegate that the window has closed a sheet.

```
- (void)windowDidEndSheet:(NSNotification *)notification
```

Parameters

notification

A notification named `NSWindowDidEndSheetNotification` (page 3424).

Discussion

You can retrieve the window object in question by sending `object` to *notification*.

Availability

Available in Mac OS X v10.1 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

`NSWindow.h`

windowDidExpose:

Tells the delegate that the window has been exposed.

```
- (void)windowDidExpose:(NSNotification *)notification
```

Parameters

notification

A notification named `NSWindowDidExposeNotification` (page 3424).

Discussion

You can retrieve the window object in question by sending `object` to *notification*.

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

`NSWindow.h`

windowDidMiniaturize:

Tells the delegate that the window has been minimized.

```
- (void)windowDidMiniaturize:(NSNotification *)notification
```

Parameters

notification

A notification named `NSWindowDidMiniaturizeNotification` (page 3425).

Discussion

You can retrieve the `NSWindow` object in question by sending `object` to *notification*.

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

`NSWindow.h`

windowDidMove:

Tells the delegate that the window has moved.

```
- (void)windowDidMove:(NSNotification *)notification
```

Parameters

notification

A notification named `NSWindowDidMoveNotification` (page 3425).

Discussion

You can retrieve the `NSWindow` object in question by sending `object` to *notification*.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSWindow.h

windowDidResignKey:

Informs the delegate that the window has resigned key window status.

```
- (void)windowDidResignKey:(NSNotification *)notification
```

Parameters
notification
A notification named NSWindowDidResignKeyNotification (page 3425).

Discussion
You can retrieve the window object in question by sending object to *notification*.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSWindow.h

windowDidResignMain:

Informs the delegate that the window has resigned main window status.

```
- (void)windowDidResignMain:(NSNotification *)notification
```

Parameters
notification
A notification named NSWindowDidResignMainNotification (page 3425).

Discussion
You can retrieve the window object in question by sending object to *notification*.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSWindow.h

windowDidResize:

Informs the delegate that the window has been resized.

```
- (void)windowDidResize:(NSNotification *)notification
```

Parameters

notification

A notification named NSWindowDidResizeNotification (page 3426).

Discussion

You can retrieve the window object in question by sending object to *notification*.

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

NSWindow.h

windowDidUpdate:

Tells the delegate that the window received an update (page 3405) message.

```
- (void)windowDidUpdate:(NSNotification *)notification
```

Parameters

notification

A notification named NSWindowDidUpdateNotification (page 3426)

Discussion

You can retrieve the window object in question by sending object to *notification*.

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

NSWindow.h

windowShouldClose:

Tells the delegate that the user has attempted to close a window or the window has received a performClose: (page 3354) message.

```
- (BOOL)windowShouldClose:(id)sender
```

Parameters

sender

The window being closed.

Return Value

YES to allow *sender* to be closed; otherwise, NO.

Discussion

This method may not always be called during window closing. Specifically, this method is not called when a user quits an application. You can find additional information on application termination in Graceful Application Termination.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSWindow.h

windowShouldZoom:toFrame:

Asks the delegate whether the specified window should zoom to the specified frame.

```
- (BOOL)windowShouldZoom:(NSWindow *)window
    toFrame:(NSRect)newFrame
```

Parameters

window
The window being zoomed.

newFrame
The rectangle to which the specified window is being zoomed.

Return Value
YES to allow *window*'s frame to become *newFrame*; otherwise, NO.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
- windowWillUseStandardFrame:defaultFrame: (page 3942)

Declared In
NSWindow.h

windowWillBeginSheet:

Notifies the delegate that the window is about to open a sheet.

```
- (void)windowWillBeginSheet:(NSNotification *)notification
```

Parameters

notification
A notification named NSWindowWillBeginSheetNotification (page 3426).

Discussion
You can retrieve the window object in question by sending object to *notification*.

Availability
Available in Mac OS X v10.1 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSWindow.h

windowWillClose:

Tells the delegate that the window is about to close.

```
- (void)windowWillClose:(NSNotification *)notification
```

Parameters

notification

A notification named `NSWindowWillCloseNotification` (page 3426).

Discussion

You can retrieve the `NSWindow` object in question by sending `object` to *notification*.

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

`NSWindow.h`

windowWillMiniaturize:

Tells the delegate that the window is about to be minimized.

```
- (void)windowWillMiniaturize:(NSNotification *)notification
```

Parameters

notification

A notification named `NSWindowWillMiniaturizeNotification` (page 3427).

Discussion

You can retrieve the `NSWindow` object in question by sending `object` to *notification*.

Availability

Available in Mac OS X v10.0 and later.

Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In

`NSWindow.h`

windowWillMove:

Tells the delegate that the window is about to move.

```
- (void)windowWillMove:(NSNotification *)notification
```

Parameters

notification

A notification named `NSWindowWillMoveNotification` (page 3427).

Discussion

You can retrieve the `NSWindow` object in question by sending `object` to *notification*.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSWindow.h

windowWillResize:toSize:

Tells the delegate that the window is being resized (whether by the user or through one of the `setFrame...` methods other than `setFrame:display:` (page 3381)).

```
- (NSSize)windowWillResize:(NSWindow *)sender
    toSize:(NSSize)frameSize
```

Parameters

sender
The window being resized.

frameSize
The size to which the specified window is being resized.

Return Value
A custom size to which the specified window will be resized.

Discussion
The *frameSize* contains the size (in screen coordinates) *sender* will be resized to. To resize to a different size, simply return the desired size from this method; to avoid resizing, return the current size. *sender*'s minimum and maximum size constraints have already been applied when this method is invoked.

While the user is resizing a window, the delegate is sent a series of `windowWillResize:toSize:` messages as the window's outline is dragged. The window's outline is displayed at the constrained size as set by this method.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
NSWindow.h

windowWillReturnFieldEditor:toObject:

Tells the delegate that the field editor for a text-displaying object has been requested.

```
- (id)windowWillReturnFieldEditor:(NSWindow *)sender
    toObject:(id)client
```

Parameters

sender
The window requesting the field editor from the delegate.

client
A text-displaying object to be associated with the field editor. If `nil`, the requested field editor is the default.

Return Value
The field editor for *client*; returns `nil` when the delegate has no field editor to assign.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

See Also
`- fieldEditor:forObject:` (page 3325)

Declared In
`NSWindow.h`

windowWillReturnUndoManager:

Tells the delegate that the window's undo manager has been requested. Returns the appropriate undo manager for the window.

```
- (NSUndoManager *)windowWillReturnUndoManager:(NSWindow *)window
```

Parameters
window
The window whose undo manager is being requested.

Return Value
The appropriate undo manager for the specified window.

Discussion
If this method is not implemented by the delegate, the window creates an`NSUndoManager` for *window*.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

Declared In
`NSWindow.h`

windowWillStartLiveResize:

Informs the delegate that the window is about to be live resized.

```
- (void)windowWillStartLiveResize:(NSNotification *)notification
```

Parameters
notification
A notification named `NSWindowWillStartLiveResizeNotification` (page 3427).

Discussion
You can retrieve the window object in question by sending `object` to *notification*.

Availability
Available in Mac OS X v10.6 and later.

Declared In
NSWindow.h

windowWillUseStandardFrame:defaultFrame:

Invoked by NSWindow's zoom: (page 3409) method while determining the frame a window may be zoomed to.

```
- (NSRect)windowWillUseStandardFrame:(NSWindow *)window
    defaultFrame:(NSRect)newFrame
```

Parameters

window
The window whose frame size is being determined.

newFrame
The size of the current screen, which is the screen containing the largest part of the window's current frame, possibly reduced on the top, bottom, left, or right, depending on the current interface style. The frame is reduced on the top to leave room for the menu bar.

Return Value
The specified window's standard frame.

Discussion
The standard frame for a window should supply the size and location that are "best" for the type of information shown in the window, taking into account the available display or displays. For example, the best width for a window that displays a word-processing document is the width of a page or the width of the display, whichever is smaller. The best height can be determined similarly. On return from this method, the zoom: (page 3409) method modifies the returned standard frame, if necessary, to fit on the current screen.

Availability
Available in Mac OS X v10.0 and later.
Available as part of an informal protocol prior to Mac OS X v10.6.

NSWindow.h

NSWindowScripting Protocol Reference

(informal protocol)

Framework	/System/Library/Frameworks/AppKit.framework
Declared in	AppKit/NSWindowScripting.h
Companion guide	Cocoa Scripting Guide

Overview

Category on `NSWindow`. Supports window scripting for all scriptable Cocoa applications by getting and setting standard properties and handling the `close`, `print`, and `save` AppleScript commands.

Tasks

Getting Scripting Attribute Information About a Window

- `hasCloseBox` (page 3945) *required method*
  Returns `YES` if the receiver has a close box. (required)
- `hasTitleBar` (page 3946) *required method*
  Returns `YES` if the receiver has a title bar. (required)
- `isFloatingPanel` (page 3946) *required method*
  Returns `YES` if the receiver is a floating panel. (required)
- `isMiniaturizable` (page 3946) *required method*
  Returns `YES` if the receiver can be miniaturized (has a minimize button). (required)
- `isModalPanel` (page 3946) *required method*
  Returns `YES` if the receiver is an application-modal panel. (required)
- `isResizable` (page 3946) *required method*
  Returns `YES` if the receiver is resizable (has a size control). (required)
- `isZoomable` (page 3947) *required method*
  Returns `YES` if the receiver is zoomable (has a zoom button). (required)

Setting Scripting Attribute Information for a Window

- `setIsMiniaturized:` (page 3947) *required method*
  Sets the receiver's miniaturized state to the value specified by *`flag`*. (required)

- `setIsVisible:` (page 3948) *required method*
  Sets the receiver's visible state to the value specified by *`flag`*. (required)
- `setIsZoomed:` (page 3948) *required method*
  Sets the receiver's zoomed state to the value specified by *`flag`*. (required)

Handling Script Commands

- `handleCloseScriptCommand:` (page 3944) *required method*
  Handles the `close` AppleScript command by attempting to close the window (and its associated document, if any). (required)
- `handlePrintScriptCommand:` (page 3945) *required method*
  Handles the `print` AppleScript command by attempting to print the contents of the window (or its associated document, if any). (required)
- `handleSaveScriptCommand:` (page 3945) *required method*
  Handles the `save` AppleScript command by attempting to save the window (and its associated document, if any). (required)

Working with Ordered Indices

- `orderedIndex` (page 3947) *required method*
  Returns the zero-based position of the receiver based on its order from front to back among all application windows. (required)
- `setOrderedIndex:` (page 3948) *required method*
  Sets the zero-based position of the receiver, based on its order from front to back among all visible application windows, to the value specified by *`index`*. If *`index`* is out of range, sets the position to the nearest value that is in range. (required)

Instance Methods

handleCloseScriptCommand:

Handles the `close` AppleScript command by attempting to close the window (and its associated document, if any). (required)

```
- (id)handleCloseScriptCommand:(NSCloseCommand *)command
```

Discussion
Extracts `close` command arguments from the *`command`* object and uses them to determine how to close the associated document—specifically, whether to ignore unsaved changes, save changes automatically, or ask the user and to identify the file in which to save the document (by default, the file that was opened or previously saved to, or an "untitled" name if the file has never been saved).

If there is a corresponding document and the window is the main window of the document, it forwards the `close` command to the corresponding document; otherwise, the window sends itself a `performClose` message, if it has a close box. This may have been handled differently in versions of Mac OS X prior to version 10.3.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSWindowScripting.h`

handlePrintScriptCommand:

Handles the `print` AppleScript command by attempting to print the contents of the window (or its associated document, if any). (required)

```
- (id)handlePrintScriptCommand:(NSScriptCommand *)command
```

Discussion
If there is a corresponding document and the window is the main window of the document, it forwards the `print` command to the corresponding document; otherwise, the window sends itself a `print` message. This may have been handled differently in versions of Mac OS X prior to version 10.3.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSWindowScripting.h`

handleSaveScriptCommand:

Handles the `save` AppleScript command by attempting to save the window (and its associated document, if any). (required)

```
- (id)handleSaveScriptCommand:(NSScriptCommand *)command
```

Discussion
The default version invokes the same named method of the window's document, if the window is the one being saved.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSWindowScripting.h`

hasCloseBox

Returns `YES` if the receiver has a close box. (required)

```
- (BOOL)hasCloseBox
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSWindowScripting.h`

hasTitleBar

Returns `YES` if the receiver has a title bar. (required)

```
- (BOOL)hasTitleBar
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSWindowScripting.h`

isFloatingPanel

Returns `YES` if the receiver is a floating panel. (required)

```
- (BOOL)isFloatingPanel
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSWindowScripting.h`

isMiniaturizable

Returns `YES` if the receiver can be miniaturized (has a minimize button). (required)

```
- (BOOL)isMiniaturizable
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSWindowScripting.h`

isModalPanel

Returns `YES` if the receiver is an application-modal panel. (required)

```
- (BOOL)isModalPanel
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSWindowScripting.h`

isResizable

Returns `YES` if the receiver is resizable (has a size control). (required)

```
- (BOOL)isResizable
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSWindowScripting.h

isZoomable

Returns YES if the receiver is zoomable (has a zoom button). (required)

```
- (BOOL)isZoomable
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSWindowScripting.h

orderedIndex

Returns the zero-based position of the receiver based on its order from front to back among all application windows. (required)

```
- (int)orderedIndex
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSWindowScripting.h

setIsMiniaturized:

Sets the receiver's miniaturized state to the value specified by *flag*. (required)

```
- (void)setIsMiniaturized:(BOOL)flag
```

Discussion
Depending on the current miniaturized state and the value of *flag*, the window may be minimized to the Dock or expanded from the Dock.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSWindowScripting.h

setIsVisible:

Sets the receiver's visible state to the value specified by *flag*. (required)

```
- (void)setIsVisible:(BOOL)flag
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSWindowScripting.h

setIsZoomed:

Sets the receiver's zoomed state to the value specified by *flag*. (required)

```
- (void)setIsZoomed:(BOOL)flag
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSWindowScripting.h

setOrderedIndex:

Sets the zero-based position of the receiver, based on its order from front to back among all visible application windows, to the value specified by *index*. If *index* is out of range, sets the position to the nearest value that is in range. (required)

```
- (void)setOrderedIndex:(int)index
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSWindowScripting.h

Functions

Application Kit Functions Reference

Framework: AppKit/AppKit.h

Overview

This document describes functions and function-like macros defined in the Application Kit framework.

Functions by Task

Accessibility

Additional information on accessibility can be found in `NSAccessibility`.

`NSAccessibilityActionDescription` (page 3956)
Returns a standard description for an action.

`NSAccessibilityPostNotification` (page 3956)
Sends a notification to any observing assistive applications.

`NSAccessibilityRaiseBadArgumentException` (page 3957)
Raises an error if the parameter is the wrong type or has an illegal value

`NSAccessibilityRoleDescription` (page 3957)
Returns a standard description for a role and subrole.

`NSAccessibilityRoleDescriptionForUIElement` (page 3958)
Returns a standard role description for a user interface element.

`NSAccessibilityUnignoredChildren` (page 3959)
Returns a list of unignored accessibility objects, descending the hierarchy if necessary.

`NSAccessibilityUnignoredChildrenForOnlyChild` (page 3959)
Returns a list of unignored accessibility objects, descending the hierarchy if necessary.

`NSAccessibilityUnignoredDescendant` (page 3960)
Returns an unignored accessibility object, descending the hierarchy if necessary.

`NSAccessibilityUnignoredAncestor` (page 3958)
Returns an unignored accessibility object, ascending the hierarchy if necessary.

Applications

Additional information on `NSApplication` can be found in *NSApplication Class Reference*.

`NSApplicationLoad` (page 3960)
Startup function to call when running Cocoa code from a Carbon application.

`NSApplicationMain` (page 3961)
Called by the main function to create and run the application.

`NSPerformService` (page 3990)
Programmatically invokes a Services menu service.

`NSRegisterServicesProvider` (page 3997)
Registers a service provider.

`NSSetShowsServicesMenuItem` (page 4001)
Specifies whether an item should be included in Services menus.

`NSShowsServicesMenuItem` (page 4002)
Specifies whether a Services menu item is currently enabled.

`NSUpdateDynamicServices` (page 4003) Deprecated in Mac OS X v10.5
Causes the services information for the system to be updated.

`NSUnregisterServicesProvider` (page 4002) Deprecated in Mac OS X v10.6
Unregisters a service provider.

Events

`NSEventMaskFromType` (page 3981)
Returns the event mask for the specified type.

Fonts

`NSConvertGlyphsToPackedGlyphs` (page 3967)
Prepares a set of glyphs for processing by character-based routines.

Graphics

`NSCopyBits` (page 3967)
Copies a bitmap image to the location specified by a destination point.

`NSCountWindows` (page 3968)
Counts the number of onscreen windows.

`NSCountWindowsForContext` (page 3968)
Counts the number of onscreen windows belonging to a particular application.

`NSDisableScreenUpdates` (page 3969)
Disables screen updates.

`NSEnableScreenUpdates` (page 3980)
Enables screen updates

`NSDottedFrameRect` (page 3970)
Draws a bordered rectangle.

`NSDrawBitmap` (page 3970)
Draws a bitmap image.

NSDrawButton (page 3972)
Draws a gray-filled rectangle representing a user-interface button.

NSDrawDarkBezel (page 3973)
Draws a dark gray-filled rectangle with a bezel border.

NSDrawGrayBezel (page 3973)
Draws a gray-filled rectangle with a bezel border.

NSDrawGroove (page 3974)
Draws a gray-filled rectangle with a groove border.

NSDrawLightBezel (page 3974)
Draws a white-filled rectangle with a bezel border.

NSDrawThreePartImage (page 3976)
Draws a three-part tiled image.

NSDrawNinePartImage (page 3975)
Draws a nine-part tiled image.

NSDrawTiledRects (page 3978)
Draws rectangles with borders.

NSDrawColorTiledRects (page 3972)
Draws a colored bordered rectangle.

NSDrawWhiteBezel (page 3979)
Draws a white-filled rectangle with a bezel border.

NSDrawWindowBackground (page 3980)
Draws the window's default background pattern into the specified rectangle of the currently focused view.

NSEraseRect (page 3980)
Erases the specified rect by filling it with white.

NSFrameRectWithWidth (page 3982)
Draw a bordered rectangle.

NSFrameRectWithWidthUsingOperation (page 3983)
Draw a bordered rectangle using the specified compositing operation.

NSHighlightRect (page 3987)
Highlights the specified rect by filling it with white.

NSReadPixel (page 3991)
Reads the color of the pixel at the specified location.

NSRectClip (page 3991)
Modifies the current clipping path by intersecting it with the passed rect.

NSRectClipList (page 3992)
Modifies the current clipping path by intersecting it with the passed rect.

NSRectFill (page 3993)
Fills the passed rectangle with the current color.

NSRectFillList (page 3993)
Fills the rectangles in the passed list with the current fill color.

NSRectFillListWithColors (page 3994)
Fills the rectangles in the passed list with the passed list of colors.

`NSRectFillListWithGrays` (page 3996)
Fills the rectangles in the passed list with the passed list of grays.

`NSRectFillListUsingOperation` (page 3994)
Fills the rectangles in a list using the current fill color and specified compositing operation.

`NSRectFillListWithColorsUsingOperation` (page 3995)
Fills the rectangles in a list using the specified colors and compositing operation.

`NSRectFillUsingOperation` (page 3997)
Fills a rectangle using the current fill color and the specified compositing operation.

`NSSetFocusRingStyle` (page 4000)
Specifies how a focus ring will be drawn.

`NSShowAnimationEffect` (page 4001)
Runs a system animation effect.

`NSWindowList` (page 4003)
Gets information about onscreen windows.

`NSWindowListForContext` (page 4003)
Gets information about an application's onscreen windows.

`NSFrameRect` (page 3981) Available in Mac OS X v10.3 through Mac OS X v10.5
Draw a bordered rectangle.

`NSGetWindowServerMemory` (page 3986) Deprecated in Mac OS X v10.6
Returns the amount of memory being used by a context.

Graphics-Window Depth

`NSAvailableWindowDepths` (page 3962)
Returns the available window depth values.

`NSBestDepth` (page 3965)
Attempts to return a window depth adequate for the specified parameters.

`NSBitsPerPixelFromDepth` (page 3966)
Returns the bits per pixel for the specified window depth.

`NSBitsPerSampleFromDepth` (page 3966)
Returns the bits per sample for the specified window depth.

`NSColorSpaceFromDepth` (page 3966)
Returns the name of the color space corresponding to the passed window depth.

`NSNumberOfColorComponents` (page 3988)
Returns the number of color components in the specified color space.

`NSPlanarFromDepth` (page 3990)
Returns whether the specified window depth is planar.

Interface Styles

`NSInterfaceStyleForKey` (page 3987)
Returns an interface style value for the specified key and responder.

Key Value Bindings

`NSIsControllerMarker` (page 3988)
Tests whether a given object is special marker object used for indicating the state of a selection in relation to a key.

OpenGL

`NSOpenGLGetOption` (page 3989)
Returns global OpenGL options.

`NSOpenGLGetVersion` (page 3989)
Returns the NSOpenGL version numbers.

`NSOpenGLSetOption` (page 3989)
Sets global OpenGL options.

Panels

`NSBeginAlertSheet` (page 3962)
Creates and runs an alert sheet.

`NSBeginCriticalAlertSheet` (page 3964)
Creates and runs a critical alert sheet.

`NSBeginInformationalAlertSheet` (page 3964)
Creates and runs an informational alert sheet.

`NSGetAlertPanel` (page 3983)
Returns an alert panel.

`NSGetCriticalAlertPanel` (page 3984)
Returns an alert panel to display a critical message.

`NSGetInformationalAlertPanel` (page 3985)
Returns an alert panel to display an informational message.

`NSReleaseAlertPanel` (page 3998)
Releases an alert panel.

`NSRunAlertPanel` (page 3998)
Creates an alert panel.

`NSRunCriticalAlertPanel` (page 3999)
Creates and runs a critical alert panel.

`NSRunInformationalAlertPanel` (page 4000) Deprecated in Mac OS X v10.4
Creates and runs an informational alert panel.

Pasteboards

`NSCreateFileContentsPboardType` (page 3968)
Returns a pasteboard type based on the passed file type. (Deprecated. The file contents pboard type allowed you to synthesize a pboard type for a file's contents based on the file's extension. Using the UTI of a file to represent its contents now replaces this functionality.)

`NSCreateFilenamePboardType` (page 3969)
Returns a pasteboard type based on the passed file type. (Deprecated. The file contents pboard type allowed you to synthesize a pboard type for a file's contents based on the file's extension. Using the UTI of a file to represent its contents now replaces this functionality.)

`NSGetFileType` (page 3985)
Returns a file type based on the passed pasteboard type. (Deprecated. The file contents pboard type allowed you to synthesize a pboard type for a file's contents based on the file's extension. Using the UTI of a file to represent its contents now replaces this functionality.)

`NSGetFileTypes` (page 3985)
Returns an array of file types based on the passed pasteboard types. (Deprecated. The file contents pboard type allowed you to synthesize a pboard type for a file's contents based on the file's extension. Using the UTI of a file to represent its contents now replaces this functionality.)

System Beep

Additional information on sounds can be found in `NSSound`.

`NSBeep` (page 3962)
Plays the system beep.

Functions

NSAccessibilityActionDescription

Returns a standard description for an action.

```
NSString * NSAccessibilityActionDescription (
   NSString *action
);
```

Discussion
This function returns a standard description for *action*.

Availability
Available in Mac OS X v10.4 and later.

Related Sample Code
Dicey
ImageMap
ImageMapExample

Declared In
`NSAccessibility.h`

NSAccessibilityPostNotification

Sends a notification to any observing assistive applications.

```
void NSAccessibilityPostNotification (
   id element,
   NSString *notification
);
```

Discussion
Sends *notification* to any assistive applications that have registered to receive the notification from the user interface object *element* in your application. Accessibility notifications require special handling, so they cannot be posted using `NSNotificationCenter`.

Availability
Available in Mac OS X v10.2 and later.

Related Sample Code
Dicey
Sketch+Accessibility
TrackBall

Declared In
`NSAccessibility.h`

NSAccessibilityRaiseBadArgumentException

Raises an error if the parameter is the wrong type or has an illegal value

```
void NSAccessibilityRaiseBadArgumentException (
   id element,
   NSString *attribute,
   id value
);
```

Discussion
Raises an error if a parameter is the wrong type or has an illegal value. This function can also be used to raise an error if an attempt is made to set an attribute's value with the wrong type or an illegal value.

Availability
Available in Mac OS X v10.3 and later.

Related Sample Code
Sketch+Accessibility

Declared In
`NSAccessibility.h`

NSAccessibilityRoleDescription

Returns a standard description for a role and subrole.

```
NSString * NSAccessibilityRoleDescription (
   NSString *role,
   NSString *subrole
);
```

Discussion
You should pass nil to this function if there is no subrole. This function returns a description of a standard role. For example, if you implement a button widget that does not inherit from `NSButton`, you should use this function to return a localized role description matching that returned by a standard button.

Availability
Available in Mac OS X v10.4 and later.

Related Sample Code
Dicey
ImageMap
ImageMapExample
Sketch+Accessibility
ZipBrowser

Declared In
`NSAccessibility.h`

NSAccessibilityRoleDescriptionForUIElement

Returns a standard role description for a user interface element.

```
NSString * NSAccessibilityRoleDescriptionForUIElement (
   id element
);
```

Discussion
This function is like the `NSAccessibilityRoleDescription` (page 3957) function, except that it queries *`element`* to get the role and subrole. The `NSAccessibilityRoleDescription` function is more efficient, but this function is useful for accessorizing base classes so that they properly handle derived classes, which may override the subrole or even the role.

Availability
Available in Mac OS X v10.4 and later.

Related Sample Code
ImageMap
ImageMapExample

Declared In
`NSAccessibility.h`

NSAccessibilityUnignoredAncestor

Returns an unignored accessibility object, ascending the hierarchy if necessary.

```
id NSAccessibilityUnignoredAncestor (
    id element
);
```

Discussion
Tests whether *element* is an ignored object, returning either *element*, if it is not ignored, or the first unignored ancestor of *element*.

Availability
Available in Mac OS X v10.2 and later.

Related Sample Code
ImageMap
ImageMapExample
Sketch+Accessibility
TrackBall
ZipBrowser

Declared In
NSAccessibility.h

NSAccessibilityUnignoredChildren

Returns a list of unignored accessibility objects, descending the hierarchy if necessary.

```
NSArray * NSAccessibilityUnignoredChildren (
   NSArray *originalChildren
);
```

Discussion
Returns a copy of *originalChildren* with any ignored objects in the array replaced by their unignored descendants.

Availability
Available in Mac OS X v10.2 and later.

Related Sample Code
Dicey
ImageMap
ImageMapExample

Declared In
NSAccessibility.h

NSAccessibilityUnignoredChildrenForOnlyChild

Returns a list of unignored accessibility objects, descending the hierarchy if necessary.

```
NSArray * NSAccessibilityUnignoredChildrenForOnlyChild (
   id originalChild
);
```

Discussion
Tests whether *originalChild* is an ignored object and returns an array containing either *originalChild*, if it is not ignored, or its unignored descendants.

Availability
Available in Mac OS X v10.2 and later.

Declared In
NSAccessibility.h

NSAccessibilityUnignoredDescendant

Returns an unignored accessibility object, descending the hierarchy if necessary.

```
id NSAccessibilityUnignoredDescendant (
   id element
);
```

Discussion
Tests whether *element* is an ignored object, returning either *element*, if it is not ignored, or the first unignored descendant of *element*. Use this function only if you know there is a linear, one-to-one, hierarchy below *element*. Otherwise, if *element* has either no unignored children or multiple unignored children, this function fails and returns nil.

Availability
Available in Mac OS X v10.2 and later.

Related Sample Code
ImageMap
ImageMapExample

Declared In
NSAccessibility.h

NSApplicationLoad

Startup function to call when running Cocoa code from a Carbon application.

```
BOOL NSApplicationLoad (void);
```

Return Value
YES if the NSApplication object was successfully initialized and can now be used from your Carbon application or NO if there was an error during initialization.

Discussion
You typically call this function before calling other Cocoa code in a plug-in loaded into a primarily Carbon application. If the shared NSApplication object is not already initialized, this function initializes it and sets up the necessary event handlers for Cocoa.

Availability
Available in Mac OS X v10.2 and later.

Related Sample Code
SpellingChecker-CocoaCarbon

Declared In
`NSApplication.h`

NSApplicationMain

Called by the main function to create and run the application.

```
int NSApplicationMain (
   int argc,
   const char *argv[]
);
```

Parameters

argc

The number of arguments in the argv parameter.

argv

An array of pointers containing the arguments that were passed to the application at startup.

Return Value
This method never returns a result code. Instead, it calls the `exit` function to exit the application and terminate the process. If you want to determine why the application exited, you should look at the result code from the `exit` function instead.

Discussion
Creates the application, loads the main nib file from the application's main bundle, and runs the application. You must call this function from the main thread of your application, and you typically call it only once from your application's `main` function, which is usually generated automatically by Xcode.

Special Considerations

`NSApplicationMain` itself ignores the *argc* and *argv* arguments. Instead, Cocoa gets its arguments indirectly via `_NSGetArgv`, `_NSGetArgc`, and `_NSGetEnviron` (see <crt_externs.h>).

Availability
Available in Mac OS X v10.0 and later.

ImageClient
ImageKitDemo
MyPhoto

Declared In
`NSApplication.h`

NSAvailableWindowDepths

Returns the available window depth values.

```
const NSWindowDepth * NSAvailableWindowDepths (void);
```

Discussion
Returns a null-terminated array of `NSWindowDepthâ  Window Depth` (page 3416) values that specify which window depths are currently available. Window depth values are converted to specific display properties using the functions `NSBitsPerPixelFromDepth` (page 3966), `NSBitsPerSampleFromDepth` (page 3966), `NSColorSpaceFromDepth` (page 3966), and `NSPlanarFromDepth` (page 3990).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSGraphics.h`

NSBeep

Plays the system beep.

```
void NSBeep (void);
```

Discussion
Plays the system beep. Users can select a sound to be played as the system beep. On a Macintosh computer, for example, you can change sounds with the Sound pane of System Preferences.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code

PDFKitLinker2
Quartz Composer WWDC 2005 TextEdit

Declared In
`NSGraphics.h`

NSBeginAlertSheet

Creates and runs an alert sheet.

```
void NSBeginAlertSheet (
   NSString *title,
   NSString *defaultButton,
   NSString *alternateButton,
   NSString *otherButton,
   NSWindow *docWindow,
   id modalDelegate,
   SEL didEndSelector,
   SEL didDismissSelector,
   void *contextInfo,
   NSString *msg,
   ...
);
```

Discussion
Creates and runs an alert sheet on *docWindow*, with the title of *title*, the text of *msg*, and buttons with titles of *defaultButton*, *alternateButton*, and *otherButton*.

The buttons are laid out on the lower-right corner of the sheet, with *defaultButton* on the right, *alternateButton* on the left, and *otherButton* in the middle. If *title* is `nil` or an empty string, a default localized title is used ("Alert" in English). If *defaultButton* is `nil` or an empty string, a default localized button title ("OK" in English) is used. For the remaining buttons, this function creates them only if their corresponding button title is non-`nil`.

A Command-D key equivalent for the "Don't Save" button is provided, if one is found. The button titles are searched for the localized value for "Don't Save." If a match is found, that button is assigned a Command-D key equivalent, provided it is not the default button.

If you create a modal panel using `runModalForWindow:` (page 163) or `beginSheet:modalForWindow:modalDelegate:didEndSelector:contextInfo:` (page 140), you can assign the key equivalent yourself, using `setKeyEquivalent:` (page 483) and `setKeyEquivalentModifierMask:` (page 484).

The *msg* argument is the message that's displayed in the panel. It can use printf-style formatting characters; any necessary arguments should be listed at the end of the function's argument list (after the *msg* argument). For more information on formatting characters, see the man page for `printf`.

When the modal session is ended, and before the sheet is dismissed, the *didEndSelector* is invoked on the *modalDelegate*. passing *contextInfo*. After the sheet is dismissed, the *didDismissSelector* is invoked on the *modalDelegate*, passing *contextInfo*. Typically, you will want to implement the *didEndSelector* but you may pass `NULL` for the *didDismissSelector*. The two selectors should be defined as follows:

```
sheetDidEnd:(NSWindow *)sheet returnCode:(int)returnCode contextInfo:(void
*)contextInfo;
sheetDidDismiss:(NSWindow *)sheet returnCode:(int)returnCode contextInfo:(void
  *)contextInfo;
```

where *sheet* is the alert sheet, *returnCode* specifies which button the user pressed, and *contextInfo* is the same *contextInfo* passed into `NSBeginAlertSheet`. *returnCode* can be one of the following:

- `NSAlertDefaultReturn` means the user pressed the default button.
- `NSAlertAlternateReturn` means the user pressed the alternate button.
- `NSAlertOtherReturn` means the user pressed the other button.

- `NSAlertErrorReturn` means an error occurred while running the alert panel.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
ImageClient
PrefsPane
QTAudioExtractionPanel
QTKitPlayer
Quartz Composer WWDC 2005 TextEdit

Declared In
`NSPanel.h`

NSBeginCriticalAlertSheet

Creates and runs a critical alert sheet.

```
void NSBeginCriticalAlertSheet (
   NSString *title,
   NSString *defaultButton,
   NSString *alternateButton,
   NSString *otherButton,
   NSWindow *docWindow,
   id modalDelegate,
   SEL didEndSelector,
   SEL didDismissSelector,
   void *contextInfo,
   NSString *msg,
   ...
);
```

Discussion
Creates and runs a critical alert sheet on *docWindow*, with the title of *title*, the text of *msg*, and buttons with titles of *defaultButton*, *alternateButton*, and *otherButton*.

See the description of `NSBeginAlertSheet` (page 3962) for information on layout, default parameters, and the selectors.

The sheet presented to the user is badged with a caution icon. Critical alerts should be used only as specified in the "Alerts" section of the Windows chapter of *Apple Human Interface Guidelines*.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSPanel.h`

NSBeginInformationalAlertSheet

Creates and runs an informational alert sheet.

```
void NSBeginInformationalAlertSheet (
   NSString *title,
   NSString *defaultButton,
   NSString *alternateButton,
   NSString *otherButton,
   NSWindow *docWindow,
   id modalDelegate,
   SEL didEndSelector,
   SEL didDismissSelector,
   void *contextInfo,
   NSString *msg,
   ...
);
```

Discussion
Creates and runs an informational alert sheet on *docWindow*, with the title of *title*, the text of *msg*, and buttons with titles of *defaultButton*, *alternateButton*, and *otherButton*.

See the description of `NSBeginAlertSheet` (page 3962) for information on layout, default parameters, and the selectors.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
AutoSample
InstallerPluginSample
SimpleToolbar

Declared In
`NSPanel.h`

NSBestDepth

Attempts to return a window depth adequate for the specified parameters.

```
NSWindowDepth NSBestDepth (
   NSString *colorSpace,
   NSInteger bps,
   NSInteger bpp,
   BOOL planar,
   BOOL *exactMatch
);
```

Discussion
Returns a window depth deep enough for the given number of colors in *colorSpace*, bits per sample specified by *bps*, bits per pixel specified by *bpp*, and whether planar as specified by *planar*. Upon return, the variable pointed to by *exactMatch* is `YES` if the window depth can accommodate all of the values specified by the parameters, `NO` if it can't.

Use this function to compute window depths. This function tries to accommodate all the parameters (match or better); if there are multiple matches, it gives the closest, with matching *colorSpace* first, then *bps*, then *planar*, then *bpp*. *bpp* is "bits per pixel"; 0 indicates default (same as the number of bits per plane, either

bps or bps * NSNumberOfColorComponents (page 3988)); other values may be used as hints to provide backing stores of different configuration; for instance, 8-bit color. The *exactMatch* parameter is optional and indicates whether all the parameters matched exactly.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSGraphics.h

NSBitsPerPixelFromDepth

Returns the bits per pixel for the specified window depth.

```
NSInteger NSBitsPerPixelFromDepth (
   NSWindowDepth depth
);
```

Discussion
Returns the number of bits per pixel for the window depth specified by *depth*.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
GLUT

Declared In
NSGraphics.h

NSBitsPerSampleFromDepth

Returns the bits per sample for the specified window depth.

```
NSInteger NSBitsPerSampleFromDepth (
   NSWindowDepth depth
);
```

Discussion
Returns the number of bits per sample (bits per pixel in each color component) for the window depth specified by *depth*.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSGraphics.h

NSColorSpaceFromDepth

Returns the name of the color space corresponding to the passed window depth.

```
NSString * NSColorSpaceFromDepth (
   NSWindowDepth depth
);
```

Discussion
Returns the color space name for the specified *depth*. For example, the returned color space name can be `NSCalibratedRGBColorSpace`, or `NSDeviceCMYKColorSpace`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSGraphics.h`

NSConvertGlyphsToPackedGlyphs

Prepares a set of glyphs for processing by character-based routines.

```
NSInteger NSConvertGlyphsToPackedGlyphs (
   NSGlyph *glBuf,
   NSInteger count,
   NSMultibyteGlyphPacking packing,
   char *packedGlyphs
);
```

Discussion
Takes a buffer of glyphs, specified in the *glBuf* parameter, and packs them into a condensed character array. The character array is returned in the *packedGlyphs* parameter, which should have enough space for at least ((4 * count) + 1) bytes to guarantee that the packed glyphs fit. *count* specifies the number of glyphs in *glBuf*. *packing* specifies how the glyphs are currently packed.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSFont.h`

NSCopyBits

Copies a bitmap image to the location specified by a destination point.

```
void NSCopyBits (
   NSInteger srcGState,
   NSRect srcRect,
   NSPoint destPoint
);
```

Discussion
Copies the pixels in the rectangle specified by *srcRect* to the location specified by *destPoint*. The source rectangle is defined in the graphics state designated by *srcGState*. If *srcGState* is `NSNullObject`, the current graphics state is assumed. The *destPoint* destination is defined in the current graphics state.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSGraphics.h

NSCountWindows

Counts the number of onscreen windows.

```
void NSCountWindows (
   NSInteger *count
);
```

Parameters

count

On output, this parameter contains the number of onscreen windows.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSGraphics.h

NSCountWindowsForContext

Counts the number of onscreen windows belonging to a particular application.

```
void NSCountWindowsForContext (
   NSInteger context,
   NSInteger *count
);
```

Discussion
Counts the number of onscreen windows belonging to a particular application, identified by *context*, which is a window server connection ID. The function returns the number by reference in *count*.

Use of this function is discouraged as it may be deprecated in a future release.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSGraphics.h

NSCreateFileContentsPboardType

Returns a pasteboard type based on the passed file type. (Deprecated. The file contents pboard type allowed you to synthesize a pboard type for a file's contents based on the file's extension. Using the UTI of a file to represent its contents now replaces this functionality.)

```
NSString * NSCreateFileContentsPboardType (
   NSString *fileType
);
```

Discussion
Returns an NSString to a pasteboard type representing a file's contents based on the supplied string *fileType*. *fileType* should generally be the extension part of a filename. The conversion from a named file type to a pasteboard type is simple; no mapping to standard pasteboard types is attempted.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSPasteboard.h

NSCreateFilenamePboardType

Returns a pasteboard type based on the passed file type. (Deprecated. The file contents pboard type allowed you to synthesize a pboard type for a file's contents based on the file's extension. Using the UTI of a file to represent its contents now replaces this functionality.)

```
NSString * NSCreateFilenamePboardType (
   NSString *fileType
);
```

Discussion
Returns an NSString to a pasteboard type representing a filename based on the supplied string *fileType*.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSPasteboard.h

NSDisableScreenUpdates

Disables screen updates.

```
void NSDisableScreenUpdates (void);
```

Discussion
Prevents drawing operations from being flushed to the screen for all windows belonging to the calling process. When you re-enable screen updates (with NSEnableScreenUpdates (page 3980)) screen flushing for all windows belonging to the calling process appears to be simultaneous. You typically call this function so that operations on multiple windows appear atomic to the user. This is a technique particularly useful for synchronizing parent and child windows. Make sure that the period after calling this function and before reenabling updates is short; the system only allow updating to be disabled for a limited time (currently one second) before automatically reenabling updates. Successive calls to this function are placed on a stack and must be popped off that stack by matching NSEnableScreenUpdates calls.

Availability
Available in Mac OS X v10.3 and later.

`NSDrawTiledRects` (page 3978)

Declared In
NSGraphics.h

NSDrawBitmap

Draws a bitmap image.

```
void NSDrawBitmap (
   NSRect rect,
   NSInteger width,
   NSInteger height,
   NSInteger bps,
   NSInteger spp,
   NSInteger bpp,
   NSInteger bpr,
   BOOL isPlanar,
   BOOL hasAlpha,
   NSString *colorSpaceName,
   const unsigned char *const data[5]
);
```

Discussion
This function is marginally obsolete. Most applications are better served using the `NSBitmapImageRep` class to read and display bitmap images.

This function renders an image from a bitmap, binary data that describes the pixel values for the image.

This function renders a bitmap image using an appropriate display operator. It puts the image in the rectangular area specified by its first argument, *rect*; the rectangle is specified in the current coordinate system and is located in the current window. The next two arguments, *pixelsWide* and *pixelsHigh*, give the width and height of the image in pixels. If either of these dimensions is larger or smaller than the corresponding dimension of the destination rectangle, the image will be scaled to fit.

The remaining arguments describe the bitmap data, as explained in the following paragraphs.

The *bitsPerSample* argument is the number of bits per sample for each pixel and *samplesPerPixel* is the number of samples per pixel. *bitsPerPixel* is based on *samplesPerPixel* and the configuration of the bitmap: if the configuration is planar, then the value of *bitsPerPixel* should equal the value of *bitsPerSample*; if the configuration isn't planar (is meshed instead), *bitsPerPixel* should equal `bitsPerSample * samplesPerPixel`.

The *bytesPerRow* argument is calculated in one of two ways, depending on the configuration of the image data (data configuration is described below). If the data is planar, `bytesPerRow is (7 + (pixelsWide * bitsPerSample)) / 8`. If the data is meshed, `bytesPerRow is (7 + (pixelsWide * bitsPerSample * samplesPerPixel)) / 8`.

A sample is data that describes one component of a pixel. In an RGB color system, the red, green, and blue components of a color are specified as separate samples, as are the cyan, magenta, yellow, and black components in a CMYK system. Color values in a grayscale are a single sample. Alpha values that determine transparency and opaqueness are specified as a coverage sample separate from color. In bitmap images with alpha, the color (or gray) components have to be premultiplied with the alpha. This is the way images with alpha are displayed, this is the way they are read back, and this is the way they are stored in TIFFs.

The *isPlanar* argument refers to the way data is configured in the bitmap. This flag should be set to `YES` if a separate data channel is used for each sample. The function provides for up to five channels, *data1*, *data2*, *data3*, *data4*, and *data5*. It should be set `NO` if sample values are interwoven in a single channel (meshed); all values for one pixel are specified before values for the next pixel.

Grayscale windows store pixel data in planar configuration; color windows store it in meshed configuration. `NSDrawBitmap` can render meshed data in a planar window, or planar data in a meshed window. However, it's more efficient if the image has a depth (*bitsPerSample*) and configuration (*isPlanar*) that match the window.

The *hasAlpha* argument indicates whether the image contains alpha. If it does, the number of samples should be 1 greater than the number of color components in the model (for example, 4 for RGB).

The *colorSpace* argument can be `NSCustomColorSpace`, indicating that the image data is to be interpreted according to the current color space in the graphics state. This allows for imaging using custom color spaces. The image parameters supplied as the other arguments should match what the color space is expecting.

If the image data is planar, *data*[0] through *data*[*samplesPerPixel*–1] point to the planes; if the *data* is meshed, only *data*[0] needs to be set.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSGraphics.h`

NSDrawButton

Draws a gray-filled rectangle representing a user-interface button.

```
void NSDrawButton (
   NSRect aRect,
   NSRect clipRect
);
```

Parameters

aRect

The bounding rectangle (in the current coordinate system) in which to draw. Only those parts of *aRect* that lie within the *clipRect* are actually drawn.

clipRect

The clipping rectangle to use during drawing.

Discussion

Draws a gray-filled rectangle, used to signify a user-interface button. Since this function is often used to draw the border of a view, the *aRect* parameter typically contains the view's bounds rectangle. For an Aqua button, use an `NSButton` object instead.

This function fills the specified rectangle with light gray. This function is designed for rectangles that are defined in unscaled, unrotated coordinate systems (that is, where the y axis is vertical, the x axis is horizontal, and a unit along either axis is equal to 1 screen pixel). The coordinate system can be either flipped or unflipped. The sides of the rectangle should lie on pixel boundaries.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSGraphics.h`

NSDrawColorTiledRects

Draws a colored bordered rectangle.

```
NSRect NSDrawColorTiledRects (
   NSRect boundsRect,
   NSRect clipRect,
   const NSRectEdge *sides,
   NSColor **colors,
   NSInteger count
);
```

Parameters

boundsRect

The bounding rectangle (in the current coordinate system) in which to draw. Since this function is often used to draw the border of a view, this rectangle will typically be that view's bounds rectangle. Only those parts of *boundsRect* that lie within the *clipRect* are actually drawn.

clipRect

The clipping rectangle to use during drawing.

sides

The sides of the rectangle for which you want to specify custom colors. Each side must have a corresponding entry in the *colors* parameter.

colors
The colors to draw for each of the edges listed in the *sides* parameter.

count
The number of 1.0-unit-wide slices to draw on the specified sides.

Return Value
The rectangle that lies within the resulting border.

Discussion
Behaves the same as `NSDrawTiledRects` (page 3978) except it draws its border using colors from the *colors* array.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSGraphics.h`

NSDrawDarkBezel

Draws a dark gray-filled rectangle with a bezel border.

```
void NSDrawDarkBezel (
   NSRect aRect,
   NSRect clipRect
);
```

Parameters

aRect
The bounding rectangle (in the current coordinate system) in which to draw. Only those parts of *aRect* that lie within the *clipRect* are actually drawn.

clipRect
The clipping rectangle to use during drawing.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSGraphics.h

NSDrawNinePartImage

Draws a nine-part tiled image.

```
void NSDrawNinePartImage(NSRect frame,
   NSImage *topLeftCorner,
   NSImage *topEdgeFill,
   NSImage *topRightCorner,
   NSImage *leftEdgeFill,
   NSImage *centerFill,
   NSImage *rightEdgeFill,
   NSImage *bottomLeftCorner,
   NSImage *bottomEdgeFill,
   NSImage *bottomRightCorner,
   NSCompositingOperation op,
   CGFloat alphaFraction,
   BOOL flipped
);
```

Parameters

frame

The rectangle (specified in the current coordinate system) in which to draw the images.

topLeftCorner

The image to display in the top-left corner.

topEdgeFill

The image used to tile the space between the *topLeftCorner* and *topRightCorner* images.

topRightCorner

The image to display in the top-right corner.

leftEdgeFill
The image used to tile the space between the *topLeftCorner* and *bottomLeftCorner* images.

centerFill
The image used to tile the center area between the other eight images.

rightEdgeFill
The image used to tile the space between the *topRightCorner* and *bottomRightCorner* images.

bottomLeftCorner
The image to display in the bottom-left corner.

bottomEdgeFill
The image used to tile the space between the *bottomLeftCorner* and *bottomRightCorner* images.

bottomRightCorner
The image to display in the bottom-right corner.

op
The compositing operation to use when rendering the images.

alphaFraction
The alpha value to apply to the rendered image. This value can range between 0.0 and 1.0, with 0.0 being fully transparent and 1.0 being fully opaque.

flipped
Specify `YES` if you are drawing the images in a flipped coordinate system; otherwise, specify `NO`.

Discussion
This function is typically used to draw custom cells that are capable of being resized both vertically and horizontally. Cells of this type are comprised of four fixed-size corner images along and a set of edge and center images that are used to fill the gaps between the corners. These cells allow you to create sophisticated looking controls that can grow and shrink in any direction without distorting the control's overall appearance.

You should prefer the use of this function over your own custom code for handling multi-part images whose size can change. This function correctly manages the subtle behaviors needed to handle resolution independence issues and to avoid visual artifacts caused by tiling the various images.

This function uses the top-left and bottom-right corner images to determine the widths and heights of the edge areas that need to be filled. If the width or height of the bottom-left and top-right images are not sized appropriately, they may be scaled to fill their corner area. Edge areas between the corners are tiled using the corresponding image. Similarly, the center area is tiled using the specified center image.

The *flipped* parameter lets you reorient the contents of each image when drawing in a flipped coordinate system. By default, images use an internal coordinate system that is not flipped. Rendering such an image in a flipped coordinate system would therefore cause the image to appear upside down. Passing `YES` for the *flipped* parameter adjusts the image's internal coordinate system to draw it correctly in a flipped environment.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`NSCell.h`

NSDrawThreePartImage

Draws a three-part tiled image.

```
void NSDrawThreePartImage(NSRect frame,
   NSImage *startCap,
   NSImage *centerFill,
   NSImage *endCap,
   BOOL vertical,
   NSCompositingOperation op,
   CGFloat alphaFraction,
   BOOL flipped
);
```

Parameters

frame

The rectangle (specified in the current coordinate system) in which to draw the images.

startCap

For a horizontal three-part image, this is the image located at the left edge of the frame rectangle. For a vertical three-part image, this image appears at the top of the screen in an unflipped coordinate system and at the bottom of the screen in a flipped coordinate system.

centerFill

The image used to tile the space between the *startCap* and *endCap* images.

endCap

For a horizontal three-part image, this is the image located at the right edge of the frame rectangle. For a vertical three-part image, this image appears at the bottom of the screen in an unflipped coordinate system and at the top of the screen in a flipped coordinate system.

vertical

Specify `YES` if the images should be stacked on top of one another to create a vertically oriented element. Specify `NO` if the images should be laid out side-by-side to create a horizontally oriented element.

op

The compositing operation to use when rendering the images.

alphaFraction

The alpha value to apply to the rendered image. This value can range between 0.0 and 1.0, with 0.0 being fully transparent and 1.0 being fully opaque.

flipped

Specify `YES` if you are drawing the images in a flipped coordinate system; otherwise, specify `NO`.

Discussion

This function is typically used to draw custom cells (such as the backgrounds for push button and slider controls) that are capable of being resized along a single axis only. Cells of this type are comprised of fixed-size end cap images and a center area that is filled by tiling the specified center image as many times as needed to fill the gap. These cells allow you to create sophisticated looking controls that can grow and shrink without distorting the control's overall appearance.

You should prefer the use of this function over your own custom code for handling multi-part images whose size can change. This function correctly manages the subtle behaviors needed to handle resolution independence issues and to avoid visual artifacts caused by tiling the various images.

When drawing a horizontally oriented control, the images in the *startCap*, *centerFill*, and *endCap* parameters should all have the same height, and that height should match the height of the frame rectangle. If an image's height does not match the height of the frame rectangle, it is scaled until it does match, which might yield less desirable results. For vertically oriented controls, the image widths are scaled instead of the heights.

The *flipped* parameter lets you reorient the contents of each image when drawing in a flipped coordinate system. By default, images use an internal coordinate system that is not flipped. Rendering such an image in a flipped coordinate system would therefore cause the image to appear upside down. Passing YES for the *flipped* parameter adjusts the image's internal coordinate system to draw it correctly in a flipped environment.

Availability
Available in Mac OS X v10.5 and later.

Declared In
NSCell.h

NSDrawTiledRects

Draws rectangles with borders.

```
NSRect NSDrawTiledRects (
   NSRect boundsRect,
   NSRect clipRect,
   const NSRectEdge *sides,
   const CGFloat *grays,
   NSInteger count
);
```

Parameters

boundsRect
The bounding rectangle (in the current coordinate system) in which to draw. Since this function is often used to draw the border of a view, this rectangle will typically be that view's bounds rectangle. Only those parts of *boundsRect* that lie within the *clipRect* are actually drawn.

clipRect
The clipping rectangle to use during drawing.

sides
The sides of the rectangle for which you want to specify custom gray levels. Each side must have a corresponding entry in the *grays* parameter.

grays
The gray levels to draw for each of the edges listed in the *sides* parameter.

count
The number of 1.0-unit-wide slices to draw on the specified sides.

Return Value
The rectangle that lies within the resulting border.

Discussion
This is a generic function that can be used to draw different types of borders inside a given rectangle. These borders can be used to outline an area or to give rectangles the effect of being recessed from or elevated above the surface of the screen.

The *sides*, *grays*, and *count* parameters determine how thick the border is and what gray levels are used to form it. This function uses the NSDivideRect function to take successive 1.0-unit-wide slices from the sides of the rectangle specified by the *sides* parameter. Each slice is drawn using the corresponding gray level from the *grays* parameter. This function makes and draws these slices *count* number of times. If you specify the same side more than once, the second slice is drawn inside the first.

The following example uses this function to draw a bezeled border consisting of a 1.0–unit-wide white line at the top and on the left side and a 1.0-unit-wide dark-gray line inside a 1.0–unit-wide black line on the other two sides. The resulting rectangle inside this border is then filled in using light gray.

```
NSRectEdge mySides[] = {NSMinYEdge, NSMaxXEdge, NSMaxYEdge, NSMinXEdge,
                        NSMinYEdge, NSMaxXEdge};
float myGrays[] = {NSBlack, NSBlack, NSWhite, NSWhite,
                        NSDarkGray, NSDarkGray};
NSRect aRect, clipRect; // Assume exists

aRect = NSDrawTiledRects(aRect, clipRect, mySides, myGrays, 6);
[[NSColor grayColor] set];
NSRectFill(aRect);
```

In the preceding example, *mySides* is an array that specifies sides of a rectangle; for example, `NSMinYEdge` selects the side parallel to the x axis with the smallest y coordinate value. *myGrays* is an array that specifies the successive gray levels to be used in drawing parts of the border.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSGraphics.h`

NSDrawWhiteBezel

Draws a white-filled rectangle with a bezel border.

```
void NSDrawWhiteBezel (
   NSRect aRect,
   NSRect clipRect
);
```

Parameters

aRect

The bounding rectangle (in the current coordinate system) in which to draw. Only those parts of *aRect* that lie within the *clipRect* are actually drawn.

clipRect

The clipping rectangle to use during drawing.

Availability
Available in Mac OS X v10.0 and later.

NSEventMaskFromType

Returns the event mask for the specified type.

```
static NSUInteger NSEventMaskFromType (
   NSEventType type
);
```

Parameters

type

The event type whose mask you want to get.

Return Value
The event mask corresponding to the specified type. The returned mask is equivalent to the number 1 left-shifted by *type* bits.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
Quartz Composer Matrix

Declared In
`NSEvent.h`

NSFrameRect

Draw a bordered rectangle.

```
void NSFrameRect (
   NSRect aRect
);
```

Parameters

aRect

The bounding rectangle (in the current coordinate system) in which to draw.

Discussion
Draws a frame around the inside of *aRect* in the current color and using the `NSCompositeCopy` compositing operation. The width is equal to 1.0 in the current coordinate system. Since the frame is drawn inside the rectangle, it will be visible even if drawing is clipped to the rectangle.

Because this function does not draw directly on the line, but rather inside it, it uses the current fill color (not stroke color) when drawing.

For a list of compositing operations and how you use them, see *Cocoa Drawing Guide*.

Availability
Available in Mac OS X v10.0 and later.

NSFrameRectWithWidthUsingOperation

Draw a bordered rectangle using the specified compositing operation.

```
void NSFrameRectWithWidthUsingOperation (
   NSRect aRect,
   CGFloat frameWidth,
   NSCompositingOperation op
);
```

Parameters

aRect

The bounding rectangle (in the current coordinate system) in which to draw.

frameWidth

The width of the frame, specified in points.

op

The compositing operation to use when drawing the frame.

Discussion

Draws a frame around the inside of *aRect* in the current color, using the compositing operation *op*. The width is equal to *frameWidth* in the current coordinate system. Since the frame is drawn inside the rectangle, it will be visible even if drawing is clipped to the rectangle.

Because this function does not draw directly on the line, but rather inside it, it uses the current fill color (not stroke color) when drawing.

For a list of compositing operations and how you use them, see *Cocoa Drawing Guide*.

NSGetAlertPanel

Returns an alert panel.

```
id NSGetAlertPanel (
   NSString *title,
   NSString *msg,
   NSString *defaultButton,
   NSString *alternateButton,
   NSString *otherButton,
   ...
);
```

Discussion
Returns an `NSPanel` that can be used to set up a modal session. A modal session is useful for allowing the user to interrupt the program. During a modal session, you can perform activities while the panel is displayed and check at various points in your program whether the user has clicked one of the panel's buttons. The arguments for this function are the same as those for `NSRunAlertPanel` (page 3998), but unlike that function, no button is displayed if *`defaultButton`* is `nil`.

To set up a modal session, send the Application object `beginModalSessionForWindow:` (page 139) with the panel returned by `NSGetAlertPanel` as its argument. When you want to check if the user has clicked one of the panel's buttons, use `runModalSession:` (page 164). To end the modal session, use `endModalSession:` (page 146). When you're finished with the panel created by `NSGetAlertPanel`, you must free it by passing it to `NSReleaseAlertPanel` (page 3998).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSPanel.h`

NSGetCriticalAlertPanel

Returns an alert panel to display a critical message.

```
id NSGetCriticalAlertPanel (
   NSString *title,
   NSString *msg,
   NSString *defaultButton,
   NSString *alternateButton,
   NSString *otherButton,
   ...
);
```

Discussion
Returns an `NSPanel` that can be used to set up a modal session. No button is displayed if *`defaultButton`* is `nil`. When you're finished with the panel created by this function, you must free it by passing it to `NSReleaseAlertPanel` (page 3998).

The arguments for this function are the same as those for the `NSGetAlertPanel` (page 3983). For more information on using a panel in a modal session, see `NSGetAlertPanel`.

The panel presented to the user is badged with a caution icon. Critical alerts should be used only as specified in the "Alerts" section of the Windows chapter of *Apple Human Interface Guidelines*.

Availability
Available in Mac OS X v10.0 and later.

NSPanel.h

NSGetFileType

Returns a file type based on the passed pasteboard type. (Deprecated. The file contents pboard type allowed you to synthesize a pboard type for a file's contents based on the file's extension. Using the UTI of a file to represent its contents now replaces this functionality.)

```
NSString * NSGetFileType (
   NSString *pboardType
);
```

Discussion
This function is the inverse of both `NSCreateFileContentsPboardType` (page 3968) and `NSCreateFilenamePboardType` (page 3969). When passed a pasteboard type as returned by those functions, it returns the extension or filename from which the type was derived. It returns `nil` if *pboardType* isn't a pasteboard type created by those functions.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSPasteboard.h

NSGetFileTypes

Returns an array of file types based on the passed pasteboard types. (Deprecated. The file contents pboard type allowed you to synthesize a pboard type for a file's contents based on the file's extension. Using the UTI of a file to represent its contents now replaces this functionality.)

```
NSArray * NSGetFileTypes (
   NSArray *pboardTypes
);
```

Discussion
Accepts a null-terminated array of pointers to pasteboard types and returns a null-terminated array of the unique extensions and filenames from the file content and filename types found in the input array. It returns `nil` if the input array contains no file content or filename types. The returned array is allocated and must be freed by the caller. The pointers in the return array point into strings passed in the input array.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSPasteboard.h

NSGetInformationalAlertPanel

Returns an alert panel to display an informational message.

```
id NSGetInformationalAlertPanel (
   NSString *title,
   NSString *msg,
   NSString *defaultButton,
   NSString *alternateButton,
   NSString *otherButton,
   ...
);
```

Discussion
Returns an NSPanel that can be used to set up a modal session. No button is displayed if *defaultButton* is `nil`. When you're finished with the panel created by this function, you must free it by passing it to `NSReleaseAlertPanel` (page 3998).

The arguments for this function are the same as those for the `NSRunAlertPanel` (page 3998) function. For more information on using a panel in a modal session, see `NSGetAlertPanel` (page 3983).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSPanel.h`

NSGetWindowServerMemory

Returns the amount of memory being used by a context.

```
NSInteger NSGetWindowServerMemory (
   NSInteger context,
   NSInteger *virtualMemory,
   NSInteger *windowBackingMemory,
   NSString **windowDumpString
);
```

Discussion
Calculates the amount of memory being used at the moment by the given *context*. If `NULL` is passed for *context*, the current context is used. The amount of virtual memory used by the current context is returned in the int pointed to by *virtualMemory*; the amount of window backing store used by windows owned by the current context is returned in the int pointed to by *windowBackingMemory*. The sum of these two numbers is the amount of the memory that this context is responsible for.

Calculating these numbers takes some time to execute; thus, calling this function in normal operation is not recommended.

If `nil` is not passed in for *windowDumpStream*, the information returned is echoed to the specified stream. This fact can be useful for finding out more about which windows are using up your storage.

Normally, `NSGetWindowServerMemory` returns 0. If `NULL` is passed for *context* and there's no current display context, this function returns –1.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSGraphics.h`

NSHighlightRect

Highlights the specified rect by filling it with white.

```
void NSHighlightRect (
   NSRect aRect
);
```

Parameters

aRect

The bounding rectangle (in the current coordinate system) in which to draw.

Discussion

Highlights the rectangle referred to by *aRect*. Light gray becomes white, and white becomes light gray. This function must be called twice, once to highlight the rectangle and once to unhighlight it; the rectangle should not be left in its highlighted state. When not drawing on the screen, the compositing operation is replaced by one that fills the rectangle with light gray.

Availability

Available in Mac OS X v10.0 and later.

Declared In

NSGraphics.h

NSInterfaceStyleForKey

Returns an interface style value for the specified key and responder.

```
NSInterfaceStyle NSInterfaceStyleForKey (
   NSString *key,
   NSResponder *responder
);
```

Discussion

Used to determine an interface style based on a key and a responder, either of which may be `nil`. An `NSInterfaceStyle` (page 4009) value specifies the style in which an interface item, such as a button or a scroll bar, should be drawn. For example, a value of `NSMacintoshInterfaceStyle` indicates an item should be drawn in the Macintosh style. The values defined for `NSInterfaceStyle` are `NSNoInterfaceStyle`, `NSNextStepInterfaceStyle`, `NSWindows95InterfaceStyle`, and `NSMacintoshInterfaceStyle`. Note that this function never returns `NSNoInterfaceStyle`.

The interface style value returned by this function depends on several factors. If responder is not `nil` and if responder specifies an interface style other than `NSNoInterfaceStyle`, this function returns the responder's style, and *key* is ignored.

Otherwise, if *key* is not `nil` and there is an interface style for *key* specified by the defaults system, this function returns the interface style for *key* from the defaults system.

Finally, if *key* is `nil`, or if there is no interface style for *key* specified by the defaults system, this function returns the global interface style specified by the defaults system.

The defaults system allows an application to customize its behavior to match a user's preferences. You can read about the defaults system in the documentation for `NSUserDefaults`.

Availability

Available in Mac OS X v10.0 and later.

Related Sample Code
Quartz Composer WWDC 2005 TextEdit

Declared In
`NSInterfaceStyle.h`

NSIsControllerMarker

Tests whether a given object is special marker object used for indicating the state of a selection in relation to a key.

```
BOOL NSIsControllerMarker (
   id object
);
```

Parameters

Term

Specify the object you want to check. This parameter can be `nil`.

Return Value
`YES` if the object is one of the designated controller markers or `NO` if it is not.

Discussion
This function helps you to create bindings between user interface elements and controller objects. The Application Kit predefines several special marker objects used as values for indicating selection state; currently these are `NSMultipleValuesMarker`, `NSNoSelectionMarker`, and `NSNotApplicableMarker`. These markers are typed as `id` and only exist for the purpose of indicating a state; they are never archived and cannot be used as object values in controls. You use this function to test whether a given object value is a marker, in which case it is not directly assignable to the object that is bound. This check is important, especially since additional markers may be added in the future.

See the `NSKeyValueBinding.h` header file for further details.

Availability
Available in Mac OS X v10.3 and later.

Related Sample Code
CoreRecipes

Declared In
`NSKeyValueBinding.h`

NSNumberOfColorComponents

Returns the number of color components in the specified color space.

```
NSInteger NSNumberOfColorComponents (
   NSString *colorSpaceName
);
```

Discussion
Returns the number of color components in the color space whose name is provided by `colorSpaceName`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSGraphics.h

NSOpenGLGetOption

Returns global OpenGL options.

```
void NSOpenGLGetOption (
   NSOpenGLGlobalOption pname,
   GLint *param
);
```

Discussion
Returns in *param* the value of the global OpenGL parameter *pname*. The available options are enumerated by the NSOpenGLGlobalOption (page 4011) type.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSOpenGL.h

NSOpenGLGetVersion

Returns the NSOpenGL version numbers.

```
void NSOpenGLGetVersion (
   GLint *major,
   GLint *minor
);
```

Discussion
Returns by reference the major and minor version numbers of the NSOpenGL implementation. This function is not the same as the OpenGL version.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSOpenGL.h

NSOpenGLSetOption

Sets global OpenGL options.

```
void NSOpenGLSetOption (
   NSOpenGLGlobalOption pname,
   GLint param
);
```

Discussion
Sets the value of the global OpenGL parameter *pname* to *param*. The available options are enumerated by the `NSOpenGLGlobalOption` (page 4011) type.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSOpenGL.h`

NSPerformService

Programmatically invokes a Services menu service.

```
BOOL NSPerformService (
   NSString *itemName,
   NSPasteboard *pboard
);
```

Parameters

itemName

Specifies a Services menu item, in any language. If the requested service is from a submenu of the Services menu, the value must contain a slash (for example, “Mail/Selection”).

pboard

The pasteboard containing the data required by the service. This data must be present for the service to succeed. On output, this pasteboard contains the data returned by the service provider.

Return Value
`YES` if the service was successfully performed or `NO` if it was not.

Discussion
Use this function to programmatically invoke a service found in the application’s Services menu.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
PhotoSearch

Declared In
`NSApplication.h`

NSPlanarFromDepth

Returns whether the specified window depth is planar.

```
BOOL NSPlanarFromDepth (
   NSWindowDepth depth
);
```

Discussion
Returns `YES` if the specified window *`depth`* is planar and `NO` if it is not.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSGraphics.h`

NSReadPixel

Reads the color of the pixel at the specified location.

```
NSColor * NSReadPixel (
   NSPoint passedPoint
);
```

Parameters

`passedPoint`

The pixel location to read, specified in the current coordinate system.

Return Value
The color of the pixel at the specified location.

Discussion
Because the *`passedPoint`* parameter is relative to the current coordinate system, if you wish to read a pixel from a specific view, you must convert points in the view's coordinate system to the current coordinate system before calling this function. Alternatively, you can lock focus on the view and then specify the pixel coordinate in the view's coordinate system.

When mapping the specified point to pixel boundaries, this method rounds to the nearest pixel. For more information on how coordinate points map to the underlying pixels, see Coordinate Systems and Transforms in *Cocoa Drawing Guide*.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
Color Sampler
Monochrome Image

Declared In
`NSGraphics.h`

NSRectClip

Modifies the current clipping path by intersecting it with the passed rect.

```
void NSRectClip (
   NSRect aRect
);
```

Parameters

aRect

The rectangle to intersect with the current clipping rectangle.

Discussion
This function modifies the clipping path permanently. If you need to undo this modification later, you should save the current graphics state before calling this function and restore it once you are done.

A side effect of this function is that it clears the current Quartz 2D drawing path information. If you used Quartz 2D functions to create a drawing path in the current context, and you want to save that path information and use it later, you should transfer it to a `CGPathRef` opaque type before calling this function. If you are using only Cocoa to do your drawing, this behavior should not affect you.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
Aperture Edit Plugin - Borders & Titles
Rulers
SampleRaster

Declared In
`NSGraphics.h`

NSRectClipList

Modifies the current clipping path by intersecting it with the passed rect.

```
void NSRectClipList (
   const NSRect *rects,
   NSInteger count
);
```

Parameters

rects

A pointer to an array of `NSRect` structures, which are combined and intersected with the current clipping path.

count

The number of rectangles in *rects*.

Discussion
This function modifies the clipping path permanently by generating a graphical union of the specified rectangles and then intersecting that union with the current clipping path. If you need to undo this modification later, you should save the current graphics state before calling this function and restore it once you are done.

A side effect of this function is that it clears the current Quartz 2D drawing path information. If you used Quartz 2D functions to create a drawing path in the current context, and you want to save that path information and use it later, you should transfer it to a `CGPathRef` opaque type before calling this function. If you are using only Cocoa to do your drawing, this behavior should not affect you.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSGraphics.h

NSRectFill

Fills the passed rectangle with the current color.

```
void NSRectFill (
   NSRect aRect
);
```

Parameters

aRect

The bounding rectangle (in the current coordinate system) in which to draw.

Discussion
Fills *aRect* with the current color using the compositing mode `NSCompositeCopy` (page 1376), which fills with the current color by copying the RGBA values. Use `NSRectFillUsingOperation` (page 3997) to fill specifying a compositing mode.

For a list of compositing operations and how you use them, see *Cocoa Drawing Guide*.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
CocoaSlides
FilterDemo
Quartz Composer WWDC 2005 TextEdit
Sketch+Accessibility
Sketch-112

Declared In
NSGraphics.h

NSRectFillList

Fills the rectangles in the passed list with the current fill color.

```
void NSRectFillList (
   const NSRect *rects,
   NSInteger count
);
```

Parameters

rects

A pointer to an array of `NSRect` structures representing the rectangles to fill.

count

The number of rectangles in *rects*.

Discussion
Fills the specified rectangles with the current fill color using the compositing mode `NSCompositeCopy`.

For a list of compositing operations and how you use them, see *Cocoa Drawing Guide*.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSGraphics.h`

NSRectFillListUsingOperation

Fills the rectangles in a list using the current fill color and specified compositing operation.

```
void NSRectFillListUsingOperation (
   const NSRect *rects,
   NSInteger count,
   NSCompositingOperation op
);
```

Parameters

rects
: A pointer to an array of `NSRect` structures representing the rectangles to fill.

count
: The number of rectangles in the *rects* parameter.

op
: The compositing operation to use when filling the rectangles.

Discussion
Fills a list of *count* rectangles with the current fill color, using the compositing operation *op*. For example, specifying `NSCompositeSourceOver` (page 1376) will blend with what's already been drawn.

For a list of compositing operations and how you use them, see *Cocoa Drawing Guide*.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
iChatTheater

Declared In
`NSGraphics.h`

NSRectFillListWithColors

Fills the rectangles in the passed list with the passed list of colors.

```
void NSRectFillListWithColors (
   const NSRect *rects,
   NSColor **colors,
   NSInteger num
);
```

Parameters

rects

A pointer to an array of `NSRect` structures representing the rectangles to fill.

colors

A pointer to an array of `NSColor` objects. The number of color objects in this parameter must equal the number of rectangles in the *rects* parameter.

num

The number of rectangles in the *rects* parameter.

Discussion

Takes a list of *num* rectangles and a matching list of color objects. The first rectangle is filled with the first color, the second rectangle with the second color, and so on. There must be an equal number of rectangles and color values. The rectangles are composited using the `NSCompositeCopy` (page 1376) operator and the order in which the rectangles are filled cannot be guaranteed; therefore, overlapping rectangles may not draw as expected. This function alters the current color of the current graphics state, setting it unpredictably to one of the values passed in *colors*.

For a list of compositing operations and how you use them, see *Cocoa Drawing Guide*.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSGraphics.h`

NSRectFillListWithColorsUsingOperation

Fills the rectangles in a list using the specified colors and compositing operation.

```
void NSRectFillListWithColorsUsingOperation (
   const NSRect *rects,
   NSColor **colors,
   NSInteger num,
   NSCompositingOperation op
);
```

Parameters

rects

A pointer to an array of `NSRect` structures representing the rectangles to fill.

colors

A pointer to an array of `NSColor` objects. The number of color objects in this parameter must equal the number of rectangles in the *rects* parameter.

num

The number of rectangles in the *rects* parameter.

op

The compositing operation to use when filling the rectangles.

Discussion
Takes a list of *num* rectangles and a matching list of color values. The first rectangle is filled with the first color, the second rectangle with the second color, and so on. There must be an equal number of rectangles and color values. Each fill operation is performed using the compositing operation *op*. The rectangles should not overlap; the order in which they are filled cannot be guaranteed. This function alters the current color of the current graphics state, setting it unpredictably to one of the values passed in *colors*.

For a list of compositing operations and how you use them, see *Cocoa Drawing Guide*.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSGraphics.h

NSRectFillListWithGrays

Fills the rectangles in the passed list with the passed list of grays.

```
void NSRectFillListWithGrays (
   const NSRect *rects,
   const CGFloat *grays,
   NSInteger num
);
```

Parameters

rects
A pointer to an array of NSRect structures representing the rectangles to fill.

grays
A pointer to an array of floating-point values in the range 0.0 to 1.0, where 0.0 represents absolute black and 1.0 represents absolute white and numbers in between are varying levels of gray. Values outside this range are clamped to 0.0 or 1.0.

num
The number of rectangles in the *rects* parameter.

Discussion
Takes a list of *num* rectangles and a matching list of gray values. The first rectangle is filled with the first gray, the second rectangle with the second gray, and so on. There must be an equal number of rectangles and gray values. The rectangles are composited using the NSCompositeCopy (page 1376) operator and the order in which the rectangles are filled cannot be guaranteed; therefore, overlapping rectangles may not draw as expected. This function alters the current color of the current graphics state, setting it unpredictably to one of the values passed in *grays*.

For a list of compositing operations and how you use them, see *Cocoa Drawing Guide*.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSGraphics.h

NSRectFillUsingOperation

Fills a rectangle using the current fill color and the specified compositing operation.

```
void NSRectFillUsingOperation (
   NSRect aRect,
   NSCompositingOperation op
);
```

Parameters

aRect

The rectangle to fill with the current fill color.

op

The compositing operation to use when filling the rectangle.

Discussion

For a list of compositing operations and how you use them, see *Cocoa Drawing Guide*.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NSGraphics.h`

NSRegisterServicesProvider

Registers a service provider.

```
void NSRegisterServicesProvider (
   id provider,
   NSString *name
);
```

Parameters

provider

The object providing the service you want to register.

name

The unique name to associate with the service. This string is used to advertise the service to interested clients.

Discussion

Use this function to register custom services not directly related to your application.

You should not use this function to register the services provided by your application. For your application's services, you should use the `setServicesProvider:` (page 171) method of `NSApplication`, passing a non-`nil` argument.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSApplication.h

NSReleaseAlertPanel

Releases an alert panel.

```
void NSReleaseAlertPanel (
   id panel
);
```

Discussion
When you're finished with a panel created by a function such as `NSGetAlertPanel` (page 3983), `NSGetCriticalAlertPanel` (page 3984), or `NSGetInformationalAlertPanel` (page 3985), you must free it by passing it to this function.

Note that the alert panel may not be deallocated immediately because it may have internal references that are released in a deferred way. You should not make the assumption that the alert panel is immediately removed from the application window list.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSPanel.h

NSRunAlertPanel

Creates an alert panel.

```
NSInteger NSRunAlertPanel (
   NSString *title,
   NSString *msg,
   NSString *defaultButton,
   NSString *alternateButton,
   NSString *otherButton,
   ...
);
```

Discussion
Creates and runs an alert panel (or dialog) with the title of *title*, the text of *msg*, and buttons with titles of *defaultButton*, *alternateButton*, and *otherButton*. See the description of `NSBeginAlertSheet` (page 3962) for information on layout of buttons, default parameters, and possible return values. `NSRunAlertPanel` runs the panel in a modal event loop.

A Command-D key equivalent for the "Don't Save" button is provided, if one is found. The button titles are searched for the localized value for "Don't Save." If a match is found, that button is assigned a Command-D key equivalent, provided it is not the default button.

If you create a modal panel using `runModalForWindow:` (page 163) or `beginSheet:modalForWindow:modalDelegate:didEndSelector:contextInfo:` (page 140), you can assign the key equivalent yourself, using `setKeyEquivalent:` (page 483) and `setKeyEquivalentModifierMask:` (page 484).

This function not only creates the panel; it also puts the panel onscreen and runs it using the `runModalForWindow:` (page 163) method defined in the `NSApplication` class. This method sets up a modal event loop that causes the panel to remain onscreen until the user clicks one of its buttons. This function then removes the panel from the screen list and returns a value that indicates which of the three buttons the user clicked. For efficiency, this function creates the panel the first time it's called and reuses it on subsequent calls, reconfiguring it if necessary.

Availability
Available in Mac OS X v10.0 and later.

TextLinks
WhackedTV

Declared In
`NSPanel.h`

NSRunCriticalAlertPanel

Creates and runs a critical alert panel.

```
NSInteger NSRunCriticalAlertPanel (
   NSString *title,
   NSString *msg,
   NSString *defaultButton,
   NSString *alternateButton,
   NSString *otherButton,
   ...
);
```

Discussion
Creates a critical alert panel that warns the user of some critical consequence of a requested action; the panel lets the user cancel the action and may allow the user to modify the action. It then runs the panel in a modal event loop.

The panel presented to the user is badged with a caution icon. Critical alerts should be used only as specified in the "Alerts" section of the Windows chapter of *Apple Human Interface Guidelines*.

The arguments for this function are the same as those for `NSRunAlertPanel` (page 3998).

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSPanel.h

NSRunInformationalAlertPanel

Creates and runs an informational alert panel.

```
NSInteger NSRunInformationalAlertPanel (
   NSString *title,
   NSString *msg,
   NSString *defaultButton,
   NSString *alternateButton,
   NSString *otherButton,
   ...
);
```

Discussion
Creates an informational alert panel that provides information related to a requested action. It then runs the panel in a modal event loop.

The arguments for this function are the same as those for `NSRunAlertPanel` (page 3998).

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSPanel.h

NSSetFocusRingStyle

Specifies how a focus ring will be drawn.

```
void NSSetFocusRingStyle (
   NSFocusRingPlacement placement
);
```

Parameters

placement
Specifies how you want the focus ring to be drawn.

Discussion
Use `NSFocusRingAbove` to draw the focus ring over an image, use `NSFocusRingBelow` to draw the focus ring under text, and use `NSFocusRingOnly` if you don't have an image or text. For the `NSFocusRingOnly` case, fills a shape to add the focus ring around the shape.

Note that the focus ring may actually be drawn outside the view but will be clipped to any clipping superview or the window content view.

Availability
Available in Mac OS X v10.1 and later.

Related Sample Code
ClockControl
Dicey
TrackBall

Declared In
`NSGraphics.h`

NSSetShowsServicesMenuItem

Specifies whether an item should be included in Services menus.

```
NSInteger NSSetShowsServicesMenuItem (
   NSString *itemName,
   BOOL enabled
);
```

Discussion
Deprecated. This function simply returns 0.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSApplication.h`

NSShowAnimationEffect

Runs a system animation effect.

```
void NSShowAnimationEffect (
   NSAnimationEffect animationEffect,
   NSPoint centerLocation,
   NSSize size,
   id animationDelegate,
   SEL didEndSelector,
   void *contextInfo
);
```

Parameters

animationEffect
The type of animation you want to apply.

centerLocation
The location at which to show the animated image, specified in screen coordinates. The animation is centered on the point you specify.

size
The desired size of the animated image. Specify `NSZeroSize` to perform the animation at the default size.

animationDelegate
The object to notify when the animation completes. Specify `nil` if you do not need to be notified when the animation completes.

didEndSelector

The selector of *animationDelegate* to call when the animation completes. Specify `nil` if you do not need to be notified when the animation completes. If you specify a selector, the corresponding method should have the following signature:

```
- (void)animationEffectDidEnd:(void *)contextInfo;
```

contextInfo

A pointer to any optional information you want passed as a parameter to the selector in the *didEndSelector* parameter.

Discussion
This function runs one of the standard system animation effects, which includes display and sound. For example, you can use this function to display the puff of smoke effect. For a complete list of animation effects, see `NSAnimationEffect` (page 4007).

Availability
Available in Mac OS X v10.3 and later.

Declared In
`NSGraphics.h`

NSShowsServicesMenuItem

Specifies whether a Services menu item is currently enabled.

```
BOOL NSShowsServicesMenuItem (
   NSString *itemName
);
```

Discussion
Deprecated. This function simply returns `YES`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSApplication.h`

NSUnregisterServicesProvider

Unregisters a service provider.

```
void NSUnregisterServicesProvider(NSString *name);
```

Parameters

name

The name of the service you want to unregister.

Discussion
Use this function to unregister custom services not directly related to your application.

You should not use this function to unregister the services provided by your application. For your application's services, you should use the `setServicesProvider:` (page 171) method of `NSApplication`, passing a `nil` argument.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSApplication.h

NSUpdateDynamicServices

Causes the services information for the system to be updated.

```
void NSUpdateDynamicServices (void);
```

Discussion
Used by a service-providing application to reregister the services it is willing to provide. To do this, you create a bundle with the extension ".service" and place it in the application's path or ~/Library/Services. The content of the bundle is identical to a normal service bundle. You then call this function.

It is only necessary to call this function if your program adds dynamic services to the system.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
SpotlightFortunes

Declared In
NSApplication.h

NSWindowList

Gets information about onscreen windows.

```
void NSWindowList (
   NSInteger size,
   NSInteger list[]
);
```

Discussion
Provides an ordered list of all onscreen windows. It fills *list* with up to *size* window numbers; the order of windows in the array is the same as their order in the window server's screen list (their front-to-back order on the screen). Use the count obtained by NSCountWindows (page 3968) to specify the size of the array for this function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSGraphics.h

NSWindowListForContext

Gets information about an application's onscreen windows.

```
void NSWindowListForContext (
   NSInteger context,
   NSInteger size,
   NSInteger list[]
);
```

Discussion
Provides an ordered list of onscreen windows for a particular application, identified by *context*, which is a window server connection ID. It fills *list* with up to *size* window numbers; the order of windows in the array is the same as their order in the window server's screen list (their front-to-back order on the screen). Use the count obtained by the `NSCountWindowsForContext` (page 3968) function to specify the size of the array for this function.

Use of this function is discouraged as it may be deprecated in a future release.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSGraphics.h`

Data Types

PART IV

Data Types

Application Kit Data Types Reference

Framework: AppKit/AppKit.h

Overview

This document describes the data types defined in the Application Kit framework and not described in a document for an individual class.

Data Types

NSAnimationEffect

This type defines the standard system animation effects, which include both display and sound.

```
typedef enum _NSAnimationEffect {
    NSAnimationEffectDisappearingItemDefault = 0,
    NSAnimationEffectPoof = 10
} NSAnimationEffect;
```

Constants

`NSAnimationEffectDisappearingItemDefault`

The default effect.

Available in Mac OS X v10.3 and later.

Declared in `NSGraphics.h`.

`NSAnimationEffectPoof`

An effect showing a puff of smoke.

Available in Mac OS X v10.3 and later.

Declared in `NSGraphics.h`.

Discussion

These effects are used to indicate that an item was removed from a collection, such as a toolbar, without deleting the underlying data. See `NSShowAnimationEffect` (page 4001).

Availability

Available in Mac OS X v10.3 and later.

Declared In

`NSGraphics.h`

NSBrowserAuxiliaryOpaque

A private data structure used internally by `NSBrowser`.

```
typedef struct NSBrowserAuxiliary NSBrowserAuxiliaryOpaque;
```

Availability
Available in Mac OS X v10.3 and later.

Declared In
`NSBrowser.h`

NSColorListAuxiliaryOpaque

A private data structure used internally by `NSColorList`.

```
typedef struct NSColorListAuxiliary NSColorListAuxiliaryOpaque;
```

Availability
Available in Mac OS X v10.3 and later.

Declared In
`NSColorList.h`

NSFocusRingPlacement

The focus ring style indicates how the focus ring will be drawn.

```
typedef enum {
    NSFocusRingOnly  = 0,
    NSFocusRingBelow = 1,
    NSFocusRingAbove = 2
} NSFocusRingPlacement;
```

Constants

`NSFocusRingAbove`
Use `NSFocusRingAbove` to draw over an image.
Fill a shape to add the focus ring around the shape.
Available in Mac OS X v10.1 and later.
Declared in `NSGraphics.h`.

`NSFocusRingBelow`
Use `NSFocusRingBelow` to draw the focus ring under text.
Available in Mac OS X v10.1 and later.
Declared in `NSGraphics.h`.

`NSFocusRingOnly`
Use `NSFocusRingOnly` if you don't have an image or text.
Available in Mac OS X v10.1 and later.
Declared in `NSGraphics.h`.

Availability
Available in Mac OS X v10.1 and later.

Declared In
NSGraphics.h

NSFocusRingType

The focus ring type is used by NSView and NSCell to configure if and how a control should draw its focus ring.

```
typedef enum _NSFocusRingType {
    NSFocusRingTypeDefault  = 0,
    NSFocusRingTypeNone     = 1,
    NSFocusRingTypeExterior = 2
} NSFocusRingType;
```

Constants

NSFocusRingTypeDefault
The default focus ring type for NSView or NSCell.
Available in Mac OS X v10.3 and later.
Declared in NSGraphics.h.

NSFocusRingTypeNone
No focus ring. If you set the focus ring type to this value, NSView and NSCell will not draw any focus ring.
Available in Mac OS X v10.3 and later.
Declared in NSGraphics.h.

NSFocusRingTypeExterior
The standard Aqua focus ring.
Available in Mac OS X v10.3 and later.
Declared in NSGraphics.h.

Availability
Available in Mac OS X v10.3 and later.

Declared In
NSGraphics.h

NSInterfaceStyle

These constants are used in NSResponder's interfaceStyle (page 2158) method.

```
typedef enum {
    NSNoInterfaceStyle        = 0,
    NSNextStepInterfaceStyle  = 1,
    NSWindows95InterfaceStyle = 2,
    NSMacintoshInterfaceStyle = 3
} NSInterfaceStyle;
```

Constants

`NSNoInterfaceStyle`
The default interface style.
Available in Mac OS X v10.0 and later.
Declared in `NSInterfaceStyle.h`.

`NSNextStepInterfaceStyle`
The NextStep interface style.
Available in Mac OS X v10.0 and later.
Declared in `NSInterfaceStyle.h`.

`NSWindows95InterfaceStyle`
The Windows 95 interface style.
Available in Mac OS X v10.0 and later.
Declared in `NSInterfaceStyle.h`.

`NSMacintoshInterfaceStyle`
The Macintosh interface style.
Available in Mac OS X v10.0 and later.
Declared in `NSInterfaceStyle.h`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSInterfaceStyle.h`

NSModalSession

Variables of type `NSModalSession` point to information used by the system between `NSApplication`'s `beginModalSessionForWindow:` (page 139) and `endModalSession:` (page 146) messages.

```
typedef struct _NSModalSession *NSModalSession;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSApplication.h`

NSOpenGLContextAuxiliary

A private data structure used by `NSOpenGLContext`.

```
typedef struct _CGLContextObject NSOpenGLContextAuxiliary;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSOpenGL.h

NSOpenGLGlobalOption

These constants are option names for NSOpenGLSetOption (page 3989) and NSOpenGLGetOption (page 3989).

```
typedef enum {
    NSOpenGLGOFormatCacheSize  = 501,
    NSOpenGLGOClearFormatCache = 502,
    NSOpenGLGORetainRenderers  = 503,
    NSOpenGLGOResetLibrary     = 504
} NSOpenGLGlobalOption;
```

Constants

NSOpenGLGOFormatCacheSize
Sets the size of the pixel format cache.
Available in Mac OS X v10.0 and later.
Declared in NSOpenGL.h.

NSOpenGLGOClearFormatCache
Resets the pixel format cache if true.
Available in Mac OS X v10.0 and later.
Declared in NSOpenGL.h.

NSOpenGLGORetainRenderers
Whether to retain loaded renderers in memory.
Available in Mac OS X v10.0 and later.
Declared in NSOpenGL.h.

NSOpenGLGOResetLibrary
Does a soft reset of the CGL library if true.
Available in Mac OS X v10.0 and later.
Declared in NSOpenGL.h.

Availability
Available in Mac OS X v10.0 and later.

Declared In
NSOpenGL.h

NSOpenGLPixelFormatAuxiliary

A private data structure used by NSOpenGLPixelFormat.

```
typedef struct _CGLPixelFormatObject NSOpenGLPixelFormatAuxiliary;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSOpenGL.h`

NSSavePanelAuxiliaryOpaque

A private data structure used internally by `NSSavePanel`.

```
typedef struct NSSavePanelAuxiliary NSSavePanelAuxiliaryOpaque;
```

Availability
Available in Mac OS X v10.3 and later.

Declared In
`NSSavePanel.h`

NSScreenAuxiliaryOpaque

A private data structure used internally by `NSScreen`.

```
typedef struct NSScreenAuxiliary NSScreenAuxiliaryOpaque;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NSScreen.h`

NSTabViewItemAuxiliaryOpaque

A private data structure used by `NSTabViewItem`.

```
typedef struct NSTabViewItemAuxiliary NSTabViewItemAuxiliaryOpaque;
```

Availability
Available in Mac OS X v10.2 and later.

Declared In
`NSTabViewItem.h`

NSTypesetterGlyphInfo

This type is a caching structure used by NSSimpleHorizontalTypesetter.

```
typedef struct _NSTypesetterGlyphInfo {
    NSPoint curLocation;
    float extent;
    float belowBaseline;
    float aboveBaseline;
    unsigned glyphCharacterIndex;
    NSFont *font;
    NSSize attachmentSize;
    struct {
        BOOL defaultPositioning:1;
        BOOL dontShow:1;
        BOOL isAttachment:1;
    } _giflags;
} NSTypesetterGlyphInfo;
```

Fields

`curLocation`
Location (relative to the baseline) for laying this glyph out.

`extent`
Required space from `curLocation` to lay this glyph out; –1.0 if not set.

`belowBaseline`
Distance from baseline to bottom of the line fragment required for all the glyphs so far, including this one (positive if baseline is above the bottom of the line fragment).

`aboveBaseline`
Distance from baseline to top of the line fragment required for all the glyphs so far, including this one (positive if baseline is below the top of the line fragment).

`glyphCharacterIndex`
Character index.

`font`
Font.

`attachmentSize`
Size of the character if it's an attachment; otherwise meaningless.

`defaultPositioning`
This block needs to be "show"ed.

`dontShow`
Don't show this glyph.

`isAttachment`
Whether the glyph is an attachment.

Availability
Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared In
`NSSimpleHorizontalTypesetter.h`

Constants

PART V

Constants

Application Kit Constants Reference

Framework: /System/Library/Frameworks/AppKit.framework

Declared in AppKit/AppKitDefines.h
AppKit/NSErrors.h
AppKit/AppKitErrors.h
AppKit/NSNibDeclarations.h
AppKit/NSGraphics.h

Overview

This document describes the constants defined in the Application Kit framework that are not defined in, or are not described in, a document for an individual class.

See *Application Kit Data Types Reference* for descriptions of other constants defined in enumerations.

Constants

There are three types of constant in this document: global variables, errors, and exceptions.

Global Variables

Color Space Names

Color-space names designate predefined color spaces.

```
NSString *NSCalibratedWhiteColorSpace;
NSString *NSCalibratedBlackColorSpace;
NSString *NSCalibratedRGBColorSpace;
NSString *NSDeviceWhiteColorSpace;
NSString *NSDeviceBlackColorSpace;
NSString *NSDeviceRGBColorSpace;
NSString *NSDeviceCMYKColorSpace;
NSString *NSNamedColorSpace;
NSString *NSPatternColorSpace;
NSString *NSCustomColorSpace;
```

Constants

`NSCalibratedWhiteColorSpace`

Calibrated color space with white and alpha components (pure white is 1.0)

Available in Mac OS X v10.0 and later.

Declared in `NSGraphics.h`.

`NSCalibratedBlackColorSpace`

Calibrated color space with black and alpha components (pure black is 1.0)

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.6.

Declared in `NSGraphics.h`.

`NSCalibratedRGBColorSpace`

Calibrated color space with red, green, blue, and alpha components.

You can also create a color with HSB (hue, saturation, brightness) and alpha components and can extract these components.

Available in Mac OS X v10.0 and later.

Declared in `NSGraphics.h`.

`NSDeviceWhiteColorSpace`

Device-dependent color space with white and alpha components (pure white is 1.0)

Available in Mac OS X v10.0 and later.

Declared in `NSGraphics.h`.

`NSDeviceBlackColorSpace`

Device-dependent color space with black and alpha components (pure black is 1.0)

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.6.

Declared in `NSGraphics.h`.

`NSDeviceRGBColorSpace`

Device-dependent color space with red, green, blue, and alpha components.

You can also create a color with HSB (hue, saturation, brightness) and alpha components and can extract these components.

Available in Mac OS X v10.0 and later.

Declared in `NSGraphics.h`.

`NSDeviceCMYKColorSpace`

Device-dependent color space with cyan, magenta, yellow, black, and alpha components

Available in Mac OS X v10.0 and later.

Declared in `NSGraphics.h`.

`NSNamedColorSpace`
: Catalog name and color name components

  The components of this color space are indexes into lists or catalogs of prepared colors. The catalogs of named colors come with lookup tables that are able to generate the correct color on a given device.

  Available in Mac OS X v10.0 and later.

  Declared in `NSGraphics.h`.

`NSPatternColorSpace`
: Pattern image (tiled)

  Identifies a pattern color space, which is simply an image that is repeated over and over again in a tiled pattern.

  Available in Mac OS X v10.0 and later.

  Declared in `NSGraphics.h`.

`NSCustomColorSpace`
: Custom `NSColorSpace` object and floating-point components describing a color in that space

  A custom color-space object represents a color space that is not necessarily predefined by the Application Kit. See “Working With Color Spaces” for information on creating custom color-space objects.

  Available in Mac OS X v10.0 and later.

  Declared in `NSGraphics.h`.

Discussion
You can use a color-space name in certain methods of `NSColor` that create or convert color objects. The name identifies the color space to be used for the operation.

Declared In
`NSGraphics.h`

Grayscale Values

These constants are the standard gray values for the 2-bit deep grayscale color space.

```
const float NSWhite;
const float NSLightGray;
const float NSDarkGray;
const float NSBlack;
```

Constants
`NSWhite`
: A constant that specifies the white shade in the 2-bit deep grayscale color space.

  Available in Mac OS X v10.0 and later.

  Declared in `NSGraphics.h`.

`NSLightGray`
: A constant that specifies the light gray shade in the 2-bit deep grayscale color space.

  Available in Mac OS X v10.0 and later.

  Declared in `NSGraphics.h`.

`NSDarkGray`
A constant that specifies the dark gray shade in the 2-bit deep grayscale color space.

Available in Mac OS X v10.0 and later.

Declared in `NSGraphics.h`.

`NSBlack`
A constant that specifies the black shade in the 2-bit deep grayscale color space.

Available in Mac OS X v10.0 and later.

Declared in `NSGraphics.h`.

NSInterfaceStyleDefault

`NSInterfaceStyleDefault` can be used to override the platform's default interface style.

```
NSString *NSInterfaceStyleDefault;
```

Constants
`NSInterfaceStyleDefault`
For more information, see the function `NSInterfaceStyleForKey` (page 3987).

Available in Mac OS X v10.0 and later.

Declared in `NSInterfaceStyle.h`.

Interface Builder Constants

Type qualifiers used by Interface Builder to synchronize with Xcode. For more information, see Communicating With Objects in *Cocoa Fundamentals Guide*.

```
#define IBAction void
#define IBOutlet
```

Constants
`IBAction`
Type qualifier used by Interface Builder to synchronize actions added programmatically with its internal list of action methods defined for a project.

Available in Mac OS X v10.0 and later.

Declared in `NSNibDeclarations.h`.

`IBOutlet`
Identifier used to qualify an instance-variable declaration so that Interface Builder can synchronize the display and connection of outlets with Xcode.

Available in Mac OS X v10.0 and later.

Declared in `NSNibDeclarations.h`.

NSWindow—Sizes

Obsolete constant values. Do not use.

```
NSSize NSIconSize;
NSSize NSTokenSize;
```

Constants

`NSIconSize`

Obsolete constant values. Do not use.

Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared in `NSWindow.h`.

`NSTokenSize`

Obsolete constant values. Do not use.

Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared in `NSWindow.h`.

Errors

Attributed String Errors

These constants represent errors generated by `NSAttributedString`.

```
enum {
    NSTextReadInapplicableDocumentTypeError = 65806,
    NSTextWriteInapplicableDocumentTypeError = 66062,
    NSTextReadWriteErrorMinimum = 65792,
    NSTextReadWriteErrorMaximum = 66303
};
```

Constants

`NSTextReadInapplicableDocumentTypeError`

Indicates a problem reading data with the specified format.

Available in Mac OS X v10.4 and later.

Declared in `AppKitErrors.h`.

`NSTextWriteInapplicableDocumentTypeError`

Indicates a problem writing data of the specified format.

Available in Mac OS X v10.4 and later.

Declared in `AppKitErrors.h`.

`NSTextReadWriteErrorMinimum`

The beginning of a range of error codes reserved for future use.

Available in Mac OS X v10.4 and later.

Declared in `AppKitErrors.h`.

`NSTextReadWriteErrorMaximum`

The end of a range of error codes reserved for future use.

Available in Mac OS X v10.4 and later.

Declared in `AppKitErrors.h`.

Discussion

These constants are returned in an `NSError` object.

Services Error Codes

These constants represent errors returned by application services.

```
enum {
    NSServiceApplicationNotFoundError = 66560,
    NSServiceApplicationLaunchFailedError = 66561,
    NSServiceRequestTimedOutError = 66562,
    NSServiceInvalidPasteboardDataError = 66563,
    NSServiceMalformedServiceDictionaryError = 66564,
    NSServiceMiscellaneousError = 66800,
    NSServiceErrorMinimum = 66560,
    NSServiceErrorMaximum = 66817
};
```

Constants

`NSServiceApplicationNotFoundError`
The service provider could not be found.

Available in Mac OS X v10.5 and later.

Declared in `AppKitErrors.h`.

`NSServiceApplicationLaunchFailedError`
The service providing application could not be launched. This will typically contain an underlying error with an Launch Services error code.

Available in Mac OS X v10.5 and later.

Declared in `AppKitErrors.h`.

`NSServiceRequestTimedOutError`
The service providing application did not open its service listening port in time, or the app didn't respond to the request in time; see the Console log to figure out which (the errors are typically reported the same way to the user).

Available in Mac OS X v10.5 and later.

Declared in `AppKitErrors.h`.

`NSServiceInvalidPasteboardDataError`
The service providing app did not return a pasteboard with any of the promised types, or we couldn't write the data from the pasteboard to the object receiving the returned data.

Available in Mac OS X v10.5 and later.

Declared in `AppKitErrors.h`.

`NSServiceMalformedServiceDictionaryError`
The service dictionary did not contain the necessary keys. Messages will typically be logged to the console giving more details.

Available in Mac OS X v10.5 and later.

Declared in `AppKitErrors.h`.

`NSServiceMiscellaneousError`
Other errors, representing programmatic mistakes in the service consuming application. These show a generic error message to the user.

Available in Mac OS X v10.5 and later.

Declared in `AppKitErrors.h`.

`NSServiceErrorMinimum`

Inclusive service error range, for checking future error codes.

Available in Mac OS X v10.5 and later.

Declared in `AppKitErrors.h`.

`NSServiceErrorMaximum`

Inclusive service error range, for checking future error codes.

Available in Mac OS X v10.5 and later.

Declared in `AppKitErrors.h`.

Exceptions

Application Kit Exception Names

These constants name the exceptions that the Application Kit can raise.

```
NSString *NSTextLineTooLongException;
NSString *NSTextNoSelectionException;
NSString *NSWordTablesWriteException;
NSString *NSWordTablesReadException;
NSString *NSTextReadException;
NSString *NSTextWriteException;
NSString *NSPasteboardCommunicationException;
NSString *NSPrintingCommunicationException;
NSString *NSAbortModalException;
NSString *NSAbortPrintingException;
NSString *NSIllegalSelectorException;
NSString *NSAppKitVirtualMemoryException;
NSString *NSBadRTFDirectiveException;
NSString *NSBadRTFFontTableException;
NSString *NSBadRTFStyleSheetException;
NSString *NSTypedStreamVersionException;
NSString *NSTIFFException;
NSString *NSPrintPackageException;
NSString *NSBadRTFColorTableException;
NSString *NSDraggingException;
NSString *NSColorListIOException;
NSString *NSColorListNotEditableException;
NSString *NSBadBitmapParametersException;
NSString *NSWindowServerCommunicationException;
NSString *NSFontUnavailableException;
NSString *NSPPDIncludeNotFoundException;
NSString *NSPPDParseException;
NSString *NSPPDIncludeStackOverflowException;
NSString *NSPPDIncludeStackUnderflowException;
NSString *NSRTFPropertyStackOverflowException;
NSString *NSAppKitIgnoredException;
NSString *NSBadComparisonException;
NSString *NSImageCacheException;
NSString *NSNibLoadingException;
NSString *NSBrowserIllegalDelegateException;
NSString *NSAccessibilityException;
```

Constants

`NSTextLineTooLongException`

Exception generated if a line is too long in a `NSText` object.

Available in Mac OS X v10.0 and later.

Declared in `NSErrors.h`.

`NSTextNoSelectionException`

Available in Mac OS X v10.0 and later.

Declared in `NSErrors.h`.

`NSWordTablesWriteException`

Available in Mac OS X v10.0 and later.

Declared in `NSErrors.h`.

`NSWordTablesReadException`

Available in Mac OS X v10.0 and later.

Declared in `NSErrors.h`.

`NSTextReadException`

Available in Mac OS X v10.0 and later.

Declared in `NSErrors.h`.

`NSTextWriteException`

Available in Mac OS X v10.0 and later.

Declared in `NSErrors.h`.

`NSPasteboardCommunicationException`

Available in Mac OS X v10.0 and later.

Declared in `NSErrors.h`.

`NSPrintingCommunicationException`

Available in Mac OS X v10.0 and later.

Declared in `NSErrors.h`.

`NSAbortModalException`

Available in Mac OS X v10.0 and later.

Declared in `NSErrors.h`.

`NSAbortPrintingException`

Available in Mac OS X v10.0 and later.

Declared in `NSErrors.h`.

`NSIllegalSelectorException`

Available in Mac OS X v10.0 and later.

Declared in `NSErrors.h`.

`NSAppKitVirtualMemoryException`

Available in Mac OS X v10.0 and later.

Declared in `NSErrors.h`.

`NSBadRTFDirectiveException`

Available in Mac OS X v10.0 and later.

Declared in `NSErrors.h`.

`NSBadRTFFontTableException`

Available in Mac OS X v10.0 and later.

Declared in `NSErrors.h`.

`NSBadRTFStyleSheetException`

Available in Mac OS X v10.0 and later.

Declared in `NSErrors.h`.

`NSTypedStreamVersionException`

Available in Mac OS X v10.0 and later.

Declared in `NSErrors.h`.

`NSTIFFException`

Available in Mac OS X v10.0 and later.

Declared in `NSErrors.h`.

`NSPrintPackageException`

Available in Mac OS X v10.0 and later.

Declared in `NSErrors.h`.

`NSBadRTFColorTableException`

Available in Mac OS X v10.0 and later.

Declared in `NSErrors.h`.

`NSDraggingException`

Available in Mac OS X v10.0 and later.

Declared in `NSErrors.h`.

`NSColorListIOException`

Available in Mac OS X v10.0 and later.

Declared in `NSErrors.h`.

`NSColorListNotEditableException`

Available in Mac OS X v10.0 and later.

Declared in `NSErrors.h`.

`NSBadBitmapParametersException`

Available in Mac OS X v10.0 and later.

Declared in `NSErrors.h`.

`NSWindowServerCommunicationException`

Available in Mac OS X v10.0 and later.

Declared in `NSErrors.h`.

`NSFontUnavailableException`

Available in Mac OS X v10.0 and later.

Declared in `NSErrors.h`.

`NSPPDIncludeNotFoundException`

Available in Mac OS X v10.0 and later.

Declared in `NSErrors.h`.

`NSPPDParseException`

Available in Mac OS X v10.0 and later.

Declared in `NSErrors.h`.

`NSPPDIncludeStackOverflowException`

Available in Mac OS X v10.0 and later.

Declared in `NSErrors.h`.

`NSPPDIncludeStackUnderflowException`

Available in Mac OS X v10.0 and later.

Declared in `NSErrors.h`.

`NSRTFPropertyStackOverflowException`

Available in Mac OS X v10.0 and later.

Declared in `NSErrors.h`.

`NSAppKitIgnoredException`

Available in Mac OS X v10.0 and later.

Declared in `NSErrors.h`.

`NSBadComparisonException`

Available in Mac OS X v10.0 and later.

Declared in `NSErrors.h`.

`NSImageCacheException`

Available in Mac OS X v10.0 and later.

Declared in `NSErrors.h`.

`NSNibLoadingException`

Available in Mac OS X v10.0 and later.

Declared in `NSErrors.h`.

`NSBrowserIllegalDelegateException`

Available in Mac OS X v10.0 and later.

Declared in `NSErrors.h`.

`NSAccessibilityException`

Available in Mac OS X v10.2 and later.

Declared in `NSErrors.h`.

Declared In
`NSErrors.h`

Document Revision History

This table describes the changes to *Application Kit Framework Reference*.

Date	Notes
2009-08-28	Added NSTextInputContext Class Reference and updated the class hierarchy diagrams.
2009-05-28	Added new classes introduced in Mac OS X v10.6.
2008-11-19	Added NSTextInputClient Protocol Reference.
2007-10-31	Updated framework illustrations.
2007-05-10	Added new classes introduced with Mac OS X v10.5.
2006-05-23	First publication of this content as a collection of separate documents.

Document Revision History
