List of Sections

List of Modules

All M68HC05 microcontroller units (MCUs) are customer-specified modular designs. To meet customer requirements, Motorola is constantly designing new modules and new versions of existing modules. The following table shows the version levels of the modules in the MC68HC705J1A MCU.

Module	Version
Central Processor Unit	HC05CPU
Computer Operating Properly	@COP0COPRT2
External Interrupt	@KBIELPA4HPD_A
Multifunction Timer	TIM15B1RTICLR_A

Table of Contents

MC68HC705J1A — Rev. 2.0

Introduction

Contents

Features

- Peripheral Modules

  - 15-Stage Multifunction Timer

  - Computer Operating Properly (COP) Watchdog

- 14 Bidirectional Input/Output (I/O) Lines, Including:

  - 10 mA Sink Capability on Four I/O Pins

  - Mask Option Register (MOR) and Software Programmable Pulldowns on All I/O Pins

  - MOR Selectable Interrupt on Four I/O Pins, a Keyboard Scan Feature

- MOR Selectable Sensitivity on External Interrupt (Edge- and Level-Sensitive or Edge-Sensitive Only)

- On-Chip Oscillator with Connections for:

  - Crystal

  - Ceramic Resonator

  - Resistor-Capacitor (RC) Oscillator

  - External Clock

- 1240 Bytes of EPROM/OTPROM, Including Eight Bytes for User Vectors

- 64 Bytes of User RAM

- Memory-Mapped I/O Registers

- Fully Static Operation with No Minimum Clock Speed

- Power-Saving Stop, Halt, Wait, and Data-Retention Modes

- External Interrupt Mask Bit and Acknowledge Bit

- Illegal Address Reset

- Internal Steering Diode and Pullup Resistor from $\overline{\text{RESET}}$ Pin to V_{DD}

Package Types and Order Numbers

Table 1. Order Numbers[1]

Package Type	Case Outline	Pin Count	Operating Temperature	Order Number
PDIP	738-03	20	0 to 70 °C −40 to +85 °C −40 to + 105 °C	MC68HC705J1AP[2] MC68HC705J1AC[3]P MC68HC705J1AV[4]P
SOIC	751D-04	20	0 to 70 °C −40 to +85 °C −40 to + 105 °C	MC68HC705J1ADW[5] MC68HC705J1ACDW MC68HC705J1AVDW
Cerdip	732-03	20	0 to 70 °C −40 to +85 °C −40 to + 105 °C	MC68HC705J1AS[6] MC68HC705J1ACS MC68HC705J1AVS

1. Refer to **Appendix A**, **Appendix B**, and **Appendix C** for ordering information on optional high-speed and resistor-capacitor oscillator devices.
2. P = plastic dual in-line package (PDIP)
3. C = extended temperature range
4. V = automotive temperature range
5. DW = small outline integrated circuit (SOIC)
6. S = ceramic dual in-line package (Cerdip)

Programmable Options

The options in **Table 2** are programmable in the mask option register.

Table 2. Programmable Options

Feature	Option
COP Watchdog Timer	Enabled or Disabled
External Interrupt Triggering	Edge-Sensitive Only or Edge- and Level-Sensitive
Port A IRQ Pin Interrupts	Enabled or Disabled
Port Pulldown Resistors	Enabled or Disabled
STOP Instruction Mode	Stop Mode or Halt Mode
Crystal Oscillator Internal Resistor	Enabled or Disabled
EPROM Security	Enabled or Disabled
Short Oscillator Delay Counter	Enabled or Disabled

Figure 1. Pin Assignments

Pin Functions

V_{DD} and V_{SS}

V_{DD} and V_{SS} are the power supply and ground pins. The MCU operates from a single power supply.

Very fast signal transitions occur on the MCU pins, placing high, short-duration current demands on the power supply. To prevent noise problems, take special care as **Figure 2** shows, by placing the bypass capacitors as close as possible to the MCU. C2 is an optional bulk current bypass capacitor for use in applications that require the port pins to source high current levels.
Figure 2. Bypassing Layout Recommendation

OSC1 and OSC2

The OSC1 and OSC2 pins are the connections for the on-chip oscillator. The oscillator can be driven by any of the following:

1. Crystal (See **Figure 3** and **Figure 4**.)

2. Ceramic resonator (See **Figure 5** and **Figure 6**.)

3. Resistor/capacitor (RC) oscillator (Refer to **Appendix A** and **Appendix C**.)

4. External clock signal as shown in (See **Figure 7**.)

The frequency, f_{osc}, of the oscillator or external clock source is divided by two to produce the internal operating frequency, f_{op}.

Crystal Oscillator   **Figure 3** and **Figure 4** show a typical crystal oscillator circuit for an AT-cut, parallel resonant crystal. Follow the crystal supplier's recommendations, as the crystal parameters determine the external component values required to provide reliable startup and maximum stability. The load capacitance values used in the oscillator circuit design should include all stray layout capacitances.

To minimize output distortion, mount the crystal and capacitors as close as possible to the pins. An internal startup resistor of approximately 2 MΩ is provided between OSC1 and OSC2 for the crystal oscillator as a programmable mask option.

NOTE: *Use an AT-cut crystal and not an AT-strip crystal because the MCU can overdrive an AT-strip crystal.*
**Figure 3. Crystal Connections with
Oscillator Internal Resistor Mask Option**
**Figure 4. Crystal Connections without
Oscillator Internal Resistor Mask Option**

*Ceramic
Resonator
Oscillator*

To reduce cost, use a ceramic resonator instead of the crystal. The circuits shown in **Figure 5** and **Figure 6** show ceramic resonator circuits. Follow the resonator manufacturer's recommendations, as the resonator parameters determine the external component values required for maximum stability and reliable starting. The load capacitance values used in the oscillator circuit design should include all stray capacitances.

Mount the resonator and components as close as possible to the pins for startup stabilization and to minimize output distortion. An internal startup resistor of approximately 2 MΩ is provided between OSC1 and OSC2 as a programmable mask option.
**Figure 5. Ceramic Resonator Connections with
Oscillator Internal Resistor Mask Option**
**Figure 6. Ceramic Resonator Connections without
Oscillator Internal Resistor Mask Option**

RC Oscillator　　　Refer to **Appendix A** and **Appendix C**.

External Clock　　An external clock from another CMOS-compatible device can be connected to the OSC1 input, with the OSC2 input not connected, as shown in **Figure 7**. This configuration is possible regardless of whether the crystal/ceramic resonator or the RC oscillator is enabled.

MCU

OSC1　　　　OSC2

EXTERNAL
CMOS CLOCK
Figure 7. External Clock Connections

$\overline{\text{RESET}}$　　　Applying a logic 0 to the $\overline{\text{RESET}}$ pin forces the MCU to a known startup state. An internal reset also pulls the $\overline{\text{RESET}}$ pin low. An internal resistor to V_{DD} pulls the $\overline{\text{RESET}}$ pin high. A steering diode between the $\overline{\text{RESET}}$ and V_{DD} pins discharges any $\overline{\text{RESET}}$ pin voltage when power is removed from the MCU. The $\overline{\text{RESET}}$ pin contains an internal Schmitt trigger to improve its noise immunity as an input. Refer to the **Resets and Interrupts** section for more information.

$\overline{\text{IRQ}}/V_{PP}$ The external interrupt/programming voltage pin ($\overline{\text{IRQ}}/V_{PP}$) drives the asynchronous IRQ interrupt function of the CPU. Additionally, it is used to program the user EPROM and mask option register. (See **Memory** and **External Interrupt Module**.)

The LEVEL bit in the mask option register provides negative edge-sensitive triggering or both negative edge-sensitive and low level-sensitive triggering for the interrupt function.

If level-sensitive triggering is selected, the $\overline{\text{IRQ}}/V_{PP}$ input requires an external resistor to V_{DD} for wired-OR operation. If the $\overline{\text{IRQ}}/V_{PP}$ pin is not used, it must be tied to the V_{DD} supply.

The $\overline{\text{IRQ}}/V_{PP}$ pin contains an internal Schmitt trigger as part of its input to improve noise immunity. The voltage on this pin should not exceed V_{DD} except when the pin is being used for programming the EPROM.

NOTE: *The mask option register can enable the PA0–PA3 pins to function as external interrupt pins.*

PA0–PA7   These eight input/output (I/O) lines comprise port A, a general-purpose bidirectional I/O port. (See **External Interrupt Module** for information on PA0–PA3 external interrupts.)

PB0–PB5   These six I/O lines comprise port B, a general-purpose bidirectional I/O port.

Figure 2. I/O Register Summary

RAM

The 64 addresses from $00C0 to $00FF serve as both the user RAM and the stack RAM. Before processing an interrupt, the CPU uses five bytes of the stack to save the contents of the CPU registers. During a subroutine call, the CPU uses two bytes of the stack to store the return address. The stack pointer decrements when the CPU stores a byte on the stack and increments when the CPU retrieves a byte from the stack.

NOTE: *Be careful when using nested subroutines or multiple interrupt levels. The CPU may overwrite data in the RAM during a subroutine or during the interrupt stacking operation.*

EPROM/OTPROM

An MCU with a quartz window has 1240 bytes of erasable, programmable ROM (EPROM). The quartz window allows EPROM erasure with ultraviolet light.

NOTE: *Keep the quartz window covered with an opaque material except when programming the MCU. Ambient light can affect MCU operation.*

In an MCU without the quartz window, the EPROM cannot be erased and serves as 1240 bytes of one-time programmable ROM (OTPROM).

The following addresses are user EPROM/OTPROM locations:

- $0300–$07CF
- $07F8–$07FF, used for user-defined interrupt and reset vectors

The COP register (COPR) is an EPROM/OTPROM location at address $07F0.

The mask option register (MOR) is an EPROM/OTPROM location at address $07F1.

EPROM/OTPROM Programming

The two ways to program the EPROM/OTPROM are:

- Manipulating the control bits in the EPROM programming register to program the EPROM/OTPROM on a byte-by-byte basis
- Programming the EPROM/OTPROM with the M68HC705J In-Circuit Simulator (M68HC705JICS) available from Motorola

EPROM
Programming
Register

The EPROM programming register (EPROG) contains the control bits for programming the EPROM/OTPROM.

Address: $0018

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	0	0	0	0	0	ELAT	MPGM	EPGM
Write:		R	R	R	R	ELAT	MPGM	EPGM
Reset:	0	0	0	0	0	0	0	0

☐ = Unimplemented   R = Reserved

Figure 3. EPROM Programming Register (EPROG)

ELAT — EPROM Bus Latch Bit

This read/write bit latches the address and data buses for EPROM/OTPROM programming. Clearing the ELAT bit automatically clears the EPGM bit. EPROM/OTPROM data cannot be read while the ELAT bit is set. Reset clears the ELAT bit.
  1 = Address and data buses configured for EPROM/OTPROM programming the EPROM
  0 = Address and data buses configured for normal operation

MPGM — MOR Programming Bit

This read/write bit applies programming power from the $\overline{\text{IRQ}}$/V$_{PP}$ pin to the mask option register. Reset clears MPGM.
  1 = Programming voltage applied to MOR
  0 = Programming voltage not applied to MOR

EPGM — EPROM Programming Bit

This read/write bit applies the voltage from the $\overline{\text{IRQ}}$/V$_{PP}$ pin to the EPROM. To write the EPGM bit, the ELAT bit must be set already. Reset clears EPGM.
  1 = Programming voltage ($\overline{\text{IRQ}}$/V$_{PP}$ pin) applied to EPROM
  0 = Programming voltage ($\overline{\text{IRQ}}$/V$_{PP}$ pin) not applied to EPROM

NOTE: *Writing logic 1s to both the ELAT and EPGM bits with a single instruction sets ELAT and clears EPGM. ELAT must be set first by a separate instruction.*

6-e_mem_a

Bits [7:3] — Reserved

Take the following steps to program a byte of EPROM/OTPROM:

1. Apply the programming voltage, V_{PP}, to the $\overline{IRQ}/V_{PP}$ pin.
2. Set the ELAT bit.
3. Write to any EPROM/OTPROM address.
4. Set the EPGM bit and wait for a time, t_{EPGM}.
5. Clear the ELAT bit.

EPROM Erasing   The erased state of an EPROM bit is logic 0. Erase the EPROM by exposing it to 15 Ws/cm^2 of ultraviolet light with a wavelength of 2537 angstroms. Position the ultraviolet light source one inch from the EPROM. Do not use a shortwave filter.

Mask Option Register

The mask option register (MOR) is an EPROM/OTPROM byte that controls the following options:

- COP watchdog (enable or disable)
- External interrupt pin triggering (edge-sensitive only or edge- and level-sensitive)
- Port A external interrupts (enable or disable)
- Port pulldown resistors (enable or disable)
- STOP instruction (stop mode or halt mode)
- Crystal oscillator internal resistor (enable or disable)
- EPROM security (enable or disable)
- Short oscillator delay (enable or disable)

Take the following steps to program the mask option register:

1. Apply the programming voltage, V_{PP}, to the $\overline{IRQ}$/V_{PP} pin.
2. Write to the MOR.
3. Set the MPGM bit and wait for a time, t_{MPGM}.
4. Clear the MPGM bit.
5. Reset the MCU.

Address: $07F1

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	SOSCD	EPMSEC	OSCRES	SWAIT	SWPDI	PIRQ	LEVEL	COPEN
Write:								
Reset:	0	0	0	0	0	0	0	0

Figure 4. Mask Option Register (MOR)

SOSCD — Short Oscillator Delay Bit

The SOSCD bit controls the oscillator stabilization counter. The normal stabilization delay following reset or exit from stop mode is 4064 t_{cyc}. Setting SOSCD enables a short oscillator stabilization delay.

1 = Short oscillator delay enabled
0 = Short oscillator delay disabled

EPMSEC — EPROM Security Bit

The EPMSEC bit controls access to the EPROM/OTPROM.
1 = External access to EPROM/OTPROM denied
0 = External access to EPROM/OTPROM not denied

OSCRES — Oscillator Internal Resistor Bit

The OSCRES bit enables a 2-MΩ internal resistor in the oscillator circuit.

    1 = Oscillator internal resistor enabled
    0 = Oscillator internal resistor disabled

NOTE: *Program the OSCRES bit to logic 0 in devices using RC oscillators.*

SWAIT — Stop-to-Wait Conversion Bit

The SWAIT bit enables halt mode. When the SWAIT bit is set, the CPU interprets the STOP instruction as a WAIT instruction, and the MCU enters halt mode. Halt mode is the same as wait mode, except that an oscillator stabilization delay of 1 to 4064 t_{cyc} occurs after exiting halt mode.

    1 = Halt mode enabled
    0 = Halt mode not enabled

SWPDI — Software Pulldown Inhibit Bit

The SWPDI bit inhibits software control of the I/O port pulldown devices. The SWPDI bit overrides the pulldown inhibit bits in the port pulldown inhibit registers.

    1 = Software pulldown control inhibited
    0 = Software pulldown control not inhibited

PIRQ — Port A External Interrupt Bit

The PIRQ bit enables the PA0–PA3 pins to function as external interrupt pins.

    1 = PA0–PA3 enabled as external interrupt pins
    0 = PA0–PA3 not enabled as external interrupt pins

LEVEL —External Interrupt Sensitivity Bit

The LEVEL bit controls external interrupt triggering sensitivity.

    1 = External interrupts triggered by active edges and active levels
    0 = External interrupts triggered only by active edges

COPEN — COP Enable Bit

The COPEN bit enables the COP watchdog.

    1 = COP watchdog enabled
    0 = COP watchdog disabled

EPROM Programming Characteristics

Table 1. EPROM Programming Characteristics[1]

Characteristic	Symbol	Min	Typ	Max	Unit

Introduction

The central processor unit (CPU) consists of a CPU control unit, an arithmetic/logic unit (ALU), and five CPU registers. The CPU control unit fetches and decodes instructions. The ALU executes the instructions. The CPU registers contain data, addresses, and status bits that reflect the results of CPU operations.

Figure 1. Programming Model

CPU Control Unit

The CPU control unit fetches and decodes instructions during program operation. The control unit selects the memory locations to read and write and coordinates the timing of all CPU operations.

Arithmetic/Logic Unit

The arithmetic/logic unit (ALU) performs the arithmetic, logic, and manipulation operations decoded from the instruction set by the CPU control unit. The ALU produces the results called for by the program and sets or clears status and control bits in the condition code register (CCR).

CPU Registers

The M68HC05 CPU contains five registers that control and monitor MCU operation:

- Accumulator
- Index register
- Stack pointer
- Program counter
- Condition code register

CPU registers are not memory mapped.

Accumulator   The accumulator is a general-purpose 8-bit register. The CPU uses the
                     accumulator to hold operands and results of ALU operations.

	Bit 7	6	5	4	3	2	1	Bit 0
Read:								
Write:								
Reset:				Unaffected by Reset				
Figure 2. Accumulator (A)

Index Register   In the indexed addressing modes, the CPU uses the byte in the index
                     register to determine the conditional address of the operand. The index
                     register also can serve as a temporary storage location or a counter.

	Bit 7	6	5	4	3	2	1	Bit 0
Read:								
Write:								
Reset:				Unaffected by Reset				
Figure 3. Index Register (X)

Stack Pointer   The stack pointer is a 16-bit register that contains the address of the next
                     location on the stack. During a reset or after the reset stack pointer
                     instruction (RSP), the stack pointer is preset to $00FF. The address in
                     the stack pointer decrements after a byte is stacked and increments
                     before a byte is unstacked.

Write:																
Reset:	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1

= Unimplemented

Figure 4. Stack Pointer (SP)

The 10 most significant bits of the stack pointer are permanently fixed at 0000000011, so the stack pointer produces addresses from $00C0 to $00FF. If subroutines and interrupts use more than 64 stack locations, the stack pointer wraps around to address $00FF and begins writing over the previously stored data. A subroutine uses two stack locations; an interrupt uses five locations.
Program Counter   The program counter is a 16-bit register that contains the address of the next instruction or operand to be fetched. The five most significant bits of the program counter are ignored and appear as 00000.

Normally, the address in the program counter automatically increments to the next sequential memory location every time an instruction or operand is fetched. Jump, branch, and interrupt operations load the program counter with an address other than that of the next sequential location.

Reset: 0   0   0   0   0   Loaded with vector from $07FE and $07FF
Figure 5. Program Counter (PC)

Condition Code Register   The condition code register is an 8-bit register whose three most significant bits are permanently fixed at 111. The condition code register contains the interrupt mask and four flags that indicate the results of the instruction just executed.

Reset:	1	1	1	U	1	U	U	U

☐ = Unimplemented   U = Unaffected

Figure 6. Condition Code Register (CCR)

H — Half-Carry Flag

The CPU sets the half-carry flag when a carry occurs between bits 3 and 4 of the accumulator during an ADD or ADC operation. The half-carry flag is required for binary-coded decimal (BCD) arithmetic operations.

I — Interrupt Mask

Setting the interrupt mask disables interrupts. If an interrupt request occurs while the interrupt mask is logic 0, the CPU saves the CPU registers on the stack, sets the interrupt mask, and then fetches the interrupt vector. If an interrupt request occurs while the interrupt mask is logic 1, the interrupt request is latched. Normally, the CPU processes the latched interrupt request as soon as the interrupt mask is cleared again.

A return from interrupt instruction (RTI) unstacks the CPU registers, restoring the interrupt mask to its cleared state. After any reset, the interrupt mask is set and can be cleared only by a software instruction.

N — Negative Flag

The CPU sets the negative flag when an ALU operation produces a negative result.

Z — Zero Flag

The CPU sets the zero flag when an ALU operation produces a result of $00.

C — Carry/Borrow Flag

The CPU sets the carry/borrow flag when an addition operation produces a carry out of bit 7 of the accumulator or when a subtraction operation requires a borrow. Some logical operations and data manipulation instructions also clear or set the carry/borrow flag.

Instruction Set

The MCU instruction set has 62 instructions and uses eight addressing modes.

Addressing Modes   The CPU uses eight addressing modes for flexibility in accessing data. The addressing modes provide eight different ways for the CPU to find the data required to execute an instruction. The eight addressing modes are:

- Inherent

- Immediate

- Direct

- Extended

- Indexed, no offset

- Indexed, 8-bit offset

- Indexed, 16-bit offset

- Relative

Inherent   Inherent instructions are those that have no operand, such as return from interrupt (RTI) and stop (STOP). Some of the inherent instructions act on data in the CPU registers, such as set carry flag (SEC) and increment accumulator (INCA). Inherent instructions require no operand address and are one byte long.

Immediate   Immediate instructions are those that contain a value to be used in an operation with the value in the accumulator or index register. Immediate instructions require no operand address and are two bytes long. The opcode is the first byte, and the immediate data value is the second byte.

Direct   Direct instructions can access any of the first 256 memory locations with two bytes. The first byte is the opcode, and the second is the low byte of the operand address. In direct addressing, the CPU automatically uses $00 as the high byte of the operand address.

Extended

Extended instructions use three bytes and can access any address in memory. The first byte is the opcode; the second and third bytes are the high and low bytes of the operand address.

When using the Motorola assembler, the programmer does not need to specify whether an instruction is direct or extended. The assembler automatically selects the shortest form of the instruction.

Indexed,
No Offset

Indexed instructions with no offset are 1-byte instructions that can access data with variable addresses within the first 256 memory locations. The index register contains the low byte of the effective address of the operand. The CPU automatically uses $00 as the high byte, so these instructions can address locations $0000–$00FF.

Indexed, no offset instructions are often used to move a pointer through a table or to hold the address of a frequently used RAM or input/output (I/O) location.

Indexed,
8-Bit Offset

Indexed, 8-bit offset instructions are 2-byte instructions that can access data with variable addresses within the first 511 memory locations. The CPU adds the unsigned byte in the index register to the unsigned byte following the opcode. The sum is the effective address of the operand. These instructions can access locations $0000–$01FE.

Indexed 8-bit offset instructions are useful for selecting the kth element in an n-element table. The table can begin anywhere within the first 256 memory locations and could extend as far as location 510 ($01FE). The k value is typically in the index register, and the address of the beginning of the table is in the byte following the opcode.

Indexed,
16-Bit Offset

Indexed, 16-bit offset instructions are 3-byte instructions that can access data with variable addresses at any location in memory. The CPU adds the unsigned byte in the index register to the two unsigned bytes following the opcode. The sum is the effective address of the operand. The first byte after the opcode is the high byte of the 16-bit offset; the second byte is the low byte of the offset.

Indexed, 16-bit offset instructions are useful for selecting the kth element in an n-element table anywhere in memory.

As with direct and extended addressing, the Motorola assembler determines the shortest form of indexed addressing.

Relative

Relative addressing is only for branch instructions. If the branch condition is true, the CPU finds the effective branch destination by adding the signed byte following the opcode to the contents of the program counter. If the branch condition is not true, the CPU goes to the next instruction. The offset is a signed, two's complement byte that gives a branching range of −128 to +127 bytes from the address of the next location after the branch instruction.

When using the Motorola assembler, the programmer does not need to calculate the offset because the assembler determines the proper offset and verifies that it is within the span of the branch.

Instruction Types　The MCU instructions fall into the following five categories:

- Register/memory instructions
- Read-modify-write instructions
- Jump/branch instructions
- Bit manipulation instructions
- Control instructions

Register/Memory Instructions　These instructions operate on CPU registers and memory locations. Most of them use two operands. One operand is in either the accumulator or the index register. The CPU finds the other operand in memory.

Table 1. Register/Memory Instructions

Instruction	Mnemonic
Add Memory Byte and Carry Bit to Accumulator	ADC
Add Memory Byte to Accumulator	ADD
AND Memory Byte with Accumulator	AND
Bit Test Accumulator	BIT
Compare Accumulator	CMP
Compare Index Register with Memory Byte	CPX
EXCLUSIVE OR Accumulator with Memory Byte	EOR
Load Accumulator with Memory Byte	LDA
Load Index Register with Memory Byte	LDX
Multiply	MUL
OR Accumulator with Memory Byte	ORA
Subtract Memory Byte and Carry Bit from Accumulator	SBC
Store Accumulator in Memory	STA
Store Index Register in Memory	STX
Subtract Memory Byte from Accumulator	SUB

*Read-Modify-
Write Instructions*   These instructions read a memory location or a register, modify its
contents, and write the modified value back to the memory location or to
the register.

NOTE: *Do not use read-modify-write instructions on registers with write-only
bits.*

Table 2. Read-Modify-Write Instructions

Instruction	Mnemonic
Arithmetic Shift Left (Same as LSL)	ASL
Arithmetic Shift Right	ASR
Bit Clear	BCLR[1]
Bit Set	BSET[1]
Clear Register	CLR
Complement (One's Complement)	COM
Decrement	DEC
Increment	INC
Logical Shift Left (Same as ASL)	LSL
Logical Shift Right	LSR
Negate (Two's Complement)	NEG
Rotate Left through Carry Bit	ROL
Rotate Right through Carry Bit	ROR
Test for Negative or Zero	TST[2]

1. Unlike other read-modify-write instructions, BCLR and
   BSET use only direct addressing.

2. TST is an exception to the read-modify-write sequence
   because it does not write a replacement value.

Jump/Branch Instructions

Jump instructions allow the CPU to interrupt the normal sequence of the program counter. The unconditional jump instruction (JMP) and the jump-to-subroutine instruction (JSR) have no register operand. Branch instructions allow the CPU to interrupt the normal sequence of the program counter when a test condition is met. If the test condition is not met, the branch is not performed.

The BRCLR and BRSET instructions cause a branch based on the state of any readable bit in the first 256 memory locations. These 3-byte instructions use a combination of direct addressing and relative addressing. The direct address of the byte to be tested is in the byte following the opcode. The third byte is the signed offset byte. The CPU finds the effective branch destination by adding the third byte to the program counter if the specified bit tests true. The bit to be tested and its condition (set or clear) is part of the opcode. The span of branching is from –128 to +127 from the address of the next location after the branch instruction. The CPU also transfers the tested bit to the carry/borrow bit of the condition code register.

NOTE: *Do not use BRCLR or BRSET instructions on registers with write-only bits.*

Table 3. Jump and Branch Instructions

Instruction	Mnemonic
Branch if Carry Bit Clear	BCC
Branch if Carry Bit Set	BCS
Branch if Equal	BEQ
Branch if Half-Carry Bit Clear	BHCC
Branch if Half-Carry Bit Set	BHCS
Branch if Higher	BHI
Branch if Higher or Same	BHS
Branch if $\overline{\text{IRQ}}$ Pin High	BIH
Branch if $\overline{\text{IRQ}}$ Pin Low	BIL
Branch if Lower	BLO
Branch if Lower or Same	BLS
Branch if Interrupt Mask Clear	BMC
Branch if Minus	BMI
Branch if Interrupt Mask Set	BMS
Branch if Not Equal	BNE
Branch if Plus	BPL
Branch Always	BRA
Branch if Bit Clear	BRCLR
Branch Never	BRN
Branch if Bit Set	BRSET
Branch to Subroutine	BSR
Unconditional Jump	JMP
Jump to Subroutine	JSR

Bit Manipulation Instructions　　　The CPU can set or clear any writable bit in the first 256 bytes of memory, which includes I/O registers and on-chip RAM locations. The CPU can also test and branch based on the state of any bit in any of the first 256 memory locations.

Table 4. Bit Manipulation Instructions

Instruction	Mnemonic
Bit Clear	BCLR
Branch if Bit Clear	BRCLR
Branch if Bit Set	BRSET
Bit Set	BSET

NOTE:　　　*Do not use bit manipulation instructions on registers with write-only bits.*

Control Instructions　　　These instructions act on CPU registers and control CPU operation during program execution.

Table 5. Control Instructions

Instruction	Mnemonic
Clear Carry Bit	CLC
Clear Interrupt Mask	CLI
No Operation	NOP
Reset Stack Pointer	RSP
Return from Interrupt	RTI
Return from Subroutine	RTS
Set Carry Bit	SEC
Set Interrupt Mask	SEI
Stop Oscillator and Enable $\overline{\text{IRQ}}$ Pin	STOP
Software Interrupt	SWI
Transfer Accumulator to Index Register	TAX
Transfer Index Register to Accumulator	TXA
Stop CPU Clock and Enable Interrupts	WAIT

Resets and Interrupts

Contents

Introduction

Reset initializes the MCU by returning the program counter to a known address and by forcing control and status bits to known states.

Interrupts temporarily change the sequence of program execution to respond to events that occur during processing.

Resets   A reset immediately stops the operation of the instruction being executed, initializes certain control and status bits, and loads the program counter with a user-defined reset vector address. The following sources can generate a reset:

- Power-on reset (POR) circuit

- $\overline{\text{RESET}}$ pin

- Computer operating properly (COP) watchdog

- Illegal address
Figure 1. Reset Sources

Power-On Reset   A positive transition on the V_{DD} pin generates a power-on reset.

NOTE: *The power-on reset is strictly for power-up conditions and cannot be used to detect drops in power supply voltage.*

A 4064-t_{CYC} (internal clock cycle) delay after the oscillator becomes active allows the clock generator to stabilize. If any reset source is active at the end of this delay, the MCU remains in the reset condition until all reset sources are inactive.
NOTES:
   1. Power-on reset threshold is typically between 1 V and 2 V.
   2. Internal clock, internal address bus, and internal data bus are not available externally.

Figure 2. Power-On Reset Timing

External Reset   A logic 0 applied to the $\overline{\text{RESET}}$ pin for 1 1/2 t_{cyc} generates an external reset. A Schmitt trigger senses the logic level at the $\overline{\text{RESET}}$ pin.
NOTES:
   1. Internal clock, internal address bus, and internal data bus are not available externally.
   2. The next rising edge of the internal clock after the rising edge of $\overline{\text{RESET}}$ initiates the reset sequence.

Figure 3. External Reset Timing

Table 1. External Reset Timing

Characteristic	Symbol	Min	Max	Unit
$\overline{\text{RESET}}$ Pulse Width	t_{RL}	1.5	—	t_{cyc}

COP Watchdog
Reset

A timeout of the COP watchdog generates a COP reset. The COP watchdog is part of a software error detection system and must be cleared periodically to start a new timeout period. To clear the COP watchdog and prevent a COP reset, write a logic 0 to bit 0 (COPC) of the COP register at location $07F0.

Illegal Address
Reset

An opcode fetch from an address not in RAM or EPROM generates a reset.

Interrupts

The following sources can generate interrupts:

- SWI instruction
- External interrupt pins
  - $\overline{\text{IRQ}}$/V_{PP} pin
  - PA0–PA3
- Timer
  - Real-time interrupt flag (RTIF)
  - Timer overflow flag (TOF)

An interrupt temporarily stops the program sequence to process a particular event. An interrupt does not stop the operation of the instruction being executed, but takes effect when the current instruction completes its execution. Interrupt processing automatically saves the CPU registers on the stack and loads the program counter with a user-defined interrupt vector address.

Software Interrupt

The software interrupt (SWI) instruction causes a nonmaskable interrupt.

External Interrupt

An interrupt signal on the $\overline{\text{IRQ}}$/V_{PP} pin latches an external interrupt request. When the CPU completes its current instruction, it tests the IRQ latch. If the IRQ latch is set, the CPU then tests the I bit in the condition

code register. If the I bit is clear, the CPU then begins the interrupt sequence.

The CPU clears the IRQ latch during interrupt processing, so that another interrupt signal on the $\overline{IRQ}/V_{PP}$ pin can latch another interrupt request during the interrupt service routine. As soon as the I bit is cleared during the return from interrupt, the CPU can recognize the new interrupt request. **Figure 4** shows the $\overline{IRQ}/V_{PP}$ pin interrupt logic.
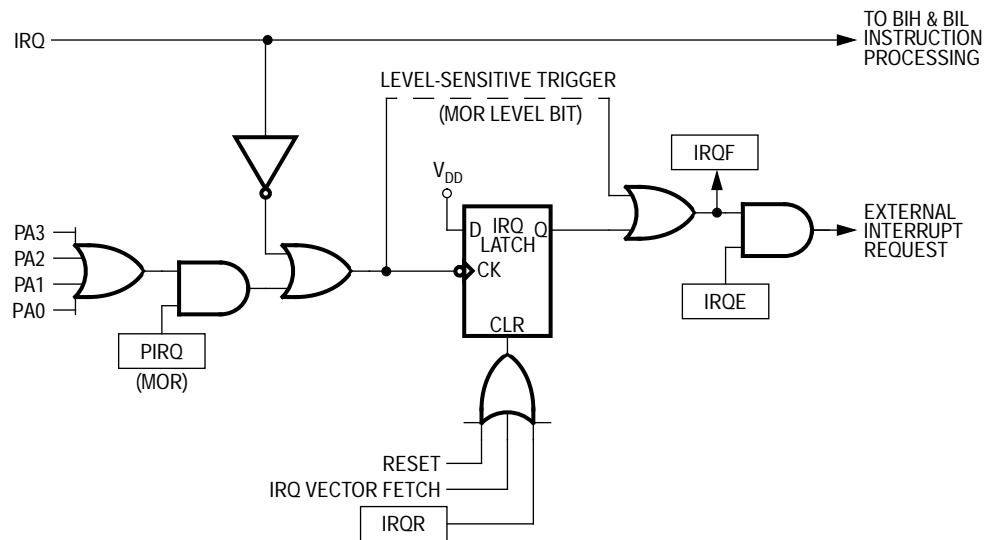

Figure 4. External Interrupt Logic

Setting the I bit in the condition code register disables external interrupts.

The port A external interrupt bit (PIRQ) in the mask option register enables pins PA0–PA3 to function as external interrupt pins.

The external interrupt sensitivity bit (LEVEL) in the mask option register controls interrupt triggering sensitivity of external interrupt pins. The $\overline{IRQ}/V_{PP}$ pin can be negative-edge triggered only or negative-edge and low-level triggered. Port A external interrupt pins can be positive-edge triggered only or both positive-edge and high-level triggered. The level-sensitive triggering option allows multiple external interrupt sources to be wire-ORed to an external interrupt pin. An external interrupt request, shown in **Figure 5**, is latched as long as any source is holding an external interrupt pin low.

Figure 5. External Interrupt Timing

Table 2. External Interrupt Timing (V_{DD} = 5.0 Vdc)[1]

Characteristic	Symbol	Min	Max	Unit
Interrupt Pulse Width Low (Edge-Triggered)	t_{ILIH}	125	—	ns
Interrupt Pulse Period	t_{ILIL}	Note[2]	—	t_{cyc}

1. V_{DD} = 5.0 Vdc ±10%, V_{SS} = 0 Vdc, T_A = –40 °C to +105 °C unless otherwise noted.
2. The minimum t_{ILIL} should not be less than the number of interrupt service routine cycles plus 19 t_{cyc}.

Table 3. External Interrupt Timing (V_{DD} = 3.3 Vdc)[1]

Characteristic	Symbol	Min	Max	Unit
Interrupt Pulse Width Low (Edge-Triggered)	t_{ILIH}	250	—	ns
Interrupt Pulse Period	t_{ILIL}	Note[2]	—	t_{cyc}

1. V_{DD} = 3.3 Vdc ±10%, V_{SS} = 0 Vdc, T_A = –40 °C to +105 °C unless otherwise noted.
2. The minimum t_{ILIL} should not be less than the number of interrupt service routine cycles plus 19 t_{cyc}.

Timer Interrupts   The timer can generate the following interrupt requests:

- Real time

- Timer overflow

Setting the I bit in the condition code register disables timer interrupts.

Real-Time Interrupt   A real-time interrupt occurs if the real-time interrupt flag, RTIF, becomes set while the real-time interrupt enable bit, RTIE, is also set. RTIF and RTIE are in the timer status and control register.

Timer Overflow Interrupt   A timer overflow interrupt request occurs if the timer overflow flag, TOF, becomes set while the timer overflow interrupt enable bit, TOIE, is also set. TOF and TOIE are in the timer status and control register.

Interrupt Processing   The CPU takes the following actions to begin servicing an interrupt:

- Stores the CPU registers on the stack in the order shown in **Figure 6**

- Sets the I bit in the condition code register to prevent further interrupts

- Loads the program counter with the contents of the appropriate interrupt vector locations:

    – $07FC and $07FD (software interrupt vector)

    – $07FA and $07FB (external interrupt vector)

    – $07F8 and $07F9 (timer interrupt vector)

The return from interrupt (RTI) instruction causes the CPU to recover the CPU registers from the stack as shown in **Figure 6**.

Figure 7. Interrupt Flowchart

Low-Power Modes

Contents

Introduction

The MCU can enter the following low-power standby modes:

- Stop mode — The STOP instruction puts the MCU in its lowest power-consumption mode.

- Wait mode — The WAIT instruction puts the MCU in an intermediate power-consumption mode.

- Halt mode — Halt mode is identical to wait mode, except that an oscillator stabilization delay of 1 to 4064 internal clock cycles occurs when the MCU exits halt mode. The stop-to-wait conversion bit, SWAIT, in the mask option register, enables halt mode.

  Enabling halt mode prevents the computer operating properly (COP) watchdog from being inadvertently turned off by a STOP instruction.

- Data-retention mode — In data-retention mode, the MCU retains RAM contents and CPU register contents at V_{DD} voltages as low as 2.0 Vdc. The data-retention feature allows the MCU to remain in a low power-consumption state during which it retains data, but the CPU cannot execute instructions.

Exiting Stop and Wait Modes

The following events bring the MCU out of stop mode and load the program counter with the reset vector or with an interrupt vector:

Exiting Stop Mode
- External reset — A logic 0 on the $\overline{RESET}$ pin resets the MCU, starts the CPU clock, and loads the program counter with the contents of locations $07FE and $07FF.

- External interrupt — A high-to-low transition on the $\overline{IRQ}$/V_{PP} pin or a low-to-high transition on an enabled port A external interrupt pin starts the CPU clock and loads the program counter with the contents of locations $07FA and $07FB.

Exiting Wait Mode
- External reset — A logic 0 on the $\overline{\text{RESET}}$ pin resets the MCU, starts the CPU clock, and loads the program counter with the contents of locations $07FE and $07FF.

- External interrupt — A high-to-low transition on the $\overline{\text{IRQ}}$/V$_{PP}$ pin or a low-to-high transition on an enabled port A external interrupt pin starts the CPU clock and loads the program counter with the contents of locations $07FA and $07FB.

- COP watchdog reset — A timeout of the COP watchdog resets the MCU, starts the CPU clock, and loads the program counter with the contents of locations $07FE and $07FF. Software can enable timer interrupts so that the MCU periodically can exit wait mode to reset the COP watchdog.

- Timer interrupt — Real-time interrupt requests and timer overflow interrupt requests start the MCU clock and load the program counter with the contents of locations $07F8 and $07F9.

Effects of Stop and Wait Modes

The STOP and WAIT instructions have the following effects on MCU modules.

Clock Generation   Effects of STOP and WAIT:

STOP   The STOP instruction disables the internal oscillator, stopping the CPU clock and all peripheral clocks.

After exiting stop mode, the CPU clock and all enabled peripheral clocks begin running after the oscillator stabilization delay.

NOTE: *The oscillator stabilization delay holds the MCU in reset for the first 4064 internal clock cycles.*

WAIT   The WAIT instruction disables the CPU clock.

After exiting wait mode, the CPU clock and all enabled peripheral clocks immediately begin running.

CPU   Effects of STOP and WAIT:

STOP   The STOP instruction:

- Clears the interrupt mask (I bit) in the condition code register, enabling external interrupts
- Disables the CPU clock

After exiting stop mode, the CPU clock begins running after the oscillator stabilization delay.

After exit from stop mode by external interrupt, the I bit remains clear.

After exit from stop mode by reset, the I bit is set.

WAIT   The WAIT instruction:

- Clears the interrupt mask (I bit) in the condition code register, enabling interrupts
- Disables the CPU clock

After exit from wait mode by interrupt, the I bit remains clear.

After exit from wait mode by reset, the I bit is set.

COP Watchdog   Effects of STOP and WAIT:

STOP   The STOP instruction:

- Clears the COP watchdog counter
- Disables the COP watchdog clock

NOTE: *To prevent the STOP instruction from disabling the COP watchdog, program the stop-to-wait conversion bit (SWAIT) in the mask option register to logic 1.*

After exit from stop mode by external interrupt, the COP watchdog counter immediately begins counting from $0000 and continues counting throughout the oscillator stabilization delay.

NOTE: *Immediately after exiting stop mode by external interrupt, service the COP to ensure a full COP timeout period.*

After exit from stop mode by reset:

- The COP watchdog counter immediately begins counting from $0000.

- The COP watchdog counter is cleared at the end of the oscillator stabilization delay and begins counting from $0000 again.

WAIT   The WAIT instruction has no effect on the COP watchdog.

NOTE: *To prevent a COP timeout during wait mode, exit wait mode periodically to service the COP.*

Timer   Effects of STOP and WAIT:

STOP
- Clears the RTIE, TOFE, RTIF, and TOF bits in the timer status and control register, disabling timer interrupt requests and removing any pending timer interrupt requests

- Disables the clock to the timer

After exiting stop mode by external interrupt, the timer immediately resumes counting from the last value before the STOP instruction and continues counting throughout the oscillator stabilization delay.

After exiting stop mode by reset and after the oscillator stabilization delay, the timer resumes operation from its reset state.

WAIT   The WAIT instruction has no effect on the timer.

EPROM/OTPROM   Effects of STOP and WAIT:

STOP   The STOP instruction during EPROM programming clears the EPGM bit
                         in the EPROM programming register, removing the programming
                         voltage from the EPROM.

WAIT   The WAIT instruction has no effect on EPROM/OTPROM operation.

Data-Retention Mode

In data-retention mode, the MCU retains RAM contents and CPU
register contents at V_{DD} voltages as low as 2.0 Vdc. The data-retention
feature allows the MCU to remain in a low power-consumption state
during which it retains data, but the CPU cannot execute instructions.

To put the MCU in data-retention mode:

1. Drive the $\overline{\text{RESET}}$ pin to logic 0.
2. Lower the V_{DD} voltage. The $\overline{\text{RESET}}$ pin must remain low
   continuously during data-retention mode.

To take the MCU out of data-retention mode:

1. Return V_{DD} to normal operating voltage.
2. Return the $\overline{\text{RESET}}$ pin to logic 1.

Introduction

Fourteen bidirectional pins form one 8-bit input/output (I/O) port and one 6-bit I/O port. All the bidirectional port pins are programmable as inputs or outputs.

NOTE: *Connect any unused I/O pins to an appropriate logic level, either V_{DD} or V_{SS}. Although the I/O ports do not require termination for proper operation, termination reduces excess current consumption and the possibility of electrostatic damage.*

Figure 1. Parallel I/O Port Register Summary

Port A

Port A is an 8-bit bidirectional port.

Port A Data Register

The port A data register contains a latch for each port A pin.

Address: $0000

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	PA7	PA6	PA5	PA4	PA3	PA2	PA1	PA0
Write:								
Reset:				Unaffected by Reset				

Figure 2. Port A Data Register (PORTA)

PA[7:0] — Port A Data Bits

These read/write bits are software programmable. Data direction of each port A pin is under the control of the corresponding bit in data direction register A. Reset has no effect on port A data.

Data Direction Register A

Data direction register A determines whether each port A pin is an input or an output.

Address: $0004

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	DDRA7	DDRA6	DDRA5	DDRA4	DDRA3	DDRA2	DDRA1	DDRA0
Write:								
Reset:	0	0	0	0	0	0	0	0

Figure 3. Data Direction Register A (DDRA)

DDRA[7:0] — Data Direction Register A Bits

These read/write bits control port A data direction. Reset clears DDRA[7:0], configuring all port A pins as inputs.
1 = Corresponding port A pin configured as output
0 = Corresponding port A pin configured as input

NOTE: *Avoid glitches on port A pins by writing to the port A data register before changing data direction register A bits from 0 to 1.*

Figure 4 shows the I/O logic of port A.
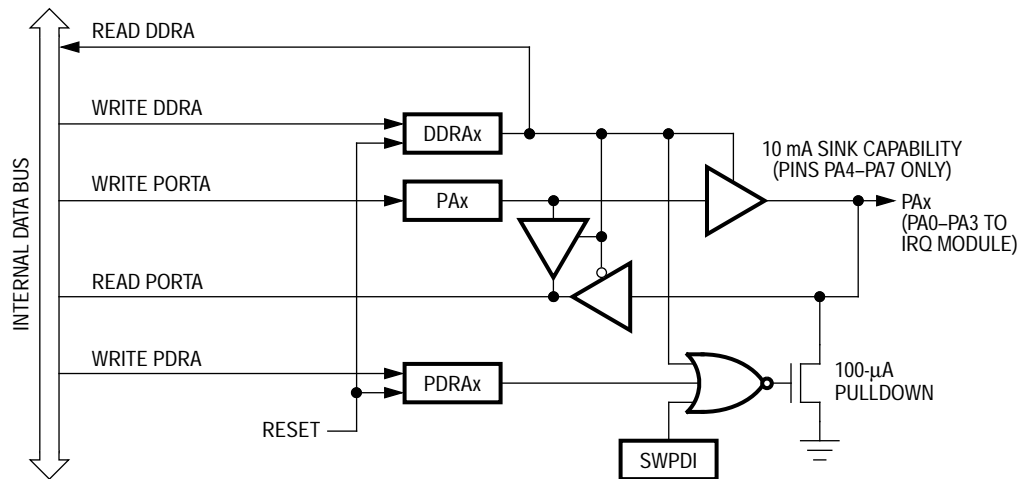

Figure 4. Port A I/O Circuitry

Writing a logic 1 to a DDRA bit enables the output buffer for the corresponding port A pin; a logic 0 disables the output buffer.

When bit DDRAx is a logic 1, reading address $0000 reads the PAx data latch. When bit DDRAx is a logic 0, reading address $0000 reads the voltage level on the pin. The data latch can always be written, regardless of the state of its data direction bit. **Table 1** summarizes the operation of the port A pins.

Table 1. Port A Pin Operation

Data Direction Bit	I/O Pin Mode	Accesses to Data Bit	
		Read	Write
0	Input, high-impedance	Pin	Latch[1]
1	Output	Latch	Latch

1. Writing affects data register but does not affect input.

Pulldown Register A

Pulldown register A inhibits the pulldown devices on port A pins programmed as inputs.

NOTE: *If the SWPDI bit in the mask option register is programmed to logic 1, reset initializes all port A pins as inputs with enabled pulldown devices.*

Address: $0010

	Bit 7	6	5	4	3	2	1	Bit 0
Read:								
Write:	PDIA7	PDIA6	PDIA5	PDIA4	PDIA3	PDIA2	PDIA1	PDIA0
Reset:	0	0	0	0	0	0	0	0

= Unimplemented

2. Typical values reflect average measurements at midpoint of voltage range, 25 °C.

Computer Operating Properly Module

Contents

Features

- Protection from Runaway Software

- Wait and Halt Mode Operation

Introduction

The computer operating properly (COP) watchdog resets the MCU in case of software failure. Software that is operating properly periodically services the COP watchdog and prevents COP reset. The COP watchdog function is programmable by the COPEN bit in the mask option register.

Operation

COP Watchdog Timeout

Four counter stages at the end of the timer make up the COP watchdog. The COP resets the MCU if the timeout period occurs before the COP watchdog timer is cleared by application software and the $\overline{IRQ}/V_{PP}$ pin voltage is between V_{SS} and V_{DD}. Periodically clearing the counter starts a new timeout period and prevents COP reset. A COP watchdog timeout indicates that the software is not executing instructions in the correct sequence.

NOTE: *The internal clock drives the COP watchdog. Therefore, the COP watchdog cannot generate a reset for errors that cause the internal clock to stop.*

NOTE: *The COP watchdog depends on a power supply voltage at or above a minimum specification and is not guaranteed to protect against brownout.*

COP Watchdog Timeout Period

The COP watchdog timer function is implemented by dividing the output of the real-time interrupt circuit (RTI) by eight. The RTI select bits in the timer status and control register control RTI output, and the selected output drives the COP watchdog. (See timer status and control register in **Multifunction Timer Module**.)

Note that the minimum COP timeout period is seven times the RTI period. The COP is cleared asynchronously with the value in the RTI divider; hence, the COP timeout period will vary between 7x and 8x the RTI period.

Clearing the COP Watchdog

To clear the COP watchdog and prevent a COP reset, write a logic 0 to bit 0 (COPC) of the COP register at location $07F0 (see **Figure 1**). Clearing the COP bit disables the COP watchdog timer regardless of the $\overline{IRQ}/V_{PP}$ pin voltage.

If the main program executes within the COP timeout period, the clearing routine should be executed only once. If the main program takes longer than the COP timeout period, the clearing routine must be executed more than once.

NOTE: *Place the clearing routine in the main program and not in an interrupt routine. Clearing the COP watchdog in an interrupt routine might prevent COP watchdog timeouts even though the main program is not operating properly.*

Interrupts

The COP watchdog does not generate interrupts.

COP Register

The COP register (COPR) is a write-only register that returns the contents of EPROM location $07F0 when read.

Address: $07F0

	Bit 7	6	5	4	3	2	1	Bit 0
Read:								
Write:								COPC
Reset:								0

[ ] = Unimplemented
Figure 1. COP Register

COPC — COP Clear

This write-only bit resets the COP watchdog. Reading address $07F0 returns undefined results.

Low-Power Modes

The STOP and WAIT instructions have the following effects on the COP watchdog.

Stop Mode

The STOP instruction clears the COP watchdog counter and disables the clock to the COP watchdog.

NOTE: *To prevent the STOP instruction from disabling the COP watchdog, program the stop-to-wait conversion bit (SWAIT) in the mask option register to logic 1.*

Upon exit from stop mode by external reset:

- The counter begins counting from $0000.

- The counter is cleared again after the oscillator stabilization delay and begins counting from $0000 again.

Upon exit from stop mode by external interrupt:

- The counter begins counting from $0000.

- The counter is not cleared again after the oscillator stabilization delay and continues counting throughout the oscillator stabilization delay.

NOTE: *Immediately after exiting stop mode by external interrupt, service the COP to ensure a full COP timeout period.*

Wait Mode

The WAIT instruction has no effect on the COP watchdog.

NOTE: *To prevent a COP timeout during wait mode, exit wait mode periodically to service the COP.*

Contents

Features

- Dedicated External Interrupt Pin ($\overline{\text{IRQ}}$/V$_{PP}$)

- Selectable Interrupt on Four Input/Output (I/O) Pins (PA0–PA3)

- Programmable Edge-Only or Edge- and Level-Interrupt Sensitivity

Introduction

The external interrupt (IRQ) module provides asynchronous external interrupts to the CPU. The following sources can generate external interrupts:

- $\overline{\text{IRQ}}$/V$_{\text{PP}}$ pin
- PA0–PA3 pins

Operation

The interrupt request/programming voltage pin ($\overline{\text{IRQ}}$/V$_{\text{PP}}$) and port A pins 0–3 (PA0–PA3) provide external interrupts. The PIRQ bit in the mask option register (MOR) enables PA0–PA3 as IRQ interrupt sources, which are combined into a single OR'ing function to be latched by the IRQ latch. **Figure 1** shows the structure of the IRQ module.

After completing its current instruction, the CPU tests the IRQ latch. If the IRQ latch is set, the CPU then tests the I bit in the condition code register and the IRQE bit in the IRQ status and control register. If the I bit is clear and the IRQE bit is set, the CPU then begins the interrupt sequence. This interrupt is serviced by the interrupt service routine located at $07FA and $07FB.

The CPU clears the IRQ latch while it fetches the interrupt vector, so that another external interrupt request can be latched during the interrupt service routine. As soon as the I bit is cleared during the return from interrupt, the CPU can recognize the new interrupt request. **Figure 3** shows the sequence of events caused by an interrupt.
Figure 1. IRQ Module Block Diagram

Register Name		Bit 7	6	5	4	3	2	1	Bit 0
IRQ Status and Control Register (ISCR)	Read:	IRQE	0	0	0	IRQF	0	0	0

Figure 2. IRQ Module I/O Register Summary

Table 1. I/O Register Address Summary

Register:	ISCR
Address:	$000A
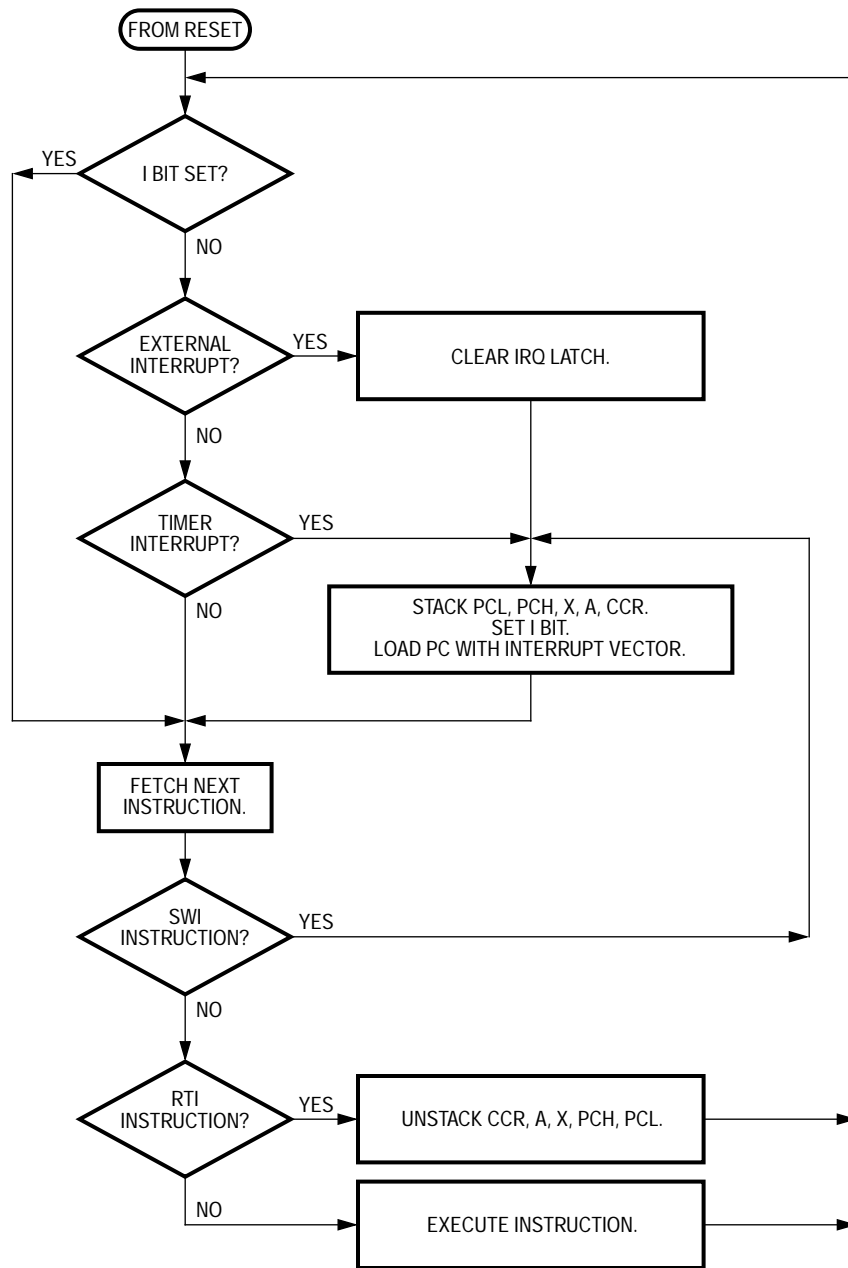

Figure 3. Interrupt Flowchart

4-@kbielpa4hpd_a

$\overline{\text{IRQ}}$/V$_{PP}$ Pin   An interrupt signal on the $\overline{\text{IRQ}}$/V$_{PP}$ pin latches an external interrupt request. The LEVEL bit in the mask option register provides negative edge-sensitive triggering or both negative edge-sensitive and low level-sensitive triggering for the interrupt function.

If edge- and level-sensitive triggering is selected, a falling edge or a low level on the $\overline{\text{IRQ}}$/V$_{PP}$ pin latches an external interrupt request. Edge- and level-sensitive triggering allows the use of multiple wired-OR external interrupt sources. An external interrupt request is latched as long as any source is holding the $\overline{\text{IRQ}}$/V$_{PP}$ pin low.

If level-sensitive triggering is selected, the $\overline{\text{IRQ}}$/V$_{PP}$ input requires an external resistor to V$_{DD}$ for wired-OR operation. If the $\overline{\text{IRQ}}$/V$_{PP}$ pin is not used, it must be tied to the V$_{DD}$ supply.

If edge-sensitive-only triggering is selected, a falling edge on the $\overline{\text{IRQ}}$/V$_{PP}$ pin latches an external interrupt request. A subsequent external interrupt request can be latched only after the voltage level on the $\overline{\text{IRQ}}$/V$_{PP}$ pin returns to logic 1 and then falls again to logic 0.

The $\overline{\text{IRQ}}$/V$_{PP}$ pin contains an internal Schmitt trigger as part of its input to improve noise immunity. The voltage on this pin can affect the mode of operation and should not exceed V$_{DD}$.

Optional External Interrupts

The inputs for the lower four bits of port A (PA0–PA3) can be connected to the IRQ pin input of the CPU if enabled by the PIRQ bit in the mask option register. This capability allows keyboard scan applications where the transitions or levels on the I/O pins will behave the same as the $\overline{IRQ}/V_{PP}$ pin except for the inverted phase (logic 1, rising edge). The active state of the $\overline{IRQ}/V_{PP}$ pin is a logic 0 (falling edge).

The PA0–PA3 pins are selected as a group to function as IRQ interrupts and are enabled by the IRQE bit in the IRQ status and control register. The PA0–PA3 pins can be positive-edge triggered only or positive-edge and high-level triggered.

If edge- and level-sensitive triggering is selected, a rising edge or a high level on a PA0–PA3 pin latches an external interrupt request. Edge- and level-sensitive triggering allows the use of multiple wired-OR external interrupt sources. As long as any source is holding a PA0–PA3 pin high, an external interrupt request is latched, and the CPU continues to execute the interrupt service routine.

If edge-sensitive only triggering is selected, a rising edge on a PA0–PA3 pin latches an external interrupt request. A subsequent external interrupt request can be latched only after the voltage level of the previous interrupt signal returns to logic 0 and then rises again to logic 1.

NOTE: *The BIH and BIL instructions apply only to the level on the $\overline{IRQ}/V_{PP}$ pin itself and not to the output of the logic OR function with the PA0–PA3 pins. The state of the individual port A pins can be checked by reading the appropriate port A pins as inputs.*

NOTE: *Enabled PA0–PA3 pins cause an IRQ interrupt regardless of whether these pins are configured as inputs or outputs.*

NOTE: *The IRQ pin has an internal Schmitt trigger. The optional external interrupts (PA0–PA3) do not have internal Schmitt triggers.*

NOTE: *The interrupt mask bit (I) in the condition code register (CCR) disables all maskable interrupt requests, including external interrupt requests.*

IRQ Status and Control Register

The IRQ status and control register (ISCR) controls and monitors operation of the IRQ module. All unused bits in the ISCR read as logic 0s. The IRQF bit is cleared and the IRQE bit is set by reset.

Address: $000A

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	IRQE	0	0	0	IRQF	0	0	0
Write:				R			IRQR	
Reset:	1	0	0	0	0	0	0	0

           = Unimplemented   R = Reserved

Figure 4. IRQ Status and Control Register (ISCR)

IRQR — Interrupt Request Reset

This write-only bit clears the external interrupt request flag.
1 = Clears external interrupt and IRQF bit
0 = No effect on external interrupt and IRQF bit

IRQF — External Interrupt Request Flag

The external interrupt request flag is a clearable, read-only bit that is set when an external interrupt request is pending. Reset clears the IRQF bit.
1 = External interrupt request pending
0 = No external interrupt request pending

IRQE — External Interrupt Request Enable

This read/write bit enables external interrupts. Reset sets the IRQE bit.
1 = External interrupt requests enabled
0 = External interrupt requests disabled

The STOP and WAIT instructions set the IRQE bit so that an external interrupt can bring the MCU out of these low-power modes. In addition, reset sets the I bit which masks all interrupt sources.

Timing

Figure 5. External Interrupt Timing

Table 2. External Interrupt Timing (V_{DD} = 5.0 Vdc)[1]

Characteristic	Symbol	Min	Max	Unit
IRQ Interrupt Pulse Width Low (Edge-Triggered)	t_{ILIH}	1.5	—	t_{cyc}[2]
IRQ Interrupt Pulse Width (Edge- and Level-Triggered)	t_{ILIH}	1.5	Note (3)	t_{cyc}
PA0–PA3 Interrupt Pulse Width High (Edge-Triggered)	t_{ILIL}	1.5	—	t_{cyc}
PA0–PA3 Interrupt Pulse Width High (Edge- and Level-Triggered)	t_{ILIH}	1.5	Note (3)	t_{cyc}

1. V_{DD} = 5.0 Vdc $\pm$ 10%, V_{SS} = 0 Vdc, T_A = –40 °C to + 105 °C unless otherwise noted.
2. t_{cyc} = $1/f_{op}$; f_{op} = $f_{osc}/2$.
3. The minimum t_{ILIL} should not be less than the number of interrupt service routine cycles plus 19 t_{cyc}.

Table 3. External Interrupt Timing (V_{DD} = 3.3 Vdc)[1]

Characteristic	Symbol	Min	Max	Unit
IRQ Interrupt Pulse Width Low (Edge-Triggered)	t_{ILIH}	1.5	—	t_{cyc}[2]
IRQ Interrupt Pulse Width (Edge- and Level-Triggered)	t_{ILIH}	1.5	Note (3)	t_{cyc}
PA0–PA3 Interrupt Pulse Width High (Edge-Triggered)	t_{ILIL}	1.5	—	t_{cyc}
PA0–PA3 Interrupt Pulse Width High (Edge- and Level-Triggered)	t_{ILIH}	1.5	Note (3)	t_{cyc}

1. V_{DD} = 3.3 Vdc $\pm$ 10%, V_{SS} = 0 Vdc, T_A = –40 °C to + 105 °C unless otherwise noted.
2. t_{cyc} = $1/f_{op}$; f_{op} = $f_{osc}/2$.
3. The minimum t_{ILIL} should not be less than the number of interrupt service routine cycles plus 19 t_{cyc}.

Figure 2. I/O Register Summary

Table 1. I/O Register Address Summary

Register:	TSCR	TCR
Address:	$0008	$0009

Operation

A 15-stage ripple counter, preceded by a prescaler that divides the internal clock signal by four, provides the timing reference for the timer functions. The value of the first eight timer stages can be read at any time by accessing the timer counter register at address $0009. A timer overflow function at the eighth stage allows a timer interrupt every 1024 internal clock cycles.

The next four stages lead to the real-time interrupt (RTI) circuit. The RT1 and RT0 bits in the timer status and control register at address $0008 allow a timer interrupt every 16,384, 32,768, 65,536, or 131,072 clock cycles. The last four stages drive the selectable COP system. (For information on the COP, refer to the **Computer Operating Properly Module**.)

Interrupts

The following timer sources can generate interrupts:

- Timer overflow flag (TOF) — The TOF bit is set when the first eight stages of the counter roll over from $FF to $00. The timer overflow interrupt enable bit, TOIE, enables TOF interrupt requests.

- Real-time interrupt flag (RTIF) — The RTIF bit is set when the selected RTI output becomes active. The real-time interrupt enable bit, RTIE, enables RTIF interrupt requests.

I/O Registers

The following registers control and monitor the timer operation:

- Timer status and control register (TSCR)
- Timer counter register (TCR)

Timer Status and Control Register

The read/write timer status and control register performs the following functions:

- Flags timer interrupts
- Enables timer interrupts
- Resets timer interrupt flags
- Selects real-time interrupt rates

Address: $0008

	Bit 7	6	5	4	3	2	1	Bit 0

Write:					TOFR	RTIFR		
Reset:	0	0	0	0	0	0	1	1

= Unimplemented

Figure 3. Timer Status and Control Register (TSCR)

TOF — Timer Overflow Flag

This read-only flag becomes set when the first eight stages of the counter roll over from $FF to $00. TOF generates a timer overflow interrupt request if TOIE is also set. Clear TOF by writing a logic 1 to the TOFR bit. Writing to TOF has no effect. Reset clears TOF.

RTIF — Real-Time Interrupt Flag

This read-only flag becomes set when the selected RTI output becomes active. RTIF generates a real-time interrupt request if RTIE is also set. Clear RTIF by writing a logic 1 to the RTIFR bit. Writing to RTIF has no effect. Reset clears RTIF.

TOIE — Timer Overflow Interrupt Enable

This read/write bit enables timer overflow interrupts. Reset clears TOIE.
    1 = Timer overflow interrupts enabled
    0 = Timer overflow interrupts disabled

RTIE — Real-Time Interrupt Enable

This read/write bit enables real-time interrupts. Reset clears RTIE.
    1 = Real-time interrupts enabled
    0 = Real-time interrupts disabled

TOFR — Timer Overflow Flag Reset

Writing a logic 1 to this write-only bit clears the TOF bit. TOFR always reads as logic 0. Reset clears TOFR.

RTIFR — Real-Time Interrupt Flag Reset

Writing a logic 1 to this write-only bit clears the RTIF bit. RTIFR always reads as logic 0. Reset clears RTIFR.

RT1 and RT0 — Real-Time Interrupt Select Bits

These read/write bits select one of four real-time interrupt rates, as shown in **Table 2**. Because the selected RTI output drives the COP watchdog, changing the real-time interrupt rate also changes the counting rate of the COP watchdog. Reset sets RT1 and RT0.

NOTE: *Changing RT1 and RT0 when a COP timeout is imminent can cause a real-time interrupt request to be missed or an additional real-time interrupt request to be generated. To prevent this occurrence, clear the COP timer before changing RT1 and RT0.*

Table 2. Real-Time Interrupt Rate Selection

RT1:RT0	RTI Rate	RTI Period (f_{OP} = 2 MHz)	COP Timeout Period (−0/+1 RTI Period)	Minimum COP Timeout Period (f_{OP} = 2 MHz)
00	$f_{OP} \div 2^{14}$	8.2 ms	7 x RTI Period	57.3 ms
01	$f_{OP} \div 2^{15}$	16.4 ms	7 x RTI Period	114.6 ms
10	$f_{OP} \div 2^{16}$	32.8 ms	7 x RTI Period	229.3 ms
11	$f_{OP} \div 2^{17}$	65.5 ms	7 x RTI Period	458.7 ms

Timer Counter Register

A 15-stage ripple counter is the core of the timer. The value of the first eight stages is readable at any time from the read-only timer counter register shown in **Figure 4**.

Address: $0009

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	TMR7	TMR6	TMR5	TMR4	TMR3	TMR2	TMR1	TMR0
Write:								
Reset:	0	0	0	0	0	0	0	0

= Unimplemented
Figure 4. Timer Counter Register (TCR)

Power-on clears the entire counter chain and the internal clock begins clocking the counter. After 4064 cycles (or 16 cycles if the SOSCD bit in the mask option register is set), the power-on reset circuit is released, clearing the counter again and allowing the MCU to come out of reset.

A timer overflow function at the eighth counter stage allows a timer interrupt every 1024 internal clock cycles.

Low-Power Modes

The STOP and WAIT instructions put the MCU in low power-consumption standby states.

Stop Mode

The STOP instruction has the following effects on the timer:

- Clears the timer counter

- Clears interrupt flags (TOF and RTIF) and interrupt enable bits (TOFE and RTIE) in TSCR, removing any pending timer interrupt requests and disabling further timer interrupts.

Wait Mode

The timer remains active after a WAIT instruction. Any enabled timer interrupt request can bring the MCU out of wait mode.

Contents

Maximum Ratings

Maximum ratings are the extreme limits to which the MCU can be exposed without permanently damaging it.

The MCU contains circuitry to protect the inputs against damage from high static voltages; however, do not apply voltages higher than those shown in **Table 1**. Keep V_{in} and V_{out} within the range $V_{SS} \leq (V_{in}$ or $V_{out}) \leq V_{DD}$. Connect unused inputs to the appropriate voltage level, either V_{SS} or V_{DD}.

Table 1. Maximum Ratings[1]

Rating	Symbol	Value	Unit
Supply Voltage	V_{DD}	−0.3 to +7.0	V
Current Drain per Pin (Excluding V_{DD}, V_{SS}, and PA4–PA7)	I	25	mA
Input Voltage	V_{in}	$V_{SS} - 0.3$ to $V_{DD} + 0.3$	V
$\overline{IRQ}/V_{PP}$ Pin	V_{PP}	$V_{SS} - 0.3$ to 2 x $V_{DD} + 0.3$	V
Storage Temperature Range	T_{STG}	−65 to +150	°C

1. Voltages are referenced to V_{SS}.

NOTE: *This device is not guaranteed to operate properly at the maximum ratings. Refer to* **5.0 V DC Electrical Characteristics** *and* **3.3 V DC Electrical Characteristics** *for guaranteed operating conditions.*

Operating Temperature Range

Table 2. Operating Temperature Range

Package Type	Symbol	Value (T_L to T_H)	Unit
MC68HC705J1AP[1], DW[2], S[3]	T_A	0 to 70	°C
MC68HC705J1AC[4]P, CDW, CS	T_A	−40 to +85	°C
MC68HC705J1AV[5]P, VDW, VS	T_A	−40 to +105	°C

1. P = plastic dual in-line package (PDIP)
2. DW = small outline integrated circuit (SOIC)
3. S = ceramic DIP (Cerdip)
4. C = extended temperature range
5. V = automotive temperature range

Thermal Characteristics

Table 3. Thermal Characteristics

Characteristic	Symbol	Value	Unit
Thermal Resistance MC68HC705J1AP[1] MC68HC705J1ADW[2] MC68HC705J1AS[3]	θ_{JA}	60	°C/W

1. P = plastic dual in-line package (PDIP)
2. DW = small outline integrated circuit (SOIC)
3. S = ceramic DIP (Cerdip)

Power Considerations

The average chip junction temperature, T_J, in °C can be obtained from:

$$T_J = T_A + (P_D \times \theta_{JA})$$ (1)

where:

T_A = ambient temperature in °C

θ_{JA} = package thermal resistance, junction to ambient in °C/W

$P_D = P_{INT} + P_{I/O}$

$P_{INT} = I_{CC} \times V_{CC}$ = chip internal power dissipation

$P_{I/O}$ = power dissipation on input and output pins (user-determined)

For most applications, $P_{I/O} \ll P_{INT}$ and can be neglected.

Ignoring $P_{I/O}$, the relationship between P_D and T_J is approximately:

$$P_D = \frac{K}{T_J + 273 \text{ °C}}$$ (2)

Solving equations (1) and (2) for K gives:

$$K = P_D \times (T_A + 273 \text{ °C}) + \theta_{JA} \times (P_D)^2$$ (3)

where K is a constant pertaining to the particular part. K can be determined from equation (3) by measuring P_D (at equilibrium) for a known T_A. Using this value of K, the values of P_D and T_J can be obtained by solving equations (1) and (2) iteratively for any value of T_A.

Mechanical Specifications

The MC68HC705J1A and the RC oscillator and high-speed option devices described in **Appendix A**, **Appendix B**, and **Appendix C** are available in the following packages:

- 738-03 — plastic dual in-line package (PDIP)

- 751D-04 — small outline integrated circuit (SOIC)

- 732-03 — ceramic DIP (Cerdip) (windowed)

The following figures show the latest packages at the time of this publication. To make sure that you have the latest package specifications, contact one of the following:

- Local Motorola Sales Office

- Motorola Mfax
    - Phone 602-244-6609
    - EMAIL rmfax0@email.sps.mot.com

- Worldwide Web (wwweb) at http://design-net.com

Follow Mfax or Worldwide Web on-line instructions to retrieve the current mechanical specifications.

Introduction

Appendix A introduces the MC68HRC705J1A, a resistor-capacitor (RC) oscillator mask option version of the MC68HC705J1A. All of the information in *MC68HC705J1A Technical Data* Rev. 2.0 applies to the MC68HRC705J1A with the exceptions given in this appendix.

RC Oscillator Connections

For greater cost reduction, the RC oscillator mask option allows the configuration shown in **Figure 1** to drive the on-chip oscillator. Mount the RC components as close as possible to the pins for startup stabilization and to minimize output distortion.
Figure 1. RC Oscillator Connections

NOTE: *The optional internal resistor is **not** recommended for configurations that use the RC oscillator connections as shown in **Figure 1**. For such configurations, the oscillator internal resistor (OSCRES) bit of the mask option register should be programmed to a logic 0.*

Typical Internal Operating Frequency for RC Oscillator Option

Figure 2 shows typical internal operating frequencies at 25 °C for the RC oscillator option.
**Figure 2. Typical Internal Operating Frequency for
Various V$_{DD}$ at 25 °C — RC Oscillator Option Only**

NOTE: *Tolerance for resistance is ± 50%. When selecting resistor size, consider
the tolerance to ensure that the resulting oscillator frequency does not
exceed the maximum operating frequency.*

Package Types and Order Numbers

Table 1. MC68HRC705J1A (RC Oscillator Option) Order Numbers[1]

Package Type	Case Outline	Pin Count	Operating Temperature	Order Number
PDIP	738-03	20	0 to 70 °C −40 to +85 °C −40 to + 105 °C	MC68HRC705J1AP[2] MC68HRC705J1AC[3]P MC68HRC705J1AV[4]P
SOIC	751D-04	20	0 to 70 °C −40 to +85 °C −40 to + 105 °C	MC68HRC705J1ADW[5] MC68HRC705J1ACDW MC68HRC705J1AVDW
Cerdip	732-03	20	0 to 70 °C −40 to +85 °C −40 to + 105 °C	MC68HRC705J1AS[6] MC68HRC705J1ACS MC68HRC705J1AVS

1. Refer to **Introduction** (opening section of manual) for standard part ordering information.

2. P = plastic dual in-line package (PDIP)

3. C = extended temperature range

4. V = automotive temperature range

5. DW = small outline integrated circuit (SOIC)

6. S = ceramic dual in-line package (Cerdip)

Contents

Introduction

Appendix B introduces the MC68HSC705J1A, a high-speed version of the MC68HC705J1A. All of the information in *MC68HC705J1A Technical Data* Rev. 2.0 applies to the MC68HSC705J1A with the exceptions given in this appendix.

DC Electrical Characteristics

Table 1. DC Electrical Characteristics (V_{DD} = 5 V)

Characteristic	Symbol	Min	Typ	Max	Unit

Supply Current (f_{OP} = 4.0 MHz)
  Run
  Wait
	I_{DD}	—	4.25
			0.57
				7.0
				3.25
					mA

Table 2. DC Electrical Characteristics (V_{DD} = 3.3 V)

Characteristic	Symbol	Min	Typ	Max	Unit

Supply Current (f_{OP} = 2.1 MHz)
  Run
  Wait
	I_{DD}	—	1.4
			0.28
				4.25
				1.75
					mA

Typical Supply Currents
NOTES:
1. At V_{DD} = 5.0 V, high-speed devices are specified and tested for $I_{DD} \leq 7.0$ mA @ f_{OP} = 4.0 MHz.
2. At V_{DD} = 3.3 V, high-speed devices are specified and tested for $I_{DD} \leq 4.25$ mA @ f_{OP} = 2.1 MHz.

Figure 1. Typical High-Speed Operating I_{DD} (25 °C)

Figure 2. Typical High-Speed Wait Mode I$_{DD}$ (25 °C)
NOTES:

1. At V_{DD} = 5.0 V, high-speed devices are specified and tested for $I_{DD} \leq 3.25$ mA @ f_{OP} = 4.0 MHz.
2. At V_{DD} = 3.3 V, high-speed devices are specified and tested for $I_{DD} \leq 1.75$ mA @ f_{OP} = 2.1 MHz.

Package Types and Order Numbers

Table 3. MC68HSC705J1A (High Speed) Order Numbers[1]

Package Type	Case Outline	Pin Count	Operating Temperature	Order Number
PDIP	738-03	20	0 to 70 °C –40 to +85 °C	MC68HSC705J1AP[2] MC68HSC705J1AC[3]P
SOIC	751D-04	20	0 to 70 °C –40 to +85 °C	MC68HSC705J1ADW[4] MC68HSC705J1ACDW
Cerdip	732-03	20	0 to 70 °C –40 to +85 °C	MC68HSC705J1AS[5] MC68HSC705J1ACS

1. Refer to **Introduction** (opening section of manual) for standard part ordering information.

2. P = plastic dual in-line package (PDIP)

3. C = extended temperature range

4. DW = small outline integrated circuit (SOIC)

5. S = ceramic dual in-line package (Cerdip)

Contents

Introduction

Appendix C introduces the MC68HSR705J1A, a high-speed version of the MC68HRC705J1A. All of the information in *MC68HC705J1A Technical Data* Rev. 2.0, **Appendix A MC68HRC705J1A** and **Appendix B MC68HSC705J1A** applies to the MC68HSR705J1A with the exceptions given in this appendix.

RC Oscillator Connections (External Resistor)

Refer to **Appendix A MC68HRC705J1A** for a description of the RC oscillator connections with external resistor.

Typical Internal Operating Frequency at 25 °C for High-Speed RC Oscillator Option
**Figure 1. Typical Internal Operating Frequency
at 25 °C for High-Speed RC Oscillator Option**

For lower frequency operation characteristics refer to **Appendix A MC68HRC705J1A**.

NOTE: *Tolerance for resistance is ± 50%. When selecting resistor size, consider the tolerance to ensure that resulting oscillator frequency does not exceed the maximum operating frequency.*

RC Oscillator Connections (No External Resistor)

For maximum cost reduction, the RC oscillator mask connections shown in **Figure 2** allow the on-chip oscillator to be driven with **no** external components. This can be accomplished by programming the oscillator internal resistor (OSCRES) bit in the mask option register to a logic 1. When programming the OSCRES bit for the MC68HSR705J1A, an internal resistor is selected which yields typical internal oscillator frequencies as shown in **Figure 3**. The internal resistance for this device is different than the resistance of the selectable internal resistor on the MC68HC705J1A and the MC68HSC705J1A devices.

NOTE: *This option is not available on the ROM version of this device (MC68HC05J1A).*
Figure 2. RC Oscillator Connections (No External Resistor)

Typical Internal Operating Frequency Versus Temperature (No External Resistor)
Figure 3. Typical Internal Operating Frequency Versus Temperature (OSCRES Bit = 1)

> ***NOTE:*** *Due to process variations, operating voltages, and temperature requirements, the internal resistance and tolerance are unspecified. Typically for a given voltage and temperature, the frequency should not vary more than ± 500 kHz. However, this data is not guaranteed. It is the user's responsibility to ensure that the resulting internal operating frequency meets user's requirements.*

Package Types and Order Numbers

Table 1. **MC68HSR705J1A (High-Speed RC Oscillator Option) Order Numbers[1]**

Package Type	Case Outline	Pin Count	Operating Temperature	Order Number
PDIP	738-03	20	0 to 70 °C −40 to +85 °C	MC68HSR705J1AP[2] MC68HSR705J1AC[3]P
SOIC	751D-04	20	0 to 70 °C −40 to +85 °C	MC68HSR705J1ADW[4] MC68HSR705J1ACDW
Cerdip	732-03	20	0 to 70 °C −40 to +85 °C	MC68HSR705J1AS[5] MC68HSR705J1ACS

1. Refer to **Introduction** (opening section of manual) for standard part ordering information.
2. P = plastic dual in-line package (PDIP)
3. C = extended temperature range
4. DW = small outline integrated circuit (SOIC)
5. S = ceramic dual in-line package (Cerdip)
