

The **seventh cervical dorsal root ganglia** are small swellings located on the seventh cervical dorsal roots, proximal to where the dorsal roots join with the seventh cervical ventral roots. The ganglia are situated in the intervertebral foramina between C6 and C7, immediately lateral to the perforation of the dura by the dorsal root.

The dorsal root ganglia are formed by the cell bodies of somatic and visceral afferent neurons. Each neuron has a single short axon, which divides into a medial branch, which enters the spinal cord via the dorsal root, and a lateral branch, which passes peripherally to a sensory end organ.
