## Introduction

*Windows Disassembler* disassembles Windows executables and dynamic link libraries. It allows the user to browse at the source code of a program without having to write it to a file. *Windows Disassembler* generates procedure directives, as well as all of the literal Windows API function call names.

Example source code is included to demonstrate how to use *Windows Disassembler*. To make these accessible, these files have been linked to this document as text file objects. Double clicking on a particular icon will invoke *Windows Notepad* with that particular file opened.

## Specifications

### Files

Works on Windows 3.x executables and dynamic link libraries only.

### Instruction Set

Translates all instructions within the 486 instruction set. It assumes that all code is intended to run in 16-bit mode (which is the mode that MS-DOS and Windows 3.1 run in).

### Operating System and Hardware

Requires at least DOS 4.0, Windows 3.1, and a 286 or above IBM compatible computer. Installation of *SMARTDRV* (which comes with Windows) is recommended.

## Operation

### Opening Files

The default file name extension is ".exe" for opening files if no extension is specified. *Windows Disassembler* processes one file at a time. If a file is opened while another one is already open, the old file will be automatically closed. When opened, the file's assembly language code appears on the screen, provided that the file has a DOS executable file header, a new executable file header, and at least one segment. Otherwise, a dialog box will inform the user that the file does not meet a particular specification.

### The Display

Displaying code in the display window is presented as an alternative to generating a gigantic assembly language source code file, since some programs are large, and the user may merely want to glance at a program's source code.

The code that initially appears in the window when a file is opened is the first segment within the file. Numbers are assigned to segments according to their chronological order within the new executable file header. *Windows Disassembler* displays one segment at a time within the window. The **View | Segment** command must be used to go to another segment. To scroll the text in the window, use the Up Arrow, Down Arrow, Page Up, and Page Down keys, or the scroll bar. To see the address offsets of each instruction, select **View | Address Offsets** from the main menu. To jump to a specific address, select **View | Go To** from the main menu and enter the address in hexadecimal format.

The **View | Far Call Names** command toggles between displaying far function call names and the actual relocation values in far **CALL** instructions (for example, **0000H:0FFFFH**).

All labels have the form of either **LxxxxH** or **DxxxxH**, where **xxxx** is a 4-digit hexadecimal number equal to the offset of the location being referenced. Labels with an 'L' prefix denote locations within the immediate code segment, and labels with a 'D' prefix denote locations within a data segment. Labels within a code segment can either be procedure labels, jump/loop labels, or data labels within the code segment. Assembler directives, while generated for source code text files, are not shown in the display window.

Strings are detected and translated by *Windows Disassembler* whenever five or more visible characters occur within a data segment.

The **Edit!** command allows the user to convert a desired range of bytes from byte declarations into instructions, or vice versa, or to give labels to a specified range of bytes. This command is necessary for programs which have data declarations in their code segments. Note that all modifications which the user has made to a segment will be lost when exiting that segment. The user can save that segment using the **Save Current Segment Only** option as a text file first before quitting to save the changes. However, when the user leaves the segment, there is no way to restore the byte settings except by specifying them over again. Selecting the **Create Separate Files For Each Segment** option will result

in the the modifications/settings being erased (lost) *before* the file is created, hence the user must use the **Save Current Segment Only** option.

## Creating Assembly Language Source Code Files

After opening an executable, the user can create an assembly language source code file for it using the **Save Text As** command. If the source code file name that the user specifies is the name of an already existing file, then that file will be automatically overwritten with the new source code file. Three options are available for generating (a) file(s). The first is to put all of the source code into one file. The name of this file will be the name the user specifies. The second option is to put each segment of the source code into separate files. Each segment's file name will be of the form **yournameN.ext**, where **yourname.ext** is the name the user specifies in the dialog box, and **N** is an integer corresponding to the segment's number and which is appended to the base-name of the file (if necessary, this base name will be truncated to perform the appending). For example, if the user specifies **work\myprog.asm** as the file name, *Windows Disassembler* will generate files named **work\myprog1.asm**, **work\myprog2.asm**, **work\myprog3.asm**, etc.. The third option is to generate a file for the current segment only (which is currently being displayed in the window). In this case *Windows Disassembler* uses the file name exactly as specified.

All editing done will be lost if the user exits a segment which the user has just modified, or if the user tries writing all of the segments to a file(s) at one time. However, if the user uses the **Save Current Segment Only** option, all modifications will remain.

The new file will contain tabs. To display the file in the way in which it was intended to be displayed, the user should set his or her editor's tab stop option to 8 spaces.

*Windows Disassembler* will create **TITLE**, **.CODE segmentname**, **.DATA segmentname**, **.MODEL LARGE**, **.486**, and **EXTRN winAPIfunc:FAR** directives. **PROC** and **ENDP** directives are also created for all exported and far procedures. In the case of non-exported functions, these procedure directives will all have the following form:

```
Functionn      PROC FAR PUBLIC
                (code)
                RETF
Functionn      ENDP
```

where **n** is the ordinal number (a decimal integer value) of the procedure in the entry table of the program's executable file header. For exported functions, the name of the function is explicitly written as it is listed in the resident and non-resident names tables in the program's header. For calls to functions in fixed memory segments, a comment is written beside the call. For example,

```
CALL FAR PTR Proc0AD0HSeg5 ; (Fixed Memory Location)
```

For far calls to procedures within the program in a different segment, **EXTERNDEF**'s are generated. Near procedures are written in the following form:

```
ProcXXXXSegN  PROC FAR PUBLIC
                (code)
                RET
ProcXXXXSegN  ENDP
```

where **XXXX** is a four-digit hexadecimal value equal to the offset of the procedure in the segment and **N** is the decimal number of the segment the procedure is in.

*Windows Disassembler* generates segment names for segment directives of the form **.CODE SEGn**, where **n** is the segment number. This name is produced in order to distinguish between segments, and can be deleted or changed. (If the segments are in separate files then the name isn't needed.) If there are exactly 2 segments in a program, *Windows Disassembler* treats the program as having a small model, otherwise it assumes the program has a medium memory model. If the program has a compact or large model, then the **MODEL** directive must be changed to reflect the actual memory model. *Windows Dissassembler 1.7* translates functions belonging to **commdlg.dll** and **shell.dll**. It also

To make the code modifiable and more readable, it is necessary that the user changes all literal addresses in the code (hexidecimal numbers) into their symbolic equivalents. For example, in the **hello** program,

```
MOV  AX, 00B0H
MOV  DX, DS
PUSH DX
PUSH AX
```

should be changed to

```
MOV  AX, OFFSET D00B0H
MOV  DX, DS
PUSH DX
PUSH AX
```

since this portion of code is passing the address of a string to a Windows function.

It is advisable that the user also makes a hardcopy of the **windows.h** file and that the user converts the **windows.h** file into its *MASM* equivalent using the *H2INC* which comes with *MASM 6.0*. *H2INC* cannot translate certain macros, such as **RGB** and **MAKEINTRESOURCE**, and hence these must be manually rewritten in *MASM* or else deleted. This way, certain constants such as message values can be replaced by their symbolic equivalents. It is also suggested that the user incorporate the **prologue.inc** file which comes with *MASM 6.0* into the program in place of the existing prologue and epilogue code to make things more legible. Finally, the user should replace all other variable names and constants with more meaningful expressions. With the **windows.inc** file generated by *H2INC*, procedure calls usually can be written in a more legible form using **INVOKES**. If the **NOCASEMAP** option is used (for employing case sensitivity), the **prologue.inc** file will need to be modified slightly. In particular, the case of three or four of the words in the **prologue.inc** file will have to be changed in order to agree. **.IF**, **.WHILE**, and **.REPEAT** constructs can also be used to make the code more clear. The steps mentioned above can be accomplished faster with the help of the *HiLevel* utility.

Windows Disassembler 1.7 always outputs the **.286** directive. If the source code generated by Windows Disassembler contains any 386, 387, or 486 instructions, the user must change the **.286** directive into a **.386**, **.387**, or **.486** directive.

## Differences Between Versions 1.5, 1.6 and 1.7

The display window from version 1.5 was altered so that as much text as possible could be fit into the window. Version 1.6 can display text in two new fonts in addition to the previous ones.

Version 1.6 and 1.7 generate procedure names in the form of **ProcXXXXSegN** instead of **ProcedureXXXX** as in version 1.5 in order to guarantee unique procedure names in programs with more than one code segment.

A bug was fixed from version 1.5 which made the program go into an infinite loop in a particular situation.

The include file used by the *HiLevel* utility has been updated and the program *HiLevel* has been slightly modified to accommodate the changes. Prologue macros have been included in the **hilevel.inc** file.

Versions 1.0 through 1.6 disassembled only 286 instructions. Version 1.7 disassembles all 486 instructions.

## The *HiLevel* Utility

**IMPORTANT: *HiLevel 2.1* was designed to work with 286 code. If there are certain 386/486 instructions in your source code, they may cause syntax errors.**

The *HiLevel* utility included with *Windows Disassembler* is a *Windows 3.1* utility which attempts to build high-level constructs out of the bare instructions generated by *Windows Disassembler*. The result is a smaller, more understandable, and more readily modifiable source code file. It will accept as input basic *MASM* programs, provided they do not have macros or certain other directives, and high-level syntax keywords. It should accept all source code generated

by *Windows Disassembler*. *HiLevel* can construct nested **.IF** statements for each corresponding block of instructions found in the given *MASM* source code file. Locals are given symbols of the form **localn** and parameters are given the symbol **parn**, where **n** is the offset of the variable relative to the **BP** register.

HILEVEL.INC

*HiLevel* also constructs "pseudo-function calls" via a macro procedure named **hCall**. The **hCall** macro is defined in the **hilevel.inc** which is included with *Windows Disassembler*. This macro does not perform any high-level operation, but rather is just a more legible way of performing a series of pushes followed by a procedure call, regardless of whether the arguments being pushed are actually being passed to the given function or not. *HiLevel* generates an **OFFSET DxxxxH** instead of **xxxxH** when a number **xxxxH** follows **DS** in the parameter list of a **hCall** invocation, since this combination is practically always a far address being passed as an argument.

The **PROC** directives produced by *HiLevel* are designed to work with either the **hilevel.inc** file or the **prologue.inc** file that comes with *MASM 6.0*. As mentioned before, when enabling case-sensitivity (via **OPTION CASEMAP:NONE**), some of the names in **prologue.inc** need to be modified in order to be made to have the same case, plus there is a defective echo statement in it which should be fixed. If *HiLevel* detects prologue code in a procedure, it then checks for matching epilogue code. If the prologue and epilogue do not logically agree, *HiLevel* generates a comment above the procedure that explains what is missing in the epilogue code, and consequently the procedure is left as is with no prologue/epilogue directives. If the epilogue and prologue logically agree, then the literal code is replaced by the appropriate prologue/epilogue directives, including the **FORCEFRAME** and **LOCAL** directives, plus by specifying any parameters.

If there is a syntax error in the source file, *HiLevel* will halt and give the line number on which the syntax error was found. Otherwise it displays the message, "**Compilation was successful! Hurrah! Hurrah!**" It may take as much as a minute to process a source code file, and as long as the user sees the disk drive light come on at regular intervals (say every 5 seconds) there is no cause for alarm. Otherwise, the system is probably hung. It is possible that *HiLevel* could hang up the system because of its limited local heap of 47,260 bytes (which is not a major problem in 386 enhanced mode, since pressing **Enter** will terminate the application. Otherwise, in standard mode, hitting **Ctrl-C** instead of **Ctrl-Alt-Delete** will sometimes terminate the application). What this means is that for programs containing extremely large procedures *HiLevel* will use up the local heap and go into outer space (stop responding). But for typical files, it should work.

HELLOHIL.ASM

As an example, the file **hellohil.asm** has been included, which is generated from **hello1.asm**. **Hellohil.asm** was assembled and linked with the old **hello2.obj** and **hello.def** files as follows:

```
ml /c hellohil.asm
link /ALIGN:2 hellohil hello2,hellohil,, libw slibcew, hello.def;
```

The only changes made were the renaming of **Proc042ASeg1** to **\_aNchkstk** (because the prologue/epilogue code requires this), the addition of double colons (::) for the global labels, and carriage returns (lines) inserted after the labels following the **PROC** directive in procedures **Proc03EBSeg1** and **Proc03FASeg1**. The last change is because of a bug (or undocumented behavior) in *MASM* that requires this. The bug is that whenever a macro call or loop-generating directive (for example, **hCalls**, **.IFs**, **.WHILEs**, etc.) occurs on the line following a **PROC** directive in which prologue code is expanded, and there is no **LOCAL** directive, *MASM* mistakenly will suppose that the macro will expand into the **LOCAL** directive. When it discovers that the **LOCAL** isn't there, it just continues assembling, but consequently it somehow distorts the expansion of the macro, so that either an error is generated or else garbage instructions are generated. The following listing demonstrates what happens if we change the **PUSH WORD PTR par4** and **CALL FAR PTR LocalFree** instructions in procedure **Proc08A2Seg1** (in **hellohil.asm**) into a **hCall** macro call:

```

089D          Proc08A2Seg1      PROC   NEAR C <NOLOADDS, NOINCBP, FORCEFRAME,
NOCHECKSTACK>, par4:WORD

                                hCall <FAR PTR LocalFree, WORD PTR par4>
= 0001          1                                ??012D = 1
= FAR PTR LocalFree      2                                ??012E TEXTEQU <FAR PTR
LocalFree>
= 0000          2                                ??012D = 0
= 0000          3
= 0000          3                                ??0130 = 0
= 0000          3                                ??0131 = 0
= 0000          3                                ??0132 = 0
= 0000          4                                IFIDN <NOLOADDS>, <NOLOADDS>
= 0000          4                                IFIDN <NOINCBP>, <NOINCBP>
= 0001          4                                IFIDN <FORCEFRAME>, <FORCEFRAME>
= 0000          4                                IFIDN <NOCHECKSTACK>, <NOCHECKSTACK>
= FFFFFFFF      3
089D 55          3
089E 8B EC      3                                PUSH  BP
08A0 FF 76 04   2                                EXITM <00H>
08A3 9A ---- 0000 E 1                                CALL  ??012E

                                RET
= 0000          1                                ??0134 = 0
= 0000          1                                ??0135 = 0
= 0000          1                                ??0136 = 0
= 0000          1                                ??0137 = 0
= 0000          2                                ??0135 = 0
= 0000          2                                ??0137 = 0
= 0001          2                                ??0134 = 1
= 0000          2                                ??0136 = 0
= FFFFFFFF      1                                ??0134 = ??0134 OR ??0137 OR ??0135 OR ??0136 OR (00H NE 0)
OR
08A8 8B E5      1                                MOV   SP,BP
08AA 5D          1                                POP   BP
08AB C3          1                                RET
08AC          Proc08A2Seg1      ENDP

```

Instead of **PUSH BP** and **MOV BP, SP**, it generates just **PUSH BP** in the prologue, and the push specified in the **hCall** call doesn't get expanded. Consequently, in *MASM 6.0*, you may want to avoid calling a macro or using a loop-generating directive as the first instruction in a procedure when:

- a.) the automatic prologue code is forced (via **FORCEFRAME**) and
- b.) there is no **LOCAL** directive.

## Bugs

### Known Bugs In Version 1.7

The screen will need refreshing after scrolling upwards, primarily within data segments, but sometimes in code segments if the user edits the bytes. This bug will not affect file generation.

The scroll bar does not work properly when displaying segments of size 7FFFH or greater. In this case the user must use the **Page Up/Page Down** and the up arrow/down arrow keys. This is because of *Windows'* scroll bar range limit of 32,726 (7FFFH).

There is a bug associated with references to procedures in fixed segments (as opposed to moveable segments).

One such case is where the segment and offset of a function are being referenced. The user might, for example, see something like the following:

```
PUSH SEG ABOUTDLG  
PUSH 00A4H ; (Fixed Memory Location)  
PUSH WORD PTR D0AC0H  
CALL FAR PTR MakeProcInstance
```

This would be an error. Supposing **ABOUTDLG** is in segment 1, the second **PUSH** should actually be, "**PUSH OFFSET Proc00A4Seg1**". The cause for this error has not been specifically determined.

### **License / Warranty Disclaimer**

You are free to distribute *Windows Disassembler 1.7* provided that no fee is charged for use, copying or distribution, it is not modified in any way, and this documentation file (unmodified) accompanies all copies. This program is provided as is without any warranty, expressed or implied, including but not limited to fitness for a particular purpose. *Windows Disassembler* may **not** be used in any unlawful or illegal manner.

*Windows Disassembler 1.7* is shareware. Continued use of *Windows Disassembler 1.7* beyond a 30-day trial period without registering is prohibited. The registration form is on the next page.

REGISTRATION

The single license fee for *Windows Disassembler* version 1.7 is only \$20.00. Registering this software entitles you to receive the latest information regarding upgrades and upgrade discounts. Please fill out this form (or a reasonable facsimile thereof) and send it with your check or money order for \$20.00 to:
