NAME

ftnchek – Fortran program checker

SYNOPSIS

ftnchek [**–arguments=***num*] [**–array=***num*] [**–**[**no**]**backslash**] [**–**[**no**]**calltree**]
[**–columns=***num*] [**–common=***num*] [**–**[no]crossref] [**–**[**no**]**declare**]
[**–**[**no**]**division**] [**–**[**no**]**extern**] [**–**[**no**]**f77**] [**–**[**no**]**help**] [**–**[**no**]**hollerith**]
[**–include=***str*] [**–**[**no**]**library**] [**–**[**no**]**list**] [**–makedcls=***num*] [**–**[**no**]**novice**]
[**–output=***str*] [**–**[**no**]**portability**] [**–**[**no**]**pretty**] [**–**[**no**]**project**] [**–**[**no**]**pure**]
[**–**[**no**]**reference**] [**–**[**no**]**resource**] [**–**[**no**]**sixchar**] [**–**[**no**]**sort**] [**–**[**no**]**symtab**]
[**–**[**no**]**tab**] [**–**[**no**]**truncation**] [**–usage=***num*] [**–**[**no**]**verbose**]
[**–**[**no**]**volatile**] [**–wordsize=***num*] [**–wrap=***num*] [*files ...*]

DESCRIPTION

ftnchek (short for Fortran checker) is designed to detect certain errors in a Fortran program that a compiler usually does not. **ftnchek** is not primarily intended to detect syntax errors. Its purpose is to assist the user in finding semantic errors. Semantic errors are legal in the Fortran language but are wasteful or may cause incorrect operation. For example, variables which are never used may indicate some omission in the program; uninitialized variables contain garbage which may cause incorrect results to be calculated; and variables which are not declared may not have the intended type. **ftnchek** is intended to assist users in the debugging of their Fortran program. It is not intended to catch all syntax errors. This is the function of the compiler. Prior to using **ftnchek**, the user should verify that the program compiles correctly.

This document first summarizes how to invoke **ftnchek**. That section should be read before beginning to use **ftnchek**. Later sections describe **ftnchek**'s options in more detail, give an example of its use, and explain how to interpret the output. The final sections mention the limitations and known bugs in **ftnchek**.

INVOKING FTNCHEK

ftnchek is invoked through a command of the form:

```
$ ftnchek [–option –option ...] filename [filename ...]
```

The brackets indicate something which is optional. The brackets themselves are not actually typed. Here options are command-line switches or settings, which control the operation of the program and the amount of information that will be printed out. If no option is specified, the default action is to print error messages, warnings, and informational messages, but not the program listing or symbol tables.

Each option begins with the '–' character. (On VAX/VMS or MS-DOS systems you may use either '/' or '–'.) The options are described at greater length in the next section.

ftnchek options fall into two categories: switches, which are either true or false, and settings, which have a numeric or string value. The name of a switch is prefixed by 'no' to turn it off: e.g. **–nopure** would turn off the warnings about impure functions. The 'no' prefix can also be used with numeric settings, having the effect of turning off the corresponding warnings. Only the first 3 characters of an option name (not counting the '–') need be provided. A colon may be used in place of an equals sign for option value assignments; however, we show only the equals sign form below.

The switches and settings which **ftnchek** currently recognizes are:

–arguments=*num*

Set level of strictness in checking subprogram arguments. Min is 0 (no checking). Max is 3 (most checking). Default = 3.

–array=*num*

Set level of strictness in checking array arguments of subprograms. Min is 0 (least strict). Max is 3 (most strict). Default = 3.

–backslash

Handle UNIX-style backslash escapes in character strings. Default = no.

−calltree
Print tree of subprogram call hierarchy. Default = no.

−columns=*num*
Set maximum line length to *num* columns. (Beyond this is ignored.) Max is 132. Default = 72.

−common=*num*
Set level of strictness in checking COMMON blocks. Min is 0 (no checking). Max is 3 (must be identical). Default = 3.

−crossref
Print cross-reference list of subprogram calls and COMMON block use. Default = no.

−declare
Print a list of all identifiers whose datatype is not explicitly declared. Default = no.

−division
Warn wherever division is done (except division by a constant). Default = no.

−extern
Warn if external subprograms which are invoked are never defined. Default = yes.

−f77 Warn about extensions to the Fortran 77 Standard. Default = no.

−help Print command summary. Default = no.

−hollerith
Warn about Hollerith constants if **−portability** option is in effect. Default = yes.

−include=*path*
Define a directory to search for INCLUDE files. Cumulative.

−library
Begin library mode: do not warn about subprograms in file that are defined but never used. Default = no.

−list Print source listing of program. Default = no.

−makedcls=*num*
Prepare a file of declarations. Min is 0 (no declaration file). Max is 511. Default = 1 if this option is specified with an out-of-range numeric value.

−novice
Give output suitable for novice users. Default = yes.

−output=*filename*
Send output to the given file. Default is to send output to the screen. (Default filename extension is *. lis*).

−portability
Warn about non-portable usages. Default = no.

−pretty
Give warnings for possibly misleading appearance of source code. Default = yes.

−project
Create project file (see explanation below). Default = no.

−pure Assume functions are pure, i.e. have no side effects. Default = yes.

−reference
Print table of subprograms referenced by each subprogram. Default = no.

−resource
Print amount of resources used in analyzing the program. Default = no.

−sixchar
List any variable names which clash at 6 characters length. Default = no.

−sort Print list of subprograms sorted in prerequisite order. Default = no.

−symtab
Print symbol table for each subprogram. Default = no.

−tab Accept DEC-style tab-formatted source. Default = no.

−truncation
Check for possible loss of accuracy by truncation. Default = yes.

−usage=*num*
Control warnings about unused variables, etc. Min is 0 (no checking). Max is 3 (most checking). Default = 3.

−verbose
Produce full amount of output. Default = yes.

−volatile
Assume COMMON blocks lose definition between activations. Default = no.

−wordsize=*num*
Set the default word size for numeric quantities to *num* bytes. Default = 4 bytes.

−wrap=*num*
Set output column at which to wrap long error messages and warnings to the next line. If set to 0, turn off wrapping. Default = 79.

When more than one option is used, they should be separated by a blank space, except on systems such as VMS where options begin with slash (/). No blank spaces may be placed around the equals sign (=) in a setting. `ftnchek "?"` will produce a command summary listing all options and settings.

When giving a name of an input file, the extension is optional. If no extension is given, **ftnchek** will first look for a project file with extension *.prj*, and will use that if it exists. If not, then **ftnchek** will look for a Fortran source file with the extension *.for* for VMS systems, *.f* for UNIX systems. More than one file name can be given to **ftnchek**, and it will process the modules in all files as if they were in a single file.

Wildcards are allowed in the specification of filenames on the command line for the VMS and MS-DOS versions, as also of course under UNIX and any other system that performs wildcard expansion in the command processor.

If no filename is given, **ftnchek** will read input from the standard input.

OPTIONS

This section provides a more detailed discussion of **ftnchek** command-line options. Options and filenames may be interspersed on a command line. Most options are positional: each option remains in effect from the point it is encountered until it is overridden by a later change. Thus for example, the listing may be suppressed for some files and not for others. Exceptions are: the **−wordsize** setting, which cannot be changed once processing of input files has started; the **−arguments**, **−array**, **−calltree**, **−common**, **−crossref**, **−extern**, **−reference**, **−resource**, **−sort**, and **−volatile** options, where the action depends only on the value of the option after the processing of input files is finished; and the **−include** setting, which is cumulative.

The option names in the following list are in alphabetical order.

−arguments=*num*
Controls warnings about mismatches between actual and dummy subprogram arguments. (An actual argument is an argument passed to the subprogram by the caller; a dummy argument is an argument received by the subprogram.)

The meanings of the setting values are as follows:

0: turn off all such warnings.

1: warn only about different number of arguments.

2: warn only about mismatch of data type of arguments and of function itself.

3: all warnings.

Default = 3.

This setting is provided mainly to suppress warnings when you wish to use **ftnchek** for some other purpose than checking for errors, for example when you only want to print the call tree. It does not apply to checking invocations of intrinsic functions or statement functions.

See also: **−array**, **−library**, **−usage**.

−array=*num*

Controls the degree of strictness in checking agreement between actual and dummy subprogram arguments that are arrays. The warnings controlled by this setting are for constructions that might legitimately be used by a knowledgeable programmer, but that often indicate programming errors.

The meanings of the setting values are as follows:

0: only warn about cases that are seldom intentional (see note below).

1: warn if the arguments differ in their number of dimensions, or if the actual argument is an array element while the dummy argument is a whole array.

2: warn if both arguments are arrays, but they differ in number of elements.

3: give both types of warnings.

Default = 3.

Note: A warning is always given regardless of this setting if the actual argument is an array while the dummy argument is a scalar variable, or if the actual argument is a scalar variable or expression while the dummy argument is an array. No warning is ever given if the actual argument is an array element while the dummy argument is a scalar variable. Variable-dimensioned arrays and arrays dimensioned with 1 or asterisk match any number of array elements. There is no check of whether multi-dimensional arrays agree in the size of each dimension separately.

See also: **−arguments**, **−library**, **−usage**.

−backslash

Handle UNIX-style backslash escapes in character strings. The escape sequence following the backslash will be evaluated according to the ANSI standard for strings in C: up to three digits signify an octal value, an x signifies the start of a hexadecimal constant, any of the letters a b f n r t signify special control codes, and any other character (including newline) signifies the character itself. When this option is in effect, a non-standard warning will be given if the **−f77** flag is set. Default = no.

If this option is turned off (the default), the backslash will be treated like any other normal character, but a warning about portability will be generated if the **−portability** flag is set. Because of the fact that some compilers treat the backslash in a nonstandard way, it is possible for standard-conforming programs to be non-portable if they use the backslash character in strings.

Since **ftnchek** does not do much with the interpreted string, it is seldom necessary to use this option. It is needed in order to avoid spurious warnings only if (a) the program being checked uses backslash to embed an apostrophe or quote mark in a string instead of using the standard mechanism of doubling the delimiter; (b) the backslash is used to escape the end-of-line in order to continue a string across multiple source lines; or (c) a `PARAMETER` definition uses an intrinsic string function such as `LEN` with such a string as argument, and that value is later used to define array dimensions, etc.

−calltree

Causes **ftnchek** to print out the call structure of the complete program in the form of a tree. The tree is printed out starting from the main program, which is listed on the first line at the left margin. Then on the following lines, each routine called by the main program is listed, indented a few spaces, followed by the subtree starting at that routine. Default = no.

If a routine is called by more than one other routine, its call subtree is printed only the first time it is encountered. Later calls give only the routine name and the notice "(see above)".

Note that the call tree will be incomplete if any of the input files are project files containing more than one module that were created in **−library** mode. See the discussion of project files below.

Technical points: Each list of routines called by a given routine is printed in alphabetical order. If multiple main programs are found, the call tree of each is printed separately. If no main program is found, a report to that effect is printed out, and the call trees of any top-level non-library routines are printed. This flag only controls the printing of the call tree: **ftnchek** constructs the call tree in any case because it is used to determine which library modules will be cross-checked. See the discussion of the **−library** flag.

See also: **−crossref**, **−library**, **−reference**, **−sort**, **−symtab**.

−columns=*num*

Set maximum statement length to *num* columns. (Beyond this is ignored.) This setting is provided to allow checking of programs which may violate the Fortran standard limit of 72 columns for the length of a statement. According to the standard, all characters past column 72 are ignored. If this setting is used when the **−f77** option is in effect, a warning will be given for any lines in which characters past column 72 are processed. Max is 132. Default = 72.

−common=*num*

This setting varies the strictness of checking of COMMON blocks.

The different levels are:

0: no checking.

1: in each declaration of a given COMMON block, corresponding memory locations (words or bytes) must agree in data type.

2: also warn if different declarations of the same block are not equal in total length.

3: corresponding variables in each declaration of a block must agree in data type and (if arrays) in size and number of dimensions.

Default = 3.

The Fortran 77 Standard requires each named common block, but not blank common, to be the same length in all modules of the program. Level 3 provides an extra degree of checking to support a frequent programming practice.

See also: **−library**, **−usage**, **−volatile**.

−crossref

Specifies that a cross-reference table be printed. This table lists each subprogram followed by a list of the routines that call it. Also prints a table listing each COMMON block followed by a list of the routines that access it. Default = no.

The cross-reference listing omits library modules that are not in the call tree of the main program. The list is alphabetized. The routines listed as using a COMMON block are those in which some variables in the block are accessed, not simply those routines that declare the block. (To find out what routines declare a COMMON block but do not use it, see the **−usage** flag.)

See also: **–calltree**, **–reference**, **–sort**, **–symtab**.

–declare

If this flag is set, all identifiers whose datatype is not declared in each module will be listed. This flag is useful for helping to find misspelled variable names, etc. The same listing will be given if the module contains an `IMPLICIT NONE` statement. Default = no.

See also: **–sixchar**, **–usage**.

–division

This switch is provided to help users spot potential division by zero problems. If this switch is selected, every division except by a constant will be flagged. (It is assumed that the user is intelligent enough not to divide by a constant which is equal to zero!) Default = no.

See also: **–portability**, **–truncation**.

–extern

Causes **ftnchek** to report whether any subprograms invoked by the program are never defined, or are multiply defined. Ordinarily, if **ftnchek** is being run on a complete program, each subprogram other than the intrinsic functions should be defined once and only once somewhere. Turn off this switch if you just want to check a subset of files which form part of a larger complete program, or to check all at once a number of unrelated files which might each contain an unnamed main program. Subprogram arguments will still be checked for correctness. Default = yes.

See also: **–library**.

–f77 Use this flag to catch language extensions which violate the Fortran 77 Standard. Such extensions may cause your program not to be portable. Examples include the use of underscores in variable names; variable names longer than six characters; statement lines longer than 72 characters; and nonstandard statements such as the `DO ... ENDDO` structure. **ftnchek** does not report on the use of lowercase letters. Default = no.

See also: **–portability**, **–pretty**, **–wordsize**.

–help Prints a list of all the command-line options with a short description of each along with its default value. This command is identical in function to the **"?"** argument, and is provided as a convenience for those systems in which the question mark has special meaning to the command interpreter. Default = no.

The help listing also prints the version number and patch level of **ftnchek** and a copyright notice.

Note: the ‘‘default’’ values printed in square brackets in the help listing are, strictly speaking, not the built-in defaults but the current values after any environment options and any command-line options preceding the **–help** option have been processed.

–hollerith

Hollerith constants (other than within FORMAT specifications) are a source of possible portability problems, so when the **–portability** flag is set, warnings about them will be produced. If your program uses many Hollerith constants, these warnings can obscure other more serious warnings. So you can set this flag to ‘‘no’’ to suppress the warnings about Holleriths. This flag has no effect unless the **–portability** flag (which is off by default) is turned on. Default = yes.

See also: **–portability**.

–include=*path*

Specifies a directory to be searched for files specified by `INCLUDE` statements. Unlike other command-line options, this setting is cumulative; that is, if it is given more than once on the command line, all the directories so specified are placed on a list that will be searched in the same order as they are given. The order in which **ftnchek** searches for a file to be included is: the current directory; the directory specified by environment variable `FTNCHEK_INCLUDE` if any; the directories specified by any **–include** options; the directory specified by environment variable `INCLUDE`; and finally in a standard systemwide directory (`/usr/include` for UNIX, `SYS$LIBRARY` for VMS, and `\include` for MSDOS).

–library

This switch is used when a number of subprograms are contained in a file, but not all of them are used by the application. Normally, **ftnchek** warns you if any subprograms are defined but never used. This switch will suppress these warnings. Default = no.

This switch also controls which subprogram calls and COMMON block declarations are checked. If a file is read with the **–library** flag in effect, the subprogram calls and COMMON declarations contained in a routine in that file will be checked only if that routine is in the main program's call tree. On the other hand, if the **–library** switch is turned off, then **ftnchek** checks the calls of every routine by every other routine, regardless of whether those routines could ever actually be invoked at run time, and likewise all COMMON block declarations are compared for agreement.

(If there is no main program anywhere in the set of files that **ftnchek** has read, so that there is no call tree, then **ftnchek** will look for any non-library routines that are not called by any other routine, and use these as substitutes for the main program in constructing the call tree and deciding what to check. If no such top-level non-library routines are found, then all inter-module calls and all COMMON declarations will be checked.)

See also: **–arguments**, **–calltree**, **–common**, **–extern**.

–list Specifies that a listing of the Fortran program is to be printed out with line numbers. If **ftnchek** detects an error, the error message follows the program line with a caret (^) specifying the location of the error. If no source listing was requested, **ftnchek** will still print out any line containing an error, to aid the user in determining where the error occurred. Default = no.

See also: **–symtab**, **–verbose**.

–makedcls=*num*

Prepare a neatly-formatted file of declarations of variables, common blocks, and namelist lists, for possible merging into the source code. The declarations are stored in a file of the same name as the source code, but with the extension changed to *.dcl*. If no declarations are written to the file, it is deleted to reduce clutter from empty files.

If input comes from standard input, instead of a named file, then declarations are written to standard output.

Variables are declared in alphabetical order within each declaration class and type, with integer variables first, because of their later possible use in array dimensions.

`PARAMETER` statements are an exception to the alphabetical order rule, because the Fortran 77 Standard requires that the expressions defining parameter values refer only to constants and already-defined parameter names. This forces the original source file order of such statements to be preserved in the declaration files.

Explicit declaration of *all* variables is considered good modern programming practice. By using compiler options to reject undeclared variables, misspelled variable names (or names extending past column 72) can be caught at compile time. Explicit declarations also greatly facilitate changing floating-point precision with filters such as **dtoq**(1L), **dtos**(1L), **fd2s**(1L), **fs2d**(1L), **qtod**(1L),

and **stod**(1L). These programs are capable of changing types of explicit floating-point type declarations, intrinsic functions, and constants, but because they do not carry out rigorous lexical and grammatical analysis of the Fortran source code, they cannot provide modified type declarations for undeclared variables.

The setting values are given by the *sum* of selected option values from the following list:

0: Do not write a declaration file.

1: Write a declaration file.

2: Normally, all variables are included in the declaration file. With this option, include only *undeclared* variables. This setting is useful if you want to check for undeclared variables, since Fortran source files with all variables properly declared will not result in a *.dcl* file. With this option, common blocks and namelist lists will not be included in the declaration file, since by their nature they cannot be undeclared.

4: The declarations are normally prettyprinted to line up neatly in common columns, as in the declaration files output by the Extended PFORT Verifier, **pfort**(1L). This option value selects instead compact output, without column alignment.

8: Causes continuation lines to be used where permissible. The default is to begin a new declaration on each line. This option is appropriate to use with the option for compact output.

16: Output Fortran keywords in lowercase, instead of the default uppercase.

32: Output variables and constants in lowercase, instead of the default uppercase. Character string constants are not affected by this option.

64: Omit declarations of internal integer variables produced by the SFTRAN3 preprocessor, **xsf3**(1L), as part of the translation of structured Fortran statements to ordinary Fortran. These variables have six-character names of the form *NPRddd*, *NXdddd*, *N2dddd*, and *N3dddd*, where *d* is a decimal digit. Because they are invisible in the SFTRAN3 source code, and will change if the SFTRAN3 code is modified, such variables should not be explicitly declared. Instead, they should just assume the default Fortran INTEGER data type based on their initial letter, *N*.

128: Use an asterisk as the comment character; the default is otherwise 'C'.

256: Use 'c' instead of 'C' or '*' as the comment character.

If any non-zero value is specified, then declaration output is selected, even if the value 1 was not included in the sum.

The declaration files contain distinctive comments that mark the start and end of declarations for each program unit, to facilitate using text editor macros for merging the declarations back into the source code.

−novice

This flag is intended to provide more helpful output for beginners. It has two effects:

(a) provides an extra message to the effect that a function that is used but not defined anywhere might be an array which the user forgot to declare in a `DIMENSION` statement (since the syntax of an array reference is the same as that of a function reference).

(b) modifies the form of the error messages and warnings. If the flag is turned off by **−nonovice**, these messages are printed in a style more resembling UNIX **lint**.

Default = yes.

In versions of **ftnchek** prior to 2.6, this option could take on various numerical values, as a way of controlling various classes of warnings. These warnings are now controlled individually by their own flags. Novice level 1 is now handled by the **−array** flag; level 2 has been eliminated; level 3 is equivalent now to setting **−novice** to yes; level 4 is handled by the **−pure** flag.

−output= *filename*

This setting is provided for convenience on systems which do not allow easy redirection of output from programs. When this setting is given, the output which normally appears on the screen will be sent instead to the named file. Note, however, that operational errors of **ftnchek** itself (e.g. out of space or cannot open file) will still be sent to the screen. The extension for the filename is optional, and if no extension is given, the extension *. lis* will be used.

−portability

ftnchek will give warnings for a variety of non-portable usages. Examples include the use of tabs except in comments or inside strings, the use of Hollerith constants, and the equivalencing of variables of different data types. This option does not produce warnings for supported extensions to the Fortran 77 Standard, which may also cause portability problems. To catch those, use the **−f77** option. Default = no.

See also: **−backslash**, **−f77**, **−hollerith**, **−pretty**, **−wordsize**.

−pretty

Controls certain messages related to the appearance of the source code. These warn about things that might be deceptive to the reader. Default = yes.

The warnings controlled by this flag include such things as comments that are interspersed among the continuation lines of a statement, lack of space between a keyword and a following variable name, and statement lines containing characters past column 72.

See also: **−f77**, **−portability**.

−project

ftnchek will create a project file from each source file that is input while this flag is in effect. The project file will be given the same name as the input file, but with the extension *. f* or *. for* replaced by *. prj*. (If input is from standard input, the project file is named *ftnchek. prj*.) Default = no.

A project file contains a summary of information from the source file, for use in checking agreement among `FUNCTION`, `SUBROUTINE`, and `COMMON` usages in other files. It allows incremental checking, which saves time whenever you have a large set of files containing shared subroutines, most of which seldom change. You can run **ftnchek** once on each file with the **−project** flag set, creating the project files. Usually you would also set the **−library** and **−noextern** flags at this time, to suppress messages relating to consistency with other files. Only error messages pertaining to each file by itself will be printed at this time. Thereafter, run **ftnchek** without these flags on all the project files together, to check consistency among the different files. All messages internal to the individual files will now be omitted. Only when a file is altered will a new project file need to be made for it.

Naturally, when the **−project** flag is set, **ftnchek** will not read project files as input.

Project files contain only information needed for checking agreement between files. This means that a project file is of no use if all modules of the complete program are contained in a single file.

A more detailed discussion is given in the section on Using Project Files.

−pure Assume functions are ‘‘pure’’, i.e., they will not have side effects by modifying their arguments or variables in a COMMON block. When this flag is in effect, **ftnchek** will base its determination of set and used status of the actual arguments on the assumption that arguments passed to a function are not altered. It will also issue a warning if a function is found to modify any of its arguments or any COMMON variables. Default = yes.

When this flag is turned off, actual arguments passed to functions will be handled the same way as actual arguments passed to subroutines. This means that **ftnchek** will assume that arguments may be modified by the functions. No warnings will be given if a function is found to have side effects.

Because stricter checking is possible if functions are assumed to be pure, you should turn this flag off only if your program actually uses functions with side effects.

−reference

Specifies that a who-calls-who table be printed. This table lists each subprogram followed by a list of the routines it calls. Default = no.

The reference list omits routines called by unused library modules. Thus it contains the same information as for the **−calltree** flag, namely the hierarchy of subprogram calls, but printed in a different format. This prints out a breadth-first traversal of the call tree whereas **−calltree** prints out a depth-first traversal. If both **−calltree** and **−reference** flags are given, only the reference form of the table will be produced.

See also: **−calltree**, **−crossref**, **−library**, **−sort**, **−symtab**.

−resource

Prints the amount of resources used by **ftnchek** in processing the program. This listing may be useful in analyzing the size and complexity of a program. It can also help in choosing larger sizes for **ftnchek**'s internal tables if they are too small to analyze a particular program. Default = no.

In this listing, the term ''chunk size'' is the size of the blocks of memory allocated to store the item in question, in units of the size of one item, not necessarily in bytes. When the initially allocated space is filled up, more memory is allocated in chunks of this size. The following is an explanation of the items printed:

Source lines processed:

Total number of lines of code, with separate totals for statement lines and comment lines. Comment lines include lines with 'C' or '*' in column 1 as well as blank lines and lines containing only an inline comment. Statement lines are all other lines, including lines that have an inline comment following some code. Continuation lines are counted as separate lines. Lines in include files are counted each time the file is included.

Total executable statements:

Number of statements in the program, other than specification, data, statement-function, FORMAT, ENTRY, and END statements.

Total number of modules:

A module is any external subprogram, including the main program, subroutines, functions, and block data units. This count is of modules defined within the source, not modules referenced. Statement functions are not included. A subprogram with multiple entry points is only counted once.

Max identifier name chars:

Number of characters used for storing identifier names. An identifier is a variable, subprogram, or common block name. Local names are those of local variables in a subprogram, whereas global names refer to subprogram and common block names, as well as dummy argument names and common variable names. Actual argument text (up to 15 characters for each argument) is also included here. The space used for local names is recovered at the end of each module, whereas the global space grows until the whole program is analyzed. Unfortunately, this figure may include some common block names and arguments stored more than once, although a heuristic is used that will avoid duplicates in many cases.

Max token text chars:

A token is the smallest syntactic unit of the FORTRAN language above the level of individual characters. For instance a token can be a variable name, a numerical constant, a quoted text string, or a punctuation character. Token text is stored while a module is being processed. For technical reasons, single-character tokens are not included in this total. Items that are not represented in the symbol table may be duplicated. The space for token text is recovered at the

end of each module, so this figure represents the maximum for any one module.

Max local symbols:
This is the largest number of entries in the local symbol table for any module. Local symbol table entries include all variables and parameters, common block names, statement functions, external subprograms and intrinsic functions referenced by the module. Literal constants are not stored in the local symbol table.

Max global symbols:
This is the number of entries in the global symbol table at the end of processing. Global symbol table entries include external subprogram and common block names. Intrinsic functions and statement functions are not included.

Max number of tokenlists:
A token list is a sequence of tokens representing the actual or dummy argument list of a subprogram, or the list of variables in a common block or namelist. Therefore this number represents the largest sum of COMMON, CALL, NAMELIST and ENTRY statements and function invocations for any one module. The space is recovered at the end of each module.

Max token list/tree space:
This is the largest number of tokens in all the token lists and token trees of any one module. A token tree is formed when analyzing an expression: each operand is a leaf of the tree, and the operators are the nodes. Therefore this number is a measure of the maximum complexity of an individual module. For instance a module with many long arithmetic expressions will have a high number. Note that unlike token text described above, the number of tokens is independent of the length of the variable names or literal constants in the expressions.

Number of subprogram invocations:
This is the sum over all modules of the number of CALL statements and function invocations (except intrinsic functions and statement functions).

Number of common block decls:
This is the sum over all modules of the number of common block declarations. That is, each declaration of a block in a different module is counted separately. (The standard allows multiple declarations of a block within the same module; these are counted as only one declaration since they are equivalent to a single long declaration.)

Number of array dim & param ptrs:
This is the sum over all modules of the number of array dimension and parameter definition text strings saved for use by the **−makedcls** option. The length of the text strings is not counted. Each dimension of a multidimensional array is counted separately.

These numbers are obviously not the same when project files are used in place of the original source code. Even the numbers for global entities may be different, since some redundant information is eliminated in project files.

−sixchar

One of the goals of the **ftnchek** program is to help users to write portable Fortran programs. One potential source of nonportability is the use of variable names that are longer than six characters. Some compilers just ignore the extra characters. This behavior could potentially lead to two different variables being considered as the same. For instance, variables named `AVERAGECOST` and `AVERAGEPRICE` are the same in the first six characters. If you wish to catch such possible conflicts, use this flag. Default = no.

Use the **−f77** flag if you want to list *all* variables longer than six characters, not just those pairs that are the same in the first six.

See also: **−f77**, **−portability**.

−sort Specifies that a sorted list of all modules used in the program be printed. This list is in ‘‘prerequisite’’ order, i.e. each module is printed only after all the modules from which it is called have been printed. This is also called a ‘‘topological sort’’ of the call tree. Each module is listed only once. Routines that are not in the call tree of the main program are omitted. If there are any cycles in the call graph (illegal in standard Fortran) they will be detected and diagnosed. Default = no.

See also: **−calltree**, **−crossref**, **−reference**, **−symtab**.

−symtab

A symbol table will be printed out for each module, listing all identifiers mentioned in the module. This table gives the name of each variable, its datatype, and the number of dimensions for arrays. An asterisk (*) indicates that the variable has been implicitly typed, rather than being named in an explicit type declaration statement. The table also lists all subprograms invoked by the module, all COMMON blocks declared, etc. Default = no.

See also: **−calltree**, **−crossref**, **−list**, **−reference**, **−sort**.

−tab Accept DEC-style tab-formatted source. A line beginning with an initial tab will be treated as a new statement line unless the character after the tab is a nonzero digit, in which case it is treated as a continuation line. The next column after the tab or continuation mark is taken as column 7. A warning will be given in the case where the line is a continuation, if **−f77** is in effect. Default = no.

−truncation

Warn about possible truncation (or roundoff) errors. Most of these are related to integer arithmetic. The warnings enabled when this flag is in effect are:

(a) use of the result of integer division where a real result seems intended (namely as an exponent, or if the quotient is later converted to real);

(b) division in an integer constant expression that yields a result of zero;

(c) exponentiation of an integer by a negative integer (which yields zero unless the base integer is 1 in magnitude);

(d) use of a non-integer array subscript or DO index;

(e) conversion of any real type to integer, or conversion of a complex value to real or integer;

(f) conversion of a double precision value to single precision, or vice-versa (promotion). This applies both to real types and to complex types.

Default = yes.

Note: warnings about truncating type conversions are given only when the conversion is done automatically, e.g. by an assignment statement. If intrinsic functions such as `INT` are used to perform the conversion, no warning is given. Promotions of real types from single to double precision are included here because such conversions imply a possible loss of accuracy that is similar to the corresponding demotions.

See also: **−portability**, **−wordsize**.

−usage=*num*

Warn about unused or possible uninitialized variables and unused common blocks.

The meanings of the setting values are as follows:

0: no warnings.

1: warn if variables are (or may be) used before they are set.

2: warn if variables are declared or set but never used.

3: give both types of warnings.

Default = 3.

Sometimes **ftnchek** makes a mistake about these warnings. Usually it errs on the side of giving a warning where no problem exists, but in rare cases it may fail to warn where the problem does exist. See the section on Bugs for examples. If variables are equivalenced, the rule used by **ftnchek** is that a reference to any variable implies the same reference to all variables it is equivalenced to. For arrays, the rule is that a reference to any array element is treated as a reference to all elements of the array.

This setting controls warnings not only for local variables but also for variables in COMMON blocks. Level 2 also controls whether a warning is given when an entire COMMON block is unused. When checking for used-before-set errors involving COMMON variables, **ftnchek** does not do a thorough enough analysis of the calling sequence to know which routines are called before others. So warnings about this type of error will only be given for cases in which a variable is used in some routine but not set in any other routine. Checking of individual COMMON variables is done only if the **−common** setting is 3 (variable by variable agreement).

See also: **−common**, **−declare**, **−volatile**.

−verbose

This option is on by default. Turning it off reduces the amount of output relating to normal operation, so that error messages are more apparent. This option is provided for the convenience of users who are checking large suites of files. The eliminated output includes the names of project files, and the message reporting that no syntax errors were found. (Some of this output is turned back on by the **−list** and **−symtab** options.) Default = yes.

−volatile

Assume that COMMON blocks are volatile. Default = no.

Many Fortran programmers assume that variables, whether local or in COMMON, are static, i.e. that once assigned a value, they retain that value permanently until assigned a different value by the program. However, in fact the Fortran 77 Standard does not require this to be the case. Local variables may become undefined between activations of a module in which they are declared. Similarly, COMMON blocks may become undefined if no module in which they are declared is active. (The technical term for this behavior is ‘‘automatic’’, but **ftnchek** uses the word ‘‘volatile’’ since it is clearer to the nonspecialist.) Only COMMON blocks declared in a SAVE statement, or declared in the main program or in a block data subprogram remain defined as long as the program is running. Variables and COMMON blocks that can become undefined at some point are called volatile.

If the **−volatile** flag is turned on, **ftnchek** will warn you if it finds a volatile COMMON block. If, at the same time, the **−usage** setting is 1 or 3 (check used before set), **ftnchek** will try to check whether such a block can lose its defined status between activations of the modules where it is declared. **ftnchek** does not do a very good job of this: the rule used is to see whether the block is declared in two separated subtrees of the call tree. For instance, this would be the case if two modules, both called from the main program, shared a volatile COMMON block. A block can also become undefined between two successive calls of the same subprogram, but **ftnchek** is not smart enough to tell whether a subprogram can be called more than once, so this case is not checked for.

The **−volatile** flag does not affect the way **ftnchek** checks the usage of local variables.

See also: **−common**, **−usage**.

−wordsize=*num*

Specifies the default word size to be *num* bytes. This is the size of logical and single-precision numeric variables that are not given explicit precisions. Double-precision and complex variables will be twice this value, and double complex variables four times. Explicit precisions for non-character variables are an extension to the Fortran 77 Standard, and are given by type declarations such as `REAL*8 X`. Default = 4 bytes.

If you want to change the built-in default value of this setting, compile **ftnchek** with the macro name `BpW` (Bytes per Word) set to the desired default value. This is not critical: the word size value does not matter for checking standard-conforming programs that do not declare explicit precisions for non-character variables or store Hollerith data in variables. This setting also does not affect the default size of character variables, which is always 1 byte. Hollerith constants also are assumed to occupy 1 byte per character.

The word size is used to determine whether truncation occurs in assignment statements, and to catch precision mismatches in subprogram argument lists and common block lists. The exact warnings that are issued will depend on the status of other flags. Under both the **−portability** or **−nowordsize** flags, any mixing of explicit with default precision objects (character expressions not included) is warned about. This applies to arithmetic expressions containing both types of objects, and to subprogram arguments and COMMON variables. Under the **−truncation** flag, a warning is given for assignment of an expression to a shorter variable of the same type, or for promotion of a lower precision value to higher precision in an arithmetic expression or an assignment statement.

Giving a word size of 0, or equivalently, using **−nowordsize** means that no default value will be assumed. Use this instead of **−portability** if you want to check only for those aspects of portability related to mixing default and explicit precision, for example to flag places where `REAL*8` is treated as equivalent to `DOUBLE PRECISION`.

See also: **−portability**, **−truncation**.

−wrap=*col*

Controls the wrapping of error messages. Long error messages that would run past the specified column will be broken up into separate lines between the words of the message for better readability. If turned off with **−nowrap**, each separate error message will be printed on one line, leaving it up to the display to wrap the message or truncate it. Default = 79.

CHANGING THE DEFAULTS

ftnchek includes a mechanism for changing the default values of all options by defining environment variables. When **ftnchek** starts up, it looks in its environment for any variables whose names are composed by prefixing the string `FTNCHEK_` onto the uppercased version of the option name. If such a variable is found, its value is used to specify the default for the corresponding switch or setting. In the case of settings (for example, the **−common** strictness setting) the value of the environment variable is read as the default setting value. In the case of switches, the default switch will be taken as true or yes unless the environment variable has the value `0` or `NO`. Of course, command-line options will override these defaults the same way as they override the built-in defaults.

Note that the environment variable name must be constructed with the full-length option name, which must be in uppercase. For example, to make **ftnchek** print a source listing by default, set the environment variable `FTNCHEK_LIST` to `1` or `YES` or anything other than `0` or `NO`. The names `FTNCHEK_LIS` (not the full option name) or `ftnchek_list` (lower case) would not be recognized.

Here are some examples of how to set environment variables on various systems. For simplicity, all the examples set the default **−list** switch to `YES`.

1. UNIX, Bourne shell:

```
$ FTNCHEK_LIST=YES; export FTNCHEK_LIST
```

2. UNIX, C shell:

```
% setenv FTNCHEK_LIST YES
```

3. VAX/VMS: `$ DEFINE FTNCHEK_LIST YES`

4. MSDOS: `$ SET FTNCHEK_LIST=YES`

USING PROJECT FILES

This section contains detailed information on how to use project files most effectively, and how to avoid some pitfalls.

Ordinarily, project files should be created with the **–library** flag in effect. In this mode, the information saved in the project file consists of all subprogram declarations, all subprogram invocations not resolved by declarations in the same file, and one instance of each COMMON block declaration. This is the minimum amount of information needed to check agreement between files.

If the file contains more than one routine, there are some possible problems that can arise from creating the project file in library mode, because the calling hierarchy among routines defined within the file is lost. Also, if the routines in the file make use of COMMON blocks that are shared with routines in other files, there will not be enough information saved for the correct checking of set and used status of COMMON blocks and COMMON variables according to the **–usage** setting. Therefore if you plan to use project files when the **–usage** setting is nonzero (which is the default situation), and if multiple routines in one project file share COMMON blocks with routines in other files, the project files should be created with the **–library** flag turned off. In this mode, **ftnchek** saves, besides the information listed above, one invocation of each subprogram by any other subprogram in the same file, and all COMMON block declarations. This means that the project file will be larger than necessary, and that when it is read in, **ftnchek** may repeat some inter-module checks that it already did when the project file was created. If each project file contains only one module, there is no loss of information in creating the project files in library mode.

Because of the possible loss of information entailed by creating a project file with the **–library** flag in effect, whenever that project file is read in later, it will be treated as a library file regardless of the current setting of the **–library** flag. On the other hand, a project file created with library mode turned off can be read in later in either mode.

Here is an example of how to use the UNIX **make** utility to automatically create a new project file each time the corresponding source file is altered, and to check the set of files for consistency. The example assumes that a macro `OBJS` has been defined which lists all the names of object files to be linked together to form the complete executable program.

```
# tell make what a project file suffix is
.SUFFIXES: .prj

# tell make how to create a .prj file from a .f file
.f.prj:
        ftnchek -project -noextern -library $<

# set up macro PRJS containing project filenames
PRJS= $(OBJS:.o=.prj)

# "make check" will check everything that has been changed.
check: $(PRJS)
        ftnchek $(PRJS)
```

AN EXAMPLE

The following simple Fortran program illustrates the messages given by **ftnchek**. The program is intended to accept an array of test scores and then compute the average for the series.

```
C       AUTHORS: MIKE MYERS AND LUCIA SPAGNUOLO
C       DATE:    MAY 8, 1989
```

```
C       Variables:
C               SCORE -> an array of test scores
C               SUM ->   sum of the test scores
C               COUNT -> counter of scores read in
C               I ->     loop counter

        REAL FUNCTION COMPAV(SCORE,COUNT)
            INTEGER SUM,COUNT,J,SCORE(5)

            DO 30 I = 1,COUNT
                SUM = SUM + SCORE(I)
30          CONTINUE
            COMPAV = SUM/COUNT
        END

        PROGRAM AVENUM
C
C                       MAIN PROGRAM
C
C       AUTHOR:   LOIS BIGBIE
C       DATE:     MAY 15, 1990
C
C       Variables:
C               MAXNOS -> maximum number of input values
C               NUMS    -> an array of numbers
C               COUNT   -> exact number of input values
C               AVG     -> average returned by COMPAV
C               I       -> loop counter
C

            PARAMETER(MAXNOS=5)
            INTEGER I, COUNT
            REAL NUMS(MAXNOS), AVG
            COUNT = 0
            DO 80 I = 1,MAXNOS
                READ (5,*,END=100) NUMS(I)
                COUNT = COUNT + 1
80          CONTINUE
100         AVG = COMPAV(NUMS, COUNT)
        END
```

The compiler gives no error messages when this program is compiled. Yet here is what happens when it is run:

```
$ run average
70
90
85
<EOF>
$
```

What happened? Why didn't the program do anything? The following is the output from **ftnchek** when it

is used to debug the above program:

```
$ ftnchek -list -symtab average

```

According to **ftnchek**, the program contains variables which may be used before they are assigned an initial value, and variables which are not needed. **ftnchek** also warns the user that an integer quotient has been converted to a real. This may assist the user in catching an unintended roundoff error. Since the **–symtab** flag was given, **ftnchek** prints out a table containing identifiers from the local module and their

corresponding datatype and number of dimensions. Finally, **ftnchek** warns that the function COMPAV is not used with the proper type of arguments.

With **ftnchek**'s help, we can debug the program. We can see that there were the following errors:

1. SUM and COUNT should have been converted to real before doing the division.
2. SUM should have been initialized to 0 before entering the loop.
3. AVG was never printed out after being calculated.
4. NUMS should have been declared INTEGER instead of REAL.

We also see that I, not J, should have been declared INTEGER in function COMPAV. Also, MAXNOS was not declared as INTEGER, nor COMPAV as REAL, in program AVENUM. These are not errors, but they may indicate carelessness. As it happened, the default type of these variables coincided with the intended type.

Here is the corrected program, and its output when run:

```
C       AUTHORS: MIKE MYERS AND LUCIA SPAGNUOLO
C       DATE:    MAY 8, 1989

100           AVG = COMPAV(NUMS, COUNT)
              WRITE(6,*) 'AVERAGE =',AVG
          END

$ run average
70
90
85
<EOF>
AVERAGE =   81.66666
$
```

With **ftnchek**'s help, our program is a success!

INTERPRETING THE OUTPUT

The messages given by **ftnchek** include not only syntax errors but also warnings and informational messages about things that are legal Fortran but that may indicate errors or carelessness. Most of these messages can be turned off by command-line options. Which option controls each message depends on the nature of the condition being warned about. See the descriptions of the command-line flags in the previous sections, and of individual messages below. Each message is prefixed with a word or phrase indicating the nature of the condition and its severity.

"Error" means a syntax error. The simplest kind of syntax errors are typographical errors, for example unbalanced parentheses or misspelling of a keyword. This type of error is caught by the parser and appears with the description "parse error" or "syntax error" (depending on whether the parser was built using GNU **bison** or UNIX **yacc** respectively). This type of error message cannot be suppressed. Be aware that this type of error often means that **ftnchek** has not properly interpreted the statement where the error occurs, so that its subsequent checking operations will be compromised. You should eliminate all syntax errors before proceeding to interpret the other messages **ftnchek** gives.

"Warning: Nonstandard syntax" indicates an extension to Fortran that **ftnchek** supports but that is not according to the Fortran 77 Standard. The extensions that **ftnchek** accepts are described in the section on Extensions below. One example is the `DO ... ENDDO` construction. If a program uses these extensions, warnings will be given only if the **–f77** flag is set. The default is to give no warnings.

"Warning" in other cases means a condition that is suspicious but that may or may not be a programming error. Frequently these conditions are legal under the standard. Some are illegal but do not fall under the heading of syntax errors. Usage errors are one example. These refer to the possibility that a variable may be used before it has been assigned a value (generally an error), or that a variable is declared but never used (harmless but may indicate carelessness). The amount of checking for usage errors is controlled by the **–usage** flag, which is set for the maximum amount of checking by default.

Truncation warnings cover situations in which accuracy may be lost unintentionally, for example when a double precision value is assigned to a real variable. These warnings are controlled by the **–truncation** flag, which is on by default.

"Nonportable usage" warns about some feature that may not be accepted by some compilers even though it is not contrary to the Fortran 77 Standard, or that may cause the program to perform differently on different platforms. For example, equivalencing real and integer variables is usually a non-portable practice. The use of extensions to the standard language is, of course, another source of non-portability, but this is handled as a separate case. To check a program for true portability, both the **–portability** and the **–f77** flags should be used. They are both turned off by default. The **–wordsize** setting is provided to check only

those nonportable usages that depend on a particular machine wordsize.

"Possibly misleading appearance" is used for legal constructions that may not mean what they appear to mean at first glance. For example, Fortran is insensitive to blank space, so extraneous space within variable names or the lack of space between a keyword and a variable can convey the wrong impression to the reader. These messages can be suppressed by turning off the **–pretty** flag, which is on by default.

Other messages that are given after all the files are processed, and having to do with agreement between modules, do not use the word "warning" but generally fall into that category. Examples include type mismatches between corresponding variables in different COMMON block declarations, or between dummy and actual arguments of a subprogram. These warnings are controlled by the **–common** and **–arguments** settings respectively. By default both are set for maximum strictness of checking.

Another group of warnings about conditions that are often harmless refer to cases where the array properties of a variable passed as a subprogram argument differ between the two routines. For instance, an array element might be passed to a subroutine that expects a whole array. This is a commonly-used technique for processing single rows or columns of two-dimensional arrays. However, it could also indicate a programming error. The **–array** setting allows the user to adjust the degree of strictness to be used in checking this kind of agreement between actual and dummy array arguments. By default the strictness is maximum.

"Oops" indicates a technical problem, meaning either a bug in **ftnchek** or that its resources have been exceeded.

The format of the error messages has been modified from previous versions for more clarity. The syntax error messages and warnings now have the filename included along with the line number and column number. **ftnchek** now has two different options for the appearance of these error messages. If **–novice** is in effect, which is the default, the messages are very similar in style to those of the previous version. (In default style, the filename is not printed in messages within the body of the program if **–list** is in effect.) The other style of error messages is selected by the **–nonovice** option. In this style, the appearance of the messages is similar to that of the UNIX **lint** program.

ftnchek is still blind to some kinds of syntax errors. The two most important ones are detailed checking of `FORMAT` statements, and almost anything to do with control of execution flow by means of `IF`, `DO`, and `GOTO` statements: namely correct nesting of control structures, matching of opening statements such as `IF ... THEN` with closing statements such as `ENDIF`, and the proper use of statement labels (numbers). Most compilers will catch these errors. See the section on Limitations for a more detailed discussion.

If **ftnchek** gives you a syntax error message when the compiler does not, it may be because your program contains an extension to standard Fortran which is accepted by the compiler but not by **ftnchek**. (See the section on Extensions.) On a VAX/VMS system, you can use the compiler option `/STANDARD` to cause the compiler to accept only standard Fortran. On most UNIX or UNIX-like systems, this can be accomplished by setting the flag **–ansi.** Also, consult the `README` file included in the **ftnchek** distribution for information on how to control which extensions **ftnchek** accepts.

Many of the messages given by **ftnchek** are self-explanatory. Those that need some additional explanation are listed below in alphabetical order.

Common block NAME: data type mismatch at position n

The *n*-th variable in the COMMON block differs in data type in two different declarations of the COMMON block. By default (**–common** strictness level 3), **ftnchek** is very picky about COMMON blocks: the variables listed in them must match exactly by data type and array dimensions. That is, the legal pair of declarations in different modules:

```
COMMON /COM1/ A,B
```

and

```
COMMON /COM1/ A(2)
```

will cause **ftnchek** to give warnings at strictness level 3. These two declarations are legal in Fortran since they both declare two real variables. At strictness level 1 or 2, no warning would be given in this example, but the warning would be given if there were a data type mismatch, for instance, if `B` were declared `INTEGER`. Controlled by **−common** setting.

Common block NAME has long data type following short data type

Some compilers require alignment of multi-byte items so that each item begins at an address that is a multiple of the item size. Thus if a short (e.g. single-precision real) item is followed by a long (e.g. double precision real) item, the latter may not be aligned correctly. Controlled by **−portability** option.

Common block NAME has mixed character and non-character variables

The ANSI standard requires that if any variable in a COMMON block is of type `CHARACTER`, then all other variables in the same COMMON block must also be of type `CHARACTER`. Controlled by **−f77** option.

Common block NAME: varying length

For **−common** setting level 2, this message means that a COMMON block is declared to have different numbers of words in two different subprograms. A word is the amount of storage occupied by one integer or real variable. For **−common** setting level 3, it means that the two declarations have different numbers of variables, where an array of any size is considered one variable. This is not necessarily an error, but it may indicate that a variable is missing from one of the lists. Note that according to the Fortran 77 Standard, it is an error for named COMMON blocks (but not blank COMMON) to differ in number of words in declarations in different modules. Given for **−common** setting 2 or 3.

Error: Badly formed logical/relational operator or constant

Error: Badly formed real constant

The syntax analyzer has found the start of one of the special words that begin and end with a period (e.g. `.EQ.`), or the start of a numeric constant, but did not succeed in finding a complete item of that kind.

Error: cannot be adjustable size in module NAME

A character variable cannot be declared with a size that is an asterisk in parentheses unless it is a dummy argument, a parameter, or the name of the function defined in the module.

Error: cannot be declared in SAVE statement in module NAME

Only local variables and common blocks can be declared in a `SAVE` statement.

Error: No path to this statement

ftnchek will detect statements which are ignored or by-passed because there is no foreseeable route to the statement. For example, an unnumbered statement (a statement without a statement label), occurring immediately after a `GOTO` statement, cannot possibly be executed.

Error: Parse error

This means that the parser, which analyzes the Fortran program into expressions, statements, etc., has been unable to find a valid interpretation for some portion of a statement in the program. If your compiler does not report a syntax error at the same place, the most common explanations are: (1) use of an extension to ANSI standard Fortran that is not recognized by **ftnchek**, or (2) the statement requires more lookahead than **ftnchek** uses (see section on Bugs).

NOTE: This message means that the affected statement is not interpreted. Therefore, it is possible that **ftnchek**'s subsequent processing will be in error, if it depends on any matters affected by this statement (type declarations, etc.).

Error: Statement out of order.

ftnchek will detect statements that are out of the sequence specified for ANSI standard Fortran 77. Table 1 illustrates the allowed sequence of statements in the Fortran language. Statements which are out of order are nonetheless interpreted by **ftnchek**, to prevent ''cascades'' of error messages.

		implicit
	parameter	
		other specification
format		
and		statement-function
entry	data	
		executable

Table 1

Error: Syntax error

This is the same as ''Error: Parse error'' (see above). It is generated if your version of **ftnchek** was built using the UNIX **yacc** parser generator rather than GNU **bison**.

Identifiers which are not unique in first six chars

Warns that two identifiers which are longer than 6 characters do not differ in the first 6 characters. This is for portability: they may not be considered distinct by some compilers. Controlled by **–sixchar** option.

Nonportable usage: argument precision may not be correct for intrinsic function

The precision of an argument passed to an intrinsic function may be incorrect on some computers. Issued when a numeric variable declared with explicit precision (e.g. `REAL*8 X`) is passed to a specific intrinsic function (e.g. `DSQRT(X)`). Controlled by **–portability** and **–wordsize**.

Nonportable usage: character constant/variable length exceeds 255

Some compilers do not support character strings more than 255 characters in length. Controlled by **–portability**.

Nonportable usage: File contains tabs

ftnchek expands tabs to be equivalent to spaces up to the next column which is a multiple of 8. Some compilers treat tabs differently, and also it is possible that files sent by electronic mail will have the tabs converted to blanks in some way. Therefore files containing tabs may not be compiled correctly after being transferred. **ftnchek** does not give this message if tabs only occur within comments or character constants. Controlled by **–portability**.

Nonportable usage: non-integer DO loop bounds

This warning is only given when the `DO` index and bounds are non-integer. Use of non-integer quantities in a `DO` statement may cause unexpected errors, or different results on different machines, due to roundoff effects. Controlled by **–portability**.

Possibly it is an array which was not declared

This message is appended to warnings related to a function invocation or to an argument type mismatch, for which the possibility exists that what appears to be a function is actually meant to be an array. If the programmer forgot to dimension an array, references to the array will be interpreted as function invocations. This message will be suppressed if the name in question appears in an `EXTERNAL` or `INTRINSIC` statement. Controlled by the **–novice** option.

Possibly misleading appearance: characters past 72 columns

The program is being processed with the statement field width at its standard value of 72, and some nonblank characters have been found past column 72. In this case, **ftnchek** is not processing the characters past column 72, and is notifying the user that the statement may not have the meaning that it appears to have. These characters might be intended by the programmer to be significant, but they will be ignored by the compiler. (A similar warning is alternatively given under the **–f77** flag if the **–columns** setting is used to increase the statement field width.) Controlled by **–pretty**.

Possibly misleading appearance: Common block declared in more than one statement

Such multiple declarations are legal and have the same effect as a continuation of the original declaration of the block. This warning is only given if the two declarations are separated by one or more intervening statements. Controlled by **–pretty**.

Possibly misleading appearance: Continuation follows comment or blank line

ftnchek issues this warning message to alert the user that a continuation of a statement is interspersed with comments, making it easy to overlook. Controlled by **–pretty**.

Possibly misleading appearance: Extraneous parentheses

Warns about parentheses surrounding a variable by itself in an expression. When a parenthesized variable is passed as an argument to a subprogram, it is treated as an expression, not as a variable whose value can be modified by the called routine. Controlled by **–pretty**.

Subprogram NAME: argument data type mismatch at position n

The subprogram's *n*-th actual argument (in the `CALL` or the usage of a function) differs in datatype or precision from the *n*-th dummy argument (in the `SUBROUTINE` or `FUNCTION` declaration). For instance, if the user defines a subprogram by

```
SUBROUTINE SUBA(X)
REAL X
```

and elsewhere invokes `SUBA` by

```
CALL SUBA(2)
```

ftnchek will detect the error. The reason here is that the number 2 is integer, not real. The user should have said

```
CALL SUBA(2.0)
```

When checking an argument which is a subprogram, **ftnchek** must be able to determine whether it is a function or a subroutine. The rules used by **ftnchek** to do this are as follows: If the subprogram, besides being passed as an actual argument, is also invoked directly elsewhere in the same module, then its type is determined by that usage. If not, then if the name of the subprogram does

not appear in an explicit type declaration, it is assumed to be a subroutine; if it is explicitly typed it is taken as a function. Therefore, subroutines passed as actual arguments need only be declared by an `EXTERNAL` statement in the calling module, whereas functions must also be explicitly typed in order to avoid generating this error message.

Controlled by **–arguments**.

Subprogram NAME: argument arrayness mismatch at position n
Similar to the preceding situation, but the subprogram dummy argument differs from the corresponding actual argument in its number of dimensions or number of elements. Controlled by **–array** together with **–arguments**.

Subprogram NAME: argument mismatch at position n
A character dummy argument is larger than the corresponding actual argument, or a Hollerith dummy argument is larger than the corresponding actual argument. Controlled by **–arguments**.

Subprogram NAME: argument usage mismatch
ftnchek detects a possible conflict between the way a subprogram uses an argument and the way in which the argument is supplied to the subprogram. The conflict can be one of two types, as outlined below.

Dummy arg is modified, Actual arg is const or expr
A dummy argument is an argument as named in a `SUBROUTINE` or `FUNCTION` statement and used within the subprogram. An actual argument is an argument as passed to a subroutine or function by the caller. **ftnchek** is saying that a dummy argument is modified by the subprogram, implying that its value is changed in the calling module. The corresponding actual argument should not be a constant or expression, but rather a variable or array element which can be legitimately assigned to. Given for **–usage** setting 1 or 3.

Dummy arg used before set, Actual arg not set
Here a dummy argument may be used in the subprogram before having a value assigned to it by the subprogram. The corresponding actual argument should have a value assigned to it by the caller prior to invoking the subprogram. Given for **–usage** setting 1 or 3.

These warnings are not affected by the **–arguments** setting.

Subprogram NAME invoked inconsistently
Here the mismatch is between the datatype of the subprogram itself as used and as defined. For instance, if the user declares

```
INTEGER FUNCTION COUNT(A)
```

and invokes `COUNT` in another module as

```
N = COUNT(A)
```

without declaring its datatype, it will default to real type, based on the first letter of its name. The calling module should have included the declaration

```
INTEGER COUNT
```

Given for **–arguments** setting 2 or 3.

Subprogram NAME: varying length argument lists:
An inconsistency has been found between the number of dummy arguments (parameters) a subprogram has and the number of actual arguments given it in an invocation. **ftnchek** keeps track of all invocations of subprograms (`CALL` statements and expressions using functions) and compares them with the definitions of the subprograms elsewhere in the source code. The Fortran compiler normally does not catch this type of error. Given for **–arguments** setting 1 or 3.

Variable not declared. Type has been implicitly defined
When printing the symbol table for a module, **ftnchek** will flag with an asterisk all identifiers that are not explicitly typed and will show the datatype that was assigned through implicit typing. This provides support for users who wish to declare all variables as is required in Pascal or some other languages. This message appears only when the **–symtab** option is in effect. Alternatively, use the **–declare** flag if you want to get a list of all undeclared variables.

Variables declared but never referenced
Detects any identifiers that were declared in your program but were never used, either to be assigned a value or to have their value accessed. Variables in COMMON are excluded. Given for **–usage** setting 2 or 3.

Variables set but never used
ftnchek will notify the user when a variable has been assigned a value, but the variable is not otherwise used in the program. Usually this results from an oversight. Given for **–usage** setting 2 or 3.

Variables used before set
This message indicates that an identifier is used to compute a value prior to its initialization. Such usage may lead to an incorrect value being computed, since its initial value is not controlled. Given for **–usage** setting 1 or 3.

Variables may be used before set
Similar to used before set except that **ftnchek** is not able to determine its status with certainty. **ftnchek** assumes a variable may be used before set if the first usage of the variable occurs prior in the program text to its assignment. Given for **–usage** setting 1 or 3.

Warning: DO index is not integer
This warning is only given when the `DO` bounds are integer, but the `DO` index is not. It may indicate a failure to declare the index to be an integer. Controlled by **–truncation** option.

Warning: integer quotient expr converted to real
The quotient of two integers results in an integer type result, in which the fractional part is dropped. If such an integer expression involving division is later converted to a real datatype, it may be that a real type division had been intended. Controlled by **–truncation** option.

Warning: Integer quotient expr used in exponent
The quotient of two integers results in an integer type result, in which the fractional part is dropped. If such an integer expression is used as an exponent, it is quite likely that a real type division was intended. Controlled by **–truncation** option.

Warning: NAME not set when RETURN encountered

The way that functions in Fortran return a value is by assigning the value to the name of the function. This message indicates that the function was not assigned a value before the point where a `RETURN` statement was found. Therefore it is possible that the function could return an undefined value.

Warning: Nonstandard syntax: adjustable size cannot be concatenated here

The Fortran 77 Standard forbids concatenating character variables whose size is an asterisk in parentheses, except in an assignment statement. Controlled by **–f77**.

Warning: Nonstandard syntax: characters past 72 columns

A statement has been read which has nonblank characters past column 72, with the statement field extended beyond the standard value of 72 columns by the **–col** setting. Standard Fortran ignores all text in those columns, but some compilers do not. Thus the program may be treated differently by different compilers. Controlled by **–f77** option and **–columns** setting.

Warning: Possible division by zero

This message is printed out wherever division is done (except division by a constant). Use it to help locate a runtime division by zero problem. Controlled by **–division** option.

Warning: real truncated to intg

ftnchek has detected an assignment statement which has a real expression on the right, but an integer variable on the left. The fractional part of the real value will be lost. If you explicitly convert the real expression to integer using the `INT` or `NINT` intrinsic function, no warning will be printed. A similar message is printed if a double precision expression is assigned to a single precision variable, etc. Controlled by **–truncation** option.

Warning: subscript is not integer

Since array subscripts are normally integer quantities, the use of a non-integer expression here may signal an error. Controlled by **–truncation** option.

Warning: Unknown intrinsic function

This message warns the user that a name declared in an `INTRINSIC` statement is unknown to **ftnchek**. Probably it is a nonstandard intrinsic function, and so the program will not be portable. The function will be treated by **ftnchek** as a user-defined function. This warning is not controlled by any option, since it affects **ftnchek**'s analysis of the program.

LIMITATIONS AND EXTENSIONS

ftnchek accepts ANSI standard Fortran-77 programs with some minor limitations and numerous common extensions.

Limitations:

ftnchek uses only one line of lookahead when analyzing a program into its basic syntactic elements. If a particular statement is difficult to identify, it may be handled improperly if the ambiguity is not resolved on a single line. This limitation applies to complex constants except in `DATA` statements, and to situations in which a variable name might be confused with a keyword. For example, if the variable name `WRITE` is used for an array, then a very long statement assigning a value to some element of this array could be mistaken as a `WRITE` statement if the equals sign is not on the same line as the word `WRITE`.

The dummy arguments in statement functions are treated like ordinary variables of the program. That is, their scope is the entire module, not just the statement function definition.

The checking of FORMAT statements is lax, tolerating missing separators (comma, etc.) between format descriptors in places where the Standard requires them, and allowing *.d* fields on descriptors that should not have them. It does warn under **–f77** about nonstandard descriptor types (like `O`), and supported extensions.

The only checking related to control of execution flow is a warning about statements that cannot be reached because they do not have a label and they follow an unconditional transfer. There is no checking for correct nesting of `DO` loops or matching of opening statements such as `IF ... THEN` with closing statements such as `ENDIF`, nor the proper definition and use of statement labels. Fortunately, most compilers will catch these errors.

If a user-supplied subprogram has the same name as one of the nonstandard intrinsic functions, it must be declared in an `EXTERNAL` statement in any routine that invokes it. Otherwise it will be subject to the checking normally given to the intrinsic function. Since the nonstandard intrinsics are not standard, this `EXTERNAL` statement is not required by the Fortran 77 Standard. See the lists of supported nonstandard intrinsic functions under Extensions below.

Extensions:

All of these extensions (except lower-case characters) will generate warnings if the **–f77** flag is set. Some of the extensions listed below are part of the Fortran-90 Standard. These are indicated by the notation (F90).

Tabs are permitted, and translated into equivalent blanks which correspond to tab stops every 8 columns. The standard does not recognize tabs. Note that some compilers allow tabs, but treat them differently. The treatment defined for DEC FORTRAN can be achieved using the **-tab** option.

Strings may be delimited by either quote marks or apostrophes. A sequence of two delimiter characters is interpreted as a single embedded delimiter character. (F90)

Strings may contain UNIX-style backslash escape sequences. They will be interpreted as such if the **–backslash** flag is set. Otherwise the backslash character will be treated as a normal printing character.

Lower case characters are permitted, and are converted internally to uppercase except in character strings. The standard specifies upper case only, except in comments and strings. (F90)

Hollerith constants are permitted, in accordance with the Fortran 77 Standard, appendix C. They should not be used in expressions, or confused with datatype CHARACTER.

The letter 'D' (upper or lower case) in column 1 is treated as the beginning of a comment. There is no option to treat such lines as statements instead of comments.

Statements may be longer than 72 columns provided that the setting **–column** was used to increase the limit. According to the standard, all text from columns 73 through 80 is ignored, and no line may be longer than 80 columns.

Variable names may be longer than six characters. The standard specifies six as the maximum. **ftnchek** permits names up to 31 characters long (F90).

Variable names may contain underscores and dollar signs, which are treated the same as alphabetic letters. The default type for variables beginning with these characters is REAL. In IMPLICIT type statements specifying a range of characters, the dollar sign follows Z and is followed by underscore. Fortran 90 permits underscores in variable names.

The UNIX version tolerates the presence of preprocessor directives, namely lines beginning with the pound sign (#). These are treated as comments, except for `#line` directives, which are interpreted, and are used to set the line number and source file name for warnings and error messages. Note that `#include` directives are not processed by **ftnchek**. Programs that use them for including source files should be passed through the preprocessor before being input to **ftnchek**. As noted below, **ftnchek** does process `INCLUDE` statements, which have a different syntax.

The DO ... ENDDO control structure is permitted. The syntax which is recognized is according to either of the following two forms:

```
DO [label [,]] var = expr , expr [, expr]
 ...
END DO
```

or

```
DO [label [,]] WHILE ( expr )
 ...
END DO
```

where square brackets indicate optional elements. This is a subset of the Fortran 90 do-loop syntax.

The ACCEPT and TYPE statements (for terminal I/O) are permitted, with the same syntax as PRINT.

Statements may have any number of continuation lines. The standard allows a maximum of 19.

Inline comments, beginning with an exclamation mark, are permitted. (F90)

NAMELIST I/O is supported. The syntax is the same as in Fortran 90.

FORMAT statements can contain a dollar sign to indicate suppression of carriage-return. An integer expression enclosed in angle brackets can be used anywhere in a FORMAT statement where the Fortran 77 Standard allows an integer constant (except for the length of a Hollerith constant), to provide a run-time value for a repeat specification or field width.

The IMPLICIT NONE statement is supported. The meaning of this statement is that all variables must have their data types explicitly declared. Rather than flag the occurrences of such variables with syntax error messages, **ftnchek** waits till the end of the module, and then prints out a list of all undeclared variables, as it does for the **−declare** option. (F90)

Data types INTEGER, REAL, COMPLEX, and LOGICAL are allowed to have an optional precision specification in type declarations. For instance, REAL*8 means an 8-byte floating point data type. The REAL*8 datatype is not necessarily considered equivalent to DOUBLE PRECISION, depending on the **−wordsize** setting. The Fortran 77 Standard allows a length specification only for CHARACTER data.

ftnchek supports the DOUBLE COMPLEX type specification for a complex quantity whose real and imaginary parts are double precision. Mixed-mode arithmetic involving single-precision complex with double-precision real data, prohibited under the Standard, yields a double complex result. The double complex counterparts of all the standard intrinsic functions for complex data are included:

```
DCMPLX    DCONJG    DIMAG     DREAL     IMAG
CDABS     CDSQRT    CDEXP     CDLOG     CDSIN     CDCOS
ZABS      ZSQRT     ZEXP      ZLOG      ZSIN      ZCOS
```

The following other commonly found nonstandard intrinsic functions are provided. All except EXIT and LOC are defined in MIL-STD 1753.

```
BTEST     IAND      IOR       IBSET     IBCLR
IBITS     IEOR      ISHFT     ISHFTC    NOT
EXIT      LOC
```

For the UNIX version of **ftnchek**, the following common UNIX intrinsic functions are provided:

```
ABORT     AND       GETARG    GETENV    GMTIME
IARGC     LSHIFT    LTIME     OR        IRAND
```

```
RAND      RSHIFT    SRAND     SYSTEM    TIME
XOR
```

Note: there are two common calling sequences for `RAND` and `IRAND`: with zero arguments or with 1 argument. By default, **ftnchek** accepts either form. If you wish to enforce strict adherence to one form or the other, you should compile **ftnchek** with one of the two macros `RAND_NO_ARG` or `RAND_ONE_ARG` set.

For the VAX/VMS version of **ftnchek**, the following common VMS intrinsic functions are provided:

```
DATE      ERRSNS    IDATE     RAN       SECNDS
SIZEOF    TIME
```

Argument checking is not tight for those nonstandard intrinsics that take arrays or mixed argument types.

ftnchek permits the `INCLUDE` statement, which causes inclusion of the text of the given file. The syntax is

`INCLUDE '`*filename*`'`

This is compatible with Fortran 90. When compiled for VMS, **ftnchek** will assume a default extension of *.for* if no filename extension is given. Also for compatibility with VMS, the VMS version allows the qualifier `/[NO]LIST` following the filename, to control the listing of the included file. There is no support for including VMS text modules.

In diagnostic output relating to items contained in include files, the location of the error is specified by both its location in the include file and the location in the parent file where the file was included.

ftnchek accepts `PARAMETER` definitions that involve intrinsic functions and exponentiation by a non-integer exponent. Both of these cases are prohibited by the Fortran 77 Standard, and will be warned about if the **–f77** flag is set. If an intrinsic function is a compile-time integer constant, **ftnchek** will evaluate it. This allows better checking if the parameter is used in declaring array sizes. Fortran 90 allows intrinsic functions in `PARAMETER` definitions.

The intrinsic functions that are evaluated are:

```
ABS       IABS      DIM       IDIM      MAX
MAX0      MIN       MIN0      MOD       SIGN
ISIGN     LEN       ICHAR     INDEX
```

The functions of integer arguments are evaluated only if the arguments are integer constant expressions. (These may involve integer constants, parameters, and evaluated intrinsic functions.) The function `LEN` is evaluated if its argument is an expression involving only character constants and variables whose length is not adjustable. The functions `ICHAR` and `INDEX` are evaluated only if the arguments are character constants. **ftnchek** gives a warning if it needs the value of some intrinsic function that is not evaluated.

NEW FEATURES

Here are the changes from Version 2.7 to Version 2.8:

1. Improvements in handling command-line settings: add support for colon as assignment operator, and extend setting switch support to include a default value to replace out-of-range values, instead of just choosing the nearer endpoint of the valid range.
2. New options: **–makedcls=***num* to generate variable declarations; **–backslash** to handle UNIX-style backslash escapes in character strings; **–resource** to print out internal resource usage; **–tab** to accept DEC-style tab-formatted source.

3. New extensions to syntax: Accept quote marks as an alternative to apostrophes for delimiting strings. Accept 'D' as equivalent to 'C' in column 1 for comments. A patch is supplied to allow "Cray pointer" syntax to be tolerated. (This patch does not include checking proper use of pointers.)
4. Provide variable names and not just position numbers in warnings about mismatches in common block declarations and subprogram argument lists.
5. Add installation validation suite to check for correct functioning after a new installation, or a new compilation with a different compiler or compiler options. The validation suite also serves to record input cases that exhibited bugs in older versions of the program, providing regression testing to ensure that changes do not introduce new bugs, or restore old ones. This test suite uncovered compiler optimizer errors on at least one system, errors which did not appear in older versions of **ftnchek**.
6. Improve memory management to avoid running out of space.
7. Update the UNIX Makefile with new targets following the Free Software Foundation standards, and create the *CHECKLIST* file to record systems for which this version of **ftnchek** has been successfully built and has passed the validation suite tests.
8. Add the *man2ps* script, and a target in the UNIX *Makefile* to use it for converting the manual pages file to PostScript.
9. Correct several small typographical irregularities in these manual pages. **troff** preserves all input spaces, so great care is needed in preparing troff input to avoid introducing spurious space into the typeset output.

Grateful acknowledgement is given to Nelson H. F. Beebe of the University of Utah for providing most of these improvements, and especially for writing most of the new code to produce variable declarations, which represents a very substantial effort.

Here are the changes from Version 2.6 to Version 2.7:

1. Fixed bugs: to allow statement functions with no arguments; to catch extra comma in subprogram argument lists; argument of `LEN` does not need to have a defined value.
2. Insensitive to blanks as per the Standard.
3. Changed behavior of options: **−f77** controls warnings about statement out of order and COMMON block with mixed character and non-character data; **−help** option now lists patch level and copyright; **−novice** controls appearance of warning messages.
4. Added handling of explicit precision and double complex data type. `REAL*8` is no longer synonymous with `DOUBLE PRECISION`, depending on the machine wordsize. Checking length agreement for character data also done properly now.
5. Checking usage status of COMMON blocks and COMMON variables.
6. Improved format of messages.
7. Support for common nonstandard intrinsic functions.
8. New options: **−arguments**, **−crossref**, **−reference**, **−sort**, **−volatile**, **−wordsize**, and **−wrap**.
9. Behavior when no top-level non-library modules found, changed from no cross-checking to complete cross-checking.
10. Added expansion of wildcards for filenames on the command line to the VMS and MS-DOS versions.
11. Parser is generated by **bison**. Formerly **yacc** was used.
12. Made changes to allow the IBM PC version handle larger files.

BUGS

ftnchek still has much room for improvement. Your feedback is appreciated. We want to know about any bugs you notice. Bugs include not only cases in which **ftnchek** issues an error message where no error exists, but also if **ftnchek** fails to issue a warning when it ought to. Note, however, that **ftnchek** is not intended to catch all syntax errors (see section on Limitations). Also, it is not considered a bug for a

variable to be reported as used before set, if the reason is that the usage of the variable occurs prior in the text to where the variable is set. For instance, this could occur when a `GOTO` causes execution to loop backward to some previously skipped statements. **ftnchek** does not analyze the program flow, but assumes that statements occurring earlier in the text are executed before the following ones.

We especially want to know if **ftnchek** crashes for any reason. It is not supposed to crash, even on programs with syntax errors. Suggestions are welcomed for additional features which you would find useful. Tell us if any of **ftnchek**'s messages are incomprehensible. Comments on the readability and accuracy of this document are also welcome.

You may also suggest support for additional extensions to the Fortran language. These will be included only if it is felt that the extensions are sufficiently widely accepted by compilers.

If you find a bug in **ftnchek**, first consult the list of known bugs below to see if it has already been reported. Also check the section entitled "Limitations and Extensions" above for restrictions that could be causing the problem. If you do not find the problem documented in either place, then send a report including

1. The operating system and CPU type on which **ftnchek** is running.
2. The version of **ftnchek**.
3. A brief description of the bug.
4. If possible, a small sample program showing the bug.

The report should be sent to either of the following addresses:

```
MONIOT@FORDMULC.BITNET
moniot@mary.fordham.edu
```

Highest priority will be given to bugs which cause **ftnchek** to crash. Bugs involving incorrect warnings or error messages may take longer to fix.

Certain problems that arise when checking large programs can be fixed by increasing the sizes of the data areas in **ftnchek**. (These problems are generally signaled by error messages beginning with "Oops".) The simplest way to increase the table sizes is by recompiling **ftnchek** with the `LARGE_MACHINE` macro name defined. Consult the `makefile` and `README` file for the method of doing this.

The following is a list of known bugs.

1. Bug: Used-before-set message is suppressed for any variable which is used as the loop index in an implied-do loop, even if it was in fact used before being set in some earlier statement. For example, consider `J` in the statement

   ```
   WRITE(5,*) (A(J), J=1,10)
   ```

   Here **ftnchek** parses the I/O expression, `A(J)`, where `J` is used, before it parses the implied loop where `J` is set. Normally this would cause **ftnchek** to report a spurious used-before-set warning for `J`. Since this report is usually in error and occurs fairly commonly, **ftnchek** suppresses the warning for `J` altogether.

   Prognosis: A future version of **ftnchek** is planned which will handle implied-do loops correctly.

2. Bug: Variables used (not as arguments) in statement-function subprograms do not have their usage status updated when the statement function is invoked.

   Prognosis: To be fixed in a future version of **ftnchek**.

3. Bug: VAX version does not expand wildcards in filenames on the command line if they are followed without space by an option, e.g. `ftnchek *.f/calltree` would not expand the `*.f`. This is because VMS-style options without intervening space are not supported by the GNU `shell_mung`

routine that is used to expand wildcards.

Prognosis: unlikely to be fixed.

ACKNOWLEDGEMENTS

ftnchek is a public-domain program. It was designed by Dr. Robert Moniot, professor at Fordham University. During the academic year of 1988-1989, Michael Myers and Lucia Spagnuolo developed the program to perform the variable usage checks. During the following year it was augmented by Lois Bigbie to check subprogram arguments and COMMON block declarations. Brian Downing assisted with the implementation of the `INCLUDE` statement. John Quinn wrote the common block usage checks. Nelson H. F. Beebe of the University of Utah added most of the new code to implement the **–makedcls** feature. The **–reference** feature was contributed by Gerome Emmanuel, Ecole des mines, U. Nancy (slightly modified). The patch for Cray pointer syntax was provided by John Dannenhoffer of United Technologies Research Center. Additional features will be added as time permits. With Version 2.5, the name was changed from **forchek** to **ftnchek**, to avoid confusion with a similar program named **forcheck**, developed earlier at Leiden University.

We would like to thank John Amor of the University of British Columbia, Reg Clemens of the Air Force Phillips Lab in Albuquerque, Markus Draxler of the University of Stuttgart, Victor Eijkhout of the University of Tennessee at Knoxville, Greg Flint of Purdue University, Daniel P. Giesy of NASA Langley Research Center, Fritz Keinert of Iowa State University, Judah Milgram of the University of Maryland College Park, Hugh Nicholas of the Pittsburgh Supercomputing Center, Dan Severance of Yale University, Phil Sterne of Lawrence Livermore National Laboratory, Larry Weissman of the University of Washington, Warren J. Wiscombe of NASA Goddard, and especially Nelson H. F. Beebe of the University of Utah, for pointing out bugs and suggesting some improvements. We also thank Jack Dongarra for putting **ftnchek** into the `netlib` library of publicly available software.

INSTALLATION AND SUPPORT

The **ftnchek** program can be obtained by anonymous ftp from many software servers, including host `netlib.org` (128.169.92.17) where it is located in directory `/fortran`.

Installation requires a C compiler for your computer. See the `README` file provided with the distribution for instructions on installing **ftnchek** on your system. Executable binary in ZIP format for IBM PC computers under MS-DOS is available by anonymous ftp from `oak.oakland.edu` (141.210.10.117) where it is located in directory `/SimTel/msdos/fortran`, filename `ftnchk28.zip`. Executable binary in binhexed stuffit format for Macintosh computers is available from sumex-aim.stanford.edu (36.44.0.6), in directory `info-mac/Development`, filename `ftnchek-28.hqx`.

The **nroff** version of this document is named *ftnchek.man*. On UNIX systems, it can be used as the man page or you can print it using the command `nroff -man ftnchek.man | lpr`. The distribution also includes a plain ASCII version named *ftnchek.doc*, a PostScript version named *ftnchek.ps*, and a VMS HELP version named *ftnchek.hlp*.

Information about the latest version and the status of the project can be obtained by the Internet command "`finger ftnchek@mary.fordham.edu`". For further information and to report bugs, you may contact Dr. Robert Moniot at either of the following network addresses:

```
MONIOT@FORDMULC.BITNET
moniot@mary.fordham.edu
```
