The OS/2 port of bind 4.9.3

Peter Meerwald

1. Juli 1996

1 What is it?

This is release 4.9.3 of bind[1] ported to OS/2. It relies on EMX[2] 0.9b fix 5 (or newer).

2 Installation

To install just take a look a the standard bind documentation[3]. The directory structure for the OS/2 port is laid down in *named/pathnames.h*. A re-compile is neccassary to customize directory names – sorry. The EMX runtime and IBM TCP/IP have to be installed.

You will find the executables in the source directories (*named/*, *tools/*, *tools/nslookup*), make install does (of course) not work (yet).

It is a good idea to have *syslogd* running the first time you start *named*. Try parameter *-d* for extensive debug info and/or *-q* for query logging.

3 OS/2 specific stuff

3.1 What happened to the code?

Actual code is pretty unchanged, I adapted the makefiles, figured out a suitable *compat/lib/lib44bsd.a*, read *conf/protability.h* very carefully :) and while doing so my OS/2 box turned into a unix-lookalike[4].

Look for __EMX__ defines in the code (you won't find many) to see what changed.

3.2 Re-compiling

Especially *named/Makefile* contains one bad hardcoded hack (I was unable get sed to work), I used tcsh 6.0.6.1 **and** bash 1.12, to me, it seems that these shells lack some features :) - well I'm very lost when it comes to shell setup/shell features - I am awaiting your hints. . .

News flash: Try ksh 5.27 to re-compile – works much better that tcsh and bash! Compiles the entier project in **one** pass, wow. . .

In order to re-compile the bind port you'll need a syslog library (on hobbes[5] for IBM's CSet, a port of the port to EMX is available from the author) and flex.

I removed the *contrib/*, *shres/*, *doc/rfc/* directory from the original distribution, some postscript files about DNS security were also removed.

3.3 Sending signals

Unix background daemons receive commands via signals that are sent to their pid[6]. bind 4.9.3 understands a number of signals: SIGINT, SIGQUIT, SIGIOT, SIGUSR1, SIGUSR2, SIGHUP, SIGALARM, SIGTERM.

A way to send signals under OS/2 is provided in the Apache httpd port[7] in directory emphApache/os2/.

4 History of the OS/2 port

- June 14, 1996 — released *bind493a.zip*

- July 3,1996 — *bind493b.zip* contains this wonderful LaTeX -README and, more important, a fix for the "core dump" bug when set up as a secondary name server (well, now everything is linked static); some cleanups were done to the Makefiles; this is just an **update** release, it contains **only** executables and this README!

5 To do

- either replace makefiles with REXX scripts or craft'em right

- include a working sample configuration

- find and fix bugs in the port :)

- make named display some debug info in its window

- provide some means to send signals to *named*

- figure out a way to have dynamic linking **and** a working fork()

6 How to contact the author

I'm very interested in your comments and flames.
