

Welcome to The Homebrew Digest Text Search and Retrieval System

To begin, click on the Search button above.

Notes about this helpfile:

The articles in this help file were gathered from the Internet and placed into hypertext format using a program we wrote. Since we let the computer do it, there was no editing of the message content whatsoever. This has been shown to be both good and bad since some of the articles are decidedly uninteresting. Fortunately, these are in the minority.

In general, you should maximize the help window when viewing this help so as to keep the lines from wrapping around.

In addition, certain punctuation characters were lost due to incompatibilities between the conversion program and the Rich Text Format. In particular, the curly braces { and } were changed to ordinary parentheses and the backslash (\) was changed to a forward slash (/) in all cases. We hope that this doesn't cause many problems.

Nearly all of the people who contributed to The Homebrew Digest are still reachable via their e-mail addresses. Feel free to write them and/or to subscribe to the HBD (see below). The Homebrew Digest is an open, and usually unmoderated forum where anything can, and often does appear. Some of the language used in these articles may not be suitable for children, but then neither is beer in general.

Homebrew Digest E-Mail Subscription Information

Send articles for publication only to homebrew@hpfcmi.fc.hp.com
(Articles are published in the order they are received.) Send UNSUBSCRIBE and all other requests, i.e., address change, etc., to:

Subject: My mashing technique

Many thanks to Mike Charlton, who confirms my feelings of inadequacy :-)
My worries about my mashing technique are:

*) My thermometer may be off. I don't think this is true, but since I want to replace it anyway, It's worth a try.

*) I may not let conversion go long enough. Two hours seems like a long time, but I should try for 2.5 sometime, with an extra heat boost to stay above 142 dF.

*) My lauter tun may be doing me in. This I doubt; it's a double-bucket affair, made from some heavy-duty stiff plastic 18 qt. food "buckets". There's about 8-10 oz. space below the spigot that of course gets wasted, but I really doubt that that's where all the good stuff is going (it would have to be the consistency of honey!)

*) The 2-row is not diastatic enough to convert the wheat and dextrin malts. I am too ignorant of biochemistry to assess this potential problem.

When mashing, I go out of protein rest up to about 152 dF (I've been shooting for a fermentable wort). I always stir carefully to avoid overheated zones in the kettle. After I reach the correct initial temperature, I cover the kettle with my insulated box (my wife knew I wast a lost cause when I built that). Temperature drops to the mid 140's in an hour or so, so I stir and boost the heat at that point. Note that if my thermometer's off, this process would be severely affected.

My lauter tun is insulated (a recent addition; I used this nifty stuff that's basically two layers of small bubble wrap covered with reflective foil), so there is only moderate heat loss during the sparge. I recycle wort with an intermediate re-heating stage. I have wondered whether I'm waiting too long before ending the recycle and going to the boiler. The final runnings come out pretty damn pale, though.

Thanks for the hints!

From: noah@cs.washington.edu (Rick Noah Zucker)
Subject: Re: Brewpub Practices - tangent on aging

I was recently in Toronto for a few days. While there I tried to hit as many brewpubs and try as many micro-brews as I could. At the Rotterdam I went on a tour and spoke with the brewmaster. While talking with him I was surprised to discover that they do not age their beers very long by our standards. He serves the lagers after four weeks, the light ales after one, and something like a porter after two. I commented on how my recent porter, although very good after a month, was phenomenal after three months. He said that as professionals they had far greater experience (easily believed) and that since they could control temperature and pressure, they did not need to age things as long as we would (this was not said condescendingly).

Do people out there believe this totally? I'll agree that they may not need to age quite as long as we do at home. However, two weeks from start to finish for a porter? Four weeks for lagers? Doesn't Bud age their lagers for 6-8 weeks? I should note that I was not overly impressed by their beers or that of their sister brewpub in Toronto (the Amsterdam) although it was much better than your mass-market swill. The other brewpub I went to there, Dennisons, was better. It is partially owned by Prince Luitpold of Bavaria. Was he the one on the Beer Hunter?

One point to raise about the aging of beer in brewpubs is that they may not have the space. If they were to double the aging time of their beer, they would need twice as many storage tanks, and they may not be able to afford that, or have the space for it.

Well, this time we don't have anyone in the family ``over there'', and perhaps it's just as well, but I noted a shipping suggestion theory; note that no one is actually going to try to send anything across the pond without being sure that it's legal over in Saudi Arabia. Stinking hole. Insert anti-arab prejudice here.

Not only might a dark beer look remarkably like a brand-named carbonated beverage if placed in a plastic 1-litre bottle, but the stuff might have a little bit of sediment in the bottom. Of course, no one would pour that sediment into a batch of diluted malt-water, and leave it to sit for a few days, if that were against local regs, and therefore no one would notice that they got a better product than the other guys who were using bread yeast.

This is the perfect opportunity to write a couple of FYIs.

"Publications for the beginner" is a good one.
"NYC-area suppliers" is also good.
"General beginner information" has already been written by Rob Gardner.

Anybody want to take a stab at listing some of the basic beginner
publications and a small narrative on each? I will if no one else
out there feels qualified.

How about someone from NYC to start a listing of suppliers?

Let's do it!

From: mcnally@wsl.dec.com
Subject: Gravity grief

I'm starting to believe that my problems with low starting gravity (see some previous messages from me) may have something to do with my sparge technique or hardware (or both). From my general feelings about how the world works, it seems that one problem might be that my grain bed is **too** deep when I have a lot of grain. I realize that there's risk of compromising the cleanness of the sparge (i.e., I might get more draff), but perhaps the problem is that the sparge water's capacity to dissolve the sugars is exhausted before it gets through the 18 inches of grain. Perhaps I could try a double lauter tun approach, and split the mash between them. Hmmmm... I also found that the settling space below the tap level in my tun is bigger than I had thought; tilting the tun might get me a couple points.

What are commercial lauter tun geometries? Dave Miller mentions that commercial breweries apply the sparge water to the grain bed very carefully to avoid disturbing it. That only really makes sense if the bed is shallow. Maybe I'll look around for fatter buckets from which to make a lauter tun, and use the fat one for heavy recipes.

From: dbreiden@mentor.cc.purdue.edu
Subject: Lager and FYIs

Mike Schremp asked about starting lagers. The one lager that my brew partner and I made went very well. We just started it like any old beer--which for us means room temp (~65-68 deg F.) and putting it in a fridge after it got going. It went pretty well. Ended up being one of our best batches.

The comments on FYIs sounds really great. I don't understand the details on creation or use or the ramifications on administering & such. But the basic idea sounds super for the novice--and for the advanced!! This raises a question I'd forgotten about. I've tried to get stuff from the archives but have failed. Could someone post or e-mail me a little primer on how to retrieve old stuff?? Many Thanks.

Rick> like a porter after two.

Rick> He said that as professionals ... they could control temperature and

Rick> pressure, they did not need to age things as long as we would

The idea sounds seductively appealing, but I think it's bull. Most -- if not all -- of the ten or so brewpubs I've been to have had beer that tasted

young. In nearby Baltimore, the stuff at Sissons tastes plain *raw*, with a

watery bitterness typical of a brew that hasn't matured enough. To a lesser

extent, same with the Baltimore Brewing Company, but they seem to lager them for a while. Even my favorite, Big Time Brewing in Seattle, had a slight edge to it.

Rick> One point to raise about the aging of beer in brewpubs is that

Rick> they may not have the space.

That's true, but they are never going to make world class beer without proper aging. I love to try the brews at brewpubs, but I can't quite stomach them for extended drinking. I'd rather have a well lagered Dark Horse (microbrew, not brewpub).

Any of you ever been to England? What's the ``Real Ale'' like? I know it's

still fermenting, and on the Beer Hunter, they said one batch of Bass was at it's peak taste after 18 days, although they didn't say whether that was

after the start of fermentation, or after being kegged, or... Does real ale

taste raw? or smooth?

Rick> Prince Luitpold of Bavaria. Was he the one on the Beer Hunter?

Yes.

> from Ireland.

Even worse than that, it is my understanding that a fair number of
"imported" brews are actually brewed in this country, and that they may
use
the "imported" label because some of the ingredients are imported. During
a
visit to Europe I thoroughly enjoyed the Heineken (sp?) in Amsterdam,
however was very disappointed by the same on tap in England. It appears
that
they ship the ingredients and brew English Heineken in England, and the
same
applies for the U.S., etc.

At least that's what I remember...

Subject: Ancient brew needs help

I have an unusual situation which is probably unresolvable, but it never hurts to ask...

A year ago this fall I brewed a batch of very dark stout, all of which seemed to go well. I then moved, and moved the batch (in the secondary) to my new place, where it sat through the year, in a closet, at high temps in the summer. I finally got back to it (and brewing) this past fall, and upon tasting and smelling it seemed okay (not infected or soured), so I thought I might as well try throwing it in a keg and priming and see what happens.

Now I have a nicely chilled barrel of extremely flat, very sweet fluid. My assumption is that there are no more active yeast with which to prime, and so I started wondering what would happen if I threw a little activated yeast in the barrel and let them work on the priming malt. I have nothing to lose, as I've already considered the batch a loss, so I'm interested in any thoughts anyone might have as to any possibility of rescue for this batch.

Cheers! - Gregg

Subject: Beer Bread

I have seen several postings over that past few months asking for recipies for cooking with beer. I discovered one while visiting relatives over the holidays that is so easy I just have to share it.

Mix in a bowl: 3 cups self-rising flour
3 tablespoons sugar
12 ounces beer

Pour batter into a greased bread pan and bake for
50 minutes at 350 degress F.

The self rising flour is important. It contains baking powder which reacts with the beer to make the loaf rise. It bakes up pretty ugly and lumpy, and by homemade bread standards (we make a lot) it isn't anything to brag about, but it is extremely easy to make and it does fill the house with that "baking bread" aroma.

I used Michelob Dry for the first loaf (I hadn't brought enough homebrew with me to use on such things), and the resulting bread was a little crumbly, but tasted very good with butter or as toast.

The second batch I made at home using a bottle of seriously overhopped lager. I beat the batter in the mixer for five minutes to improve the bread's texture. The texture was better and the hop flavor gave the loaf a very interesting character. I will soon try a left-over bottle of Christmas ale to see if I can produce a spiced bread.

Happy baking.

Subject: Homebrew Digest #560 (January 03, 1991)

I was wondering whether anyone could help me out with a question ?
After mashing for a long while we, the fairview brewing cartel,
perform a starch test on the mash. We find that when we add
iodine to the wort we obtain a negative result, indicating a
lack of starch. If we place the iodine on a grain and crush
the grain a little, a positive result is obtained. Would one
expect this ? Is our grain not finely enough ground ? would
one expect ahazy wort if the grains were too finely ground ?

Agreed. The better beers out here appear to be those which have been aged
a
little longer. McMenamin's, the local chain of pubs, tend to underage
their
beers, which taste young.

"Real Ale" is just plain old beer, made the same way our local brewpubs
make
it. CAMRA, the Campaign For Real Ale, has made a thing of insisting that
pubs serve (and brewers brew) cask-conditioned ales, non-pasteurized and
non-filtered. While some American micro-brew-pubs do not cask-condition,
choosing instead to serve direct from aging tanks, there is basically no
difference between garden-variety (isn't it nice to be able to talk about
Real
Beer that way?) American microbrew and garden-variety English Real Ale.

One could argue, even, that much bottle-conditioned homebrew meets most
of
CAMRA's requirements for Real Ale, which makes us all Real Ale Brewers,
as long
as we aren't using lager yeasts...

Subject: keg pressure, carbonation

I recently filled two kegs with brew and decided to artificially carbonate instead of dealing with more yeast sediment. I tried bubbling the CO2 from the bottom at 15-50 psi, and it still didn't carbonate after a three days. (My pressure guage may be off) Two weeks later the brew is only slightly carbonated, yet I get a monstrous head in the glass. My beer fridge isn't working right now, so everything is room temperature.

Questions:

- 1.Does the beer have to be refridgerated to hold the carbonation.
- 2.Is there something about the C-kegs that gives a giant head upon dispensing robbing the beer of carbonation.
- 3.Has anyone had this problem before, and how did you fix it.

Aaaaaaaarrrrrrrrrrggggggghh!!

Subject: Aging

Some of the brewpubs in Seattle try to condition (age) their ales before kegging (or in some cases before serving). The Big Time Brewery, winner of 3 gold medals at the GABF (and no fluke to be sure), has them in a sub 40f conditioning room in serving tanks. Brewer Ed Tringali makes the batches early enough so that they can be aged somewhat before serving. Sometimes demand pushes the timetable up a bit.

Funny story: a friend of mine supplied A-B with some new brewing kettles some years back; enough kettles to double the output of beer. It was later that he noticed that A-B had not added one lagering tank to their plant. A-B had apparently found ways to speed up the aging to push the beer to the market faster. True story.

Some homebrewers have started to cold condition the secondary fermentations (fermentations) of ales. In a fridge at 40f the wort clears off quickly and the flavors mellow a little bit. For some types of ales this is not recommended because of the flavor profiles necessary. Personally I have enjoyed the ales better this way. Back at 60f the bottles carbonate just fine.

...
> The idea sounds seductively appealing, but I think it's bull. Most --
if
> not all -- of the ten or so brewpubs I've been to have had beer that
tasted
> young...

The matter of aging beer seems to come up once or twice a year in the
HBD.
I've taken--and continue to take--the position that properly-made beer is
at its best as soon as possible after it's finished. For lagers,
naturally,
that doesn't mean a short lagering period is better; it means that
they're
at their best right at the end of lagering. For ales, younger is almost
always better. As soon as an ale has finished fermenting, settled out,
and
is carbonated, it should be ready to drink. There should be no "off"
flavors.

I'll go a little further out on the limb and say that there is no such
thing as a "young" or "raw" taste for beer (unless you choose to equate
"young" and "fresh":-). The tastes which make very young ales
unpalatable,
or the effects which cause them to taste better with some age, are
properly
called "faults" in brewing the beer. There are a few mistakes which will
give a young ale a harsh taste, and which will age out...but that doesn't
mean the aging is necessary; it simply mitigates the mistakes. (I should
know; I've made enough of the mistakes:-) A beer should taste just fine
(except for being a bit flat) at bottling time.

>...In nearby Baltimore, the stuff at Sissons tastes plain *raw*, with a
> watery bitterness typical of a brew that hasn't matured enough...

An unpleasant bitterness (as contrasted with the expected pleasant hop
bitterness) is generally the fault of extracted tannins, which results
from
mishandling whole grain. It will age out.

Saudi Arabia has two types of police, the regular police and the "religious" police. The latter enforce the religious customs such as the ban on alcohol, the ban on pork products or images (people have had their Porky-Pig comic books confiscated during Saudi airport customs checks), and women's public attire (women who show too much leg can expect to having their ankles swatted with sticks). The religious police can enter your house without a warrant if you are suspected of religious crimes. Also, in Saudi courts if you are a foreigner you are automatically guilty (ask anyone who has ever been in a traffic accident there).

On the other hand, Saudi stores sell all the paraphenalia needed to make home-made wine. They have large bottles of Welch's grape juice with special mouths that make in-bottle brewing easy. They also sell yeast. Figure that out.

> (short of bribery, as I am poor) restraint of relaxation.
> Please help!
> Al Taylor

I asked this question a while back and got a variety of responses--they can be summed up as follows:

It is perfectly legal to transport the stuff. You may have trouble carrying it on, but this too is legal if the stuff is sealed--I presume that opening it on a plane could be bad, tho'. One story (Pete Soper I think) gives the moral that decent looking labels may help. Of course, care should be taken in packing etc, but if you carry on you'll have to take it out & show the officials.

I will take the plunge in early March and take some homebrew on a flight to Oregon; if anything odd comes up--I'll share the experience. On a related note, I've heard various rumors about moving liquor and/or beer and wine over state lines being illegal in some areas. Does anyone out there have any real knowledge of this sort of thing?

Marc San Soucie writes:

>there is basically no difference between garden-variety [...] American
>microbrew and garden-variety English Real Ale.

I assume that you mean no difference in the brewing techniques? I.e. that no additives are used, and that the beer is not pasteurised or filtered. As a long standing fan of British 'real ale', I think it tastes quite different to any microbrew or brewpub beer I had here in the US! Apart from the expected differences of style that you find between any two 'real' beers, British real ale has virtually no carbonation (could you even pressurize a wooden cask? Actually metal kegs are quite common for real ale too), and is served at "cellar" temperature (i.e. warm by US standards!) either by a vacuum hand pump or by gravity right from the keg. In contrast, all of the American 'real ales' I've had have been served the traditional US way: cold and carbonated, using CO2 pressured taps. As an aside, IMHO a good test of a beer is to let it warm up to room temp and see how it tastes then. Sierra Nevada and Anchor beers improve this way, while Bud etc become even less drinkable than when their taste is chilled out!

Subject: Care and feeding of pen-style Ph measuring devices

I have one of those pen-like electronic Ph measuring devices. I have been using it for about a year now and am basically very happy with it.

The docs that came with the meter mentioned that keeping the business end wet (with de-ionised water) would prolong the devices life.

I have a few questions that I'd like some help with:

1. What if I don't keep it wet, by how much will the devices life be shortened ?.
2. What techniques do people suggest for keeping it wet between use, assuming I may not brew for a couple of months between uses ? (the protective cap is not a large enough reservoir and it dries out within days).
3. When using, do people just dip it into the mash, or extract liquid only from the tun and then dip into that ?.
4. The supplier of my unit sent me a note recently saying that the manufacturers information for calibration was incomplete, and that I should use distilled water with a known buffer in it to render a Ph of 5.0. I don't understand how calibrating against a known value of 5.0 is any better than a known value of 7.0 (+- .1) - typical distilled water. Any ideas ?.

Hoppy new year to all..

Stan.

>

I've artificially carbonated kegs of beer before by filling the keg
about half full of beer (4 gals in a quarter barrel), adding CO2 to
about 30 psi, and shaking the keg vigorously to get the CO2 to dissolve.
Then I'd repeat this, and relieve the pressure to about 10-15 psi.

Subject: Rinsing bottles

I gave a six pack of homebrew to a friend, and when I got the bottles back, discovered he hadn't rinsed them. So, I decided to take my bottle brush after them. After cleaning the first bottle, I noticed it was much cleaner than other bottles that I had so dutifully rinsed. Upon closer examination, I realized that my bottles all had varying degrees of film on the inside. So yesterday, I modified my bottle brush, put it in the chuck of my drill press, and proceeded to clean four cases of bottles using water, detergent and bleach. They look much better now.

How often will I have to do this? Every time I bottle? Every few batches? Every time I rinse? Now that I'm aware of it, I don't think I'll be happy unless I brush clean them every time.

> expect this?

Absolutely! Husk material will respond to iodine in a manner very similar to starch (especially if your color vision is as distorted as mine), which quite often leads new grain brewers to conclude that starch conversion is not complete, when in fact the problem is that their grain is ground, rather than cracked! Your test would indicate to me that everything's just perfect. Don't change your grind!

Here's how I do it:

- 1) Chill your beer as much as you can. (Obviously not below 32F)
- 2) Turn up your regulator to 30 PSI.
- 3) Lay your keg on its side.
- 4) Shake your keg 200 times. (Sort of rolling it back and forth)

You may need to shake it more times if your beer is warmer or your shake is less vigorous.

The last time I did this I rolled it back and forth 400 times in a nice relaxed manner with the beer chilled to about 40F. It works great. Nice tiny bubbles too.

> 1.Does the beer have to be refrigerated to hold the carbonation.
>

No, just make sure your kegs are sealed good.

> 2.Is there something about the C-kegs that gives a giant head upon dispensing
> robbing the beer of carbonation.
>

No, But your dispensing pressure may be too high. I dispense mine at 5 PSI, and store at 10 PSI. If your dispensing pressure is too high then the beer will be squirted out with loss of vigor and cause a lot of foaming and thus loss of carbonation. Also, before a serving session let free any excess pressure in the tank via the pressure release valve.

> associated with faulty home-brewed alcoholic beverages.
> Methanol poisoning, which can lead to blindness or death, was a
serious
> problem during Prohibition in the 1920s.
>

OK, here we go...

This is 1991, I live on the planet Earth, and Elvis is really dead. It
sounds
like a rough way to go, but methanol?

I just checked with a chemist buddy down at Bend Research. Methanol is
obtained
from pyrolysis of wood at extremely high temperature. The temperature of
boiling water (alcohol) is insufficient to convert ethanol to methanol.
Brewer's yeast does not manufacture methanol. I'm not a chemist, but I
am
a physicist, and I'm inclined to take the chemist's word above that of
the
military.

Sounds to me like typical shithead military propoganda to keep soldiers
from doing that which nature and boredom beckons to.

Oh, and hey: methanol poisoning in the Prohibition years seems likely to
have come from the desperate and direct consumption of methanol-
containing
fluids, not brewed at home.

And finally this note...if soldiers are going blind from something in
Saudi Arabia, it's, ah, well...

From: polstra!norm@uunet.UU.NET (Norm Hardy)
Subject: Real Ale

There is more to Real Ale than meets the tongue, so to speak....

To be an authentic Real Ale, it must be hand pumped from the (preferably) wooden cask; i.e., no CO2. The beer comes to the pub quite young and it is up to the pub to monitor and serve the stuff when best suited. Obviously, the beer changes character as the cask is emptied.

There are a few places in Seattle which offer "Cask Conditioned" ale, that which is served from the steel keg but hand pumped. Believe me, there is a big difference in mouth feel when the beer has its own natural carbonation, albeit light, compared to a CO2 pumped beer. Often it is much easier to drink two such beers; they go down so easy!

Subject: Re: Homebrew Digest #563 Patriotic Duty [R(18)]

All right people, lets get serious. I have just about had it with the way some of you are putting down the situation in Saudi Arabia. Do any of you have any idea what is really going on over there?

First of all, Military regulations forbid the brewing of alcoholic beverages on any installation. Especially one in a host country that prohibits alcohol consumption. The military briefs all its personnel about the host country before they are shipped over seas. If these soldiers are brewing their own stuff, they are going against military regulations as well as the laws of the host country.

Unless you have a military background or are now in the military, I suggest that you get your facts straight before you bring them to the attention of others.

Yes, we are in America, and Elvis is really dead. So just talk to someone who knows the facts and get your stuff straight before you open your mouth.

In the US, you can go to a gun store, buy a high powered rifle with a
scope
& ammunition. And you can buy it with little waiting period or
background
checking. But you can't use it to kill someone. Figure that out.

Just because you can do something, doesn't make it right. Our soldiers
are
guests over there & they should abide by the Saudi laws. I wouldn't
allow
a smoker to smoke in my house. I think the Saudis are showing great
tolerance for our soldiers in thier country...

There seems to be an increasing trend for brewpubs to offer their beers
in
the "Real Ale" cask-conditioned/hand-pumped/cellar-temp style. They can
be found (e.g. Portland's Bridgeport beers, Denver's Wynkoop) and are
remarkably like their British cousin's in mouth feel and quaffability but
probably have a more "US" flavor profile due to the predominant use of
ingredients from this country (Cascade hops, for example.) When
frequenting
these brewpubs - and frequent them we do - I'll order a cask-conditioned
brew more often than not.

Answering based on experience of 12-18 years ago:

> 1. What if I dont keep it wet, by how much will the devices life be
> shortened ?.

The tip of the electrode is a semipermeable material; letting it get completely dry can ruin it permanently, or at least mean you have to soak it for some time before you can get reliable results.

> 2. What techniques do people suggest for keeping it wet between use, assuming

> I may not brew for a couple of months between uses ? (the protective cap

> is not a large enough reservoir and it dries out within days).

In the lab, we usually stretched a material like very heavy, soft plastic wrap over a small container of water and poked the electrode through a small slit in this covering. This is easier when the electrode is clamped to a stand. I'd say sacrifice an old mug---evaporation through tiny slits in multiple layers of wrap should be minimal.

> 4. The supplier of my unit sent me a note recently saying that the
> manufacturers information for callibration was incomplete, and that I should

> use distilled water with a know buffer in it to render a Ph of 5.0. I dont

> understand how callibrating against a known value of 5.0 is any better than a

> known value of 7.0 (+- .1) - typical distilled water. Any ideas ?.

I wouldn't assume that distilled water is reliably as close to neutral as

.1; the problem is that if /anything/ gets in, the pH will change radically.

The pH of 7 at room temperature means that one H₂O in every 1.8e9 is split into

H⁺ and OH⁻. It doesn't take much to shift that balance---are you sure that

sulfur oxides in your air are low enough that the distilled water wouldn't

pick up a couple of parts per billion?

A buffer is a mixture (usually a weak acid and one of its soluble salts

that will absorb significant amounts of acid or base with little net change

in pH; a standard buffer is much more likely to be at the specified pH than

distilled water is. Not sure why they recommend a buffer at 5.0; possibly something about the electrode, possibly because most buffers are

somewhere

acid. If you were being picky (and covering a wider range than is necessary

for beer, which I think runs mostly pH 5-6) you'd get an alkaline buffer and

check somewhere around pH 9-10 as well.

Your chemistry is correct as far as it goes. However, the story didn't say what they'd been "brewing" from. I've heard of desperate people trying to make drinkable alcohol from things as strange as Sterno(TM) and its relatives (cf your comment about sources of methanol during Prohibition). I also wouldn't be surprised if the story said "methanol" because somebody thought that would be simpler than trying to explain fusels, which I think are toxic in larger quantities. (Sure they taste dreadful. If you're seriously bored when you're not thinking about how your leaders are busily trying to get you killed, are you going to care what it tastes like if it means you might not have to be sober?)

This was my understanding. I was told that the poisoning might have
resulted from not letting the first third of the distillation blow off.
You are only to collect the middle third from a "run".

There is some methanol and other higher alcohols produced from standard
fermentation. Perhaps the way they distilled their beer concentrated
these.

>I'll go a little further out on the limb and say that there is no such
>thing as a "young" or "raw" taste for beer (unless you choose to equate
>"young" and "fresh":-).

Good point. However, I can tell you this is *exactly* what I did for
the first couple years of my brewing. When introducing newcomers to
homebrew, I always make the analogy of fresh vs. store bought bread.
They almost always understand this, and enjoy the beer even more. Only
after going back and tasting budmilob did I notice that a certain type
of flavor was missing. I now equate this flavor with "freshness".
This enables me to relax even more than I used to (-:

Subject: frozen homebrew- What to Do?

Several weeks ago we had several days of below freezing temperatures and some of my homebrew, bottled only a week, froze in my refridgerator which was in my garage. Several bottles broke, but the rest froze up. I've since gradually thawed out and is sitting in my basement waiting for a solution as to what to do from the net.

I've tasted the beer and it tastes okay but is poorly carbonated, I mean POORLY. The beer is now aged 4 weeks in the bottle and little to no carbonation.

Did the yeast get killed? Is there any way to recarbonate the beer ? Anything else I can Do?

If it matters, the beer was a lager type malt extract and I was using red star dry lager yeast.

Any suggestions would be greatly appreciated.

Duane Smith

Subject: Some Thoughts on Extract Efficiency

Since this seems to be a popular topic these days, I thought I'd throw my 2 cents into the fire, and make a few conjectures as to what may be going on with poor extraction efficiency.

First, my normal extraction rate is pretty close to 30 SG points/gal/lb with a low of 29.3 and a high of 31.4 over the last 10 batches. I use the 'classic' 2 bucket lauter tun (inner bucket has 1/8 inch holes on 1/4 inch centers, as per TCHoHB), with sparge times running 90 to 110 minutes, depending on grain bed depth (i.e. amount of grain/batch).

I crush my malt rather on the fine side, with the largest bits of endosperm (the starchy white part) being on the order of coarse corn meal, sizewise. No whole or half grains, but lots of large husk pieces.

Now, why can't some people get better extraction rates than the 10-20 points/lb they get now? The lautering equipment is usually very much the same, so where is the loss coming from?

1. Mash too cold. You have to get the mash temp. above 149F to gelatinize the starches so they might be converted. If you are mashing at 150F, you'll want to be sure your thermometer is well calibrated. A few degrees of overshoot on the initial boost to starch conversion may be a good thing.
2. Malt ground too coarsely. This hurts on two fronts. Larger bits of endosperm longer to gelatinize, locking starch away from the enzymes, and not holding the sparge water in contact with the mash long enough to wash out the sugars efficiently. We do have to compromise, since grinding *too* fine introduces problems with set mashes, husk tannins, etc. The ideal malt mill would powder the endosperm, leaving the husk in 2 or 3 large pieces. Ideally, sparging should take *at least* 90 mins with a 2 bucket lauter tun.
3. Not sparging enough water. For a five gallon batch and a relatively thick mash (1.3 - 1.5 qt/lb), You should have to sparge around 5-5.5 gal. If you are sparging so as to collect total runoff of 5 gal., you're probably throwing extract away.

This is all for what it's worth, and I'm sure

some of you will take me to task on as few points,
but hey, it works for me! :-)

From: George Bragg <George_Bragg@carleton.ca>
Subject: pH meters

My understanding of the matter is, the bottom of the electrode is a very thin glass layer, permeable to hydrogen and very few other cations (positive particles, for those who don't know). Inside is a little pool of an acid (hydrochloric?) and reference wires. The pool of acid's concentration of hydrogen ions changes by concentration gradients when placed in substances of varying pH's, and the reference wires pick this concentration change up and register it as a potential difference on the meter, which is interpreted as pH by us who don't know better :-). The tip of the electrode, if not kept wet, will allow the little H⁺ ions in the electrode pass out through the electrode, and the acid will dry up, meaning there is no reference point for the wires.

This, of course, is a simple explanation - I learned it just today in analytical chemistry, and I could be misinterpreting a couple of facts, but it does sound right...

Disclaimer: Do not try this at home. We are trained idiots.

Subject: Rinsing Bottles

Not yet owning a dishwasher, my method for cleaning bottles has stabilized into the following steps:

- (1) Rinse real good after using, drain upside-down.
- (2) Since our present sink (until the wife puts in the smaller one to make room for the dishwasher) is large enough for 52 bottles (12 oz) or 40 bottles (17 oz), I soak the bottles in a bleach bath (2% or so) for a couple of hours. This removes the layers of film that accumulate.
- (3) Upon rinsing with the bottle jet sprayer and hanging on a bottle tree,
I usually go the extra mile and bake the bottles at 300f for 60 minutes.
Cool down takes awhile so I usually do the baking late at night or early in the day. Very few broken bottles, by the way.

Oh, I remove all labels and foil before any of this. A large 10 gallon plastic bucket outside does the job holding the liquid and bottles.

Subject: New reader..and weird problem...

Hi,

I'm a new reader of the mailing list and thought I'd introduce myself.
(I've finally figured out VI!!)
My name's Chuck Morford, I live in Miami (Somebody has to...) and I've
been
brewing for 2 years...Mostly sweet stouts since those are my favorites,
but
I've brewed an occasional lager for my friends...

Someone earlier mentioned a homebrew warehouse in Florida, could you
please
post an address?

Also, I have a strange problem with the last batch I brewed. It was an
American lager, and it had a haze when at room temp, but, when chilled it
was crystal clear. Now, I've had the opposite problem before and I know
how to
cure that. But what can I do about it? The beer tastes fine at room temp
and
at 50 degrees, so I'm pretty sure it's not yeast...Maybe I should just
"Relax".

Subject: Sam Adams the Maltster?

I checked out a book from the library called "Brewed in America" by Stanley Baron, copyright 1962 by Little, Brown, and Company. It is a VERY detailed study of USA brewing from the earliest settlers on.

On page 75 I came across the following that might interest you: "In spite of what most historians have said, however, it appears that [Samuel Adams] was exclusively a maltster and not a brewer. It was a traditional trade in the family."

He was born in 1722, graduated from Harvard in 1740 and made efforts to enter the practice of law. But he tried instead to start his own business with a 1000 pound loan from his father, who owned a malting establishment. Sam loaned half of it to a friend who never repaid. Soon after the "default", Sam joined his father's business.

Sam Adams, Sr. died in 1748, leaving Sam, Jr in charge. The malthouse was gone in 1763 as Sam Adams had by then become an active and dynamic politician.

What is so interesting about all this is the hype that Jim Koch continually throws out in his marketing of the Sam Adams beers. The beers are fine, very good actually; so why the hype? Anyway, inquiring minds want to know.

Subject: Low OG question

I'm a beginning homebrewer, and have been reading the digest for a few months now. I just started my first batch, a porter recipe from a mail order supplier. I'm using a blow-off system. The ingredients were 4 lbs of (liquid) hopped malt extract and 3 lbs of dried malt extract, plus some black patent malt and flaked barley which I put in grain bags and removed from the wort when boiling began.

Anyway, the recipe says that OG should be 1.054 to 1.067. I only measured 1.033 at 84F, which corrects to around 1.040. Any ideas what went wrong? It seems like there should be little variance from the normal numbers - that is, X lbs of malt extract and Y gallons of water should produce an OG of Z - case closed, right? Is it possible that I didn't "stir" the carboy enough after putting the wort in and filling with water, i.e. could the liquid have been dense at the bottom and less so at the top where I sampled? I also checked the hydrometer in 60F water and it reads very close to 1.000. I'm trying not to worry about this....

Subject: less sparge water than is orthodox

In HBD #565, Todd Enders shares some thoughts about sources of low extract:

> 3. Not sparging enough water. For a five
> gallon batch and a relatively thick mash
> (1.3 - 1.5 qt/lb), You should have to sparge
> around 5-5.5 gal. If you are sparging so
> as to collect total runoff of 5 gal.,
> you're probably throwing extract away.

I disagree. Perhaps it's my lauternig system, but I don't use nearly this much water, and my extract rate is very good: 5.5 gal at 1050 from 8 lb. of UK 2-row in my latest batch. Other recent batches have had similar rates of extraction. This works out to be about 34 points/lb., but then UK malt has a higher proportion of starch than US.

(Btw, the pros don't necessarily use this pts./lb. system. It involves the erroneous assumption that the proportion of solids in the wort is a linear function of SG. Not true, but an acceptable assumption within, say, the range of 1030-1060 into which almost all of our brews, other than barley wines, fall. English and Canadian brewermasters, at any rate, seem to use percent wt./wt. of extract - see my posting of last September.)

I use a Bruheat bucket for my mash, and sparge in the same container. The grain (ground fairly fine) lives in a bag with a mesh bottom and impermeable sides. During the sparge I hoist it up so that the bottom of the bag is 4 inches above the bottom of the bucket. There's a spigot about an inch above the bottom of the bucket. Because gunk collects at the bottom of the bucket during the mash, I drain all of the first runnings out and pass them back through. There's about 2 gallons of them. Then I run 2.5 gallons of water at 77C through. Total collected: 4.5 gallons. No doubt I'm leaving a little behind, but at 34 pts./lb., how much can be left?

PS: despite my mania for the metric system, all of theses figures are US gals.

Hoppy sparging,

Rob (bradley@math.nwu.edu)

Subject: Primary fermenter options

Okay, I finally got out, bought a beermaking kit, and my brewpartner and I started our first batch (a bitter ale, using two cans of Cooper's hopped bitter extract). We had a few problems, the most notable of which is that his new stove, which has the new-fangled embedded burners (i.e., you don't see a metal coil, you see a solid cast-iron plate) wouldn't get hot enough to boil 3 gallons of wort; but we got around that eventually, and boiled our wort. If you're considering a new cooktop, watch out for this!

Things seem to be going fine, so I've a few questions I'd like to ask.

First, on primaries. Our kit came with a plastic bucket primary, but Papazian suggests using a glass carboy. His logic (allowing the tannins and other vernicious nasties to blow out the top) makes good sense, and it strikes me as odd that this wouldn't be universally suggested. The obvious question is "is there a good reason to use a plastic bucket for the primary?"

Second, on small batches. It seems to me that brewing small batches could be a handy way to check out wierd brews or minor variations of a single recipe. Does anyone out there do this?

Third, on the law. Papazian, I think, says that homebrew cannot be legally removed from the premises except for a beer-tasting event. Can anyone comment on federal and/or Ohio laws regulating homebrewing of beer?

Subject: Chilled Yeast

In HOMEBREW Digest #565, Duane Smith discussed his frozen brew:

Several weeks ago we had several days of below freezing temperatures and some of my homebrew, bottled only a week, froze in my refridgerator which was in my garage ...

I've tasted the beer and it tastes okay but is poorly carbonated, I mean POORLY. The beer is now aged 4 weeks in the bottle and little to no carbonation.

Did the yeast get killed? Is there any way to recarbonate the beer ? Anything else I can Do?

Wow. It caught you at the worst possible time. I had something similar happen last year, where a blizzard left my beer & I stranded without heat for several sub-freezing days, but as it was still in the fermentor, I just dosed it with fresh yeast & bottled, after it thawed.

The fact that you're not getting any carbonation suggests that the yeast has gone dormant, and probably flocculated out. It may or may not return from the dormancy. If I were in your position, what I'd probably do is:

- 1) Slowly bring the beer up to room temperature. After a couple of days of that, invert each bottle several times to rouse the yeast. Leave it for another week, then open a bottle to see if anything's happening. If not, ...
- 2) Open 'em all, and gently decant to a sanitized vessel. Pitch new yeast, and rebottle.

Needless to say, the second course is a last resort. Unless it were pretty damn good beer, I'd probably save it for the slugs before I'd go to that much trouble.

That must have been the same freeze that destroyed my water system and wort chiller. No fun at all.

From: meyer@tcville.hac.com (Mike Meyer)
Subject: Re: Low OG question

In HBD #565, Randy Pals asks about a batch of porter he is fermenting with a blow-off on the primary. He is getting lower-than-expected OG, and wants to know:

>Is it possible that
>I didn't "stir" the carboy enough after putting the wort in and
>filling with water, i.e. could the liquid have been dense at the bottom
>and less so at the top where I sampled?

I've had this same problem with measuring OG when using a closed primary. There seems to be a lot of stratification between the cold water you put in the primary to prevent thermal shock, and the hot or warm wort, and it is very difficult to mix the layers once you are in the carboy, as you can't fit a spoon in to stir, and there isn't enough headroom to effectively shake. For this reason, I've stopped using the blow-off altogether, mainly because I have yet to discern even the slightest difference in final beer quality anyway.

One note: I haven't tried this since my brewing partner bought a wort chiller, which I suspect would solve the problem handily. Curiously, I have had no oxidation problems in the beers I did with a closed fermentation, and I didn't siphon the hot wort into the carboy.

My suggestions to you, Randy are to

- 1) Don't worry. Your suspicion is correct about the densities not being mixed properly.
- 2) Try cooling your wort more before adding to the carboy.
- 3) It looks like you added the wort first, and topped off with water. Try putting in water first, adding some wort, mixing thoroughly, adding more water and wort, mixing again, etc. Better yet, mix some of the wort and water before adding to the carboy.
- 4) Have a vigorous yeast starter ready (at least 2 packets of dry yeast pre-started for at least a few hours in some wort). You will be exposing your wort to a lot of air by doing all of this mixing and shaking, so you want a quick start on fermentation.

Hope this helps,

Mike Meyer meyer@tcville.HAC.COM

Hi. My name is James Dryfoos and I live in Durham North Carolina.
I joined to list recently and up to now have just observerd. From the
content of the digest I feel like a beginner -- although I have made
simple homebrew for several years.

I am curious about feedback on the above topic of rinsing bottles.
I find this the worst part of the whole process.
I normally clean gunk out of bottles right away so later all I need is
really
to sterilize. I use the above method of soaking in a bleach solution.
This and the process of then rinsing is a drag (I also use a bottle
washer).
Are there better ways? Is baking the bottles necessary? I have not
heard this before. I feel like since I use bleach I need to
painstakingly
rinse the bottles. Is something like bbrite a better alternative?

Any advice would help. What about this bottle tree thing? I usually just shake out the bottle. It is usually still wet when I fill it with my primo brew. Oh yea, is using a dishwasher sufficient? What should be used as detergent if so?

Thanks. Jim Dryfoos :-)

Subject: Specific Gravity Measurement Errors

A comment to those people concerned about low extraction efficiencies:
As an extract-adjunct brewer, I don't usually have to concern myself with good sparging technique and the like. Recently I brewed my first attempt at a barleywine and learned a lesson about the measurement of specific gravity.

I formulated a recipe that should have given an initial gravity of about 1.080. Just before pitching the yeast I siphoned a sample and measure a gravity of only 1.060! I took some more samples with the same result, and double-checked my calculations. I pitched the yeast and puzzled about it for a few days.

I spoke with Jeff Casey about my experience and he suggested that there might be a density gradient in the wort, with heavier readings at the bottom. I went home and took samples from the top and bottom of the fermentation vessel. The readings differed by more than 20 points. The average was less than 1.040, so there is indeed a significant gradient. (My initial samples were taken from near the center of the primary, after a settling and cooling period of 2 hours.) The gradient effect is almost certainly more pronounced in a high-gravity wort like barleywine, but it is clearly a factor even in dilute liquor if one wants to make measurements with an accuracy of 2 or 3 points. A good stirring prior to sampling will reduce the gradient error. I will now take my initial samples immediate after aerating the wort.

Between temperature corrections, density gradients, errors in the calibration of the instrument, and errors in reading the instrument, I suspect that it is difficult to measure specific gravity with an absolute accuracy of better than plus or minus 2 or 3 points. Relative measurements (such as the difference between starting and finishing gravities) will be more accurate, but I wouldn't be concerned about differences of 5 points when comparing with someone else's results.

Subject: Mead + bees

Just brewed my first batch of mead (Barkshack gingermead) yesterday (Sun.
) ,
and racked and pitched this morning. Beautifully clear and sparkling.
Something happened, however that struck me as rather odd. While I was
boiling
the honey, my house was attacked by bees! Found several in my garage,
got them
out, closed it up, went inside, and found several more there! Had to do
'em in.
They were coming in the vent for the fan above the stove. Turned on the
fan
and had no more problems. This really struck me as odd that the bees
would be
so attracted to the smell of boiling honey. Used six pounds of Cucamonga
and
about four pounds of homemade. Oh well, learn something every batch, I
guess.

Subject: Any Grain Growers out there?

So with all this talk about growing hops, I was wondering if anyone out there has tried to grow and use there own grain? I started the hop thing last year and I was highly pleased with the results. This spring I hope to extend my scratch brewing urges by growing enough grain for a single batch.

I have somewhat successfully malted barley but I believe that I started with a bad choice of barley for beer. Everything generally worked but the taste was a lot stronger then I had hoped. Unfortunately I will be using barley seed from the same source and I fear that I might get similar results should I actually succeed in having it grow.

So.... Has anybody tried this successfully? Does anybody have any ideas on what I might do to reduce errors? Finally, does anybody know of a better source for barley then my source (local feed store supplys me now - the barley is actually meant for birds and livestock to eat).

Thanks for any help.

Subject: yeast vs. yeast

I cultured some yeast (Wyeast German Ale) from an early batch. The culturing seemed to go well, nice krausen, etc. (LOTS of yeast nutrient seemed to be the trick). Anyway, I pitched this into a fresh batch and waited. Nothing. After 24 hours I pitched in some dry yeast, which caught within 6 hours and is doing just fine.

So, what happened to the first batch of yeast? The only thing I can think of is that I shocked it (I spaced out and tossed it in when the wort was about 60 degF. The yeast was sitting at closer to 70 degF). If there's still some of the original yeast alive, what happens to those creatures when another strain starts up? Does the first strain get killed off, or can they both keep going?

The reason I'm wondering is that the ferment is taking longer than what usually happens with this (more or less) standard batch.

From: Dan Needham <dann@hpsadlb.hp.com>
Subject: Re: Yard Glass usage/etiquette
Full-Name: Dan Needham

The yard-long glasses that I have used had a long tapered part and a round reservoir at the bottom. While drinking you must rotate the glass around its major axis when you get to the fluid in the bulbous reservoir or the beer in the bulb will come rushing into your face. You essentially use centrifugal force to overcome gravity. This prevents the contents of the reservoir emptying at once after air starts entering the bulb.

Be aware that these glasses hold about three beers!

Subject: Same 'ol things

Howdy again!

After messing with losing my account at the end of another school year, I set up my own news and email feed at my house. I'll never miss another HBD! ;)

I have a request for information from a few other folks on a local Homebrew Echo out here in San Diego on Fidonet. If any *KIND* soul out there could email me some mail order houses that are *RELIABLE* and have good merchandise, I would be eternally grateful.

Those of you in the San Diego area who attend the QUAFF meetings... I have a nice Oatmeal Stout that may be ready for the meeting on Wednesday.

For those of you who aren't...has anyone considered a "beer exchange" via the net? It costs a few bucks to send a beer across the globe. I wouldn't mind trading with someone...might lend a bit of excitement to the trip to the 'ol mailbox. "Look Honey! It's not a VISA BILL...it's a bottle of homebrew!" ;) ;) ;)

From: Todd Enders - WD0BCI <enders@plains.NoDak.edu>
Subject: Recipe: Scotch Ale

This is the first try at formulating my own recipe. It turned out quite nice, malty with just a touch of hops. If you want a change from highly hopped brews, but still want something substantial, you might want to try this. But be forewarned, you may not be able to drink just one! :-)

My Own Scotch Ale (5 US gal.)

6# Klages 2-row Malt
1# Munich Malt(10L)
1# Dextrine (Cara-pils) malt
8oz. Crystal Malt (80L)
4oz. Black Patent Malt
1C Dark Molasses
.75oz. 6.2% alpha East Kent Goldings
Wyeast #1028 London Ale yeast
2/3C Corn sugar (priming)

Mash in: 2 gal. water @ 138F
Mash pH: 5.2 (adjust with Calcium Carbonate)
Protein rest: 30 mins @ 131F
Conversion rest: 30 mins @ 158F
Mash out: 5 mins @ 168F

Sparge: 5 gal. water @ 165F

Boil: 90 mins
Hops: 1 addition, 30 mins from end of boil

OG: 1.055
FG: 1.015

Pitched 12/24/90. Racked to secondary: 12/26/90. Bottled 12/31/90.

This has to be one of the smoothest batches I ever brewed. It is really smooth even after only 2 weeks in the bottle. The rather intense malt flavor and low hopping rate make this a refreshing change of pace from my steady production of IPA's.

Subject: Extract Barleywine recipie

I heard a call for extract-based barleywine. I made a batch of this about a year ago. It was so good that I've got two batches of it running in tandem. I'm really pleased with it, it's got a nice balanced flavor.

Boil for 1 hour:

12 lb Fermentatin Settlement bulk light malt extract
.5 lb honey
1 lb British Dry light malt extract
1.5 lb corn sugar
2 oz Chinook hops (13.2% alpha)
2 oz Cascade hops (5.5% alpha)

In last 30 minutes add 2 t Irish moss

Boil for another 30 minutes:

2 oz fuggles
2 t sparkeloid

Pitch *Champagne* yeast when cool.

I bottled after 7 months and it was *wonderful.*

Byron Burch's recipe from "Brewing Quality Beers":

For 5 gals.:
8 # light DME
3 # crystal malt
1.5 # Munich malt
1.5 oz. chocolate malt
8 oz. 100% dextrin powder
2 oz. Eroica (boiling hops) (22 AAU)
3 oz. Cascade (dry hop)

Charlie Papazian's recipe (from TCJOHB tables):

for 5 gals.:
8 to 10 # light DME
1 # crystal malt
3 to 4 oz. Fuggles (boiling hops) (15 to 20 AAU)
0.5 oz. Fuggles (dry hop)

My current attempt:

For *>>> 2 <<<* gallons:
5 # Alexander's pale malt extract syrup (=0.5 gal. of the stuff)
1 # crystal malt, steeped and twice sparged
11 AAU Nugget hops (boiling)
0.5 oz. Cluster (finishing hops)
0.5 oz. Cluster (dry hop)

Subject: Another New Hampshire Homebrew Club initiative

Hi -

Here is another initiative to start a Homebrew Club in NH. Anyone within striking distance is welcome to apply. Please send the attached form to John at the enclosed address. John started with the Zymurgy distribution list for NH. He doesn't have net access, so I am posting this for him.

Thanks, and sorry for the bandwidth if you are too far away to care.

Cheers...Gary

ATTENTION HOMEBREWERS!

The winter issue of Zymurgy magazine features a brief article concerning the 1991 A.H.A. Convention to be held in Manchester, N.H. Shouldn't our state be represented by at least one homebrew club? If you are willing to spare just a few hours each month, we can make this happen. I know that this can be a sacrifice, after all in a few hours you could make or bottle a batch of your finest homebrew!

Anyone that is interested is invited to an open "Brew" house. It will be held on Saturday, February 16, 1991. It will be held from 1:00 to 5:00 p.m. (In case of a snowstorm, it will be held on Sunday, February 17, 1991. Call if there is any doubt.) Please bring along a few of your favorite beers, and start thinking about an appropriate club name.

Please find enclosed an information/response sheet for you to fill out and return A.S.A.P. If you need extra copies to hand out to homebrewers that you know that do not subscribe to Zymurgy, feel free to photocopy what you need!

I know that some of you may have to come from far away, but please make every effort to come --- or at least respond. Let's try to make this a terrific homebrew club --- something that we can all share and enjoy as well as be proud of.

Thank you for your time.

From: Ken Schriner <KS06054@UAFSYSB.UARK.EDU>
Subject: Ancient brew needs help

The easiest remedy to a flat beer in the keg: Boost the CO2 pressure for several days, thereby forcing the beer to carbonate. Normally, after I keg a beer (any beer), I raise the CO2 pressure to about 20 lbs for one week. Then I lower the pressure to serving level. I usually lower the pressure by turning down the regulator and removing homebrew from the keg.

(A nasty job, but someone has to do it :-)

For my setup, serving pressure is about 8 lbs. Of course, everyone's serving pressure will vary depending on liquid tube size, length of liquid tube, height difference between keg and tap, temperature, beer type, head size preference, etc.

Using CO2 from the bottle for carbonation instead of priming when kegging is the easiest way I have found to carbonate beer. It is also the most repeatable for me (probably because its the easiest.)

Subject: micro in MO, Boulevard Brewing Company

I had the pleasure of touring the facilities at Boulevard Brewing Company over Christmas 1989. I gleaned the following from the tour.

Boulevard Brewing Company
PO Box 414881
2501 Southwest Blvd.
Kansas City, MO 64108
(816) 474-7095

The Brewmaster is John McDonald. John has spent much time in Europe researching beers and brewing. He has done a fair amount of apprentice brewing there also. His intention is to bring back the type of traditional style beers brewed in KC before Prohibition. At the time he produced only Boulevard Pale Ale, but had plans to produce a Wheat Ale and Bull-E-Porter during 1990.

Boulevard Pale Ale is a medium bodied, light amber colored ale. The fresh flavor characteristics are produced from blending two-row pale malt with a small amount of roasted carmel malt to give it its rich color. The sweetness of the malt blend is nicely balanced with a Cluster hop used for bittering and Cascade hops used for aromatic qualities.

At the time they were capable of producing 2,000 bbl per year. They only had a keggling line and ale was available in 1/2 and 1/4 bbl kegs. I drank it first at a Mexican restaurant named Ponads or Ponachs or something like that. The restuarant was also located on Southwest Blvd (The Boulevard to Kansas Citians.) At the time, Pale Ale was not available in bottles.

The Brewery is a 12,000 square foot warehouse on the Boulevard. Equipment at the brewery includes a 35 bbl, 50 year old copper brew kettle imported from a family brewery in Germany. New stainless steel fermenting tanks were fabricated in Missouri.

John McDonald was a most gracious host for our tour. They have a tasting room very nicely done in oak. Windows overlook the brewery floor. We were treated to as much Pale Ale as I could handle. I got to steam up my glasses over a mass of Pale Ale wort in copper brew kettle. Even got to stir the wort and bung a keg. Great fun.

By the way, they have great t-shirts.

Subject: Beer for the Slugs

I'd like to suggest an alternative use for undrinkable beer. I like to try obscure beers that my local liquor store gets occasionally, but some of them have been real losers. I also use this method of disposal for bottles of Old Style Light and Falstaff that appear in my refrigerator during parties. I boil bratwurst in them! A little malt flavor, a little hop flavor... not bad. Also, I certainly don't like bratwurst enough to sacrifice a Liberty Ale or Twickenham Bitter (mine).

Subject: Re: bottle washing

Jim Dryfoos writes:

>I normally clean gunk out of bottles right away so later all I need is
really
>to sterilize.

This is the most important thing you can do to make bottling easier.

>Is baking the bottles necessary?

No.

>I feel like since I use bleach I need to painstakingly
>rinse the bottles.

When I used to bottle, I used to soak in bleach solution (1 or 2 tblspns
per gallon of water) and then run hot tap water (160F) through the
bottle via my Jet Bottle Washer for about 10 seconds. Some brewers
don't even rinse out the bleach solution.

>What about this bottle tree thing?

A bottle tree is like an artificial X-mas tree without the needles.

>Oh yea, is using a dishwasher sufficient?

Some have a "sanitize" cycle -- I've never used one but some brewers
say it works. Cleaning out the bottles immediately after use is very
important if you use a dishwasher. One brewer had posted an article
where he put some flower or something in a few test bottles to see
if the dishwasher really cleaned them. I don't recall his results,
but every dishwasher is different, so you would have to try the test
yourself anyway.

>What should be used as detergent if so?

DON'T use detergent. A soap film of any kind will kill your head
(well, your beer's head anyway). In fact, when I go to bars, I
insist they reuse my glass so that the first beer washes most of the
soap film out and the rest of the beers have a much more stable head.

As I've already said, I no longer bottle -- I've found that keggling,
in the long run, is about half the effort (partly from the lack of bottle
washing effort and partly from not needing to decant the beer anymore).

Al.

Here's mine, the best beer I've ever brewed (and getting better by the year!)

Marigold Ale:

10 lbs Munton&Fisson Light un-hopped extract
2 lbs marigold honey
4 Oz. Fuggle leaf boil
1 Oz. Cascade pellets finish
Munton&Fisson Ale yeast
champagne yeast (I used red-star 8-)

(It may not seem like enough hops at first glance, but it is...)
Pitch ale yeast first, then after activity has subsided, pitch
champagne yeast. Rack after clearing and let stand a LONG TIME in
secondary - this will continue developing a long time, so you don't
want to bottle too early and get over-carbonated. After bottling, wait
A LONG TIME (> year).

Watch out, you can get addicted to barley wine!

wa

From: Pete Soper <soper@maxzilla.encore.com>
Subject: baking bottles

I've been using my oven to sterilize my bottles for a few years. Digest old timers may recall that when this came up, Dick Dunn suggested that this could be hazardous since the uneven heating could weaken the bottles and cause them to fail when put under the pressure of carbonation. I decided to keep quiet about this until I had collected some data. I guess around two thousand bottle's worth is enough to report on this with confidence.

First, Dick is 100% right, that in some cases the bottles will be permanently weakened; depending upon the amount of headspace in the bottles, this could pose one heck of a health hazard. However the good news is that this weakening does not happen if the oven is started out at a low temperature and then ramped up a little at a time and the maximum temperature is kept moderate. I start at 160 and go up one wee skoshin ever few minutes, getting to 275-300 after maybe an hour. Based on what I've read it takes quite a while at this temperature to get guaranteed sterilization. I usually hold around 275 for a couple hours and then turn the oven off, letting it cool for 24 hours prior to bottling; I believe that trying to "force" the cooling of the bottles would be very risky.

I forgot a batch of bottles were in my oven once, got hungry the next day and prepared to cook a pizza. Let's see "preheat oven to 450". OK, oven preheated, open oven door: Darn if there aren't 50 very hot bottles in there. Over half of those bottles failed during the two weeks after bottling and all the rest were discarded to avoid the risk of more failures. I was careful to minimize the headspace and so when the bottles broke they did so with no "explosion" whatsoever; they just typically cracked with a "clink" and drained.

With a couple inches of headspace there would have been more drama.

But aside from this adventure with stupidity I haven't had a bottle failure recently; I'm 100% certain no bottles have broken in the past 18 months. I use the same pool of bottles over and over and some are pretty light weight, but I'm now quite satisfied that using my oven carefully is a way to avoid having to soak the bottles in sterilant.

Having said this, I believe that bottles must be *absolutely clean* prior to any sanitizing or sterilizing operation. The bottom line for me is making all the bottles of a batch of homebrew consistent. Careful mixing of priming sugar

or extract is about the other 70% of consistency, IMHO. Thinking about
the
discussion of stratification of wort, keep in mind that just pouring your
priming sugar on to top of the new beer and then bottling *doesn't make
it* and
will result in terrible variations in carbonation levels.

> ...While I was boiling
> the honey, my house was attacked by bees!...
> ...This really struck me as odd that the bees would be
> so attracted to the smell of boiling honey...

Not odd at all. The bees were seriously offended by your mistreatment of their elaborate, extensive efforts at creating a wondrous foodstuff (and meadstuff:-). They sent emissaries to attempt to inform you of the error of your ways.

DON'T BOIL HONEY!

It isn't necessary, and it damages the flavor.

Just heat it gently to sterilize. In fact, for typical mead proportions, you can boil the water (and any other ingredients you might need which actually require a boil, if any), turn off the heat, and add the honey. The temperature will remain high enough to kill off the baddies without hurting the honey.

Subject: Re: Primary fermenter options

>From: Bill Thacker <hplabs!hp-1sd.cos.hp.com!cbema!wbt>

>First, on primaries. Our kit came with a plastic bucket
>primary, but Papazian suggests using a glass carboy. His logic
>(allowing the tannins and other vernicious nasties to blow out
>the top) makes good sense, and it strikes me as odd that this
>wouldn't be universally suggested. The obvious question is "is
>there a good reason to use a plastic bucket for the primary ?"

Well, food-grade plastic buckets are cheap and plentiful. Glass carboys are more expensive, less plentiful, and subject to breaking from being dropped, banged against something, or even temperature shock. Plus, they are harder to carry when full of beer. Also, since you can reach into a plastic bucket, it is easier to stir in yeast or priming fluid, take samples, clean, etc.

OTOH, plastic scratches easily, leaving places for bacteria to grow (note that the sanitizing solution won't get in there to kill them). So you may need to change plastic buckets more often.

Most people I know that use a glass primary use a 6 1/2 or 7 gallon primary and don't use the blowoff method. The majority opinion seems to be that blowoff doesn't really reduce the bitterness of your beer and is capable of causing explosions should the blowoff tube become clogged.

I switched from plastic to glass after the first year. I think glass is better, but still miss the ability to take samples by simply dipping in a sanitized measuring tube. I do use a plastic bucket for mixing in the priming liquid before bottling.

>Second, on small batches. It seems to me that brewing small
>batches could be a handy way to check out wierd brews or minor
>variations of a single recipe. Does anyone out there do this ?

It makes a lot of sense. However, I am so lazy that I figure I might as well make 5 gallons each time, getting more beer that way if it turns out good. Also, if you use a secondary fermenter, it helps to have it full to the top to avoid contact with too much air and the resulting oxidation. Still, I have seriously considered buying a 3 gallon glass carboy for the very purpose of making small batches (or maybe two for splitting a 6 gallon batch and testing different yeasts or somesuch).

>Third, on the law. Papazian, I think, says that homebrew cannot
>be legally removed from the premises except for a beer-tasting
>event. Can anyone comment on federal and/or Ohio laws
>regulating homebrewing of beer ?

I can't comment knowledgably on Ohio laws. However, having read the federal laws on homebrewing, there is nothing in there restricting transportation of your homebrew. I know in Virginia that there are laws restricting the amount of alcohol you can legally transmit across state lines (primarily designed to limit people going to cheaper neighboring states and stocking up). We

can legally take our homebrew anywhere we want that doesn't
restrict the presence of alcoholic beverages.

>From: DRYFO001%DUKEMC.BITNET@ncsuvm.ncsu.edu

>I am curious about feedback on the above topic of rinsing
>bottles. I find this the worst part of the whole process.

>Oh yea, is using a dishwasher sufficient? What should
>be used as detergent if so?

I find it sufficient to sanitize my bottles using the
dishwasher. I set it to rinse and heat dry (skip the wash
cycle). The steam from the heat dry should sanitize all the
bottles.

I also try to keep all bottles clean by rinsing after use and
occasionally tossing them into the dishwasher with other dishes.
You want to be careful not to leave any soap residue on your
bottles, though.

I too think that rinsing is a pain. That's why I don't do it. I
just rinse after use, soak in something like 3 tbsp bleach / 6 gal
water for a half hour, drain the bottles and put them back in the
case. Then, I put paper towels in the lid of the case (over the tops
of the bottles) and invert the case overnight. I have now done
this for at least 5 batches and have not had any carbonation
problems or infections. It is really a quite painless process,
but certainly not as thorough as you could be if you wanted to
be.

Subject: Bottle Rinsing, Quite Yeast

I have noticed some concerns about bottle cleaning and yeast that does not really get going. I thought I would contribute some clinical evidence.

Bottle Washing
=====

I have brewed about eight extract batches in my brewing career and I have yet to produce a spoiled bottle. I rinse the bottles after I pour myself a cool, refreshing, homebrew and put them in the dish drainer upside down. This keeps mold nuggets from forming in the bottom.

10 minutes before I bottle I thoroughly rinse the bottles with a bottle washer using the hottest water I can come up with. I then stick them on a bottle dryer I made out of a 2x4 and 1/4" dowels. (The bottle dryer gets sponged off with a bleach solution before the bottle washing.)

This bottle cleaning procedure is apparently completely sufficient. Like I said, out of about 450 bottles produced I have yet to get a bad one. Make your homebrewing as easy as possible.

Slow Starting Yeast
=====

At the moment, I am fermenting my first batch that uses liquid yeast. Apparently liquid yeast is not as robust as the dried stuff. This batch took *much* longer to get going than *any* of the dried yeast batches. I brewed on a Wednesday night (late), pitched at Thursday lunch, and it was not until Saturday night that it really started to bubble. The dried yeast batches usually got going in less than 24 hours.

I am in the secondary fermenter now. All looks good. All is right.

Subject: feed barley

In HBD 566 Jeff Miller mentions that he malted his own barley, and was unhappy with the results, and goes on to say that he purchased his barley from a feed store. Well, there's the problem right there. If you watch the ag. commodities reports on the news, you'll notice that they quote separate prices for feed barley and malting barley, and the price is substantially lower for feed barley. The difference between the two is that by definition, feed barley is anything which isn't quite good enough to be used as malting barley. For example, if a farmer is out combining his malting barley and is suddenly hit by a major rainstorm, he suddenly has a crop of feed barley.

If you want to find a better class of grain, don't go to the feed store. Try your local grain elevator around August or September. Of course, that's no problem here in the Land of the Amber Waves of Grain (North Dakota, in my case) but it may be more complicated in other parts of the country.

From: durbin%cuavax.dnet@netcon.cua.edu
Subject: brew on planes, bacteria infections

I just got back from Germany with my case of fresh German beer, half Schneider Weiss(hefe-weizen) and half Andechs doppelbock. Originally I packed the case up real good in a baax and was going to check it in, but when I went they asked about it and I told them what was in it and they said no way(no glass, cans are okay). So I had a back up plan and put the bottles in my carry on bag, gave the plastic case to my dad and checked in my carry on stuff. Other than that no problems or hassles. So you shouldn't have any trouble on domestic flights as long as you carry on your brew. Also I noticed that German weizen beer bought in the states doesn't taste as good as in Germany, I think mainly because its not as fresh. The head on american bought weizen dissipates more quickly after pouring. Speaking of weizen beers, the bavarian dialect for weizen is weiss, so weiss beer in Bavaria is different than elsewhere in Germany,

thus causing a bit of confusion to visitors who like weizen beer.

I bottled the week before I left, and came home to a couple of cases of homebrew. One bottle I opened gushed foam(not like a real gusher) when I opened it, but all the others I've drunk have been ok. I was thinking that

bottle might have had a bacterial infection, any ideas?

> effectively shake.

Here is an easy solution to your problems:

Take a sterile turkey baster, stick it in the hole of your carboy, suck up some beer, and then squirt it back in with some vigor, then repeat many times. This will accomplish several things: 1) It will mix up your different 'layers' of beer; 2) It will create an even temperature through out the carboy; 3) It will aerate your beer; 4) It will allow you to easily extract some beer for your hydrometer readings; 5) It will allow you to mix in your yeast rather than letting it all settle on the bottom.

This is what I do, It works great! But remember to leave enough head space for the foam you produce, otherwise it oozes over the sides. My baster is a cheap one and squirts a little beer out of the sides every time I squeeze it. So this is the messiest part of my brewing processes, but it gives me an excuse to wash the kitchen floor. (Albeit with beer :-)

Happy squirting,

Subject: The Wholesale Homebrew Club

I should have just posted this info here in the first place:

The Wholesale Homebrew Club
5760 Bird Road
Miami, FL 33155

(305) 667-4266

Here are a few prices, all are typical, both in size and price.

- 1) M & F Malt Syrup 6-3.3 lb. cans-Unhopped \$29.84
Hopped \$32.49
- 2) M & F Dry Malt 55 lb. barrel -Unhopped \$89.64
Hopped \$94.30
- 3) Hop Pellets by the pound \$ 5.25
- 4) Leaf Hops by the pound \$ 5.25
- 5) Specialty Malts-5 lb.\$ 4.10
- 6) Corn Sugar-50 lb. \$20.13
- 7) Crown Caps-printed overruns-70 gross!! \$32.78
- 8) Wyeast liquid culture-six pack \$15.90

All prices don't include postage, but is very reasonable, considering the size of these orders. Membership fee is \$25, minimum order is \$100. Great idea for clubs. Remember, if you live in the Washington, D.C. area, call me before you sign up, I want to share this thing (i.e., I want to defer part of the cost of the membership!)

By the way, I would like to see more recipes, or just ideas about recipes, posted on the newsletter. If you all are nice, I'll tell you my recipe for Cranberry Beer (actually, I'll post it anyway soon). Pucker up!

Subject: More questions about Barley sources

First, many thanks for all of you that had info regarding my barley experi-
ments. Now on to another question.

I believe my previous results were indeed related to feed grain versus malting barley were correct. From Kevin Vang's response I got the impression that perhaps this feed grain might make an ok source to grow new grain that might actually be of malting quality. Is this correct?

I have also been getting the pre-requisite mail order planting guides that come out this time of year and noticed that the Burgess catalog sells seed quality barley. Anybody got any ideas on what I might get if I plant some of this? Anybody got any ideas on how much to plant for a minimum of 5 gallons of beer? I already ordered 2# and I hope to plant in a 6' square area.

I know this may be lots of work but I just can't get past the notion of trying to brew a beer entirely from scratch. Maybe I have latent tendencies to blow up my tv, move to the country, and find homebrew on my own!

> (well, your beer's head anyway). In fact, when I go to bars, I
> insist they reuse my glass so that the first beer washes most of the
> soap film out and the rest of the beers have a much more stable head.

As I recall, the individual that tested a dishwasher's cleaning ability
used
ketchup as his test goo. The dishwasher worked well to remove the gunk.

I've been washing my bottles in the dishwasher for over a year now --
about 10
or 12 batches. I just rinse the bottles as I empty them, and run them
through
with the rest of our dishes, detergent and all. Once or twice I tried
sending
the bottles through a second time, without detergent, right before
bottling. I
didn't see any difference in the head retention of the final product, so
I
conclude that at least my dishwasher rinses the detergent out very
effectively. Dishwasher soap is formulated to rinse easily, so that makes
some
sense. For the truly curious, we use whatever dishwasher detergent is on
sale,
and we have a real fancy Kenmore dishwasher, with more buttons than a
747.

Subject: Malt Extract

Ok, I'm relaxing and not worrying. I think it's great fun to make variations in recipes and then see what results. But I would also like to try a couple of the recipes in TCJOHB without making too many changes. The local homebrew supply shop (actually it's about 1/2 aisle in a local natural food co-op) carries little variety in malt extract. My question is: what major differences exist in syrups? If Papazian calls for hopped John Bull Dark in his recipe, would I be making a big change by using hopped M&F Dark instead? I know I can just try it and see, but I really want to try to brew a couple of these recipes as accurately as possible. So if any of you extract brewers know of switches that should not be made, or maybe which syrups are the most similar, I'd really appreciate that information.
Thanks,

Chris Shenton writes:

>I was intrigued by the initial argument that the only reason to age beer
>was to cover up some defects in the beer -- made some sense. But then
how
>does that justify the German lagering tradition?

Lagering is not the aging of completed beer. Lagering is the
FERMENTATION.

When the fermentation takes place at higher temperatures (60, 65, 70F...
) ,
the yeast produce more by-products (besides CO2 and alcohol) such as
esters. Conversely at lower temperatures (50, 45, 40F...), the yeast
produces less of these by-products. You'll notice the difference between
lagers and ales is generally in the fruitiness of the ales. Compare two
mass-produced beers such as Hacker-Pschorr Lager and Bass Ale. Or if
you like your beer on the hoppy side, compare Samuel Adams Boston Lager
and Anchor Liberty Ale. Getting back to underaged beer, I have to agree
that aging helps soften "mistakes" like excessive tannins. Brewing
beer (I am told) consists of over 200 chemical reactions, many of which
continue well after the beer is bottled (if it is not pasteurized and
filtered) or kegged. If you are ever in Chicago, stop by Goose Island
Brewpub. I just got off the phone with their brewmaster (so I could
get my facts straight) and we discussed this very issue. He claims
that 95% of his customers cannot identify an additional 1 or 2 weeks of
aging. He agrees with the concept that, if the beer is properly made,
it does not need as much aging as if it: 1) was not mashed properly,
2) boiled long enough (to drive off DMS and other certain nasties), or
3) was made with bad water or crummy ingredients. Now some facts.
Goose Island serves their ales after 14 days. They like to wait 4 weeks
to serve their lagers, but during the busy season, it ends up being
23 days. The two batches of dopplebock that they made this year were
both served only after 5 weeks. He said they counteract the shortened
aging of lagers during the busy season by making their Specialty Beers
(not their regular four) ales. This reduces demand for the lagers and
gives them more cooperage for lagering. IMHO, Goose Island beers are
excellent! I don't consider their "aging" times very long yet the
quality of their beers is apparent. I wish that I could consistently
ber beer as good as theirs. (I'd like to add that I have no affiliation
with Goose Island Brewing other than being a satisfied customer.)

Oh, yes. One more interesting bit of data. Goose Island's brewmaster
mentioned a "green apple" flavor that he claims you can taste when
the beer is not aged enough. I have yet to taste such a flavor, maybe
it is dependent on his yeast (they do their own culturing). Maybe
some of you have tasted this kind of flavor in a young beer that
aged out.

Al.

I expect that this, rather than ramping up the sterilizing temperature,
is the key. All of the Swedish glass-blowing plants I visited last summer had a
"lehr"---an annealing oven-with-conveyor-belt in which the glass was
cooled from ~500 (C? F?) to around room temperature over ~24 hours. Glass is
probably not quite as subject to cooling stresses as stone (since it's a
supercooled fluid rather than a rigid crystal) but many varieties will shatter
outright if cooled too quickly (e.g., oven-hot glass dumped in cold water), so it
wouldn't be surprising to find weaknesses in any type that's been
thermally mistreated.

The people at Sam Adams's Boston brewery (they definitely still have some
of their brewing farmed elsewhere) recently produced a "cranberry lambic"; I
wouldn't swear it's worth a trip up from NYC, but it's definitely
interesting; you can find it on tap at the Sunset if you come to Boston.

From: cjh@vallance.HQ.Ileaf.COM (Chip Hitchcock)
Subject: freshness of beer

wrt Chris Shenton, Andy Wilcox, et al.):

The attitude that all beers should be just right just after carbonation is questionable. At the very least, consider barley "wines" in relation to grape wines; almost no fermented grape juice is good immediately, and some varieties continue to improve for not just years but decades. Recent reviews have noted the 1988 Thomas Hardy Dorset Ale and this year's holiday ale from Geary as being particularly likely to improve with age.

Freshness can be an asset, but there are some things which just can't be ready immediately. Remember, we're not laboratory chemists, working with exact quantities of exactly known substances; we mash or stew grains, boil hops (and sometimes spices), and wait for the results to finish mixing and reacting with each other, sometimes for days, sometimes for years. The flavor profile of a good beer is probably complex enough that reproducing it from pure chemicals wouldn't be worth the effort even if it were possible.

My best personal example of ingredients "marrying" over time was a batch of Papazian's Deep Sleep Stout, which has lots of crystal and black malts and roasted barley. For several weeks after bottling, a mouthful of this stuff would go sweet-sharp-sweet-sharp.... It finally homogenized, and I'm still not sure the raw form wasn't more interesting (it was certainly novel), although the mature form confirmed my belief that Papazian has entirely too much affection for black malt. (I wonder whether he likes single-malt Scotch, and if so whether he's one of those masochists who think Laphroig is a pale shadow of a properly smoky whiskey....)

Some commercial types (e.g., Jim Koch) have started making a big thing about freshness. It's possible that the light lagers they mostly deal with are so delicate (especially if left on a shelf at temperatures up to 80F, instead of a cellar where they belong) that aging beyond the lagering actively hurts the beer, but for heartier beers I would expect this generally isn't so. My /personal/ tastes mostly exclude lagers---I like dark beers and strong bitters (and fruit juices rather than light lagers if I'm so thirsty I want to gulp quarts)---but I won't get into an argument about which is better, just about what conditions are better for the beers.

Subject: flakes in my beer!

I have a question about a strange beer occurrence:

Our eleventh batch of beer is a dark ale (brewed from extract with some crystal malt) which has been in bottles for a week. There is some strange foam around the surface of the beer in the bottles, and little flakes floating on the top.

When I pour a bottle into a mug, the flakes float on the surface of the beer in the mug. They are not very solid and dissipate quickly when touched. The beer tastes OK and is reasonably carbonated, given the brief conditioning.

Is this a bacterial infection? Will it go away with longer conditioning, or should we drink all the beer quick before it gets worse? Should we take Papazian seriously and stop cracking the specialty grains in the same room as we brew? (He says the dust has lots of bacteria.) Any suggestions would be appreciated!

Not worrying, just trying to learn something ...

=the sides every time I squeeze it. So this is the messiest part
=of my brewing processes, but it gives me an excuse to wash the
=kitchen floor. (Albeit with beer :-)

I didn't respond to this the first time because I thought someone else would
and I didn't want to be redundant.

Stirring your wort is EASY! I use a long-handleld plastic spoon that I originally purchased from a local homebrew store for stirring during the boil
(I now use a large stainless spoon). I sanitize it and insert it into the neck
of the carboy upside down and stir. I usually don't siphon off the trub; with
good hot and cold breaks, I sometimes get very visible strata developing in the
carboy that eventually settle out. From watching the effect of stirring on
these layers, I can tell that stirring in this manner does a very effective job
of mixing the wort.

I like the spoon because it is essentially a solid rod of food grade plastic.
I sometimes stir using my hard plastic siphoning cane but it is not as stiff as
the spoon handle.

On a different topic, yeast seems to be hardier than most people give it credit for.

On 12/4 I brewed a smoked beer (O.G 1.052) and stuck it in the fridge (ostensibly 40F) to ferment. On 12/17 I left town to visit my parents over the holidays. The fridge is in the garage and shortly after I left the outside temp went to -20F and stayed for a while. When I returned on 12/31, this carboy was frozen solid (another batch which was further along was not frozen when I returned although it may have frozen and thawed during this period). I moved this to an area of 60F where it thawed after two days and resumed fermenting.

I have not bottled this yet because of an injured hand so I can't report on how it tastes. I've inadvertently frozen commercial beers in the past and it will ruin the taste (such as it is). However, the yeast (Whitbread lager) seems to have survived the freezing.

Subject: Swiss or French Supply House

It's been a while since I posted my inquiry asking if someone who follows this conference is aware of a Swiss or French based supply house or mail order store that I can purchase from.

I have been dragging my supplies back from the states and the U.K. whenever I get the chance. This is less than an optimum solution and one that still hasn't permitted me to pick up some much needed carbons.

Does someone out there have a suggestion on at least where I might be able to locate a local carbon supplier?

From: Steve Anthony <steveo@Think.COM>
Subject: Bad Batch

Well, I recently experienced my first bad batch of beer in 6 years of brewing! Perhaps a post-mortem is in order. I thought if perhaps I described the taste/smell/appearance of the beer some kind souls out there in brewnet-land could fill me in on what exactly the infecting agent was.

First off, I've recently started using Papazian's krausening method of priming. I sanitize a 1g glass jug and rack about 1/2g of unpitched wort to it. This gets stoppered and put in the fridge. I pitch (WYeast) and ferment as usual. When it's bottling time, I add the appropriate amount of gyle to my bottling bucket (note, right out of the 1g jug. Perhaps I should boil this to pasturize?) and add the fermented wort. Bottle it up and wait.

I noticed that the beer never cleared. About the top 1-2" of the champagne bottles I use were clear, the rest was cloudy. This was after about 4 weeks. Secondly, there were flakes of something floating at the surface. The beer was *very* overcarbonated. I tossed it in part because I didn't want to run the risk of glass grenades in the basement!

The smell and taste I can only describe as *very* bitter. Kind of like a overzealous IPA; boiled with 5oz of Bullion, or some such. The bittering was overpowering. Couldn't get a hint of malt sweetness or anything.

That's about it. I have three new batches fermenting right now, and I don't want them to turn out bad. The only idea I have right now is to either prime with corn sugar boiled in water, or boil the gyle. I haven't changed any other of my techniques; same bottles, jugs, carboys, etc.

Any ideas?

Subject: heating and cooling bottles

Way back when I was an art student blowing glass we cooled our work slowly (annealed it) to avoid breakage.

If the glass is cooled too quickly, the outside and thin parts become fully rigid before the inside and thick parts have finished contracting, when the thicker parts do begin to contract, the already rigid parts of the piece have to give, something glass is not good at. Sometimes the breakage is immediate, sometimes quite delayed. I had a goblet develop a spreading crack months after it was made because it was incompletely annealed.

We cooled our work at the rate of 100 degrees/hour starting at ~1100 degrees. If the glass pieces are relatively thin and of consistent thickness (like a beer bottle) you could probably cool them faster than this without seriously weakening them.

Note that the temp/time rule applies to heating glass too.

Subject: temperature after bottling?

I'm now brewing my first batch of beer from a ``True Brew'' kit. The instructions say that after bottling the beer should be stored at about 70 F for a week to ``condition'', and then after that it should be stored at 50 F for another four weeks.

My problem is that I am unable to store the beer at the 50 F temperature. What will happen to the beer if I continue to keep it at 70 F. Would it be better to keep it in the refrigerator at ~ 40 F?

In general, can anyone explain to me what happens to the beer after it is bottled and what effect temperature has on this.

Thanks for your help.

Subject: distillation controversy

First, I'd like to echo Karl Wolff 's plea to terminate discussion of Arabic Law/military policy/illegality of distillation/liquor on aircraft and so on. It's neither here no there.

Second, I'd like to challenge anyone (here I go) to quote from any text on distillation, a passage relevant to the presence of methanol in alcoholic brews obtained from natural grains and brewer's yeast. I admit that thermodynamic laws persist in that all the air in the room in which I sit could suddenly rush over into the corner and stay there, and I will never finish this sentence due to asphyxiation. But a sufficient concentration of methanol in fermented grains to produce poisoning would indeed seem remote.

Being from the Ozarks, I can say with certainty that it is possible for people to distill superb vodka with quite primitive equipment and straightforward process. This is not a recommendation, since it is illegal. I don't do it, and wouldn't advise anyone else to without a license. But it is not necessarily a process which results in something other than ethanol-rich liquor.

If anyone has any facts (and I mean quotable) to the contrary, please feel free to speak up, and I will humbly bow out.

Florian

From: polstra!norm@uunet.UU.NET (Norm Hardy)
Subject: Lager Fermentation Control

Here is a quick update on the use of refrigeration control for getting the proper temperatures for lager fermentation.

I purchased the "Hunter Energy Monitor AC Model 42205", a \$50 digital device which allow accuracy to +2 -1f within the fridge. The worst variance will be less due to the volume of the fermenter relative to the fridge volume.

It is a snap to use, just plug in your fridge to the front of the device and then plug it into an outlet (mine is at the 5 ft level). Set the day and date, and then set the temperature you want to hold the fridge at. A flexible probe goes into the fridge. That's it.

It has a timer to prevent the fridge from cycling on more than once every four minutes; but that's a safety feature you'll never need worry about in most all cases anyway, unless you continually by the minute open the fridge door to worry about your lager.

It apparently goes down to 40f, plenty cold enough for the primary ferment.
For lagering colder than that, simply turn the switch to manual and let the fridge take control again for the colder temperature. The monitor will keep track of the temperature so that you could set your fridge control to what you need.

Basically, it works. The unit is designed for air conditioning and is probably cheaper in areas where Hunter (look up FANS in the yellow pages) is popular.

I'll let you know how the German Pils turns out (the grain was brought in from Bamberg through a local supply shop).

If I remember Miller correctly, the main concern is *soap*, not
detergent. Something tells me that the phrase "soap film" is
not called "detergent film" for a reason.

Specifically, Miller says not to use a "rinsing agent" (or
something similar that removes spots or somesuch) precisely
because it leaves a film.

>with cleaning who knows what). Thanx in advance.

As far as I know, most of us *can't* tell. I avoid the bottles
with twist-off caps, but others say they use them successfully.

1) Ask your friends if they drink the stuff like Lone Star or Bud
Dry. Then ask them to save the bottles (and the case
they came in--very handy for storing the bottles of your
homebrew in).

2) Buy yourself a couple of cases of Samuel Adams and reuse those
bottles.

3) I reuse all kinds of bottles, including the Anchor
Brewing small, roundish bottles. Plus, IBC Root Beer bottles
work nicely. If you want to get strange :-), use one or two
plastic soda bottles (1 or 2 liter) to save on the number of 12
ounce bottles you need.

4) My favorites are the ones with the resealable ceramic-top
bottles (Grolsch-style). No use of a bottle capper needed.

Steve,

I have had a couple of batches go "bad" where they acted identically to yours, i.e., only the top couple of inches cleared in each bottle and they tended to gush when opened. In my case I am 99 percent sure that it was a lactobacillus infection. I believe that this is the most common type of infection that homebrewers experience.

I am, however, a little puzzled by what you describe as an extremely bitter taste in the beer. Lactobacillus imparts a distinctively sour taste to the beer and this is what I experienced... maybe someone else can explain a bitter taste?

I think it would definitely be wise to boil the gyle before krausening.

Dave

This is what we do. Works very well. We don't boil it before adding -- I
figure that I've been pretty clean in my procedure, and besides, the beer
is alcoholic now.

Steve> The beer was **very** overcarbonated.

I doubt you've got an infection -- if you've been careful. I think you're
using too much saved wort for priming. We use -- typically -- a bit less
than 1.5 Liters, but it all depends on the OG of the saved wort. Check
Noonan for a table of carbonation levels versus amount of saved wort at a
specific gravity.

From: durbin%cuavax.dnet@netcon.cua.edu
Subject: re:freshness of beer

In Germany all beers have a date that they can be sold till, along with the the alcohol content. I believe this is to be so they are still fresh. From my experience with Weizen Beer bought in Germany or the same brand and type bought in the states, there is difference in freshness. Some 1/2 liter bottles still have the date on them, usually 1 year or so after that date. The dates on the bottles (the ones in Germany) seem to me to be no more than 6 months from when it was bought.

I drank some Sam Adams in Germany (wanted show my friends there are some good American beers). Looking at the bottle we noticed it was brewed and bottled in Germany. My roommate said he thought it didn't taste as good as the stuff in the states but I didn't think it tasted much different. Of course we had already had a few brews.

Subject: U.S. Open Homebrew Competition Announcement

Following is a brochure just sent to all the homebrewing clubs
in the U.S. FYI....

THE U.S. OPEN HOMEBREW COMPETITION
Hosted by the Carolina Brewmasters
April 27 & 28, 1991 !!! Charlotte, NC !!! Don't miss it !!!

ENTRIES: due by April 12, fee is \$5.00/ENTRY, 3 bottles/entry

Send entries to: U.S. OPEN HOMEBREW COMPETITION
c/o Alternative Beverage
114-0 Freeland Lane
Charlotte, NC 28217

The Beer Judge Certification Test will be given in Charlotte
on Fri. April 26.

In conjunction with BREWCO and ALTERNATIVE BEVERAGE, awards will be
presented for those beers which merit recognition (i.e., Best of
Category, Best of Show, etc.), as well as for the Club with the Most
Winning Beers, and the Novice Brewer Award. (How about a Best
from the Net prize?!) Winning recipes will be published in Zymurgy.
Some free entries to the AHA National will be awarded.

This will be a great, beery time in Charlotte on April 27-28,
and we hope many of you will be able to join us.

If you would be interested in judging (AHA & HWBTA
sanctioned competition), contact Kinney Baughman at (704) 963-
6949, our Competition Judge Director. (Netlanders, e-mail me
at BAUGHMANKR@APPSTATE.BITNET)

Should you have any further questions, contact Doug MacKay at
(704) 376-4916, our Competition Organizer, who can also help
you with lodging information.

CLUBS: Please let us know how many entries your club will
send, and how many of you can act as judges, preferably by
March 27.

AHA categories will be used, however, the competition orga-
nizers reserve the right to combine categories if necessary.

SPRINGFEST '91 happens during our competition, which will
allow our guests/judges from out of town to join with hundreds
of thousands of people and artists from all over the country
for a weekend of music and sunshine.

See you in Charlotte!!!!

----- end clip -----

The American Brewmasters with Alternative Beverage have
conducted three national competitions (The National
Homebrew Club Brew-off) as well as hosted the 1989 HWBTA
national competition. These guys are experienced at big

competitions and this one promises to be one of the better competitions in the country.

As mentioned above, I am the Competition Judge Director, so please let me know if any of you would be interested in coming to Charlotte to judge. As mentioned above, we will be giving the Beer Judge Certification Exam. Remember, even if you haven't taken the exam, points are given retroactively.

Shopowners, if you would like to donate prizes, please contact me as well.

As added enticement for the trip, Springfest is THE largest street party in the state of NC. They literally close off downtown Charlotte, put bands on every street corner; food, crafts, and art exhibits down each street, and a wild and riotous time is had by all! Add to that the two BrewPubs in Charlotte: The Mill and Dillworth Brewing Company, and there will be more than enough events and places to go to keep the adventurous satisfied.

The U.S. Open Competition will be a great way to break the Winter chill and usher in the Spring. So pass the word to your local homebrew clubs and friends.

Get brewing and send in those beers!!!

Cheers,

Kinney Baughman : Beer is my business and
baughmankr@appstate.bitnet : I'm late for work.

>lagers and ales is generally in the fruitiness of the ales.

I omitted one important (albeit quite obvious) piece of information:
At higher temperatures the fermentation completes quickly, whereas at
lower temperatures the fermentation takes longer. This longer
fermentation
means that the beer must be stored. "Storage" in German is "lager,"
hence
the name.

^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^

The stored wort has no protection from invading nasties -- no
competition by yeasts and no CO2 to ward of the aerobic organisms.
The lower temperature helps but over, say, 10 days is ineffective.
If there is any opportunity for spoilers to get in they will simply
take over. I usually save extra wort left over from the boil for
krausening, yeast culturing, etc., and always boil it before using.

A couple of times I found visible mold colonies atop the refrigerated
wort. This despite having boiled the jars and racking tube and of
course used perfect ;-) sanitation for everything else. I now fill
the jars and pasteurize before refrigerating, just as in canning
other foods for long-term storage. Suspenders + belt, as it were.

From: Brian Capouch <brianc@zeta.saintjoe.EDU>
Subject: Carbonation in ruh beer

I wonder if any of you out there have ever had this "problem." I brewed a batch of beer on Christmas eve, and have been assessing it the last week or two for gravity and taste.

This batch, and this has happened infrequently but a few times in the past, has a wonderful pinpoint carbonation right now as it sits in the secondary, even though its gravity is now stable, and it looks and tastes like it is ready to bottle.

My question is this: why would this beer do this? Why would other batches *not* do this?

If it weren't for the infection potential (about which I'm working up a posting) I'd just siphon it out of the carboy into my glass, and dispense (pun intended) with all the hassle of bottling. I also wonder how to figure out how much priming sugar to use--I did this once before to some sparkling beer, and got grenades a month later.

Subject: Re: More questions about Barley sources

Jeff Miller asks about "seed" barley, and wants to grow his own.

I would say, if you're going to go to all the trouble of growing, harvesting, threshing (ughh) and malting your own barley, you ought to take the time to do a little investigating. I'm reasonably certain that barley bred to be good animal feed will probably be very different when it's malted than barley grown for malting.

You could call, I would expect, your local "county agent," who is also called an "agricultural extension agent." S/he will work jointly for the US Dept. of Agriculture, the state you live in, and the local county government. These people advise on agricultural issues and technologies, and I believe you'll find one in every county in the USA. Anyway, see if you can find one of these people, and see if they can find some names of varieties that you can order for malting purposes. Once you've got the name of a variety, call around (yellow pages) and see if you can find someone who'll sell you seed. You might have to buy a 50-lb sack of it, however, and that will plant about 40,000 square feet. Your leftover seed barley, if it hasn't been treated with chemicals, would be a great source of practice material for your malting process. From what I understand you'll need it.

I visited the Briess facility in Chilton, WI, a little over a week ago. It was a wonderful visit, and I learned more about malting than I knew before I went in there. I just wish I'd been a more knowledgeable observer. Malting is a biological process as well as an industrial one, and slight slipups render the product either unusable or badly impaired with respect to quality. Also be aware that the same variety of barley will differ widely in its malting characteristics depending on where it is grown, how it's fertilized, and the growing season's weather.

Be sure, if you buy "spring" barley, to get it planted as early as you can. This helps it get an early start on weeds that would compete with it, and helps it complete its growing before (*I don't have any idea where you live*) the weather warms up and it's subject to drouth and diseases caused by the humidity of summer. If you buy a "winter" barley, don't plant it until the fall. I don't know if barley is available as either, or both, or what, but it makes a huge difference in its cultivation.

Good luck--keep us posted on your results.

I've never seriously looked for supplies in Europe, but I'm sure you can track down carboys somewhere. My new 3-gallon carboys were manufactured in Italy - Italian home-winemakers apparently use glass carboys for their fermentations. Carboys and demi-johns should be easy to find. I suggest looking in the yellow pages (or the French/Swiss equivalent) for winmaking suppliers.

A few questions have come up about the Hunter Energy Monitor Model 42205, also known as the Hunter Air-Stat.

In Seattle look up Sutter Home and Hearth in the phone book. They have at least 3 in stock (at last look) and order 6 at a time if there is sufficient demand. They are bemused that it is so popular for brewing.

In other locales, look up in the Yellow Pages under Fans. Try to find by brand the Hunter fans. If not, try looking under Air Conditioning for the Hunter brand.

If not, write the Hunter Fan Company
2500 Frisco Avenue
Memphis, TN 38114.

I paid the full \$50 list price; you can probably do better. It is worth whatever you can get it for.

The *DEDICATED* lager brewer will use the programming ability to have it automatically lower the temperature up to 4 times per day to slowly get to the desired point without having to do it manually. The only drawback is that you have to change the programming the next day or it will go back to those 4 temperatures again. No big, just reprogram it the next night for the following day.

I don't bother, the HOLD feature is working great. But now, I have to change my brew sheets to reflect a time chart showing the fermentation temperatures per day. This could get serious, but then nobody said that duplicating Andechs would ever come (easy).

Subject: Yeast attenuation

I know what "yeast attenuation" means in a qualitative sense: the more attenuative the yeast, the more fermentables get converted. My question is - what does it mean quantitatively, e.g. if a yeast yeilds "apparent attenuation of 73 - 77%", how do I use those numbers? A first guess would be that a 75% attenuation of beer with OG of 1.060 will yeild a final gravity of 1.015. Is this correct?

>other batches *not* do this?

I used to occasionally have this happen to me, though thankfully
I never ended up with any bottle-bombs. Also had another
problem, namely that my airlock only had tiny bubbles in it, no
big ones going glub, glub.

So I mentioned that here and got lots of responses, mostly
suggesting that the top to my airlock must be on too tight.
Voila! Now I make sure that the top is on very loosely. I get
great glubs in the airlock and no more carbonation of any kind in
the secondary (I think, have been lazy the last few batches about
taking out samples to measure S.G.).

Subject: lagering

There have been a couple of comments lately on just what "lagering" really means. I don't know the origin of the term but I do have an observation to share.

Until recently, I have not had the facilities to do cold fermentations; I have made several steam beers, however. These beers were fermented and then aged at 60-70F. Usually, I take beer out of the aging/storage area and refridgerate a day or less before planning to serve. On those occasions when get-togethers are cancelled at the last minute, the beer can sit in the fridge for a week or more. I've noticed that this storing of the beer at lower temperatures for even as short a week makes a marked improvement in the taste. I've not yet had the opportunity to make comparisons of this technique with beers that were fermented cold.

>it sits in the secondary, even though its gravity is now
>stable, and it looks and tastes like it is ready to bottle.

Assuming you don't have an infection, the key word is "secondary." If you rack a beer that has fermented completely out, the brief exposure to oxygen causes the yeast to biochemically change gears. I've been told that it enters malo-lactic fermentation. Whether that's technically correct or not, the upshot is that the yeast is triggered into fermenting the higher-order oligosaccharides, namely, what brewers usually call dextrins, which contribute to mouth-feel/body.

From a practical standpoint, you can't stop this without pasteurizing the beer or otherwise killing the yeast. From a commercial standpoint, you're brewing "dry" beer.

>I also wonder how to figure out how much priming sugar to
>use--I did this once before to some sparkling beer, and got
>grenades a month later.

DO NOT BOTTLE. It can take well over a month for the yeast to do all your dextrins. Wait until the pinpoint carbonation stops, then prime and bottle normally.

There are two ways to avoid this kind of secondary fermentation: 1) (the hard way) rack to secondary while primary fermentation is not complete; 2) (the easy way) when racking to secondary, add the same amount of sugar/malt that you would when priming. The latter way adds enough sugar to allow the yeast to consume the oxygen without digesting dextrins, and will totally prevent this phenomenon. There's actually a third way, which is what I use: since I brew only ales and use fast-acting yeast, I do away with racking to secondary altogether.

>

...

>Specifically, Miller says not to use a "rinsing agent" (or
>something similar that removes spots or somesuch) precisely
>because it leaves a film.

Geeze! I have a beer glass collection I brought back from Europe. Routinely, I stick all the glasses in the dishwasher, dump in a bunch of Cascade Detergent, and run it. The glasses come out sparkling clean. The beer poured into these glasses will form an adequate head. I just can't see any problem with treating bottles the same way.

The alternative for bottles, if you are really a fanatic, is to wash them with a solution of 1 tbsp TSP in a gallon of warm water, rinse thoroughly until the glass is squeaky clean. Then cover the top with aluminum foil and bake the bottles at 350 F for one hour. If there exist any microorganisms in the bottles after that treatment which could spoil your beer, well, you've got the makings for a real exciting SF film (beg your pardon for the pun).

Don't forget to change the gaskets. You can buy them in large quantities from many supply stores or mailorder. I have heard that you should change it once before your first reuse and then "occasionally." Some digesters have said they change gaskets every two times, others don't change them even at the beginning. If I didn't keg, I would probably change them every three or four reuses. Your milage may vary.

Subject: A call to New England home brew clubs

The following letter was FAXed to me by Karen Barela, AHA Conference Director.
She is very interested and excited about getting New England area clubs directly involved with the upcoming AHA Conference in Manchester, NH. She gave me permission to post her letter here, and for it to be distributed freely. If your club hasn't seen it, please show it to your fellow members.
If you've been thinking about joining a NE-area club, there's never been a better time!

I know that there are a handfull of active clubs scattered around New England now. Though there are not yet any well-established clubs in New Hampshire, there are currently two starting up in the New Hampshire/NE Mass. area. Gary Mason posted information about both in HOMEBREW DIGEST. John Welch is actively working to start a club, and the kickoff meeting will be February 16 at his home in Pembroke, NH. See HB Digest #331 for info, or call or write John at 418 Nadine Rd, Pembroke, NH 03275, (603) 485-8381, or reply to me for information.

Additionally, the Wort Hoggs Home Brewers Club is gaining perceptible momentum and will be meeting again January 25 in Tyngsboro, MA. See HB Digest #498 for general info, or reply to me if you want to try and make the 1/25/91 meeting or any future meetings.

This early activity is getting me psyched about the Conference, and I'm confident that New England's home brew clubs, both new and mature, will be ready to welcome the AHA and the world's home brewers to Manchester in June!

-Dan

A Division Of The Association Of Brewers

1/22/91

Dear New England Club:

We're thrilled to be holding our Homebrew Conference in Manchester, N.H., close to many of you. In case you haven't heard, the dates are June 19 to 22, 1991, and the festivities will be at the Center of New Hampshire Holiday Inn. Registration information for both the Conference and the Competition will be available in the spring issue of ZYMURGY.

As a New England club, several events concern you. Thursday night, June 20, will be club night, where any club that wants one gets an exhibit space for their T-shirts, mugs, pins, and especially beer! To reserve a space, call Dan Fink at the AHA. Remember to start brewing your club beers soon, so they'll be crystal clear and delicious to impress other beer lovers at club night. The Homebrew Expo will have its first of two nights running alongside club night, so there will be plenty of interesting equipment and supplies in addition to fine club beers. After club activities wind down the hospitality suites will run well into the night. If you are interested in renting a hospitality suite, contact Karen Barela at the AHA.

On Friday, the New England Brewers Tasting will be combined with the second night of the Homebrew Expo. Both events will follow the gala awards banquet, so be prepared to check out the latest supplies and equipment while tasting some fine commercial beers served by the brewers. On Saturday, the plan is to tour breweries throughout New England, so here's your chance to introduce your club to brewers from all over the U.S. and Canada. How about hosting brewery tours of your area for groups of conference goers? Or maybe help arrange for some Conference attendees to attend the Red Sox game with your club? How about hosting a club party and beer tasting? The AHA will help arrange transportation from Manchester and back again, and we'll assist you in any other way we can.

These are just some preliminary ideas for you to think about. Remember, Saturday is **your** day to promote your club, get to know to others. [sic] have fun **and** get some recognition for your club and its beer! If you tell us your plans by the end of February, we'll help you however we can, and we'll be sure to publicize your activities at the Conference and in the program. Contact Karen Barela at the AHA for more information or help with getting your plans moving.

We're looking forward to seeing you at the Conference!

Fermently,

Karen Barela
AHA Conference Director

From: Allen Akin <allen@atd.dec.com>
Subject: Dishwashers for Bottles

I routinely use a dishwasher for cleaning and sanitizing bottles. I've had no problems with bottle clarity, brew infection, or head retention.

Most times I've used ordinary dishwashing detergent. As added protection against soap film, I use detergent in the first wash period but not in the second (i.e., I put detergent in the external cup but not in the the latched soap compartment).

Just recently I decided to be more ecologically correct :-) and tried washing soda instead of detergent. As far as I can tell, there's no difference in the result.

I always use the ``pot scrubber'' cycle with heated drying.

As Miller suggests, I scrupulously avoid the use of a rinse agent. However, I've never run an experiment to determine what happens if rinse agent is present.

Subject: Re: Homebrew Digest #570 (January 24, 1991)

>From: randy@aplcomm.jhuapl.edu (RANDALL SCHRICHEL (NCE) x7661)

>I'm getting ready to make my first batch of home-brew, all I
>need is bottles to put it in. I know that the returnable type
>longnecks (Bud & Coors) are usable, but they're hard to find

You know, I was thinking the same thing. My brew partner and I
have been buying six-packs of domestic long necks to provide
ourselves with bottles, but it is a painful process (for both my
taste buds and my wallet). There are a few beers that come in the
right bottles that are actually drinkable (Dominion Lager and Pete's
Wicked Ale, for instance) but we can't afford to drink the stuff
all day long.

So I went to a bar near school and asked the bartender what they
did with their bottles (they served Bud, Bud Light, Bud Dry, Miller
and Lite, among other yucky brews, all in long-neck bottles). She
said they pay a \$1.20 deposit on each case of bottles and routinely
send them back to the brewer for re-filling. I asked if I could have
a couple cases of these bottles, and she got the manager, who went
around back himself and brought out the bottles. He didn't even charge
me the \$1.20 per case deposit, he just let me have them.

The only thing is that the Lite bottles aren't quite the right shape/
size, but they outta work out if i'm careful when I bottle. The moral
is just go to your favorite local bar and ask them for their bottles.
Depending on what kind of beer they serve it should be really easy to
acquire a few cases real cheap; even if i'd paid it would only have
cost me \$2.40.

Randy

Subject: Bottles, ad nauseum

Now I may be a simpleton (may?), but what's the deal with going through all the trouble of BAKING your bottles. Is there an assumption that there are ANY little nasties that can withstand more than 3 parts per million of common household bleach for more than a few minutes? Let's put that one to rest. I have used the simple bleach method for all of my 20 batches of beer, and it I wanted to be aggressive, I double the bleach, but even that is probably unnecessary. I use 2-4 ounces of bleach per 5 gallons. None of my batches have been infected. Most importantly of all, isn't it a pain to bake your bottles?! Perhaps I take those immortal words too seriously, but it always seems to work:

RELAX. DON'T WORRY. HAVE A HOMEBREW. (and I mean it!)

Subject: lager brewing questions

With the winter time here I finally have a place in my apartment (the basement) where temperatures are pretty consistent and cool (the basement is heated to ~45 degrees to keep the pipes happy). I decided that now was a time to begin trying my hand at lagers (I had tried a room temperature fermentation with lager yeast and the results were pretty mediocre). Also this time I was pretty meticulous about sanitation and water preparation (ala Miller's book recommendation). Ok, my OG was around 1040 and I used a Wyeast lager yeast (I have the exact one written on my brewsheet at home can't recall right now). Several unexpected things happened and I'd like some feedback as to whether these are common to lower temperature Lager fermentations or whether I fouled up somewhere. Here they are.

1) Very long lag time for fermentation to complete (~10+ days). I know from miller that the particular yeast I used is slow to start and, no, I did not make a starter culture but, geeze this seemed awful long.

2) When the fermentation did begin the fermenter was giving off a very strong odor. It was kinda "tangy" (but not like vinegar though).

3) I racked to the secondary after about 14 days and the odor was so strong that I was convinced that I had produced something other than beer and would have to toss the lot. But I was going to see this through!

4) I took the fermentation lock off the top last night (~1 month in the secondary) and wiffed the contents. Yikes, sulphur-dioxide. Also the contents of the carboy was pretty carbonated (little "pin-points" that people have been talking about in the last two digests).

At this point I'm pretty discouraged and am ready to toss the whole batch without any further ado but I siphone some off and take a SG reading. It's 1012. HmMMM that seems OK. I taste it. My gosh it tastes pretty dang good. The stuff has a slight egg bouquet (yuck) but the flavor is good. I bottled the stuff and am storing it in the basement.

Ok, I have all kinds of theories about what might be at work here (including prolonged contact with decaying yeast to explain my rotten eggs) but I've never encountered this before. Is the stuff OK? Will the sulphur-dioxide "go away"? Are there common mistakes made by neophyte lagerers which yeild some, if not all, of the odd results I mentioned above?

At any rate I'd appreciate it if some of you more experienced lagerers out

there would comment. As we have more cold weather for ~2+ months here in N.E I intend to attempt at least one more lager before returning to ales for the warmer months (or until I can afford the equipment).

In HBD571, Fred Condo writes:

Assuming you don't have an infection, the key word is "secondary." If you rack a beer that has fermented completely out, the brief exposure to oxygen causes the yeast to biochemically change gears. I've been told that it enters malo-lactic fermentation. Whether that's technically correct or not, the upshot is that the yeast is triggered into fermenting the higher-order oligosaccharides, namely, what brewers usually call dextrins, which contribute to mouth-feel/body.

There are two problems with this statement. First, malo-lactic fermentation involves conversion of malic acid into lactic acid. This process is part of the activity seen in secondary fermentation of fruit lambic beers, and is brought about by bacteria, not yeast. It does not involve dextrins. I don't really see how a yeast can spontaneously begin consuming dextrins. One possibility is that a wild strain that's more attenuative has been introduced.

Second, as Dave Miller repeatedly insists in TCHoHB, dextrins do not contribute to body. Protein, and only protein, does.

Sorry I can't say anything constructive. My beers are sometimes a little bubbly in the sedimentation tank (I hesitate to call it a secondary, since there is no intent that the beer ferment; it's for clarification), but I've never worried about it.

From: pms@sfsun.West.Sun.COM (Patrick Stirling)
Subject: Oatmeal Stout Recipe (Extract)

Mike Tavis asked for an Oatmeal Stout Recipe. Here's one I used recently, based on another that was also posted in this forum:

8lb British Amber Malt Extract
0.5lb Plack Patent grain (cracked)
0.5lb roasted barley (cracked)
0.5lb Chocolate Malt grain (cracked)
1lb Steel Cut Oats
2oz Eroica (boil)
1oz Fuggles (finishing)
Whitbread ale yeast

Procedure:

Crack all grains (except the oats), add to about 2 gal cold water (incl oats), bring to a boil (my table top range takes almost an hour to do this). Remove the grains with a strainer when boiling and add the malt extract and boiling hops. Boil for an hour. Add the finishing hops and continue boil for a minute or two. Turn off heat and let steep for 15min. Put about 4-6" of ice into a plastic bin and strain the wort into it. Sparge. Bring up to volume (5.25 gal) with cold water and mix well. I find that the temp by now is down enough to pitch (i.e. <80F). Rack into 6gal glass carboy and pitch the yeast (I just throw in the dry stuff). Use a blow off tube for the first couple of days! I.e. A plastic tube from the carboy into a jar of water. Bottle when the fermentation is done (usually 2-3 weeks).

I really liked this beer! Dark and smooth with a 'creamy' mouth feel. No specific oatmeal flavour, but lots of body. A light brown head.

The only problem I had was that after about 3 months in the bottle it developed a distinct off flavour. could be from the ice I suppose, or maybe it got oxygenated during the bottling.

Subject: Bottles and a general question.

I've been getting this digest for about a week. I'm gearing up to try some homebrewing for myself. I've seen some notes about bottles. The implication was that long neck bottles are better, or something like that.

Do I need to use some special type of bottle, or can I save my Guinness and Portland Lager bottles. I'm trying to get some Grolsch bottles but they're not common and when full, cost the earth.

I'd appreciate some words of wisdom.

On a broader subject: I have rather poor eyesight and reading the available books on the subject will be most difficult. My wife does read to me, but she isn't particularly interested in brewing, so won't read much at a time. If any of you have on-line material about brewing, beer types, chemistry of yeast, etc., I'd appreciate a copy. I use a talking terminal and can listen to anything sent easier than reading books.

Thanks for any help, both on the bottles or on the general subject.

Subject: Labels, off and on

I'm new to this digest, so if it's been discussed recently I missed it.

I've found a good tool for removing the lables from bottles. A stainless steel scrubbie ('Chore Boy' is one brand).

An overnight soak with a little detergent in the water reduces the need for elbowgrease, rub or peel off what comes off easily, then go after it with the scrubbie, and rinse.

Real foil (like on the tops of 'Harp' bottles) benefits from a once-over with the scrubbie **before** the soak. Last night I soaked two 'Harp' bottles, one I 'pre-treated' the other I didn't. This morning, the 'pre-treated' one came clean very easily, the other? it's still soaking.

Some of the lables I was removing were my own. They were Avery brand peel-and-stick lables that I printed by running them through the laser printer on manual feed. I had feared that I would have an awful time getting them off, but, after a night's soaking they rubbed off very cleanly, no scrubbie needed.

Glue-stick will hold a label on quite well **unless*it*gets*wet** at which point it is likely to flop off on it's own. If your not going to ice your bottles this will work well and remove **very** easily when the time comes.

Subject: looking for info on bocks

Folks,

First of all, thanks for all the replies regarding my yard-glass request!

Now, I'd like to hear people's opinions of bock-style beers.
Specifically:

- o What are the characteristics of a good bock?
- o What is your favorite commercial bock?

The homebrew club that I belong to is having a bock night (in April).

Most

of us are going to try to brew some sort of bock for it. I'd appreciate
any

bock info you could provide. Also, if anyone has a (mostly extract) bock
recipe I'd love to get a copy.

thanks,

tony (The Sparging Flocculators -- Allover, Ma)

Subject: Washing Soda

Allen writes:

>Just recently I decided to be more ecologically correct :-) and tried
>washing soda instead of detergent. As far as I can tell, there's no
>difference in the result.

When I used to bottle, I found that washing soda worked well to remove labels from bottles (even the really nasty foil ones). However, I noticed that after soaking in a pretty strong washing soda solution, when the bottles dried they had a white film on the outside (and on the inside, I'm sure). I don't exactly know what the film was, but it rubbed off without much trouble. I'm definately not a Chemist, but I figure that the film (a sort of powder, actually):

1. did not wash off, even with the hottest water,
2. was maybe a product of a reaction between the Wa-Soda and the foil,
3. was maybe a product of a reaction between the Wa-Soda and the glue, or
4. was maybe Wa-Soda itself.

As it turns out, the only way I could get it off was to soak in a lemon juice and water solution. Since then, I never use washing soda on the inside of bottles I plan to refill.

Al.

From: "Ihor W. Slabicky" <iws@sgfb.ssd.ray.com>
Subject: Samuel Adams Cranberry Lambic

I have had the opportunity to try some new brew from the folks at Samuel Adams - Cranberry Beer. To quote from their table cards:

Samuel Adams
Cranberry Beer

This Cranberry Beer is our version of a traditional Belgian Lambic. Like all Lambics, it is made with fruit, a top-fermenting yeast and wheat and barley malt. The portion of wheat malt produces a lighter taste and rich creamy head. After breweing, this wheat beer is fermented a second time with fresh cranberries and pure maple syrup is added to balance the tartness of the fruit. This beer combines the tart dry character of the cranberry with the light refreshing taste of the wheat beer. A special New England brew for the holidays!

My impressions: it is a light beer with little or no malt taste. The taste starts off with a fresh sour/tart taste, almost like freshly made sour milk (just the taste part of fresh soured milk or yogurt, not the consistency :-)) and then changes to the tartness of cranberries. I can't really tell if there is maple syrup in it or not (I am used to the taste of Grade B syrup, so any lighter tasting maple syrups don't do much for me in the taste department). The color is a deep rich dark red - almost burgundy, and a nice head of pinkish foam tops it. I like the taste and the refreshing quality of it. I could see drinking this during hot weather - the tartness would be quite refreshing, I would think. Referring back to their tabel card, I would have to agree with their description: take a wheat beer, add some sour milk taste to it, add cranberry juice, sweeten with maple syrup (tho I can't tell), and you have your Cranberry Lambic!

For those intereted, I had this at Doyle's, located on Washington Street, in the Jamaica Plain section of Boston, about five blocks away from the Forest Hills T-station (I may be wrong on the station). They list it as Cranberry Lambic, and a pint costs \$2.75...

Doyle's is a nice place for a brew - they seem to have most of the Boston area breweries covered, and do bring in some other brews, also. They had Anchor Christmas Ale on tap, which to me tasted like a cold spiced muffin or cold spiced something. I was not very impressed by the Anchor, and as I was also having a Cranberry Lambic that night, I did not have the Anchor again. I have had the Cranberry Lambic a few times, each time I expect the milky-sourness I described above to turn bad, but it never does - each time it tastes as fresh as the first time.

From: card@apollo.hp.com
Subject: FLAT LAGER

I've got a totally flat batch of light lager. I'm suspecting that I probably killed the yeast (wyeast 2035 USA) by shocking it into a cold fridge (40F). I took the beer out and let it sit for a few days at 65F but no apparent difference. I'm ready now to add a few dry yeast grains to each bottle as Papazian recommends.

It's only been about 10 days since bottling but I would expect some carbonation by now, although my experience with lager is quite limited (ie. none). Is lager carbonation behavior much different than ales?

My brewing procedure went like this:

- * I pitched the (pre-started) yeast at 68F. SG ~ 1040
- * Primary fermentation 5 days at an average of 58F (55-60).
- * SG 1015
- * Secondary @ 40F. (probably should reduced in 5F increments)
- * very little (1 bubble every 2 minutes) secondary fermentation.
- Left 2 weeks ~<1015
- * bottled the cold beer and primed with 3/4 cup corn sugar
- * returned to refrigerator at 40F
- * + 7 days totally flat
- * removed 3 days to 65F >>> still flat

* p.s I also primed the last few bottled with molasses>> same results >>>> flat.

So:

1. should I just wait? Am I just being too impatient?
2. Add dry yeast
3. Add 2035 slurry I got from the secondary. Note this was still fairly active (?) higher concentration?

From: Steve Dempsey <steved@longs.LANCE.ColoState.Edu>
Subject: Vierka yeast?

Circa HBD #531 there were a couple of brief postings re: Vierka yeast. I ran across a couple varieties of this brand and picked them up for an experiment or two despite the poor reviews.

Tonight I prepared a starter using the Vierka mead yeast. At least it says yeast on the package. This stuff looks like no dried yeast I have ever seen before. It looks more like the non-pelletized form of irish moss, or maybe herbal tea leaves, or maybe sawdust. Lots of oddly shaped and strangely colored bits. It does not taste like much of anything and I'm feeling no strange side-effects yet :-).

It was rehydrated at 90F and cooled to 65F over 60 minutes. The stuff has not dissolved after 4 hours. Chunks of unidentifiable organic matter lurking at the bottom of the starter bottle and a few floaters appear as slightly bloated versions of the dry stuff before pitching. Sure wish I had microscope handy.

Has anyone used Vierka mead yeast before? Does my description fit the stuff you got? How about other Vierka yeasts?

I guess the tried and true Red Star Montrachet will save this batch. Sigh.

Subject: relaxation

I'd like to post a discovery that may add to the relaxation and lack of worrying to you folks out there.
In the 40+ batches I've made a few times now & then the bubbling never really seems to take off... IN this last batch I made I was at home while it went through it's peak. The thing bubbled like it was attached to a fishtank airpump for 5 hours then settled down to the slow glurg phase. Had I not been home I would have missed it & possibly worried.

By the way, are there any homebrew suppliers in the Atlanta area?

From: Ken Schriner <KS06054@UAFSYSB.UARK.EDU>
Subject: roto-kegs

I have used the roto-kegs. I thought they were terrible. I could never get them pressurized. The tap leaked. I finally had to take the top off and let the beer drain out of the keg. Of course it was flat and tasted terrible this way. I tried several times to make this work.

My suggestion: Forget roto-kegs and move on directly to stainless steel soda syrup kegs. They work well. The cost is more than roto-kegs, but they work so much better.

From: Jim Culbert <culbert@m43>
Subject: jane you ignorant.....

Oops.

In HBD#572 I posted a request for advice on lagers. I referred to smelling "sulphur-dioxide". Didn't mean to confuse anybody. Just flaunting my ignorance of high school chemistry. What I think I meant was hydrogen sulphide. The net effect is the important thing. The stuff smelled like eggs!

Also one more question.

My last recipe used 5lbs of malt extract. This left me with approx. 1/2 a can of malt. I sealed the top with plastic wrap and an elastic band and put it in the fridge. Is there any reason I shouldn't use this in my next batch of beer? There's nothing growing on it. I hate to waste the stuff but then again I'd hate to ruin a whole batch of brew just to save a few bucks.

Date: Tue, 29 Jan 91 09:08:38 CST
From: rickel@cs.utexas.edu (Jeff Rickel)
Subject: Aging ale, cooling wort

Two questions:

1. For those of you who believe that aging an ale for a few extra weeks can soften harsh/off flavors, what temperature do you recommend? Is room temperature (60-70 degrees) better than refrigerator temperature?
2. A friend of mine cools his wort by adding (previously sterilized) ice. This is convenient for me since I use a partial mash with about 3 gal of wort, so I have to top up with a couple gallons of water anyway. I tried his method by adding 1 gal of ice and 1 gal of refrigerated water to my 3 gal of wort, and I got down to pitching temperature in about 20 min. This seems so convenient that there must be something wrong with it. Is there any reason to avoid this method?

Thanks,
Jeff Rickel

Subject: Beer Bottles

I've been seeing people asking about finding suitable bottles for homebrew the last few issues. I've found a source that may be appropriate for some of you, and also constitutes a good deed.

Socorro NM is a relatively small town (pop. 9000) and we've been a little slow to jump on the recycling bandwagon, but a group of volunteers now collects recyclables (newspaper, Al, cardboard, plastic and GLASS) once a month at a central location. Entirely staffed by volunteers. So, once a month I put in 2 hours, always sign up for glass detail, work out a month's worth of aggression by smashing bottles, and usually score at least a dozen U.S. champagne and cider bottles for my homebrew.

Keep on brewin'!

Sounds about right to me. We had a pilsner that took *months* to ferment
out, but turned out pretty good in the end.

>
> At any rate I'd appreciate it if some of you more experienced lagerers
> out
> there would comment.

Yes, have "Relax, don't worry, have a homebrew" tatooed on the back of
your wrist where you can consult it whenever you want.

All of your "problems" sound familiar to me, but we've never made a
lager we didn't like. (OK, we've only done two lagers, but they were
both great.)

Date: Tue, 29 Jan 91 12:53:13 PST
From: florianb@chip.cna.tek.com
Subject: lager questions entertained

In #572, Jim Culbert asks some questions about a stinking lager brew:

>1) Very long lag time for fermentation to complete (~10+ days). I know from
>Miller that the particular yeast I used is slow to start and, no, I did not
>make a starter culture but, geeze this seemed awful long.

You use "lag time" and "complete" in describing the same apparent effect. Lag time refers to the time between pitching the yeast and the time at which the yeast are in an obvious state of cell division (fermentation). Long lag time can result from several causes including incorrect temperature, insufficient yeast population in the pitched solution, temperature shock, lack of oxygen, and poor yeast culture. I have experienced lag with the Wyeast cultures. In these instances, I have paid close attention to the factors I mentioned above and got yeast lag in spite of my best efforts. I can only conclude that since my conditions were right, the yeast cultures were sick. I suggest that you review your notes to see whether any of the above factors could have affected the yeast. Also, you should always figure out how much yeast is required for the recipe and use a starter to obtain that amount. Finally, 10 days is not unreasonable for the time to complete fermentation in a lager. You are doing well.

>2) When the fermentation did begin the fermenter was giving off a very strong odor. It was kinda "tangy" (but not like vinegar though).

>
>3) I racked to the secondary after about 14 days and the odor was so strong
>that I was convinced that I had produced something other than beer and would
>have to toss the lot. But I was going to see this through!

>
>4) I took the fermentation lock off the top last night (~1 month in the secondary) and wiffed the contents. Yikes, sulphur-dioxide. Also the

Occasionally, I have also noted a sulphury smell arising out of the brews (lagers) I made using Wyeast cultures. Again, this odor can result from a variety of factors, including the use of Munich malt. There's no guarantee that Wyeast is pure. About a year ago, John Polstra (Seattle) and I (Bend, Oregon) experienced batches with infections simultaneously--both batches being fermented with Wyeast Pilsner yeast. In your case, I would suspect an infection of wild yeast. You could have nearly eliminated the smell by dumping in a cup of corn sugar into the secondary (carboy) and letting it sit in the basement for a month, then bottling. The escaping CO2 from the carboy "scrubs" the sulphur (dioxide) smell from the brew. I have used this technique successfully. But you should continue to work at figuring out what is the cause of the smell, more than figuring out what to do about it once it happens.

Finally a word of encouragement. When I began brewing lagers about three years ago, I was shocked at how difficult it is to get a lager just right. As time passed, I began to refine my techniques and pay attention to such things as precise temperature control, proper

use of starters, protein rest in the mash, proper lautering, proper sparging temperature, and so on. Now, a lot of it has become second nature. I'd like to encourage you to not give up, but persevere! Keep making lager and keep reading the good books. Your efforts will pay off eventually!

> wrong-shaped bottles?

Sorry I should have been more specific. The capper I use is a bench
capper
(two levers you push down and out over the bottle to mash the cap on).
The bottles I use must have a lip about 1/2" below the top of the bottle
or my capper has nothing to grab onto while i'm pushing down. Most
import
bottles don't have this lip, and domestic long-necks do. The Lite
bottles
I got have the "lip", but it's slightly rounded and my capper has a
tendency to slip off while i'm pushing down.

If i'm careful when capping, i.e. maintain an even pressure on both
levers
and keep a slight inward pressure to keep the cap seated right, there
isn't
a problem with the Lite bottles. Incidentally, the Lite bottles also
have
foil labels with glue that doesn't seem to dissolve in the hot bleach
solution I use on the rest of the bottles. Argh! What a hassle. When am
I gonna start kegger? :-)

Subject: Fermenting in donut buckets, and baking bottles

> I happened to be eating donuts at Krispy Kreame tonight and they were
> selling the buckets they get the donut filling in.

Dunkin Donuts also sells the buckets they get filling in, from anywhere
between free to \$2 each. I've bought a bunch of them to use for holding
dilute bleach with all the other hardware that needs to be sanitized, or
to
hold water that's been boiled and cooled, or racked beer while it's being
bottled. I wouldn't use one for a fermenter, since even after dozens of
uses mine still smell slightly like donut filling, and they've got a
rough
textured inside wall, which makes it seem like cleaning wouldn't be 100%
effective. The buckets are presumably food grade, at least to the extent
that Dunkin Donuts donut filling can be considered "food", so using one
as
a fermenter might be worth a try.

> household bleach for more than a few minutes? Let's put that one to
rest.

I don't use bleach on bottles, I just clean them and bake them. Baking
is
no harder than soaking them in bleach, it's a lot less messy, and it's
just
as unlikely that there are any nasties that can survive 60 minutes at 300
degrees. I've got a septic tank, and I don't like the idea of pouring
several cups of bleach down the drain; it does bad things to the flora
that
live in the septic tank and break down the waste.

Where does one obtain Steel Cut Oats? I just flipped through my Jan 22 Home Brewery catalog and didn't find them there. Can I just go down to the grocery and pick up a pound of cut oats?

Also I have a quick question about cracked grains. I only plan to have a small quantity of specialty grains around at any time, and I guess my choices are to buy it cracked or crack it myself. How hard is it to crack the grains myself (using everyday implements; think minimalist kitchen)? How well do already-cracked grains keep, say, in the freezer?

Looking forward to making the Oatmeal Stout!

>Subject: roto-kegs

>i'm soliciting opinions, and this may be one of the
>FAQ's, but does anyone have or have experience with
>the roto kegs, and roto casks?

An additional problem concerning roto kegs:

My wife bought me the 2 gal roto keg awhile back and the problem I am having is that no carbonation is produced if you follow their directions. The directions say not to fill the roto keg more than 2/3 of the way, because if filled further when the CO2 is added it will collapse the keg.

The problem is that the large head space in the keg prevents proper carbonation. One way around this problem is to fill the keg to the top to eliminate the head space, but you must remember to drink 1/3 of the beer the first time you open the keg and then add the CO2.

The CO2 connection on top of the 2 Gal roto keg has two metal "rod" type things sticking up which are used to connect the little CO2 "seltzer" type canister. This CO2 canister doesn't put out enough pressure to artificially carbonate the keg. Does anyone know if there is an adapter for the larger CO2 tanks for this type of connection?

One additional question:

Does anyone know where lids with pressure relief valves for Firestone kegs can be purchased?

Subject: bottle cleaning - old tip

For the sake of folks just getting going, one standard trick for un-labeling commercial beer bottles, which works well with almost all non-foil labels: Soak in warm water with ammonia. The ammonia is remarkably effective on most "permanent" glues that don't yield to straight detergent-water. Try it and let the bottles soak for a while. Most labels just float to the surface.

Second-order tips:

Rinse thoroughly afterward. The ammonia will evaporate, but you don't want glue residue on the insides of the bottles. Use cheap "clear" ammonia--you don't want sudsy 'cause it's harder to rinse off, and the expensive stuff (like Parsons) has crappy cheap perfume that's really hard to get rid of. If the surface of the label is really shiny, score it a few times 1-2 cm apart (to let the soak penetrate under the surface) and soak longer. Use time instead of elbow grease.

I done this several times with no problems. Just treat it like other
food and
don't leave it in there forever. If anything does grow in it, boiling
your
wort should take care of it. BTW, a plastic coffe can lid will fit well
on
most 1.5 kg cans of extract.

The only problem with this is that freezers frequently harbor lots of
bacteria
which can contaminate your ice. Just be sure you have your ice protected
from
the air in your freezer.

One brewpub you might try is the Bandersnatch Brew Pub in Tempe. They have an excellent milk stout and India pale ale. They also sell it by the bottle in several stores in the Pheonix area.

It's easy to find. It's located directly off the ASU campus, directly across from Sun Devil stadium, which can be seen from all over town.

It's also the home of the Beer-in-the-Face Club...

Subject: Rice

I have a friend who doesn't like my beers because they are 'too heavy', even the light ales that start at 1.040. He drinks Bud Light.

Just for fun, I thought I'd try to brew something like Bud, so I followed George Fix's advice in the so-called 'all-grain issue' of Zymurgy. I used one-third rice and two-thirds malted barley and the starting gravity was 1.044. The fermentation was sluggish and after 10 days the gravity had dropped to only 1.030. My usual experience with this yeast (Sierra Nevada) is a complete fermentation in that time.

This reminded me of a barley wine I made a few years ago. I used a lot of rice in that one, too, because I wanted to make a very light-colored barley wine. That fermentation never completed, and I assumed at the time that I had reached the limit of the yeast.

Now I wonder if it's the rice. Those are my only experiences with rice, and both have been odd. In both cases, I cooked the rice separately (brought it from room temperature to a boil in an hour; it looked gelatinized) and then let it cool to 154 and added it to the main mash which was already at 154. I don't have iodine; I just mashed it for the usual hour. I had no problems with the sparge or boil or chilling.

Has anyone else used rice successfully or unsuccessfully?

Does anyone know if cooking rice produces sugars which aren't fermented by certain yeasts? George didn't say what yeast to use, but I assume he meant a lager yeast, and I used Sierra Nevada in both cases. I don't think that's a lager yeast, although at my temperatures (65-70) it appears to be a bottom fermenter.

You have to be careful when you say "sterilized." I think what you mean is sanitized, or just simply boiled. In any case, I do a similar thing. I chill a couple of gallons of boiled tapwater in the fridge and about 8 hours before starting the boil, I stick one in the freezer. It crusts over with ice, but is mostly still liquid. I dump this water right into the kettle after I'm done boiling and get a much better cold break than I used to (simply covering the pot and sticking it into the fridge till I've sanitized the carboy and put 2-3 gal of cold (pre-boiled) water in it). I end up getting less trub in the primary and leaving more in the kettle. My intention is to eventually get an immersion chiller. Then I can do full boils, get better hop extraction, and the only thing I would have to do in advance is start my yeast.

Subject: Washing Soda for Cleaning Bottles

Algis Korzonas mentioned problems with a residue apparently caused by washing soda used to clean bottles in a dishwasher. I also had a long email discussion with Don Wegeng on the same subject.

I certainly haven't detected any film or residue. Nor have my beers exhibited any head-retention problems or soapy flavors. Perhaps this is because I used the soda only in the first phase of my dishwasher's extensive pot-scrubber cycle. (According to the manual, the whole cycle consists of a wash/rinse phase, two rinse phases, another wash phase, and two more rinse phases.)

However, if you're the least concerned about using washing soda, then don't sweat it. Ordinary dishwashing detergent seems to work perfectly. I'm certainly happy with the results, and won't go back to cleaning and sanitizing bottles by hand.

Subject: Phoenix brewpubs (after the trip)

Some interesting results. To the individual that mailed me that there are none - please look again. 8')

To the person who mentioned Jabberwocky - I think you may mean Bandersnatch (which is, after all, literarily related). It is on 5th, about a block off of Mill, right at the University. They have three regular brews (IPA, Premium Ale, and Milk Stout), and a floater (a fair brown ale now). They were the first brewpub in Arizona (ca. 1988). I had samplers, and decided upon the IPA (though in retrospect, I think the Premium was better). The brown and stout were OK (though I still prefer SS Oatmeal). One interesting note - the Pointe at Tapatio is supposedly bringing them in as their house brand (that news from the resort folks, not the brewer). Food (lunch) was quite OK.

There are at least three others in the area. One is at Camelback, and one is at Frontier Town - I don't know where the third is. Two of them are named (oh for such creativity) Hops, and Barley. The other is "something Al's" or maybe the reverse, I think - it's at F.T. The ownership of Bandersnatch, and either Hops or Barley (or both) are somehow intertwined).

Not bad for a few minutes investigation and one lunch, eh?

Cheers...Gary

Subject: Vierka yeast?

< Tonight I prepared a starter using the Vierka mead yeast. At
< least it says yeast on the package. This stuff looks like no dried
< yeast I have ever seen before. It looks more like the non-
pelletized
< form of irish moss, or maybe herbal tea leaves, or maybe sawdust.
< Lots of oddly shaped and strangely colored bits. It does not taste
< like much of anything and I'm feeling no strange side-effects yet :-
>).

I posted a very similar message to the HBD sometime around 6/30/90. I didn't get any replies, so I wonder how widely used Vierka mead yeast is. I don't have anything encouraging to say about it. I pitched it despite its dubious look (after rehydrating) and after four days of no activity, I threw in a couple of packets of Red Star. Fermentation started about 8 hours later.

The best thing I can say about Vierka mead yeast is it didn't ruin the mead. It was a traditional mead, no herbs, spice, or hops, and the only thing I don't like about it is a slight yeasty taste. Since it was my first mead, I can't be sure where the yeast taste came from, but I have my suspicions.

Subject: Chaucer's Mead

I just opened a bottle of Chaucer's Mead, produced by the Bargetto Winery of Soquel, CA. This is a wonderful drink. It is self described as a medium sweet wine and is indeed quite sweet. My two batches of mead and the handful of other homebrewed meads I've tried have been rather dry, which is just fine. But somehow, this mead (Chaucer's) conjures up the images of gods and kings imbibing strong, intoxicating drinks out of mazers. It is 11% alcohol by volume, not incredibly strong by wine standards, and has a very strong honey bouquet. It feels rather thick on the tongue and has just a slight medicinal aftertaste, much subtler than my homebrewed meads. This is the mead I'll shoot for on my next try.

By the way, I was surprised to see it on the shelf because I had read there weren't any commercial examples of mead in the US. Not true any more. Are there any other commercial meads out there? For those of you in the Seattle area, I bought this mead for \$9 in a little wine shop on 45th Ave N. The name escapes me, but it was 1/2 block west of Food Giant.

Subject: I didn't mead to

Since mead is a popular subject today, I think I'll jump in. I was at an Ethiopian restaurant (and great jazz club) called Rassalas two nights ago in San Francisco. Feeling curious, I ordered a glass of "Ethopian white wine" called Orls, which turned out to be mead. They served it ice cold, and once it warmed enough to have some taste it was OK. Not great, but OK.

The Ethiopians also make a passable lager, which I can't remember the name of.

Warning to future Mead Makers: I made a batch with a friend a year and a half ago. We tossed in lots of citrus fruit rind, a pound-and-a-half of cranberries, and a some ginger. It fermented without incident, but the result is all ginger. There isn't even a hint of the fruit or cranberries. The exact amount we used is written down somewhere, but I do remember that we kept it down to a few ounces for the 5 gallons.

Subject: grains

Randy T. asked about cracking grains. I just recently had to crack a couple of lbs. of crystal (my supplier was cleaning her mill). I used a coffee grinder, after having cleaned out any coffee dust. It is one where you press on a button, and it grinds. Stop pressing, it stops grinding. So you can choose your desired coarseness, more or less. It worked very well. As long as you're not planning on all-grain batches, it will serve the purpose (and it works for coffee too....). One thing: it will turn your grain into fine dust pretty quick if you're not careful.

Of course, the old-fashioned (and energy-conscious) way is to crack the grains by rolling a bottle over them.

Russ (in Manchester, NH, site of the 1991 AHA National Conference !!!!)

Date: Thu, 31 Jan 91 09:42:30 PST
From: pms@sfsun.West.Sun.COM (Patrick Stirling)
Subject: Steel Cut Oats & Cracked Grains

Randy Tidd asks

>Where does one obtain Steel Cut Oats?

I got them in a local "real" food store (Rainbow Grocery in San Francisco). They have them in bulk. In case you don't know, they're oats that have been cut up (presumably with a steel blade), into maybe 3 or 4 pieces per grain. The resulting bits are about the size of a large pinhead. In fact I suspect that Scottish "pinhead" and American "Steel Cut" are the same thing.

>How hard is it to crack the grains myself?

I used to crack grains with a rolling pin, it works well. It's a bit of a chore for any more than a couple of pounds though. Now I have a hand operated mill which is great. A large heavy cast aluminium (I think) device with a hopper and a long handle.

>How well do already-cracked grains keep, say, in the freezer?

I've never tried this. I'd recomend cracking your grains as late as possible. I used to get the shop to crack my grains; once I waited several days before brewing, and I there was a noticeable drop in the aroma. The beer turned out fine though.

Subject: New Kegging Idea?

A lot of the readers of this list are probably familiar with the small, approx 1.5 gallon "mini-kegs" that some German beers are available in. I don't remember what they are really called - they appear to be made of a light metal and are barrel shaped. There is a sealed opening in one end that accepts a plastic spigot, which is then gravity fed. There are also inexpensive CO2 canister systems for more long term use (I have one of these).

Anyway, I got to thinking the other day about trying to use one of these for homebrew. Before I cut one open (after drinking the beer, of course) I thought I'd see if anyone else had played with this idea, or had any suggestions. The hard part appears to be refilling the container, but I may learn more after I open one.

Any thoughts?

From: hersh@expo.lcs.mit.edu
Subject: Temp to Age Ales

Louis Clark says in #574 that aging ales at room temperature is recommended.

I have to heartily disagree with that. My reasons are as follows.

1) British Ales (real ale, cask conditioned) are stored at cellar temperatures, which is certainly below 60-70F (say 50-60F). These beers tend

to undergo aging in the keg as they are dispensed.

2) German Ales (Alts, Kolschs) are aged at cold temperatures (see Norm Handys accounts from Germany), typically 30s to low 40sF.

3) Many American brewers such as The Commonwealth Brewing CO. cold condition their beers.

Having Cold conditioned many of my own Ales, I find that this enhances clearing of the beer by forcing additional yeast out of solution. Forces chill haze precipitants to form and eventually settle out of solution if they are present in the beer. The sedimentation of these elements alone will substantially brighten the beer (hence the name Bright Beer Tanks for the process) and remove these components from contributing to the flavor.

Higher temperatures can (not necessarily will) promote oxidation.

- Jay H

PS Boo Hoo Digest #573 never made it. Having just gotten back on after a vacation and job switch I was wondering if anyone else has experienced sporadic digest service, or if I should question (torture??) my local post-master??

From: hplabs!garth!phipps (Clay Phipps)
Subject: Helles Doppelbock & Wyeast #2308 ("Munich")

It's not getting any wetter or cooler out here in Silicon Valley, so this weekend I decided that it was "now or wait'll next year" for the helles doppelbock that I've wanted to brew for a long time. I've also wanted to try out liquid "the one change that will make the biggest improvement in your brews" yeast. I bought a packet of Wyeast #2308

"Munich" lager yeast packet, which struck me as best for a helles doppelbock.

Because of a change in plans a few weeks ago, it had been sitting in its full puffed-up glory in my refrigerator, and I was concerned about its continued viability. So I made a starter from dried malt extract boiled in a pint of water, then cooled. After 24 hours, the starter had a slight kra(e)usen, and the fermentation lock glubbed now and then.

I half-assedly partially mashed Munich malt, crystal malt, and dry malt extract (the latter totaling 4 lbs., the latter 4 oz. (vol.) for enzymes only)

for an hour at 150 F (a real partial mash [cf. Miller] looks like a big time-sink, and what I did apparently extracted plenty of grain goodness)

did whatever the rest is called at 168 F, sparged, then added 10 lbs. of 2-year-old bulk Lodi light malt extract, boiled with Hallertauer and Saaz hops for 1_1/2 hours, let cool, and got an original s.g.: 1.080. 8-] This is comparable to the original s.g. around 1.075 for doppelbocks readily available in California, e.g.: Ayinger Celebrator, Paulaner Salvator

[cf. Fred Eckhardt: The Essentials of Beer Style].

I was looking for last-minute hints and reminders about when it was best to pitch starters, when I found a discussion of #2308 in the Zymurgy yeast special issue: "VERY UNFORGIVING", followed by a recommendation that it be used at temperatures in the neighborhood of 40 degrees F. Relaxing thoughts of sipping the brew on a chilly North Coast April night changed immediately to worry. I have no way to maintain a reliably low fermentation temperature; I planned the brew to be the closest approximation

possible to a helles doppelbock using home "steam-style" technology, hopefully taking advantage of what is typically the coolest time of the year in San "4 years of drought in a row" Jose. Despite my worrying, it was getting late, the starter was whispering "pitch me", so I did. Unfortunately, devoting a refrigerator, closet, or basement corner to the fermenter is not an option--I live in an overcrowded top-floor apartment.

My questions:

- [1] Was my quasirigorous treatment of the specialty grains sufficiently better than just steeping the grains in the brewpot before it boils?
- [2] Just how does unforgiving Wyeast #2308 avenge itself?
- [3] What kind of liquid lager yeast works well for "steam-style" beer?
- [4] Will Wyeast #2308 finish fermentation from 1.080 by itself, or should I expect to use some more alcohol-resistant yeast to complete it?
- [5] How long should I expect fermentation to take?
- [6] Will aging the brew make much of a difference in the implied loss of drinkability caused by unforgiving or avenging yeasties?

[The foregoing may or may not represent the position, if any, of my employer,]

Subject: Recipe Archives

I've a proposal for the readership:

I'm interested in collecting all the recipes I can find from the Homebrew Digest and compiling them into a book.

Here at Intergraph, we have a special publication system that can produce camera-ready copy from text files. It's called DP/Publisher, and I worked in the division that created it, so I'm quite conversant with it.

With everyone's permission, I'll create the book of recipes and send a full set of master pages to the administrator of the Digest. He can do with it as he pleases; I'm sure that anyone who wanted a copy of the book would be willing to pay for it. I ask no money; simply keep my name in the front matter of the book as the person who produced it.

If there is an archive of the recipes available, I'd like information on how to download it or receive it by email.

How does the readership feel about this proposal?

Subject: Recipe Archives

I'd like to throw in my two cents concerning two topics that have been recently in discussion.

Firstly, for those interested in labelling their bottles, I have found a good, cheap method. I created my logo on paper, and reduced it on a Xerox machine to a good bottle lable size. I think I could fit about 6 on a page. I ran tons of these off, cut them up, and stuck them to my bottles with Elmer's Mucilage. This stuff is great. It is very manageable, adheres well to glass, and even stays on when you wash your bottles in bleach. If you want to take your labels off and replace them, it's easier to do so when they are dry, not wet.

I've also been reading a lot about methods of chilling wort. I use an immersion cooler, which is capable of lowering the temperature of 5 gallons of wort from 212 F to 72 F in just a few minutes. To make one of these heat-exchange devices, go to a plumber's supply store and get between 25 and 50 feet of copper tube, about 1/2 in. in diameter. Coil it up so that the diameter of the cooler is suitable to your setup. Bend the two ends of the tube so that they come out of the same end (the top) of the coil. You can fasten some rubber hose to the ends of the tube for water in and out. You might also weave some copper wire through the coils to keep them firmly in place. I hook one end of the hose to my faucet via my bottle-washer, and seal the leak with a plastic bag and some big rubber bands.

Before using the cooler to lower the temperature of your wort, stick it in the pot for the last 10 minutes of the boil to sanitize it, and then run the water through it. This cooler is one of the best toys I have, and I think it is well worth the not-too-great investment to make one.

Subject: Where's the Brew?

I will be leaving Gambier (Nobeer) Ohio to work at Fermilab near Chicago, and I would like some advise on any good regional brews / brewers /clubs et al in the area. I am sure there must be a great variety of cultural fermentation in the area. If a new list of brewing books in print arrives before I depart I will post it (last chance!). I hope I don't miss too many issues of my favorite list!

Subject: Various Comments

The following are some replies on various subjects from Erica Daly. I send her (and others) a copy of HBDS. Any questions or comments she'll see, or send 'em to me direct and I'll see she gets them.

jack.l.webb%office.wang.com
Jack Webb - Wang Labs, Lowell MA

I have been reading other Home Brew Digests and have a few replies:

To make a non-alcoholic beverage for children:

Many grocery stores sell a root beer extract in the baking aisle, next to the artificial flavorings & spices. The box or bottle contains instructions. You will need to buy extract, bread yeast (one packet = 1 tbsp), 5 # of cane sugar. I used 2 liter soda bottles (just bleach or B-brite and rinse). All instructions I found said not to use plastic soda bottles, but if you put them in a cool place (less than 60 degrees) and leave an inch or two air space when bottling, they should not burst. I do not reuse them more than a few times because the plastic does expand.

I tried a few brands. "Party Time" a store brand was terrible. McCormick tastes like store bought rootbeer. Some homebrew supply shops have rootbeer extract. Rainbow Flavors, PO Box 22, Osage Beach MO 65065 sells extracts by the bottle(\$3.95), 6 for \$15, or case \$25. One bottle makes 4 gallons. Flavors include root beer, birch root beer, sarsaparilla, passion fruit, spruce beer, strawbeery, ginger beer, ginger ale, cherry, cream, cola, eggnog, orange, raspberry.

Homegrown supplies:

My brother grew barley last year. He gave me an entire pound to add to my tumultuous porter. I just roasted it at 325dF until it looked ready. He also grew hops which did okay for the first year. Bear Creek Nursery, PO Box 411, Northport WA 99157 has 3 types of hops listed in last year's catalogue (Cascade, old early cluster, tettnang). No barley or other grains listed. Many fruit & nut trees though. 14 varieties of grapes including chardonnay & sauvignon blanc.

Winemaking:

I tried making wine from a Vigneron kit. It was ready in 3 weeks. Any extra aging is an improvement. Most wines should be aged 6 months to 1 year. The kit was from Portugal and contains english & metric measurements. The first thing I did was read the instructions several times, and convert all measurements to english with the aid of the weights & measures table in Webster's dictionary. All utensils must be sanitized with B-brite. There is no cooking necessary. Just warm tap water and cane sugar. The kit contains about 10 packets of pre-measured ingredients to add at various stages. Most of the steps are done on day 1. In a few days, carefully shake the carboy. Several days later add more sugar and water. The last few days there are a couple more packets to add. These later steps are very easy, just mark them on your calendar, so you don't forget them. If you have beer making supplies, then you probably don't need to buy anything else. A glass carboy is highly recommended. I bought my kits (white - was semi dry, & red - was sweet) from Beer Wine & Hobby, Woburn MA 01801-6206, they made 5 gallons wine. The cost was approx 1/2 of store bought Gallo, and tasted much like Gallo wines. There are other wine concentrates that I think you add and measure your own yeast, etc. They are higher priced, and supposedly higher quality. The kit made a reasonable table wine, and was also very good for cooking.

From: Jack Webb <JACK.L.WEBB@OFFICE.WANG.COM>
Subject: Bock Recipe

In HBD #572, Tony G was asking for Bock lore/recipes. While I'll pass on the lore part (I'm far from knowledgable), here's a recipe that worked well for me in the past.

Note that this is for a Dopplebock (double bock), which is a pretty potent brew - fair warning! The recipe is based on the Dopplebock recipe in Papazian's Homebrew Bible.

The Grommator

1/2 pound Pale malt
1/2 pound Crystal malt
1/2 pound Chocolate malt

9.9 pounds (3 cans) dark malt extract
1 pound dry Amber malt extract

3 1/2 ounces Saaz hops (bittering)
1/2 ounce Hallertauer hops (flavoring)

Lager Yeast

3/4 cup Corn Sugar (for bottling)

Roast the Pale malt in the oven at 325 degrees for about 15 minutes or until golden brown. Crack the grains and add to 1 1/2 gallons cold water. Bring to a boil. Just before "serious" boiling starts, remove the grains.

Add the extracts and bittering hops. Bring to a boil. Boil for 60 minutes. Add the flavoring hops and boil for an additional 5 minutes. Remove from the heat, cover and let steep for 15 minutes.

Strain the wort into 3 1/2 gallons of cold water in the primary. Pitch the yeast. Fermentation should start quickly.

Add the Corn Sugar at bottling time.

NOTES:

I used hop plugs on this batch (1st time for me). Wonderful stuff. They expand and give the appearance of using whole fresh hops. They smell great!

I think this had a considerable influence on the taste of this brew.

Strain the wort as much as you can - there will be a lot of "stuff" floating around because of the quantities used.

OUTRAGEOUS fermentation should start the next day and continue for a couple of days before subsiding. I fermented this batch at about 65 degrees for a week, then racked to a secondary. Additional fermentation/lagering continued for 3 more weeks at 45-50 degrees (sorry, no SG readings - I don't bother). I bottled then (rack again - still had a lot of sediment), and let it lager in the bottle refrigerated to about 40 degrees for a month.

IMHO, it came out really well. Very dark and smooth, lightly carbonated, with a considerable alcoholic "whammy". Great sippin' beer.

>*This figure sounds awfully high...could I have misheard it?

OK, here is my understanding. In our modern era of corporate raiders, someone bought out the parent company of Heileman. Of course this person borrowed heavily, leaving the company with a *lot* of debt. It left Heileman with \$780M of the debt.

Whatever you think of the propriety of this kind of action, most analysts feel that Heileman will be able to get out of bankruptcy because it has a solid business (apparently unlike some of the other companies involved in the corporate takeover).

Subject: Re: Steel Cut Oats?

>>>> On Wed, 30 Jan 91 08:20:27 EST, rtidd@ccels3.mitre.org (Randy Tidd) said:

Randy> Where does one obtain Steel Cut Oats? I just flipped through my Jan 22

Randy> Home Brewery catalog and didn't find them there. Can I just go down to

Randy> the grocery and pick up a pound of cut oats?

I'm finishing up drinking an all-grain batch of oatmeal cream stout. My third all-grain, and my best ever, IMHO :-) (very similar to Young's Oatmeal Stout). OK, enough bragging -- if anyone wants the recipe, I'll be happy to send it.

I got steel cut oats at a health food store. Postings here a few months ago recommended them over regular oatmeal. Others have used the imported British oatmeal sold in tins, but I haven't tried that.

Randy> Also I have a quick question about cracked grains. I only plan to have

Randy> a small quantity of specialty grains around at any time, and I guess my

Randy> choices are to buy it cracked or crack it myself. How hard is it to

Randy> crack the grains myself (using everyday implements; think minimalist

Randy> kitchen)? How well do already-cracked grains keep, say, in the Randy> freezer?

I rolled the grains under a wine bottle, in a heavy plastic bag. Not great, but sufficient. I'd be wary of pre-cracked grains sitting around absorbing moisture -- but perhaps I'm just paranoid.

Best of luck on the stout!

Subject: RE>Homebrew Digest #574

Reply to: RE>Homebrew Digest #574
Oats: Regular old Quaker oats work fine! Anything you can get in a food store will do. Just be sure to mash them, and don't over do it with (1lb/5 gal. recipe) quantity or you could be looking at a stuck sparge. Oats get pretty mushy in the mash.

Minimalist Kitchen: A rolloing pin works well for cracking small amounts of grain and if you are just talking adjuncts to an extract recipe, the grain particle size isn't as critical as in a full mash. Use enough pressure to break open the husks to expose the insides of each grain. Don't grind the grain, as this will almost certainly give you too small a size and result in extracting too much of the tannins (or graininess) into the wort.

RotoKegs: GET RID OF IT! Stick with a REAL keggng set-up of stainless steel.
Use the R-Keg on the picnic table instead of a pitcher.

HBD #573: Did we jump a number? I don't seem to have #573 anywhere.

Subject: soaking off labels

A follow up to Dick Dunn's comments in the last issue of HBD concerning soaking off lables from beer bottles with ammonia:

I haven't tried ammonia but I found that clorox and water also works very well if you let them soak long enough. As Dick said, the trick is to let time do the work, not elbow grease.

I'd suggest buying a 15 or 20 gallon trash can. Fill it with water and clorox (or ammonia). Add a couple of cases of bottles and let them soak for a couple of days. You'll be skimming the labels off the top instead of scraping them off with your fingernails.

Alas, I didn't discover this trick until I had already removed about 40 cases worth of beer labels the hard way.

Cheers, | Beer is my business and
Kinney Baughman | I'm late for work.

> gasket? Can I use this as a primary fermenter? (It is 5 gal.) Can I
> just drill a hole in the plastic lid for the blow-by tube or
fermentation
> lock?

Sure. Almost anything can be used as a primary. If you're making 3-gallon batches, you can use it with an airlock. If you're making 5-gallon batches, the blowoff tube will be required. I share your concern about the gasket. If you can't readily find a replacement, you might try giving it 15 minutes in the pressure cooker, but since it was designed for one-time use it probably won't survive. I'm assuming, by the way, that since it was used as food packaging, it's food-grade plastic. It's important that it not be (too) scratched inside, as smooth surfaces are much easier to sanitize.

Subject: Bottle Types

In HOMEBREW Digest #572, Dan Graham asked:

> ... I've seen some notes about bottles. The
> implication was that long neck bottles are better ...
> Do I need to use some special type of bottle ...

Not really. It's usual to recommend using the returnable "bar longnecks", because they're built like trucks. Any bottle I've ever seen that was designed to use a twist-off cap simply looked too flimsy to trust, and there are many on this net who've ended up with a cellar full of "glass grenades" due to a combination of weak bottles and over-enthusiastic priming, incomplete fermentation, excessive ullage, or infection. One thing to consider is the degree of carbonation you wish to have in your beer. I make English-style ales that have very little carbonation, so I can afford to be casual about my glass (though some of my older barleywines are getting pretty peppy!), but someone who likes their beer to go "PSST, DAMMIT!!" when the cap is popped would need to be much more selective.

Some bottles don't work well with some cappers. When I started, I blew \$11 on a two-handled capper, only to find that if the neck was too thick, or the flange beneath the cap too short, I'd break the bottle before the cap was sealed. I sent a lot of otherwise good bottles off to recycling before my wife found a bench capper for \$3 at a yard sale. I haven't broken a bottle or had an incomplete seal since.

For parties, I've used 2-liter screw-top plastic pop bottles. They're acceptable for lesser ales brewed to be swilled all at once within a month of brewing. For contests, Anchor bottles work extraordinarily well, as their shoulder shape minimizes bottom-cake disturbance while pouring, and their dark pigmentation won't convince judges to detect evidence of light-damage, whether any exists or not.

> I'm trying to get some Grolsch bottles but they're
> not common and when full, cost the earth.

Some swear by these, but I've never understood the attraction. I have a few and seldom use them.

Subject: Cooling water

Here's my little trick: Before I start boiling my wort, I put one of those

2.5-gallon bottles of OZONATED (not chlorinated!) in my freezer to chill. I

make up my all-extract wort with 2.5 gallons of preboiled tap water and boil

for around an hour. I dunk my beer pot in a sink of cold tap water for about

5-10 minutes twice. While the wort is cooling in the sink, I pour the bottled

water into my sterilized carboy, then follow with the partially cooled wort.

The results is a wort ready to pitch (around 60-70 degrees F) with a yeast

starter, for which I use about 4 packets or 30 grams of dry yeast.

The water in the freezer should have a little ice in it, but don't worry.

I recommend this method over the "sterilized" ice method for two reasons:

1)It's fast and easy (I imagine a lot of ice trays)

2)It's reproducible-it's easy to measure one bottle

3)It's a great quality control measure (it beats the hell out of D.C. Metro municipal water)

I know that was three, but give me a break, they made me stop using my fingers

and toes years ago. Try it you'll like it!

From: dbreiden@mentor.cc.purdue.edu
Subject: Bottles

I've seen more discussion about what kind of bottles to use. I realize this is a perennial topic and many people are tired of reading about it, but I just couldn't resist throwing in my \$0.02.

I was given a case of Labatt's IPA as a gift. It was bottled in special 125 year anniversary bottles, very nice brown bottles--no label except around the neck--instead, the glass is embossed with a picture of the original brew house. These bottles are beautiful, and I was dismayed when I saw that they were screw-top.

After thinking about it, I decided to try one for homebrew--they are returnable bottles, the only drawback is the screw top. I went ahead with a crown cap. I put it on very carefully. The seal looked pretty good, and the beer carbonated just as well as the beer in "regular" bottles. This one data point was rather encouraging, and I plan to use more of these bottles with my next batch.

I have heard that screw type caps are available in some places. Has anyone actually seen these? Better yet--anyone used them? Is any special equipment needed to put them on bottles?

Regards,
- --Danny

From: Jon Binkley <binkley@beagle.Colorado.EDU>
Subject: Re: Brewpubs in Denver/Boulder

In response to Mark Castleman's query, Denver and Boulder each have one brewpub.

The Walnut Brewery in Boulder is currently **THE** chic spot in Boulder. There is always a line outside to get in. It is where the beautiful people go to be seen. Once inside you get to pay a lot for food and drink beer which is quite chilled and quite carbonated.

While also very popular, you can usually at least get through the door of the Wynkoop Brewery in downtown Denver. The food is decent and reasonably priced. They have a full range of beers, my favorites being the Bitter and IPA, both served from hand-pumps. They usually carry at least one insipid, chilled, over-carbonated beer, too, for those who like that sort of thing.

Gosh, I hope my biases didn't come through!

Hmmm. I have done that in the winter, just putting the container
out on the porch for several hours or overnight and thawing a
little indoors.

For those of us with little free space in our freezers, you can
get a bunch of those *huge* plastic cups that come with lids and
solid plastic straws. I pour boiling hot water in them to
sanitize, cover with plastic wrap, allow to cool to room
temperature, put in fridge to cool further, and put in freezer to
cool even further.

You can pop these huge ice cubes right out of the container into
your wort (a little tricky, they have to partially thaw before
they will come out). Then you stir them in the wort carefully
until they melt. You now have a cool wort you can
siphon/strain/pour into your carboy and add yeast to.

John "The first time is tricky, though, with the timing of
thawing ice, cooling wort, starter yeast, etc." DeCarlo

P.S. A neighbor who ran a homebrew supply store in Arlington had his
water
analyzed and pronounced just fine for brewing ales.

Subject: Re: malt vs sugar for priming

Duane Smith asks:

>What would be the ratio for priming if you want to substitute
>dry malt for sugar for priming.

Corn sugar has approx. 20% more fermentable sugar by weight than
dry malt extract. Therefore, to substitute, weigh your normal
priming corn sugar, add 20% and then weigh out that amount of
dry malt extract.

Subject: bottle labels

Hello all.

For the first time last week I used B-Bright to clean my bottles. This stuff worked great. I soaked the bottles for 30 min in a solution of B-Bright and was able to peel (slide) the labels right off. The stuff costs about 50 cents for 2 cases of bottles and it does not hurt the beer.

Happy Brewing,

MJ

Subject: Gusher

My parents just offered to buy me a 40 qt. stainless boiler for my birthday (I guess I won them over with my partial mash beers at Christmas). They found a pot at a local store for \$95. That seems reasonable from what I've seen on the net. The problem is that this is a standrd stockpot that will cover only one burner. I've found in my 16 qt. partial mashes that it takes an eternity to bring that volume to a boil. I can't imagine getting seven gallons to a boil with only one burner.

Does anyone out there know of a source for a 40 qt. boiler which will straddle two burners (bottom at least 15" across). If not, how do you all-grain brewers do it? Please e-mail responses to me. If I receive any requests, I'll forward whatever I learn.

I found a standalone gas burner at a garage sale a few years ago for
two dollars. It took about twenty dollars of plumbing to connect
it up in my basement brewery. This works great! There's no more mess in
the kitchen, especially if it boils over, but even if it didn't,
there was always a mess to clean on the stove.

Subject: Re: Gusher

Many of my "customers" consider the gusher a trademark of my beer, so I feel qualified to offer my answer to the question of gushers. In my experience, two things cause gushing:

1) Bottling too soon

(This tends to be more a problem for me with darker, more complex beers where I didn't leave the beer in the secondary long enough and the slow, final fermentation was still going.)

2) Infection

(This is where I got my reputation, since I had this infection for six batches in a row. All these beers overcarbonated in the bottle slowly, over a period of 1-4 months. It was a very benign infection in that all of these beers tasted just fine after the foam subsided. I finally cleaned all my equipment and all my bottles thoroughly, and the problem disappeared.)

I suppose that if you keg (I don't), you could add:

3) Over-pressurizing

(The carbonating or the dispensing pressure could be too high.)

Chilling the beer will help in that more of the CO2 will get dissolved in the beer. When pouring the beer, I sometimes put a small dab of margarine on my finger and touch it to the foam -- this helps the foam subside quicker. I have also been known to use skin oil from my cheek or forehead; don't do this to someone else's beer, as you will likely gross them out. I have often thought that it might be possible to gently lift the cap to release some initial carbonation, and then reseal the cap for each bottle in a batch of gushers. I haven't tried this yet.

Clean your equipment. I found that pouring boiling water through the bottles was not doing the job -- when I looked closely I could see a left-over film, so use the bottle brush. Don't reculture yeast from this batch into your next one(!).

Subject: re-use of twist-off bottles, brewpubs in Denver/Boulder

In digest #576 dbreiden@mentor.cc.purdue.edu asks about re-using bottles with twist off tops:

I have been doing this for over a year now with no problems (either with sealing or bottles breaking/exploding). I use one of those fancy Italian bench cappers. I don't know how well other cappers would work. Also, my brews seldom hang around more than a few months. I guess I'm another fresh ale fanatic ;-).

In digest #576 Jon Binkley <binkley@beagle.Colorado.EDU> offers his opinions about the Walnut Brewery in Boulder, and the Wynkoop Brewery in Denver:

Let me offer another point of view. As far as the beer is concerned, I and my friends have all found the the Wynkoop's beers to be somewhat thin and lacking in body. The Walnut Brewery's beers are better in this respect. I particularly enjoy their bitter and their stout. The food in both places is good, with the Wynkoop leaning more towards traditional pub fare, and the Walnut offering more trendy dishes, like duck enchiladas. One has to order with care if one wants to spend less than \$10 for lunch at either place. The Walnut is popular, but if you avoid high traffic times (weekdays 12-1 for example), it's not hard to get seated when you walk in. (Hint: you can get a table in the smoking section much more quickly than in the non-smoking section. Odds are you won't encounter smokers, since no one in Boulder smokes anyway ;-)). Just my two cents.

> these).

A friend and I have both used these 5-liter "kegs" many times. They seem to hold up quite well in the long run, and take a lot of the drudgery out of bottling, since each one holds the equivalent of 14 12-oz bottles. There are a few pointers that we can pass on that might save you some trouble:

- 1) You MUST have one of the CO2 tapper systems, because gravity tapping requires that you punch a hole in the keg to let air in, which obviously ruins the keg. The tappers cost \$8 - \$12, depending on where you buy them. Use the CO2 "sparklet" canisters that RotoKegs and gourmet soda-water makers use. The sparklets are about \$0.50 each, and I generally use 1 or 2 per keg when tapping.

- 2) Be sure to buy only those kegs that have a soft rubber gasket on top. Some brands use a plastic gasket, and these cannot be removed without breaking them.

- 3) Use a flat (standard) screwdriver to carefully remove the rubber gasket--a screwdriver with smooth edges is best since it won't tear into the rubber. (I use the one on my Swiss Army Knife.) The plastic plug that fits in the rubber gasket is most easily removed by adding some water to keg and shaking both the water and plug out at the same time. Be sure that the plug doesn't go down the sink drain!

- 4) When filling the keg, it's handy to have a flashlight to see through the 3/4" hole (with a siphon tube in it) to determine where the beer level is. I generally leave approx. 3/8" of head space, and prime the same as I would for bottles.

- 5) When replacing the gasket/plug combo, work it carefully back in with the screwdriver. Early experiments with a hammer resulted in damaged kegs, which did interesting things later with a very carbonated beer. :-)

- 6) Standard sanitization practices apply. Be sure to sterilize the gasket and plug separately, and re-sterilize after assembly.

I hope I haven't made this sound difficult, because it is a very simple, inexpensive procedure that makes bottling much more enjoyable.

There are three common causes for gushers (in order of probability, IMHO)
:

1) Bacterial infection -- beer was perfectly carbonated two weeks and three

weeks after bottling, then after 4 or 5 weeks began to get overcarbonated.

Solution: re-evaluate your sanitation techniques (plastic fermenters are

much more likely to promote bacterial infections than glass fermenters;

are you putting your thermometer down on the counter then back into the

beer?; is your racking hose all grunged up with stains that don't come

out?; etc.) You can categorize the source of your problem into two general categories: a) before bottling (all bottles gush equally), or b) during bottling (some bottles gush more than others). This will help

you determine where to concentrate your sanitation improvements.

I noticed "Granny Smith" in the name of the beer. Did you add apples? The bacteria could have come from the apples. You can't boil the apples or you will "set the pectins" (I don't know anything about fruit

in beer -- I'm just quoting people who do). Maybe steaming the fruit for a second or two will sanitize without doing much harm [someone with

fruit beer experience please comment?]. Even your yeast could have introduced the bacteria.

2) Premature bottling -- beer was almost flat after 1 week, pretty carbonated

after 2 weeks, overcarbonated after 3 weeks, glass grenades after 4 weeks

(note that this timetable is temperature dependent -- you could have grenades in a week at 75F). Solution: know what your expected final gravity should be and check for it (note that different yeast and other factors contribute to this) to be stable near the expected gravity

for a few days. I, on the other hand, don't follow this advice and just keep the beer in the fermenter for a "long enough" time. Not very

scientific, but I do judge from airlock activity and let it sit an extra

week after the airlock doesn't emit bubbles anymore.

3) Wild yeast -- same symptoms as 1). A more attenuative yeast could have

gotten into your beer somewhere along the way (very likely from the fruit, if indeed you used apples), and was overpowered by the yeast you pitched.

Later, when the yeast you pitched was done with all the sugars it can eat, the wild yeast started munching on the more complex sugars left behind by the pitched yeast. Probably not very likely.

In general, more information is needed to solve problems of this kind: ingredients (including yeast "brand"), temperatures, equipment and procedure. A while ago, I had a few batches with bacterial infections, but I still don't know what was the problem: I improved sanitation in so many areas, that I don't know which one fixed my problem. Once you establish a routine that produces bacteria-free beer, stick with it. After a while it goes fast, but you always have to be conscious to not cut corners on sanitation.

Very observent of you. I didn't figure this out until brewing my first all-grain batch. Besides the time problem, it seemed like the stovetop got pretty hot.

I used my Coleman "Powerhouse" white gas camp stove for a batch or 2. It was much better than the electric stove, but didn't feel it was designed to run that hot, that long. So I sprung for ?35,000 btu cast iron propane burner and lived happily ever after. I think they go for around \$70 now, well worth it.

Subject: I'm Forever Blowing Bubbles ...

In HOMEBREW Digest #576, Jeff Chambers has a familiar problem:

> After eight batches, I've had my first mis-fortune with a gusher. What
> exactly causes them?

Well, that seems to depend on the gusher. Most commonly, it seems to be contamination of some sort. Dry yeasts frequently are the cause of this sort of misery. Edme has had a known problem with wild yeast contamination for more than 2 years. The form this seems to take is millions of beady bubbles, and determined fobbing from the bottle upon opening. Various kinds of bacterial and yeast contamination will produce similar effects. The solution is to change to clean yeast, use a closed fermentor, minimize the beer's exposure to air (especially breezes from outside), and watch your sanitation.

The other major cause is too high a fermentable content at bottling. This can be caused by overpriming, but is more commonly a case of premature bottling. A sudden temperature change can shock the yeast into temporary inactivity, and we're all fooled at some point about whether fermentation really is over. Bottling sometimes rouses inactive yeast, and it picks up where it left off.

A friend dropped off a bottle with the Edme variety of contamination, and I tasted it last night. I couldn't finish it, as it had a strong phenolic taste to it, but that's not usual. The last two batches I made with Edme yeast both gushed, but didn't develop off-flavors until they were almost 6 months old. It was this that finally gave me the "push" I needed to try Wyeast, and I've never looked back. Or had another gusher.

From: David Suda <suda@babbage.Colorado.EDU>
Subject: hops and dextrin

I have a couple homebrew questions:

In the hops special issue of Zymurgy, there is an article on calculating hop bitterness in beer. Calculating the IBUs sounds like a great way to get consistent results, but one thing bothers me. All the calculations depend on the table which lists percent utilization vs. boiling time. Anybody know if this table is for whole or pelletized hops? Is the utilization rate different? What reference was this table taken from?

Another thing I've been wondering about is dextrin (cara-pils) malt. Miller claims it adds "smoothness and sweetness". If this character is due to complex sugars in the malt, why aren't they broken down during starch conversion? Are the sugars in dextrin malt structurally different from those which come from other malts?

While I disagree with some other points of Jon's, I have to give him credit for following the advice some of us have been giving about Boulder for a while--namely "forget Boulder Brewery!" (which he did, completely... 'nuff said there:-).

> The Walnut Brewery in Boulder is currently *THE* chic spot in Boulder.

That may change. Cheer up, Jon...maybe a few yuppies will learn about decent beer in the process. Nothing stays popular with yuppies for too long; they have an attention span seldom reaching a year for anything like this. The brewery is repaying loans and making money...which a lot of new brewpubs never do.

> There is always a line outside to get in. It is where the beautiful
> people go to be seen. Once inside you get to pay a lot for food
> and drink beer which is quite chilled and quite carbonated.

I haven't had to wait much. If they're getting that much business, so much the better...I'd like to see them rewarded compared to Boulder Brewery because their beer is a lot better. I've been there and I ain't beautiful people! The beer is colder than it needs to be, but hardly the maltsicles you get at some bars. To my tastes the carbonation is almost right. (I'm not arguing with Jon so much as offering another opinion.) Some of the food is good; some is admittedly yuppie-silliness. (duck enchiladas? gimme a break!) They'll sort that out as long as they keep making good beer.

The bitter is the best of the lot. Buffalo Gold is good for warm weather or wimpy companions. Forget the wheat. The brown and the stout are OK.

> While also very popular, you can usually at least get through the
> door of the Wynkoop Brewery in downtown Denver...

And that's not Yuppievillage??? A few blocks down from the financial district?

>...The food is decent and reasonably priced...

They need to figure out fish'n'chips...which is *not* supposed to be grease'n'batter with a side of starch. They also need a source of bangers that taste like bangers. Generally the food is good, but they have some notable weak points.

>...They have a full range of beers, my favorites
> being the Bitter and IPA, both served from hand-pumps...

They certainly manage a good set of adequately-hopped beers in English style (which some would call "warm and flat" but which connoisseurs will recognize as "cellar temperature and moderately carbonated":-). Beyond having a very good set of beers and good food, the Wynkoop is of real interest to homebrewers for the particular reason that Russ Scherer (? sp?), the brewmaster, got into this whole thing after winning Homebrewer of the Year at the AHA annual some years ago. (Is Darryl going down a similar path?:-) It's a success story where a lot of brewpubs have done poorly because (occasionally) they couldn't make good beer or (far more often) they couldn't see the difference between homebrewing and running a business.

O,BTW...it's pronounced wine-coop, which can save you two rube-points when you go there.

I have been looking for one of these for quite a while now and as soon as I can commit some space in my basement or garage (too many projects going at any given time) I plan on moving out of the kitchen. That should make my wife happy! Your guess of 35000 BTU is right on and I've watched one of those things bring a double batch of Rocky Raccoon (12 gallons) to a boil in no time flat. My father has been using that burner for a year or so now and he can get his 12 gallons to boil faster than I can with the 3 or 4 gallons that I usually use. I checked around town a bit and found that I can get one from the local welding supply shop for about \$45. I think I'll grab one when I go down there to get the CO2 tank for my new keggng setup. Wish me luck!

I don't know of anyone that uses their kitchen stove for mashing since,
as you
noticed, it takes too long. I know several people who use gas water
heater
burners. You can probably get them for free from people throwing out
dead
water heaters. Most of the time they get replaced due to water leaks and
the
burners are fine. They put out about 35,000 to 40,000 BTU which is fine
for
bringing 5-7 gallons to a boil. I am looking for a 100,000 BTU burner to
use
for 15 gallons. You could hook it into the gas line for your clothes
dryer in
the garage or basement or maybe in the kitchen. I think you can also get
some
parts to make them work with propane.

Subject: Gusher again

Thanks to all who responded to the gusher problem.

From those inputs, I have deduced that the most likely cause for gushing in my case is due to Premature Bottling. Going back over my notes I was in a bit of a hurry (Not Relaxing mind you) to bottle this batch before the Christmas Holiday Season (seeing it is a Xmas beer). This explains why the first few batchs didn't seem to gush at all, while now it splews for a good 5 minutes. I'm not ruling out an infection because Although I clean all the equipment thoroughly when I brew, I probably ought to give everything a good scrubbing. Thanks again for your input.

From: Seth Adam Eliot <se08+@andrew.cmu.edu>
Subject: odd smell

This is only the third batch that I've brewed, but this is a first for this problem.

The beer has an odd "sulfurous" smell. I describe it as "sulfurous" because of its similarity to the "rotten egg" sulfur compound smell. (not nearly as strong or noxious though).

The beer is a Mount Mellick brown ale, made using a hopped malt extract, with some extra hops thrown in for good measure. The smell was evident when the beer was in the fermentor and has carried over to the bottled and conditioned product.

I don't know if it is truly a sulfur compound, and possibly caused by sulfites (used liberally to clean all equipment and bottles), or exactly WHAT it is.

any ideas?

Yes it does work well. I have made light lager with one pound of honey
and 4 lbs extract.
It lightened the body and increased the achol.
Yes the fermentation did last a bit longer and the aging was slowed a
bit also.

Subject: Homebrewed Wort chiller

I've been using a homemade copper coiled immersion wort chiller for 3 years with great results. The main expense is the copper and some copper welding, if you want to get fancy. Just take care how you wrap it. 3/8 inch seems a good diameter to use, although others may find success in larger sizes.

Subject: EKU-28

About seven years ago, when I lived in Southern California, I used to have a beer at a German restaurant called EKU-28. It was about 13 or 14% alcohol. I don't know if it even was technically a beer, but I liked it at the time. (I don't know if I still would). I have tried to find it since and meet with stares and blank expressions. I know it wasn't a fig newton of my imagination, but I sure can't find it or anyone who has ever heard of it out here in New England.

Am I mentally deranged, or is/was there such a thing as EKU-28. If so, is it still made, or can it be approximated at home?

From: R_GELINAS@UNHH.UNH.EDU (Russ Gelinias)
Subject: SN yeast culture

Chris S. had a problem with culturing SN yeast. I've also tried to culture it (3 times), also with no luck. I'm in New Hampshire, and had also wondered if being on the Right coast was the problem. With his posting I'm more convinced that the trip back east is too much for the yeast (pardon the rhyme). I've also noticed that the yeast in *my* SN bottles is not necessarily pasted to the bottom of the bottle (it's mostly on the bottom, but loosely), which is in disagreement with what people on the list have said about *their* bottles having a solid bottom mass of yeast. This may also be an indication of travel-weariness. In any event, I've given up on culturing it.

I have cultured a Wyeast strain from a batch I had brewed in May 1990, so I know it (culturing) can be done, but apparently not with SN yeast back east.

From: Martin A. Lodahl <pbmoss!malodah@decwrl.dec.com>
Subject: Cheap Chillers

In HOMEBREW Digest #577, the celebrated Bill Thacker inquired:

> I've seen ads for immersion wort chillers; priced under \$30, as I
> recall. But it looked to me like they were nothing more complicated
than
> a coil of copper tubing with a hose clamped on each end and a faucet
> fitting on one hose. Seems like that would be easy to make at home
> for under ten bucks. Am I missing something important ? (Like, oh,
> say, "copper and homebrew react to form an unstable fissionable
> compound." 8-)

... and the world, as we know it, will collapse into the
Void. I've seen those ads too, and they remind me that quantity
pricing is a wondrous thing. In my area, the going rate for a 50'
roll of 3/8" soft copper tubing is in the near vicinity of \$20, even
at the "warehouse" stores. Add a compression fitting on each end,
with a 3/8"-male-pipe-to-1/4"-female-pipe bushing and a 1/4" hose
barb, and you're in the \$25 range before you've even looked at the
plastic tubing or the Gilmore fitting or whatever you choose to use.
I've never tried just clamping to the copper, for fear of leaks.

This type of chiller is indeed easy to make, and easy to use. I
believe it to be a Good Thing(tm) to have, but you might as well
make it rather than buy it, especially if you have a cheaper source
than I do for copper tubing. The first one I made used 100' of 1/4"
tubing, and looked like a potful of spaghetti, when in use. My
present one, using 50' of 3/8" tubing, chills faster but uses more
water.

A note concerning maintenance of immersion chillers: with my first
one, I made only a token effort to get the water out of the coils
after use, because it wasn't easy, and because, after all, that
water would never touch the beer, would it? Then we had an
unusually hard freeze, and the chiller burst in many places ...

Subject: Cheap Chillers

To any of you who may be lucky enough to live in dairy country, I thought

I would let you in on a cheap piece of brewing equipment. A milking machine.

Old milking machine pails are great. They are usually stainless steel. Contain from 4 - 7 gallons. Usually come with a sealable lid (though you may have to plug a few extra holes). Best of all, since they are becoming

outdated as dairying equipment, a buyer may be able to buy 2 or 4 of them for \$20 at an auction.

I happen to have one (I've heard they are usefully distilling accessories)

when brewing my first batch of homebrew, so I had planned on using it for a priming pail. Then I smashed my carboy. So I used my milking machine for

a fermenter and bought a second to use for priming.

Milking machine pails can be used on the stove, then don't break, and they have sturdy handles.

Subject: Search for Large Stainless Boiler

I'm going to try one last time.

First, thanks to all who replied to my last post regarding full boils and how one gets them to boil. As you may recall, I was looking for a source for a stainless boiler, 30-40 quarts, which would straddle two (gas) stove burners.

The consensus was "bag it dude." Most suggested getting a 36,000 BTU propane burner which could be used outside or in the garage. I may have to resort to that but I'd rather not brew outside (although I can see the advantage in the summer!) and my wife would be somewhat unsupportive of another capital investment at this point (especially as I am trying to con her into buying a used refrigerator for my brewing. She doesn't like beer.) My wife likes to exclaim "pennies a beer... Hah! But I digress.

I'm certain that I recall a post a few months ago that someone found just the kettle I'm looking for. I've looked through all my back issues and cannot find it. Please, if you're out there, e-mail me!

Finally, thanks to all of you on the net for leading me from rank beginner back in August to seasoned veteran :-) now. Without you I wouldn't be having all this fun brewing now.

From: BAUGHMANKR@CONRAD.APPSTATE.EDU
Subject: Solving boilover

A hint to prevent boilover from EVER happening again.

In case you've noticed, boil over only occurs at the very beginning of the boil. It appears to be a result of a protein "skin" that forms as the wort heats to a boil. When steam collects under this skin and comes forth all at once, as it does once the boil begins, it blows a big wort bubble all over creation.

I started skimming the wort of the creamy white head that forms as the wort comes to a boil and have never had a boil over since.

But doesn't this affect head retention on the beer, you say?

Nope.

Cheers,

Kinney Baughman | Beer is my business and

Subject: uncappable domestic champagne bottles

Advice to people who bottle in domestic champagne bottles:

Before accepting bottles into your collection (and de-labeling them, sanitizing them, etc.), it's a good idea to check and see if they will fit a cap. I used to think they all were cappable, but I recently encountered about 2 cases of Cook's champagne bottles which have mouths which are slightly the wrong shape. It seems to be just this one batch of bottles ... I have a number of other Cook's bottles which cap just fine.

(Fortunately I had enough other bottles to finish bottling the batch.)

You don't have to actually clamp a cap down to test whether it will fit ... just see whether a cap can sit squarely on the mouth of the bottle.

By the way, the beer was a version of Papazian's "Crystal Honey Lager". It's good! I like the honey flavor ... first time I've tried that.

I've seen ads for immersion wort chillers; priced under \$30, as I recall. But it looked to me like they were nothing more complicated than a coil of copper tubing with a hose clamped on each end and a faucet fitting on one hose. Seems like that would be easy to make at home for under ten bucks. Am I missing something important ? (Like, oh, say, "copper and homebrew react to form an unstable fissionable compound." 8-)

30 is pretty reasonable. i was quoted over 40, so i made mine for 20 with some bendable hose from the hardware store. it works OK, but not great. then i realized i needed some washers for the hoses.

i think the wort chiller in the freezer is a good idea. i will try it myself. i usually leave my batches sit overnite with a closed lid since i usually have one too many homebrews while making it and get lazy. anyone see problems with this (i haven't)?

>How much should one add for a 5 gallon batch? How fine should
>the beans be chopped/ground?

OK, I decided I wanted to make a coffee stout (which turned into a coffee ale when I was out of certain ingredients). After perusal of back issues of this Digest, and finding several people saying the 1/2 lb. of coffee beans was too much, I decided to add 1/4 lb. of coffee beans.

So, I bought some French Roast at the store, and just dumped 1/4 lb of beans into the primary fermenter after heating them not to the boiling point in a little water. No chopping or grinding.

In the future, I will use about a handful (1 or 2 oz.) instead, as this still has an overpowering coffee flavor (you can't tell it is beer).

I have seen it at local establishments that carry wide varieties of beers (including a local Safeway) in the Washington DC area, so it isn't a figment of your imagination. You might try the more knowledgeable purveyors of beer in your area, as it isn't available everywhere. It is mildly famous to beer drinkers as being a very high-alcohol beer (I guess more properly a barley wine).

I generally use 1 cup of dry malt to substitute for 3/4 cup of
corn sugar, and have no complaints. I believe the general ratio
is that corn sugar is 100% fermentable, while dry malt extract is
80% fermentable. Your mileage may vary.

A restaurant called EKU-28? Sounds like a great place to me, but don't
eat
and drive! :-)

Dan> It was about 13 or 14% alcohol.

Yeah, the second strongest beer in the world, behind Samiclaus.

Dan> I have tried to find it since and meet with stares and blank
Dan> expressions. ... but I sure can't find it or anyone who has ever
Dan> heard of it out here in New England.

Dan> Am I mentally deranged, or is/was there such a thing as EKU-28.

Those are two very different (and not necessarily related) questions :-)
!

Yeah, I can get it easily enough here in DC; not quite New England. It
ain't cheap, but it's less expensive than Samiclaus. Michael Jackson
waxes
eloquent (for a paragraph or two) in his World Guide to Beer.

Dan> If so, is it still made, or can it be approximated at home?

I believe EKU stands for Erste Kulmbach <something>, and that it is made
in
Kulmbach, Germany. EKU is a *big* brewer.

I've never tried to brew a bock, let alone a dopplebock, and certainly
not
something as heavy/alcoholic as EKU. But I'd like to. Miller mentions
that
there are problems with all-grain versions of dopplebock-class beers, and
employs extract in his recipe.

If anyone out there has got a great spicy dopplebock, I'd love to hear
it.
Anyone brewed a super-high-test batch? What problems did you encounter?
or
did you just use the first runnings from the mash (then make a full-
bodied
beer out of the rest)?

Eku-28 is the barley wine produced by the Eku brewery, the 28 referring to its proof (being 14% alcohol). I assume it is still available although I have not had one in years. I submit to those in the net more experienced in making barley wines about how to go about making it.

I first ran across Eku-28 in a bar in Madison, WI several years ago. The bartender had on a T-shirt emblazoned with the inscrutable phrase "I survived two Eku-28." My companion and I asked him what his shirt meant and he explained that he had gotten it at some special promotion for Eku-28, where they dared the brave to drink a pair of them in one evening. (I hope they had designated drivers. :-) I have tried the brew and frankly did not care for it. Perhaps I got an old bottle but the memory is still so unpleasant that I am not inclined to try it again. (Fortunately, other barley wines I have had have been much better, particularly Old Knucklehead. Yum.) I like Eku's other beers, though.

The front page of Wednesday's (2/6) food section of the Washington Post had an article on homebrewing featuring two area homebrewers. The article describes the process these two use & gives the recipe for making a double batch of a partial mash IPA. If anyone wants me to send them the recipe they use, let me know -- if there is an overwhelming response, I'll post it.

IMHO, the article gave a good introduction to homebrewing. It went into some detail but was definitely written for novices. At the end, it even gave phone numbers and addresses for AHA, BURP (a local club: "Brewers United for Real Potables"), and three local homebrew supply stores (unfortunately none in Northern VA -- does anyone know of any?)

A humorous side note: these two brewers term commercial swill as "lawn mower beer" since it is "beer like Budweiser that you ride around on your lawn mower with."

Happy brewing.

Subject: Thanks and a question about winemaking

First off, thanks very much to those kind souls who responded directly to my question about EKV-28. It seems that it is a doubleback type beer that is available, but not common. I'll have to look further afield than New Hampshire state liquor rip-off stores to find it I guess.

Now the question at hand. I am not only interested in brewing beer at home, I want to try winemaking too. Is there a digest for home winemaking?

Subject: Cheap Chillers

I'd like to add to Martin Lodahl's comments on immersion chillers.

I like to stick mine in the boiler ten minutes before the end of the boil to take care of anything I may have missed when cleaning. The second time I did this, the rolling boil ceased. It took almost ten minutes to resume. The problem was the large thermal mass of the water left in the tubing from last use. Now I run hot tap water through the chiller (160F) to heat the copper, then blow the water out. I've had no problem since.

I got my tubing at a hardware store. 50 ft. for \$10. I believe it's 1/4 inch. Works great. I just press the tubing on; no hoseclamp or anything. I then nested successively larger pieces of hose over the other end, building it up to garden hose size, and attached a garden hose fitting ~\$1.95. A hoseclamp holds that end together. That screws onto my bottlewasher adaptor on the kitchen sink. No leaks, no muss, no fuss.

Subject: Re: Priming Question...

James,

I was in a similar situation a few weeks ago (no fault of my cat :-)).

I was told that taking white granulated sugar, after boiling it with the juice of a lemon is a fine substitute for corn sugar. I did it and it worked quite well. The heat and the citric acid do the magic. I boiled less than a cup of water, added 3/4 cup of sugar, squeezed in half a lemon, and five minutes later, poof! priming material. Good luck with the Kolasabrau!

Subject: Priming Question...

I have a batch of pseudo-Imperial Stout ready to bottle and I discovered last evening that I had no corn sugar (actually I discovered that my cat had torn open the bag...this also explains the white powder all over her nose, I had imagined the worst). My question is, can I prime for bottling

using dry malt? If so, how much should I use (I usually use 3/4 cup corn sugar)? I seem to remember mention of converting between corn sugar and dry malt, but can't remember the rough amounts. So, has anyone tried this?

Will it work? I must know! The Kolasabrau cannot wait!

Subject: deterioration of kegged beer

I have had a problem with homebrew stored in stainless steel kegs (the Cornelius/Pepsi variety). The beer is good for the first 3-6 weeks, but gradually picks up a sour off-flavor. After 10-14 weeks, it is virtually undrinkable. The clarity and head retention remain as they originally were; only the flavor is affected. It happens to all of my beers that I choose to keg (very few at this point) regardless of type of beer, type of process (extract or mash), etc. The more well-hopped varieties survive a bit longer, perhaps. I suggest an infection of some kind; any ideas? The kegs were kept refrigerated with CO2 overpressure, the yeast at the bottom was drawn off until the beer was clear, and the kegs and all known removable parts were cleaned with a dilute bleach solution and thoroughly rinsed before using. I'd appreciate any suggestions/ideas/similar experiences.

Thanks,
Steve Russell

Subject: Priming

With all the recent talk about priming with dry malt or with cane sugar and lemon juice I feel I must add my little bit of heresay:

I know it isn't good practice, but I have had great success priming with plain old white sugar (cane sugar). Maybe my brew needs a little more aging time or something, but I would definitely NOT worry about using it if in a bind. I do plan to switch to corn sugar in future batches-- I'd thought I was using corn sugar all along :-)

Subject: Alex Trebek knocks homebrew

Did anyone happen to see the episode of Jeopardy last week with the homebrewer? There was a guy on, who was introduced as a stock broker as he came out, so I booed him. During the interview section, Alex said something like, "I understand you have a very different hobby."

It was then that the guy said he was a brewer. Alex told him that he knew a guy who brewed and had spent 15 years developing the perfect recipe, and that it tastes terrible, and were this guys beers as bad.

The broker was quick to point out that everyone who tries his brews likes them better than commercial brews, but I don't think he was very convincing in refuting Alex's implied claim that it is a somewhat off-the-wall, semi-crackpot thing to do. Certainly doesn't compete with working crosswords in pen :-)...

Another topic: I built a semi-cheap tubing in the garden hose chiller and am wondering about keeping it sanitized. What do those of you who have these things do to keep them clean? Bleach seemed to leach out some brown colored gunk on a test piece of copper, so I'm not crazy about that idea. I was just thinking of running boiling water through it before use, but I'm also worried about the water that remains in both shell and tube side after its use. If not used for a while, has anyone had any problems with mildew in these systems?

One final question: As a group of us stood outside last weekend experimenting with our first all-grain batch, warming our hands and palates around one of those blast furnace propane burners, the notion as to the safety of the device came up. Does anyone use one of these things inside? I was brought up in a charcoal grill only family (we never used propane or knew anyone who did, except my uncle who had his barbeque blow up in his face once) and was wondering if the combustion is incomplete enough with one of these things such that you get significant buildup of CO to be a health hazard. I already know that you are not supposed to store a tank with fittings in a closed area, incase of small leaks, but what about using it inside? Also, we had the thing at no more than 1/4 throttle, for lack of a better word, and it seemed that anymore could conceivably do serious damage to a cheap boiling kettls. Any comments?

Thanks for any answers.....Mike Zentnerzentner@cn.ecn.purdue.edu

From: Ken Schriner <KS06054@UAFSYSB.UARK.EDU>
Subject: road trip

I am aware of one brewery and one brew pub close to I-70. The first, Boulevard Brewing Company, is located at 2501 Southwest Blvd ("the boulevard" to locals) Kansas City, Missouri. I posted to this group about it several weeks ago. Excellent pale ale. The brewmeister will probably be more than willing to give a personal tour. Phoning ahead may help (816) 474-7095. I believe this brewery was written about recently in zymurgy. (I don't get zymurgy, other netters may have more info about the article.)

Just down the road (I-70) in Lawrence, Kansas, is the Free State Brewpub. I didn't like their beer as much, but it was still great (I think Boulevard's pale ale is fit for gods.) The wheat beer would be very refreshing for a hot day. Free State's porter was delightfully sweet and almost chewy. I don't have an address (somewhere in the 6 or 7 hundred block of Massachusetts street, Mass street, to the locals.) The food at free state was ok, but there is better to be found in Lawrence. Free State has an outside beir garten drinking area that is reportedly very nice (it wasn't open when I was there.)

I travel the road (Highway 71) from Fayetteville AR to Kansas City MO quite often. I'd be interested to hear of any breweries near to this road. (Near being within an hour's detour.)

(Loved the recent idea of using old milking machines for primaries and secondaries and possibly boiling pots. Stainless steel on the cheap.)

Subject: Garlic beer

In response to Jimmy Dee's request for info on garlic beers, I brewed the following recipe last year. It was one of my all-time most popular beers, although I always made sure that people tasted it before I told them what the secret ingredient was.

For 7 gallons:

steep for 30 minutes:
0.75 lb 40L crystal malt
0.25 lb roasted barley
boil for 1 hour:
4.5 kg Munton & Fison dark malt syrup
2 oz Perle hops (7.5% alpha)
1 oz Willamette (4.6% alpha)
3 large garlic cloves chopped fine

1 oz Willamette for finishing
ale yeast
OG 1.058
FG illegible

Next time I make this I'll probably use more crystal and more hops.

Good luck,
Louis Clark

Depeche> 28% Alcohol.

Well, the first is about right -- I think it's really about 12% (Samiclaus is at 14%). That 28% is way out of line -- that would practically make it Scotch!

The 28 *actually* means the OG in Degrees Plato, which translates to an SG of about 1.112.

Subject: patience

I need to add to/correct a couple of my recent postings.....

First, there was a question as to whether it was possible to culture Sierra Nevada yeast on the east coast. Well, at this point it seems that it * is* possible, because after more than 2 weeks of no activity (and just when I was about to throw it out), my SN culture came to life, and now has a nice krausen! So (Chris?), hang in there and be patient.

I also had pitched some re-cultured Wyeast (German ale #1007?), which didn't (seem) to catch, so I pitched some dry yeast, which did catch immediately. I had a question re. what happens to the first yeast in such a situation. Well what happened is that the second yeast did its job, then the Wyeast * slowly* kicked in. In fact, so slowly that I thought the ferment was done, and I bottled the batch. But now I've got semi-gushers that have all the flavor and aroma of a primary fermentation, ie. sulphur, esters, cloves(!),....
. Arghhhhhh! (The clove flavor is interesting; it's alot like the clove flavor in a German wheat beer. Similar strains?) Unfortunately, the batch is barely drinkable.....

I know this is kind of drastic, but would it be possible to empty all the bottles back into a carboy, and let it ferment out?

Anyway, in both cases a little patience (has/would have) helped.....

Subject: Beer one of the oldest, most enjoyed foods

[from _The Washington Spectator_ February 15, 1991]

Beer is one of the oldest and most widely enjoyed foods, according to Alan Eames, who has spent 20 years studying the frothy brew. He writes: "The making of beer--a trade traditionally presided over by women 'brewsters'--was a vital aspect of economic, social and religious life in Sumeria and Babylon 4,000 years before Christ."

In those times, a hieroglyphic symbol for food was a pitcher of beer and a loaf of bread. Pharaohs were buried with miniature breweries to insure a supply on the trek to the afterworld. And beer was the major component in ancient Egyptian medicine. The Vikings used a beer called "Aul" to pump themselves up for their daring raids. Valhalla was "no less than a giant alehouse, where beer kept the company 'in a constant state of bliss.'"

I made my first batch of homebrew. It tastes OK. I did, however, put one six-pack in the frig (at bottling time) and it is flat. I assume that the frig is too cold for the yeast to become active and add the proper amount of carbonation. This is not much of a problem for me, as it is only 1 six-pack. I have a friend who put his entire batch in the frig! It is mostly flat as well.

My question:
Should we be able to remove the bottles from the frig and save the homebrew or is it flat for life?

Subject: Ancestral Brews

Here is a article that you might find interesting.

reprinted w/o permission from County Living, March 1991

ANCESTRAL BREWS

by Christopher Brooks

Historic beer recipes feature a subtle blend of spices.

On display in a small museum in German Bavaria is the oldest beer in the world. Though it was a hot afternoon the day I gazed on this exhibit, my thirst for refreshment wasn't stimulated in the least. Once, during Roman times, this might have been the pride of some Teutonic tribesman; but now, the beer resembled little more than pipe dottle and ashtray debris.

Admittedly, I've long argued that certain beers (namely those containing live yeast cells) will enjoy an improvement in flavor if they are allowed to age for several years. But this German ancestral brew takes that idea a few steps too far: Not even the best-made beer can be expected to last for more than 50 years. It would appear, then, that the suds of yore are gone for good.

Appearances, however, can be misleading. The brewery Dupont (no relation to the chemical firm), of Belgium's Walloon region, produces a beer based on a recipe from more than a full millenium ago. Those who wonder what a beer of antiquity might have tasted like would do well to try this product, appropriately named Cervesia Archeosite. The crisp, clean palate and clarity of this well-made ale may be of a quality far beyond that of its forefathers, but a subtle use of herbs in the brewing lends a certain aura of authenticity to the flavor.

While sipping this tasty bit of brewing history, my mind drifted back to a day in college when the professor of my Advanced Brewing class, Dr. Gustav Bierstube, lectured us on the brewing practices of the Middle Ages. A bent-over, wizened man with a florid complexion and long white beard, there were those of us who felt he had firsthand knowledge of that era. ". . . Und it was very common before hops were discovered for plants, roots and various other vegetable matter to be used to counterbalance zee sveetness of zee malt. Ve know zat much earlier, Egyptian brewers even went so far as to use crab claws, crushed eggshells, and similar sorts of flotsam in zeir concoctions. . . ." The high point came when Dr. Bierstube presented the class with a large bottle of medieval beer he'd recreated using documents from 900 years before. I say high point only because the moment of tasting relieved us for a brief time from that man's long-winded ramblings. The beer itself, unfortunately, was so heavily spiced with oregano, thyme, and bay leaf that it was more appropriately suited for marinating lamb than for drinking.

Cervesia Archeosite proved to me, however, that it is possible to recapture at least a part of the brewing world's past and still make it palatable. Oddly enough, while Flemish immigrants were responsible for introducing the English to hops, it is now their descendants, the Belgians, who are most active today in spicing up the industry. Dupont is just one of many to produce a beer of hoary heritage following a folkloric recipe. Jo Crombe's family brewery, which bears his surname, is the

last in Zottegem to carry on that village's distinctive brewing style. Inherent in the tradition is the use of spices, the exact identity of which Mr. Crombe refuses to divulge. His beer, Oud Zottegems, undergoes a respectable four to five months maturation in tanks, and will continue to improve in the bottle for several years. The sample I tried had been bottled just a few months before, yet the amber liquid showed remarkable clarity. At that age, the aroma is quite spicy, hinting at clove, or possibly coriander. Full-bodied with an undercurrent of honey, the spices integrate well with the malty palate, making Oud Zottegems a tradition worth preserving.

Dried orange peels and coriander seeds appears to be among the most popular of combinations in this area of brewing. The De Kluis brewery pioneered this melange early on, using it for its popular wheat beer. This product has become so successful that no less than five other brewers now follow a similar recipe. There's a limit, I believe, to the amount of flattery a drinker-or brewer-can take when it comes to this sort of imitation. Why not show some imagination and try something unusual in the beer, perhaps juniper berries and nutmeg? That's what the Riva brewery adds to its Vondel: The result is a beer with a mildly spiced aroma and a rich, slightly fruity, off-sour palate. Very pleasing to my way of drinking--er, thinking--but as of yet no other brewers have followed the lead.

By far and away the brewery with the most experience in this field of botanical brewing is Du Bocq, which is located in the Belgian Ardennes. I was dazzled by the heady fragrance when the brewery's director, Baudoin Belot, led me into the large walk-in refrigerator, where a variety of seasonings are stored. In the several oversize sacks around me were the five kinds of spices Du Bocq uses for its various brews. Only the brewmaster knows for sure what blends are employed for each particular recipe, but with coriander seeds, ginger, dried orange peels, star anise, and clove at his disposal, the flavor combinations seem nearly limitless.

As I was feeling somewhat lightheaded when we emerged from the cooler, Mr. Belot thoughtfully directed me back to his office for refreshment. Of the beers sampled, I found the use of spices to be so subtle as to be nearly imperceptible. More noticeable in the bouquet than the flavor, spices here--and in general--seem to contribute something of a complexity or finesse to a beer's palate. I discerned an orange-citrus aroma in St. Benoit; there's a nuance of star anise--and possibly clove--in La Gauloise; Regal Christmas enjoys the slightest hint of clove and ginger root; and Triple Moines's nose and palate are influenced by that old favorite, a coriander-citrus combination.

It should be noted that Dr. Bierstube is not the only one to overdo the use of herbs and spices in his brew kettle. The brewery Huyge, near historic Ghent, produces several fine brews, including Artevelde and Cuvee de Namur, but when it created Minty, a peppermint beer, I found the use of mint leaf by the brewer to be anything but subtle. A similar heavy-handed award goes to Oud Alkmaars, of the Netherlands. Ginger, not mint leaf, is the chosen ingredient here, yet even ginger-ale freaks may find this one has a bit too much "snap."

A far more successful attempt at a ginger ale is made by none other than Boston's Commonwealth Brewing Co. This brew pub is conveniently located just one block from the Boston Garden, the well-known sports arena, and its full range of eight draft and four bottled ales should prove more than ample for even the most athletic of thirsts. Among the draft options is a Ginger Ale that owner Richard Wrigley insists is made with real ginger root added during the fermentation stage. The resulting brew has a delicate, spicy ginger palate, and is much milder than Oud

Alkmaars.

Every year as Christmas approaches, the Anchor Steam brewery treats the beer-drinking public to a special seasonal brew. Labelled "Wassail," this deep, ruby-hued brew fits the English tradition beautifully by possessing an immensely complex aroma of nutmeg, possibly mace, with cinnamon, and maybe even allspice. The flavor of this full-bodied beer is far less intimidating; with an emphasis being on a pleasing maltiness and a nutmeg-hops quality that lasts through to the finish.

Interestingly, Anchor's inspiration for this brew may have come from across the San Francisco Bay, in Hayward, where Bill Owens runs Buffalo Bill's Brewpub. Each fall Owens whips up a garden-fresh batch of Pumpkin Ale, which he describes as being "adapted from a 1776 recipe of Thomas Jefferson." A 10-gallon batch of this historic brew calls for: 16 pounds of pale malt, 1 pound Crystal malt, 2 ounces fuggles hops, 10 pounds of pumpkin (cleaned, sectioned, and baked 1-1/4 hours at 350F), 1 teaspoon ground cinnamon, 1 teaspoon pumpkin-pie spice, and 2 ounces fuggles hops for dry hopping (to be added while the beer ages to contribute a hoppy aroma).

And so it seems that some brewers both here and abroad have brought the drinker full circle through the ages of brewing. We can enjoy spiced beer from the Middle Ages, Pilsner from the 19th century, Pumpkin Ale that revives the spirit of '76, or we can even settle for a 20th-century lager. And while yes, a second helping of Pumpkin Ale sounds tempting, I'm still hesitant about that pint of Egyptian crab claws.

Subject: Re: Coffee in homebrew

In HBD 578 Jon Binkley <binkley@boulder.colorado.edu> writes:

>Has anyone used coffee to flavor a porter or stout?

>

>How much should one add for a 5 gallon batch? How fine should
>the beans be chopped/ground?

pHere is a recipe that I have used several times now with excellent
results.

It's an extract with adjuncts brew but I don't let that bother me. The
Sierra Nevada yeast culture is not terribly attenuative and the last
batch

was a bit sweeter than I'd prefer. Next time I'll use Wyeast's Irish
Stout Yeast that Florian and others have recommended.

This is based fairly on and is still very close to "Baer's Stout" from
Dave Baer of Sun.COM. I call it "Speedball Stout".

4oz Flaked Barley
4oz Medium Crystal malt

6# Dark Australian malt extract
1/2# Dark Australian dry

4oz black patent malt
4oz molasses

2oz cascade (bittering) at 4.7 AAU
0.6oz northern brewers (aromatic) ? AAU
1/3lb Coffee, whole bean (I use Peet's Costa Rican, a fairly dark roast)

We've been using a Sierra Nevada yeast culture for the last few
batches and it's been a very nice brew. Prestarted Wyeast
British Ale yeast has worked well also.

OG: 49 - 51
FG: 17 - 20
Fermentation temp: 55 degF though I've done it much hotter.

Steep 50 minutes at 153 degF: flaked barley and crystal malt

Boil 90 minutes.
Add black patent and molasses at 45 min.
Bittering in thirds each 30 min.

Fill a hops bag with the coffee and aromatic hops and add to the
hot wort just before chilling. If you don't have a wort chiller
you'd better wait until pitching. Remove the bag after about
24 hours or when the fermentation is going strong, whichever is
longer. Rack to secondary once initial fermentation has died
down, about 5 to 6 days. The last couple of times I've left the
bag of coffee beans and hops until racking without over doing the
coffee flavor. This cuts down on the potential for contamination.

From: Mark.Nevar@hp-lsd.cos.hp.com
Subject: EKU-28

I'm probably not the only person responding to this, so I'll keep it short.
The 28 in EKU-28 does not correspond to it's strength, per se. It stands for the original gravity in degrees Plato. Just like bottles of Pilsner Urquell with the 12 on them. PU is brewed to 12 degrees Plato. EKU is brewed to 28 degrees Plato. A measurement once done revealed an alcohol content around 13% by volume. I don't have Jackson's book with me to check. I believe that, like Samiclaus, the alcohol content is not measured with every batch.

>(the Cornelius/Pepsi variety). The beer is good for the first 3-6
>weeks, but gradually picks up a sour off-flavor. After 10-14 weeks,
>it is virtually undrinkable.

Mine also is virtually undrinkable after 10-14 weeks, because it is
virtually gone (usually after 3 weeks, tops.) I have kept a couple
that long and have some suggestions (read on), but my first suggestion
is to drink more, and more quickly. (If only all of life's problems
were so simple.) There has been much discussion about >fresh< beer
and the desirability of having >fresh< beer.

>The clarity and head retention remain
>as they originally were; only the flavor is affected. It happens
>to all of my beers that I choose to keg (very few at this point)
>regardless of type of beer, type of process (extract or mash), etc.
>The more well-hopped varieties survive a bit longer, perhaps.
>I suggest an infection of some kind; any ideas? The kegs were kept
>refrigerated with CO2 overpressure, the yeast at the bottom was drawn
>off until the beer was clear, and the kegs and all known removable
>parts were cleaned with a dilute bleach solution and thoroughly rinsed
>before using.
>I'd appreciate any suggestions/ideas/similar experiences.

I used to have a problem with the large o-ring making the beer have a
slight Coke smell (my kegs are the coke variety.) I soaked them for
several weeks in a very strong bleach solution, changing the bleach
solution many times. It got rid of that problem.

I also note in your post that you may not have removed half of an inch
from the liquid tube in your keg. I have done that, so that the yeast
remains undisturbed on the bottom of the keg. I don't see how that would
effect the flavor of the beer, maybe others care to postulate about that.

Still, drinking it quicker is possibly the best solution.

Subject: Re: Eku-28

In Homebrew #579 Jeff Benson writes:

>Eku-28 is the barley wine produced by the Eku brewery, the 28 referring
>to its proof (being 14% alcohol).

Then later, Depeche writes:

>To the best of my knowledge, Eku-28 got it's name from it's strength.
>28% Alcohol.

I think they're both wrong. If I remember properly, Eku-28 (Kulminator--which would indicate that its style would properly be called a Dopplebock) has a starting *gravity* of 28 degrees Plato. It seems that Europeans are able to parse such figures better than we are; Moretti Doppelmalto (sp.?) has 18 with a little degrees mark on the foil on the neck of the bottle. It's a pretty strong beer in its own right, to give you an idea of how tremendously alcoholic Eku is. Jackson, if I remember right, in one of his books says that it would most properly be served, "in tiny kegs, to be found around the necks of St. Bernards."

Several knowledgeable people in the micro- and pub brewing industry have complained that lots of beginning *professional* brewers don't know about the Plato measure; it's discussed in most of the books on brewing that I have.

Subject: Re: EKU-28

I've heard of and tried EKU-28 and have seen it in a liquor store in Champaign, IL as recently as last October. I don't recall seeing it here in the Chicago Metro area, though. As I recall, it tasted quite alcoholic (I tried it about 8 years ago). You might try Celebrator Dopplebock by Ayinger (sp?) as a substitute for a high-alcohol commercial beer and try dopplebock recipes as a starting point. EKU-28, although I wasn't very fond of it, reminds me of a guy with whom I went to UofI. He bet us all that he could drink 6 EKU-28 in one night. He did (actually he had 6.5 because the guy at the store let us try a bottle in the store). We didn't catch him "calling Ralph on the big white phone" but wasn't that the night that he piloted a dumpster into Boneyard Creek?

Don't you just love the net? One question, two different answers,
and IMHO (backed up by a reference), both of them are wrong! Don't feel
bad, guys, this happens all the time on the net.

EKU-28 is a German Double Bock. The "28" refers to its original gravity
in degrees Plato (which is roughly the same as degrees Balling). 28
degrees Plato corresponds to a specific gravity of about 1.112.

Quoting Michael Jackson's New world Guide to Beer (p. 51):

The alcohol content of the famous E.K.U. Kulminator 28-degree
version has reached a height of 10.92 (13.5).

[The two numbers are percent alcohol by weight and by volume,
respectively.]

I saw quite a bit of EKU-28 in bottles at grocery stores in Munich during
my
visit there last month. In discussing Bocks with the locals, I never
heard anybody mention it. That leads me to suspect it's not one of the
best Double Bocks available in Munich.

WHAT: Second Greater Sacramento Home Brew Fest

WHEN: Saturday, April 13th

WHERE: Robert Nielsen's place
8005 Dana Butte Way
Citrus Heights

We had so much fun last October, that we're going to do it all over again! There were six brewers, with a couple different beer types each. It was interesting to taste a variety of beers made by a variety of brewers!

So, if you live anywhere near Sacramento California, come on over, and bring a beer of your choice. This is two months advance notice, so you even have time to brew a quik batch!

Be careful if you want to bring a brown ale though, (We had 4 or 5 R+R Brown Ale's last time!).

I'll be providing munchies that go together good with beer.

Subject: a couple of questions

Hi,

I have a couple of questions for those of you who are using a beer keg as a brew pot. It seems the only type I can get has fill hole about half way up the side[I think that this is patchable? If it isn't can I leave the wooden bung in?] but otherwise seems ok. Is there anything I should look out for? Anything

I should get done to the keg while it's at the welders? Also would a pair of 30 litres(7.5US gallon)pails be big enough to sparge 15-20 of grain? BTW I will be doing mainly [totally?] infusion mash.

On an unrelated matter does anybody have an all grain version of the raspberry stout that appeared in Zmurgy awhile back?

Thanks

Nick

Subject: Re: Re: Crackin grain

I'm afraid I've deleted the posting, but I'd like to try to answer the question anyway (as best as I can from memory).

There are two reasons to avoid grinding the grain too finely:

- 1) stuck mash -- when sparging the grain, if the grist is too fine, it can "clog" your lauter tun, and
- 2) boiling husks -- if your grist is too fine, you can get husk particles in your boil which is not usually recommended (boiling husks will extract tannins which, in larger concentrations, cause astringency and chill haze (the tannins react with the proteins in the beer and produce a haze when the beer is chilled)).

The literature recommends breaking each grain into 3-5 pieces, however a representative of Briess Malting Co. (sp?) said at a lecture, that many breweries literally powder their Black Patent and don't bother to keep it out of the boil. She didn't say why, but maybe (and this is all pure speculation on my part) the flavor of Black Patent covers up the astringency, maybe there are no tannins left in BP, maybe BP is used in such small amounts by breweries that the effect is minimal, maybe some other reason. Any ideas?

Subject: Aquarium-pump-driven Heat Exchanger?

A few months ago, one of this mailing-list's regulars (Norm Hardy?) reported on his continuing efforts to find an appropriate pump to drive a heat-exchanger-style wort chiller. In the last episode that I read, he thought that he was close to a good solution.

Out here in Too-D*mn-Sunny California, we are entering what looks like the 5th straight year of a drought, and a heat exchanger design for a wort chiller looks like a good way to minimize the waste of our precious water during the brewing process.

Could whoever was working on this project please give us an update, including identifying the manufacturer and model number of the pump used?

Subject: A Trip to Germany & Denmark

A while ago, I mentioned that I was going on a trip that would include Germany and Denmark, and asked for tips. Thanks to all who wrote me. It turned out that I couldn't squeeze in nearly as much beerology into my trip as I had fantasized. Next time, I'll have to make a real beer trip, as this trip only whetted my appetite for some really fabulous lagers. I only make ales at home, so it was interesting to be in the land of real lager, as opposed to the uninteresting commercial lagers we generally have here in the States.

As it turns out, I only have three points of interest worth posting about, one in Munich and two in Denmark. Here are excerpts from my notes:

December 5, 1990, Andechs (near Munich)
The weather in Bavaria is cold and overcast. Last night we had lightning and thunder and rain, but today we had a gentle snowfall.

On October 3, Norm Hardy wrote about the Andechs Kloster brewery, a monastic brewery whose coasters boast "Since 1544." Norm said that they served a Spezial Helles and a Dunkel Doppelbock. Today, they were serving the Helles, but the Bock was a single. I had 0.5 l of each, the Bock with lunch, and the Helles afterwards. Since it's the off-season, the bus from Herrsching was nearly empty, and there was no one in line for the self-serve lunch and beer service. The dining hall was about 1/3 full, populated with local people (some in traditional Bavarian feathered hats and liederhosen) and a few tourists from elsewhere in Germany. A couple from Hamburg were the only other people at my table. (It's a little weird being a solo tourist.) However, I have nothing but good things to say about avoiding the tourist season.

On to the beer: The Dunkel Bock was a deep, reddish brown, and crystal clear. The nose was aromatic with hops, but not overpowering. The flavor was perfectly balanced, without any cloying sweetness or bitterness. There was a hint of caramel in the foreground. The finish was clean and hoppy. This was an amazingly smooth beer. In many lagers, you get a strong malt and a strong hop flavor/bite. In this bock, the hop and malt flavors were so completely blended that I could hardly tell where the malt ended and the hops began. This can only come from patient aging.

The carbonation was fairly low, and the head died fast, but the lacework stayed on the glass mug until the busser took it away and dumped it into a

tub of water. The lacework was a visual clue to the great mouthfeel of this beer. The beer was fairly low in alcohol taste for a bock, but I could feel the effect after finishing 1/3 l with lunch.

The Spezial Helles shared many of the fine characteristics of the Bock, so I'll concentrate on the differences. The color was medium golden, and the head was rocky and short-lived. The flavor was a bit more bitter, since there wasn't the caramel flavor of dark, sweet malt. The bitterness lingered long and pleasantly on the tongue, nearly 30 seconds!

Both the bock and the helles had very, very small bubbles, less than 0.1 mm in diameter. Also, both seemed higher in alcohol than your typical homebrew recipe, but then again, I'm still suffering from jet lag, so that could be it. There wasn't an alcohol taste to these beers. And I'll say it again: I've never had smoother beer.

December 19, 1990, Copenhagen
On September 25, Chip Hitchcock (cjh@vallance.eng.ileaf.com) mentioned a brewpub in Copenhagen near the main entrance to Tivoli. Of course, Tivoli was closed in December, but a friend and I managed to find the place. (It helps to know that a main entrance is called a hovedingang in Danish).

The name of the place is Bryggeriet Apollo (The Apollo Brewery), and it seems aimed pretty squarely at a tourist crowd, judging from its location near one of the biggest tourist attractions and from the prices (19 kroner for a 25 cl glass of lager). That works out to nearly \$3.50 for an 8-oz. glass. According to the nice-looking bilingual (Danish/English) brochures they had at each table, the "slim 25 cl glasses" are to make sure "that the dense foam will not collapse and that the beer will not go flat while you are enjoying it."

This is not to say that it wasn't worth it. Despite its tourist orientation, the interior was very nice, an airy multi-level brick building decorated yuppie style with the hand-made (then-East-)German brewkettles prominently featured in the middle. The front of the pub was a deli/pub area. More restaurant-like sections were downstairs and in back up half a level. The place was not crowded (another time I was glad to be travelling in the off-season). We sat in front and sampled the two brews available in December, their standard Apollo Lager and Jul 01--Yule Ale, or actually, Christmas Lager. (That 0 stands for a slashed O.)

The Christmas Lager was amber, with good head retention (maybe those slim glasses work!) and lacework. The unfiltered beer was slightly turbid. The flavor and nose were subtle and well-balanced, much less assertive than a German lager, and smooth and clean. There was a pleasant hop aroma. The

finish was clean.

After that, we tried the Apollo Lager, which was actually very similar in both appearance and characteristics. The only differences were a slightly lighter color and a lingering, pleasant hops aftertaste.

That was that, and then it was off to the train station.

Earlier, the conference I was attending went on the Carlsberg tour. This was a huge operation. It was interesting to see the accreted buildings, with 19th-Century neoclassical stuff alongside modern ultrautilitarian industrial buildings. The best line out of the tour came out of the narration of the multimedia presentation they have: "Carlsberg Brewery," the narrator intones as the film shows shots of the statue of Thor in his chariot that decorates the pinnacle of the old brewhouse, "is not the oldest brewery in the world, but, with each passing year, it becomes older."

The tour included a tasting of several beers. I didn't take any notes, but I recall that the two best beers were a reproduction of their first beer, a dark, somewhat sweet lager from 100 years ago (also mentioned by Chip) and a black-label premium lager. Their other beers were pretty boring, really, considering Germany was only a few dozen km to the south...

Subject: Beer deterioration in Kegs

10-14 weeks!! You're just not drinking fast enough! Beer is a fresh product, and its flavor will change over time. I have been using 3 gallon kegs. I have been typically cold aging them 1-2 weeks to allow the beer to settle and brighten. This is similar to the lagering that German Ales undergo (as per Norm H's discussions from his trip to Germany). I then try to drink them in the next 3-4 weeks. I think that 10 weeks is the upper limit. I have noticed that even in this time frame the flavor changes. I doubt you have an infection Steve, just a fresh living product susceptible to flavor changes.

The one suggestion I would make is to perhaps change your yeast. What yeast do you use?? The type of yeast will effect how long the beer can survive. Even after chilling there will be yeast in the beer (unless you cold filter) and the properties of the yeast strain may have an effect.

I've been using Whitbread Ale mostly of late.

EKU-28 does exist, and is (IMHO) one of the vilest substances sold for
human
consumption. It is clear and reddish, and is similar in flavor to Thomas
Hardy or Old Nick ale, but far harsher. I first tried it at Bertha's in
Fells Point, Baltimore; and before long we were using Oatmeal Stout as a
chaser. I've seen it in many of the better beer stores in the
Baltimore/Washington area. Not sure how you would make it -- doesn't
yeast die off at around 10% alcohol content? -- but it is probably
similar
to a barley wine. Like them, perhaps the flavor mellows with age.

BTW, I'm getting ready to brew my second batch (a porter), am new to this
digest, and am enjoying it immensely.

From: Douglas Allen Luce <dl2p+@andrew.cmu.edu>
Subject: Distributor-type kegs

I am considering brewing the beer for a party in March. I figured I'd whip up something fairly light to appease the masses.

My limited experience to date (all of 6 months worth) has been restricted to bottled beer. I figure that for the volume this party might require, I should go keg.

Money is my driving factor for this venture. Of the kegging discussions I've read in the digest, I've only come across obscure references to anything but soda cylinders.

What I'm wondering is if a half-keg (the normal distributor-type 15 gallon barrels) can be employed as a dispensing vessel with any luck.

I figure that I could get three of these on deposit, yank out the stuff in the neck, clean it out with some sort of solution, fill it full of the fermented beer, prime it, replace the stoppering setup, and let it carbonate naturally. Then I could use a hand pump (from the distributor) to dispense the beverage.

Since getting the CO2/regulator/support is prohibitively costly for me, this seems like my only (and best) alternative (other than buying the kegs full).

I've no idea how to undo the lock on the keg, no idea how it should be cleaned, no idea if the carbonation can complete successfully in this vessel. I figure that there must be answers to these questions.

Auxiliary considerations are aluminum/stainless steel. I figure I'd bite the bullet on the metallic taste aspect, and not worry about this alheimers crubbage right now. And, since the consumption would be in a single day, I'm not worrying about oxidation due to the hand pump.

Thanks in advance to anyone who would share their experience with me.

Subject: Question : Final Gravity too High ?

Is this going right ???
I'm not sure if I'm worrying too much or not, please help.
I have a batch of brown ale (per Dave Miller's recipe) sitting quietly in the carboy as we speak(type !). Anyway, here is what's happening, I put this batch in the carboy on the 21st of Jan., the yeast I used was cultured from a Sierra Nevada bottle (several actually). The fermentation started out like normal, creamy white head on top of beer, bubbling every 4 seconds or so. After 3 days the airlock was no longer bubbling, so I assumed the fermentation was complete
- -- WRONG. The gravity was still about 1029 after starting out at 1035, so I racked the beer into a second carboy at which point fermentation began in earnest once again (bubbling every 4 seconds or so). In fact, it's bubbling at an unbelievable rate, it's overflowed, the house is full and it's oozing out into the drive way. Anyway is this good for the grass?? (Just Kiddin) :*(
)
Next after approx. 8 days it slowed down to 1 bubble/minute, so I racked into another carboy, checked gravity - THE PROBLEM - it's still at 1022, it has been sitting in this carboy for 2 days with no signs of any activity. Now my question is, could this be the final gravity or should I consider pitching some other type of yeast ??

The recipe is a variation of the brown ale in Dave Miller's book, I am a beginning brewer (just a few batches under the belt).

1 cup black patent
2 cups crystal
1 cup dextrin
1 lb. brown sugar
1 oz. fuggles
1/4 oz. cascade (finishing)
1 3.3lb can of John Bull light extract (unhopped)
1 lb. domestic light dry malt extract

I made a batch identical to the above last time without the dextrin malt and used M & F yeast in it and the final gravity came out to 1005. So the only difference is the dextrin and the Sierra Nevada yeast. Could the dextrin malt change the final gravity by that much ?? By the way, my friends and I thought the last batch WAS outstanding.

Sincerely,

Low on homebrew and possibly thinking about worrying !!

Subject: Wort Overnight

In HOMEBREW Digest #578, tim "Where's My Shift Key?" wicinski asked:

> i usually leave my batches sit overnite with a closed lid since
> i usually have one too many homebrews while making it and get lazy.
> anyone see problems with this (i haven't)?

Neither have I, but I've gotten the most alarming reactions when I describe this approach. After the boil, I chill the wort down as much as I reasonably can, first by running tap water through my immersion chiller, then switching to recirculating ice water. Usually I get down to the low 40's to mid 30's Farenheit, depending on ambient air temperature and the volume of ice, in about an hour. I then strain this icy wort through my (sanitized) lauter tun to separate it from the hops, and leave it overnight in a capped carboy. By morning the break material has neatly sedimented out, and the wort has warmed up to a reasonable pitching temperature, so I dump my yeast culture into the fermentor, and rack the trub-free wort in on top of it. Works great.

The usual stated objection to this is infection. I'm not all that concerned. Any critters landing in the wort during the hops straining operation (the only real opportunity) would be rendered comatose by the cold. Unless I let the wort sit all day, it's unlikely they could recover in time to gain an advantage over the yeast. As a practical matter, they never have yet. The key is getting the wort cold enough, fast enough.

Subject: mashing equipment

I saw the discussions about finding a burner big enough to boil large quantities of liquid last week. Saw some info last weekend that I just remembered. Service Merchandice has on sale (as we speak) a 135,000 btu propane setup. The burner was about \$50.00 and used a standard gas grill tank & fitting setup. The tank was about \$19.00. These prices may be off a bit but the whole thing was pretty cheap I recall.

Second I have been playing with a way to control temperature of small mashes that I have been using in partial mash recipes (getting my feet wet for the real thing :-)).

I have an old electric frypan which has a thermostat to control the pan temperature. I fill the pan with water and set my mash kettle in it. I then set the thermostat to the "desired" temperature and sit back and watch. Notes,

1) The thermostat is pretty crude on these things so I had to play around to find the settings which achieved the desired mash temperatures. When I found them I re-marked the dial on the thermostat.

2) I'd achieve even better control if I wrapped insulation around my mash bucket.

I've only done this for small mashes (2.5 - 3.0 gallons) but have had good results. I'm so glad I didn't throw it out when I tossed the Ginsu knives and the Salad Shooter.

-Jim

Subject: EKU-28

In response to the EKU-28 mail messages I read last week, allow me to quote
from Fred Eckhardt's "The Essentials of Beer Style":

"The high alcohol content [of doppelbocks] lends a 'barleywine' flavor to some, and indeed doppelbocks do fit the barleywine profiles, except they are bottom fermentd. ... [Eisbocks] are extra-strong doppelbocks created by freezing the beer ("ice-bock"), and removing some of the water in the form of ice. This has the result of concentrating the beer, making it much stronger, and sweeter-tasting on the palate." He includes EKU 28 in this category and provides a profile of EKU 28 as having 9.3-9.4% alc/wt (i.e., 11.6-11.8% alc/vol) with hop ibu levels of 26-29.5. EKU 28 gets its name from the fact that the original gravity expressed in Plato units is between 27.5 and 28.8.

Indeed, as someone else responded, it is available at many Washington D. C. area Safeway food stores and liquor stores. I haven't had it in ten years but I certainly remember thinking the taste wasn't good enough to want me to have it again. Plus the price has been jacked up to about \$12.00 a six-pack! Still, next time I'm up there, I'll buy a bottle. I'd rather spend that kink of money on something that tastes good like any Samuel Smith's product. As an aside, if one must try EKU 28, then one must try Samiclaus. In the DC area, Samiclaus used to be available at Safeways and many liquor stores. But this year it was harder to find with the response of many liquor store owners saying "it doesn't taste good, it doesn't sell well, and it costs a lot". And for the last two years, they discontinued brewing their "pale" and now only offer "dark". The good news is the stuff ain't bad after keeping it around for a year or two!

Subject: Rotten Egg Smell

Seth Eliot writes:

>This is only the third batch that I've brewed, but this is a first for
>this problem.

>The beer has an odd "sulfurous" smell. I describe it as "sulfurous"
>becuase of its similarity to the "rotten egg" sulfur compound smell.
>(not nearly as strong or noxious though).

>any ideas?

In "The Complete Joy of Home Brewing", Papazian writes (page 109):
"Occasionally homebrewers will experience a rotten egg aroma in their
fermentation. This is not an unusual occurrence of fermentation. It is
caused by certain strains of yeast that produce hydrogen sulfide that is,
in turn, carried away by carbon dioxide. Changing your yeast will remedy
the problem".

As only a beginner myself, I can't add any information to the guru's
statement!

Subject: Beer deterioration in Kegs

10-14 weeks!! You're just not drinking fast enough! Beer is a fresh product, and its flavor will change over time. I have been using 3 gallon kegs. I have been typically cold aging them 1-2 weeks to allow the beer to settle and brighten. This is similar to the lagering that German Ales undergo (as per Norm H's discussions from his trip to Germany). I then try to drink them in the next 3-4 weeks. I think that 10 weeks is the upper limit. I have noticed that even in this time frame the flavor changes. I doubt you have an infection Steve, just a fresh living product susceptible to flavor changes.

The one suggestion I would make is to perhaps change your yeast. What yeast do you use?? The type of yeast will effect how long the beer can survive. Even after chilling there will be yeast in the beer (unless you cold filter) and the properties of the yeast strain may have an effect.

I've been using Whitbread Ale mostly of late.

EKU-28 does exist, and is (IMHO) one of the vilest substances sold for
human
consumption. It is clear and reddish, and is similar in flavor to Thomas
Hardy or Old Nick ale, but far harsher. I first tried it at Bertha's in
Fells Point, Baltimore; and before long we were using Oatmeal Stout as a
chaser. I've seen it in many of the better beer stores in the
Baltimore/Washington area. Not sure how you would make it -- doesn't
yeast die off at around 10% alcohol content? -- but it is probably
similar
to a barley wine. Like them, perhaps the flavor mellows with age.

BTW, I'm getting ready to brew my second batch (a porter), am new to this
digest, and am enjoying it immensely.

Subject: Distributor-type kegs

I am considering brewing the beer for a party in March. I figured I'd whip up something fairly light to appease the masses.

My limited experience to date (all of 6 months worth) has been restricted to bottled beer. I figure that for the volume this party might require, I should go keg.

Money is my driving factor for this venture. Of the kegging discussions I've read in the digest, I've only come across obscure references to anything but soda cylinders.

What I'm wondering is if a half-keg (the normal distributor-type 15 gallon barrels) can be employed as a dispensing vessel with any luck.

I figure that I could get three of these on deposit, yank out the stuff in the neck, clean it out with some sort of solution, fill it full of the fermented beer, prime it, replace the stoppering setup, and let it carbonate naturally. Then I could use a hand pump (from the distributor) to dispense the beverage.

Since getting the CO2/regulator/support is prohibitively costly for me, this seems like my only (and best) alternative (other than buying the kegs full).

I've no idea how to undo the lock on the keg, no idea how it should be cleaned, no idea if the carbonation can complete successfully in this vessel. I figure that there must be answers to these questions.

Auxiliary considerations are aluminum/stainless steel. I figure I'd bite the bullet on the metallic taste aspect, and not worry about this alheimers crabbage right now. And, since the consumption would be in a single day, I'm not worrying about oxidation due to the hand pump.

Thanks in advance to anyone who would share their experience with me.

Subject: Question : Final Gravity too High ?

Is this going right ???
I'm not sure if I'm worrying too much or not, please help.
I have a batch of brown ale (per Dave Miller's recipe) sitting quietly in the carboy as we speak(type !). Anyway, here is what's happening, I put this batch in the carboy on the 21st of Jan., the yeast I used was cultured from a Sierra Nevada bottle (several actually). The fermentation started out like normal, creamy white head on top of beer, bubbling every 4 seconds or so. After 3 days the airlock was no longer bubbling, so I assumed the fermentation was complete
- -- WRONG. The gravity was still about 1029 after starting out at 1035, so I racked the beer into a second carboy at which point fermentation began in earnest once again (bubbling every 4 seconds or so). In fact, it's bubbling at an unbelievable rate, it's overflowed, the house is full and it's oozing out into the drive way. Anyway is this good for the grass?? (Just Kiddin) :*(
)
Next after approx. 8 days it slowed down to 1 bubble/minute, so I racked into another carboy, checked gravity - THE PROBLEM - it's still at 1022, it has been sitting in this carboy for 2 days with no signs of any activity. Now my question is, could this be the final gravity or should I consider pitching some other type of yeast ??

The recipe is a variation of the brown ale in Dave Miller's book, I am a beginning brewer (just a few batches under the belt).

1 cup black patent
2 cups crystal
1 cup dextrin
1 lb. brown sugar
1 oz. fuggles
1/4 oz. cascade (finishing)
1 3.3lb can of John Bull light extract (unhopped)
1 lb. domestic light dry malt extract

I made a batch identical to the above last time without the dextrin malt and used M & F yeast in it and the final gravity came out to 1005. So the only difference is the dextrin and the Sierra Nevada yeast. Could the dextrin malt change the final gravity by that much ?? By the way, my friends and I thought the last batch WAS outstanding.

Sincerely,

Low on homebrew and possibly thinking about worrying !!

Subject: Double Diamond recipe

In the last issue Chris Hudson asks for a recipe for an Ale like Double Diamond. I have tried to make DD three times now - this recipe came reasonably close:

9# Pale ale malt
1# crystal malt
3/4# Brown sugar
1/2# malto-dextrins (presumably ~3/4# cara pils would do the same)
2 Oz Williamette (60m) 1/2 Oz (steep) (AAU's unknown, but DD isn't a bitter beer!)
Infusion mash @ ~156F
Whitbred dry yeast
IG=51 FG=10 (my sparge wasn't too efficient then)
1/4# lactose at keggng

My notes say that it was close in flavour but a bit light in both colour and body compared to the real thing.

From: sherwood@adobe.com (Geoffrey Sherwood)
Subject: sourness

It never occurred to me, but I think I have a keg-sourness story as well.

My wife is very enamoured of cider and I have attempted to make several batches. My first attempt (many, many moons ago when I was still in school) worked beautifully, using 5 gallons of fresh-pressed Macintosh apple cider, various spices (cinnamon and nutmeg, I think), 1/2 cup Jack Daniels (mixed with the spices to extract their oils), 3 lb corn sugar, and pasteur champagne yeast. This I bottled. It was so-so for the first two months, then got *lots* better. I was quite pleased with the result.

So, when she asks, I say sure -- cider is easy! Sure it is. I tried three batches in Miami, ambient temp 80F. The yeasty concoction tasted *horrible* even after several months bottle aging. Fine -- probably fermented to warm so the yeast taste predominated. After moving to the SF bay area I tried again, this time using the Ironmaster cider concentrate and fermenting at 60 degrees. I didn't understand about campden tablets, so I screwed up the first batch (I put the air lock on after adding them). The next batch I covered with a towel for the first 24 hours to allow the SO2 to escape. The batch took about a month to ferment. At the end of it, I tasted the result: a bit bland, but no off flavors! I keg it, priming it like I do my beers. After a month I chill it and taste it -- it is starting to get a real sour taste. Not a pleasant sour taste, but a rotten one. After a month in the refrigerator (maybe cold aging would help the taste???) the sour taste got so bad I could see there was no help for the result and poured it down the drain.

After the posting of a couple of days ago, I have inspiration: maybe just storing in the keg is the problem. I still have a dozen cases of bottles from my bottling days, so I will give bottling a try.

Has anyone out there seen similar results from cider?

After cooling the wort to the 40F range, you could warm it back up
to pitching temperature by running hot water through your immersion
"chiller".

Subject: Cleaning Flow-Through Chillers

In HBD #580, zentner@ecn.purdue.edu (Mike Zentner) asked about cleaning and sanitizing a tubing-in-the-garden-hose flow-through wort chiller.

I have this kind of chiller. All I do to keep it clean is to run a couple of gallons of boiling water through it before and after each use. Do this with the chilling water turned *off*, obviously, so that the entire length of tubing gets good and hot.

I also knew a guy who cleaned his chiller with some electric dishwasher detergent (Electra-sol, or whatever) in hot water. "Poor man's caustic," I think he called it. I'd probably try that before using bleach on copper. But, I think that if you rinse with boiling water *promptly* after each use, that will be all that's needed.

Subject: pump for chiller

Clay Phipps asks about a suitable aquarium pump to drive an immersion wort chiller.

I don't have a wort chiller, but I do have a marine aquarium. My main filter is driven by a Project RS-500 pump. This delivers 500 gallons per hour at a 4 foot head. That translates into a really amazing mess when you start the pump while the outlet hose is resting on top of the tank instead of inside the tank.

The pump cost around \$60.00. It's fully submersible, and has a large prefilter to keep crud and bits of ice from getting into the impeller blades. It should be perfect for a chiller -- just fill a 5 gallon tub with water and ice, stick the pump in the bottom, plug it in and let 'er rip.

If you don't need 500 gph flow rates, you can get by with what fish people call a powerhead. This is a very small submersible pump, usually offering a flow rate from 60-150 gph. Powerheads cost from \$15-\$35.

Get a magazine called Freshwater and Marine Aquaria and check the mail order ads in the back for the best prices on this stuff.

I have not done any kegging, so I cannot comment on that.
However, I *have* brought beer to parties.

Personally, I would bottle the beer in the 2 liter soda bottles
(save some from some other party, rinse them out, then sanitize
with a bleach solution). For a 5 gallon batch, this works out to
be around 10 or so, not unreasonable for bringing somewhere, and
really very little work at bottling time.

I am not so sure about keeping beer in those plastic containers
for long periods of time, but for a short while before a party
they are perfect, IMHO.

From: Tony Plate <tap@ai.toronto.edu>
Subject: Re: Question : Final Gravity too High ?

I have had a similar problem with my last couple of batches.

In the most recent one I used a yeast starter cultured from a bottle of Chimay.

The recipe was a partial mash for 5 gallons:

7 lb Pale Malt Extract (20% rice malt, I think)
2 lb Munich
1 lb 2-row pale
3 oz Crystal
1.5 oz Black Patent
8oz "Brew Body"
.75 lb Honey
.75 lb Demerara sugar

2oz Goldings
2oz Hallertau

I mashed at around 150F for 1 hour, sparged with 160F water, then boiled for an hour.

I topped up with cold (pre-boiled) water to 5g and pitched the yeast at 75F. The yeast took a while to catch, but after a few days it was very active, with a thick layer of brown stuff on top in the primary.

OG 1064 @ 67F
Day 5 1050 @ 64F
Day 7 1032 @ 63F Strong fermentation
Day 11 1022 @ 65F Fermentation seemed completely finished -
no bubbles, no froth left on top.
Racked to secondary, fermentation seemed
to start again
Day 15 1020 @ 64F

I am at day 22 now, and the fermentation is still going on in the secondary, but very slowly. It tastes and smells good.

I checked my hydrometer - it reads 1000 in water at 60F.

Anyone get any suggestions on why the fermentation stopped early? Might it have anything to do with the rice malt in the extract? - I've used this in my last two batches. My plastic primary has some visible scratches, could nasties be getting in there and causing the fermentation to end prematurely?

If I bottle it at 1020, should I add any priming sugar?

Subject: Bottle Size

I recently had an experience with homebrew that I have never seen addressed anywhere before. Last week (2/6) I bottled a batch of bitter ale (5 gallons). Normally I bottle entirely in 25 ounce bottles for convenience. However, this time, because I like to sample early and sample often as the beer conditions, I put up a few 12 ounce bottles. In any case, I sampled one of the 12 ounce bottles on 2/11 (5 days after bottling) and found it to be the best homebrew I had ever experienced. I was, needless to say, delighted! I then sampled another bottle last night (2/13) along with two friends (with whom I wanted to share this glorious experience), so I opened a 25 ounce bottle and it was mediocre to poor... barely any head and just not sufficiently conditioned basically and a rough around the edges feel. My question is, can bottle size effect the end result of conditioning? Can it effect how fast it takes beer to condition? Or, was this most likely a mere statistical fluctuation.

From: ken@oldale.pgh.pa.us (Kenneth R. van Wyk)
Subject: lagering conditions

I've made quite a few lagers now with the help of my Hunter AC thermostat, and one question continues to haunt me. Why do my primaries take so long to complete?

As an example, I brewed my latest lager (named Auld Lang Stein) on New Year's Eve using 8 lbs Klages and .5 lbs dextrin malt step mashed at 135F (15 minutes) and then 155F (60 minutes) for a rather dextrin-rich wort. I'm using Wyeast Bavarian Lager yeast (can't recall the number) that's been started in a 1 pint bottle and always has a good krausen going before being pitched. After cooling the wort, I filter out the hops and pour it into the primary carboy (with a 1" OD plastic hose blow-by). The pouring is done by a siphon hose, but with the hose end suspended well above the wort; I'm quite sure that the wort is getting properly aerated (but please correct me if I'm wrong). Finally, I pitch at about room temperature and let the primary start rockin-n-rollin before putting the carboy in the fridge, which is at 52-54F.

Still, my primaries take about a 4-5 weeks! The beer tastes (IMHO) super - silky smooth lagers that I'm extremely happy with. But, at 1 month+ per primary (and about 3-4 weeks of secondary), I'm very limited in the amount that I can brew. I'm not worrying, honest I'm not. I'd simply like to brew more lagers and I'd really rather not buy yet another refrigerator. :-)

If anyone has any ideas and/or suggestions as to why this is happening, please (!) let me know.

Ken

P.S. To the guy who asked about using a sawed-off keg for a boiling kettle, look for Annheuser-Busch (Budweiser) kegs. I realize that you're from Canada, but surely this bud-crud gets imported there?!

P.P.S. To the guy who successfully cultured Sierra Nevada yeast on the East Coast - be careful! I tried the same thing a while back and ended up with something that can best be described as EVIL. Perhaps it was in my method, but the culture had a great krausen going and certainly looked and performed like a healthy culture. Make sure that the culture smells and looks great before pitching it into a batch of beer. Don't count your yeasties before they're batched. (Sorry, incorrigible punster...)

From: dinsdale@chtm.unm.edu (Don McDaniel)
Subject: Bruheat Experience

I'm going to stir up some controversy.

I'm seriously considering a Bruheat system for both mashing and boiling. I just called a mailorder house for info and was told that they don't carry the product because it scorches the grains. He felt there was no way to get good results from it. He suggested I talk to someone who has one. So all of you who have one... what do you think of it? Do you avoid scorching by stirring or have you not seen a problem? I'd also be interested in what kinds of beer you brew. Naturally Porters and Stouts would be less revealing of such a problem than say, Pilsners.

Assuming that mashing can be accomplished successfully, how does it boil? How long does it take to get to a boil after sparging? The guy I spoke with said they're ok for boiling but not sparging. I'm not interested in paying for a thermostatically controlled heater just to boil.

I'm eager to start all-grain brewing and the idea of automating part of the process is appealing.

E-mail or post as you see fit.

have chilled new brew, and later found it flat. He asks:

> Should we be able to remove the bottles from the frig and save the
homebrew or
> is it flat for life?

Probably recoverable. The area I have for beer storage gets cold in
the winter, often colder than the inside of my refrigerator, but
carbonation always develops, eventually. I've had it take as long
as 4 weeks before a batch could really be said to be carbonated, but
it's never failed me altogether.

In HOMEBREW Digest #580, Ted ...

> ... received a 10 liter EDME brewkeg that has tap problems. The valve
> (attached to a threaded cam) does not lift properly when the knob is
> twisted. Anyone have any hints? I sent this tap back to the CELLAR
> in Seattle and they put it back together but the same thing happens.

I've never seen the EDME keg so I'm guessing here, but from your description, the tap sounds to me like the British-made "drum tap". This is an excellent tap, and I use one on my lauter tun, but it does have this one annoying habit. The actual closure is effected by a thick synthetic rubber cap that fits over the end of the valve stem. On mine, that cap came loose after about a year of use, and at inopportune moments would close by itself. Sometimes I could force it back into place with a dowel, and sometimes it was necessary to empty the tun by some other means. A real drag.

I finally disassembled the tap by forcing aside the turn-stop rib and turning out the stem. If anyone knows a better way to do this, I'd love to hear it. To keep the cap in place, I used a drop of cement, and reassembled. No trouble since.

Subject: High Final Gravity

In HBD 581, Tony Plate says he brewed a partial mash with

... 2 lb Munich
1 lb 2-row pale
3 oz crystal...

and mashed at 150F. His FG is a disturbing 1.020.

I'm no expert, but I'm working on it :-). I spent much of the past weekend studying brew chemistry in Miller's book. From what I read, this is my guess:

That mash temp is quite high and would result in de-activating the alpha-amylase enzymes and retarding the activity of beta-amylase (the best compromise temp for both enzymes is 121F. pH is also important at this point and should be 5.0-5.5). The result would be poor breakdown of the malt starches to fermentable sugars and hence a high final gravity. This situation is worsened by the fact that much of the grist is Munich, a high-kilned malt in which much of the enzymes are already deactivated.

My guess is that your fermentables are already eaten up. Hence you should use the normal amount of priming sugar.

From: polstra!jdp@uunet.UU.NET (John Polstra)
Subject: Re: Bruheat Experience

In HBD #581, dinsdale@chtm.unm.edu (Don McDaniel) asked about using the Bruheat system for mashing, sparging, and boiling. I've been using one for almost 3 years.

> So all of you who have one... what do you think of it?

It works just fine once you figure out its limitations and stop trying to exceed them.

> Do you avoid scorching by stirring or have you not seen a problem?

With any reasonable mash thickness, the Bruheat **will scorch** when the heat is on, unless you stir constantly. Forget any "set it and forget it" dreams that you might have been entertaining.

I almost always perform a 3-step mash, as follows:

Protein rest: Put 1 quart of hot water per pound of grain into the Bruheat. (E.g., for a recipe that uses 8 lbs. of grain, use 2 gallons water.) Turn on the heat and raise the water to 132 degrees F. Turn the heat off and leave it off. Stir in the grains. The temperature will settle around 123 degrees. Let it rest 30 minutes, stirring every 5 minutes. Do not turn on the heat, or I guarantee you'll get scorching. The Bruheat is simply a bucket at this point.

First saccharification step: As soon as the protein rest has begun, put about 1 quart of hot water per pound of grain onto the stove to boil. At the end of the protein rest, add about half the boiling water to the Bruheat. Stir well and measure the temperature. Add more boiling water if necessary to achieve the desired temperature. (Depending on the beer style and the types of grain, I usually aim for around 150 degrees.) Stir every 5 minutes. Let this rest last for about 10 minutes, depending on the style of beer. If the temperature drops too much during this rest, you can turn on the heat. But be sure to stir constantly while the heat is on. Stir in such a way that the current from the spoon is blowing across the heating element.

Second saccharification step: Turn on the heat and stir stir stir (your arm will get tired). Monitor the temperature and remove the heat when you achieve your desired temperature. Depending on the style of beer, I aim for up to 158 degrees. If your thermometer has any lag at all, you will have to compensate for it by turning off the heat a little early. When you reach the desired temperature, turn off the heat and leave it off. Let this rest last until conversion is complete (usually around 20 minutes or so). If the temperature sags too much, turn on the heat again and stir until you've got it where you want it.

Mash out: Turn on the heat and stir until the temperature reaches 168 degrees. Turn off the heat and let the mash rest for at least 5 minutes.

A couple of additional points: (1) Forget the thermostat, it's virtually useless. (To mention just one deficiency, it's **not calibrated**!) You have to be there stirring anyway, so control the

heat yourself by hand. (2) It helps to insulate the bucket by wrapping a folded towel around it and securing the towel with a bungee cord. Also, set the lid on the Bruheat when you're not stirring. (3) It helps enormously to have a low-mass fast-response electronic thermometer.

> I'd also be interested in what kinds of beer you brew. Naturally
> Porters and Stouts would be less revealing of such a problem than say,
> Pilsners.

Using the above methods, I've had excellent success even with light lagers. When you clean the heating element at the end of the brewing session, you can tell right away whether any scorching occurred. (For that matter, you can smell a scorch instantly when it happens.) I haven't had a scorch for a long time using the Bruheat.

> Assuming that mashing can be accomplished successfully, how does it
> boil? How long does it take to get to a boil after sparging?

It works fine for boiling, although I don't use mine for that any more. As I recall, it takes it about 15 minutes to boil 6 gallons from sparging temperature. I sparge in a separate bucket, but I use the Bruheat to keep my sparge water at 168 degrees. It works great for that, and that's one time when I do get some use out of its thermostat.

Why use the Bruheat, I hear you asking? (1) It has enough oomph to raise the temperature of a mash very quickly. (2) The element has low thermal mass so that when I turn off the heat I see almost no temperature overshoot. These two properties permit me to actually achieve my desired mash temperatures and schedules, to within say 1 degree F. and two minutes of time.

Subject: Your Dream BrewPub!!

What would be at your Dream BrewPub? I am looking for ideas to include in a business proposal that I am writing for an Entrepeneurial class at school. I got the idea after starting to homebrew a few months ago:-) Who knows, if it looks good, I might even start the business.

Currently, my brewpub experience is limited to one visit to the Allegheny Brewery here in Pittsburgh. (Of which I was quite impressed) Other than that, I only know what I have read in several newspaper articles.

Several items that I would like feedback on are

- 1) What do you think of the establishments that you have visited. What are their strong points. What do you feel their weaknesses were.
- 2) What type of food did they serve and was it good? Was it worth the price?
- 3) What types of beer did they serve? How much did it cost?
- 4) If you owned a brewpub, what types of beer and food would you serve?
- 5) How much money do you spend when you visit a brewpub. How much of this is for food, and how much is for beer.
- 6) How often do you go?
- 7) What would make you go more often?

Any other help such as were I might find statistics on the brewpub and microbrewery industry would be appreciated.

I will post a summary of the results on the board.

Subject: Cider

My partner and I have been working for some time on making some
cider that would approximate Strongbow Dry Cider. Our first batch, using
Pastuer Champagne yeast, was a very cloudy (and VERY strong) batch that
left a lot of people puddles on the floor. To insure the continued
viability
of our friends, we switched to Red Star Ale yeast. The batches worked
out
much better, with much shorter fermentation times. We ferment the stuff
in
the gallon glass jugs that it comes in, the only addition being a
fermentation
lock stuck in the neck. It seems that any sort of pastuerized cider will
work.
(What is the difference between juice and cider) (Or wine and hard cider
for that matter?) We add 1/2 c of cane sugar to each jug before pitching
the yeast (Wedon't really care if it tastes cidery!) and let it sit for
about 1 1/2 weeks.
We don;t know how well it keeps, or whether it improves with age, since
it
never stays around very long.

Subject: making beer green

[I see folks are getting started in time this year...usually we seem to end up waiting 'til the first week in March.]

The usual bar method of making beer green for St. Patrick's Day is to put a drop of green food coloring in the glass before drawing/pouring the beer.

This level of coloring doesn't work out well for homebrew colored before bottling, 'cause something seems to latch on to the color and precipitate it out. I don't know just what grabs it, but I've seen a pale-green beer with bottle sediment of a most amazing hue. Also, given a homebrew with substantial malt, hence good color, the green food coloring (weakened a bit) with the gold of the beer gives a rather unpleasant (IMNHRNWO) color.

Several years ago, I made a batch of beer for a going-away party on 3/17, with which I attempted to produce multiple colors in one batch. (The batch was labeled "SPA" on the caps, allowing everyone to think it was "St. Patrick's Ale", when in fact it stood for "strangely polychromatic ale." :-) I left some bottles plain and added red, green, or blue coloring to various others. The red worked out OK, although I didn't use enough color and it faded a bit, giving a result approximately like a darker amber ale. The green gave the aforementioned bile (vile?!) green. The blue did best at producing the shade of green I wanted; I'd suggest this basic (blue+gold) => green approach.

The color seems to continue fading with age. That shouldn't be too much of a problem since if you start today you'll only have a few weeks in bottle/keg.

Subject: Re: Drum Tap

I may have fixed the EDME BREWKEG tap. After polishing of the keg of SCUD bock (named for its exceedingly high carbonation due, I think to WYEAST 1007 [strange and sulphurous, beasties,they]), I dissassembled the tap whlie still attached to said keg,, sterilized it and put a smidgen of vaseline in the threads. I made sure that it did not touch the beer passage.

I kept the keg full of H2O for a day in the fridge andto test, I tried the tap

(It works like a champ....for the time being)

Now it's full of bitter/brown and I'll say more in about a week.
PS: At Richmond Brewers we were discussing WYEAST 1007 and came up with the question "What would typify a German ale?" We couldn't come up with any regional or style type that would fit WYEASTs 1007 name?

Bashon regardless, Ted

Subject: Aeration

bryan@tekgen.bv.tek.com writes about stuck fermentations and aeration.

While I can't comment for sure on the first issue, it seems like a lot of people go through a lot of unnecessary trouble to aerate their wort. Prior to pitching, I remove the red spring loaded thing from my bottle filler, sanitize the white plastic tube, and put it in the neck of the carboy and just whip the heck out of the wort for a few minutes. When I'm done, there is usually a good 2-3 inch head of foam on top. It seems when you whip the tube around, the fluid passing by the submerged end of the tube causes air to be bubbled in to the point where you can hear it. Anyhow, it must work pretty well, because until recently, I have been letting my wort sit overnight to cool (just built a chiller) and I'm guessing that warm wort can drive off dissolved oxygen pretty well. I typically pitch a 12-18 oz starter made with a wyeast packet in the morning, immediately after this aeration process. Fermentation will usually take off full blast within 8-10 hours, sometimes even sooner.

This method seems to work better than just attempting to slosh stuff around in the filled carboy and is easier than rigging up some bubbler pump.

This will probably not work well with a 5 gallon filled primary. I use a 6.5 gallon carboy, so there's a good amount of head space to get up a good velocity on the tube.

Naw -- just torque 'em off.

Duane> Do you use pipe thread tape on the treads to prevent leakage. I'm
Duane> also assuming that you can use a standard size wrench to remove
Duane> these.

I used pipe thread tape -- figured it had to help, and that Teflon
wouldn't hurt me or my beer, even if there were contact.

I have some problems getting at the thing with a box wrench because the
rubber boot/handle interferes with it. So, I'm trying to locate a
socket (7/8", I think) which is deep enough to accept the valves and
reach
the flat sides; not much luck, so far -- nothing deep enough, but perhaps
a
spark-plug socket would work...

In HBD #581, Randy Tidd (rtidd@ccels3.mitre.org) asks about using green food coloring for a St. Patrick's day beer:

> I was going to add some green food coloring at priming time... would it
stay
> in solution or sediment out? Do yeast like green food coloring? What is
in
> green food coloring, anyway?

Well, my friends and I did exactly this about a week ago for our latest batch of pale ale. It takes a fair amount of food coloring to tint five gallons of beer. (I didn't measure it, but probably about 1/4 to 1/2 of one of those tiny squirt bottles you get at the grocery store.) The color we achieved was, well, interesting. It's more of a sludgy green than the typical St.-Patrick's-Day-green-beer green. The beer was named "Pond Scum" after we saw the color. On the positive side, it's still green, the yeasties are fine, the beer carbonated well, and it tastes great. I think it will go over fine on St. Patrick's day.

If you want to shock your brother, beer like this should do it. :-)

From: dinsdale@chtm.unm.edu (Don McDaniel)
Subject: Large Canning Pots

In HBD #582 Craig Flowers asks "where are the large enamel canning pots"

As I'm the one who stirred all this talk up, I guess it's up to me to summarize.

Craig asked about 36+ quart pots. I've not found anything that large except for 40 qt. stock pots in stainless or aluminum. The best source for these appears to be Rapids in Cedar Rapids MI. Sorry, but I don't have the address here at work. Feel free to mail me if you're interested.

As for enamel, I looked all over town here without success. A thorough catalog search revealed the following:

-

8 gal. enamel over steel (~16.5" diameter)\$35

The Home Brewery
P.O. Box 730I've ordered one of these and expect it this
Ozark, MO 65721 week.
800/321-BREW

-

8 gal. enamel over steel \$32
w/chrome spigot\$45

The Cellar
14411 Greenwood Ave N.
P.O. Box 33525
Seattle, WA 98133
206/365-7660
800/342-1871

--

After a long and arduous search, I have determined that there is no such thing as a 32+ qt. stainless pot which will straddle two burners. The best bet is to get an enamel pot and be more diligent about stirring.

Yep - I'm in San Jose, CA, in the east hills, an area which is very warm and dry. My Cascade is sprouting like crazy right now. This will be the third year. The Willamette has not sprouted yet; in general, it has been much less productive and vigorous than the Cascade.

I propogated the Cascade last year by digging straight down with a sharp shovel to separate two bunches of sprouts at the root level. One I left, and one I moved to another hole. Worked great - I'm planning on repeating this year with both the Cascade and Willamette.

>the alpha-amylase enzymes and retarding the activity of
>beta-amylase (the best compromise temp for both enzymes is 121F.

I hate to suggest this, but you're going to need to go back to the book and study those temperatures a little further. 121F is a good temperature to effect what's known as a *protein rest*, but will never allow any starch conversion.

I mash my body-ful beers at about 158F; for dryer beers somewhere in the low 150s seems appropriate.

Subject: To Keg or not to Keg

I'm a new homebrewer with bad eyesight. Bottling is one of the most difficult tasks for me, I either get them far too full, (all over my shoes) or two-thirds full, neither is acceptable. I have read a lot about keggling in this digest, but most of the discussion is by those already into this. I see in the Foxx catalog that I can get a keggling setup, complete, I think, for around \$200.

Now, my questions, if I may. What are the downsides of keggling, not counting the cost of the equipment. Does the keg need to be refrigerated, (I assume so, but I thought I'd ask)? Can I transfer directly from the secondary, or primary if that's all I use, to the keg? How long does the beer remain good in the keg? Is there more of a problem with freshness as the get becomes empty? If I make a half batch of a new brew, can I keg that, or does the keg need to be filled.

I guess those are enough for now. Sorry I can't just pick up a book and read all about it, but I haven't found any homebrewing books on tape yet. Thanks to any and all for your patience and, hopefully, answers.

Subject: High Final Gravity

I was having some misgivings regarding my last post so I looked it up in Miller's book, and sure enough...I was wrong.

150F is a perfectly normal starch conversion temperature. When I said 121, I was thinking of a protein rest temp. Furthermore, it is the beta-amylase which works at low temp and the alpha-amylase that works at higher temps.

So...please disregard my previous comments on the cause of the high final gravity. Next time I'll value accuracy over speed when formulating a response.

From: Chris Shenton <chris@asylum.gsfc.nasa.gov>
Subject: kegging -- excessive foam and low carbonation

A while ago, I posted a tale of woe, trying to get my first keg batch to carbonate. My second through fourth (most recent) had similar problems: excessive head, but rather low carbonation. I primed with 1.5L saved wort (at about 1.060, 1.050 and 1.080SG, respectively), according to calculations a la Noonan. After Florian's recommendation, I reduced the CO2 pressure to sane levels, which meant I rarely had to apply CO2 from the cylinder.

Now, the third batch, a stout, began to develop nice carbonation after maybe 3 weeks, and the froth seemed to dissipate. I don't know if this is due to sufficient aging, or reduced pressure in the keg due to consumption of beer. The second and fourth batches didn't survive long enough in the fridge to tell, really (tasted too good :-), although the fourth sat in the keg at cellar temperature for 3 weeks before cooling. Some of this may be due to the high gravities, I'm not sure.

Anyone else encounter similar behavior? When I bottled, I always got textbook carbonation -- maybe even a little too much, and the froth was normal for style(s)...

I've just put a fermenter full of lager (based on Norm Hardy's Andech's/Munich -- thanks!) in the fridge, and I could use some hints on fermenting and lagering it. (eg: if `lagering' the period *after* priming?
or does it apply to the whole cold-ferment, cold-prime, cold-store thing?
)

Thanks again!

Subject: Stuck Fermentations, O2 content, and MY working answer

I agree with Brian Olson (HBD #582) that these problems are caused by low O2 in the wort. The easiest way I have found is to drop your cooling water (I use a 2.5 gallon bottle of artesian water that has been cooled to near freezing) through a funnel into the primary. The water splashes about merrily and gives it plenty of time to pick up oxygen. This is followed with pouring the wort (remember it should be somewhat cooled, since boiling hot wort can hold almost NO oxygen) into the fermenter to mix with the cooling water. I have brewed about 10 batches like this and all the ferments have been complete. Admittedly, I once brewed a heavyweight barley wine that took a pitstop halfway through the ferment, but that was before I started working with this method. A quick note about cooling with ice. As sterile as it might be, ice contains almost no oxygen either, losing it all in the process of freezing. This may also contribute to a stuck ferment. Give it a shot.

From: polstra!norm@uunet.UU.NET (Norm Hardy)
Subject: Lagering

A question was raised about lagering. Since the word means "to store" one must imply that the beer has finished or just about finished fermenting. The storage could be considered in the secondary or the bottle or keg. Personally, I see no value of lagering for more than a month before bottling. Then, and this takes patience, I let the bottles remain at the lagered temperature until they are consumed. Sometimes I run out of fridge space, so the basement floor has to suffice.

With the Hunter Airstat hooked up to the fridge, here is a typical lager:
Primary: 65 - 48f - 53f for 3-4 weeks. The raise up to 53 takes place during the last 4-5 days (diacetyl rest)
Secondary: 48 - 38f for 2-4 weeks.
Bottling: 44f or thereabouts.

Trying not to shock the yeast, I change the temperature a maximum of 4-5 degrees a day.

Carbonation has always been satisfactory, with enough time in the bottle.

Subject: Heat Exchanger Pump

In HOMEBREW Digest #580, Clay Phipps asked:

> A few months ago, one of this mailing-list's regulars (Norm Hardy?)
> reported on his continuing efforts to find an appropriate pump
> to drive a heat-exchanger-style wort chiller. In the last episode
> that I read, he thought that he was close to a good solution ...
> ...
> Could whoever was working on this project please give us an update,
> including identifying the manufacturer and model number
> of the pump used?

Clay may have been thinking of a series of items I posted a year ago concerning my Search for the Perfect Pump. At the time, I was using an immersion chiller fabricated from 100' of 1/4" tubing, which restricted the flow rate to the point where I doubt that much heat was picked up by the last 75' of the coil. My present chiller uses 50' of 3/8" tubing, and no longer requires all the waste-gate whigmaleeries I needed with the other chiller.

The pump I've settled on is a Teel 1P579C. Scarcely larger than a pint beer bottle, this pump has two garden-hose fittings, and connects to any 117v grounded outlet. It's not silent, but is a lot quieter than an electric drill. I have no idea what it's flow rate is, or what it cost (a friend was cleaning out his garage, and ...), but from the quality of its construction, I would imagine it's not cheap.

Subject: Filtered Air

In HOMEBREW Digest #582, Bryan Olson offers:

>I've seen a few postings about fermentations that stopped at a high F.
>G,
>then seemed to restart for a little bit after racking.
>
>My 2 cents as to why this happens is there was not enough oxygen in the
wort.

Hmm. I don't think that's the cause. Fermentation truly gets under way when the oxygen in the wort is all gone, the mitochondria have shut down, and the yeast have gone anaerobic. Commercial producers of bakers' yeast have discovered that the key to maximum yeast production and minimum alcohol production is lots of oxygen. In effect, alcohol is a waste product of the yeasts' anaerobic metabolism. We aerate the wort to help the colony multiply rapidly after inoculation.

>Is anyone using sanitize/sterilized air or medical oxygen to oxygenate
thier
>wort? If so, I'd like to hear what they are using.

This topic came up at the last meeting of my homebrew club, and it seems that at least one of the members has been using filtered air for some time. His filter is a length of large (>1") plexiglass pipe, which he packs full of sterile cotton, and hooks to an automotive air compressor. That must move enough air to really froth-up the wort! I have no more information than that.

Subject: What!!!??? Support MADD???!!! You *MUST* be on drugs!

In Homebrew Digest #584 STAFINIAK@hermes.psycha.penn.edu posted an announcement of an upcoming homebrew competition at the Dock Street Brewery to pick a new beer recipe for them to brew. He said that the registration fee of \$5 would go to MADD.

I question the wisdom of beer drinkers giving money to a group that seems to be increasingly losing its focus on the problem of drunk driving and stepping up efforts to make it more difficult to buy beer and other alcoholic beverages. Their track record seems very poor in this regard. If memory serves me correctly, I believe they were instrumental in forcing states to raise drinking ages, that they supported tax increases to the brewing industry, and that local chapters have been seeking limits on liquor licenses and generally making it more difficult for people to buy or sell beer, wine, or other alcoholic beverages.

I'm sorry, but there is absolutely no way that I will give one red cent to neo-prohibitionists. If MADD focuses ONLY on public education effort and legislative effort to increase penalties for convicted drunk drivers, then fine, I will support them, but as long as they seek restrictions on the free trade of alcoholic beverages, then I feel that NO homebrewer, brewery, brewpub, retailer, or consumer of beer wine and liquor, should give MADD any money.

Why stroke the mangy cur that bit you?

From: andy@wups.wustl.edu (Andy Leith)
Subject: Stuck fermentation

While Al Taylor (HBD #584) is correct in saying that large amounts of O₂ are needed at the start of fermentation so that the yeast can multiply, once fermentation is underway O₂ is no longer necessary. A lack of O₂ will result in a slow fermentation (not enough yeast) it should not result in a completely stuck fermentation. The problem is most often the result of the yeast settling out too soon and no longer being able to do its job. The best thing to do is either to pitch some more yeast into suspension, or to rack the wort into a new container (carefully so as to avoid aeration). This will stir the yeast back into suspension and fermentation should start up again. All this assumes of course that the problem is not that the yeast has been stunned by a high alcohol content.

From: William (Bill) Mayne <mayne@sun10.scri.fsu.edu>
Subject: Cooling wort before pitching

Since after I mix the hot wort from the boil with cold water in the fermenter the temperature is normally down to a point which yeast can tolerate I have always followed the practice of pitching the yeast immediately. A book on homebrewing recommended this since it takes several hours for the wort to cool down to ideal fermenting temperatures. The rationale was that it is better to start fermentation immediately since the layer of CO₂ produced in the fermenter provides some protection against bacterial infection. Although my results have been good, IMO, I am starting to question the wisdom of this practice.

I recently switched to William's dry ale yeast, which starts very quickly. Yesterday I brewed a batch and noticed that within a couple of hours, while the temperature was still above ideal, the fermentation was going so fast the airlock was literally blowing a constant stream of CO₂. If there was any interval between bubbles it was a tiny fraction of a second, too short to notice. I wonder if such fast fermentation is a result of the wort still being warm, and if it might not be better to let the wort cool first so the fermentation can proceed at more modest rate and at a suitable temperature. Besides what I have said here, what are the pros and cons? Should I at least chill the water to be mixed with the hot wort to get the initial temperature down more? On the other hand, my present procedure works. So maybe I shouldn't fix it.

Subject: Homebrewing Dry Beer

I'm trying to get my brother turned onto homebrewing, so I asked him what his favourite kinds of beers were, hoping I could brew up a batch of each to impress him. He said Pale Ale (no problem) and Dry beers (yuck!). I don't particularly like dry beers, so I was thinking of brewing a half-batch of a wimpy dry beer he might like.

Does anyone have any tips on making dry beer? Can I do it with only extracts and some specialty grains? Someone told me that the fermentation is somehow extended to ferment out all the sugars from the beer, leaving it with no aftertaste. This doesn't sound quite right to me.

I've been sipping on some Righteous Real Ale (by the recipe from Papaizan's book), and I think it's my best beer so far! It came out very dark (almost black) and bitter. After 2 1/2 weeks of aging in the bottle, it's delicious!

Happy brewing!

There are two home brewers clubs in the Washington DC
metropolitan area.

1) BURP (Brewers United for Real Potables) is now entering it's
tenth year as a home brew club. I have been consistently
impressed with the level of knowledge the members have and have
been a member for two years now.

Bill Ridgely is past-president and there is a new suite of
officers, but his is the only number I have available at the
moment. For more information, you can call Bill at 703-971-5744
or write to:

BURP
7430 Gene Street
Alexandria, VA 22310

2) BANOVA (Brewers Association of Northern Virginia, I think).
They have had a couple of meetings and were supposed to be
working on bylaws and officers. Have not attended, but am always
interested in anything to do with home brewing.

Contact Miles Smith at 703-237-8956 for more details.

Finally, a minor plug for my BBS at 703-448-0926 (Fidonet
1:109/131). I keep copies of the Homebrew Digest along with some
miscellaneous brewing files there. Also there is a Fidonet home
brewing conference called ZYMURGY. And there is a message area
devoted to information on local brew clubs and their meetings,
etc.

Subject: Dry hopping

I am looking for info/experiences anyone has concerning dry hopping. Off and on I'll see a recipe calling for dry hopping and, really, I wouldn't know exactly what to do. Miller and Papaizan only seem to give sketchy details. Miller seems to suggest that hops are dispensed directly from storage into the secondary. But I to wonder as he does if this is a bit risky. I've also heard of people making "hop tea" by boiling the hops and straining, then adding this tea to the secondary. Anyway my questions are when during secondary fermentation is best to dry hop (a week or so before bottling? When secondary fermentation begins?). And most importantly what is the best method of dry hopping?

Subject: low/non-alcohol beer tasting results

Curiosity and lack of respect for my taste buds has once again driven me to throw a non-alcohol beer tasting. We tried 16 (that's right, 16) different examples, hoping to find something drinkable. The results are in, and there were some surprises this time.

Though none of the beverages sampled really qualified as a good beer, the top three were close enough that they could be confused on a hot and thirsty day. The products sampled were:

Wartech Firestone HaakeBeck
O'Doul's Clausthaler Sharp's
Moussy Germania Kingsbury
Paulaner Thomasbrau Texas Select Kaliber
Goetz Pale Near Beer Texas Light Dark Maxi Malz
Kaiserdom Malz

The three best, in order:

Thomasbrau was much better than anything else on the list. Slightly sweet, lightly hopped (as almost all of these were), well balanced, medium bodied and pleasantly colored and carbonated.

Kaliber was the most heavily hopped beverage on the list, but suffered from less body, balance and aroma than Thomasbrau.

Germania suffered only from being too sweet. It has a honey aroma (which it shares with most of the German alkol-frei beers, including Thomasbrau), but too little hops to balance it.

Some things learned in this tasting:

- o Alcohol-free beers tend to sit on the shelf a long time (:^) and the flavor definitely suffers for it. Several of the lighter beverages (especially the American entries) suffered from skunkiness. The Kingsbury smelled so bad no one would taste it!
- o Most of the German entries tasted like raw wort, as if fermentation were incomplete in a real beer.
- o The two Malz products (Maxi und Kaiserdom) would be a good substitute for root beer. Very sweet, but rich, flavor and great body. We really regretted not having any ice cream to try a float with them.
- o Alcohol free beer still isn't close enough to the real thing.

Still no breakthroughs, but a pleasant enough evening, and everyone could drive home afterwards. The only product I'm going to try and duplicate is Maxi Malz, for floats and picnics with the kids.

Subject: freshness dating on beer

I saw something at my local package store that surprised me - freshness dating on beer. On cans of Peil's Real Draft, the can label says that the best consumed by date is listed on the bottom of the can, and the bottom of the can has a printed date. Piel's is brewed by Heilman's now. I saw these about a week ago, say February 20, and the date on the bottom was April 1, 1991. I don't know how long the beer has been sitting at the store...

I can't wait for the package stores to have shelves set up like the supermarkets do - those shelves where they sell out of date products. Or, as some supermarkets do, they just dump the 'out of date' stuff in a dumpster... :-)

But dearest, I have to finish this beer before it goes bad...

Ihor

Regarding Dry Beer and Randy Tidd's request at how it is made:

According to Dr. Michael Lewis at UC Davis, Bud Dry is the same mash formula as regular Bud, except that it is mashed so as to achieve the most fermentables. The mash-in puts the mash at 40 deg. C for 20 minutes then the temp is raised to 55 deg. C for another 20 minutes and then raised again to 70 deg. C for a final 20 minutes. Normally the mash goes directly from the 40 deg. mark to the 70 deg. mark where it sits for 40 minutes. The temp changes occur when the boiling rice is added to the grains. This period of mash at the lower middle temp allows the beta-amylase to work on what starch has gelatinized (Am. barley must be heated to at least 65 deg. C for full gelatinization, however beta-amylase has very low heat tolerance) and convert it to lots of fermentables. The other character to the beer is no aftertaste, so very little bittering hops are used (which in the case of Bud, means almost NO HOPS!).

I don't think you will be able to reproduce this with extracts since I don't know of any which include rice. Williams in San Leandro, CA offers an extra light which is 27% corn and they have rice extract on its own. So you could try getting the lightest you can find, make a wort of a low gravity (1.035), and pitch a very attenuative yeast (Anheuser-Busch yeast is available from some yeast banks). Be careful not to scorch the wort when you boil in order to keep the caramel down.

Regarding Ken Johnson's request for an explanation of "mash-out":

Popular explanation is for deactivation of the enzymes. My understanding is that this really isn't necessary since the boil will do this quite nicely. You do want to keep the wort and sparge as warm as possible to keep the sugar flowing and to assist in dissolving them from the grains into solution. 75 deg. C seems to be the optimum sparge temp. as it will achieve the above without beginning to extract tannins and other unwanted character from the grain husks.

Subject: Re: mashing out

In HBD #585, kjohnson@argon.berkeley.edu (Ken Johnson) writes:

> Could someone please tell me the reason for a mash out. Is it to
> deactivate the enzymes?

Yes.

> To raise the mash to sparging temp.?

Yes.

> What?

Both of those reasons. A common question goes like this: "Once all the starches are converted to sugars and there aren't any left, why does it matter whether the enzymes get deactivated or not?" Well, there are sugars and then there are sugars. You don't always necessarily want conversion to run its full course. Cutting it off a little early can give you more body, and more unfermentable sugars for a sweeter palate. The mash out gives you more control over the character of the final product.

Raising the mash to a good sparging temperature is also an important reason for the mash out. To get an efficient sparge, the temperature needs to be right around 168 degrees F. Any colder, and you'll leave too much of the mash product behind in the grains. Any hotter (above 170) and you'll start to get astringent flavors from the husks. If the grains aren't already around 168 degrees when you start the sparge, you'll never get them up to that temperature from the sparge water alone.

"Self-knowledge is always bad news." -- John Barth

Date: Tue, 26 Feb 91 13:17 EST
From: "Eric Roe" <KXR11@PSUVM.PSU.EDU>
Subject: Temp, mashing out, extract efficiency

In HBD #585, Bill Mayne writes about a fast-starting fermentation. You may want to take your own advice and not fix your procedure. If you're happy with the results, keep doing what you're doing. If, however, you notice cidery flavors in your brew, this might be the result of initial fermentation taking place at too high of temperatures. I use a wort chiller and try to get my batch down to about 60 degrees F before I pitch. The initial fermentation using this method is not so instantaneous. A batch of wheat beer took almost 36 hours to begin active fermentation with Whitbred ale yeast. This weekend I brewed a batch of porter, pitched with Munton & Fison ale yeast, and it took about 18 hours to start active fermentation. So far I haven't had a problem with any infections, even with the long lag times. If you do change your procedure, just remember to keep everything clean, and contamination shouldn't be a worry.

Regarding mashing out, Ken Johnson writes:

>Could someone please tell me the reason for a mash out. Is it to deactivate
>the enzymes? To raise the mash to sparging temp.? What?

Mashing out deactivates the enzymes, but it also forces unconverted starch particles into suspension. This aids in their filtration during the sparge, and results in a clearer runoff. You've got be somewhat careful with your temperature here. If you mash out at too high of temperature, the starch will degrade (burst) into sticky proteins and undermodified carbohydrates. These will dissolve and can contribute to cloudy runoff, stuck runoff, and down the line, chill haze.

Here's a question for my fellow all-grain brewers out there. What kind of extract efficiencies are you getting? I've been unable to find any references as to what are good percentages, and what percentages aren't so good. The batch of porter I brewed this Sunday (using 10 7/8lbs of grain) ended up with a OG of 1.055 and a volume of 5.25 gallons. Using Noonan's formula for extract efficiency this came to about 59.5%, or about 6 1/6lbs of extract out of 10 7/8lbs of grain. I calculated the total possible efficiency for the malts I was using to be 70.7% (about 7 2/3lbs extract out of 10 7/8lbs of grain).

On another note, does anyone have a good recipe for an all-grain
raspberry
stout. I'm anxious to try making some sort of fruit beer.

From: "DRCV06::GRAHAM" <graham@drcv06.decnet@drcvax.af.mil>
Subject: Brewing with bad eyesight

I'm collecting the equipment I need to start brewing and have a few oddball questions. I can't see much at all, (taste buds NOT affected), and have some questions about things y'all probably take for granted.

1. Can I successfully do all extract batches without using a thermometer.

This presupposes that I can tell when liquid is boiling. How about introducing some specialty grains, can I still work without a thermometer?

(I haven't found a talking thermometer yet.)

2. Filling bottles could be a comedy of errors if one can't see the level

of beer in the bottle. One answer, of course, is kegging, but I'll ask about that in a separate post. Is there a device that can premeasure 12 ounces so I can just fill and pour into a bottle without having to see the liquid level?

3. The only place in my house that has decent fermenting temperatures is the basement. I don't fancy carrying a 5 gallon carboy down the cellar stairs when I can't see where I'm going. Is there any reason that I can't

divide the batch in two and pitch half the yeast in each, thus only carrying 2.5 gallons downstairs at a time?

4. Does anybody know if Zymurgy is available on tape? [just kidding, I don't think so, but it WOULD be nice!]

Thanks for the help.

Dan Graham

(Don't ask about my reading labels, I like the mystery of what I'm gonna get when I open the bottle.)

The Home Brewery sells a mixture of light dry malt and rice solids in a size handy for 5-gallon batches of "American Pilsner", might be appropriate for Randy's project. They're reachable at 1-800-321-BREW (no connection, just satisfied customer etc.) and centrally located, so shipping to anywhere continental isn't prohibitive. I haven't tried the mix, but their other house brand "Yellow Dog Amber" makes an interesting pale ale.

Thanks for the interesting details. Protein rest at 55 and conversion at 70 sounds ok, but what's that 40-degree rest for? Comments from the experts?

Subject: mead recipe

In reply to a mead question on the Homebrew Digest, I thought I'd post my favorite recipe. I've edited it down to the minimum, since it was originally written for novice brewers. Being new to this group, I assume from what I've read that y'all are more experienced than I am.

To make a one gallon batch:

2 pounds honey - three if you like it sweet
one gallon of water
two teaspoons of washed and thinly sliced ginger (use a piece of ginger about the size of your thumb)
lemon-peel (orange peel) about 1/2 of the peel on the fruit (don't keep much of the white "pith" of the rind - just the yellow (orange) part)
mead-yeast (buy it in powdered form in the store)

Cook the honey and water together till it starts to boil. All the while, skim off the white and brown foam that forms on the surface. This step is very important! Once it is boiling, add ginger and lemon-peel.

Boil for a few minutes (five). Don't boil away the liquid too much!

Work it with mead yeast (strain out the ginger and lemon peel when putting it in the primary fermentation vat). If you can't find mead yeast use champagne yeast or "general purpose wine yeast".

Work it in the primary fermentation vat for two or three weeks. pBottle. I don't usually charge the bottles, I just bottle before the fermentation is complete.

Wait a week (to get the "charge"), then store in a cool, safe place. Warning: The yeast is still active and there is lots of residual sugar. This can make explosive bottles! The resulting drink should be fizzy with a relatively sweet taste. (You can run it dry as well.) Remember to refrigerate it for at least a day before you drink it to force the yeast to settle out.

If it tastes bad or smells bad - throw it all away and start again.

Send me a sample if you are successful! :-)

Enjoy, and may your bottles never burst!

Subject: dry hopping

In HBD 586, Gerald Winters asks about dry hopping. I too was intrigued, and somewhat worried about sanitation. However, given that Dave "Wash the Drapes" Miller doesn't worry about contamination from hops, I figured I should go for it. The first batch I dry hopped was a variant of Miller's Steam beer; it came out well, though the hop nose was muted. I have a batch waiting patiently for an upcoming week-long party that's basically a pale ale made with Chimay yeast (bizarre, I know) that was dry hopped with 2 ozs. of Kent Goldings. Early samples revealed a *fabulous* aroma of fresh hops. Seriously, sticking my nose in the top of the beer glass was like sticking it in a bag of hops. I can't wait for a few (dozen) more . . .

Procedurally, all I did was put the hops into the carboy then rack from the fermenter over them. They tend to float, so I stirred a little with my racking tube. I dosed the stuff with polyclar at the same time. The rest with the hops was two weeks. I siphoned it off after that time, separating the hops by wrapping the intake end of the racking tube in a plastic pot scrubber (actually about half a plastic pot scrubber) and then wrapping that in a hop bag. I let that settle for a couple of days (I think I added another tablespoon of polyclar, just to get some CO2 out) then bottled.

Miller suggests chopping the hops in a blender before adding them. This seems like a bad idea to me, as it would make racking much more difficult.

Subject: Re: grains and hops

Mary Jane "Pete" Kelly asks about storing leftover grain and hops.

I normally just keep leftover grain in a cool cabinet. Hops should be very tightly wrapped and put in the freezer, if you want to keep them fresh.

However, there's another thing to do with leftover hops. If you have a small amount, say a half ounce, put them in a loose open basket hanging in the kitchen. Add a little to the basket every time you brew. They will lose their freshness and most of their bitterness by airing out, and in the process impart a wonderful aroma. The best thing, though, is that after a year or so of airing out, they will be perfect for making a framboise.

Subject: Grain storage info for Pete

Re: HBD #586:

What is the best way to store left over grains and hops?
Can they be stroed? If they can be stored how long will
they keep. Should one store them in air tight jars out of the
light, in the fridge or in the freezer?

Thanks in advance,

Pete

Well, Pete my partner & I have found that good 'ol Ziploc-type plastic
storage
bags work great! Of course, we always force out all the extra air that
we can
before sealing the bag. As for the freezer/refrigerator -- we DO store
all our
grains and hops in the refrigerator. They keep just fine! Since we buy
many
(6-8) batches worth of grains & hops, keeping them fresh is essential!

The latest streamlining we've done to the process has been to do our bags
of
adjunct grains ahead of time. Here's how it works. We spend a couple
hours
one evening weighing, cracking and filling bags with the appropriate
grains.
We've found that we like to use cheese cloth and make our own disposable
grain
bags that can be pitched in the garbage when the boil begins. Its cheap,
works
great and saves on the clean up. (I *HATE* cleaning the reuseable grain
bags!!)

Each pre-made brew bag is sealed in its own Ziploc bag. A piece of paper
in
each bag lets us know which one of our favorite recipes it contains.
Since we
dedicate a page of our brew log to the evening we do this, it contains
the
detailed list of what's in each bag! It really works great for us.

The other process is that when purchasing bulk malt extract we use
containers
that hold one batch worth. We use two types of malt in each batch and
can
pre-mix it & weigh it at the time of purchase. At brew time, we just
dump one
pre-mixed, pre-measured container into the pot! VOILA!!

Doing just these two things has greatly increased the whole reason Slug &
I
brew -- **TO HAVE FUN**!!!

Subject: CIDER

In HDB #583 (which was sent to me today, thanks guys!) Don Graham asks about the making of cider. I tried to send this to you directly Don, but our mailer doesn't like your address.

We use one package of either M&F or Red Star Ale yeast for 5 gallons of cider. We start the yeast in some warm sugar water about 1 hour before pitching.

We add 1/2 to 3/4 c of regular sugar to each gallon jug. We have found that this gives the taste that we like. More than this will result in a more potent brew, without much added sweetness. Less than this results in a VERY dry final product. The final alcoholic strength is 5-7%. Plenty strong for us.

After pitching the yeast we put a stopper and fermentation lock in each jug. The stopper is secured with some duct tape (just to make sure). Fermentation (bubbles through the lock) usually starts in about 10-12 hours and continues for 7-10 days. The yeast settles to the bottom, making it really easy to filter out.

We have never tried carbonating the stuff, so I don't know how well that the jugs would take the pressure. Just a feeling though, I wouldn't try it.

We also don't know how well it keeps, as it is never around for very long. We use pasteurized cider as a starting point (we don't trust the murky natural stuff) and keep it refrigerated after the fermentation is done.

I hope this helps. Feel free to ask anything else (this is our 15 minutes of fame!).

Subject: Burlington, VT beer place

In #586 Darryl Davidson asked about places to go for beer in Burlington and the Boston area.

Well, it's been too long since I've hung around Boston (except I'd recommend the Harvard Square area, in general; then check the music section of the Phoenix for Irish music), but if you're in Burlington....

Definitely check out the Deja Vu Cafe on Pearl St. An extensive selection, plus enough clientele to minimize the risk of "over-ripe" bottles. Take time to enjoy the woodwork, too; rumor has it the builder took more than a year to get it right. I've heard that Burlington has a brewpub now, but it's new since I left. I'm sure the folks at the Deja will be happy to give you directions.

If you can make it to the White River Junction area, you might want to tour the Catamount brewery. They make several different brews, but they all have too much hops for my taste.

The Burlington area has a homebrewers club, but I don't have their address with me. If you can find William Mares in the phonebook he can tell you. You might be able to find it at the brewpub, too.

Hope you enjoy New England. Dress warm. And let me know what you find for beer places, either directly or thru the list. I don't get back home often enough to be able to keep up them myself. *sigh*

Life is too important to be taken seriously.

Have fun!

From: Jeffrey Marc Shelton <js8f+@andrew.cmu.edu>
Subject: Women and Beer

In reading the responses that people sent me (thanks to everyone who did) about what selection/atmosphere/prices/etc. they wanted in their Dream BrewPub, there were references to the fact that there are a lot of women who do not like beer and that perhaps I should also sell wine in order to draw the husband/wife, boyfriend/girfriend crowd.

From my personal experience of those people that drink, about 85% of the men I know like beer, but only about 50% of the women do. I can't seem to find any distinguishing characteristics between those that drink beer and those that do not (i.e. those that don't are more picky eaters.) This somehow leads me to the conclusion that this phenonemum is more of nurture instead of the nature. Somewhere in childhood, (discounting those that would not like beer anyway) females are "trained" not to like beer.

This brings into some important marketing aspects that I might wish to consider. For example, I know that more women are drinking "light" beer now that it is available. Is this because it tastes better/different than regular beer (I am not under this impression) or that it has been marketed differently and comes across as being more "socially" acceptable (less calories, etc.) The would be a case of nurture. Say that in my BrewPub I sell a beer hypothetically called "For Women Only." (This is an extreme case, in reality I would not be as blatant in naming the beer "For Women Only.") Do you think that women would be more inclined to like the beer and frequent my establishment more even though the beer is of a similar type than others I sell? How about if it was a Pale Ale instead of a Lager?

Any comments either supporting or contridicting these statements?

Thanks
Jeff

From: Mike Charlton <umcharl3@ccu.UManitoba.CA>
Subject: Framboise and Wort Chilling

Bill Crick
Gay Mason

Bill Crick asks about Framboises. My brewing partner and I are in the process of brewing a framboise. We are now in the secondary (just added the raspberries). I'm not sure I remember the recipe exactly, but here's a stab at it:

7 lbs. Lager Malt
3 lbs. Wheat Flakes
1 oz. 2 year old Cluster hops that had been baked for 20 min.
7 lbs. crushed raspberries
WYeast #1056 American Ale Yeast

We did a beta glucan rest at 120 degrees for 30 mins, a protein rest at 130 degrees for 30 mins, and a saccharification (sp?) rest at 155 for 1 hour. Be extra careful with the sparge because it has the potential to be very slow (although we managed to whip right through in 45 mins.). We boiled the wort for 2 hours, leaving the hops in for the entire boil. Cooled with an immersion chiller to 42 degrees and strained into a carboy.

After 8 hours we racked the wort off of the trub and pitched the yeast. We left it in primary for 2 weeks and then racked it into a carboy and added the raspberries. We had a bit extra so we are doing a small fermentation (without the raspberries) of about 3/4 gallons. To this we added a teaspoon of yogurt to try to get a lacto bacillus infection and produce lactic acid. If it produces anything interesting I'll post the results. Anyway, I can't comment on how this beer will taste as it is still in secondary and is fairly experimental.

Gary Mason asks about wort chilling. The reason that I don't pitch the yeast before I rack the wort off of the trub is that during the initial uptake of sugar and oxygen, the yeast will actually use trub in preference to oxygen.

I have found that this produces an unacceptable amount of fusel alcohol in my beer (gives it a strong bitterness at the back of the throat). This initial uptake of oxygen (or trub) occurs within the first few hours of respiration (basically just after you pitch the yeast) and thus I would say that it is inadvisable to pitch the yeast before you have gotten rid of the trub. I've tried it both ways, and racking before I pitch the yeast has always given me superior results. After perusing George Fix's book ("Principles of Brewing Science" or something like that) I get the impression that several large breweries like to "carry over" the trub to the fermentation. This is apparently because some breweries have a hard time oxygenating their wort. The fatty acids in the trub will give the beer a soapy flavour which

some people like. I believe that Miller Lite must be one of those beers. One of these days I'm going to try a split batch to see the difference between an under-oxygenated wort with "trub carry-over" and a normal wort without the trub. I think it would be interesting. I think to get away with the trub carry-over you need a large pitching rate (to minimize the length of the respiration time) and perhaps a low temperature fermentation (to minimize the amount of other by-products).

Subject: Re: Women & Beer

Dear Jeff -

If you want the local chapter of NOW picketing your brew pub you'll
market a
beer especially for women.

I agree with your statement that women have been educated that beer is a
"man's
drink". Men continually feel/are taught that they need to take care of
us
because we're helpless. We're such delicate creatures that we could
never
handle such a strong drink as beer. And women have been told the same!
Let's
not perpetuate it by continuing this inaccurate message. Beer is a drink
for
PEOPLE.

Being a woman I have to deal with enough discrimination everywhere else,
let's
keep it out of the pub! Market to beer drinkers, not genders.

Regards,

Stacey Jueal

PS - Lots of us like stout you know!

Subject: exploding cider

In HBD #588 Mark Castleman and Sterling Udell write about making hard cider.

> After pitching the yeast we put a stopper and fermentation lock in each >jug. The stopper is secured with some duct tape (just to make sure).

I **strongly** recommend against this practice. The stopper is not going to come out unless the hole gets clogged somehow. If it can build up enough pressure to push out the stopper it can build enough to explode the jug. Blowing a stopper is messy; blowing a jug is much messier and dangerous.

It isn't so much that they're "trained" to not like beer so much as they're (a) not encouraged to try it (beer is often an acquired taste) as much as the guys are and (b) are discouraged in some circles (beer IS perceived in some circles as being a "macho" or "blue-collar" drink). A lot of it has to do with one's cultural upbringing.

I LIKE a good beer. I'm also half Slovak. Beer is very prominent in many eastern European cultures. My Grandmom used to say "pizza isn't pizza without a good beer." On my father's side of the family, almost NOBODY drinks beer. They're Jewish, and you don't hear much about "kosher beer." They like their wines (dry as well as sweet) and their cocktails, but beer? Ugh. For THEM, beer isn't part of their culture, and it's also looked upon as "blue-collar." After their years in the service, my father and his brother occasionally drank beer, but rarely. Dad preferred ale.

> This brings into some important marketing aspects that I might wish
>to consider. For example, I know that more women are drinking "light"
>beer now that it is available. Is this because it tastes

I also suspect most Americans don't LIKE beer, but drink it for social reasons. Why would ANYBODY drink most of those DRY beers out there if they LIKED the taste of beer? In much of American culture, it's considered "unladylike" to drink beer.

>Say that in my BrewPub I sell a beer hypothetically called
>"For Women Only." (This is an extreme case, in reality I would not be as

I think you'd have even less "woosy" women drinking the beer if you gave it too specific-sounding a name. If a woman is more concerned with being "ladylike" than with what she's consuming, a very WIMPY beer with a name like "Lover's Lager" or "Petunia Pale" might get her attention. Overall, I'd say pick something soft and flowery if you're aiming at the woosy women, but keep it within the theme of whatever else you're naming your brews.

- --Lynn

Subject: Problems getting digests

Hi,

I've missed a couple of issues lately[583&587]. These two issues don't seem to have made it to the archive site either. Am I the only person to have missed these issues? If so could someone in the Toronto area mail me these two issues?

Thanks
Nick

Subject: framboise hints

bnr-rsc!crick (Bill Crick) asks:
> Anybody with some experience with Framboise care to post a recipe, and
primer?

I've made a few batches of framboise. Raspberries is a great addition
to beer! Here are some "rules of thumb":

1. I've found that to get the best flavor, you should add the raspberries as late as possible. Make a smallish batch (about 3 gal) of your favorite beer to use as a base. Add the berries when you rack the base to secondary. You will get a trub of berry skins and seeds within a couple of days, just rack again to remove.
2. For the best nose, prime with raspberry juice. Folks in Colorado: look for Merlino's juice; it works well even though it has added sugar.
3. Frozen raspberries sold in the poly bags works ok. Plus they are more inexpensive than buying fresh.
4. Finally, a light bodied framboise is great in the summer!

From: (Mark Stevens) <stevens@stsci.edu>
Subject: "For women only" beer"? Dumb idea.

In reference to Jeffrey Shelton's idea of marketing a beer made only for women, I'd agree with the people who find that a bit hokey or insulting.

I also believe that no brewpub should *EVER* sell a beer made by an industrial brewer and that, in general, they should NOT brew diet (aka, "light") beers. In my various brewpub travels, I've found no brewpubs that specifically brew a diet beer, although a sensible approach was taken by the Vermont Brewing Co. in Burlington VT. They offer a diet beer, but they make it on the spot by mixing 1/2 club soda and 1/2 the beer of your choice. This lets you pick the flavor of beer, or even try a variety, albeit in a watered down version---this still results in a better drink with more flavor than any of the commercial diet beers. An even better solution might be to promote a beer with 1/3 fewer calories...but instead of a watered down beer, you get a 9 ounce glass instead of a 12 ounce glass. This seems to make the most sense, but I don't see anybody doing it.

As far as wines go....this may not always be practical. In some places a brewpub is not allowed to sell anything but beer. Other areas will allow it. The Blue Ridge Brewing Co. in Charlottesville VA offers a selection of locally-made wines: this is a very attractive way of keeping with the small-and-local-is-best philosophy of the brewpub, however, I can't really give the Blue Ridge high marks overall because they also sell Bud and Bud Light---the most heinous of sins for a brewpub---makes it seem like they talk quality when it suits them, but when there's a buck to be made, they'll gladly pump more piss than a Roto-Rooter man.

As an aside...the Vermont Brewing Co. also makes *ALL* their own sodas. No commercial products---no Pepsi, no Coke, not even a 7-Up. (What a wondrous world that has such brewpubs in it.)

The key to attracting women (and men too for that matter) is to offer high-quality products consistently and to effectively communicate why and how your product really is better. The key is not to insult educated consumers with hokey names and silly gimmicks.

Subject: Re: Homebrew Digest #589 (March 05, 1991)

Some random comments...

- Just cycling the bottles through a dishwasher is **not** sufficient. My last batch slowly developed a gusher-type infection, and the only significant process difference was in the bottles. Now I soak at least 24 hours in a chlorine solution, then run the bottles through the "dry" (a.k.a. "plate warm") cycle in the dishwasher. (I noticed that there's always some water in the drain area of my G.E. dishwasher, and although it's demonstrably clean enough that plates don't kill me, it has got to have some residual bacteria lurking in there that would love to be sealed in a bottle with a culture medium for a few weeks.)

The most embarrassing moment came at a friend's housewarming. One of the gift bottles had some kind of **algae** growing in it. (At least, that's how a doctor/beer maker present identified it.) Ecch! I wanted to die..

It's Clorox, mega-strength, from here on out.

- Did your hydrometer come with a little typewritten sheet of paper that had a "Specific Gravity Correction Factor" table on it? It says something like "add 0 at 60, add 1 at 70, add 2 at 77," etc. I decided to whomp that into a graph for my own amusement. Through the miracle of the unix spline(1) program and a little PostScript hacking, I came up with the appended document. If you have a PostScript printer handy, just dump it to it. If you have other devices around with a different interface (HPGL, maybe? Hi, Rob!), you can snip out the data points and do your own thing with them.

- Stacey Jueal makes some good points. I checked the Tied House in Mountain View the other night: most people, men and women, were drinking beer, with a scattering of wine drinkers. But there **were** wine drinkers. One of them was my wife, who makes and drinks beer but invariably prefers a glass of Cabernet. (She likes beer, but she **loves** wine.)

A brew pub is a business, and it only makes sense to offer as many alternatives as you can afford, in order to attract the widest variety of customers. (You wouldn't think of not stocking soft drinks and fizzy water, right?) But there's no need to market a brew directly to women. Make sure that one of your brews is made (and described) as "light, fresh, and crisp, with a refreshing flavor" (a classic Pilsener, maybe?) and you'll get all the people who are suspicious of the brown bilge water we beer snobs love to drink :-)

Enough. Salud!

From: Chris Shenton <chris@endgame.gsfc.nasa.gov>
Subject: ``Real" lambics/framboise/kreik ?

Making framboise has recently been discussed, and the emphasis seems to be:

1. Make a beer.
2. Add fruit to secondary.
3. Proceed as usual.

You surely can make a good fruit beer that way, but -- no slander intended

- -- I don't think that qualifies it as a framboise.

Mike Charlton <umcharl3@ccu.UManitoba.CA> says he's trying to culture lactobacillus from yougurt, as I belive, Cher Feinstein suggested many months ago. This is getting closer to what was mentioned in [yow -- how do you spell his name?] <The Guy Who Wrote> the AHA book Lambic. (Interesting book, by the way).

The description in the book mentions 3 or 4 different strains of yeast and bacteria which are vital to producing the true Lambic character. He also says that you can buy these, if you've got some excess cash (\$50/culture comes to mind), and can prove you know what you are doing (eg: letterhead); that's a bit pricey and/or difficult for us homebrewers...

Anyone tried this (any UC Davis types out there)? Do you think we could try to convince Wyeast to go for it and offer a mixed strain? Lambic indicated you have to add the various yeasts/bacteria at different times during the beer's life, and this may *really* complicate the commercial availability of a ``Wyeast #4001 Lambic'' strain... If, however, they offered different cultures of the separate strains, we *could* subculture them in our private (or club) yeast banks.

Thoughts? I'd like to stimulate discussion on how we can get some true lambics going in the US...

Yours in wild yeast --
Chris

From: cjh@vallance.HQ.Ileaf.COM (Chip Hitchcock)
Subject: beer and women

From a very small sample of friends, my suspicion is that more women than men admit to a dislike of hops. It's not clear whether this is biological (yes, there are some differences in sensory perception---mostly not the ones that sitcoms usually get off on) or training---it may be that hops are enough of an acquired taste that men drink beer because other men do, while women (absent this social pressure) drink what they like. Do/did more women drink beer in cultures where decent beer is/was generally available, or is/was it irretrievably associated with lower classes and/or hard physical work? Other factors:

- serving size---some marketing types think they managed to get more women to drink American runoff by putting it up in smaller bottles (and how much of this is conditioning that "ladies" have delicate appetites and don't like large servings?)
- anti-conditioning---many women probably get the impression while still students that the smell of beer is irretrievably linked with obnoxious behavior. Let's not get into pro- vs anti- neoprohibitionism; just consider the number of high schools and colleges at which getting drunk (cheaply, i.e. beer) and acting rowdy (not to mention crudely or violently lecherous) is either a sacred duty or the easy way of dealing with incredible boredom in the middle of nowhere. Moreover, leftover mass-market lager spoils quickly once unsealed and smells //terrible//.

PS to the person looking for brewpub advice: one of the deficiencies of Commonwealth (the only major deficiency before they started weakening their beer) was the absence of fruit juices. Sometimes some parts of a group don't want alcohol and don't want soda/tonic/pop; fruit juice straight or with plain seltzer is getting popular.

Subject: Travelling with and for beer

Toward the end of March I will be visiting a friend in Seattle, Washington. I'd like to bring along a selection of homebrew, and visit some local brewpubs/microbreweries while there.

So first, has anyone here ever taken homebrew on an aircraft ? My first guess was to carefully package and cushion the bottles, then put them in my check-in luggage. Anything I should be aware of ? Would I be better off to ship the stuff (a six-pack or thereabouts) via UPS instead ?

And if someone would care to recommend Seattle brewpubs, especially those near the University of Washington area, I'd be much obliged. For that matter, if any of you'd care to meet me at one of them, the first round is on me !

Dave Beedle writes:

>I pitched the yeast last night about 11 (it took a while for the stuff
>to cool). This morning there is some activity but not as much as I
>expected. I also notices a .25 to .5 inch layer of brownish white stuff
on
>the bottom of the carboy. What is this stuff? Is this normal?

Sounds like a virulent Anthrax infection to me. Hmmm, let's check the
mail
header... Oh, Dave's in Illinois -- I ought to be safe enough out here in
California. Whooeee, that Anthrax is bad stuff.

The stuff in the bottom of your carboy is called trub. It's mostly
congealed
protein, mixed with other stuff that comes out in the boil - bits of hops
and
whatever. It's perfectly normal. Using EDME yeast, my bet is that your
fermentation will be going vigorously by the time you get home tonight.
See
Mike Charlton's post immediately preceeding yours in HBD 589 for a
discussion
of why some folks try to remove the trub before pitching yeast. And, BTW,
thanks for explaining that, Mike. I might give it a try, if I feel lucky.
With
my sanitary procedures, or lack thereof, I feel like every uninfected
fermentation is a stroke of luck. Leaving the unpitched brew just sitting
for
12 hours might make me nervous.

Subject: Kosher Beer, Burlington & Boston Pubs

In Digest #589 the following remark appeared.

> On my father's side of the family, almost
>NOBODY drinks beer. They're Jewish, and you don't hear much about
>"kosher beer."

The fact that your father's family didn't drink beer with the implication that beer isn't kosher is nonsense. Beer is one of a group of foods considered Parve. That means it is neither meat nor dairy.

The only concern with regard to beer is that it contains yeast. Therefore during Passover beer is not supposed to be consumed by Jews, since * during Passover* Jews are not supposed to consume yeast (in honor of those who ate unleavened bread during the Jews exodus from Egypt). Thus the phrase seen on many foods this time of year "Kosher for Passover" meaning the product has not been prepared with yeast, is obviously not possible for beer.

Beer is in fact kosher and consumable at all other times of the year by Jews. A beer produced in Isreal named Maccabee (sp??) is available in some places in the US. I have never tried it and can't comment upon it, other than to say it is kosher.

If your father's side of the family didn't drink beer it is possibly because wine is a very important beverage in Jewish religous tradition, and they probably never developed a taste for beer.

In Burlington Vt, do visit the Vermont Pub & Brewery (run by Greg Noonan of Brewing Lager Beers fame). It is right across the park from city hall.

In Beantown my favorite places are
Brewpubs:

Cambridge Brewery at 1 Kendall Sq (actually about 2-3 blocks from Kendall Sq T Stop where Hampshire & Broadway merge).

Commonwealth Brewing Co. (near the Boston Garden 1 or 2 blocks South)

Beer Bars:

Doyles Braddock Cafe (Washington Ave in Jamaica Plain, close to the orange line)

Sunset Bar & Grill (corner of Harvard and Brighton in Alston)

Cornwalls in Kenmore Sq.

There are some others, but these are the first tier of beer bars.

Enjoy
Jay H

Subject: unusual homebrew situation

Last Sunday I brewed 2 similar batches of beer, 1 using Red Star dry lager yeast and 1 using liquid lager yeast. The liquid yeast started first and blowout occurred 24 hours later. the dry yeast blewout at about 48 hours and everything appeared normal. The carboys are on a table in a heated room @ 75 F.

The liquid yeast completed total fermentation after 6 days and is bottled. At 7 days the dry yeast filled up my fermentation lock completely and started heavy fermentation again. I had to reinstall my blowout tube again for another day.

What gives? Any ideas.. Is this beer going to be okay. There are no unusual odors or anything. I've used this yeast 7-8 times and nothing like this has ever happened before.

Thanks for any ideas.. Duane Smith

From: <SU0751A%DRAKE.BITNET@CUNYVM.CUNY.EDU>
Subject: Cider going BOOM!

It rather sounds as if something needs to be cleared up here. In our cider endeavors, Mark Castleman and myself have occasionally had a stopper (with fermentation lock) come adrift from its jug. We assert that the yeast - quite active, always - has done this "by sheer force of will", but in reality I think that it's due to using the wrong size stopper. Our local brewing supply store, New_City_Market here in Des Moines, has a fairly limited stopper selection. Their sizes jump from 6 to 9 1/2, the latter being what we use for the cider.

Using Tree_Top cider jugs (fairly standard, to my eye), the 9 1/2 stopper is an **EXTREMELY** tight fit; I had to seriously work to get one out of the jug tonight. At a guess, number 8 stoppers would be just perfect for these jugs. I would suggest anyone else trying cider to attempt to find this size stopper. The 9 1/2 stoppers will occasionally force themselves out, especially if they're wet.

We have never had a plugged fermentation lock, even though we do sometimes get a little blowoff if the jug is too full. Under no circumstances do I think we are in danger of an exploding cider jug - unless the alcohol within spontaneously ignited, which might be a real possibility with a few of these brews! :)

Date: Today, Mountain Time
From: rdg@hpfcmi.fc.hp.com (Rob Gardner)
Subject: Stuff Happens

I've been getting lots of messages complaining of missing digests, erratic service, etc. Please keep in mind that most of the problems you are likely to encounter are not under my control, and so I cannot do very much to help. If you sporadically miss digests, it is unlikely to be a problem at this end, but is probably some sort of network thing. Consider the possibility that your address on my list is unreliable, and perhaps send an alternative. If you stop getting digests completely, then it probably means that mail to your address has been bouncing, so I've removed your address from the mailing list. In that case, it is necessary to resubscribe with a hopefully better address. Remember that I don't have infinite time to figure out various mail problems, and I am very likely to blow away any address from the list that is costing time to babysit. I'll try to keep the archives up to date for back issues; Please do not send me requests for back issues, as I generally delete these immediately without responding.

Sorry to be taking this position, but it's just impossible to personally reply to every message that comes in. My primary goal is to keep network traffic here to a minimum, since I've already had several nasty encounters with bean counters, auditors, and administrators, and the digest has had a few scrapes with death. So please try to make things easier for me here, and be more tolerant of the occasional glitch.

Having said all this, remember to relax and don't worry. I'm doing my best to keep the digests going out regularly in spite of stormy weather. Thanks for all your patience and support!

Rob, your humble and busy publisher

Can't agree with you here, Mark. If this helps a brewpub stay in
business,
I'm perfectly content. There aren't a whole lot of people willing to
spend
\$5 per beer for a night of drinking. If the Bud sales partially
subsidize
the in-house brews, that's even better (doubtful though). Personally,
I'll
drink swill beer to save cash from time to time, allowing me to sample
more
good beers.

As far as wine sales go, I don't have much of an opinion, since I am
not
much of a wine drinker. A good idea if it helps the brewpub stay in
business.
The yups seem to drink alotta wine at brewpubs ;) .

My personal preferences run towards more traditional slum bars, with
stages
and sawdust on the floors. Bands nightly! Even better if there's an
addi-
tional quiet room to relax and taste the in-house brews. Although I like
brewpubs, I find that the um, more yupscale ones get a little too boring
on
repeated visits.

From: bates@bjerknes.Colorado.EDU (John Bates)
Subject: Travelling with and for beer

I posted my only experience with shipping beer UPS before the holidays.
UPS
had completely shashed my shipment (probably dropped a 50 lb box on it)
and
they said tough, no apology no refund, nada. I talked to the AHA about
this and they assured me they use UPS all the time to ship beers to
tastings but
did suggest you not identify it as beer. Someone was writing an article
on
this for Zymurgy, but it has not been published yet. They hinted that
Papazian had written to UPS and gotten an OK, but I asked for a copy and
have
yet to see anything official. This suggests there is no uniform UPS
policy
on this and you take your chances with whomever you happen to deal with
at
UPS.

Undaunted, I packed a couple of homebrews in a nice box and carried it on
the plane for my holiday travels. I had no hassle as it went through the
X-ray. Others on the
Digest have reported mostly similar experiences, with an occasional
hassle,
but Federal law says it's OK. I would caution putting homebrew in the
check-in luggage, I just don't trust the temperature/pressure changes
that
occur in the cargo hold.

Subject: Brewpub marketing

This thread is very interesting to me as I was very near (and still trying)

to being a brewpub owner. First I'd like to say that Jeff (the person planning the dream brewpub) doesn't need conjectures or perceptions, he needs facts. For example:

> From a very small sample of friends, my suspicion is that.....

This is somewhat useful as it states the source of the data and clearly states that a conclusion was DRAWN. Statements such as:

>some marketing types think.....

and

>many women probably get the impression....

are useful only when considering the source. Is he an expert in the field?

If not, what are his sources for this information? There are hundreds, nay, thousands of reports of studies conducted to answer questions such as,

who drinks beer, where do they drink it, what attracts them to a particular

product, etc. Many of these reports and findings can be found in industry

magazines and marketing magazines and reference books. Judgements based on

facts lead to business success. Guesses often fail.

As for marketing a beer or beverage toward women: this is an extremely good idea and nearly essential. Chip wrote recently:

> Sometimes some parts of a group

> don't want alcohol and don't want soda/tonic/pop; fruit juice straight or

> with plain seltzer is getting popular.

This is very true and supported by industry trends as reported in The New Brewer (published by the Institute for Brewing Studies)(volume and number not handy but available). Offering an 'off' beverage (meaning not the main

staple which is beer) is a way of marketing a product to the non primary sales audience. As it happens, many marketing studies are described

demographically with sex being a major division. Therefore reports may state that women drink less beer. The response is to market a product

(or

special beer) towards women. Now we all know (and Stacey pointed out recently) that MANY women LIKE beer. It's just that women are the

largest

targetable group from the population of those who drink less beer (under the per capita average consumption say).

There are many ways to market a beer towards women (or the lighter beer drinkers in general). Some would be change the taste and ingredients of a

beer, special advertising of an existing product, use a particular name, lighten the aftertaste, etc. There are probably hundreds of ways, some admittedly better than others. You would probably want to pick a

marketing plan that would encompass the WHOLE target population, not JUST women. "Lite" as part of the name, does this well.

Mark Stevens writes:

> I

> also believe that no brewpub should *EVER* sell a beer made by an

>industrial brewer and that, in general, they should NOT brew diet (aka, "light")
>beers.

Why is there a problem about brewing 'diet' beers? Your in business to make money and if you can justify brewing it with potential new sales, why not do it? Without looking at any demographics about dieting people, I have observed the many advertising campaigns for Slim-Fast (spokesperson: Tommy Lasorda), Weight Watcher's (Lynn Redgrave) and other such products. This would indicate to me that there is a large targetable population out there that I may be able to sell beer to.

>They offer a diet beer, but they make it on
>the spot by mixing 1/2 club soda and 1/2 the beer of your choice. This
>lets you pick the flavor of beer, or even try a variety, albeit in a
>watered down version---this still results in a better drink with more
>flavor than any of the commercial diet beers.

In your opinion it's better. This also sounds like a very good way to reach someone who wants a lighter beer. It sounds like a good marketing idea.

>An even better solution
>might be to promote a beer with 1/3 fewer calories...but instead of
>a watered down beer, you get a 9 ounce glass instead of a 12 ounce
glass.

This sounds like a rotten idea. I believe, (again without the benefit of demographics) that dieters would want to consume the same amount of substance without the same caloric intake. They may just end up ordering more 9oz glasses than they would 12 oz. Essentially your saying, if you want less calories, just drink (and eat) less. Chances are, if someone is on a diet, they may already be having problems controlling their amount of intake. They may perceive a 9oz glass as a rip-off.

>....I can't really
>give the Blue Ridge high marks overall because they also sell Bud and
>Bud Light---the most heinous of sins for a brewpub....

If you were REALLY interested in quality yourself, you wouldn't judge a place on what they sell but on the quality of the product they make. Consider all the people drinking Bud and Bud Lite as subsidizing the quality beer in your hand. Also, try to introduce a Bud drinker to the homemade product. Most places (this can be backed up) will make more money per serving of their beer than per Bud. The problem of profit comes in when you can't sell enough of your own product when it is the only one offered.

>The key is not to insult educated
>consumers with hokey names and silly gimmicks.

HOKEY names and SILLY gimmicks are indeed a bad idea, however, using a name or gimmick to sell a product is the way of business. Just watch a few TV commercials to find that out. Consider that a potential investor in your brewpub will consider beer brewed on the premises as just a gimmick to get people from other bars, to your bar. I do not believe there are many brewpubs out there just to raise the American consciousness of good beer.

They want to make money and brewing your own beer brings people in.
That's
why you'll see many brewpubs that are 'in'. Do you really believe ALL
those people are beer connoisseurs like the people of this digest? To be
sure, there are few of us, but people (the average Joe and Jane) are
starting to appreciate good beer. That is why the brewpub craze is not a
fad as many investors believed in the early going.

My apologies about the length of this post.

From: ico.isc.com!rcd@raven.eklektix.com (Dick Dunn)
Subject: beer-drinking women

(I should get Diane to post her views on this herself, but she's busy and traveling. Besides, I'm right here at the console, and isn't that what husbands are for...to be barefoot and programming?:-)

My best guess is that the supposed tendency for women not to like beer is something that's been marketed into place. If the marketing for real beer appeals to the macho image, you've got a problem trying to market the same product to women, because the images clash.

Diane grew up in England, then moved to the US. Overall, she's pretty independent, and her tastes are eclectic, which accounts for some of her preferences, but still I think the Briton in her has substantial influence.

Her beer preferences are roughly:

- barleywine (ours, Bigfoot, Old Foghorn, Hardy's)
- doppelbock (Salvator in particular, and an occasional Samichlaus or EKU 28)
- stouts (homebrew, Tooth's Sheaf, SN, Mackeson) and Anchor Porter bitter and west-coast-ale style (SN Pale Ale, Anchor Liberty, etc)
- ...with the obvious seasonal shifts, and of course mead/melomel factored in wherever possible...

What's more, she's able to convince women friends to give these a try... and as often as not, they like them! I think the stereotype "women like light beers" is WORSE than a marketed misconception. It may serve Schlud-willer well, especially since their "lite" products are cheaper to make, but I don't see any substance to it. You could just as easily argue the mis-generalization "women don't like beer" on the basis that they avoid it because the US mass-marketed stuff is insipid.

(and yes, we're both involved in our brewing...although there are certain procedures for which she claims only men have the required expertise, such as washing bottles.:-))

Subject: traveling w/homebrew

Bill Thacker in #590 wanted to know about traveling on commercial aircraft with homebrew.

I have always carried on homemade beer in a case or 1/2 case and placed it under the seat in front of me. 1/2 cases seem to fit best for obvious reasons. When I go through the security/X-ray check and they ask me what it is I just say "beer". Never had any problems. However, the last time I did this was in early January, i.e., before Desert Storm, so if security has tightened, this may no longer be possible.

As far as packing it in luggage, JUST SAY NO! For one thing, glass bottles are susceptible to breaking in luggage. I have had it happen to me (Kahlua, not beer). Yuck! For another, homebrew is sensitive to bottle conditioning more so than any other alcoholic beverage I know of. Going topsy-turvy, sideways, rearways, and upside-down ways won't help the beer flavor/clarity/color/aroma any. Anyhow, the airlines always recommend against putting glass in luggage and are not liable for damages when your glass breaks.

By the way, people carry on wine bottles all the time; wineries often sell travel cases (cardboard, usually) to facilitate this. So in principle, if someone at a security check gave you trouble, you could appeal to their common sense. The only thing airline types seem to get anal about is the whole "fitting under the seat in front of you" idea. There are overhead racks, too, I guess!

ON ANOTHER NOTE.....I'm still looking for brewers in Central New York, especially Ithaca, that are receiving this newsletter. Please send me e-mail or give me a call (Steve at 273-7306 eves, 255-4648 days); I would like very much to exchange beers and information locally.

Subject: &*\$#@ bottling wand, mead

Last night I was bottling a gallon batch of mead*
using that most marvelous of inventions, the bottling wand.
All was going well until the orange plastic valve assembly
dropped off the wand into the bottle I was filling. When I
pulled the wand from the bottle, Surprise! mead all over the
floor. When I lost the siphon, a hose-full of mead whooshed
back into the carboy and stirred up a bunch of sediment. @*%\$&*%!

I'm tempted to glue the bloody thing together, but I fear that
doing so will make the wand nearly impossible to clean thoroughly.
Perhaps there is a better designed bottling wand available?
Oh, another feature, if you boil the plastic tube it may well
end up looking like a shilelagh, I know :^)

-Carl

* I'm very happy with the mead, it is a very simple recipe:

1 gallon bottled water (I don't really trust our tap water)
2# generic honey
zest and juice of one medium lemon

simmer these together and skim off the scum *as*it*rises*
(if you wait for it all to rise so you can skim just once
and you miss the moment, the scum sinks, never to rise again)
I pitched directly into the wort/must (what is it when you're
making mead?):

1/4tsp Red Star Champagne yeast

and kept it at room temp (65-72) for 5 weeks where it bubbled
about once every 5 seconds for the whole time. In fact it was
still going when I bottled, yes, I plan to begin drinking it soon,
before it becomes a grenade six-pack.

Subject: Garlic Beer from TCJOHB

Forwarded message:

Several weeks ago someone asked about the garlic beer that Mr. Papazian mentioned in TCJOHB.

I talked to the people that brewed the infamous concoction and what they told me to do is boil up a can of light malt. After the boiling is done, throw about 3 to 4 HEADS of garlic (A head is the whole bundle of garlic), thoroughly smashed. Let the beer ferment out and carbonate normally. Don't add the garlic during the boil or you will boil off the aromatics that give garlic its unique smell and flavor.

In the last message I wrote about this I speculated that the best use for this brew would be cooking seafood. The original brewers agree with this although they still contend that it goes great with pizza...

>what it's called) At \$8.00 a 3-pak, its pricey.
>Ted)TSAMSEL@USGSRESV.BIT)

I believe you're describing their "lover's beer"--the fatuous brew that comes in a neo-phallic bottle and features a couple on the box with red diagonal color-swatches on their cheeks-- I haven't tasted it, but a general rule of thumb is that Fischer beers are about as bad as imports can be.

Although I realize I'm risking some kind of cultural war here, I would venture to say that in my humble experience French beers in general are a poor investment--they ought to stick to making wines over there, which they are indeed good at. :-)

The Fischer's people are very marketing-oriented; they are looking to sell their beers to the sort of y-people who would buy it *because* it's horrendously priced and packaged in a manner that Bozo the Clown would blush over. They haven't heard that those people don't exist anymore, or perhaps they're trying to milk the dregs a bit.

>can be.

Not necessarily so, at least in regard to Fischer Bitter d'Alsace, a
reasonably pleasant ale. Don't confuse it with Fischer AMBER d'Alsace,
which
is fairly putrid stuff.

More significant to home brewers, however, is that this beer comes in
sturdy, brown, Grolsch-type bottles that hold 22 ounces! They're perfect,
in
my humble opinion, for bottling homebrew, as the oversize bottles roughly
halves the bottling effort and one provides just about the right amount
of
beer for my wife and me to share over dinner. (I get 20 ounces, and she
gets
two ounces. <whap!>)

My primary source of homebrew supplies (Basement Brewmaster in Milwaukee) is no longer doing mailorder. They had some of the highest quality, low price supplies I've seen.....I'm really disappointed they no longer do mailorder. Anyhow, it seems that I'm now in need of a new supplier. Hope you all can help me out. Is there a particular supplier that you've used and think highly of? Someone who carries whole leaf hops, bulk extracts, and Wyeast strains? Please give me some suggestions. E-mail would likely best. I know there is a list in a long ago previous HBD, but I don't believe it's annotated.

Hope to hear from someone soon.....warmer weather is on the way!

Date: Thu, 7 Mar 91 09:28:15 -0500
From: zentner@ecn.purdue.edu (Michael Zentner)
Subject: Fischer brew and Mead

Regarding the "lovers beer", everyone seems to think of the bottle as a phallic symbol. My first impression was that of a deoderant bottle. Guess it just depends on how you look at it.

Well, being the immensely curious sort, we had to give it a try. I, for one (and apparently only one) enjoyed the brew. It was just a different taste. I didn't go into it expecting to taste "real beer", so I wasn't disappointed by the bastardization of "normal" beer flavour by overzealous use of "exotic" ingredients. I think it's refreshing when someone tries to do something different (sometimes it works and sometimes it doesn't). While I wouldn't rush out to buy another 3-pack, I certainly would not recommend that anyone NOT try it. Of course, I like to tinker with strange things in my brews too. Kein Rheinheitsgebot hier!

Speaking of out of the ordinary things, we brewed a (I guess) melomel last weekend with strange results. The basic recipe was:

16 lb wildflower honey
5 gallons water
acid blent to .45 tartaric
5 kiwis
3 star fruits
1 lb cranberries
MeV liquid mead yeast culture

Pasteurized the honey and fruit at about 180 F for 10-15 minutes, ran through a chiller, pitched with VERY vigorous aeration. Will let it sit with the fruit in for 7 days, then rack off. IG 1.125.

Now for the weirdness. Has anyone used this strain yet? I pitched at about 6 PM. No real activity the following day until about 4 PM. The strange thing was, it did not start out gradually at all. Nothing happened until about 4, and then, all of the sudden, there was a violent eruption of foam out of the airlock. No warning at all. I suspect some strangeness with this yeast based on my starter as well. It was a honey based starter with acid adjustment and honey about 2-3lb/gal ratio. As I swirled the active starter in it's champagne bottle before pitching into the mead wort, it released copious amounts of gas, foaming up very much like carbonated champagne does, with a quickly subsiding head. It smelled great, so I pitched it anyway. The fermenting mead smells great as well.

Also, has anyone used star fruits before? I think I would like to experiment with these in larger quantities, as I suspect that the total fruit content of the mead above will contribute very little fruity flavour, given that most recipes call for closer to 7 lb total fruit. We tasted a little of the star fruit before tossing it in and it really was a refreshing blend of grape and apple flavour. I suspect that in significant quantity, this would be a great flavouring agent.

Date: Thu, 7 Mar 91 09:54:38 EST
From: bolt@tom.WEC.COM (Conway A. Bolt, III 5-8810)
Subject: Best way to pitch yeast

I have a question concerning pitching of yeast. Assuming that you are starting with dry (packaged) yeast, is it generally better to activate the yeast first and later pour the liquid into the wort, or just pour the dry yeast directly into the wort and let it activate there? Usually I activate the yeast first, but on a recent batch forgot to do so and just dumped the dry yeast directly into the wort. Fermentation seemed to start much faster this way. Could this be due to thermal shock, eg. pouring yeast merrily multiplying away at room temperature into a wort which may only *approximately* room temp?

Activating the yeast first seems to make the most sense, but OTOH dumping the dry yeast directly into the wort eliminates a step in the process, but most importantly (I would think) the risk of infection since the yeast comes in contact with fewer vessels and less air. Both methods seem to brew beer of (IMO) high quality. Suggestions?

Yow -- I was in Seattle last year -- brewpub heaven. And I just returned
from a trip to San Francisco. At one brewpub I went to (only 2 in SF?),
the
bar-guy asked if I had ever been to Seattle! I thought CA was the place
to
go, but Noooooo. Enough ranting.

I *really* enjoyed the Big Time Brewing Company; best beer of all the
brewpubs I visited. Pike Place wasn't open then, so I don't know. Big
Time
is in the University area. I've heard they've done very well in a number
of
left-coast competitions.

I also visited Merchant Du Vin (importer for things like Sam Smith,
Lindemans, and other great beer), downtown. Fun place, beautifully
appointed, lots of souvenirs, and great T-shirts for sale.

This is just the viewpoint of a tourist, and I'm sure you'll get lots of
feedback from HBD readers in Seattle, but I thought I'd give you a
beerhunter's view.

Subject: More beer marketing

A few comments regarding the marketing of beer. (I'm not a Digest subscriber, but read copies of Roger Locniskar's digests)

The Commonwealth has been mixing soda and beer for years, calling it amber tops and bitter tops, although they haven't tried to call it diet. It's really good on a summer day, or if you've got work to concentrate on.

I don't believe there's anything wrong with brewpubs selling Bud. I've seen people walk out of the Commonwealth because they don't serve Bud, dragging their friends who have taste buds with them. You just shouldn't put neon Spike McKensie's in the window... (In Massachusetts, you can't serve commercial beers at a brew pub.

As far as women are concerned, it should be noted that when Miller bought the rights to Lite Beer, it had been a failure because the previous owners had tried to market it to women. It took Ray Jay Johnson and all the ex jocks to get people drinking the junk.

About wine, the Cambridge BrewPub serves their own white wine "Made through a unique process using barley". It's rather nice, light and crisp (Not your average barleywine). It's not a big draw for Yups, though. They only mention it on the back of a folder on the tables, and Y people probably think it's uncool because it's not all grapes. The Commonwealth used to serve wine and Black Velvets (50% champagne on top of 50% stout; yum!) but the Puritans on Beacon Hill stopped them; you can only serve your own alcohol at brewpubs.

> although they still contend that it goes great with pizza...

Thanks for the tip.

In the meantime, some friends and I went ahead and brewed a gallon or
so of garlic beer. In one gallon, we boiled (yes, boiled) three cloves,
finely
chopped. We bottled it a couple of nights ago, and it smelled pretty
garlicky.
I'm looking forward to trying it. We've decided to wait until it's
crystal
clear and then order a pizza (of COURSE it goes great with pizza) and
break it
open. I'll let you know how it comes out, if you're interested. I can
even
post the recipe.

Thanks again.

Subject: Boilovers

Last week, while boiling up a batch of steam beer, we had a boilover of what can only be described as Biblical proportions. After several hours trying to clean wort off my floor (and stove, and cabinets, and walls, and cat)

I decided Never Again!

My question is: How does one prevent this tragedy from reoccurring? (After all, we did lose about 1pt of wort!) The batch we were making contained two can of extract and 1/2lb of crystal malt (if that matters).

On a sepearte note, with regards to the brewpub conversations, I guess I'll throw in my shillings worth (inflation, you know). Iowa's only brewpub (in Iowa City) serves 3 of their own brews + several commercial beers. The day that we were there the ale line was clogged, so all we had to choose from was stout or Irish-style lager. They also had things like Bass and Heinekin, as well as the standard commercial domestic swill. While I had no desire to try super-dry extra-lite (or whatever) I realized that the masses consuming this stuff meant my pint of lager was only \$2.50, not \$5.

I know if I ran a brewpub (which has crossed my mind quite a bit lately) I would probably have some commercial lite beer on tap for the folks who wanted it (along with a prayer for the healing of their tastebuds). I could brew it myself, but I wouldn't want to tie up the equipment with making it.

Here endeth my sermon.

Subject: re: women and beer, etc

I love a good row, and it seems this has the potential for being one, so I'll throw in my 1 cent worth (my opinion of my opinion). For the record, my wife loves stouts (Mackeson's, Old Australia, Sheaf, and mine in particular), porters (Sam Smith's Taddy), doppelbock (Celebrator is superb), and many other strongly flavored beers. In fact, it has been my experience (yes, I recognize the lack of significance of anecdotal data in marketing decisions) that anybody who drinks my homebrew likes it better than the over the counter swill made by the big brewers -- and my beers are NEVER diet, and always strongly malty and generally heavily hopped. At the very least, I have cultivated friends who appreciate real beer flavor. At most, there are lots of people out there who can develop a taste for real beer, given the opportunity. It's possible that the cultural influences on gender differences in drink preferences are a factor that need to be taken into account; however I would not recommend naming a beer "for women only". I agree with Stacey Jueal that this would be a quick way of alienating a large part of the targeted population. Bear in mind that there are lots of men who have absolutely NO palate and will prefer corn lager until the palate is trained to know what really tastes good :).

I suggest using descriptive names for your beers. After all, the Brits have done this for years: stout, strong ale, bitter, mild. People will get the idea without your saying specifically that something is for one kind of person or another. Can you imagine trying to sell a beer that's marketed as "strictly for the blue collar worker?" I doubt that would fly, even though being a blue collar worker is nothing to be ashamed of -- singling out a group for "special" treatment can be construed as derogatory.

On another subject: Fischer's <whatever that number is> is truly the worst tasting swill I have ever encountered in the beer section of the grocery. However, they did market it well enough to get me to try it ONCE. But you can bet that I, and probably most other people who have tried it, will never make that same mistake again. That's the sort of thing that really makes me wish for bad things to happen to a manufacturer. Bankruptcy, say. If the choice is between this garbage and Bud, I'll be awful thirsty.

Subject: Insulating Carboys

I've luckily stumbled across some 10 gallon carboys. These carboys also have a thick styrofoam jacket to put them in. The bottom half of the jacket covers the bottom half of the carboy and the top half covers the rest so the carboy can be completely contained. I plan on cutting a hole in the top of the styrofoam jacket for the airlock to fit through. My question concerns heat buildup from fermentation. I've heard a vigorous fermentation increases the temperature of the wort. Would there be a heat problem if I completely jacket my carboy? I do have a spare freezer that I use to maintain a constant external temperature of whatever I desire. I dont want my wort temp. to get too high.

Subject: Real Women Drink Real Brew

Here's another anecdotal data point for you. I've been a woman ALL MY LIFE (amazing, isn't it? :-)) and I like strong stouts, porters and barleywines and don't like pilsners and light lagers. Of course, I also like single malt whisky.

I have to admit, though, that the macho aura associated with strong tasting drink leads to some comical incidents. More than once I have gone out with a group of guys and ordered the darkest ale or strongest Scotch in stock, and then the guys feel they have to prove their manhood by ordering similarly and they don't like it and I snicker quietly to myself.

for us.

Did you boil or otherwise pasteurize the cider before adding the sugar or
pitching the yeast?

According to this, you used 3-3/4 to 5 cups of sugar for a 5-gallon
batch?

That seems to me to be a lot of sugar, but then again i've never made
cider.

I'm looking into making some lighter beverages for the upcoming summer
(mead, cider, fruit beers). For you people making the small batches
(1 gallon) of mead, how long is it from brewing to drinking?

Also, does anyone have a good recipe for a light raspberry ale?

OB brewing story: I made a batch of oatmeal stout as per the recipe
posted to the digest a few weeks back. Everything went great, but the
initial fermentation bubbled over in my 7-gallon primary and filled
up my fermentation lock with wort! Suprised me. Guess i'll have to
figure out how to rig up a blowoff tube to my primary.

Subject: other brewpub beverages

If anyone were doing a brewpub, I would STRONGLY recommend serving hard cider if at all possible. It retains the 'homebrew' mystique (assuming you make it yourself, of course) and provides an alternative to those who do not care for beer. My wife is absolutely enamored of the stuff. My parents do not like beer *at all*. I told them of my pub travels in Britain and they listened politely. Until I mentioned that Linda had gone ga-ga over the ciders that *every* pub in Britian (well, we only visited 30 some) served. Suddenly they were *very* interested. It does help that my father is from northern Michigan (with a heavy influence of Cornish miners) and grew up with hard cider and pasties as common occurrances.... In any event, they now plan on visiting a lot of pubs when without the cider they would scarcely darken their doorways.

When we went to British Columbia we were also amazed at the variety of cider sold there. Actually, I think they are much better than those sold in Britain (cleaner taste, more appley). I wish we could get some here in the SF Bay area. Blackthorn is available (and fairly decent) but is \$10/6-pack and has lost something in the travelling. Lyon's Brewery has cider from 'Napa City Cider' on draft which is quite good (but 30 miles away). As an aside, does anyone know anything about this cider? I would love to get it in 5 gallon lots!!

I had one of those "Biblical proportion" boil-overs myself and it sure
made a

mess!!! I found a solution that works for me. This may sound
simplisitic but

I've found that keeping a glass of cold water handy near the boiling wort
eliminates this problem. Whenever I see that the wort is "building" up
for a

boil-over, I just dump a couple of ounces of cold water in and the head
drops

instantly. Since the propensity to foam up seems to occur primarily near
the

beginning of the boil, I just baby-sit the pot until this phase passes.

Hope this helps.

Subject: women and beer tastes

In the US, it is nearly accepted gospel that women only like lighter beers. But is not true worldwide. I was a volunteer at last year's Great American Beer Festival for the Bayern Brewing Co. from Montana. The brewmaster (a native born German) said that where he grew up, women usually drink the darker, heavier beers but the men prefer lighter beers.

As a second anecdotal reference, last Christmas I drove to Wisconsin to visit relatives. Of the homebrews I brought along, the women seemed to prefer the heavier beers, such as a heavy Irish Stout (tastes great), while the men had to urged to try something other than their accustomed lite beers (less filling ;-).

First of all, homebrewing is alive and well in Alabama. At least it is in Huntsville. Why, we even have a homebrew supply store. As for the Premier, I have not personally used it but I have sampled a batch that an office mate made using a can of Premier and a can of John Bull dark. It was very black, very tasty, and had a dark brown head. Because of his results, my next batch will probably be the "Wise Ass Red Bitter" just to give the Premier a try. I wouldn't use the yeast however. Pick up a can or two and give it a go.

Subject: my 2 cents on the bruheat
To: homebrew%hpfcmr@hplabs.hp.com

I have been brewing with the Bruheat for five years now, and I wouldn't want to mash without it. There are some things you need to know when you use it, though.

1. You need a *lot* more water in your mash. The usual description for the ideal consistency for the mash is that of a thick porridge. With the bruheat, you want something like a thick soup. Don't use the amounts of water given in the Papazian's tables in TCJOHB; it won't be nearly enough. Two reasons: first, if your mash is too thick, you get the scorching on the heating element problem. Second, if your mash is too thick, heat will be distributed very unevenly. (Now that I think about it, the first problem is just an extreme case of the second, so there's only one problem.) What I usually do is fill the bucket about half full of water and then start adding my grain, stirring constantly. When it starts getting too thick (experience is the best guide here) I add another quart or two of water. You can get water at the right temp straight out of the tap, so I don't worry about the temperature. I know the books all warn against too thin a mash, but so far I haven't noticed any dire consequences.

2. Even when the mash is thin enough to prevent burning, you will still have to contend with uneven temperature distribution. The cure is frequent and vigorous stirring. Get yourself a well-sanded hardwood stirring stick and put it to good use. You don't necessarily need to stir continuously, but you should stir at least every few minutes. As long as you're hovering over the bucket stirring, check your thermometer. You will need to constantly monitor the temperature and adjust the heat accordingly. Money spent on a high quality laboratory thermometer is money well invested.

3. Occasionally you will get stuff burnt onto the heating element. We have extremely hard water here, so I get layers of gunk caked onto the element no matter what I do. This will lower your efficiency tremendously. Things will go much faster if your element is kept shiny clean. I clean mine off by scrap-

ing it with a wire brush. Make sure the brush has fairly soft bristles (brass is best) so you don't damage it. *Don't* clean your element by soaking it in bleach or something nasty like that. A friend did that once and ate the stain-less off the surface and ruined it.

4. Don't even consider buying a 110 V model. I initially bought a 110V Elect-rim mashing bin, and I quickly realized my mistake. It works great for holding a mash at a constant temp, but it takes forever to increase the temp between steps. Don't even ask how long it takes to boil. If you can find a 220v Electrim, though, I would buy that instead of the Bruheat. The Electrim is made from a rigid plastic with a reinforced rim, while the Bruheat is made from a soft plastic. A floppy container is not very comforting if for some reason you need to lift it while it is full of boiling wort.

5. What's better than a Bruheat? Two Bruheats, of course! After brewing for a while, I realized that making a batch of all-grain beer takes approximately all day long, most of which is spent standing around waiting or cleaning up the unspeakable mess I can't quite seem to avoid making. So, as long as your kill-ing time, you can make two batches at once and have twice as much beer for about the same amount of time and effort. If you can't afford two, talk a friend into getting one. Then you can share, and you can make brewing a social occasion. (Try making it a social occasion anyway, and you can try to pass off some of the work onto someone else. After all, isn't it fair that the consumers of a product bear the costs of producing it?)

6. If you are an extract brewer, buy a bruheat. Then you can do full wort boils without screwing around searching for propane burners and huge stock pots. Also, if and when you take up mashing, you will already own the major new piece of equipment you will need.

In sum, if you keep it clean, water down your mashes, and supervise the proceed-ings carefully, and generally don't ask the Bruheat to do more than it's able to do, it will make you happy and keep you supplied with excellent brew.

Subject: Pacific Northwest Travels

Greetings All!

I too am traveling to Washington State (maybe Oregon too) in the near future.
The Big Time Brewery sounds great - 3 golds at the GABF! I like the names of the winners too - Prime Time Pale, Coal Creek Porter, and Old Woolly Barley Wine. Is Big Time Brewing Co. a brewpub? Or can one find their stuff on tap at a variety of bars? This is important as I'm not sure how much time I'll be spending in Seattle. For all you Northwesterners, is Cooper's the place to hit to find a good variety of fresh, draught products? Is there someplace better to go if I'm limited on time? I'm interested in trying Bert Grant's ales, Big Time, Sierra Nevada (CA of course, but we don't get it here in the Midwest), etc.

Another item that I haven't seen addressed - CONGRATS to Seattle's Brews Brothers for taking the club competition's Hail to Ale (IPAs). John (Polstra), the recipe (of Jack Hagens) in the last club newsletter looked like a winner; obviously, it was! By the way, Brews News is a great looking and informative club posting. Keep up the good work! Another personal note - to Norm Hardy - Your winning pale ale of two years ago is a super recipe. When will you be posting last year's 2nd place recipe? Did you again use Wyeast 1028? It's a nice yeast. Thanks!

All for now,

Subject: Final report on The Wholesale Homebrew Club

As promised, here is a report on how my first experience with the membership warehouse supply company in Florida went. First of all, it took quite some time to finally get all the supplies. I got the dry malt after about 2 weeks of mailing my check (pretty good, I thought). However, some of the malt syrup was back ordered to England and they didn't ship any of the rest of the order until all of it was ready to ship. I finally got the remainder of the order after about 4.5 weeks. Calls for help were not handled with much concern on their part, but I made the mistake of worrying. I know I should listen to Charlie Papazian more often, but it was nearly a \$500 order. Now that I have received the whole order and I can bury my face in a big pile of hops, I'm not nearly so "unrelaxed". Many of you out there in HBD-land have wondered about the high cost of postage. Well, postage worked out to be about 25-30 cents/pound. Total cost of:

55 lb. unhopped dry malt	\$115.68	\$2.00/lb.!!!
6-3.3lb cans M&F syrup	\$42.00	\$7.00/can!!!
50 lbs corn sugar	\$33.70	\$.66/lb.!!!
leaf hops-1 lb.	\$8.00	
Caps-printed-70 gross (10,000)	\$45.00	\$.60/200 caps
Specialty grains-5 lb.	\$6.50	

These are DELIVERED prices, actual price. I would like to know if these AREN'T the best prices around, but they are more than 50% less than most of the retail prices in this area. Other supplies for sale are:

- Hops pellets and leaf-20 varieties
- Speciality malts-including plain malts in 55 lb barrels
- Wine making ingredients and supplies
- Kegging equipment
- Yeast, dry and liquid (weast)
- Cappers, carboys
- Fruit pressers
- Soft Drink and Liquor Extracts
- Stainless Steel Stack Pots (5 gallon cap-\$67.00 Is this a good price? 'cause I really want one.)

Anyhow, that's the lowdown. I'm not necessarily endorsing them, but I think the prices are pretty good. Their phone service basically sucks, and delivery is somewhat less than prompt. But... I would like to hear some feedback on the above mentioned prices, so drop me a line!

Subject: All this about women and beer

I don't know how relevant this really is, but I think it is interesting to reflect on the info that it was the WIFE who brewed the family beer way back before a central location made it for each town--the extreme case of a brew-pub. Of course this distinction developed because the husband was busy doing farming or whatever while the wife was at home cooking and cleaning and etc. so she could tend the brew--I guess it was like baking the bread every day (the wife became master of yeast,eh?).

I wonder if gender mattered to the drinking of beer way back then. And if not, when did the current state of affairs develop (we all seem to acknowledge that a greater percentage of men drink beer than women).

My notes on the subject: I was shocked the first time I ever saw a female drink beer--I was about 8 yrs old. I never thought it happened! My mom drinks some occasionally, but never at home so I never saw women drinking beer. I've also noted that men who claim "I don't like beer" are often classified as whimpy or effeminate. I'm not saying it's right, but I do know that it happens. Personally, I don't like to hear anyone say those four words--I'm really into the social aspect of beer appreciation.

Subject: Sassafras in stout

Has anyone had experience using sassafras in beer. I was originally going to try making a raspberry stout, but the only berries that I've come across in my area have sugar added -- they're also not very cheap, and adding 3 pounds or so would start getting a little costly.

One of our local grocery stores has fresh sliced sassafras root, but I'm unsure of how potent an additive it would be in a stout. It comes in a 2oz bag and smells very nice (plus it's a dirt cheap \$0.49). In TCJoHB, Papazian mentions the use of licorice root, but unfortunately he doesn't give a measurement by weight. He just says use a 4 to 6 inch piece of root. Any info appreciated.

Thanks,

Eric

Subject: Extract efficiency

First let me say thanks to those of you who replied to my extract efficiency question in HBD #586. Since then, I've done a little research on the subject. Here is a summary of the responses plus a few tidbits I've discovered.

- * There are at least two way to measure extract efficiency. In Greg Noonan's book Brewing Lager Beer it is measured as a percentage using the following formula:

$$\frac{(\text{degrees B}+259)*\text{degrees Blbs extract}}{\text{Volume of wort} * \text{3100wort}} = \text{in}$$

$$\frac{\text{lbs extract in wort}}{\text{lbs grain mashed in}} * 100 = \text{extract efficiency percentage}$$

Efficiency can also be measured as points per pound using the formula:

$$\frac{\text{Volume of wort} * (\text{SG}-1) * 1000}{\text{lbs of grain mashed in}} = \frac{\text{Points}}{\text{pound}}$$

In Papazian's TCJoHB he states that one pound of malt in one gallon of water will yield a SG between 1.025 - 1.030. The numbers correspond to 54%(1.025) - 65%(1.030) using Noonan's formula. Obviously 54% yield is somewhat on the low side. Yields higher than 1.030 are definitely possible.

- * Extract potentials are lower with malts such as munich, caramel, dextrin, and darker malts.
- * Some grain adjuncts have more extract potential than that of malted barley. Corn is one example.
- * With decoction mashing you can get upwards of 80% extract efficiency with fully modified british malts. The usual is around 70-75% e.e.
- * Often it is impossible to crack ALL the grain with a standard "corona" style grist mill. The uncracked grains yield no extract, and thus will lower your efficiency slightly. It might be interesting to figure out what percentage of the grains remain uncracked, this could then be deducted when calculating your efficiency (if it's a significant enough number to bother with).
- * Looking in some of the recipes in Zymurgy I see that some people get downright poor efficiency. I suppose this could be an error in the printing (ie. the recipe says ingredients for 5 gal, but it's supposed to be for 10).
- * If your efficiency is above 60% you can be pretty pleased. Below 50% and you should seriously look over your procedure.

* In one of my replies someone states they are getting around 87-91% efficiency. Using Noonan's formula this would be impossible. The writer mentions Miller. Is this yet another method of determining e.e.?

Happy mashing,

Eric

Subject: **Micros in St. Louis**

In HBD Doug Roberts ask about A micro in St. Louis.

As far as i know there in none yet. Dave Miller is romered to wanting to start some type of brewery there. The law was only recently changed in MO regarding small brewing operations so not much has happened yet. The only Micro in the state is near or in KC.

If you have any inclination of visiting the big boys of brewing Budwiser, don't. There brew house is closed for remodeling until 1991.

replies to hbd 593...

I've been able to culture live yeasts from samples that have been frozen in liquid nitrogen for 2 hours...

Sassafrass root has a compound in it (I forget it's name) which causes cancer (Doesn't everything nowadays...) BUT I've seen sassafrass extract (for making tea) which has the nasty ingredient removed (\$2/10oz).

> Eric

I gave this a try a few months ago. I used about one oz. of sassafras bark, since I could not find any sassafras root around where I live. I made a light ale, with about 4 lbs of light malt extract and three lbs of honey. I added half the bark to the boil. Unsatisfied with this, I then made a tea with the other 1/2 oz and warm water, and added this to my primary.

Unfortunately, I'm not very happy with the results. The resultant beer tastes mainly like tree bark! It smells more or less like what I had hoped it would, but the taste is bitter and strange enough to make drinking this more work than pleasure. I should have used less, clearly, but I'm not sure that even a small amount would have been an improvement over no sassafras bark at all.

Maybe sassafras root would work better than the bark; if you try it I hope you'll post your results. I've thought about trying a little root beer extract in something like a stout. Has anyone out there ever tried this before?

From: Todd Enders - WD0BCI <enders@plains.NoDak.edu>
Subject: Extract Efficiency, a Matter of Semantics

I see that there's a little mixup as to the way Miller cites extract efficiency vs. Noonan. Miller quotes extract efficiency as % of theoretical maximum extract (ca. 35 points/lb/gal for lager malt), whereas Noonan gives the actual percentage of sugars converted/extracted per pound of grain.

So, if I'm getting 87-91% efficiency as per Miller, what I am saying is that I'm getting 30-33 points/lb/gal. It might be instructive to compare both systems to obtain a sense of perspective. But from my experience, it should be relatively easy to get 30 points/lb/gal of extract if your mashing procedures (grinding, temp. control, sparging, etc) are correct.

Of course, the real issue is: do my procedures make good beer? If so, there is little incentive to change. We are all striving to make good brews, so the comparison of extract efficiency is of some value, at least to see how our mashing compares with others (or with theoretical values). But trying to squeeze the last point or two out of your mash borders on excessive worry :-)!

1 cup/gallon is a lot of sugar? If I want a strong cider, I will use 3-
5 cups
PER GALLON of sugar...this usually comes out very dry and alcoholic, but
still
tastes like apple cider. I only use dextrose (corn), not cane/beet
sugar.

I haven't had any problems with any soda bottles that don't have
the screw-off caps. I have been told that the pressure in
american sodas is greater than the pressure the beer should be at
when carbonated (i.e., sodas often fizz when you open them, beer
should never fizz when you open it).

>Also I keep seeing things about a glass secondary (carboys),
>I can get plastic ones from water coolers, is there any harm
>in using a plastic one?

I don't know. However, I have heard that most of these plastic
water cooler containers are not "food-grade", since they don't
expect to store anything acidic in them (like wort). So stuff
could leach out of them.

>Many of you out there in HBD-land have wondered about the high
>cost of postage. Well, postage worked out to be about 25-30
>cents/pound. Total cost of:
>55 lb. unhopped dry malt \$115.68 \$2.00/lb.!!!

This is typical. I looked at three catalogs that sold 55 lb.
buckets of dry malt. Prices were from \$116 to \$123.

>6-3.3lb cans M&F syrup\$ 42.00 \$7.00/can!!!

I have gotten 6 lb. packs of extract from Williams for as little
as \$10, in groups of 6 (on sale, but 11-11.50 isn't unusual).

>Specialty grains-5 lb.\$ 6.50

Last place I ordered from all their specialty grains were
\$1.00/lb.

>These are DELIVERED prices, actual price. I would like to know
>if these AREN'T the best prices around, but they are more than
>50% less than most of the retail prices in this area.

I think they are better than going to a store and buying one
pound or one can of something, but are about average for buying
large quantities mail order.

On the other hand, if those prices reflect the addition of the shipping
costs (55lb @\$115 is great if \$30 of that is shipping and \$85 is basic
cost), then you got a great deal.

>Stainless Steel Stack Pots (5 gallon cap-\$67.00
>Is this a good price? 'cause I really want one.)

I have seen 10 gallons ones with copper bottoms for \$99 (want to
get one for myself some day).

Subject: Capping champagne bottles

I just got a case of champagne bottles and want to bottle in them. The normal 28 mm. caps I use on beer bottles do fit, but they don't come down on the sides of the bottle top as snugly as they do on the 12 oz. bottles.

My capper, an Italian device whose name I can't remember for my life, says

that a set of tongs for 30 mm. caps may be obtained for champagne bottles.

Am I going to have to get those different tongs and use 30 mm. caps, or will the caps I have do. I tried a couple and the seal seems to be very tight, just the sides being funny as I just mentioned. Do I have a problem? (Not to worry, though!)

Subject: India Pale Ale

I'm teaching a friend of mine how to brew. The second training batch will be an extract India Pale Ale from the CJoHB. I have a question about the amount of gypsum to add. With a recipe for 5 gal of:

7 lb pale malt extract
1 lb crystal malt
.5 lb toasted pale malt
2 oz cfj90 aa=~9.8
.5 oz cascade aa=~6.8 (both pellet)
gypsum
Wyeast London Ale

what amount of gypsum would one want to use. East Bay water has less than 10 ppm Ca and all the other good ions, so we're starting out with pilsnerish water. I was thinking of adding 2 tsp. of the gypsum. All comments on the IPA brewing and water salt content for specific beer types welcomed. Also, what pH range are we talking about? If it's not in there, how would one easily change the pH?

curious,
kj

Subject: What about tea beer?

Okay, we've all heard about/made/tried beers with coffee in them. I happen to be a tea lover, and I'm wondering if anybody out there has ever made a beer with tea. Just before Christmas this year, I made a rather wonderful liqueur with jasmine tea, and I'm becoming more and more convinced that a beer made with some sort of tea would not at all be a bad idea. Anybody out there have any experience with this? Any ideas as to why it might be a bad idea?

And for those of you who want to try out making the Jasmine Tea Liqueur, here's the recipe:

1 pint dark rum
1/2 cup jasmine tea
1 cup sugar syrup

Steep the tea in the rum for 24 hours, and remove. Make the sugar syrup by boiling 1 cup of sugar in 1/2 cup of water (it will be VERY thick). When the syrup cools, add to the rum. It's ready to drink immediately. This is a very nice after dinner liqueur, but you may drink it any time you want to. If the tea flavor is too strong, try steeping for a shorter time, cutting down on the amount, etc. Likewise, the amount of sugar may be a bit excessive for many tastes, so experiment.

Cheers,

Paul

Subject: Campden vs yeast

I just finished working my way through the first of the recipes in the ``Making Mead'' book I've got (can't remember the authors -- they're very British, the cover's orange). The part that confuses me is the adding of the Campden tablets. The directions were something to the effect of ``add two Campden tablets, wait 24 hours, then add the yeast.'' The idea, as I understand it, is to kill all the little beasties that managed to wander in while you weren't looking. So why doesn't the yeast die? Especially since they say to add another tablet after each racking.

If the theory is that the sulphite settles out, thus not coming into contact with the yeast, it seems like any movement of the fermenter runs a good chance of killing the yeast.

I think I'm confused....

Subject: 1990 Recipe for Craig

A question about the 2nd place Pale Ale recipe from 1990 - Cascade Pale Ale:

It was exactly the same as the previous 1989 best of class winner, but the 1028 yeast attenuated further than planned. I entered it as a British Bitter and a Pale Ale. The Pale Ale got the 2nd place. The Brit Bitter got knocked out in the 1st round.

I just bottled this year's "version", the same except for .25 oz Cascade cones in the secondary for dry hopping. Very nice beer, fermented and conditioned in 19 days. It helps to get a proper yeast starter, indeed.

>like to try to recreate something like St. Leonard's or 3 Monts or
Jenlain.

>Also, has anyone had any luck culturing yeast from these brews?

Jenlain is the only one of the beers mentioned that I'm familiar with, and I haven't tried to duplicate it, but I know where I'd start. I'd take a good brown ale recipe, substitute a German hop for the English to about the same degree of bitterness (and keep it all in a single application, 60 minutes before the end of the boil), "goose up" the pale malt significantly while holding the crystal and dark malts constant, and ferment it with a lager yeast of mild attenuation and neutral character. That should get you into the "fine tuning" range.

I've read that Jenlain pasteurizes their beer, which is counter to customary biere de garde practice, and pretty much precludes culturing the yeast. My recollection is that it didn't taste like a yeast of great truth and character, so that's probably not a great loss. Good luck!

From: R_GELINAS@UNHH.UNH.EDU (Russ Gelinias)
Subject: glass scratches, update

I know that scratches on a plastic fermenter are a perfect breeding ground for all those things that we don't want in our beer, but just how dangerous are scratches on a glass carboy? The scratches are the result of the metal part of a carboy brush rubbing against the glass. I fill the carboy with water and bleach when it is not being used. Will days of soaking kill off any critters?

Now a follow-up: I cultured a batch of Wyeast german ale yeast, tossed it in a batch, nothing (seemed to) happen, so I pitched dry yeast, which worked fine. Soon after bottling, I started getting gushers, with all the indications that the German yeast had started up. The beer was undrinkable at that time. So I emptied all the bottles back into a carboy, added ~.5 cup of corn sugar, and stirred it up alot. It fermented quite a bit more (and I gave it a good shake every day to try to get any dissolved off-flavors to bubble out). After about a week (maybe more, I don't have the brewsheet with me), I bottled it (again) with 0.5 cup sugar. It's been bottled for ~2 weeks now, and it tastes just fine!!!! A little bit flat (to be expected after all that shaking), but no off flavors. Alot of work for one batch, but I'm not complaining.

Subject: Extract Efficiencies

There has been some discussion lately regarding extract efficiency. It's good to see this discussion. Over the years it has seemed to me that discussing extract efficiency is like comparing professional salaries. People just don't do it!

I use a 5 gallon igloo cooler to do my mashing and sparging. I get around 30 points per gallon. I've found that extract efficiency depends on grain type. I've had bad luck with American 2-row Klages (25-27 points per gallon), but get 30-31 points on English 2-row. Imported grains cost more, but, IMHO, are worth it because they give better extraction, and less grain is needed. In addition, I've just started tracking sparge times - slower sparges give better extraction. With my equipment, I've noticed that bigger batches (5 gallon) give a better yield than small (3 gal) batches. I suspect that the depth of the grain bed affects extraction.

Although I don't worry a great deal about extraction rate per se (a few points either way doesn't really matter); I feel that good extraction rate is indication that "the mash went well". Good extraction rate implies that the grain bed settled well, resulting in clearer beers with less phenol content. Good extraction rate implies that less grain is used, and less grain implies less tannins in the beer. Higher extraction means less grain is needed, helping the pocketbook, and reducing brewing effort.

The real bottom line is that the taste tells the tale, and that extraction rate doesn't matter. I feel that beers with good extraction rates are cleaner and better tasting than those with low extracts.

Subject: Carbonation and Priming

I recently tried to make a batch of pale ale without using any sugar.

To do this, I used M&F tinned Malt and amber dried malt in the fermenter. And that seemed to work well. I used the same amount of dried malt as I would have used sugar (I was using the recipe on the M&F can).

Then when it came time to prime, I tried to use some Geordies canned malt instead of sugar. I boiled up the Geordies so that I had ~ a cup of 'new' wort and mixed that in to prime.

Now almost a month later, I have a clear beer, with yeast at the bottom, but little carbonation. It seems to me that I should have used more Geordies. Any suggestions as to how to estimate amounts for this sort of half-assed kruesenning I did? Or was I insane to prime without sugar?

Oxygen, Yeast and Good Brewing Practice

This is a summary of an outstanding talk given by the eminent Dr. George Fixx, a kineticist from the University of Texas, at the First Annual Southern California Homebrew Conference.

George was asked to pull out some practical advice from the wealth of information in his recent book. He said what he did was look back and see what he'd changed from the early days of his brewing to the present. The two most important areas concerned oxygen and yeast. The following is how to apply this to homebrewing.

Regarding oxygen, it is important to prevent its introduction into hot wort, because at that time it will very rapidly (seconds to minutes) oxidize the phenolic (and other unsaturated) components therein. This includes the alpha acids from hops, among other things. The oxidation products can produce off flavors and contribute to a very short shelf life in the finished beer.

Contrary to the above, cold wort should be thoroughly aerated. The breakpoint is about 70F (20C) for aeration: do it below this temperature to allow rapid growth of yeast; above this, see previous paragraph. Oxygen here is also good in preventing growth of some bacteria, and wild yeasts don't get as good a chance to compete with the ones you want under these conditions. Shaking the wort is not adequate to really oxygenate it. George recommends an aquarium pump WITH A FILTER to keep out particulates, like the one advertised in Zymurgy. Bottom line: if your fermentations start quickly and never get stuck, you are probably in good shape here.

Yeast was the other big area to George. He used to think reuse was bad news; however, he learned that if you want to reproduce a great beer you've just finished and can get (or have) unpitched wort ready quickly, the yeast from the secondary is THE BEST IN THE WORLD for getting more of the same.

Washing yeast, George believes, can best be done with cheap beer (e.g. Keystone) acidified to approximately pH 2.3. He feels the most detrimental part of washing

is not the low pH but the different osmotic pressure inside and outside the yeast when the standard acidified water wash is employed. Also, he recommends only washing every fourth to sixth time; washing each and every time can increase the percentage of wild yeast unacceptably.

Speaking of washing with grocery store beer, George had a suggestion for the rinse after sanitizing, before filling the carboy with wort: use the cheap stuff. Beer absorbs the leftover chlorine and/or sulfites quite nicely-- use your nose! He recommends a 12 ounce beer for a 5 gallon fermentor. Swirl it around so it contacts all surfaces and sniff the result. He is also suspicious that a lot of the off flavors blamed on bacterial infections (in the case of advanced brewers) actually come from remaining sanitizer. Chlorinated phenols are detectable by taste at very low levels, and have obnoxious flavors, sometimes metallic in nature. So rinse with the bee-ee-squared-arr. If George had a brewery of his own, he would.

Hope this info helps y'all make world-class beer.

tried
> this before?
>
> Terry Noe

I have made a 'root beer ale' by using a can of malt extract (light)
along
with the root beer extract, and then fully fermenting it out. It tasted
like a dry root beer (not at all sweet, of course), but had a kick to
it. :-) It was hard to drink more than one at a time, and it left the
taste of root beer in my plastic primary, which didn't go away until
I had used it 5 or 6 times. I doubt that I would try this again...

Subject: Calculating Bittering Units

I have just been reading the Winter 1990 issue of Zymurgy and came across a definition of International Bittering Units, which is a measure of how bitter a beer is (Or should be). The definition given is .000133 oz. of IsoAlpha Acid per Gallon of solution or about 1 mg./L.

I have been trying to figure out what the bittering unit figure would be for my latest brew, a respectable classic pale ale, but I keep coming up with a number much larger (An order of magnitude larger) than I have been expecting. The formula that I have been using is one of my own devising, but

I think it should at least be close to the expected figure.
Here is my formula:

Total Bittering Units = (Amount of Hops used * % Alpha Acid content)/.000133
Bittering Units/ Gallon = Total bittering units / Total gallons

My numbers are as follows: 2 oz. of 4.5% AAU hops, 6 Gallons.

$(2 * .045)/.000133 = 676.69172$ Total Bittering Units
 $676.69172 / 6 = 112.78195$ International Bittering Units

I have been expecting a number in the range of 10 to 30....

Is my formula wrong? Am I working without all of the needed info?

If anyone has an answer, or a formula that works, please let me know...

From: Pete Soper <soper@encore.com>
Subject: Re: Campden vs yeast

dworkin@habitrail.Solbourne.com (Dieter Muller) asks about Campden tablets.

The basic notion behind Campden tablets is that for wines and the like that have fruit-based ingredients it is not a good idea to boil so boiling cannot be used to kill infection organisms. The metabisulfites in Campden tablets when mixed with water create a dilute sulfur dioxide solution which is used in place of boiling to sanitize the must. Another key notion is that wine yeast is resistant to a certain amount of SO₂. The 24 hour wait that many wine making books specify gives the dilute SO₂ solution time to nail infection organisms while there may also be some loss of SO₂ to the atmosphere in the process, reducing the concentration that the yeast have to contend with.

The theory is not that the sulphite settles out, so moving the fermenter poses no danger.

Are there alternatives to sulfites for wine making these days? With the pressure to get these substances out of wine because of the allergy problems, I wonder if there are alternatives that we can use at home?

Subject: Types of bottles used.

I'm going to try using the plastic soda bottles next time I bottle some brew.

I see a few advantages/disadvantages;

Advantages;

- 1) They're bigger, thus fewer bottles with which to hassle.
- 2) They're designed to contained carbonated beverages.
- 3) No need to buy caps, as one can re-screw the cap.

Disadvantages;

- 1) They're plastic. Somehow seems criminal to bottle beer in plastic bottles.
- 2) They're bigger, thus could have problems if I don't drink it all and disturb the bottom. Also, might lose some carbonation

Any thoughts, or experiences? Has anyone used other then recappable beer bottles?

From: pkel@psych.purdue.edu (Paul L. Kelly)
Subject: Alcohol-free beer

I have tried a few no alcohol beers (e.g. Kaliber), and have found them wanting in one or more ways, such as too watery, not hoppy, etc. My wife, an avid homebrew fan, is now pregnant and has sworn off alcohol for the duration. I would like to make it possible for her to satisfy both her desire to drink real beer and her wish to not consume ethanol. So how would a homebrewer make alcohol-free beer? I have thought about boiling off the ethanol, priming, and inoculating with yeast, but I'm afraid the boil after fermenting would be detrimental to the flavor. Is there some other way of removing alcohol from a fermented product? Any suggestions would be greatly appreciated.

Thanks,

Paul

From: dworkin@habitrail.Solbourne.COM (Dieter Muller)
Subject: Summary: Campden tablets and mead

I recently (was it really only yesterday?) sent off my confusion over Campden tablets, mead, and yeast. I got replies from:

loc@bostech.com
smithey@hulder.css.gov
sherwood@adobe.com

Here's the summary:

smithey> Duncan and Acton, I think -- a brewing friend of mine has it, smithey> and I borrowed it recently when I made my first batch of mead.

This is indeed the book under discussion. I can't really recommend it for the first-time brewer.

loc> No need to be confused about Campden tablet and yeast.8-)

Well, when your only source of reference is a book written by people that assume you already know about wine-making....

sherwood> The campden tablets make SO2 which comes out of solution and sherwood> dissipates into the atmosphere. The directions usually say sherwood> to cover the batch with a towel for those 24 hours -- this sherwood> allows the SO2 to diffuse out. If you put an airlock on it sherwood> (I did this before realizing what was involved) you can sherwood> indeed kill the yeast when you add it.

Yup. Dead yeasties. *sigh*. It's time for another trip down to the guy that sells brewing supplies out of his sitting room. For some reason, I always feel a little odd about that....

smithey> I think the idea is that the the "active ingredient" in the tablets
smithey> escapes as sulphur dioxide (?) gas over the 24 hour period, so the
smithey> waiting is not only to give time for wild yeasts and bacteria to
smithey> die, but also for the mead to become safe again for your yeast.
smithey> As for the sulfiting at each racking, our guess is that you wait
smithey> for the mead to "finish" (either ferment all the way out, or until
smithey> it reaches the desired dryness), then rack and sulfite. This stops
smithey> the yeast, and your mead is pretty much finished. The additional
smithey> racking and sulfiting is to allow the mead time to settle/
clear,
smithey> and the sulfiting is to inhibit acetic acid producing bacteria,
smithey> which would like to turn your mead to vinegar. My mead has been
smithey> in a 3 gallon glass carboy for a couple of months now, the first
smithey> sulphiting definitely stopped any remaining fermentation, and I've
smithey> racked/sulphited once.

Honey vinegar sounds intriguing, but I must admit it's not quite what I'm looking for.

loc> The addition of one campden tablet each time you rack, does not raise
loc> the sulfite concentration high enough to kill healthy yeast (it just weeds out the weak ones :-)). This addition of sulfites at racking
loc> also protects the mead from oxidation when you rack.

loc> Just to fill in the cracks a bit more: There is some controversy over the need for the initial sulfites anyway (especially if you make great meads, those with #2.5-3.5 of honey per gallon of water). Honey is naturally antiseptic and hence the controversy. Some people say it is not worth the chance and sulfite anyway. Personally (since I make great meads) I tend to avoid any extra sulfites. I do use them at racking and do use them when I make small meads. Additionally, I will add 1/2 tsp. of sodium metabisulfite per gallon at bottling time if I am making still mead. This prevents the mead from undergoing a secondary fermentation while in the bottle. (I'm not fond of watching corks fly out of bottles in my cellar and having a sack mead rinse the floor, but that's a different problem|-0)

loc> I also prestart all my yeast so that there is a minimum of lag after pitching. I boil up 1/4 cup each of orange juice and water, cool it, add a tablespoon of yeast nutrient, put all of that in a sterile bottle, pitch the yeast in there, put a lock on it and let it go for 24 hours before pitching the 'must'. I think of it a appetizers for my pets.:-)

Subject: Summary: Campden tablets and mead

Greetings!

I have several questions to ask the collective wisdom of the homebrew readers. I have been reading this mailing list for about 6 months now and have been very impressed with the comprehensive and understandable answers given to most questions. Here goes:

- 1) Has anyone used the soda-type (cornelius?) stainless steel kegs for primary fermentation? It seems that using these would have numerous advantages over the glass carboys that I am now using.

Advantages:

They don't break.
They are easy to move.
Stainless-steel is not going to impart anything to the fermenting beer.
They are narrow enough so I can fit two of them, side by side in the incubator (refrigerator) instead of one glass carboy.
They are easier to clean (wide-mouth).
You can transfer the contents from one keg to another by pressurized CO2 (no exposure to oxygen and no siphoning or pumping).
A filter cannister can be put in-line between primary and secondary fermenters to reduce sedimentation and clarify the beer when transferring.
You can easily draw off small amounts for checking specific gravity.

Disadvantages:

Have to rig up some type of fermentation lock or blow tube.
Can't see through stainless steel.
Sanitation of various inlets and outlets.

Any other comments about doing this?

- 2) I have a 6lb bag of liquid weizen extract from Williams. Does anybody have a good wheat beer extract recipe they would like to share? I would like to make a 5 gallon batch for this summer. Do I need a special strain of yeast for wheat beer or can I use my Sierra Nevada culture?

- 3) Speaking of Sierra Nevada, does any one out there have an extract recipe that comes close to SN Pale Ale? I have seen this question before but no answer. Making a decent copy of SN Pale Ale is my goal in life :-). A homebrewer friend claimed that SN used CFJ-90 hops. Has anyone ever heard of these before? Where can I get some?

- 4) Our wort chiller is made out of 1/4 inch copper tubing. My brew partner is a microbiologist and he is concerned about possible affects from passing hot wort through 10 feet of copper tubing. Is this going to affect

the flavor of the beer or our health in any way or is he just being paranoid? Does anyone know where I can get 1/4 to 3/8 inch stainless steel tubing to use instead of copper? How much does it cost per foot?

My brew partner and I recently upgraded much of our brewing equipment and our first batch using the SN yeast culture, a wort chiller, racking off the trub, and a temperature controlled refrigerator (set to 60F) has come out by far to be our best yet. Many thanks to all of the great suggestions that have come from the digest!

I eagerly await your answers and comments to the above questions.

Thanks,
Bruce Hill

Subject: Brewing Sheet

Hi All,

I recently downloaded Chris Shenton's bewsheet that he put together in the Latex format via anonymous ftp from mthvax.cs.miami.edu. It's a very useful document in which you can tabulate procedures and ingredients for a particular batch (thanks Chris :-)). As I looked over the sheet, I must admit that I don't quite understand some nomenclature and symbols. The questions are:

Under the "Malts, Grains and Adjuncts" area, there is a column reserved for a quantity in units oL (degrees L)? I'm not familiar with this unit convention. Anyone have an idea?

Under the "Prodedure" section there are some unfamiliar terms: "Mash-in, Acid Rest, and Mash-out." I can conjecture what these *might* mean but if someone knows for sure it would be nice to have the real scoop.

Thanks for the info!

Subject: Boilovers, small lager space

You've got to keep an eye on your pot near the beginning of the boil especially. FOr gas stoves no problem, turn down the heat, for electric, you'll have to use the cold water approach. Handy tip gleaned long ago from this digest.

Take a soapy sponge and wipe down the stove top . This makes cleaning subsequent boilovers mcuh easier.

You could consider a 3 gallon carbouy. Also Cornelius kegs can be used to ferment in by attaching the CO2 in hose up and placing the end in a jar to serve as an airlock. Cornelius comes in 3 and 5 gallon sizes.

Avoid plastic water coolers unless you know they are of a type of plastic that is safe for alcohol storage. Remember when plastic liquor bottles first came out, they were not sufficiently tested. Seems the plastic that was used leached carcinogens when in contact with alcohol. Wouldn't want this happening, eh??

Subject: A recipe for Bitter - Draught Bass

Hello chaps,

I've been reading the digests for a few weeks now and I thought it was about time I contributed. Bill Hunter, who told me about the list, asked if I had a recipe for bitter I'd like to share. Can a duck swim?

This is one of my faves. It appears in the book by Dave Line called "Brewing beers like those you buy", Amateur Winemaker, ISBN 0-900841-51-6 .

I don't know if it's available in the US and I haven't seen anyone mention it in the digest. Reproduced without permission (I won't tell if you don't).

'Gallons' is UK gallons - please make the appropriate conversion for the amount of water you add if you wish to use US gallons as a measure.

Stage 5 Gallons Original Gravity 1045 25 Litres

1 7lb Crushed pale malt 3500g
1 8oz Crushed crystal malt 250g
1 3 gallons (UK) Water for bitter brewing 15 litres
3 2oz Fuggles hops 60g
3,4,5 (1+0.5+0.25) oz Goldings hops (30+15+10)g
3 1tsp. Irish moss 5ml
3 1lb Invert sugar 500g
5 2 oz Brewers yeast 60g
5 0.5 oz Gelatine 15g
6 2 oz Soft dark brown sugar 60g

Brewing stages:

- 1 Raise the temperature of the water to 60C and stir in the crushed malts. Stirring continuously, raise the mash temperature up to 66C. Leave for 1 1/2 hours, occasionally returning the temperature back to this value.
- 2 Contain the mashed wort in a large grain bag to retrieve the sweet wort. Using slightly hotter water than the mash, rinse the grains to collect 4 gallons (UK) (20 litres) of extract.
- 3 Boil the extract with the fuggles hops and the first batch of goldings for 1 1/2 hours. Dissolve the main batch of sugar in a little hot water and add this during the boil. Also pitch in the Irish moss as directed on the instructions.
- 4 Switch off the heat, stir in the second batch of goldings and allow them to soak for 20 mins. Strain off the clear wort into a fermenting bin and top up to the final quantity with cold water.
- 5 When cool to room temperature add the yeast. Ferment 4-5 days until the specific gravity falls to 1012 and rack into gallon jars or a 25 litre polythene cube. Apportion gelatine finings and the rest of the dry hops before fitting airlocks.
- 6 Leave for 7 days before racking the beer from the sediment into a primed pressure barrel or polythene cube. Allow 7 days before sampling.

Some explanations and tips (please don't take offence if you're already familiar with the terms):

Water for bitter brewing means hard water. If you're on soft water (your kettle doesn't fur up) then add some water treatment salts or even a couple of spoonfulls of plaster of paris.

Invert sugar is sugar that has been cooked for a couple of minutes over a low flame. Some of the chemists can probably explain what effect that has. I don't usually bother, I just use the sugar (normally a soft brown sugar, not that 'orrible white granulated.

I use isinglass finings instead of Gelatine, it's lees messy and does the same job (slightly more expensive though). Isinglass apparently comes from the sexual organs of certain fish. Makes you wonder what else the ancient brewers tried!

A tsp is a tea-spoon. The quantity is not critical, all the irish moss does is help to precipitate out the hot break.

In the book ,Dave Line refers to several ways of getting brewers yeast. These include going down to your local and asking the landlord for a half of cloudy bitter with lots of lumps in it. Not recommended if you don't get on with the landlord. I don't know what is available in the US but the important thing is to use a top-fermenting yeast (not a lager yeast). Another source is the sediment in certain bottled beers (Worthington's White Shield was a popular choice of home brewers at one time.)

In an emergency the dried homebrew yeasts can be used but I think they leave a nasty taste.

One consequence of using a top fermenter is that it will produce a thick creamy froth with brown bits in it. My personal technique is to remove the brown stuff every day and discard it, since it is dead yeast and can make the beer taste funny if it is allowed to get back into the brew.

Don't mix quantities: pick either the 25 litres list or the 5 gallons list and stick with it.

I tend to use slightly longer times in stage 6. I tend to use anything up to 10 days before barrelling (or bottling) and I usually leave it 3 weeks in the barrel/bottle before sampling it. I find this leads to a more pleasant taste and better carbonation. One advantage of using glass jars is that you can see when the beer is clear before you barrel it.

Hope you enjoy it.

Regards

Pete

Subject: Kosherness and Champagne Bottles

Is kosher beer possible? I thought idea of observing un-leaveness (sp?) was to remind people of the suffering the Jews endured during their exodus from Egypt across the desert. They had no yeast, nor the time luxury to let bread dough rise during the trip. They had to make food from just flour and water to stay alive. Even if you filter the yeast out, you still created the beer with the yeast. Perhaps a lawyer would argue.

My local home brew store sells plastic champagne bottle corks for the European size champagne bottles. They also sell the wire clamper downer do-dads that hold the cork in. These work great, and the champagne bottle of beer is quite a festive thing to bring to your next dinner party.

Also true. That's a good reason to bottles both ways. Having a pitcher
handy to pour the big bottles into is nice--but having single serve
bottles
AND big bottles is definitely wise.

> Any thoughts, or experiences? Has anyone used other then recappable beer
> bottles?

Yes. I got my hands on some really nifty bottles. Evidently, Labatts
thought
real hard about selling beer in 2 litre plastic bottles, but changed
their
mind or put things on hold--the result is that they had tons of BROWN 2
litre
bottles that were made to hold alcohol, and differed and supposedly
resist
O2 infiltration very well--better than the regular bottles I think. I
have a connection who got me a bunch of these bottles.

I've bottled and tried one brew out of one of these, and everything was
super.
Carbonated as well as anything, no weird flavors, really no disadvantage-
-
well, the 5 of us did have to put away a lot of brew before moving on to
the
next sample.

I presume that using garden variety soda bottles would work just as well.
I
would take care to keep them in the dark as they are clear, but other
than
that--go to it. I would also keep an eye out for replacement caps. I
wonder
how many times you can use one of those caps before any loss of seal. I
wonder how many times you can use a bottle.

Stephen> had ~ a cup of 'new' wort and mixed that in to prime.

Stephen> ... but little carbonation. It seems to me that I should have
Stephen> used more Geordies. Any suggestions as to how to estimate
amounts
Stephen> for this sort of half-assed kruesenning I did?

Naw -- this should work fine. Normally, people use dry malt extract to
prime, and I've used molasses. You have to get the amount right so that
you
have the same suger content as your usual 3/4C corn-sugar. I think
Papazian
says that 1C dry extract is about right, but check the book to be sure.

Something I've been doing for the past 10 batches or so is to boil up
some
extra wort with your batch, save the excess in the fridge, then prime
with
that. It usually seems to take about quart to get proper carbonation, and
Noonan gives the figures and equations (of course). I'm doing grain, so
adding a bit extra is easy -- with fixed-sized cans, I'm not sure the
best
way to handle this; you could just reserve 1 quart in a bottle and just
ferment the rest.

(Never by sugar again!)

Subject: Re: Kosher Beer

Bill Thacker writes:

> It's worth pointing out that some fining agents (um, isinglass and
> Irish moss, I think) are derived from various bits of animal guts,
> so that beers using these would not be strictly vegan (or is that
> (vegetarian?). (Don't you get sick of people who use too many commas ?
)

Isinglass is made from the stomachs of fish, so it's pareve though not
vegan. Irish moss is seaweed, so it's not only OK for vegetarians, but
absolutely de rigeur! Gelatine is usually made from bones and hooves, so
it's not vegetarian. Some of the bones are from nonkosher animals, but
there
is a minority opinion among some rabbis that it is so far removed from
the
original unclean animal that it is acceptable, which is why Jello is
labeled
kosher.

One thing I don't know about the kosher status of beer is the process of
malting. Foods that touch the ground after some stage in their
preparation
become nonkosher. On the one hand, wheat that has been threshed on the
ground is perfectly acceptable. On the other, any can that falls off the
conveyor belt in the Crisco factory is thrown away so that Crisco can
keep
kosher status. Malt is germinated along a floor, where it is turned by
shovels or automated machinery over a period of several days. I don't
know
whether this counts or not.

Subject: Re: Calculating Bittering Units

On Tue, cmorford@umbio.med.miami.edu (Speaker-To-Bankers) said:

cmorford> I have been trying to figure out what the bittering unit figure
cmorford> would be for my latest brew, a respectable classic pale ale,
but
cmorford> I keep coming up with a number much larger (An order of
magnitude
cmorford> larger) than I have been expecting.

There are some numbers in Noonan which I translated into a formula which
gives reasonable values. Your mileage may vary.

$$AAU = IBU * Gallons / 22.472$$

Example:

Eckert says Ayinger Maibock is 26.5 IBU
I want a 5 gallon batch

$$\Rightarrow AAU = 26.5 * 5 / 22.472$$
$$\Rightarrow AAU = 5.89$$

This is from memory, so check the constant in Noonan to be sure; it's the
right ballpark, tho.

You'll have to derate the hops based on boil time, of course. I use a
simple linear degradation, eg:

$$AAU = IBU * Gallons \frac{60 \text{ minutes}}{22.472 * Boiltime}$$

I think Pete Soper's got much more detailed information on the effects
of
boil time and other factors on hop utilization.

Hope this helps.

Subject: Wet-towel Cooling

Danny asked about the efficacy of a wet toewal for cooling the fermenter. I used this technique last summer in my 70 degree basement. I'm in a dry climate (Albuquerque, NM) in which evaporation was very effective. I had to wet the towel twice a day because I didn't have it in a bucket of water.

I experienced a 5 degree temperature drop in the wort with respect to the cellar temperature. One problem: things grew on the towel so that it smelled pretty musty after a while.

Danny Breiden writes:

=====
In the past couple of digests, the question of fermenting in a warm apartment came up, and the suggestion of a wet towel around the fermenter was given. I've heard of this suggestion before, and I am left wondering how good it really works.

Let's say we've got a 75 degree room--low humidity--and a wet towel around the fermenter. What sort of temperature should this result in? Would the fermenting wort actually drop below 70 degrees??
=====

Somebody (Pete Soper, I believe) did an extensive test of the wet T-shirt cooling system. With the addition of a small fan blowing on the wet T-shirt I recall the temperature drop from ambient was in the range of 10 degrees Fahrenheit, or more. It's a very effective cooling system. Pete, if you're out there, was it you and do you still have the data? Or, perhaps a UNIX guru can get into the archives in Miami and grep for the original article. It involved using three digital temperature probes, one for ambient, one under the T-shirt, and one inside the fermentor.

Yes, I do!

> Advantages:

> They don't break.

[Lots of good reasons removed]

> You can easily draw off small amounts for checking specific gravity.

Yup, All the best of reasons!

I've been using soda kegs to ferment in for the last few months. They're
really great. The best few things about them that I've found are:

They're very easy to clean, racking is a sinch, and they don't break!

> Disadvantages:

> Have to rig up some type of fermentation lock or blow tube.

> Can't see through stainless steel.

> Sanitation of various inlets and outlets.

For the blow off tube:

Remove the CO2 inlet as to leave the threaded nub. Then a
piece of 1/2" tubing can be slipped over and held tight with
a clamp. Works great.

For the fermentation lock:

Same as connecting the blow off tube, except cut your tubing of
at about 2 or 3 inches. Then insert you air lock into the tube
and afix with a clamp.

Can't see through the stainless steel:

Yeh, I miss being able to watch the wort ferment...

Sanitation of the connectors:

Take them off and soak 'em in B-Brite.

One other disadvantage:

When racking you either suck up some yeast or leave some beer
behind. There is no perfect length for the out tube. However,
I've found removing 1 inch to be a good medium.

Subject: Plastic Homebrew Bottles

Jim White sez:
> I'm going to try using the plastic soda bottles next time I bottle some
brew.
[...]
> Any thoughts, or experiences? Has anyone used other than recapable beer
> bottles?

I haven't tried these bottles (yet), but plan on using a few for
bottling
my next batch. I have a good friend who makes a phenomenal amount of
homebrew,
who uses them frequently.

The advantages are clear: they make bottling MUCH easier. They lose
carbo-
nation if you open them and leave alone too long, but you can minimize
this
by screwing the caps down tight, or getting those soda keepers you
sometimes
see in the KMarts. The key is to use a lot of 1 liter bottles, and plan
on
drinking the beer soon after opening. The 2 liter bottles could be
useful
for parties, or if you're really thirsty ;) .

I have tasted no off-flavors from the plastic. Since some sodas are
fairly
acidic, I'd think the bottles would be fairly resistant to leaching. Does
anyone think the problems mentioned with the plastic water bottles as
carboys
would apply to plastic soda bottles (alcohol leaching nasty crud from the
plastic)?

Subject: Calculating IBU's, Fining agents

Re: Calculating Bittering Units, two ounces of 4.5%aa hops in six gallons of wort would give you about 33.6 IBU. This is assuming that you boiled the hops for 60 minutes which would give you 30% utilization. The formula to do this is as follows:

Weight (oz) * %U * %AA * 7462
----- = IBU
Volume (gal)

%U = percent utilization (boiled 60+ minutes this number is 30%)

%AA = alpha acid percentage

Note: express all percents as their decimal equivalent.

See the 1990 special issue of Zumurgy for more information.

You're right on the money with the isinglass. It is made from the swim bladders of fish. Irish moss, however, is made of seaweed. There is also a product called japanese isinglass which is also made of seaweed. I don't know of anyone using it as a fining agent in beermaking though.

> is a microbiologist and he is concerned about possible affects from
> passing hot wort through 10 feet of copper tubing. Is this going to
affect
> the flavor of the beer or our health in any way or is he just being
> paranoid? Does anyone know where I can get 1/4 to 3/8 inch
stainless steel
> tubing to use instead of copper? How much does it cost per foot?
Yow! A stainless wort chiller! What a concept! I don't know what
stainless tubing costs but I'd guess it was very expensive compared to
copper. Also, I've tried bending stainless tubing and it's TOUGH. I
wouldn't want to create a coil of the stuff, even 1/4 or 3/8 inGH. I
wouldn't want to try to make a coil of the stuff, even 1/4 or 3/8 inch O.
D.,
without professional machine shop-type equipment. Not to mention that
copper has far superior thermal conductivity than stainless.

Wif you're concerned about contamination of your wort, why not use your
existing chiller but invert its operation? That is, instead of running
the hot wort through the chiller, put the chiller into the hot wort and
run cold water through the chiller. I've seen it suggested here in the
digest a couple times that one could simply place the empty chiller into
your wort pot a few minutes before the end of the boil and let the
boiling wort sanitize the outside. Other folks have described setting
up a pump to push ice water through their chiller, thereby getting more
efficient cooling as well as conserving water. I've never heard of
anyone had any noticeable affect on the taste of
their brew.

re: Calculating Bittering Units

The formula here is close. But you've missed one important point: notice that the definition of IBUs is .000133 oz. isoalpha acids per gallon. You get isoalpha acids by isomerizing the alpha acids in the hops during the boil. However, this isn't a one way reaction. An equilibrium is achieved after about an hour of boiling where between 25 and 30% of the alpha acids have been isomerized. Higher gravity worts reduce this figure. Pellets produce higher utilization rates than whole hops (probably because more of the lupulin is exposed in pellets when they are crushed). With this addition, your estimated IBUs are between about 28 to 34 IBUs.

Subject: Carbonation and Priming

[...]

Then when it came time to prime, I tried to use some Geordies canned malt

instead of sugar. I boiled up the Geordies so that I had ~ a cup of 'new'

wort and mixed that in to prime.

Now almost a month later, I have a clear beer, with yeast at the bottom,

but little carbonation. It seems to me that I should have used more Geordies. Any suggestions as to how to estimate amounts for this sort of

half-assed kruesenning I did? Or was I insane to prime without sugar?

hmmm...i've tried priming with malt too. i can offer the following with the warning that i've only tried it once. i've never primed with sugar, i have good luck with honey, and bad luck (weapons-grade) with molasses (but i love the taste).

i recently did an experimental 2.5 gal brew. when time came to bottle, i made a stupid arithmetic mistake while trying to figure out how much dry malt extract (mutton and fisson unhopped amber) to use and tossed 1 cup of powder into 2.5 gal of wort. i decided i'd made a heinous error after the bottling was done and braced myself for a batch of gushers. however, after 1 week of aging the beer was fine! the taste was good and the carbonation was perfect.

the quantity still seems unusual to me, though, and in spite of the excellent results, i'll be a bit sceptical until i've seen it happen two or three times (with four carboys going now, i shouldn't have to wait long!).

caveat brewer.

Subject: Re: Alcohol-free beer

There is a short article in the 25 August 1988 issue of New Scientist describing a new process for making low-alcohol beer. The British water purification company Elga is marketing reverse osmosis equipment for removing the alcohol from beer. The article says, "In Elga's technique the beer is brewed in the normal way, and placed in a tank with pure water on the other side of a thin separation membrane. This membrane allows both water and alcohol molecules to pass. When enough pressure is applied to the beer, alcohol and water molecules will pass from it into the pure water, and can be pumped away. Between 40 and 60 per cent of the alcohol is removed in one cycle but the procedure can be repeated to remove as much alcohol as the brewer wants." It sounds like this procedure would not suffer from the same drawbacks as the traditional "distillation" technique. It also sounds like someone with enough technical experience and an old RO water purifier could rig up a similar system at home. Anyone want to take a shot at it and let us know how it works? By the way, the article also mention that Elga's equipment was being used by the brewers Elgood's, Young and Harvey.

Subject: Wort composition vs. Mashing schedule

Hi all. I have a fairly technical question here. First, I'll say why I need the info, though. I'm taking a course on expert systems and as part of it we are supposed to do a feasibility study on building an expert system of our choice. I decided to do something with brewing. My idea is to build a system that will take a recipe and determine what kinds of effects that are likely to be produced by it (ie. The colour, body, taste, etc.). I've decided to limit myself to the aspects of the malt that will affect these attributes. Anyway, I would like to be able to give a statement about the dextrin content of the wort given a specific recipe and mashing schedule. Does anyone know where I could find information that would help me? For instance, given a recipe that consisted of all pale malt, perhaps a graph of the rate that alpha amylase chops up the dextrans vs the temperature. I could then make some crude statements on the dextrin content of the resultant wort.

Thanks for any help you can give me,
Mike Charlton

Isinglass is derived from the air bladders of sturgeon.

Irish moss is, I think, a kind of sea weed.

Certainly a beer brewed made using isinglass is not strictly or even unstrictly vegetarian. This is just one of many ways we may get hidden meat products. For those concerned about it this is a good reason to drink home brew. Commercial beers not subject to the German purity law not only may not be vegetarian, they may contain lots of chemicals. (Three "nots" in one sentence! Sorry, Miss D (high school English teacher).) IMO alcoholic drinks should be subject to the same labeling requirements as other foods in the U.S.

BTW, I am vegetarian, not vegan, and I am not so strict that I necessarily abstain from commercial beers for the reasons explained above, though I prefer home brew and don't use isinglass or other gelatin in mine. I avoid knowingly consuming meat, but figure if I unknowingly consume a tiny amount of some animal product it won't hurt me.

From: cjh@vallance.HQ.Ileaf.COM (Chip Hitchcock)
Subject: priming with wort

Papazian and Miller both talk about this (Miller rather slightly). Applying their formulas and estimates of the weight of fermentable sugars in wort, I tried 12 oz of wort @ 1.056 in ~2.3 gallons of bitter; this was supposed to match 1/4 cup of corn sugar (instead of 3/8---bitter is not supposed to be highly carbonated). The result was almost flat, which may reflect on the formulae or on the yeast---my landlady, who makes bread from what doesn't fill a bottle (sometimes combined with the dregs from the secondary) said it took much longer than usual to rise.

Papazian's formula calls for something like 2 quarts of unfermented wort as priming for 5 gallons, which suggests that if you put in only a cup of normal-strength wort you were massively low.

Subject: RE: Homebrew Digest #595 (March 13, 1991)

Hi all,

Bruce Hill asks a question that I have been wanting to ask for awhile now. I recently bought a copper wort chiller through mail order. It came kinda dark so I washed it in the sink with hot water and soap. It came a little cleaner but I was still wondering about it. I boiled it in the wort the last 15min of the boil to sterilize it, then ran cold water through it to cool the wort. When I pulled it out it was really shiny and the wort had a little bit of a film on the top that I had never seen before. When I racked it to the secondary I left an inch of wort behind to hopefully leave it there. I also left an inch behind when I racked again to the priming bucket. My question is should I drink this??? This is my first all grain batch and I hate to through it out, but hate to kill anyone!! Do they sell stainless-steel tubing?? Thanks: Bob T.

>
>Here is my formula:
>
>Total Bittering Units = (Amount of Hops used * % Alpha Acid content)/.000133
>Bittering Units/ Gallon = Total bittering units / Total gallons
>
>My numbers are as follows: 2 oz. of 4.5% AAU hops, 6 Gallons.
>
>(2 * .045)/.000133 = 676.69172 Total Bittering Units
>676.69172 / 6 = 112.78195 International Bittering Units

The main thing that you missed in your formula was the percent utilization of the alpha acid. If you do a full wort boil for at least 60 minutes then you will get approximately 30% utilization from the hops. A shorter boil or a more concentrated wort (less than full wort boil) will decrease the utilization number.

Assuming that your utilization was 25% then the IBUs (using your calculation) is 28.

I use the IBU calculation from Fred Eckhardt's "The Essentials of Beer Style"
The calculation for your beer (with some assumptions) is:

6 gallons * 3.8 litres/gallon = 22.8 litres
2 ounces hops * 28 grams/ounce = 56 grams hops
56 grams/22.8 litres = 2.46 grams hops per litre
2.46 gr/litre * .045 (%Alpha Acid) * .25 (utilization) = .028 gms/litre
.028 * 1000 = 28 IBUs

So with a 25% utilization assumed, our numbers agree!

Dave

Subject: More on sassafras, using spruce

In HBD #594 Joe Uknalis writes:

>Sassafrass root has a compound in it (I forget it's name) which causes
>cancer (Doesn't everything nowadays...) BUT I've seen sassafrass
extract
>(for making tea) which has the nasty ingredient removed (\$2/10oz).

Well, after seeing this I decided to check things out a bit. Here's the
info. I looked in The Complete Book of Herbs & Spices and there is
was,
lumped in with a bunch of other hazardous plants. Sassafras root and
bark

contain the chemical safrole which gives the plant its distinctive
flavor.

Unfortunately, it's also a pre-carcinogen. When consumed, it's converted
to a carcinogen which effects the liver of animals. There is no proof of
it's detrimental effect in humans, but to be on the safe side the FDA
banned its use as a food additive. It was the original flavoring in root
beer and a certain brand of chewing gum called chicle. Currently you can
get sassafras extract (with the safrole removed) and a powder called file
(pronounced fee lay) which is often used in cajun/creole cooking. File
is

made from the leaves of the sassafras plant which contain no safrole.

Well, now that I've eliminated the idea of using sassafras in my stout I
want to try some other exotic flavoring. Since spring is almost here and
I've got a Norway spruce in my backyard, I figured I'd harvest a couple
of

ounces of sprigs. Anyone got any advice. Should I steep it or add it to
the boil. How much should I use -- in TCJoHB there's a recipe for a beer
called Kumdis Island Spruce Beer. Papazian says to use 4 oz and boil for
45 minutes. Anyone tried this or something similar? Thanks much for any
words o' wisdom.

Subject: Wort chillers and 1/4 inch tubing

For anyone reading the recent discussion on wort chillers made out of 1/4" OD copper tubing, I'd advise not to do it. Go with something a little wider.

Has anyone else who used 1/4" OD tubing had the problem of a very slow (counterflow, not immersion) wort chiller? I built one of these, and found that when initially starting it up, the cold break material falls out so quickly that I had to bang on the thing to get it to start flowing all the way through. After that, flow did not stop, but it took a good 45 minutes at least to chill a partial (3lb grain, 6.6 lb extract bock) grain batch. It took even longer with our 16 lb honey mead. You don't think about the increase in viscosity of high-sugar solutions upon cooling, but that mead took forever to get all of it through the chiller. I'm using gravity feed, and the hot reservoir is about as high above the chiller as ceiling constraints will allow, and it's still very slow. I'm going to rebuild it with 3/8" OD, like most books suggest.

Regarding stainless steel tubing...copper is expensive enough when you're talking about 3/8" or wider. I have not noticed any metallic flavours in the worts that have run through my copper chiller, even with the extremely long contact time.

Also, as far as sanitizing copper, I'd recommend baptism by fire as the best method. I ran a quick test for about a day. I soaked little sections of refrigeration tubing in 1) a water solution, 2) a solution of B-brite, and 3) a bleach solution. Basically, nothing happened to the one in the water solution. Also, there was no discoloration on the BBrite sample, but it developed a disgusting musty smell. On the outside, the bleach sample appeared normal, but looking at the inside, there was plenty of the quite recognizable oxide material. So, during my boil, I've been bringing an additional 2 gallons of water to a boil and running it through the system (in the absence of cooling water, of course) first, before the wort.

I've made spruce beer an annual spring tradition in my brewing practices. I've found that everyone that I have given it to has liked it (including Shelly Jacobs - local big shot and all around beer guzzler). I did however find one interesting comment in some old literature that said something about spruce beer being quite tasty once you get used to the taste of turpentine.

I used one of Charlies beers to base my recipe on but I don't recall the name;
I do remember that Charlie described the flavor as tasting like Pepsi if that helps at all.

Anyway, the beer I make is a brown beer that uses similar amounts of spruce new growth (candles) to Charlies and also uses a bit of hops. I'll try to remember to bring in the recipe if you are really interested.

Different trees produce different flavors. I think that you will find getting 4 oz's of this stuff will require you to use many trees or to defoliate the one in your backyard! (I made 40 gallons last year so I did lots of trimming). When the product is done you will taste a strange bitter flavor that is nothing like gin nor hops. Suck on one of the new growths and you will get a slight incling of the taste to come. I've found that the beer lasts awhile but I think it is best if drunk within 9 months. I still have some around from last years brew and it has changed considerably. It is lots drier and much more bitter then originally.

Subject: Spruce beer

In HD 596, Eric Roe asks for tips on making spruce beer. Here's my experience with spruce.

My brew partner and I used Papazian's 'Kumdis Island Spruce Beer' recipe as our guide, though it wasn't exact (I don't have my notes in front of me). I recall we used about 4-6 oz of fresh spruce tips and only the new growth at the end of branches (the part that appears in the spring and is a lighter green than the rest of the branch). Our rationale was that the new tips would be less bitter than older, more mature branches. (Whether that's true, I don't know). We placed the spruce in the boil at the start and left it in for about 30 min., then scooped it out (total boil was about 60 min.). The rest of the brewing cycle was pretty normal.

The resulting beer had a rather intimidating amount of spruce flavor. The spruce completely overwhelmed the hops and nearly the malt taste as well. It had virtually no head, probably because of the spruce oils. This is not to say it was undrinkable, but those who tried it had the proverbial love-it-or-hate-it reaction. Those who didn't like it really hated it and those who liked it had a sort of religious fanaticism over it and would always ask for a bottle when they visited. Personally, I liked it but it wasn't something I wanted to drink every day, just when I was in the mood for it.

Here's what I would do different next time. 1) Use less spruce. We definitely put in too much. I would try only 2 oz next time. 2) Put the spruce into the boil at the end, say the last 10-15 min. Alternatively, steeping the spruce separately would probably work as well. 3) I would like to experiment with different species of spruce tree (I think the sprigs we used came primarily from blue spruce) to see which produces a better spruce flavor. Also, I'd like to compare the taste from more mature spruce branches with those of new shoots. Perhaps I'll split a batch some day and experiment a little.

From: guy@bevsun.bev.lbl.gov (Aran Guy)
Subject: More on Moss

Irish Moss is called Carageen or Carageenan. It is an extract of seaweed harvested off the coast of Ireland. The traditional method of harvesting as carried out by the Aran Islanders involves raking the seaweed into a curragh. (A boat consisting of a thin framework of wood coated with hides or canvas, and periodically tarred to provide some semblance of waterproofing.)

The seaweed is dried on the public quay and then ferried to the mainland for processing.

Since carrageen is used in many food products as a thickening and homogenizing agent, factory ships are now usually used to harvest and process the carrageen.

Guinness is the largest single purchaser of carageen in the world, so it is quite a proper ingredient for homebrew.

Subject: CFJ hops, plastic bottles

CFJ-90 hops are very high AU hops (10+). The name has changed to Centennial, at least that's what Freshops had in their 1990 harvest. I haven't used the Centennial hops (yet), but I'm thinking about SN pale ale too, so maybe I'll use them on that. I was **very** happy with the results from the CFJ-90 of last year.

A warning about 2-liter plastic bottles: I've had a few bottles that did not carbonate. The caps seemed to seal ok, and other exact copy bottles **did** carbonate. All I can suggest is to make sure the plastic-rubber seal inside the cap is pliable, so as to make a good seal. Maybe if it is too old and stiff, it loses it (much like a rubber Grolsch-type seal).

Subject: Vegetarian Beer, Cornelius as Primary Fermenter

Isinglass is from fish bladder (who ever thought of using this stuff anyway??).

Irish Moss is a type of seaweed, strictly vegetarian.

I am very careful about this as my brother is an uncompromising veggie and he'd never let me forget it if I served him a non-veggie beer.

Main disadvantage to doing primary in the Cornelius is the sediment. All that stuff sinks to the bottom, thus being the first stuff to get pumped out through that narrow tube. The tube gets easily clogged though since it is so narrow. If you siphoned out if it you might be OK. I know of some people who do their secondary in the Cornelius and have cut off the bottom of the tube so it stays above the yeast level which is lower for secondary. Some of them do use the inline filtering you mentioned. I too have been considering trying primary lagering in the cornelius, but I have a 3 gallon carboy and think I will probably do the primary in that, and do the secondary in the cornelius.

My friend Jeff who runs the Modern Brewer in Cambridge Mass., now sells 50ft Stainless immersion chillers for ~\$55. This has fittings on it. His number is 1-800-SEND-ALE

Subject: lots o' topics (longish)

Date: 14-Mar-91 Time: 11:47 AM Msg: EXT00667

Hello there! I'm new to this discussion, but am getting ALL SORTS of good tips & ideas.

On sulfites in wine & mead: Even if you do not add sulfites, some are produced in the fermentation process. You will note that they say "No sulfites ADDED" on wine bottles. There was a nice discussion of "organic wine" making in the last Wine Spectator that talked about this.

On kosher: there are some commercially produced kosher beers (maccabee from Israel, Coors (!)), so it is possible. I called one of the certifying organizations (718-756-7500) and asked about doing it at home. The rabbi suggests doing everything yourself (malting, etc) as you have more control over cleanliness. That is the main requirement, cleanliness. The food being processed on the ground is ok if it is clean. He also said you should check that the yeasts you use are certified kosher, just to be sure. Isinglass and gelatine are right out. There are no kosher for Passover beers, as the restrictions there are on adding yeast, using grain, etc. There are no kosher for Passover vodkas, for example, except those distilled from fruit. There was a nice article recommending good Kosher for Passover wines (apparently not a contradiction in terms) in yesterday's (Wed.) NY. Times. I'll post some recommendations if people are interested.

On timing and Mead: Like wine, if you want an interesting Mead, expect it to take longer. I have a friend who makes mead that is ready to drink within 6 weeks of bottling. It is sweet, he adds no acids to it, and many people like it. Another friend makes a pop-like mead that he puts in beer bottles in the fridge, and it is ready quickly as well. He doesn't let it finish fermenting, and gets lots of bubbles. If you follow recipes in Duncan and Acton, adding

powdered citric, tartaric, malic and tannic acids, expect it to take at least a year (if not more) after bottling to be near palatable. You will get something very wine-like after a few years of patience.

On women and beer: (This is MHO) Being a woman and coming from a non-beer-drinking family, I was first exposed to (commercial) beers at college frat parties. I never really liked the stuff, but learned to drink it. The problem for me was bitterness and a lack of real taste other than that. Once I started trying imports and then homebrew I learned that I like darker, more flavorful (and less bitter) beers. I still don't like lagers much, even homebrewed they remind me of Bud et al. For some people learning to like beer is a lengthy proposition... certainly commercial stuff is not easy to love on average. Also, there has been an image problem. The image of a beer drinker is that of a guy in a t-shirt on the couch (with his large tummy) burping and watching the game. Women are less likely to identify with this image. This perception does seem to be changing, but still, beer is marketed at men, not people. Look at the ads. Men on the boat with bikini clad babes, college guys going to the game, grizzly bears, rams, bars filled with men. I'm not saying beer advertising is more sexist than panty-hose ads, but it is a marketing ploy: target your consumer. Women do drink less beer than men.

On Brew-pubs: (again MHO) I want to go to a place that I can find good beer and that my friends will have fun. We don't need dancing and wildness, just an interesting crowd and good company. I am slowly introducing them to beer from micros and homebrew, but it takes time. Old habits (I'll have a miller lite) are hard to break. Having a brewpub with a few commercial beers would be good

for business. I'll go, my friends will go, it will be fun, they'll be exposed to good brew, and the owner will profit. A pub can't survive just from regulars, it needs walk-ins as well.

Seems like the diameter of the CO2 tube and hole would be too small to
pass
much gunk, especially hop leaves. (Same problem which convinces people to
use 1 inch diameter tubing for blow-off.) Have you had any problems?

Also, are you primary-fermenting in the keg? what do you do about all the
trub? or do you transfer from your boiler in a way which leaves it all
behind?

Subject: IBU - Copper tubing

C. Morford has a problem with International Bittering Units.

I haven't verified that .000133 oz per gallon is in fact one part per million, which is what one IBU is, so there may or may not be a problem there.

The glaring error is in the equating of alpha acid concentration with isoalpha acid concentration.

Alpha acids do not suddenly and completely isomerize. It takes time, and not all of the alpha acid isomerizes. The most common figure I've seen for a 60-90 minute boil is about 30%. (If you boil for five minutes only, you get about 5% isomerization, and that's why aroma/flavor hops don't contribute much bitterness).

Therefore, if you multiply your 112 by .30, you get 34, which looks better, but is pretty low for an IPA. Maybe you've got other arithmetic problems here, or maybe you don't like your IPA too hoppy.

In the same HD issue, Bruce Hill's buddy worries about hot wort in copper.
Use your head, Bruce Hill's buddy! Have you never seen a copper kettle in a brewery? I don't think you have anything to worry about. I have heard that you shouldn't run carbonated water (obviously this applies to finished beer) through copper, and I have never learned why. Someone once surmised that the carbonic acid dissolves copper. Maybe we already have enough copper in our diet. Maybe it's a plumbing concern: you don't want to erode your tubing. Whatever the answer, it doesn't apply to hot wort.

And another thing. I'm sure copper is better in a heat exchanger than steel. Conducts heat better, right? It's also easier to work with.

I have used copper tubing in wort chillers for ten years, and I see no reason to change. I'm a little curious about what the inside of the tubing looks like since I never clean it. I just rinse with boiling water before and after use.

Subject: "washing yeast"

Howdy,

Some one recently posted some tips for making better beers. First off, thanks for the info; as a beginning brewer any info i can get is much appreciated.

The post talked about reusing yeast in the trub from a beer start another beer, ie culturing yeast (right?). The post talked about "washing the yeast". What does this mean? I'm thinking of trying to culture yeasts (to cut down on the cost of Wyeast, and because it looks like fun) and so i'm trying to understand the whole process. Any comments would be helpfull. Thanks,

steve

Date:Thu, 14 Mar 91 18:26 EST
From: <S94TAYLO%USUHSB.BITNET@CUNYVM.CUNY.EDU>
Subject: Hard Cider recipe wanted

I'm sure I will be deluged with responses to this request, but I like to get mail. I want to make up a batch of lightly sweet sparkling hard cider using something snappy like MacIntosh apples with a high alcohol content (10-12%!) probably for a halloween bash, or an end of summer party if I get too anxious. Since I have no cider press (come on now, let's be honest, how many of YOU out there actaully have a cider press!?), I am wondering if apple juice might work just as well, and certainly it's much easier to go buy 10-12 cans of apple juice than to find a press and then press out five gallons of cider. I might also like to throw in some cinnamon (sp?) and really impress my non-brewing boozier friends. Please help!

Also, I have some sage (where did they come up with that phrase?) advice for beginning homebrewers out there. Some of this comes from various published sources (TCJoHB, Zymurgy, primarily), some from my limited experimentations aimed at making things simpler. In sum, these tidbits have significantly improved my beer enough to convince me to enter this years National Competition and not be embarassed.

- 1) Sanitize EVERYTHING. A good soak in household bleach (.25-.5 cup/5 gallon) works is great for everything but the bottle caps.
- 2) Boil ALL your water before adding any ingredients. This drives off the chlorine before it gets a chance to get at and react with anything in the wort. I have started using ozonated bottled water for the same reason and also for greater convenience. Cooling it in the freezer for a couple of hours is an EXTREMELY fast and simple way of cooling your wort to close to a pitchable temperature.
- 3) Forget about the hydrometer until it's time to bottle. I never get my wort mixed well enough after adding the ice-cold (and more dense) water to get an accurate reading anyway. I just check it at the end to make sure that it hasn't changed in 2 or so days.
- 4) Stick with long-neck returnable beer bottles. They are cheap (\$1.20/case), they will always work, they conveniently travel, will always be accepted in competitions, and allow for a greater variety of inventory of beers (imagine having 10 half-full (or is it half-empty?) kegs for who knows

long).

Some of these pieces of advice are sure to be questioned by some more experienced brewers out there, and I am happy to discuss differences of opinion

with them anytime, maybe we will both learn something. However, if I started

doing this stuff from the beginning, my beer would be much better today.

Give

it a try and good luck!

They may soon have some competition for the title of Carageen Kings;
I heard that McDonalds has announced a new barfburger consisting
of de-fatted beef extract glued together with carageenan (named
the "McLean burger"?). If this latest marketing ploy succeeds
sufficiently well for this derivative-burger to take over any
significant fraction of their zillions served per year, we may
be facing a seaweed shortage crisis! :-)

> 45 minutes. Anyone tried this or something similar?

I'm trying this now; the "Spruce Juice" went into the carboy on Saturday.
I followed Papazian's recipe to make a five-gallon batch of Special Red
Bitter using malt extract, then cut enough twigs from the blue spruce I
planted after Christmas to loosely fill a 20-oz cup. The twigs were
rinsed
off, then tossed into the wort for the final twelve minutes of the boil.
I didn't want to overdo it the first time, especially after reading in
this digest how easily a small amount of exotic additives (ginger, tree
bark, coffee, etc.) can overpower the brew.

Yesterday, I tasted the sample which I took to measure the SG. The pine
taste and smell were definitely present but not excessive; they added
extra
sharpness to the brew on top of the hops. Hard to say more from a flat,
sweet,
yeasty sample only halfway fermented, but I'll keep you posted.

One question: on reviewing the recipe, I see that I omitted the 1/8 lb.
of
roast barley which should have been in the wort. Would it hurt the brew
if
I added it at this point? I was thinking of boiling the barley in a quart
of
water, cooling it to room temp, and straining it into the carboy.
Reasonable?

Subject: Culturing yeast -- I'm having problems (as usual :-)

I got some test/culture tubes and Agar Agar (from a health food store), and am trying to culture some different flavors of Wyeast.

I mixed up some wort, added the agar agar (why the repetition, by the way?), filled the tubes, then capped and steamed them for 30 minutes. I cooled them at an angle to get the classic slant. All seems fine so far.

After using the contents of a package of Wyeast for my latest batch, I flamed a sewing needle, swished it in the yeast package and inoculated the slants with the residual liquid in the pouch. On the final slant, I just poured the dregs from the pouch into the tube. I then let them hang out on top of the fridge.

Now, after 4 days, I'm seeing some odd results. The one which got the juice poured in shows obvious signs of fermentation: small bunch of bubbles on top of the agar² at the bottom of the slant. The others don't seem to be doing anything. I don't see mold or any other signs of life.

Any thoughts? have I screwed things up? did I add to much extract to the agar? I only want them to reproduce, not make beer-jello.

PS: did anyone else notice in the latest Zymurgy (I got mine yesterday) that *all* the winning recipes used Wyeast? Nice market to corner!

Subject: Adding flavor/color...

Hi Ho! Welp, my first batch (entitled Digital Dregs: Power Down Dark) is in the bottles (and on the counter, floor, wife, etc ;-), however it should really be called Brown Out Ale! How does one add color? I also tried a little of the stuff while bottling and found it pretty tame. I figure next time I might add some roasted barley? Maybe some hops? What is the bitterness rating of extracts and is there a list or something?

My second batch is happily bubbling away now...Great Midwest Vinyards Barley Wine is its title. I took the advice of my local homebrew store in making this, thought I'd see what others think...

I use: 2 900g cans of Tom Caxtons Barley Wine extract
3lbs light dry malt
10g Casscade (finishing - You can still smell the hops at my house!)
3-3.5 gallons of water
2 5g packets of Tom Caxton yeast

I have this in a 5 gallon carboy. The foam, etc can't reach the top so there is no blow off. I understand the blowoff gets rid of some hop resins and stuff, how much of a problem is it not to have any blow off?

Mind you I'm not at all worried; just curious!

TTFN

to
> use 1 inch diameter tubing for blow-off.) Have you had any problems?

Yes, the hole is rather small, actual size for blow off is about
3/8". I am very careful to strain all of the hops from my wort.
I have never had a problem with a plugged hole (in my kegs).

As a matter of fact that is the reason I know ferment in kegs. I
once had a nasty experience with a carboy that got it's blow-off
hole plugged with hops.

Now, If for some reason, I do end up with hops in my keg and it
does get plugged up, I have two courses of action. First the
pressure relief valve, and second the out tub which reaches to the
bottom of the keg. Between the two I should be able to reduce the
pressure enough to safely fix the block. Of course one could
always take a coat hanger to the plugged up hole, but this would
result in beer on your ceiling.

Also, If you fear a vigorous ferment you could attach blow-off
tubes to both the in and out connectors. This is what is
recommended in the Zymurgy special issue "Brewers and their
gadgets".

> Also, are you primary-fermenting in the keg? what do you do about all
the
> trub? or do you transfer from your boiler in a way which leaves it all
> behind?

Sad to say, I don't do anything about the trub. I just ferment on
it for three days. I primarily make heavy ales and don't notice
any nasty side effects. If I was to make a lighter beer I would
think more seriously about racking off the trub.

This again brings up the main downside to fermenting in a keg.
When you rack the beer off the trub or yeast you can't see where
the beer ends and the gunk begins. So you either loose some
precious beer or you drag along some gunk. I've found one inch to
be a happy medium. I usually run the first liquid into a glass
until it runs clear of debris. Of course one could experiment
with different length tubs for different stages of fermenting and
for different recipes. But that's a little to nerdy for me.

Overall I much prefer fermenting in a keg than a five gallon glass
suicide device. Your choice.

Subject: Sassafras and Cancer

When I was getting my masters in public health, I was alarmed at the amount of things that were being discovered as carcinogens. I am naturally the suspicious type, so I started investigating the research methods. What I found was a sad state of affairs. I don't want to digress too far here, and I don't want to start a war. (If you dislike what I'm saying, flame me personally, I'll be happy to debate you.)

I would go ahead and use sassafras with impunity, just as I would use red dye number two and cyclamates, were they available. Just because some substance produces cancer in lab rats when administered in absurdly huge quantities does not mean they are unfit for human consumption. All this is, of course, strictly my opinion, but in my opinion, the only thing that causes cancer in rats is experimentation itself.

Dan Graham

Relax, have a homebrew and some aldehydyl pyrenes. (produced when steaks are char broiled, supposedly carcinogenic, and delicious!)

> Steph
>

Cams with much overlap are designed for power, not low-end torque. High torque (RV-type) cams usually have no overlap whatsoever, at the expense of losing power at higher RPM's. With no overlap, there is a good vacuum produced in the cylinder before the intake valve opens, thus, when it does, it really sucks in the fuel/air mixture. This is especially important at very low RPM. If the fuel/air velocity is not kept high at low RPM, then the mixture condenses on the walls of the intake manifold, causing stumbling and rough running (i.e. low torque). Cams with a lot of overlap do not run well at low RPM - hence the familiar 'loping' idle of 'fast' cars...

Agreed, *just* adding headers is not the right thing to do. Headers are just one part of the whole system. Changing one part of the system will usually require tweaking of another part of the system. If you change the camshaft, then headers will make more sense since the engine will be able to 'breathe' better. This means that a carburetor jetting change will be required, too!

Subject: Copper counterflow chillers

Regarding the use of copper tubing for wort chillers, I believe it's the way to go. As mentioned in other posts, copper has a much better heat exchange rate than stainless steel. Copper is also easy to work with. If you're making your own chiller, sweating connections is a fairly simple procedure (not to mention kinda fun). Stainless is hard to work with and expensive. Also, I don't believe you can solder stainless -- you either have to weld it, use a compression fitting, or have the ends threaded. Since copper has had quite a long history with brewing I see no problems in using it. I just wish I was lucky enough to have an eight gallon copper kettle.

Also in HBD #597 Mike Zentner writes about using 1/4" OD tubing in his chiller. I made the same mistake (Greg Noonan must be nuts to recommend such small diameter tubing). Once I got the chiller assembled I decided to test it by putting water through it. The flow rate was incredibly slow. I was using 22' of tubing and I calculated it would take over an hour for 5 gallons of water to flow through. I didn't even think about the fact wort would have a heavier gravity -- luckily I didn't try using it for my beer. After the disappointing results I took it apart and replaced the 1/4" OD tubing with 3/8" OD tubing. The chiller worked much better with the larger diameter tubing. Now I can cool 5 gallons in about 20 minutes.

The flow rate would be even faster if I just made a minor modification to my system. I too would recommend using 3/8" OD tubing for making counterflow chillers.

As for sterilizing, I fill the chiller with water and start a siphon. Then I put the wort-in end into a pot of boiling water and let this flow through the chiller. After the boiling water has flowed through I simply place the wort-in end into the hot wort. I turn on the counterflow cold water, the siphon continues, and voila, cold wort starts coming out. No muss, no fuss; just make sure you don't interrupt the siphon at any of the above stages.

Greetings All!

Thanks for the personal responses. My trip to the Pacific Northwest looks full! Much to see AND taste.

John (Polstra) - I'm looking forward to our afternoon (Sun., 24 March). I'll give you a call when I get into Seattle. Cooper's, the Red Door, Big Time, et al!!!

Norm (Hardy) - Many thanks for the note on your winning pale ale. Hard to beat the combination of pale and crystal malt (O.G. 45-50), Hawaiian golden brown, cascade and goldings; all crisply perked through with Wyeast 1028. A winner! To those out there who haven't seen the published recipe, see Zymurgy Special Issue '89 (vol. 12, No. 4).

Mark (Castleman) - the Heartland club recently had a meeting in West Des Moines. Damn, just missed you! Next one - Sunday afternoon, April 7. Drop me a note with a street address and I'll post you a map. You and your partner are very welcome. I'm sorry to say that I won't be at that meeting. I'll be up judging in Madison's Big and Huge regional competition. Also put this date - Saturday, May 4, National Homebrew Day - in your book. We'll meet at that time.

All for now,

Craig Olzenak

Subject: Whitbread Ale yeast

I've sampled a number of very different brews made with Whitbread Ale yeast and have found them all to have a sharpness that is not what I'm looking for in my brewing. I'm looking for a `breadier' flavor from the yeast. For example, Catamount (amber?) has the sharp flavor, O'Keef's from a corner store in Montreal had the bread flavor. Could anyone suggest a brand of yeast that might get me what I want?

Hmmm, I wonder, might Canadian not-for-export beers have culturable yeasts?

Subject: Sassafrass

When you put tree bark or roots in your boil, you will get tannins in your wort, producing unpleasant flavors. The thing to do is to crunch the stuff up and put it in a nylon or cheesecloth bag the way you would your specialty grains, and steep the stuff in the wort as it is heated to boiling, removing it when the liquid begins to boil.

Subject: Re: Homebrew Digest #594 (March 12, 1991)

This is a very enthusiastic plug for the best brewing supply store in Seattle, Brewers Warehouse. They have a very broad selection of fresh Wyeast (I bought a packet of 1056 dated March in the third week of February), a couple of dozen varieties of hops, fresh and pellet, lots of different grains, the usual variety of extracts plus an Aussie extract that they package in bulk, and piles of other supplies, books, accessories and gadgets. They sell complete mashing systems, cornelius keg systems, etc, etc...

They sell a "grain card" - you pay for 50 lbs up front, then get it in whatever quantities you want, fresh when you want it. Grain card prices are \$.80/lb for klaages and \$1.00/lb for other grains. Pay-as-you-go prices are a bit higher.

For a catalog and accurate info, call or write:

Brewers Warehouse
4520 Union Bay Place NE

From: Pete Soper <soper@encore.com>
Subject: evaporative cooling

Last July I tried using a wet T-shirt for cooling. Here is a slightly truncated repeat of the posting about that.

This is a followup about evaporative cooling of fermenters. I recently [7/90] started a porter fermenting and since my fridge was tied up with lagering another beer I couldn't use it. So I used the wet T-shirt trick but this time I instrumented everything to track the actual temperatures. Note that I had a little fan blowing air on the T-shirt constantly and the fermenter (7 gallon glass holding 5.6 gallons of wort) was in a pan of water so the shirt was constantly wicking water up. Also, this was in a small bathroom which was kept with the A/C vent open fully and the door shut all the time. Outdoor highs were generally upper-80s to mid-90s and lows were around 65. The house A/C thermostat was set at 77 degrees. I had a thermometer under the T-shirt and in contact with the glass of the fermenter, an electronic thermometer probe in the wort and a third thermometer to measure the overall bathroom temperature. In addition I took rough measurements of the time between fermentation lock "glubs". Here is what I measured:

Day inside under in lock glubs
bathroom T-shirt wort per minute

0,1pm	65	59	75	0
0,8pm	65	59	65	1
1,8am	71	66	67	10
1,6pm	68	62	63	30
2,8am	71	66	68	120
2,6pm	65	60	62	90
2,8pm	65	60	62	40
3,8am	71	66	68	30
3,6pm	65	61	62	2
4,8am	68	65	65	4
4,6pm	64	61	61	2
5,8am	69	64	65	2
5,5pm	64	60	61	1
6,8am	70	65	65	1

I was concerned with getting the wort temperature down after pitching since it is against my religion to exceed 70 degrees with an ale fermentation and my tap water was so warm my chiller wouldn't do any better than 75. Anyway, I was pouring water on the T-shirt to augment the wicking action and hoping for the best when I put the thermometer in the wort a few hours later. I was amazed to see that the wort had cooled 10 degrees in 7 hours. Despite the large drop in temperature I had CO2 production after just a few hours and a nice cover of

foam a few hours after that. Except for the first few hours I relied on the wicking action of the shirt to keep it wet. Note that it is important that the shirt be all-cotton or as close to this as possible. The more polyester in the shirt the less effective the wicking will be.

One observation is that when the temperature outside the house was high the A/C ran a lot which pumped a lot of cold, dry air into the bathroom containing the fermenter. As can be seen, the wort temperature was driven down at the end of each day's A/C activity and warmed back up overnight when the A/C was almost idle (and the air in the bathroom grew warm and damp).

> with this unit convention. Anyone have an idea?

"Degrees Lovibond" is a means of measuring the color contribution of the grain to the finished wort. Crystal malt, for example, is available in 20, 40, 60, 120 degree L gradations, and for all I know, others. If you're brewing to a specific style and need to match a color standard, you really need to know what the color contribution of each component will be.

> Under the "Prodedure" section there are some unfamiliar terms:
> "Mash-in, Acid Rest, and Mash-out." ...

Mash-in: The initial mixing of grain & water. In thicker mashes, also known as doughing-in. The distinction between the two, as I understand it, is that in mashing-in, grain is added to water, and in doughing-in, water is added (gradually) to grain. The result, in any case, should be that all grain is wetted with warm water, and no dry pockets remain.

Acid rest: Not commonly used now (but possibly about to see a revival, after Papazian's "Sour Mash" article in the latest Zymurgy), this process involves holding the grain at a mildly warm temperature to enhance the growth of lactic acid-producing bacteria on the grain husks. This would rather effectively lower the pH of the mash.

Mash-out: The process of heating the mash to 168F or so, to stop enzyme action and liquify the sugars for a more efficient sparge.

A couple of weeks ago I gave a copy of the column I'd written for the brewclub (Gold Country Brewers' Association) newsletter to a friend to proofread, as I value her considerable skill with the English language. Her reaction made me aware of just how specialized the brewer's vocabulary is ...

>is needed.

I do stovetop step mashing (primarily), and typically get around 35
points per pound per gallon from American 2-row pale malted barley
(presumably Klages-based lager malt), and 32.5 points from English
2-row ale malts. Clearly, different equipment & methods produce
different results. My lauter tun is made from a 7-gallon
tapered cylindrical wastebasket, with a false bottom made from
a discarded soap bucket, lined with a jellymaker's straining bag.

>In addition, I've just started tracking sparge times - slower
>sparges give better extraction. With my equipment, I've noticed that

>batches.
>I suspect that the depth of the grain bed affects extraction.

I can't claim to have quantified it, but I have the same impression
about the relationship of flow rate and extraction. I now
recirculate wort until the flow suddenly slows, before beginning the
sparge. I get both clearer wort and better extract that way. And
I've clearly seen the same effect as Mike when brewing small batches,
and suspect the same cause.

>The real bottom line is that the taste tells the tale, and that
>extraction

It has been about a year since I was last in Cincinnati, but I am reliably informed that Wallaby Bob's (which was in a huge mall far to the northwest of downtown Cincinnati) has gone belly up. No great loss. Saddled with a hokey fake-Australian theme, it had good-looking brew kettles (an odd thing to see in a mall), but I've had much better beer at homebrew club meetings. Cloudy, poorly carbonated, short on flavor.

>Kentucky -- Ft. Mitchell (Northern Kentucky)

A great place! If the beer's not quite up to the quality of Sierra Nevada (for example), it is certainly good; and the brewery -- a veritable Disneyland of beer, with an incredible collection of beerphernalia and two OK restaurants -- is worth a special trip.

Subject: Wort chiller cleaning

I finally made my wort chiller -- it was amazingly easy. I haven't used it yet, but am getting ready to soon. I have been storing it in my bottling bucket, which apparently had some water in the bottom, and some of the copper oxidized. Since this is going to be an immersion-style chiller, I want to get the outside of the tubing as clean as possible before dunking into the wort.

I read somewhere (either in the digest or rec.food.drink) about a guy that tried to clean his chiller, but when he dunked it in the boiling wort it got REALLY clean, and all the stuff from the tubing came off and made a film on top of his wort. I think the reason is that the wort is pretty acidic, and a boiling acidic solution did a great job of cleaning his copper. Does anyone have any way to clean the copper BEFORE immersion in the wort? I was thinking of washing with hot ammonia then rinsing well with water, but I don't know if that would do the trick.

Also, I helped a friend of mine bottle his first batch yesterday. He really grumbled about delabeling and washing all those bottles by hand. When we siphoned the beer into the bottling bucket, he said "why can't we just leave it in here, and use this bucket as a keg?" The bucket is a 5-gallon food-grade plastic bucket with a snap-on lid, and a spigot about 1/2" from the bottom. I couldn't think of a real good reason why NOT to use it, except that the pressure would be too high and would cause a leak of CO2 or beer. Anyone care to comment?

Oh yeah, can someone e-mail me the address to Zymurgy so I can get a subscription?

From: PEPKE@SCRI1.SCRI.FSU.EDU (Eric Pepke)
Subject: Freezing homebrew

I've had some odd experiences with freezing homebrew.

About a year ago, I made and all-grain Framboise. It came out very well, with the exception of a slightly harsh taste. I waited several months ago for the harshness to go away, but there was no effect. Now, normally, when I drink a framboise or an ale, I take it from room temperature, put it in the freezer for a few minutes just to cool it off to slightly below room temperature, and open it. This one time, I forgot about the bottle of Framboise in the freezer. When I saw it the next day, it had frozen slushy. I swore quietly to myself, and put it out to thaw. When it had thawed, the flavor was perfect--the harshness had entirely disappeared. I froze the remaining bottles, and there was a similar improvement in all of them.

A couple of months ago, I made an all-grain version of Ruddles County loosely based on Dave Line's recipe. On the day of bottling, the unfinished beer tasted great. I primed with a small amount of brown sugar as per the directions. On the day after bottling, the beer was fully carbonated and tasted great. (If you are wondering why I sampled it so early, it is because it has been my consistent experience that all-grain ales are ready for consumption almost immediately.) Three days after bottling, the beer was approaching gusher stage and had distinct off flavors. I opened three or four bottles, and the story was the same. In a panic, I put the remaining bottles into the freezer. Only one burst. The remaining beer, when thawed, was and is close to perfect. The flavor and degree of carbonation is exactly what I had hoped for, and the beer is clear enough to read through, in spite of the fact that no finings were used.

Subject: Copper - a Chilling Thought!

Fred Condo (and others) have been discussing use of copper in breqing equipment. This is a perenial topic; it comes up whenever the swallows return to San Juan Capistrano.

> Lately, a lot of people have been posting messages fearful of
> copper cooling tubes. The traditional brewing kettle is made of
> copper. For example, Sierra Nevada, one of the best micros in
> America, if not the world, brews and lauters its brews in a pair
> of copper kettles that came from Germany. Therefore, I think
> no one has anything to fear from contact between copper and
> beer or wort.

The problem with this argument is that homebrewers brew in tiny quantities compared with the "big boys". Because our volumes are smaller, we have a proportionally larger surface area with which to pick up copper ions. Surface area to volume ratio determines the chemistry and physics of the situation. The result is that we get much more copper in our beers than real breweries get.

Maybe two years ago (maybe more?), some brewer with a calculator (and lots of free time) came up with estimates of copper content in beer. He assumed that an "L" length copper tube of "D" diameter has "A" units of surface area. Using the density of copper and assuming that the tube loses a monolayer of copper-oxide molecules each use, "N" copper molecules go into solution. Converting to parts per million, we are pushing the FDA limits on copper in food.

Perhaps someone has very old archives, or has free time and a calculator, and can get the details of this analysis. In the meantime, I'm going to use my copper chiller and not worry!

From: "Eric Roe" <KXR11@PSUVM.PSU.EDU>
Subject: Small bottles

In Pennsylvania, Latrobe Brewing Co sells Rolling Rock beer in what are commonly called "pony cases." Each case contains 24 7 ounce bottles. The only disadvantages are that you've got to do something with the Rock, and the bottles are made out of green glass. The green glass shouldn't be too much of a problem because the case they come in is sturdy, and keeps out most light. As I recall pony cases are pretty cheap -- \$7 to \$8 comes to mind. Some of our local bars go through many of these per night. Whether or not you can find ponies in other parts of the US, I don't know.

REGARDING Bay Area Events

Since there is a large contingent of Bay Area & No. California Brewers reading this I thought I'd do a bit of advertising for some approaching events.

AHA First Round at Anchor.

Many of you may know that the National has been split for the first round eliminations this year between Boulder, Boston, and San Francisco. I am the local Registrar. Direct mailings have gone out to all BJCP judges and to local non-registered judges who are known to Brook Ostrom (the local judge director for this). In an effort to involve as many regional judges as possible, I am soliciting via the electronic connection. What we are planning is to conduct the judging on two consecutive Saturdays (4/27 & 5/4) at Anchor. We need to have 50 judges on each day to judge at two sittings. Judges within 2 hours of San Francisco are asked to participate on the 27th and those beyond to come on the 4th. A Beds for Brewers Program and multiple entertainment, meals are in the works. If you are interested in participating as a judge or steward (we'll need those too, as well as plain old volunteers) contact Brook ASAP.

Brook Ostrom
2631 G St.
Sacramento, CA 95816
916-442-7626

If you live close enough to the Anchor Brewery and would like to help out with the un-packing and sorting of the beers, give me a call.

Russ Wigglesworth
775 Chestnut St.
San Francisco, CA 94133
415-474-8126

I realize that many of you have reservations as well as out and out problems with the AHA and this event (some of which I share), however, I see this as a step in the right direction. I would like to see this event succeed so that we can continue to improve the National and gain a little more control over the AHA in general. Please help us make this work!

+++++

BJCP Exam, Bay Area

Byron Burch asked me to put out some feelers as to the interest level of the Bay Area locals toward taking the BJCP Exam this spring. We need a 60 day lead time to set it up, and a minimum of 4 takers to make it worth while. If you want to take the test in May, please let me know and I'll arrange for a space and get back to Byron. Call me at the above address or via the Net.

Subject: Copper Dupe

I followed the same directions that Mike Zentner and Eric Roe did to make a wort chiller with 1/4-inch OD copper tubing. Question for those of you who rebuilt yours: Can I replace the 1/4-inch copper tubing with 3/8-inch copper and use the same 1/2-inch plastic tubing for the outer tube? The surprise of my week was to discover that the plastic tube cost more than the copper!

From: jayl@Corp.Sun.COM (Jay Littlepage)
Subject: Flat beer...

My last batch, for a variety of reasons, sat in the corner of the garage in the secondary for nearly three months before I was able to bottle it (it was intended to be a honey steam, but after spending all winter in the secondary it's now a honey lager). My problem is that the fermentation seems to have gone too well, or the yeast just bagged it out of sheer boredom. I neglected to take a hydrometer reading because there was a pretty good yeast pack in the secondary and it had been at a no-glub state for quite a while. I now have two cases of great tasting but flat beer with unfermented corn sugar at the bottom of the bottles.

Any ideas on how to goose these bottles? I don't have a CO2 setup. I'm leery (not worried) about opening the bottles and introducing new yeast for sanitation reasons and because of the low gravity of the beer, but if someone has had success doing this i'd like to hear about it. I've been making half-and-halves with stouts in the meantime.

Subject: Liquid yeast and small batches

As I am beginning my homebrewing avocation, I realize that I'll probably brew in smaller than five gallon batches since I am the only person I know in my immediate vicinity who likes beer.

If I'm using a dry yeast, dividing the package in half, or even in fourths is no real problem, but I like the sound of using liquid yeast. How can I use liquid yeast for 1, 2 or 3 gallon batches? I know I can use a portion and discard the rest, but that's EXPENSIVE. Is there a liquid yeast available in small packages, or is there a good way to save Wyeast once it's opened?

Not worrying ... but wondering ...

I think I may get it: if I put headers on my car to increase the
pull-through on the carburetor, I could hook the output of the
carburetor draft tube to the input side of my blow-off valve on the
carboy, and if I had a long enough tether, I would then be able to drag
race, and at the same time create a positive blowoff for my primary.

Or could I??? :-/

From: MEHTA01@UTSW.SWMED.UTEXAS.EDU
Subject: Wort needs more than jump start???

Hi.

i've made a few batches of homebrew and have had really no serious problems and certainly no worries :-) but i have a problem with a friend's

batch that i would like to get an answer to:

i feel sort of responsible, for he got all excited about homebrew after tasting my last batch and decided he wanted to try making some himself.

We bought Munton's new Australian Lager extract and Amber dried malt.

The yeast was in a little packet stuck to the top of the can and we decided to

use it, against my intuition, but i figured, it's a first batch, we don't need

to go all out.... Well, the wort was ready with a SG of 1.028 and we tossed

the dry yeast in, and NOTHING! After two days, we added some more yeast (my

friend forgot what kind he added -- i told him to keep notes, but he wasn't

worrying about it.. :-))

Anyway, now, one small bubble every 15 seconds rises to the surface and that's

it!

The funny (strange) thing is that the extract (before boiling) seemed to form some sort of coagulate, or aggregate like small whitish feathers (i

guess some sort of proteing aggregation phenomenon) and would begin to precipitate if i stopped stirring. However, after the boil, the wort looked more

like WORT and the exrtact seemed to be dispersed throughout the water (no aggregates or precipitates were seen...), so we decided to go ahead and use it.

Has anyone seen the same phenomenon before? Why is this happening? No gypsum or Irish moss or anything other than the extract and the malt powder was added...

Is the wort no good? Is the yeast need a kick in their seats? How does one kick yeast in their seats (if you can find 'em) ?

Not worried, but wondering???

Please send email to mehta01@utsw.swmed.utexas.edu

or to shmehta@elbereth.rutgers.edu

From: zentner@ecn.purdue.edu (Michael Zentner)
Subject: Re: Copper Dupe

Nick Thomas asks about using his 1/2 inch tubing to reconstruct a chiller with 3/8" OD copper in place of 1/4". This brings up a favourite topic, what to do with leftover failed brew projects that don't work out and that your wife doesn't want sitting around.

First, though, sure, I'd try to use the 1/2 inch tubing, but I suspect that it will require quite a fast flow rate, given that you have 1/2" ID surrounding 3/8" OD. This leaves you an annulus of 1/16" around, whereas before, you had a 1/8" annulus (with the 1/4" tubing). If your 1/4" one was like mine, you had no problem with cooling efficiency, cooling water being at a mere trickle to get the temperature down to 20C. Using rough estimates, one can calculate an approximate value of increased flow rate:

Volumetric flow rate is directly related to the linear velocity (average across the cross section of flow) and the cross sectional area. Suppose that the walls of refrigeration tubing are 1/16" (just a guess). In the two chillers, the ratio of how much hot stuff will be flowing in the

3/8" chill compared to the 1/4" chiller is:

$$\frac{\pi \left(\frac{3}{8}\right)^2 - \pi \left(\frac{1}{16}\right)^2}{\pi \left(\frac{1}{4}\right)^2 - \pi \left(\frac{1}{16}\right)^2} = 2.776$$

(the pi's cancel out)

this ratio gives us a ratio roughly of how much more hot stuff will be flowing through the tubing in the new chiller. That is, there now will be 2.776 times the quantity of the 1/4" chiller of hot wort flowing through the chiller in the same amount of time. This is a conservative estimate, since I think the linear velocity will also be greater, but here I've assumed them equal in the interest of being conservative.

Now, for the chilling fluid side, we can compare the ratio of the areas of the annuli: (old/new)

$$\frac{\pi \left(\frac{1}{2}\right)^2 - \pi \left(\frac{1}{16}\right)^2}{\pi \left(\frac{1}{4}\right)^2 - \pi \left(\frac{1}{16}\right)^2} = .1875 \text{ (old annulus)}$$

Now, if we assume that the heat transfer rate will be the same as the old chiller in the new chiller (and it won't, it should be slower

since we are dealing with laminar flow of the wort, thus taking it longer to transfer the heat from the hot "middle stream" of the hot side of the chiller), then we'd like roughly 2.776 times the flow in cooling fluid of the old chiller, $2.776 * .1875 = .5205$. Examining the area (again, not including pi) of the new annulus, we get:

$$\frac{1}{2} \frac{3^2 - 2^2}{8} = .1094$$

Therefore, we would need to up the flow rate by a factor of $.5205 / .1094 = 4.758$. What is seen, then is that the chilling will happen 2.776 times as fast, but the required flow of cooling water is 4-5 times as high, thus using more water than the older design. Again, these are conservative estimates, not exact calculations, so the flow rate may even need to be higher.

So, go ahead and try the old 1/2" tubing you have and see what happens. What do you have to lose? You can always uncoil it and buy bigger hose. The cheapest source of hose is garden hose. if you don't want to deal with the things on the end of the hose, cut them off. You could try 5/8" hose. I got lucky last weekend and found hose with an inside diameter larger than 5/8" at a store called Big Lots.

As for what I'm going to do with the left over 1/4" tubing? Either make an immersion chiller or build a styrofoam box with the tubing inside as coils, which carry ice water from an external cooler in a cycle around the inside of the box, to be used as a lagering system, since I don't have a place or budget for another refrigerator now.

Feel free to correct me if you've tried this already and know that my estimates are wrong...I'd be interested.

> job of cleaning his copper.

How about actually using a boiling acidic solution? A little
vinegar in a pot o' boiling water will probably do a fine job of
shining up your copper before your wort does it.

Subject: Private stock liquid yeast

Concerning Dan Graham post about The Homebrewer's Store's private yeast product...

I was in Bccchus and Barleycorn in Merriam KS (Kansas City for all practical puposes) recently and noticed that they too were selling cultured liquid yeast for about \$1.50 a bottle. The bottles were labled Bud Lager I believe, which made me think it was from a Wyeast package. There was no number associated with it though. Anyway, these bottles were ready to go so I used one and the beer turned out great. I don't know if it's really fair for them to do that (reculture and resell the product). I guess it could have been their own yeast, but it didn't look like they had any lab facilities.

Is that the same situation with The Homebrewer's Store, or do you mean they have developed their own strain?

Give it a try and let us know how it comes out.

Yes, it works fine. But mine is about 15' long (if I remember correctly) and that's really not quite long enough. My next one will be at least 25'.

> The surprise of my week was to discover that the plastic tube cost more
> than the copper!

Next time, just buy a 1/2-inch garden hose. That's much cheaper. It doesn't have to be food grade since the beer never comes in contact with it.

Actually ammonia probably won't work -- it's an alkali (base). You might
try a soaking the chiller in a solution made of water and vinegar for a
few
hours or overnight. That should get the copper nice and shiny.

If treatment in weak acid really cleans copper without doing anything
nasty to it, why not soak the tubing in some diluted vinegar? Hell,
it couldn't do anything worse to it than the wort, as long as you get
the pH into the same ballpark.

Subject: alcohol content

How can I measure the alcohol content of my beer, without taking two hydrometer readings and subtracting? I don't really trust the initial hydrometer readings of freshly boiled wort - It's usually not mixed up enough. Even if I stir it, the heavy stuff at the bottom settles out before I can get a reading. I'd take out the siphon and get a reading from the middle, but that's a pain - one more thing to sterilize, and it still wouldn't take into account fermentation of the shit at the bottom.

Especially in my last batch, the stuff at the bottom showed signs of fermentation (like big gushers of sediment suddenly coming to the top, and then settling out again)

From: adams@bostech.com
Subject: Cu and Rocks

Adding to the copper discussion...

The latest Zymurgy indicates that copper deficient rats who drank Budweiser lived 6 times as long as rats who drank water. I seriously doubt that Bud is brewed in copper vessels, so perhaps beer causes the body to absorb copper more readily. This would be bad news if we are making beer that contains near maximal quantities of copper, wouldn't it?

In regard to Rolling Rock, there are 2 styles of 12 ounce bottles. One is the twist off, short neck, and the other is the way cool long neck painted label variety. It's a lot of fun to make homebrew stout in Rolling Rock bottles, as long as you keep them in the dark. I've never seen the ponies in New England. They would come in handy, though.

From: rransom@bchml1.aclcb.purdue.edu
Subject: Sanitizing, Sanity, and Multiple Yeast-Caking

SANITIZING, SANITY:

The homebrewing world is saturated with a paranoia about cleanliness, sanitization, and even sterilization. I used to be one of the horde of brew freaks that chlorinated, sulfited, boiled, and even autoclaved their wares before allowing wort or beer to see them. I've been brewing for more than eight years, and I've found that this is unnecessary and downright detrimental to a fine brew.

Cleanliness is a must. Don't go gonzo and use oven-cleaner scrub pads or difficult to rinse detergents, but get those nasty deposits off your fermenters and other equipment. Rinse bottles well after using and well before putting in beer (my ritual is 3 times after drinking and 3 times before bottling). Old deposits can be removed by soaking in hot hot water, with perhaps a bit of bleach, but rinse well.

Sanitization is a waste of time. I know this will draw flack from the horde, but hear me out. Germs and yucky old microorganisms that are in your wort before it gets boiled (I'm talking all-grain mash here) will die in agony in the boil. If your yeast is worth talking about, much less using, it will kick the stuffing out of any organisms that derive from the spores which live through a boil. Yeast produce a host of anti-microbial secondary metabolites, primarily alcohol, carbon dioxide, and the attendant fall in pH which fermentation generates, but there are a host of other compounds which yeast produces that inhibit competitors. The point is that a good pitch will leave the brewing yeast far ahead of the rest of the nasty things you don't

want growing in your wort (there are quite a few yeast cells in 14 g).

I will outline below my primary weapon in the war against contamination but here are a few other pointers:

---use glass fermenters: those plastic bucket things are an accident waiting to happen. Can't be cleaned completely, allow too much oxidation; come on, spend the extra money. Live a little.

---move up to all-grain mashing: my beers are soo very much better and incredibly cheaper (malt from the local maltster is about 19 cents a pound if you can get a number of brewers together to buy; we get 1000+ lb lots) than when I did it out of cans. Boiling the whole wort is a great sanitizer.

---don't transfer to a secondary: here I get into serious trouble with the horde. I've had more trouble with off flavors and contamination from transferring that all disappeared when I stopped doing it. As you'll see below, I have gone to the opposite extreme.

---rinse, don't chlorinate: tap water has enough halogens in it already, don't add more. Chlorine hasn't helped my few contamination problems, gives me a headache, and ruins my angel-soft hands. I think it gives an off flavor too, but

it may be imagination. The main problem is that it inhibits yeast growth, which is like shooting yourself in the foot to cure hangnails. A healthy, hearty yeast strain is all important.

- clean stainless steel kegs with boiling water: a panfull of boiling water added after washing and rinsing your keg is a great step to remove trace detergent, microstains, and to effectively sanitize. Dump in it, seal the keg, put on some CO2, and blow it all out your tapper. Clean and fast.
- rinse problem areas with boiling water: my immersion chiller gets soaked with boiling water, etc, etc.
- don't bother!: I never use chlorine, often don't rinse with boiling water, use as little detergent as I can, and in general don't worry about it. I haven't had a bad batch in years.
- keep it cool: well, yes I had some bad batches, but this was in an Indiana high summer, with fermentation temperatures in the 70's and up. Sharp mouth feel and tinny taste is an indication of temp problems. Keep it in the 50's and you're in heaven, but 60's are nice too.

Well, enough of that. Now for the really controversial method of insuring a great yeast pitch:

...AND MULTIPLE YEAST-CAKING

I brew 10 gallon batches by an all-grain mash, and ferment in 6 to 6.5 gallon glass containers (acid carboys). I generally put 5 gallons of beer in each, so there is plenty of head room. I start "new" fermentations whenever I have taken a break from brewing, every few months or so. The "new" pitch is 1 package of Whitbread Ale yeast (14g foil packets) per 5 gallons. I let my beers ferment for 1 - 3 months (yes, months) without transfer to secondary, and then when ready I brew another batch.

When the new batch is done boiling and is ready to be cooled, I bottle and/or keg the last batch. One of the nice things about Whitbread yeast is that the yeast cake is very firm, so I can recover ALL the beer. After siphoning off the beer I replace the lock and finish bottling the old and cooling the new. I then pour (violently) the new wort on top of the old yeast cake.

Sound horrid? I have brewed up to 10 "generations" on the same cake and it is wonderful. The beers get progressively smoother and especially creamier, with heads to die for and teeny tiny bubbles. The beers are ready to drink right out of the fermenter, and after three days in the keg with minimal priming are being drunk. Totally finished. Best idea I ever had.

Some pointers:

- use Whitbread ALE yeast
- ferment as cool as possible (50-55 degrees F)
- don't let the old cake sit long without beer on it. 20 minutes is a good number.
- ferment at least 3 weeks, or as long as you can stand it.
- this works best for beers in the SG 1.045 and up range, but if you ferment at a low temperature you can make a smashing light.

I've also noticed that my beers are very clear very soon after keggung. The

yeast has mostly settled by the time I keg, and the second pint is clear as crystal.

I've used this method for the last two years with no (NO) contamination problems and no (NO) yeast bite. The fermentation is gentle with no huge masses of foam to blow off (I never have to use a blow off tube), and the hideous looking rings of dried yeast have no effect on the next wort (if you fill the later fermentations past the level of the old one).

Before blasting this method, try it.

Thanks for listening, lots of love:

Richard Ransom (Father Barleywine)

Subject: Copper in Beer (Zymurgy-Winter 91)

One reader doubted that Bud is brewed in copper kettles, but I would guess that it is. Copper is the industry standard for brewing kettles. In my experience, copper has been used in every brewery I have visited or heard about, including Coors (their brewing room is incredible: 40-50 500+ barrel kettles all in one room.) Since copper is a micronutrient, the amount required to make rats more healthy, or humans for that matter, is quite small. Since very few homebrewers use copper brew kettles, maybe users of copper immersion coolers SHOULD sanitize right in the wort, to get all the health benefits of homebrew we have been claiming for so many years ("Trust me, honey, it won't give you a hangover, no matter how many you drink.")

From: hplabs!ardent!uunet!pdn.paradyne.com!jgg (Joe Gabriel)
Subject: Offtaste Beer

My beer partner and I have been brewing since early January. Our first batch (came with kit) was a delightful amber. We ventured on to an Ironmaster Lager, then to a John Bull Bitter. The problem that we are experiencing, starting with our second batch and continuing through 3 more batches is, what can be most accurately described as, a "metallic" offtaste in our finished product. We have been pounding our heads trying to figure how to get rid of this repugnant flavor. Here are some of the things we think may be contributing to the problem:

1. second batch (Ironmaster Lager) was 2nd staged in a plastic container for an extra week.
2. heavy bleach solution used to sterilize bottles...rinsed with cool water.
3. inability to chill wort to below 80 degrees before pitching the yeast.
4. again, sterilizing the bottle caps with heavy bleach solution, then rinsing with cool water(caps are taken directly from post-rinse cool water dish, and placed onto filled bottles to be capped).

I vote for 2 and 4 for the most likely culprits in the case of the "offtaste" beers. The reasons being, thinking way back when, our first batch bottles were rinsed thoroughly with warm water. Also, the bottle caps used for that batch were not sterilized at all.

Admittedly we are novices in this homebrew business, and we appreciate all the help and wisdom we can get from more experienced homebrewers. So, any comments and/or further ideas on how we can rid ourselves of the offtaste we've been experiencing will be appreciated. Thanks in advance.

Subject: Culturing Chimay Yeast: A Question

A question, for brewers who've succeeded in culturing Chimay yeast from the bottle: is that stuff slow and fastidious in its action? Does it normally tend to mostly hang around the bottom of the bottle, adding to the burdens of its parents? Or is it just that I've had two bad batches in a row?

The first attempt I threw out after 10 days. It had shown a little activity on about the 3rd through 5th days, but not at all what I'm accustomed to. That didn't surprise me; the bottle was more than 2 years old. The bottle I'm working on now was dated 09-90, but the results are substantially the same. I'm getting about 2 glups per minute after 3 days, with no visible surface activity. This evening I plan to dump the whole works into a flask of starter, laced with yeast nutrient. Maybe that'll help.

Is this normal behavior for this yeast?

Subject: Cleaning your wort chiller

B-Brite works real well for cleaning wort chillers. Set the chiller in a bath of B-Brite, leave ti there while your wort boils, rinse it off with cold tap water, then drop it into the boiling wort to assure sterility. Never a problem in 2 years doing it this way.

From: Darren Evans-Young <DARREN@UA1VM.UA.EDU>
Subject: New acid carboys

What do you acid carboy users do to clean your newly obtained carboys? I've rinsed and rinsed and rinsed with hot/cold water, bleach solution, sodium bicarb., etc., and I still have this slight film that seems to rise to the surface. I dont want to ruin a batch (or have toxic beer).

Any suggestions?

Darren

What do you do with your trub? It didn't sound from your description
that you were using the cool-way-down-let-warm-overnight-and-rack method
I've read about here and in Dave Miller's TCHOHB.

I've not tried that method because I hate to waste the wort that
inevitably would be left with the trub. Also I generally don't want
to have to finish a brewing session the next morning. I'd like to
go to sleep with everything all set.

I haven't heard much about my method here. I have a fine-mesh nylon
straining bag that I use to filter the chilled wort. I put it in a
stainless steel colander, suspend the colander above a big bucket,
and pour 65 degree wort into it. When it gets clogged I squeeze all
the standing liquid through it, dump the dry trub, and continue. 2-3
iterations are enough.

The amount of dry trub always amazes me. I'd guess this procedure
nets 3-4 cups of it. (I use a half teaspoon of Irish moss during the
last 15 minutes of the boil. I don't know how much the Irish moss
is responsible for since I've never omitted it.)

Perhaps the squeezing is allowing trub to get through, or perhaps
the wort isn't chilled enough for it all to precipitate out, but
I notice that a half inch of sediment accumulates almost immediately
in my carboy. And when the fermentation gets going lots of particles
disperse throughout the churning beer. (I'd love to hear comments
regarding this approach. With only my eighth batch in the fermenter
I still have lots to learn.)

How do you deal with trub accumulation? I've heard that the oils in
it serve as yeast food and contribute to fusel alcohols and other
off flavors. Is this not true? Or do you avoid getting it into the
fermenter in the first place? If so, how?

Any other single-stagers want to comment on trub?

> hideous looking rings of dried yeast have no effect on the next wort
(if you
> fill the later fermentations past the level of the old one).

I imagine that in order to maintain the same volume of beer atop an
increasingly thick yeast/trub cake you'd have to fill higher anyway,
but I'm surprised that you have been able to use a cake ten times
while always filling the fermentor above the level of dried deposits.
It seems as though you'd run out of headroom after only two or three

batches. Most of my batches were fermented with Wyeast 1007 (German Ale), and the krausen is always at least two inches high. Does Whitbread Ale yeast not froth up as much? Or do your low fermentation temperatures result in a lower level at high krausen? How much does the cake increase in volume from batch to batch?

Is it perhaps not critical that the yeast deposits be covered with liquid at the start of a new fermentation?

Thanks for the great idea. I'll certainly try it with my next batch.

From: eisen@ileaf.com (Carl West)
Subject: Multiple yeast caking

The London Museum Catalogue has a photograph of a 15th century jug that has a tap-hole about an inch from the bottom. The author speculates that it was for holding a liquor that had a sediment. After reading Richard Ransom's article it strikes me that this would be a perfect vessel for making beer (albeit somewhat small, it looks as if it would hold about 1.5 gallons).

It is my impression that beer in those times was drunk pretty much direct from the fermenter, no priming, no bottling. If this were the case, I could imagine a modest household having a couple or three of these fermenting jugs in the cellar or buttery which were regularly replenished with wort as they got low. I would guess that with an appropriate yeast, and steady consumption, a steady flow of beer could be maintained. Such a system would not require that the household brewer make huge batches of wort (which would be a plus because BIG pots were at least as hard to come by then as now), but only a gallon or two at a time. It also appears that it would save a good deal on sanitation and cleaning requirements.

Seems too simple. Not enough to worry about.

Now, Richard, the questions:

1. With this huge 'pitching' rate, is the reason you're not getting 'yeast bite' the fact that you're not aerating the wort *much*? You've already got the population, all the yeast has to do is get on with it's _anaerobic_ metabolism (is that a word?). Is that it?
2. What about trub?
3. What happens if you don't remove ALL the beer from on top of the cake (as would likely be the case in the scenario above) before adding the new wort?
4. I'm an extract brewer, is there any thing you would suggest changing in your method to adapt it to extract brewing?

-Carl (my second batch is getting better with time) West

From: BAUGHMANKR@CONRAD.APPSTATE.EDU
Subject: Cleaning the Bruheat element

Thought I'd pass along a recent discovery. Much has been said in these electronic pages and others about the problem of caramelization of sugars on the Bruheat element. Thanks to a hint from Tom Fogelson, formerly of Sebastian Brewers, I've found that the Bruheat element can be painlessly cleaned by adding a gallon or so of water to the Bruheat (enough to cover the element) after a round of beer-making, adding one tablespoon of B-Brite and boiling for a few minutes. The white crust comes off immediately. Blackened crust takes more patience-a couple of boilings, several days of soaking, and then light scrubbing with a non-abrasive pot scrubber.

Please pass this advice along to your Bruheat brewing buddies.

Subject: Seattle Beer and Travelling: Summary of Responses

As promised, here is a summary of responses I received about carrying beer on commercial airlines and Seattle beer.

On flying froth, my foamy friends freely forwarded the following advice:

In general, it was agreed that it is safest to carry on the beer, as opposed to checking it in. One writer suggested wrapping the bottles in socks. Several mentioned that the Gulf situation may have airlines a bit edgier over this, but I understand that the gov't has lifted the big security crunch, so perhaps that's no longer a problem.

On the other hand, Subbakrishna Shankar (sxs32@po.CWRU.Edu) had this horror story:

> I once tried to take a couple of bottles of my homebrew
> on a domestic flight in my carry on luggage and was unsuccessful.
> I was forced to throw away my precious brew, with no reasonable
> explanation given.

As a tie-breaker, I called Continental. The person I spoke with had to go check with management, but after a few minutes returned and told me that carryon would be best (for my beer's sake, not because of restrictions) and that there should be no problem.

I'm swayed by Danny Breiden (dbreiden@mentor.cc.purdue.edu), who suggested that bottles with labels would be more likely to pass a suspicious security guard, and who also recommended against packing too thoroughly -- you might have to open it all up for the guards.

Shipping via UPS was generally discouraged; cost is about \$7-9 per dozen, and UPS apparently would as soon not haul beer. Also, concern was raised about poor handling and extremes of temperature.

On Seattle's finest, a festive flurry of facts flooded forth. Several brewpubs and bars were suggested:

Big Time Brewery (University Way N.E. between 41st and 42nd) is very convenient to the University of Washington. Several people recommended it, but without many specific comments.

Cooper's Ale House (8065 Lake City Way NE) - Wide variety (15, by one author, 21 by another) of local beers on tap, and prices are reasonable.

Dew-wamps (Spelling conjectural) - Apparently a fairly new brewpub near the Kingdome, across from FX McRory's. Emphasis on cask-conditioned ales in the British style.

Redhook (or Red Hook, depending on author) Ale Brewery (3600 Phinney Ave. North) - Beer served at The Trolleyman, adjoining. Non-smoking,

gives brewery tours. One writer suggested that the same beer can be had for less money four blocks east at the Red Door Tavern (Fremont), which has 20-30 good beers on hand and a good menu.

The Latona Pub (6423 Latona NE), Red Door Alehouse (3401 Fremont Ave. N. Fremont) and The Duchess (55th NE) were all recommended as good bars for finding local brews. So was FX McRory's (near the Kingdome); 20 or so beers on tap, including Paulaner, Bass, and Young's, over 80 bourbons, and first-rate food (a steakhouse).

Several beers came recommended by name:

Kemper Brewing (Hales) - Thomas Kemper Helles Lager, Hales Pale Ale
Redhook - Redhook ESB
Hart Brewing (Kalama) - Wheaten Ale, Snowcap Ale (seasonal), Sphinx Stout
Pacific Brewing Company (address not needed) - one author told me to avoid this place, saying the beer was lousy.
Hood River Brewing (Bridgeport, OR) - Full Sail Ale
Bridgeport Brewing (Bridgeport, OR) - Blue Heron Pale

For buying beer for takeout, Larry's Market (100th and Aurora) was recommended.

My gratitude to those who sent in responses (I hope I didn't overlook anyone !):

From: rransom@bchml1.aclcb.purdue.edu (FATHER BARLEYWINE)
Subject: RE: Sanity and Insanity, cont.

Hello again girls and boys---

I received several mail messages about my little missive (or rant, as it was described; at least they said "great rant") already, most about the trub issue.

Currently I immersion coil cool my wort in the boiler, and then filter it with a new nylon mesh filter funnel. This is a nifty new item from the local HB store, consisting of a large plastic funnel with a separate nylon mesh filter that fits snugly into it (easily cleaned). I have to filter in stages, removing the hops and trub as the filter clogs, but compared to my old method of running the beer through the coils it's much faster. I used to filter the trub with a funnel stuck in the end of the hose connected to the coils covered with cheesecloth. The pollen grains from the hops clogged the cheesecloth,

slowing the rate but also yielding a nearly complete filtration. Slow.

At any rate, I don't have much problem with buildup of the yeast cake, and it's so firmly packed that the buildup that occurs doesn't take up much

space. The yeast does stay in suspension for about 2 weeks after suspending

the old cake in new wort, but after 4-8 weeks most stuff settles. I also chill my freshly kegged brew a bit, and since I don't cut off my uptake tube

at all (it runs right to the bottom of the keg) I get the settled stuff to come out in the first pint. After the first pint is drawn the rest is crystal clear (sometimes two pints over a few days are required to clear all the settled yeast).

I get my grain from Briess Malting near Madison, and we buy in lots of over 1000 lbs. Before shipping we get 2-row American for 19 cents/lb, after

shipping about 23 cents. I highly recommend their 90 levibond crystal.

Here's a quick recipe:

crush:

16 lbs. 2-row brewer's malt
2 lbs 40 l crystal malt
2 lbs 90 l crystal malt

bring 5+ gallons water to 180 degrees, pour into 40 qt. or larger cooler chest, stir in crushed malt. Check temperature, should be near 155 degrees. Mash stirring every 15 minutes for 2 hours.

Sparge with 170+ degree water to yield 12 gallons. Boil for 1 hour, adding

2 oz Northern Brewer leaf hops (Freshops) at 30 minutes

3 oz Hallertauer leaf hops (Freshops) after turning off heat

Cover and let sit 5 minutes. Cool and pipe onto the yeast cake from a past batch (see HB Digest #600).

SG: who cares? It's strong.

Ferment at least 2 months at <65 degrees. Drink.

I'd like to describe my 10 gallon mashing setup in a later article---so
watch
out. Thanks for the comments, it makes me feel like I might know
something
after all.

Love and frothy heads

Subject: Re: Sanitizing, Sanity, and Multiplr Yeast-Caking

I couldn't help but notice that our Purdue contingent (Zentner and Ransom) were long winded in HBD #600. Are you guys on spring break? :-):-):-

Although I sanitize a bit more than Mr. Ransom, I feel he has some good points. I am appalled when I read people use a half cup of bleach per 5 gallons of water to sanitize. Some even suggest, "a bit more just to be on the safe side." I can't believe using MORE bleach can make anything safer.

I hope they don't add an extra cup of bleach to their washer just to be on the safe side. I could lead to more problems than it solves. I use 2 tablespoons (sometimes less) of bleach per 5 gallons of water as recommended in TCJoHB. Charlie explains that this is plenty. I suggest re-reading some sections of TCJoHB (and TCHoHB) every once in a while just to keeps things in perspective lest we get too carried away.

Richard Ransom's post also demonstrates that brewing can be a forgiving craft. Quoting Miller (TCHoHB, p.108) "I have stessed precision in describing the procedures, but the truth is that malt is a rather forgiving material." He says this in reference to mashing, but I feel it can be extrapolated , to an extent, to cover the whole craft. Please don't think I'm saying Richard is getting lucky when re-using the yeast cake, but rather that there is some leeway to break from strict procedures. Experimenting here and there could lead to easier and better procedures (and beers).

I have used the slurry from the bottom of one fermenter to immediately pitch into warm wort. It worked ok. Of course, it didn't occur to me to use the SAME fermenter. I think I'll try it once. The problem is, I'm always making different types of beers and using yeasts that are said to be "best" for that style. Then again, ten gallons of similar ales doesn't sound too bad.

I would agree with your conclusions about chlorine bleach. Most homebrewers use a tremendous amount. Chlorine is highly reactive with anything organic, and this can actually lead to reduced effectiveness if the equipment being sanitized is not physically clean first. Once it is clean, it takes only a small amount to get the baddies that are hanging around. Because of chlorine's activity, it also immediately reacts with beer. And it does so forming compounds with some of the hop components called chlorophenols, which have a low taste and aroma threshold.

As was noted in a previous digest, the emminent Dr. Fix recommend rinsing your bleached equipment with cheapo store bought beer. I personally have moved away from using bleach, and instead rely upon boiling water for sanitization. I don't worry about scratches in plastic, because the plastic itself gets to near 212. Anything that isn't killed by this procedure is well stunned--good enough for my yeast (from a starter and active) to make the environment unpleasant.

Subject: Beer in Chicago, Beer in Madison, Beer in Kenosha

Ahh, what the heck, I might as well add to the noise and ask for recommendations for spots to get a beer in Chicago IL, Madison WI, and Kenosha WI. I'll be heading there in mid-April.

As this info is probably not of general interest to the group, perhaps it would be best to email responses directly to me.

Re: Richard Ransom's minimum effort brewing system --

First, I'd just love to sit around drinking beer and listen to Richard and Pete Soper debate technique. Talk about opposite ends of the spectrum :-
) My main question, like everyone else, was the trub issue.

Second, this debate reminds me of one that's been going on over in rec.aquaria, regarding the "right" way to set up an aquarium. Bottom line in both cases seems to be "If it works, don't fix it." There are so many variables (ambient temp, dampness, population of wild yeasts & molds...) involved that it's hard to say whether Richard's methods would work for Pete.
I guess that's the main argument for using a more rigorous routine -- I'm pretty sure Pete's methods would work for anybody, as he is removing as many variables as possible.

>I've had two bad batches in a row?

Martin,

For my trappist ale I cultured the yeast from a 750 ml bottle of Chimay Cinq Cents dated 5-90 and the yeasts activity was very close to what you described above. I saw no activity at all for six days, and then a very slow increase until it developed a moderate krausen on day ten. After pitching, the culture seemed to behave similarly to other ale yeasts I've used. The resulting brew was very close to what I had in mind when I started. I think the unique characteristics of the Chimay ales are due almost entirely to the strain of yeast employed. Thank you Father Pere Theodore for this gift to brewing.

From: Dave Sheehy <dbsh@hprnd.rose.hp.com>
Subject: Re: Culturing Chimay Yeast

Martin Lodahl (and a while ago Chris Shenton) ask about culturing Chimay yeast:

Last January I was successful in culturing Chimay yeast and have brewed a batch of Trappist Ale using Miller's recipe. My previous attempts at culturing yeast from a couple of different trappist ales failed. I believe my success this time was due to several factors:

1. One of the local liquor stores had just widened their selection of import beers so I was reasonably sure that the bottle of Chimay I purchased hadn't been sitting on the shelf in the store very long.
2. It was January, so if the bottle had been shipped around in the last few months it probably had been kept reasonably cool the whole time (and not been baked in a warehouse or on the back of a truck!).
3. I bought a 750 ml bottle which gave me a lot more yeast sediment to start with.

Then again I guess it could be just plain dumb luck. Anyway, I pitched the sediment into a beer bottle with some wort in it, attached an air lock and waited. It only took a couple of days to get going as I remember. My pitching solution is usually between a 1/4 and a half cup of dry extract in a pint of water (I don't measure the extract I just eyeball it). I boil the pitching wort with a couple of hop pellets, chill in the refrigerator and it's ready to go. From my experience with culturing yeast from a bottle if at first you don't succeed, try, try again (yeah, I know, I couldn't help myself).

I made up an all grain batch of Miller's Trappist Ale (S.G. around 1076 or thereabouts) chilled it down and pitched. Oops, I forgot a step. Before pitching I stepped the starter up from about a half a beer bottle (~6 oz) to a pint. Now, I'd never seen a top fermenting yeast before (could be because I only recently retired the ol' plastic bucket and have been using the 25L acid carboy for only a few months now) but I can't say that anymore. Chimay yeast ferments quite strongly and it formed about a 1/2 inch thick layer of yeast on top of the wort. After about a week of furious activity it slowed down and it was another couple of weeks before I transferred to the secondary. It sat in the secondary for about a month mostly because I didn't have time

to bottle it. At bottling time, it had a F.G. of 1010 so Chimay yeast exhibits reasonably good attenuation. Best of all, after a couple of weeks in the bottle it tastes like Chimay. Not exactly like it, but hey, I'm not quibbling.

P.S. to Martin (and Robert Nielsen too) I am planning on attending Robert Nielsen's Home Brew Fest (although I haven't RSVPed to Robert yet. Hey Robert does this qualify as an RSVP?) and will bring some of my homebrew Chimay to sample. You are welcome to a bottle to culture from.

I'm also a member of the GCBA so we could work out an exchange that way too.

P.P.S. to all brewers in and around the Sacramento area. If you're looking for a Hunter Energy Monitor unit the Home Depot at Madison and Manzanita has 'em for \$30 plus change.

>yeast nutrient. Maybe that'll help.

>
>Is this normal behavior for this yeast?
YES, YES, YES.... it is normal for the dregs of a bottle of Chimay to
take
forever if dumped directly into a 5 gallon+ batch of beer. I have
successfully
cultured Chimay several times from the bottle. I got tired of doing this
and
now have the yeast on agar slants (very fuzzy strange looking yeast!).
Your problem (IMHO) is that you expect the yeast to be as strong as a
WYeast
package... it ain't!. Every time I have cultured the yeast it took 5-7
days to
reach a pitchable level (i.e. more than an inch of head).
I culture the yeast very carefully using 1/4 cup light malt, 1/4 cup Corn
Sugar, 3/4 quart Filtered Tap Water in a Crannapple Jar. The mixture is
boiled
for 15 minutes in the microwave then cooled quickly in a water bath. The
jar
should have a tea cup or almost empty fermentation lock on the top to
prevent
any infection while it is resperating during the cooling phase. After
the
mixture is cooled to room temperature, inoculate with the botton 2 inches
of
beer from a Chimay bottle. It will look like the thing is dead until
early on
the 5th day (I promise), but after that it will come nicely to a full
krausen
in the next two days.
Chimay is a wonderful yeast to ferment with - if you have a strong
culture -
imparting a real sharp/tangy flavor to the beer
Brewers in the San Jose area can get slants directly from me for \$2.50
each. I
have about 12 different 'Original Bottle' yeasts cultured currently.
Current
stock:

Guinness Stout
Boulder Porter (Top fermenting - sweet)
Sierra Nevada Pale Ale,
Worthington WhiteShield
Pure Red Star Ale
Sante Fe Ale
Duvel Belgium Ale (Bottom fermenting - clean)
Orval Belgium Ale (Bottom frementing - sweet)
Chimay Belgium Ale (Top Fermenting - sharp)
Anchor Ale
Anchor Lager (YES! the Steam Beer* Yeast)
Gordon Biersh Lager

If you get the chance to visit western Europe, look for one of the "open air" museums (for example, the Freilands Museet outside of Copenhagen or the Openlicht Museum near Arnhem, Netherlands). These have a variety of buildings that were scheduled to be torn down, but because of their historical interest, they were moved. There are a number of farm houses, but one constant among them all is the little brewery in the corner. There is a fireplace, usually on the other side of a wall, and on top of it is a copper kettle built into the house. It holds about 10-15 gallons. Nearby you'll usually find several wooden tuns for primary fermentation. Occasionally you'll see some casks for holding the racked beer. The museum near Arnhem actually has a small brewery/bakehouse. The bakehouse side is in use and you can buy some very nice muffins and scones there, but the brewery is unused. You can, however, see the shallow pans near the roof and the small room used as a maltings, another for storage, and the main area with a large copper kettle and a lauter tun built into the floor.

Subject: Making Malt Vinegar

In the February "California Celebrator", Byron Burch has an article about making malt vinegar. I immediately had a craving for fish and chips! Has anyone else tried this? He says to get a malt vinegar bacteria culture from a home brew supplier and put it in a gallon jug with 2 bottles of beer. The gallon jar is covered with layers of cheesecloth. After 5 or six weeks, it should be done. The resulting vinegar can then be used as a starter for 8 more bottles of beer. Can I go to the store and buy a bottle of malt vinegar and use it ffor a starter? Is the stuff in the store pasturized so that you can't do that? (Now all I need is a deep fryer to make fish and chips!)

>only person I know in my immediate vicinity who likes beer.

Well, that is (was?) also the case with me. I don't drink a lot
of beer, ranging from one to five bottles a week. No one else in
the immediate vicinity drinks beer.

However, the beer keeps great in the cellar. I just finished a
bitter I made a year and a half ago and it still tastes really
good. I just don't brew as often as many others, plus I have
lots of different brews to choose from.

Plus, whenever we have a party, I don't have to buy any beer for
it :-).

Also, I usually use a couple of the 1 or 2-liter plastic soda
bottles, and save it for parties, either at my house or a
friend's.

>If I'm using a dry yeast, dividing the package in half, or even

>opened?

Well, no matter what the size of your batch, the more yeast you
can put into it, the better. I wouldn't divide dry yeast into
fourths or such, just use a whole packet or two even for small
batches. You *can't* put too much yeast in the wort!!

There are ways of culturing yeast and saving it for later, but
I'm not qualified to tell anyone how to do it.

The best advice someone gave me early on was not to use too much
bleach, as already mentioned. Two tablespoons per five gallons
is plenty. Remember, the bleach you *smell* in the water is not
attacking bugs.

In my experience, five minutes after I dump the bleach solution
out of the fermenter, etc., I can't smell the bleach in there any
more.

Subject: Yeast on slants -- what's it look like?

A few digests back, I whined about apparently not being able to get yeast to culture on slants -- there was no sign of life, infection or otherwise after 4 days. Well, I got no replies :-).

Yesterday, I looked again, and there is some very slight lumpiness on the carmel-colored agar². No furriness/fuzziness. No all-white patches, just something which looks a little different than last week.

What do your slants look like? What dilution of extract to you mix with your agar?

Thanks.

Subject: Original gravity estimate

I've been "estimating" initial gravity as follows: Take a sample of the boiling wort. Let it cool. Measure its gravity. My boils are about 3.5 gallons, so I add 1.5 gallons of water (at a gravity of 1.0) to get 5 gallons. So, if the wort measured 1.080, I would estimate $(3.5 * 1.080) + (1.5 * 1.0) = 5.28$ worth of "weight" in the full 5 gallons. Divide by 5 to get 1.056 OG. Not exact, but it should be close. Am I forgetting anything?

Subject: Chimay Yeast and Bottling Dates

In the recent discussions of the culturing of Chimay yeast there have been two references to bottle dates. I have a bottle in my cellar that I'm saving until I'm ready to culture the dregs. I examined it the other day and can find no date on it. Is the date coded? Where should I be looking?

I recieved the Chimay and a 750 ml bottle of Corsendonk Monks Brown Ale for my birthday last month. I split the Corsendonk with the friend who gave it to me. We had a religious experience! As soon as it warms a little, I MUST make a trappist ale. From the discussion here and in Miller's book it seems there is really no substitute for original trappist yeast.

Subject: Re: Homebrew Digest #602 (March 22, 1991)

Howdy,

My brew partners and i have just bought our first package of Wyeast. First of all, i understand from the directions on the package that the yeast should be started some time before we're ready to pitch it. The package says "1 day for every month after the code date". Do i really believe this? Break the inner seal, adn the yeast will be ready for pitching in 2 days?

Second: We would like to use this yeast in another fermentation (after the current one). I gather from recent net comments that if we wanted to use this yeast immediately after the current fermentation, we could just dump some of the trub from the bottom of the 1st fermenter into the new one. Is this correct?

Now, suppose that we don't want 10 gals of the same beer around (picky aren't we?). How can we keep the yeast around 'till we're ready for it? I've heard something about putting it in a beer bottle (all very sanitized) and putting in the fridge, and then getting it started in a mixture of water and malt before pitching. Is this basically correct? What details do i need?

Thanks for all your help ...

steve

Subject: Using rocks to boil the wort

Being a geology-type person, I hope I can talk semi-knowledgably about rocks, even if I can't tell malt from hops! :)
The question about rocks shattering at high heat gets a resounding NO!
If the rock does not contain water trapped in pockets that can convert to steam, nothing will explode. Crystalline rocks (ie granites) are probably better for this, because they were formed at temperatures above 600 degrees a lot of time any way. Besides, with limestones you run the risk of limey beer due to dissolution of the calcium carbonate - definitely not a treat!

As for poisonous rocks, believe it or not, the answer could well be yes.

Many rock-forming minerals contain such unpleasantries as lead, arsenic, or heavy metals. As a general rule, stay away from any pretty, metallic minerals. They'll contain things like sulphides, which would help to sterilize the wort, but wouldn't do much for the yeast. As I say, they probably use granitic rocks, due to the low content of soluble minerals.

I believe you have rauchbier confused with steinbier. The former is a
normal
dark lager beer made with malt that has been dried over smokey beech log
fires. Steinbier is indeed made by adding hot rocks to the wort to
induce
it to boil.

Subject: culturing Chimay Ale yeast

I've Cultured two batches so far, both from 750 ml bottles of Chimay Red Ale. I boiled about 3/4 lb of dry malt extract for each bottle. The frist bottle I stored at 65 F, and it wasn't going at all after 2 days, so I moved it to a kitchen cupboard at 75-80F. Within a day it was spurting through the airlock. I started the second batch and left it at 75F, and it took 2 days to reach the air lock. Both batches took off and fermented very rapidly for around a day and a half, and then it was over just like that. like 150 blubs a minute from an econo-lock air lock after 24-36 hours. less than 1 blub a minute 24 hours later.

Subject: RE: Yeast/Small Batches

RE: HBD #599 - Dan Graham's yeast questions:

Dan: I am a novice brewer (2 extract dry yeast, 4 partial mash yyeast) batches

Taking the advice from the HBD the best things I did for taste improvement were partial mash and liquid yeast. Since it takes as much effort, equipment cost, 3 gallon and 5 gallon carboys are about the same price, I would brew in 5 gallon batches. I use a glass 6.5G (\$12) primary and glass 5G secondary.

A pak of liquid yeast isn't like a pak of dry yeast from a population stand point. Per Miller's book on homebrewing it is important to have a large population at pitch time. Hence the need to produce a starter. With the use of this method I have had very active fermentation within 24 hours of pitching on all 4 batches using liquid yeast. It takes about 4-5 days from when I activate the culture in the pak until my starter is ready to pitch.

I usually activate on Monday and brew on Friday.

This is how I re/use liquid yeast: 1) start per directions on the pouch.

2) When inflated, 1-2 days, make a starter I use a 1.5L wine bottle half full of wort, insert air lock 2 days later its ready to pitch. I make this wort from 6oz dry malt in quart of water and boil 15 minutes with a few hop pellets and 1/2tsp yeast nutrient. Cool in fridge add strained contents to the wine bottle and pitch pouch contents when starter fluid is at room temp. When the starter exhibits active fermentation, about 2 days I brew.

3) After pitching and mixing the starter with may 5 gallons of wort I save 6 oz of the aerated wort in a bottle with air lock in my fridge. I have reused a month later by letting it sit at room temp for a couple days and pitching to a starter wort like #2 above with no problems. I do this to get 2 batches per yyeast which yeilds a per batch cost for yeast of 2.50 +- .25 I did not mention sanitation, it is a given for all brewing. Also I did not try to 3culture this. I will not brew another batch with dry yeast, the results are worth the extra cost, \$2.5 vs \$1, and would recommend it for any brewer.

Using this method I plan 2 batches ahead. I used 1056 AM ale yeast for 2 test batches which were very similar to see if my process worked. I used 1028 British ale for a Brown Ale and Bitter. I try to use the type yeast that goes with a certain style. I will use 1056 again. (and again)

I have wanted to make malt vinegar for some time and I plan too this summer. Vinegar seems to like warmer temps for fermentation about 80 F is what I have read.

I question using bottled beer in making vinegar; how do the hopps affect the flavor?

Before using store boght vinegar read the lable. It is often pasturized and filtered. Thus you will have no mother to innoulate your beer.

Good luck

Subject: Michael Jackson visits Ithaca

Greetings all....

If any of you happen to be in or near the Ithaca, NY, area during the week of April 2nd, know that MICHAEL JACKSON, author of the books THE NEW WORLD GUIDE TO BEER and THE POCKET GUIDE TO BEER will be visiting our town that week.

There will be a dinner at the Statler Hotel, Cornell University, on Tuesday, April 2nd at 7pm. The theme is "pairing beer with food". In addition, on the following night, Wednesday, April 3rd, the Ithaca Homebrewers Club will be taking Mr. Jackson to dinner at a local restaurant. Later that night, at 8:15pm, Mr. Jackson will be the honored guest of our brew club at our monthly meeting, which will be held at the CHAPTER HOUSE BREWPUB, 400 Stewart Avenue, Ithaca. All are welcome to attend our meeting (as usual) and bring homebrews. Mr. Jackson will be tasting Chapter House beers and our homemade beers and offering his advice/praises/criticisms. He will also be signing copies of his book for any who bring them.

If anyone thinks this is enough to warrant an unplanned road trip to Ithaca and you'd like more information, let me know. My home phone is 607-273-7306 (leave message), work is 607-255-4648; ask for Steve. Better yet, send e-mail to:

>available in small packages, or is there a good way to save Wyeast once
>it's opened?

My two cents for what ever that's worth (~2 cents) would be to
put the liquid yeast in a sterile bottle (I like 1/2 gallon booze
bottles)
of a sugar (not table) & water mixture and put an airlock on it. This
would
probably be sufficient for short periods of time. Each time you need some
yeast, sterilize the outer lip of the bottle and pour accordingly. For
longer
periods > 1 week, I would suggest the same sugar/water mix, but 1/4 fill
several sterile beer bottles instead. Sterilize the bottlecaps and cap
em. I
have used this latter technique to store lager yeast for several weeks at
a
pop in my fridge. I highly recomend refrigerating the sealed containers
as
glass grenades & wives don't mix.

My other suggestion would be to get higher quality friends
(ie the kind that likes good homebrew) and then you could brew in more
economical quantities. Try combining your ham radio & beer making hobbies
and broadcast at 1000w that a new batch is ready.

From: hplabs!bnr-vpa!bnr-rsc!crick (Bill Crick)
Subject: Chlorine

A lot of people are using what I would consider far too much chlorine bleach.
A few teaspoons per gallon is lots! In fact I use it very little, except for blasting otherwise tough to clean stains. I rely on Sanitone soap powder, and lots of boiling water.

Note that according to my wife, the food scientist, many food grade plastics will absorb fairly large amounts of chlorine, and they will difuse out later

This means that if you use a large concentration of chlorinw bleach in or on plastic, you can rinse your brains out, and still end up with chlorine that is in the plastic coming out and contaminating you beer causing astringent, plastic, bandaid smell problems.

This discussion came up because a friend ran into this problem after changing one thing in his process. He had went from detergent, and boiling water cleaning, to nuking a stubborn yeast stain out of a plastic primary fermenter carboy with chlorine bleach!!

Also I think boiling caps is ridiculous! I've used somewhere between 5000 - 10000 caps right out of the box, and never had a problem ever. Remember, by the time you get to bottling, your beer has enough alcohol to be fairly resistant to contamination. This is the reason beer was a popular beverage over the last few thousand years, because it can be made in less than clean room conditions and still be sdate to drink.

Granted, keeping things clean gives you more consistant results, and I'm not advocating dirtiness, but back off with the sever chemical warfare!

Isn't there a beer in Europe (Germany/Austria) that is made by
using heated stones to heat the wort - the name might be 'Stein Bier'.

I haven't seen it around here much - saw a bit of it about 4 years
ago. Tasted great - a smokey tasting lager that looked a bit reddish.
Loved it! The beer from Brazil, Xingu, reminded me a quite a bit of
the taste, tho Xingu is a literally black lager.

Subject: Yeast Slants

Chris Shenton asked about what yeast on slants does/should look like.

The yeast looks like white cream on the top of the agar. It should not look furry or fuzzy. In some strains of yeast, there may be a slight yellowish color.

For the agar, I use 1 tablespoon of light, dried malt extract to 1 cup of water. This has worked well for me, although I am considering bumping this up just a touch (a touch mind you, like maybe a heaping tablespoon per cup). Currently I do not use any yeast nutrient in the agar mix, but I do use yeast nutrient when making a starter from a culture.

Subject: Re: Grapefruit taste

I, too, produced a batch with a grapefruit taste (in fact, my first). Since I used a low-acid hop (Fuggles), and mashed from the grain (albeit not too well), I attributed it to the taste of the hops, heightened by the low alcohol content (due to the lousy mashing). I have never repeated this result, but then again I haven't mashed since then either.

Just to change the subject, I'll pose a question: what is the current going rate on 5 gallon tap jars?

Subject: Re: engine rebuilding, cams, etc.

I had some difficulty with a recent HBD posting. In particular, the nomenclature became somewhat garbled:

>> I believe the problem at the low end has something to do with
>> a process called scavenging, where the departing exhaust gasses
>> help pull in the fuel mixture. I always changed to a cam with good
>> overlap when I was doing performance machines, and never had

No, no. The process is called "autolysis", and it occurs when the fuel has become depleted. In this case, the yeast strongly overlap and eat each other.

>Cams with much overlap are designed for power, not low-end torque.
>High torque (RV-type) cams usually have no overlap whatsoever, at the
>expense of losing power at higher RPM's. With no overlap, there is a
>good vacuum produced in the cylinder before the intake valve opens,
>thus, when it does, it really sucks in the fuel/air mixture. This is
>especially important at very low RPM. If the fuel/air velocity is
>not kept high at low RPM, then the mixture condenses on the walls of
>the intake manifold, causing stumbling and rough running (i.e. low

I agree. Fuel/air mixture is important in the low-RPM startup phase. But the consequence of low air/fuel ratio is to cause hesitation in the takeoff, and later to reduce the tendency of the yeast to stick to the bottom of the fermenter. A small yeast film on the side of the cylinder is unimportant.

Subject: collection of "yeast" on side of carboy.

Quick question: The last 2 batches I brewed had yeast deposits or something to that effect develop on the side of the carboy after 4-5 days of fermentation. Its never occured before during the previous 10 batches.

Used Wyeast liquid lager yeast and it was a single stage fermentation.

I bottled the brew several days ago and at that point it tasted good and smelled ok. Any thoughts.

From: Martin A. Lodahl <pbmoss!malodah@decwrl.dec.com>
Subject: Yes, Chimay ...

Thanks to all for the posted and e-mailed answers to my question on culturing Chimay yeast. As it happens, I was a wee mite premature: within hours of my sending the question off, the culture was in the rudest of health and spirits! I recultured anyway, and by the time I was ready to pitch, the inoculum was MORE than ready! I had that reassuring "white blanket" effect within a few hours, and have had a vigorous and healthy ferment ever since.

A few of the comments led me to believe I'd left too much out of my initial posting, and a few just seem to need repeating, so:

From: mmatttox@fws132.intel.com (Mike Matttox ~)
" . . . I think the unique characteristics of the Chimay ales are due almost entirely to the strain of yeast employed. Thank you Father Pere Theodore for this gift to brewing."

Amen, Mike, Amen. See you at the SactoBeerFest.

From: pencin@parcplace.com (Russ Pencin)
" . . . it is normal for the dregs of a bottle of Chimay to take forever if dumped directly into a 5 gallon+ batch of beer."

Whoops. Time to explain what I was doing. The initial culture was taken by boiling 4 Tbsp light DME for 20 minutes in two cups of water, and then cooling it in its (covered) pot in a water bath. When it was down below 80F, I swabbed the cork and neck of the 750ml bottle of Chimay Rouge (which I'd chilled over night to encourage settling) with isopropyl alcohol, flamed it, opened it, and decanted all but the last couple of inches to a pitcher. Then I poured the wort into the bottle, shook vigorously to aerate and break up the yeast cake, and fitted an airlock. So the glup-rate mentioned in my question is in reference to a 2-cup "batch" in a 750ml "fermentor".

To reculture, I made up another batch of starter wort, adding an unnecessary pinch of yeast nutrient, and cooled it in a 500ml Erlenmeyer flask. Then I shook up the bottle to get everything back in suspension, did the swab-and-flame routine again, and dumped the contents of the bottle into the flask. More shaking to aerate, then I fitted an airlock to the flask. It seems to have worked.

Russ again:
"Your problem (IMHO) is that you expect the yeast to be as strong as a WYeast package... it ain't!"

That was indeed my standard of comparison.

From: dinsdale@chtm.unm.edu (Don McDaniel)
"In the recent discussions of the culturing of Chimay yeast there have been two references to bottle dates. I have a bottle in my cellar that I'm saving until I'm ready to culture the dregs. I examined it the other day and can find no date on it. Is the date coded? Where should I be looking?"

I was using a 750ml bottle with a cork closure, and the bottling date was stamped on the cork. The date was "09-90" (I refuse to believe in a bottling date of "06-60"), and its performance suggests

that's recent enough, though Dave Sheehy's reference to the importance of the time of year in which the shipment takes place sounds right to me.

Thanks again to all. If it turns out well, I'll post a recipe.

From: jpb@tesuji.dco.dec.com (James P. Buchman)
Subject: Odd growth; spruce

An update to those who asked about spruce beer: we just bottled our five-gallon batch of Special Red Bitter ale with added spruce branches. We had filled a pint cup loosely with the smallest spruce twigs, dumped them in the wort for the last ten minutes of boil, then fished them out. I hoped that this would add just an accent of pine to the bitter; however, successive samples from the carboy over the last two weeks have had an increasingly heavy pine scent and flavor. Not sure how drinkable this will be when bottled. Next time I'll put in 1/4 as much and work up from there.

Another disturbing item about this batch: there was a patch which looked like grayish mold just below the neck of the carboy when we bottled. It was about 2" in diameter; none was on or in contact with the beer itself. Was this mold, bacteria, or something equally nasty? We bottled anyway, taking care not to touch this patch with the siphon.

Two possible reasons for this:

- 1) I removed the airlock twice during fermentation, on days 6 and 9, to take SG measurements.
- 2) The corner in which I keep the (green glass) carboy is shadowy but not totally dark; indirect sunlight can reach it.

Advice?

Thanks,
Jim Buchman

Subject: Yeast Culturing and GrapeFruit Beer

Chris Shenton <chris@endgame.gsfc.nasa.gov> asks about yeast cultures

> Yesterday, I looked again, and there is some very slight lumpiness on
the
> carmel-colored agar^2. No furriness/fuzziness. No all-white patches,
just
> something which looks a little different than last week.
>
> What do your slants look like? What dilution of extract to you mix with
> your agar?

It depends on the yeast you are using (in my limited experience). I have found that it takes at least 2 weeks before I get anything really visible on my slants. This may be slow, but I don't know. Wait another week and You'll probably see a little more than you do now. I have noticed that different yeasts look different on the slant. WYeast #1056 is pretty clean and white, but a culture from a couple of bottles of Chimay Rouge is quite biege in colour. My brewing partner also made up a culture from a Hogaarden beer and it is nice and white, but sitting on a clear jelly-like substance. We haven't tried it yet (should be interesting...), but I don't really think it is infected.

nt@Eng.Sun.COM (Nick Thomas) asks about a beer that tastes like grapefruit juice

> And a troubleshooting question - I've got a batch
> that tastes almost,
> but not quite like fresh squeezed grapefruit juice.

This used to be a common flavour with my brewing partner and me (although he won't admit it). I think it is a combination of fruity esters, phenolic tastes and fusel alcohols. We were using Doric yeast and not racking the wort off of the trub before we pitched the yeast. Changing from Doric to WYeast #1056 got rid of the esters and phenolic part, but the most dramatic change came when racking the wort off of the trub before pitching the yeast. I can not recommend this strongly enough! Get a wort chiller and chill your wort down below 70 degrees F (hopefully below 50). Strain off any hops and put the wort in a glass carbouy. When the trub has finished settling (or when wort is up to pitching temperature -- whichever comes *last*) rack the wort into another carbouy and pitch the yeast. I usually loose about 1/2 gallon of wort doing this. Since I generally top up to 5 gallons with pre-boiled water after this procedure, I add 10% extra of everything in my recipes (works out very well). In an article in Zymurgy, someone mentioned that the leftover wort can be filtered and canned (normal jam canning procedure) and used to krausen the beer. This is an excellent idea, but one that I haven't tried yet.

Mike

> a mixture of water and malt before pitching. Is this basically
> correct? What details do i need?

My brew partner and I have had good results with bottling the slurry at the bottom of the fermentor. In once case, we kept the bottle in the fridge with an air-lock. In another, we just sealed the sediment in a bottle. In both cases we made a 1-liter starter a couple of days before brewing, and the results were excellent.

From: polstra!jdp@uunet.UU.NET (John Polstra)
Subject: Re: calcium chloride availability?

In HBD #604, smithey@hulder.css.gov (Brian Smithey) asks:

> Does anyone out there have experience using calcium chloride for mash
> acidification ...

Yes, I've been using calcium chloride to treat my brewing water for a little over six months, with very good results. I use a mixture of calcium chloride and gypsum, to get the optimal amount of calcium ions in the water (50 to 100 parts per million) while keeping both the chloride and sulphate levels relatively low. Using the calcium chloride allows me to avoid that sulphate bite that comes from using gypsum. (By the way, I don't really think of the water treatment as "for mash acidification," although the calcium ions do help to keep the pH down. I suppose that's just a terminology nitpick.)

I bought my calcium chloride (and other water treatment chemicals) from a local laboratory chemical supplier. Most medium-sized cities have one. Check your Yellow Pages under "Chemicals". You might try asking a pharmacist, too. If all else fails, I know that there are mail-order chemical suppliers that carry this sort of thing. Ask your local high school chemistry teacher.

There are several variants of calcium chloride available. The difference between them is the number of water molecules bound to each molecule of CaCl_2 . I believe that the best form to use is calcium chloride dihydrate, which has two water molecules per molecule of calcium chloride. The chemical formula is $\text{CaCl}_2 \cdot 2\text{H}_2\text{O}$ (lower the subscripts where appropriate and change the "*" to a dot). The reason this form is best is that it is the only one that is stable. The other forms either absorb more water from the atmosphere over time, or give some up, thereby changing into something else.

Also, make *sure* you use only food grade chemicals. These are labeled either "USP" or "FCC". (Both mean food grade, and I don't know what the difference is between the two.) Any chemical that's not specifically labeled this way could well have such impurities as lead, mercury, and arsenic.

You may get a choice of crystals, granules, powder, etc. Obviously, the finer it's ground up, the easier it is to dissolve in water.

One gram of $\text{CaCl}_2 \cdot 2\text{H}_2\text{O}$ per gallon of water will add 72.0 parts per million of calcium ions and 127.4 parts per million of chloride ions.

I've been using two different mixes of calcium chloride and gypsum, depending on the style of beer. (Note: I begin with Seattle water, which might as well be distilled water -- it has virtually nothing in it.) When I want to bring out the hops a little bit, I add:

0.392 grams/gallon of $\text{CaCl}_2 \cdot 2\text{H}_2\text{O}$ (calcium chloride dihydrate)
0.764 grams/gallon of $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$ (gypsum)

(I know, it looks like too many decimal places, but I measure enough for 16 gallons at a time and I have a scale with a resolution of 0.1 grain = 0.006 grams. See below.) That adds 75, 50, and 113 parts per million of calcium, chloride, and sulphate, respectively.

When I want to emphasize the malt, I use this:

0.347 grams/gallon of $\text{CaCl}_2 \cdot 2\text{H}_2\text{O}$
0.407 grams/gallon of $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$

That adds 50, 44, and 60 parts per million of calcium, chloride, and sulphate, respectively.

I treat **all** the brewing water: mash water, sparge water, the works. To do this relatively painlessly, I measure out the proper amount of chemicals for 16 gallons, and mix them into a quart (32 oz.) of water. That creates a concentrated elixer which I simply add to my brewing water as I go along, at the rate of 2 fluid ounces per gallon of brewing water. (The chemicals won't completely dissolve in the quart of water, so you have to give it a vigorous shaking just before you pour.)

You obviously need an accurate scale to mess with this. Per the helpful advice of several other HBD subscribers, I use a reloading scale (designed for measuring gunpowder) that I got from the local sporting goods store for about \$50.

Finally, if you're used to brewing in calcium-poor water, be prepared for an astounding increase in your extract efficiency. The first time I treated my water, I happened to be trying to duplicate a batch that I had brewed previously. The recipe and procedures were identical. But where the OG had been 1.055 without water treatment, it was 1.064 with water treatment. Obviously, the character of the beer was completely different from the first batch! Plan on recalibrating your intuition about recipe formulation.

Subject: Re: Seattle Beer and Travelling: Summary of Responses

I just want to make a few minor corrections to the posting from Bill Thacker <hplabs!hp-bsd.cos.hp.com!cbema!wbt> in HBD #601 about Seattle beers. I would have done it sooner, but figured somebody else would respond.

> Dew-wamps (Spelling conjectural) - Apparently a fairly new brewpub near
> the Kingdome, across from FX McRory's

It's the Duwamps Cafe / Seattle Brewing Co. It's on the corner of Queen Anne and Thomas, near Seattle Center (where the Space Needle is). That's nowhere near the Kingdome or FX McRory's. Not really a brewpub, more like a (quite good) restaurant that also brews beer. I find their beers really excellent.

> Kemper Brewing (Hales) - Thomas Kemper Helles Lager, Hales Pale Ale

Kemper and Hales are two different brewing companies. Both are certainly worth trying.

> Pacific Brewing Company (address not needed) - one author told me to
> avoid this place, saying the beer was lousy.

The real name is Pacific Northwest Brewing Company, and their beers are indeed of rather poor quality as well as overpriced. In fact, the crumminess of the beer is exceeded only by the brewmaster's elevated opinion of them.

But be careful -- there's a *different* brewery called Maritime Pacific Brewing Company, which has been making very nice beers. Their staple product, Flagship Red Ale, is a sort of alt beer style. Maritime Pacific is not a brewpub, but you'll find the product on tap at Cooper's and the Red Door.

Other than these few minor nits, I thought Bill's summary was very good. Thanks, Bill, for taking the trouble to post it.

Subject: Colonna Cappers

Hi. I'm new to the digest, and this is my first posting. From what I've seen so far, I should've subscribed long ago.

<Could those of you who have used the Colonna bottle capper give me some
<information about its durability and ease of use? From what I've seen in
<the catalogs it looks like a good design but my local supplier has had
<trouble with it. He says that the nylon gears on his self-destructed.
<Before that, it had a very stiff action. Is his experience common?

I've used my Colonna capper for about 2 years. In that time I've brewed about 25 batches, some of them 12 gallon batches. (Bottling 12 gallons certainly makes Cornelius kegs look attractive!!) I've never experienced a single problem with the capper. Its action is smooth and firm, and the gears show no signs of problems. My previous capper was adjusted by tightening a set screw which held the lever mechanism on a vertical bar. It was always slipping and had to be readjusted in the middle of a batch. The movable plate of the Colonna has none of these problems. From my experience, I'd recommend it highly.

Cheers,
CR Saikley

Subject: CaCl2

<Does anyone out there have experience using calcium chloride
<for mash acidification, and/or know of a source for the stuff?
<I spent some time over the weekend with my city water analysis
<and Miller's TCHOHB, and I think I'd like to experiment with
<this. Gypsum is going to be out for me, as my sulfate and
<sodium content are already quite high.

I've been using CaCl2 in my mashes for about 1 1/2 years. It seems to produce a "rounder, smoother" beer taste, although I haven't done the definitive experiment of holding all other things equal and substituting CaCl2 for gypsum.

Berkeley water is quite soft, so I don't need to add alot of Ca. The phytase reaction can easily overcome the relatively unbuffered water to drop the mash pH to the desired level. I've found that 1/2 to 1 tsp. is plenty in a mash of 25-30 lbs. of grain (12 gallon batches) to get the pH down to about 5.3.

I often add a bit more CaCl2 into the kettle. Partly because the Handbook of Brewing (Master Brewers Association of America) claims that the optimum concentration of Ca in the kettle is higher than the optimum in the mash, and that some Ca is left behind in the mash, diluted by sparging etc. But mostly I add it because it makes me feel good!

As far as sources go, I found it ironic that CaCl2 is available from Mallinkrodt (sp?), the large chemical supply company in Dave Miller's hometown of St. Louis. I picked up a very large (5 lb.?) jar for \$7 from a lab supply in Oakland that was going out of business. Any lab supply should either have it or be able to get it.

Cheers,
CR Saikley

From: Pete Soper <soper@encore.com>
Subject: hops,fermenters,yeast,CaCl

My Cascade hop plants are starting their second season. There are around two dozen shoots visible with the tallest around a two inches with some green showing. They have migrated around the bed quite a bit and are coming up in four areas despite having started as two rhizomes in March of last year. They first appeared around the 12th of March. This is on the northern border of climate zone 8 in central North Carolina.

I heard that American Brewmaster has rhizomes again this year.

I got a new catalog from Great Fermentations of Marin (i.e. not the one run by Byron Burch and Nancy Vineyard) and two items in it caught my eye. One

is a 6.5 gallon carboy in a foam shell. The actual capacity is an eyelash less than 7 gallons. The other item is a 3 gallon fermenter that appears to be glass (listed with the 5 and 6.5 gallon items). Some Digesters have written of a desire for these in the past and might find them useful. I've never bought anything from GF of Marin, don't know them, etc. Order line is 800 542 2520 and this is in California.

About the appearance of yeast cultures. The appearance of colonies on solid media like wort agar turns out to be genetic and quite diverse. I've seen colonies on petri dishes that looked like lace with amazingly intricate patterns, perfectly smooth round bumps, bumps with "nipples", and so on. Wyeast

2042 (Danish lager) looks quite different from other yeasts on slants.

The yeast layer has a sort of rough texture and is almost parchment white. I agree that any fuzzy appearance is a very bad sign; I've seen this fuzz start as what looks like a spider web thread around an eighth of an inch long and

24 hours later occupy all of the open space of a culture tube (one with an air leak). Also, how fast yeast colonies become visible on the nutrient surface in

a culture tube is, for me, a function of how many cells I put on the nutrient, with some variation with temperature and the viability of the yeast. For the slants I made from monoclonies of Wyeast cultures a thin layer of yeast was

usually present 48-72 hours after I streaked the yeast on (at about 75F)

. I used a 10 microliter loop and actively fermenting wort so I guesstimate I put around 10-40k cells on the slant.

My slants of each type were inoculated from wort developed from a single colony grown on a petri dish. I streaked the dish with very dilute fermenting

wort from a Wyeast packet or bottle dregs, arranging by design to put just 10-20 cells on the media in each dish. With a bottle of Orval I think I got just *three* cells and they took weeks to grow into colonies visible to the naked eye. The Wyeast multiplied very much faster and was usually visible in 72 hours. Going this way if I'm lucky my slants for each type have literally a single cell as a parent and will hopefully be a known quantity for a long time. The argument could be made that Wyeast is pure in the first place and I wasted my time going through the plate culture step.

It's just about time to reculture all my slants (oh boy, I'd rather pull my toenails out :-)) and for reculturing I'll just pitch the slant to a 50ml starter and then streak with this the next day.

By the way, it is wise after making your wort agar slants and dishes to give them a few days to show any signs of contamination before inoculating them.

Carolina Biological sells supplies for yeast work and also sells calcium chloride (source requested recently). The price for culture tubes and the like is pretty reasonable but the price for ACS calcium chloride is painful (\$27.15 for 125 grams). If you do buy this, know that calcium chloride is so hygroscopic it and will suck moisture out of the air and go into liquid solution right before your eyes, so keep the lid on tight.

Carolina Biological is easy to deal with and doesn't act like god almighty the way Fisher and other supply houses do when you approach them as an individual. In fact I think at the current rate only Burroughs Welcome and Dow Chemical will qualify to do business with Fisher within a few years : -)
The number of CB is 800 547 1733 from the west coast (somewhere in Oregon) and 800 334 5551 from the east. The one bad thing is they charge significant bucks for their catalog. Schools can get it free but Joe Anybody pays around 17 bucks.

After getting my own weight in catalogs from Cole Parmer, Thomas and so on and truck loads of any catalog to do with electronics or computers it really floored me to have to pay for this catalog that I could put to good use.

Subject: Overpitching, Barley Wine

Someone said that you can't put in too much yeast. You can over pitch!
I forget what the symptoms are, but I seem to remember flavor, and too
much
foam. Commercial pitching rates are on the order of an ounce of yeast
per gallon? I remember 3 lbs per barrel??

Regarding making barley wine from grain. One possibility is to only use
the
first runoff from the grain bed without adding any sparge water.
This will have a gravity about twice what you expect for the whole batch
What do you do with the rest? I can think of two ideas.
Use the second run (sparge water runoff) to make a real light lager, and
toss
it in ye olde keg for summer quaffing;-).
Take the second runoff, and add extract to make what is basically an
extract
beer with a bit of mash added?

Note that you'll need to do a big batch, or accept a half batch of barley
wine! Your typical ten pound of grain batch would give you about 2.
5gallons of
say 1.090 initial runoff? If you want a full batch, you'll have to do
two
mashes or figure out how to deal with twenty pounds of grain?
Nopte: The gravity reading above is off the top of my head. NO flames
please!

another idea is to boil half a regular batch away, but that could be
tricky
to do without excessive carmelization, not to mention a good chance of
having
it rain in your kitchen;-)

From: Marc Rouleau <mer6g@fuggles.acc.Virginia.EDU>
Subject: Re: Acid Carboy Source Near Virginia?

A week ago I asked about the availability of acid carboys near Virginia. I received several "me too" responses, and a couple of suggestions. I also combed through back issues of the homebrew digest looking for previous pointers.

One person suggested that I try the local homebrew shop, which is really just a small collection of supplies in the corner of a scrungy pool hall. He said he'd had good luck getting them to order stuff they don't normally carry. The person I spoke with gave me the phone number for her supplier, Wines Inc. of Akron, Ohio. Well it turns out that Wines Inc. sells wholesale only, but that didn't matter since they were all out of big carboys and didn't know when they'd get more. The local shop would've sold one of this doomed-to-be-backordered carboys to me for \$17 plus shipping.

In a back issue someone suggested checking with chemical companies. The Charlottesville Yellow Pages told me that we didn't have any locally, so I dropped that idea. It sounds like a promising solution for some of you though. I bet they'd be pretty cheap.

The winning suggestion came from Chris Shenton, who wrote asking me to let him know if I find out and mentioned in passing that he bought one from Colonel John Canaday of Boulder, CO about a year ago. I found his phone number in an old digest and called him up. His current price is \$14 plus shipping, and while he doesn't always have them in stock it sounds as though he gets pretty frequent shipments. He was expecting one in the next day or so, and he warned me that they usually only last for a few days. His trusting send-me-a-check-when-you-get-it approach warmed my heart. Call (303) 442-2789 to get yours.

So it'll run me about \$20 after shipping, but I'm not aware of any alternatives.

Subject: Re: Food Processor

Tom Nolan asks about using food processors to crush grain.

The problem with a food processor is that it gives a very uneven crush. After it is processed, the crush will be a mixture of many different sized particles, from flour to uncracked grains. The husks will be powdered, which is undesirable both for the filter bed and for the cloudiness of the beer.

Nevertheless, I have made a couple of good all-grain batches using food processed grain. The lack of whole husks makes a grain bag more desirable, and there is always the possibility of a stuck mash, but it does work. In a partial mash, it should work pretty well.

Currently, I use an old cranked meat grinder with a blade similar to a Corona to do my crushing (I'm too cheap to go buy a Corona.) It requires a delicate touch to maintain the right size, but it's fast.

Subject: Alternative Expellant Gases

Has anyone ever considered using something other than CO2 in their keg systems?
Being that this gas tends to carbonate the brew, more than a few sources have said not to use it. Obviously O2 is a poor choice due to oxidation. What about N2 ? This is a cheap, readily available, non-oxidant, non-carbonating gas. I don't know, however, what N2's solubility in H2O is, in reference to CO2's.

Subject: Re: Colonna cappers

Jack Baty asks about Colonna cappers:

We have both types. The gears on mine are quite large. It would be very difficult to strip them with reasonable capping force. You can to some degree control the tightness of the action with a screw adjustment. It is not a "well oiled" feeling, though, but it certainly is not "very stiff".

All in all, I'm happy with it. It requires less effort than the twin lever capper and I have not snapped off any bottle necks in the Colonna. Is it worth what they ask for it? I don't know...different for every brewer.

It was for me, because now my wife helps with the capping whereas she did not before because the twin lever was not as easy to use. The only thing about it to be careful about is when you move it, make sure you have a thumb on the adjustable height plate, as it is not secured in and is heavy enough if dropped on a sock foot to cause a good deal of pain (and can gash your linoleum). No, it has not self destructed, but I have probably only bottled 400-500 bottles with it. It is very heavy plastic, with some obvious metal parts.

Subject: Hoppy beers

Hi there-

A friend and I are semi-beginner brewers, 5-10 batches each. We've been sampling some local (Oakland/Berkeley, CA) beers that have an amazing hoppy flavor and bouquet. Examples would be Anchor Liberty Ale, Triple Rock's RoboHop (tm...) (local specialty brew, doubt if many people caught it) and Pacific Coast's Blue Whale Ale (again a local one). Tim tells me that Marin Co. Brewing Company has some similar beers, but I haven't tried them. Of these Anchor Liberty is the weakest in terms of the hop bouquet etc, but I thought it has a wider range.

We've tried a few attempts at brewing these (hops at the end of the boil, dry hopping etc) but have had not much success at the intense hop bouquet/flavor. Not the bitterness, that's relatively easy...

If some of you brewers that have successfully done this could email/post the recipies and results, We'd be darn happy.

Relaxing anyway

From: jayl@Corp.Sun.COM (Jay Littlepage)
Subject: Cappers, Cusinarts, DME, GF-Marin, and a question:

My two cents on a few recent postings:

I bought a Colonna capper mid-way through bottling my very first batch. I was using screw-top bottles (i'm older and wiser now) and snapped the neck on 5 out of the first 10 bottles. Eight years and thousands of bottles later the Colonna is still going strong. One of my best purchases.

Cuisinart grinding: I got tired of crushing grain with a rolling pin and started using the cweese. It was easy but uneven; some hulls weren't touched, others were obliterated, with the ratio dependent on how many pulses you gave it. I finally invested in a Corona and have been very happy. It's actually faster than the cuisinart, given that I don't have to clean the corona to my wife's satisfaction after every use :-)

DME: I've been brewing entirely with extracts, as my one and only mash attempt was not good. I definitely go with DME over liquid extracts, due to cost, ease of storage and handling, and better control over my recipes. The only time I use liquid is if I have something specific in mind that I can't accomplish with DME - I like, for instance, a can of John Bull dark in my stouts, and I'll use IREKS liquid extract for my germanic recipes.

Great Fermentations of Marin: I get nearly all of my ingredients from Steinbart's in Portland or from one of the two GFs. Service from both GFs has been outstanding, in my experience. I've had orders from both appear on my porch within 36 hours of ordering (granted, I live 30 miles away). In one instance, the date on the yeast I ordered was 3 months old, so GF-Marin sent me two packages, just in case. Good folks.

Re-using slurrys, and my question: I've re-used the yeast pack from my primary in a number of batches by simply dumping into a sterilized mason jar and refrigerating. Never any problems. I used a batch of wyeast chico ale 4 times before I started getting suspicious. My biggest problem has been the length of time between batches in which I want to use the same yeast - I brew 6-8 batches a year and vary the styles I brew. What would people recommend as a refrigerated "shelf life" for the yeast before chucking it?

Mike,

Being a confirmed Hophed, I have to reply. I have been very successful
with
getting intense hop bouquet/flavor in my brews. I brew primarily English
Bitters, Pale Ales, and Porters. I use only leaf hops which I buy
directly from
Freshops (very good quality IMHO).

For the best hop flavor, I add 3/4 to 1 ounce of hops at the end of the
boil,
right after I remove the kettle from the burner. I let them steep for
10-15
minutes and then begin cooling the wort with my immersion chiller. For
hop
bouquet, I dry hop. My technique is to ferment in the primary for
approximately
one week and then rack to a secondary, adding the dry hops. I let it
continue in
the secondary until fermentation completes (1-2 weeks).

For my bitters, I have used upwards of 1 1/2 - 2 ounces of Willamettes
(for dry
hopping) for a 6 1/2 gallon batch. The Willamettes give a wonderful hop
bouquet
(again IMHO). For my Pale Ales and Porters, I tend to use Cascades, but
have
found that I have to use less of them or they become overpowering.

From: Dan Needham <dann@hpsadlb.hp.com>
Subject: Saving yeast, propane burners
Full-Name: Dan Needham

There has been a number of comments on re-using yeast. I'll add a couple of comments. First, I highly discourage capping yeast saved from the bottom of a primary fermentor. (BIG mess, repaint ceiling). Use an airlock. Also I only re-use yeast one time. It may be coincidence, but there seems to be some degradation in flavor with subsequent batches. Of course you can get more using laboratory re-culturing techniques.

There have recently been inquiries about propane burners. I have seen two types offered in stores and catalogs. One is a 32,000 BTU burner and the other is a 110,000 BTU burner. The prices seem to range from \$40 to \$75. Note that I think the 110,000 BTU burner is the cheapest -- I don't have my catalogs in front of me.

If you have a burner that you can recommend or discourage purchasing, please post or e-mail your comments. Please include as much detail as you can (e.g. BTU rating, size, source, price).

Thanks for any help!

Dan Needham

P.S. I just kegged up a batch for my new draft system. It's a wheat beer for an Easter party -- I know what to bring to the pot luck ;-)

I quit buying canned extract and now use only dry malt, if I don't do an all-grain brew. You have much better control over your brews using dry instead of syrup, as you don't know what else is in the syrup besides malt - corn sugar is a common additive. I use only light dry malt, that way, I can make just about any beer I want. If I want to make a darker beer, I just use crystal/chocolate/black patent malt as needed.

Subject: SAVING YEAST

The recent thoughts about using your yeast slurry again and again is just what I wanted to hear. I like the idea of reusing a yeast that has produced a fine beer. I'm interested in saving the slurry, or a significant portion thereof for later use. My initial thought would be to bottle a champagne bottle of it with a little fermented out beer in it for moisture. I'd cap the bottle and keep it in the frig. Will this work? I've been told by a homebrew supplier that one can keep yeast this way up to two years. This sounds long to me, but I'm not a biochemist. Comments anyone?

Anchor dry hops their Liberty Ale (so they said after the tour in Dec.).

I've been using a technique mentioned previously here in my last couple
of batches. At keggling time, I make a "hop tea" by steeping 1 oz. of
Cascade hops in 2 cu. water for two hours at 120 deg. F. Just before
adding to the keg, I mix the keggling sugar in, too (some may be concerned
about not boiling to sterilize, etc., but I have not had a problem).

I've found that this adds a very nice, green/herbal touch to the
aromatics (I'm describing this poorly). It is, however, nothing like
the aromatics that Sierra Nevada has. At any rate, I and my friends
like the results.

Yo! My most popular beer is a steam beer brewed with five pounds of Australian dry malt extract. Turns out just fine.

> Are there any advantages/disadvantages to trying this? As I
> understand it dry malt has approx. 20% more fermentables than
> liquid malt extract.

Several advantages: it's much easier to store a half-used container, much easier to measure, easier to use when priming, and comes in handy when cooking. I can't think of any disadvantages; in fact, unless I'm brewing something exotic, it's all I use.

As for fermentables, malt syrup is about 20% water by weight. DME is basically anhydrous, so for a recipe calling for five pounds of syrup I substitute four pounds of DME. This works out to 1/.8, or 25% more fermentables per pound.

Some tips: DME is voraciously hygroscopic. Store it in an airtight container, or it will turn back into malt syrup 8<:^). When measuring, weigh, don't use volume. Powders can settle quite a bit. Weigh out all you want to use before you start the boil and fog up the kitchen, or at least keep the container as far from the kettle as possible.

Has anyone ever done any brews using only dry malt as the primary ingredient? If so how did it turn out?

I made a dark amber ale from 3 lb dry light malt extract and 3 lb dry dark malt extract. It turned out pretty well. But I think I also used a pound or two of crystal malt, which always seems to improve the beer over just using malt extracts.

Subject: Chimay, Lambic? Mais, Non!

In HOMEBREW Digest #605, Ron Garrison asked:

> ... Does the Chimay yeast or do any other of the Belgian
> beers provide the same or similar yeast culture that is found in
Lambics?

With a certain hesitation, I must say no. While there are a few similar components in the "inoculum" (both contain *Saccharomyces cerevisiae* and at least one bacterial component), the effect is altogether different. The distinguishing factor in Chimay's flavor profile is a range of spicy flavors, dominated by 4-vinyl guaiacol. In lambics, sourness dominates, with a lactic acid tang being the most noted flavor. Some other Belgian beers share this characteristic; Gouden Carolus and Rodenbach come to mind. I personally would be more inclined to try the "additive" method Guinard suggested in his book, using successive inoculations of pure cultures. The problem with trying to use bottle cultures for this purpose is the sheer complexity of the fermentation: at least three strains of yeast and two of bacteria are needed to create something that tastes like a lambic. These critters all have very different life cycles, so in culturing the dregs of a lambic bottle (assuming you could find a non-pasteurized one) you'd be getting the "winners", the strains that were active most recently. The strains from the early part of the process would probably only be present in small numbers and with questionable viability. And to culture from something other than a lambic would give you something else, something that is not likely to taste much like a lambic.

Guinard spoke to our homebrew club (Gold Country Brewers' Association) earlier this month, and said something I find my self agreeing with. He asked that if we make something that tastes like a lambic, we not call it by a lambic name, unless we brewed it within 15 miles of Brussels and used the traditional materials and methods. Like Port, Calvados, Armagnac, and the other classic beverages associated with a small geographic area, lambic deserves its identity. What happened to Champagne shouldn't happen to lambic, kriek, and framboise.

From: grumpy!cr@uunet.UU.NET (C.R. Saikley)
Subject: Chimay, Malaria

With all the recent talk about culturing Chimay yeast, I thought I'd share some of my past experiences.....

The first time I used Chimay yeast was in May of '89. The beer brewed was christened "Trappist Monkey" and was one of four golds awarded at the 1989 Sonoma County Fair. It was very tasty, and the two judges gave it scores of 37 & 39 on a 40 point scale. Here is the recipe, which is anything but authentic.

8 lbs Klages pale malt
4 lbs Munich malt (10L)
1 lb crystal malt (40L)
1 lb malted wheat
1 lb wheat flakes (unmalted)
2 oz chocolate malt (uncracked)

1 lb dark brown sugar

2 oz Cascade hops (I didn't have time to age them 3 years!)

1 qt starter cultured from Chimay dregs

Mash temp 158F, pH 5.3
1 hour mash, final temp 155F
Mash out with 1 1/2 gal boiling water, resultant temp 168F
Sparge @ 168F, sparge water acidified with lactic acid to pH 6.5
Collect 8 gals sweet wort
Add brown sugar
Boil 1 1/2 hours
Add all hops (60 min boil)
Cool to 70F (counterflow chiller)
Pitch Chimay starter
Single stage fermentation, 2 months, temp ????
Prime with 44 oz sweet wort (from the original brew, stored very carefully)
Bottle, yield 6 gals
Starting gravity 1.072, terminal gravity 1.014

There's an unusual story behind the 2 month single stage fermentation. After pitching, the carboy was placed in a water bath in my basement, and I went off to Indonesia. After my return, subsequent hospitalization and recovery from malaria, I decided that it was time to check on my poor neglected brew. When I lifted the lid on the water bath, I was horrified to see that everything (carboy, water, airlock) was covered with a thick green fuzzy mold. A little too in keeping with Belgian tradition for my tastes; I guess the bleach added to the water bath had long since evaporated. Fortunately, the carboy's interior was slime free. With great trepidation, I tasted the dubious brew, and religious bliss ensued. I wouldn't recommend this fermentation technique to everyone, especially the part about the malaria, but it worked out well. Maybe I should've saved some of that fuzzy stuff.....

I'll pun in my comments about re-using yeast derived from the slurry.

I have tried this several times with mixed results. In these experiments, I sloshed around the leftovers in the fermenter, poured it into a swing-top bottle, and put it in the back of the refrigerator. On two of the occasions, the yeast autolyzed to produce a material so terrifying in its intense and sickening odor, I was unable to use it for anything except revitalizing the veteran colonies of our septic tank. On one occasion, I noticed the autolysis, but used the material to make a starter. The odor persisted into the finished beer anyway. With this, I cannot recommend using the slurry to propagate yeast. After all, much of this material is simply dead yeast, trub, hop leavings, protein-tannin complexes, and other gunk.

If one is interested in re-using yeast, it is perfectly acceptable to simply do one of the following: (1) take a sample of the finished beer and use it to make a starter. This assumes that you are ready to brew a new batch when the previous finished beer is not yet packaged. However, this is very simple to achieve in practice, with a little planning. (2) Use a bottle of finished beer to make a starter. I have used both of these methods with good success. The starter made with the finished, bottled beer may take a while longer to activate, but it should do so in two or three days at the proper temperature.

In any case, re-using the yeast should only be done for 2-3 generations. After that, purchasing a new culture would be advised.

I was in Milwaukee first week of January, for the 2nd time in a year.
I visited the Water Street Brewery in downtown Milwaukee, and the
Bavarian Wursthaus (Hampton Ave exit, at Rt 41 intersection, across
from the Timmerman Airport).

If I went again, I wouldn't bother with the WSB. VERY expensive small
glasses of OK brew. I liked the Oktoberfest, but it wasn't amazing. Instead,
I'd go directly to the Bavarian Wursthaus and order some more of that
amazingly fresh Spaten, or the Warsteiner Pils, or any of the other numerous fresh
German brews.

I was told I should check out Strecker's, another microbrewery, but noone
seemed to know how to get there. It's supposed to be great beer, and is
available in bottles there.

From: capnal@aqua.who.edu (Alan Duester)
Subject: airport security & homebrew

There have been several postings/questions about carrying homebrew on aircraft recently. Now that the war-related terrorism threat is supposedly over, I think security will slowly be drifting back to its former levels.

My security experiences have been at Logan International Airport in Boston, mostly through the Northwest Airlines (with International departures to U.K., etc.) terminal, plus a few through United Airlines domestic (minor security position serving only 2-3 gates at this checkpoint). 5 or 6 trips total with homebrew.

I owed a friend a case of homebrew for doing up labels for me. He lived in Chicago. I on Cape Cod. I never attempted to send beer via checked baggage. (Have you ever seen how they treat that stuff, fer ghod's sake? *My* beer deserves better than that!).

I carry either 6 or 12 bottles in 6-pack carriers in a heavy brown paper bag through security (one level high, carried only by the bottom). Any more than that is unwieldy, and in addition to my mini-duffel, is too much for only-carry-on travel.

My worst experience is that the security personnel for NW wanted to try a bottle! They backed down when I asked them to get some glasses. Once at United, they ran it through the X-ray machine twice and asked what it was. I had more problems with the chocolate-orange cheesecake I was bringing in for the party! I've also carried 1.5 liter bottle of Grand Marnier to Japan in carry-on with no problems. I normally carry the HUGE Swiss Army knife, a maglite flashlight, and a Leatherman in my Nerd pack, and these get searched (unless I take them out of the pouch and stick them in my jacket pocket and run it through X-ray).

My bottles had labels, but they were obviously homemade, and not in color. Plain or Diet Coke caps, depending on batch.

My suggestions? Ask them to get some glasses, and offer to have them open a bottle. It's gotta be better than the swill you can buy on the plane! Remember that security personnel have had their senses of humor surgically removed. If there are any problems, ask for the supervisor for the terminal. Be prepared to spend a few extra minutes at the checkpoint.

I look pudgy, bearded, flaky Germanic with light hair (I guess). I would think swarthy, dark-haired middle-eastern looking folks might have a few more problems.

Subject: Re: Reusing slurry

Back in the summer I put a liter of slurry into a just emptied vodka bottle (there was some beer mixed in with the slurry), and put it in the fridge. I brewed another batch a few months later with yeast started as follows.

- 1) Sterilize a one gallon jug
- 2) make an all malt starter from extract (no hops so you don't have to worry about it getting light struck). Boil this to insure sterility. You should make a quart to 1/2 gallon of this.
- 3) add a pint of the slurry to the starter and puit an airlock on.

I used the Wyeast German Ale in this manner.

The first pint was restarted after 3 months and worked fine. I just used the second pint 2 weeks ago, it too worked fine (though I'm told this was perhaps a long time).

From what I understand the keys to my success were

- a) using a vodka bottle meant it was sterile
- b) having a not too thick slurry meant that when it settled there was a protecting layer of flat beer over the slurry.
- c) restarting a fairly large amount of slurry meant enough viable cells to take off in the starter.
- d) essentially the quart to 1/2 gallon of starter is actively fermenting when added to the rest of the wort, infusing a high volume of active yeast.

This approach lets me get 3 uses from a single Wyeast, cutting the cost to a level that's competitive with dry yeast and allows me to brew when I want to, not when the yeast wants me to.

Subject: Wyeast Lambic Cultures Announced

This article recently appeared in Brewprint, the official newsletter of the Boston Wort Processors.

WYEAST TO PRODUCE A LAMBIC YEAST CULTURE FOR THE HOMEBREWER

In a continuing effort to expand their product line, Wyeast Laboratories of Mt. Hood, OR have announced that they will soon start selling pouches of mixed cultures of *Brettanomyces bruxellensis* and *Brettanomyces lambicus* to the homebrewing trade. These are the same yeasts as the wild ones that inoculate the lambic worts of Belgian brewers in the Senne Valley of Belgium.

The recommended use of this "wild" yeast is rather unusual, to say the least. Wyeast suggests that the homebrewer inoculate the brewhouse with the yeast culture by spreading small amounts of actively fermenting culture throughout the room. Because it is a naturally occurring wild yeast, *Brettanomyces* is very vigorous and will quickly establish itself as the dominant "wild" yeast species.

This will allow the homebrewer to replicate the actual preparation of a lambic beer in their own home. The hot wort can be allowed to cool slowly overnight in open shallow containers whereby *Brettanomyces* will inoculate it. It can then be racked to a closed primary fermenter and fermentation continues in the normal manner. Introduction of the proper bacterial cultures (also available from Wyeast) and aging (as discussed in Jean-Xavier Guinard's excellent book *Lambic*) will produce an authentic lambic beer. Of course the homebrewer can also add cherries or raspberries to make a kriek or framboise.

Because this is a one-time purchase, the cost will be higher than normal for Wyeast products, probably in the \$20 per pouch range. For more details, contact Wyeast @ 1-800-APR-FOOL (227-3665) or call your local homebrew supply store.

Subject: LP Gas burner for homebrewing

Thanks to the couple of people who sent me the clue, I went to Service Merchandise in Manchester, NH, and bought it. Herewith are the facts:

Identification: 2MBM (Service Merchandise number)
"Cookmaster" (on the burner and packing box)
UPC 94428 13122
Price: \$69.97 (probably varies by location)
Rating: 135K BTU
Accessories: 10 1/2 Qt aluminum pot & basket - no lid (separate price \$49.95)
Approved LP regulator and hose
Warranty: Five years
Manufacturer: Masterbuilt Manufacturing, Inc.
1645 Second Avenue
Columbus, GA 31901
(800)288-1581 for orders

*** Some assembly is required ***

The unit is a 3 1/2" (approximately) diameter, two piece cast burner and venturi pipe. At the outer end are a spring loaded air shutter and a needle valve. The hose screws into the valve on one end, and the regulator on the other. The burner is attached to a frame of rigid metal strap and bar that serves as a tripod for the whole affair, and which mounts a six inch high sheet metal wind collar (remember, this is intended for outdoor use). The burner surface is about 8 1/2" above the bottom of the legs. The cooking vessel is held about 11 1/2" above the bottom of the legs on three arms of metal bar, (similar to a gas countertop) which are welded to the tops of the legs. The only problem I see (for me, anyway) is that these arms are about 1/2" below the top edge of the wind collar. My Vollrath 38 quart brewpot is about 1/2" larger in diameter than the collar. That means that I will have to balance the pot on the collar top (it sort of nests in, because the pot's bottom is rounded, and the smallest part fits inside the collar, but not far enough so that the pot rests on the arms). I will probably solve that problem by having an additional set of bars welded on top of the existing arms, which would bring them to the top of the collar. Or, I could cut down the collar, but that could get messy (and I HATE working sheet metal).

Among several other (expensive, in my opinion) accessories available is a leg kit (Item # LK-26: \$15.95) that raises the unit 26". This might be handy for waist high cooking.

I hope this helps someone else in their quest for adequate heating.

Cheers...Gary

Subject: pseudo-lambics and an ale recipe

Can someone out there who has the Lambic book or anyone who has tried to make a lambic post or send me a basic recipe that will give me some idea of what kinds of ingredients to use and what quantities. Extract recipes, please. The reason I say pseudo-lambic is that I am going to try to culture yeast from a bottle of Schultheiss Original Berliner Weisse. We bought some last week and popped a couple expecting a normal, everyday, old wheat beer and instead got something that tasted a hell of a lot like a lambic. If any one sees this stuff, give it a try, it is very unusual. Anyhow, I am sure if i use this yeast, i may not get something that tastes just like an authentic lambic, but i don't really care, the fun is in the attempt!! Thanks in advance.

Now to share the recipe from my first solo batch of beer (I have been my husband's trusty brew assistant for far too long :)). I derived it from a recipe i pulled off the digest over a year ago, but made some significant changes.....Here goes:

PURDUE RED HOT APPLE ALE

4 lb. Mountmellick Brown Ale Kit (Hopped)
1 lb. Light DME
1 lb. Honey
1/2 lb. Crystal Malt
4 lbs. Sliced Winesap Apples (from Purdue Hort. Farms---hence, the name)
2 tsp. cinnamon
1 cup Cinnamon Imperials (Red hots)
10 g. burton salts
1 tsp. Irish Moss
1 pkg. Brewer's Choice London Ale Yeast (#1028)
2/3 c. dextrose to prime

Bring 3 gallons H2O to boil and put in brew bucket to cool. Bring 1.5 gallons H2O and crystal malt to boil. Remove grain. Add extract, honey, burton salts, and irish moss and boil for 15 minutes. Add red hot candies. Turn heat to low after candies melt. Add apples and cinnamon and steep 15 minutes. Dump into brew bucket, then transfer to primary. I made malted applesauce out of the apples by the way!

This ale is a nice light beer with little bitterness. You can't really taste the red hots too much, but the are definitely in the aroma. My husband had

his doubts about this since the only hops were whatever was in the
extract,
but he was pleasantly surprised. Everybody seemed to like this, and in
just
a couple of months, all we have left is a sixer. We're going to sit on
that
for a while, cause we think this will age nicely. Anyhow, red hot
candies
make a very nice addition to the brew. I think they might be good in
some
other styles, too.

"Drink all you want. We'll brew more!"

Subject: What Makes Beer Taste Great?

Date: Thu, 28 Mar 91 13:21:54 PST
From: Martin A. Lodahl <pbmoss!malodah@decwrl.dec.com>
Subject: Chimay, Lambic? Mais, Non!

In HOMEBREW Digest #605, Ron Garrison asked:

> ... Does the Chimay yeast or do any other of the Belgian beers
> provide the same or similar yeast culture that is found in Lambics?

With a certain hesitation, I must say no. While there are a few similar components in the "inoculum" (both contain *Saccharomyces cerevisiae* and at least one bacterial component), the effect is altogether different. The distinguishing factor in Chimay's flavor profile is a range of spicy flavors, dominated by 4-vinyl guaiacol. In lambics, sourness dominates, with a lactic acid tang being the most noted flavor. Some other Belgian beers share this

Hmm, that 4-vinyl guaiacol reference reminded me to tell you of the article that appeared in the February, 1991 issue of R&D Magazine, on pp. 74 to 78. It is titled "What Makes Beer Taste Great?", by Jay R. Powell and Senja V. Compton (of Bio-Rad, Digilab Division, in Cambridge, MA). The article is about the use of a GC/FTIR interface accessory, along with use of a liquid nitrogen cold trap, and use of Gram-Schmidt chromatograms to analyze the components present in aqueous systems. So, they decided to try this on five brews: Singha Lager (Thailand); McEwan's Scotch Ale (Scotland); Guinness Extra Stout (Ireland); Schultheiss Berliner Weissebeir (Berlin); and Liefman's Frambozenbier (Belgium). they list a whole bunch of various components which they found in beer, some sample G-S chromatogram for the five brews, and a pretty good description of the brews...

R&D Magazine is one of those 'free-bie' magazines you can get at work...

I hear this a lot, but I've yet to hear a satisfactory explanation.
Exactly why/how do yeast "mutate" or "weaken" over multiple
"generations"? Wouldn't the weaker yeast suffer a competitive
disadvantage with respect to the stronger yeast?

And how do you explain the experience of the yeast-caking guy from
a coupla weeks back -- he was doing ten fermentations from a single
packet of dry yeast.

Subject: DRY VS. LIQUID EXTRACTS.

Recently, there has been a discussion of the merits of dry versus liquid extracts. Several posters say they have switched to dry because it is easier to control and less costly. The control aspect I can understand easily. The price part is what's giving me trouble.

Now, dry extract has 25% more bang per unit weight than liquid, according to a chart posted in this digest back in December, 1988. The chart listed the sg of fermentables given as a rating for one pound in one gallon of water. Dry malt extract was listed as having an sg of 45, and syrup as 36.

That is indeed a 25% increase for the dry. Problem is, I can't find dry extract for the same price as liquid, or for even only 25% more.

I checked my twenty odd catalogs and found liquid extract for as low as \$1.15 per pound, but could not find dry extract (in bulk) for less than \$2.05 per pound.

Maybe I have the wrong catalogs????

Subject: Water Conservation

As I was brewing yesterday, I began to contemplate the water rationing that has been imposed on many drought stricken California homebrewers. Naturally, my thoughts turned towards conservation, especially while my counterflow wort chiller did its thing.

Does anyone out there have a sense for how much water is required for each gallon of brew produced ? I'm sure it's alot considering sterilization, rinsing, wort production, wort cooling, and cleanup. The amount would probably vary substantially depending on whether you were an extract or all grain brewer. I've read that very efficient commercial breweries (AB etc.) are able to get their water/beer ratio down to 8/1.

Furthermore, what ideas have people come up with for water conservation ?

I've tried cleaning up with the water coming out of my wort chiller. That water is pretty cool, which is an inconvenience, but it can be done.

Suggestions ?

Are you sure about this Jay? I believe that getting "light struck" is
associated with oxidation which is a problem whether or not you have
hops in your beer or not. Or is getting "light struck" associated with
the hop oils? Anyone else care to comment?

Subject: inactive liquid yeast

Trying our hand at liquid yeast for the first time, I may have started the incubation period a day too soon. I suspect this since upon pitching the yeast at a wort chilled to 60 degrees, it has been 36 hours and no "glubs" to be seen or heard yet. What is the recovery(if any) from this situation. Could the yeast be re-activated by taking some of the trub off the bottom of the fermenter(hopefully taking some yeast with it), then boil with some malt, to cool, then re-pitch? Could the initial yeast pitch at a cool 60 degrees caused the then active culture to go dormant. I am trying to stay relaxed, BUT, this was supposed to be our *BEST* batch of brew yet.

The 8:1 figure is mentioned in, among other places, "Malting and Brewing Science" by Hough et al. My experience at Pilsner Urquell was that they are using upwards of 20:1! I, too, live in drought plagued California, and my rough calculations for a batch of beer are in the 6-8:1 neighborhood as well. For example: 15 gallons of beer, 50 gallons of cooling water, 5 gallons lost in the mash, 5 gallons to clean fermenters, 5 gallons to clean kegs: 80 gallons to make 15 -> 5.333. I'm sure I'm missing other miscellaneous losses. Some of the things I do are:

- None of the water is dumped down the drain. Any water I am through with goes into watering the plants.
- I *do* wash my brewing utensils with the outflow from my immersion chiller. In fact, I collect the first 5 gallons, which are pretty hot and wash from there.
- I sterilize wherever possible with boiling water rather than bleach. Boiling water doesn't need several rinses. And the rinse water can go back into the pot and be used to sanitize more equipment.

> the hop oils? Anyone else care to comment?

Light struck is defect noticeable by a skunky or catty aroma. This is
brought on by a transformation in one of the hop constituents under the
influence of green light. This compound is converted into a mercaptan,
one of a class of extremely aromatic compounds. (Natural gas is
odorized with a mercaptan, at about 5 ppb.)

Oxidation is the trademark of an old or mishandled beer. There are
many components of beer that will react with free oxygen. The results
can include winy and sherry notes in the aroma and flavor, or a wet
cardboard taste at the back of the mouth. Cooled bitter wort is
aerated to include O2 for yeast growth, but after that point O2 should
be prevented from contact with beer. Racking and bottling are
especially troubling times for homebrewers in this respect, and this is
why judges are wary of beers with large headspaces (this isn't always
an indicator of an oxidized beer; I've just been playing with my new
counter pressure bottle filler and I got a number of bottles about
2/3rds full, but covered with CO2). It is impossible to keep oxygen
out entirely, but the less available, the longer the shelf life.

>Exactly why/how do yeast "mutate" or "weaken" over multiple
>"generations"? Wouldn't the weaker yeast suffer a competitive
>disadvantage with respect to the stronger yeast?
>

I'll take a shot at this one.

There are two reasons for not repitching forever: contamination,
and what is incorrectly called the "petit mutation".

The first is clear: whenever the beer contacts air or anything
else, there is the chance that another organism could be introduced.
While the population of that organism may not be large enough to make
a significant difference in any given batch, it's likely to grow
over time, or be snuffed altogether by the yeast colony. All
breweries have problems of this sort, sooner or later.

The other is a little less obvious. Yeast pitched in the fermentor
first go through an aerobic phase, where they use the dissolved
oxygen in the wort, through respiration, to grow and multiply. In
any colony, some of the yeast will be respiratory-deficient, and
will not reproduce as rapidly. Commercial yeast production is
conducted in aerated media to maximize the reproduction rate, and
naturally, the effect of this is to give a significant "edge" to the
yeast that can most effectively reproduce in an aerobic environment.

If an agar/wort plate is thinly streaked with a yeast culture
growing in liquid media, some of the resulting cultures will grow
faster than others, even if the original culture was a pure
single-cell culture, and even if the resulting plate cultures are
also single-cell cultures. The smaller ones are the
respiratory-deficient strain, called "petit" by Pasteur. These will
not be at the same disadvantage in a culture that is repeatedly
repitched and therefore spends most of its life in an anaerobic
environment, and over time will become a larger fraction of the
total population. While this behavior may have begun as a mutation,
its effect on the overall action of the culture is natural selection
in action. What you'll notice is successively longer lag times, and
slower starts once it does begin to move.

>And how do you explain the experience of the yeast-caking guy from
>a coupla weeks back -- he was doing ten fermentations from a single
>packet of dry yeast.

...And he was keeping the whole volume of the yeast, so his
pitching rate became successively higher. That helps a lot.

Subject: How to make a sweet mead.

Kent Reinhard asked about making sweet mead.

Three ways spring to mind:

1. Drink it before it's all fermented out
(fizzy and yeasty)(not to be drunk
at the same time as 151, oooo...bad juju)
2. Stop the yeast before it's done, Camden tablets or
refrigeration can do the trick
(fizzy, not so yeasty)
3. Put in so much honey that there will be sugars
left over when the yeast stops because of
the alcohol. Three or more pounds per gallon
(still and sweet, A couple years of aging can
really improve such a mead)

Subject: Multiple yeast strains (question)

Not that I've read everything about brewing, but, nothing I've read says anything about using more than one kind of yeast at a time. How about, say, an ale yeast with a champagne yeast? I would expect the ale yeast to make fairly short work of most of the sugars and poop out, whereupon the champagne yeast would be free to continue and take the alcohol content way beyond what the ale yeast was capable of. Is anything like this done? Or would something bad happen?

From: T2R@ecl.psu.edu
Subject: Water conserving wort chillers

On water conservation when chilling brew, it can be done. When rinsing out stuff during the latter half of my brew (after sparge) I collect the rinse water into a 5-gal. plastic jug. (rather than dump it down the drain) I then run this in combination with a gallon or two of ice through a immersion chiller to chill the brew. I use a gravity feed setup. A large bucket with a spigot is placed one to two feet above the wort, a rubber hose connects this to a copper coil in the brew. Another hose goes from the coil to a collection bucket two feet below the wort. About half way through the chill, the water in the lower bucket is dumped back into the top bucket and more ice is added. This setup cools the wort to around 75'F in about 25 minutes.

From: BAUGHMANKR@CONRAD.APPSTATE.EDU
Subject: Repitching yeast with BrewCap

Another wrinkle in the repitching of yeast discussion is using a BrewCap. After draining about a cup of yeast, you'll be into the clean white barm that is excellent for repitching. Sterilize the valve carefully, park your new batch of beer close by and drain a quarter cup of barm directly into the fermenter. No muss. No fuss. No culturing.

> MC2331S@ACAD.DRAKE.EDU

Now wait a second here. Is this the same Florian that contributes to this
journal? Is Florian the Dreamer also Florian the Holy?? I dunno -- the
guy
always struck me as some kind of troublemaker...

On to my question of the day. I've been having problems getting my
carbonation consistent from batch to batch. Thanks to Pete Soper's advice
I'm no longer plagued with variations from bottle to bottle within a
batch,
but I'm still getting wide variations in carbonation from one batch to
the
next. How wide, you ask?

Well, right now I'm working on an English bitter and a porter. The bitter
is **very** strongly carbonated. Way too much for the style, and for my
taste. This was primed with 3/4 cup of corn sugar in a 5 gallon batch. I
used Wyeast London Ale yeast. The porter is absolutely flat. This was
primed with 1/2 cup of corn sugar in a 5 gallon batch, and used Wyeast
Irish Ale yeast. Both batches have been in the bottle for more than four
weeks. There are no signs of infection, and both are clear. The bitter is
crystal clear, and the porter is as clear as any porter I've ever seen.

Both batches were allowed to ferment out completely in the secondary tank
before bottling. My priming technique is to make a syrup of corn sugar in
about 1 pint of boiling water. I put the syrup in the bottom of my 7
gallon
carboy and siphon the beer out of the secondary (into the 7 gallon carboy
with the priming syrup, of course). I then stir for a full minute with
the
racking tube, and proceed with bottling. I use no fining agents other
than
a bit of Irish Moss at the end of the boil -- nothing that might strip
yeast out of suspension in the secondary.

I think Jay's correct. My (somewhat foggy) recollection is that "light struck" beer is the result of a photochemical reaction in some component of the hops.

From: rransom@bchml1.aclcb.purdue.edu (FATHER BARLEYWINE)
Subject: Mutants, slurries, and Yeastoids

There has been a lot of discussion recently about reusing yeast. Several contributors have suggested bottling the cake from the bottom of the fermenter and using this material to pitch the next beer.

My suggestion (HB Digest #600) is to put the next beer directly onto the old cake. This eliminates several problems with storing the yeast: there is little chance of contamination, little oxygen is introduced, and exploding bottles are avoided. The main question to be addressed is about

"mutants", however.

The yeast you buy in pure form from commercial distributors is always a distribution of various different yeast isolates, and even within a theoretical "pure" race of yeast there is individual variation. When you brew beer, you are passing the yeast through many generations of growth under

a specific set of conditions which vary through the course of the fermentation.

The composition of the yeast changes as various isolates grow and die back as

conditions change; some isolates will prefer aerobic conditions, some anaerobic, some high sugar, some low, etc. If you were able to isolate and

analyze the various different isolates present in your brew as fermentation

progresses you would see different distributions over time.

By reusing yeast cakes you are effectively breeding for a yeast population that likes the conditions under which you brew. You will gradually

eliminate populations that like conditions you never expose your yeast to, and

vice versa. This is why I think it important to avoid culturing yeast under

odd conditions (like bottles in the refrigerator, slants, etc) because you

may eliminate isolates to the detriment of the resulting brews.

This point is especially important when culturing out of commercially distributed bottles. Commercial brewers often use different strains for various stages of their fermentations, and in the case of the Belgian beers

sometimes brew the initial stages with yeast and the later stages with yeasts

and bacteria, or with wild yeasts. When you pull out the culture from the

bottle, you are seeing the final yeast distribution (at best), and may also

have the other organisms that are only used in the final stages of the brewing.

Distribution also affects the yeasts, since the bottles usually are subjected to a variety of unpleasant conditions (temperature changes, light,

agitation) which will affect the dormant yeast cells. I find culturing out

of bottles (whether commercial or my own) to be unsatisfactory because the

conditions in the bottle are very different from the fermenter.

Think of the yeasts as little people, eating and excreting into your

brew (okay, maybe you shouldn't think of them as people). As time goes
by and
zoning laws change, unpleasant neighbors move in, city sanitation
facilities
degrade, and grocery stores close up, the people that thrive in adversity
take over and the nice ones hibernate (how about bears? hmmm, bear
excreta
does bring up nasty images). Putting the entire city in the refrigerator
or
into a pressurized container is bound to affect the inhabitants. Be
gentle,
and try not to think of bear shit when pounding back your next homebrew.

>the hop oils? Anyone else care to comment?

>Al.

I'd have to agree with Jay. Light struck requires hops, and is a completely

different spoilage mechanism than oxidation.

Oxidation is typically the result of getting too much air into your wort/beer at the wrong stage in processing. Its taste is described as "cardboardy".

Light struck occurs when light at ~520 nm (green) strikes the beer and causes

certain chemical changes to take place. This reaction requires hop compounds

as a precursor. It results in the formation of mercaptans, and its taste is

described as "skunky". Appropriately, mercaptans are the active ingredient in

a skunk's odor!!

However, hop resins are known to inhibit the growth of many bacteria, fungi

etc., which is certainly desirable in a yeast starter. I prefer to add hops

to my starters, and avoid the light struck problem by storing them in the dark. (Insert IMHO's and smiley faces wherever appropriate.)

Subject: Diggin' in the archives.

Well, I'm still digging into the Homebrew Digest archives and learning a helluva lot.

I went back as far as the archives did, to November 1988, and started reading forward.

The file for January, 1989 seems to be missing part of digest 62 and all of digest 63. February begins with 64 and Jan ends in the middle of 62. I know this is a longshot, but could someone send those two ancient ones to me?

Again, I'm looking for digest numbers 62 and 63, both at the end of January, 1989. I know I'll probably get several copies of both, but that's a lot better than not having them, especially since 62 ended right in the middle of a discussion on water treatment that I was very interested in.

Thanks in advance to any who respond.

Subject: Lambic cravings

NEW ENGLAND vacation notes=====

First, thanks to all who posted me info on New England breweries several weeks

ago. In no order of preference, I can recommend the following:

Northampton Brewery's current canine ale. Old Brown Dog with a white pizza

was fantastic. Alas, the atmosphere is NOT comfortable enough. The air was more 'dinner and a beer' than 'brewpub with good food.'

Catamount's grand reopening tour (they are in open house phase after building

on additional facilities. Strangely, as I came into White River Jct., I took every turn needed to make the shortest path to the brewery (without a

guide or map)! As jumbled as the town's layout is, I was amazed and made sure to drink an extra sampler glass as an offering to the Beer God (esse)s.

Vermont Pub was only a short mid-day stop, but the Dogbite Bitter was a

fine ale, with all the astringency it's name suggests. I was in Burlington

to see grad schools, and between the campus's look and this brewery, I think there are few better places to be stranded for a few years.

The Yankee Brew News (in vino veritas, in cervesio felicias): in a phrase,

"So this is what living in an active brewing community would be like."

Again, thanks to Tom Fawcett, Chris Brown, Mark Gryska (and the Valley Fermenter

meeting invite), and Pete Davis.

LAMBIC RECIPES AND TIPS WANTED=====

Now, I was intro'd to Lambic's while in New England, and I simply MUST know

more!!! Since my only clues so far include 'wild Belgian yeasts and bacteria' I

suspect I cannot make my own. I'll name my twelfthborn (no guarantee of progeny

implied) after anyone who teaches me otherwise. Do fruit ales and such come

close enough to these in taste? What might? Do they have the same aging times

as mead (and if so, can someone who drinks mead compare the quality of the 'net

sensory overload', since my first batch of mead is waiting to be started) ?

CHAUCER MEAD?=====

A last note: while staggering around MA, VT, NH, and NY, I found myself running

into repeated mention of 'Chaucer Mead.' EVERYONE 'used to stock it' (except

for two who used to stock something else they couldn't remember a name for),

nearly everyone was 'going to restock some' and expected it to be available in

several weeks, and one genius in Amherst insisted that it was probably not legal

in MA due to international trade restrictions and/or alcohol content
(thus sim-
ultaneously comparing mead with certain wines and Everclear). Needless
to say
I am confused, and appeal to your worthy opinions for clarification.

Subject: Coriander & orange Beer, Sweet mead, Light Struck

Bill Murphy of the Boston Wort Processors recently won 1st in the fruit beer category at the Westport competition (and was one of the difficult to eliminate contenders for best of show) with an Orange & Coriander Beer. I will try to get his recipe (perhaps Mike Fertsch the Worts Newsletters Editor has it online already??) and post it here. It was a really nice beer.

To make a sweet mead you need to use a less attenuative yeast or to go with a higher starting gravity, or do both. Try ale yeasts instead of Champagne yeast (though I've heard Red Star California Champagne or Flor Sherry are less attenuative than Pastuer Champagne). A technique I used to get a medium sweet draft cider was to fortify with Cane and Brown sugars as well as some malt extract (1/2lb, 1/4lb, 1lb respectively in 1.5 gallon h2O) and use an ale yeast to ferment. This produced a nice result with 3.5 gallons of Apple cider. I suspect that making a must with say 2-3lb honey per gallon of water and the same 1.5 gallon water with similar added sugar or malt extract mixture might achieve the same effect. I would recommend continuing use of the sugar/malt extract or sugar only method since honey contains a complex range of sugars and is known to take longer to ferment for this reason, while the "fortification" sugars are simpler, will probably ferment first, and thus will bring the alcohol content closer to the yeasts exhaustion level. Then when the yeast subsequently consumes the honey to raise the alcohol level past its threshold the residual sweetness that remains will be mostly that of honey. This should give more of the "mead" flavor and honey sweetness I think you may be looking for. All this sounds nice in theory, but I can't swear from experience that it works. However it seems like a reasonable approach so perhaps you can try it and report to us on it.

One more plug for the two mail order places owned by friends of mine (nice people who premise their operations on fair prices and satisfied customers)

Modern Brewer, Cambridge Mass. 1-800-SEND-ALE
Hennessey Homebrew, Troy, NY 1-800-HOBREWS

One more time Al, skunkiness and oxidation are 2 entirely different things
1) Skunkiness occurs as a result of light breaking a chemical bond in the acids extracted

from hops during the boil. The resulting chemicals that arise from the breaking of the bond are chemically similar to the compound sprayed by skunks. They have the same aroma hence the term skunkiness for the phenomena of light struck

2) oxidation however results from the introduction of oxygen into the beer. This can occur in two places

a) introduction of oxygen into *HOT* wort as apposed to chilled wort. This

promotes the creation of phenolic and other off aromas and flavors.

According to George Fix

this process occurs very rapidly in hot wort. However introduction of oxygen into chilled

wort promotes yeast growth without engendering these chemical reactions

b) Introduction of oxygen into the beer after fermentation. This will lead to the

corruption of the aroma and flavor typically described as cardboardy or stale. Check the

Zymurgy troubleshooters issue for specific chemical compounds effects involved with this.

From experience I can tell you that unhopped extract in a clear glass starter container

left on my kitchen counter (not directly in sunlight but very near direct sunlight) has

never shown any signs of light damage (as evidence by skunky aromas) either in the starter

or the finished beer. If it makes you feel better though simply cover your container or get

one of those dark brown 1 gallon photography style jugs (Modern Brewer sells them for

\$2.50). I reiterate I have never experienced any problems and to the best of my knowledge

know of no correlation between light damage and beer other than that which exists for the

above cited reactions of hop oils.

I am unable to explain the mechanisms whereby yeast mutate, since I am not a yeast scientist. The symptoms of degeneration include lack of or slowed activity, turbidity, and off-flavors. I have noticed all three of these.

I am unable to explain the experience of the person you refer to since I didn't do the research he/she did. It is quite possible that since dry yeast was used, the additional off flavors, turbidity, and slow activity may have been masked by the natural tendency of dry yeast to exhibit these symptoms in any case. That is my experience, too.

The subject of yeast degeneration has been discussed in several references. Please refer to:

From: cjh@vallance.HQ.Ileaf.COM (Chip Hitchcock)
Subject: light strikes

wrt Algis Korzonas's questions about the relative effects of oxygen and light:

"light-struck" beer is beer in which some of the hop oil molecules have been broken (rearranged??), usually by the effect of light around 520nm. The result is an odor similar to skunk (slightly less pungent, but just as unpleasant). We were shown this at the recent Dr. Beer session; bottles of Molson's from the same suitcase, half of them left in a window for 2 days and the other half kept in the dark. The smell was so bad when the test bottles were opened that most of us refused to taste them.

This has nothing to do with the presence or absence of oxygen, which (I understand) tends to produce harsh tastes (not necessarily as much smell) if introduced //when the wort is warm//. (I expect that light damage could happen even at low temperatures, since the energy is being applied directly to the bond.)

From: Jay.Littlepage@Corp.Sun.COM (Jay Littlepage)
Subject: Re: Water Conservation

The drought is the basic reason why I haven't invested in a wort chiller. After all the reports of quality improvement due to eliminating trub via cold break i've been thinking about ways to get a cold break without wasting water.

An immersion chiller that recirculates water from an ice bath would work, but at this point I don't want to invest in the chiller materials and pump that would be required.

In my last batch I poured the wort on to three half-gallon ice cubes made from milk cartons. I let the ice melt (5 min) and then drained to a carboy. I was able to pitch immediately. In my next batch i'm going to make one gallon ice cubes by microwaving a freezer-bag full of water then freezing. It should be more sanitary and work pretty well.

From: polstra!norm@uunet.UU.NET (Norm Hardy)
Subject: Yeast slurries

Two respected brewers have both commented that getting yeast slurries from the SECONDARY fermenter is highly desirable. George Fix of AHA fame and Ed Tringali of the Big Time Brewery in Seattle (3 gold medals at the GABF).

With that as a clue, I have set up a scheme whereas I bottle the ale on Saturday, save the yeast slurry from the secondary, and then brew the next day. After 30 minutes of boiling (before hops are added), I remove 8 to 12 ounces of wort, cool it, and pour it into the yeast slurry that has been sitting at 65f with an airlock on top of the bottle. This feeding of the yeast usually results in a quick startup of less than 12 hours; often much less than that. Oh, there is usually around a cup of slurry collected.

How long will this work? Who knows; to be safe I wouldn't push it past 2 repitching unless the beers are quite good.

With lagers I have to wait a week to allow a proper buildup of yeast before repitching. Then I have to resort to an extract starter ala Papazian. Works just fine. so far....

Subject: saving water

In HD 608, CR Saikley asks how other brewers save water.

I'm not the most conservative of brewers, but I manage to squeak under my daily allotment of 50 gallons, and I brew almost weekly.

I save all water that runs through equipment to rinse it, like through the wort-chiller before and after brewing, and I save all chlorinated water that either sits in equipment or runs through it to sanitize it. I save the former in whatever steel vessels are around, and I save the latter in plastic.

I don't re-use this water in the brewery. I lug it upstairs five gallons at a time and use it to flush the toilet. If I don't have any company over, one brew's waste water lasts a week. (If I am expecting company, I flush the toilet in advance, in the normal, wonderfully effective, well-designed way.)

I feel good about how much water I save by almost never flushing the toilet. However, I'm convinced that if God had intended toilets to not be flushed, she wouldn't have given them little handles, and I can't wait to get back to normal water availability here.

Subject: Air on bottling

I have yet to bottle my first batch, but maybe I have a suggestion for those who are having problems with air in their bottles.

I took a homebrew course, and the instructor said that when you bottle, bang the bottle on the table then immediately cap. When the beer foams up--it will remove the oxygen and the cap will keep it out.

Anyone have any experience with this?

From: smc@styx.desktalk.com (Steven M Cohn)
Subject: Re: Homebrew Digest #609 (April 03, 1991)

The definitive Guide to Nitrogen Compounds:

N2 - Diatomic Nitrogen: Colorless, odorless, almost inert
NO - Nitric Oxide: A colorless, poisonous intermediate in the production
of nitric acid (HNO3)
N2O - Nitrous Oxide: Laughing Gas
NO2 - Nitrogen Dioxide: Poisonous brown gas found in smog.

Of these, I suspect that N2 is probably the one that Guinness uses,
although,
N2O is an interesting idea. . .It does come in the same kind of
cannister.
It's been a while since I took Chem, anybody know anything about the
reactivity of N2O with beer? I thought I remembered it being a fairly
stable
compound, but that was many homebrews ago. . .

Steve

Subject: saving water

I too was shocked at the amount of water wasted in using an immersion wort chiller. What I do is put the coil (20 ft. 3/8" id copper) into a sink of ice water, set the hot wort on the counter next to the sink, and my primary on a chair in front of the counter, and siphon the wort through *slowly* . You can adjust the rate of flow by moving the exit tube up or down. It takes a lot of ice. I freeze milk cartons and plastic ice cream buckets full (or if I forget, I run to the MiniMart and buy some during the boil) and it always melts amazingly quickly. It takes about 20-30 minutes to chill a 5 gallon batch down to 60-70 degrees. When you are done, you have a sink full of warm water to clean up with.

From: Dan Needham <dann@hpsadlb.hp.com>
Subject: Carbonation in kegs
Full-Name: Dan Needham

I recently kegged up a batch of wheat beer in my new draft system. I followed a chart of CO2 PSI vs. Temp for different volumes of CO2 for different styles of beer. At 42 degrees F. I used 17.5 PSI to (hopefully) yield about 2.9 Volumes of CO2 in the beer. I rocked the keg around for a few minutes while the CO2 was being applied through the down-tube via a beverage fitting. Four days later when I tapped the keg it was nearly flat! I don't think the keg leaks -- I bought it new, and tested it for pressure retention before I put beer in it. There was extremely little head space in the full keg. It was stored at about 40 degrees F. on its side during the four days.

Would any keg veterans like to comment on this? Suggestions as to what might have happened or proven processes that you use would be appreciated.

The beer was quite good even with the low carbonation ;-)

From: burghart@stout.atd.ucar.EDU
Subject: stuck barleywine

My partners and I brewed a barleywine recently (O.G. ~1.075), starting it with a packet of Whitbread ale yeast. We allowed the ale yeast to go as far as it would willingly go, and racked to a secondary (@ ~1.035). The beer tasted great at this point, though still quite sweet. We pitched a packet of Red Star champagne yeast to ferment it further, and nothing happened. We have aerated, added yeast nutrient, pitched another packet of champagne yeast (started this time), aerated some more, but none of these has made the beer go any further. The recipe is based on Wayne Allen's recently posted Marigold Ale, with 10 lbs. M&F light extract and 2 lbs. honey, and our carboy is in a 65-70 deg. F room. Any ideas out there on how to get our fermentation to continue?

Thanks in advance,

Subject: second greater sacramento area hombrew fest

WHAT: Second Greater Sacramento Area Bi-Annual Home Brew Fest

WHEN: Saturday, April 13th

TIME: 8 p.m.

WHERE: Robert Nielsen's place
8005 Dana Butte Way
Citrus Heights
(near Sunrise Mall)

We had so much fun last October, that we're going to do it all over again! There were six brewers, with a couple different beer types each. It was interesting to taste a variety of beers made by a variety of brewers!

So, if you live anywhere near Sacramento California, come on over, and bring a beer of your choice. I want to hold it to two beers, cause last time we had many more choices to sample than we could handle. We tried though :-)

Be careful if you want to bring a brown ale though. Last time I think everybody brought a Brown Ale! Especially the R+R Brown Ale kit :-)

I'll be providing munchies that go together good with beer.

Please RSVP so I can make sure to get directions distributed.

Robert

From: Chris Brown <CBO@CORNELL.CIT.CORNELL.EDU>
Subject: Dinner With Michael Jackson

As a neophyte home brewer and relative newcomer to this discussion group, I was fortunate enough to meet another net.homebrewer in the Ithaca area. He quickly invited me to join the Ithaca Homebrew Club and I enthusiastically accepted. Well if timing is everything, I would seem to have a lot going for me. Micheal Jackson was coincidentally invited to speak at Cornell and host the first club meeting I was to attend.

The club took Mr. Jackson out to dinner before the meeting. The restaurant that was selected was the Coyote Loco. Naive me, I never made the connection that it was a Mexican restaurant. Imagine meeting a British brew expert, drinking American homebrew, and eating Mexican food.

I arrived a bit early. I had yet to meet any of the club members (even the one who introduced me to the club, since we had only spoken over the computer). I stood near the bar patiently with my hands in my pockets. I didn't know exactly what to expect when Mr. Jackson would be brought in.

Although he's not exactly a household name (well...), I still expected him

to be surrounded by people asking questions and competing for attention. Rather, he was led in and stood near the bar directly next to me. The two

of us were essentially equally alone. I quickly introduced myself, and then proceeded to stand there unable to think of anything to say. I hadn't

really prepared anything because I assumed I wouldn't have much of a chance

in Hell to talk to him at all.

Gradually the club members turned and introduced themselves and began to

chat. Until then I didn't know which were brewers and which were just customers. I soon realized that I was the only one besides Mr. Jackson who was wearing a tie. Jeans and T-shirts seemed to be the standard dress.

I was immediately struck by the casual attitude of the whole affair. One

of the brewers asked Mr. Jackson about the popularity of cider in England.

He responded that since it is taxed differently from beer and hence much less expensive that it was primarily popular among the younger crowd who "just want to get shit-faced". I knew right then and there that all formalities and decorum were right out the window.

There were around 15 people in attendance. The restaurant had two tables

set up to seat us all. When it came time to sit I nabbed a corner seat as

I'm left handed and didn't want to compete for elbow space. Much to my surprise, Mr. Jackson got seated right next to me. I was still having trouble thinking of things to say. As a two-batch homebrewer I couldn't come up with any questions that wouldn't have been analogous to asking Bobby Fisher how a rook moves. To be honest I was quite content to just sit there and listen to the conversation.

Before the waiter came around, some of the other brewers at the table opened bottles of their brew for him to try. He tried each in turn, but made the honest observation that sipping beer between bites of nachos and salsa wasn't the most professional way to adjudicate the flavors.

One of the brewers at the table asked him how he got his start in this rather unique field. He said that he was first a newspaper journalist, and that he kept trying to work beer into his pieces simply because he really liked beer. One thing led to another and here he is. They asked him for some previews on his piece on the Baltic Breweries, but he simply said that his memory wouldn't be able to do justice to his writing and that we should just be patient and wait for the rest of the article to come out.

Mr. Jackson remained at our table through the salad course, but when the main dish arrived he moved to the other table so that others could share his company. If first impressions say anything, his would say that he's an unpretentious, unassuming kind man who simply enjoys good beer and the company of good people. You would think him more a rather quiet, portly pub-goer than the world renown expert that he is. All in all, though this wound up being a rather unspectacular event, it is a memory that I will cherish the rest of my life.

Subject: using maize in recipes

I've been drinking my first batch of beer. It's a bit thin and the head doesn't last long, though it is well carbonated. I think I can solve this problem by adding flaked maize to the original recipe. Is this correct?

Given the correctness of the first assumption, I'd like to get some guidelines on the use of flaked maize, if possible. My first brew used a can of M+F unhopped light and a can of M+F unhopped dark, 2 oz. Cascade Loose and Red Star Ale Yeast in a 5 gal. batch. The beer was primed with 1.2 oz corn sugar per gallon and bottled in Grolsch bottles. How much flaked maize would I add to this recipe and would I add it to the boiling wort and when would I add it to the wort, etc.?

Many thanks. This brewer's network has been invaluable for yet another beginning homebrewer.

"...well, I'm done in the lab for another night... Think I'll go home, relax and have a homebrew 8~) 8~)..."

Subject: re: National Homebrew Day

Mark Castleman asks:

> Does anybody know whether is is a coincidence that National Homebrew
> Day is the same day (May 4) as the feast of St. Florian (one of the
many patronsof brewers)?

I guess coincidence, but let's try to find out / figure out. National
Homebrew Day should be the first Saturday in May. Does the feast of St.
Florian have a fixed day-in-month, or is it also a first-Saturday? I dug
back into the old Zymurgy--the first mention I see of National Homebrew
Day
is in the second issue, where it's the day of the first National Homebrew
competition, May 5, 1979. So my naive guess is that Charlie picked a
weekend spring day that was likely to be nice for a festival, and
christened it.

(Why didn't we learn important stuff like this in history class?:-)

> total population.

This doesn't seem to make sense biologically. I can see that repitching might not select for respiration /as/ /much/ /as/ true aerobic reculturing.

However, the respiratory phase is where most reproduction happens; this would suggest that if you pitch a packet/starter/culture/slurry with a certain R/r ratio (where R is normal and r is respiratory-deficient), the slurry at the end of fermentation would have a higher R/r ratio unless so much yeast was pitched that there was no respiratory phase. The amount of time in the anaerobic phase shouldn't matter, since very little reproduction happens then (natural selection only works if the survivors reproduce). Even if r were more attenuative, that should simply mean that R

would go dormant first---you might get different ratios in different layers

but most of the recommendations seem to start with stirring up all the sediment and saving some of the resulting slurry.

As a tangent to this, I'd note the opinion/experience of several Wort Processors that single-cell cultures tend not to be as attenuative as their

sources until they've gone through a couple of repitchings---suggesting a positive correlation between respiration and attenuation?

From: lee@raj2.tn.cornell.edu (Hasung Lee)
Subject: generations of yeast

I have been a sourdough bread maker for seven years now. Recently my husband Joe returned from duty at NATO in Brussels where he acquired a taste for Belgian Lambics. He recently took up homebrewing to reproduce the taste he couldn't find in America. Initially he tried using different yeasts, however, he was unable to achieve that authentic Lambic "bite".

Last month a friend from Belgium visited and brought some Chimay beer. Joe cultured the yeast from this bottle and made what was his best Lambic effort to date. BUT he was still not satisfied with the results.

On the advice of our local brew supplier, who explained the open fermentation vats found in Belgium, Joe decided to recreate in our house the atmosphere found in Belgium. To do this he took the sediment from a Lambic batch, thinned it with water, put it in a windex bottle, and sprayed it all around our kitchen. After a few days for incubation in the kitchen Joe brewed another Lambic which he let cool overnight in an open bucket. The resulting beer was exquisite.

Unfortunately, my subsequent efforts at baking sourdough bread have proved disastrous. I no longer can make anything that tastes remotely like the award winning bread I used to bake.

This has put a tremendous strain on our marriage as a result. While my husband Joe is ecstatic about his authentic Lambic, I have lost my impetus for pursuing what was once a most rewarding hobby. I mean if he can have his hobby, why can't I have mine.

Does anyone have any suggestions, short of divorce, so that we can return to our normal lifestyle? Perhaps there is a way we can change the atmosphere in the kitchen periodically? Please respond if anyone has any clues as to what we can do.

Fretfully yours.

Sara

How do!

J. Muller asked in Homebrew digest from April 4 about Jamaican Stout and N2O. I don't know about the N2O but if the beer was brought into the country illegally it might have had ganja as an ingredient. I doubt that US Customs would let anyone bring it in legally as ganja (marijuana) is a controlled substance. On many of the caribbean islands they make something called "bush tea" which is tea from the leaves of indigenous plants or bushes. Often it is made from ganja. I would guess that putting it beer would give something to go along with your Alice B. Toklas brownies.

Subject: hallucinogenic Jamaican S

Well gang, I have now brewed my first three batches. All are seemingly healthy and at least one is very tasty (the other two are too young to tell as of yet).

If I may make a suggestion which could conceivably save water, time, and risk of infection:

For my second and third batches I purchased the water from a bottled water

company in Minneapolis (Glenwood Inglewood). It comes in glass 5 gallon carboys for only \$10.55 (deposit for the carboy is \$6) and has three advantages as far as I can see.

- 1) good water
- 2) sanitary as all heck
- 3) cheap carboy

The way we used it was to pour some of the bottled water into the brewkettle

and brew with it with the rest sitting in the carboy (covered for sanitation)

in a cool place. As you can see, there is no rinsing of the fermenter to get rid of chlorine and when the batch is finished, simply return the carboy

to the bottled water company for a refill (for \$4.55). This way you will always have good water (use spring water) and a clean fermenter. Also, there is no problem with keeping the carboys if you wish. I should also make

it clear that you receive a new carboy every time, just like beer returnables.

It really seemed to work well for me and I think I'll do it all the time from now on.

If anyone has any questions, just e-mail me.

Subject: Things to see in Milwaukee

Well, I hardly consider myself an expert on area brewpubs and the like, but since there hasn't been much response to the queries about Milwaukee, I'll give it a shot.

If you visit on a weekend, you owe it to yourself to try to get to the Sprecher Brewing Company. They are a small microbrewery just south of downtown. Their 'tour' consists of a visit to their brewing room, a discussion of their processes, and of course unlimited sampling of their brews (at least until the next group comes through). Their beers are excellent - be sure especially to try their Special Amber, the Milwaukee Weiss, and (yes!) their Root Beer. Call (414) 272-BEER to get the tour times. Their address is 730 West Oregon Street. To find it, head south on Water street from Wisconsin Avenue downtown. After approx. 1.5 miles look for Oregon Street. Turn right and drive west to 730 West - you'll see signs. The brewery is tucked back behind some other buildings.

If you are unable to make it to the brewery, many of Milwaukee's restaurants now have some of their brews on tap. Try Saz's on west State Street (just a few blocks west of the Miller Brewery). Fun place, good ribs, and many good brews on tap.

Though other friends of mine disagree, my advice is to avoid the Water Stree Brewery, a restaurant on north Water street. I have never enjoyed any of their beers - I'm still convinced they were serving a bad batch of stout on St. Patrick's Day, figuring that no one could tell the difference. Yech.

There's a newer microbrewery in town called the Lakefront Brewery. I've never been there, but I've heard good things about their beers and their tours, which are on Saturdays at 1:30 and 2:30. They're at 818-A East Chambers, phone is 372-8800. If you have ever ordered brewing supplies from Mark May at The Basement Brewmaster, look him up at the Lakefront, which I guess is his day job.

Another favorite pub is Zur Krone, an old German tavern at 839 south 2nd street. If you only have a short time to visit, and you want to experience a true Milwaukee beer hall, this is a good choice. Not the place to go for ferns, food, or elegant atmosphere. They have a huge selection of bottled and tap beers.

And of course there are the the huge lawnmower beer factories in town. Miller and Pabst run tours throughout the week (see how to make Genuine Draft Light!). They can be fun just to see the sheer size of their operations, and learn a lot of brewing history. A great Saturday can be had by hitting a mid-afternoon Miller tour, then sit and listen to the live music in their outdoor beer garden before wandering over to County Stadium to catch a Brewers' game. Makes drinking the beer worthwhile.

So here at least is a weekend's worth of beer-related tourism. I'd love to hear about any other favorite haunts of the locals, since I'm still relatively new to the area.

Tom

Subject: Water Conservation

I don't post often to this discussion, but really enjoy the topics. After reading all of the Water discussions, I realized that I might actually be doing something right and semi-unique. I am an all grain brewer, currently brewing six gallon batches of wort. The largest water saving area, IMHO, is the cooling phase. I saw a design for an immersion chiller at the Oakland Beer Conference that really seemed to make sense. The design has two verticle 1/2 inch copper tubes that are 12 inches tall, capped at the bottom and fitted with a 3/8 inch tubing orface at the top of each. The tubes are connected by six 30 inch single coils of 3/8 inch copper tubing silver soldered at 1 inch increments. Cold water enters the top of one verticle and equally distributes itself through the six short coils and exits thru the top of the other verticle pipe, thus increasing the effective cooling surface area many many times over the standard single coil type. Having built this cooler, I found myself with about 20 feet of tubing left over. So, I made a flat coil that will sit in the bottom of a small dutch oven that I have. The night before I brew I place the flat coil in the dutch oven, fill the dutch oven about half full of water, and put it in the freezer. When I get ready to cool the wort, I run the kitchen tap water thru the frozen flat coil into the vertical immersion chiller and out to a 7 gallon carboy. It takes 28 minutes, and between 5-6 gallons to chill the 6 gallon batch to 70 degrees. This is mainly accomplished by constantly monitoring the output temperture (by feel) adjusting the kitchen tap to keep the output just slightly warm. The carboy water is then used to wash a load of clothes, which includes the towels and stuff from brewing. Well, that's the way I do it. Hope it helps someone else..

Subject: carbonating kegs
Full-Name:

Dan Needam writes:

I recently kegged up a batch of wheat beer in my new draft system. I followed a chart of CO2 PSI vs. Temp for different volumes of CO2 for different styles of beer. At 42 degrees F. I used 17.5 PSI to (hopefully) yield about 2.9 Volumes of CO2 in the beer. I rocked the keg around for a few minutes while the CO2 was being applied through the down-tube via a beverage fitting. Four days later when I tapped the keg it was nearly flat!

Dan does this mean that the CO2 was applied for only a few minutes ? If so, there's your problem. Put the CO2 into the gas valve and leave it there. I've never investigated the minimum time required to carbonate, but I've applied gas on Thursday and had fizzy beer on Friday.

Hope this helps

Subject: Re: Repitching

Many thanks to those of you who have participated in this discussion of yeast reuse. I have concluded that pouring fresh cool wort on the dregs of a just-bottled batch is well worth a try. I have a few more questions. I'm brewing on Saturday, and there won't be another HBD before then, so could you cc: your response to me at marc@Virginia.EDU?

According to Martin Lodahl, over time I will breed a respiratory-deficient strain of yeast due to the fact that my population spends most of its time in an anaerobic state. This seems intuitively sensible to me.

Please correct me if I have this wrong, but my impression is that the aerobic phase is mainly useful in order to get the yeast to multiply. In fact, it's really something of a necessary evil, since the yeast produce various unpleasant odors and flavors during this phase. Once in an anaerobic state they absorb the off flavors from the aerobic phase and start making good beer.

So from this I conclude that as long as the pitching rate is very high (as it would be if I use all the yeast from the previous fermentation), I should minimize aeration of the cool wort. Is this the case?

Also, is there any reason to care if my yeast are respiratory-deficient as long as I have a whole bunch of them? Perhaps it's actually desirable that they be adapted to anaerobic activity? What are the long-term (a year or more) effects on a yeast population of protection from oxygen?

Subject: Flaked Maize

Dan Strahs writes:

I've been drinking my first batch of beer. It's a bit thin and the head doesn't last long, though it is well carbonated. I think I can solve this problem by adding flaked maize to the original recipe. Is this correct?

I wouldn't recommend adding flaked maize to a brew at all unless you are willing to mash. Maize has lots of starches, but no enzymes to convert the unfermentable starches to fermentable sugars. You don't want these starches in your beer.

Many commercial breweries add corn to their brews, but not for its body building properties. They add it because it's cheaper than barley, and it imparts less color, flavor and body. The inclusion of corn in the mash allow them to produce a beer that caters to the average American palate. (i.e. thin and watery!)

You'll probably get more satisfying results by adding crystal malt or carapils. One or two pounds can easily be added to a five gallon extract batch. It is best to avoid boiling the grains, as this can result in extraction of undesirable tannins from the husks. One way around this is to simply place the grains in your brew water before heating. Then as you are bringing the water to a boil, remove the grains when the temperature reaches 165-170. This should allow you to get most of the sugars, dextrins, etc. from the grains and leave most of the nasties behind.

Subject: Soda keg fermentation

I wrote the article about soda keg fermentation that is in the 1988 special issue of Zymurgy.

My method requires acquiring some extra keg parts.

- 1 two connector bodies, remove the valves.
- 2 one gas side dip tube.
- 3 one liquid side dip tube, cut to half length.

To ferment more than one beer at a time you need more valveless connector bodies and gas side dip tubes. You can get the extra parts from Foxx or those that sell used kegs have parts from kegs that would not seal.

For the blow off stage of fermentation, fit the keg with the two valveless connector bodies each with a gas side tube. Attach a blow off hose to each connector body, secure with a hose clamp, and place free ends in water. The blow off hoses fit tight over the outside of the connector body. Using two blowoff hoses is in case of clogging in one hose, this may be over kill. If you were to use one blowoff tube, then the other connector body (with valve) could get clogged up from the blowoff.

After blow off is done, replace one valveless connector body with a normal connector body. Place a fermentation lock on the other valveless connector body. A short hose for the connector body and one for the fermentation lock and a reducer are required for this.

The half length liquid tube is used to take hydrometer readings. This avoids any reading problems from trub or yeast at the bottom.

For racking I use a normal length liquid tube. The first cup or so will have sediment so I discard this. I stop racking when the sediment at the end is in the tube (clear plastic). I use two sets of hoses and fittings for this.

This is all done with Firestone pin lock 5 gallon kegs. My fermentation kegs do not have over pressure valves, making one less thing to clean and sanitize around, hence the dual blow off hoses.

Subject: Re: Calculating IBU's

Byron Burch gave me the following values for hop utilization:

Minutes
Boiling
> 45 28-30%
15 to 45 8-12%
< 15 5%

There is an acid reaction at 45 minutes boiling time, that causes the non-linearity of the utilization. He uses hop additions at 60, 30, 15 minutes boiling time.

Also note that cool down time will affect utilization. If you change batch volume, but do not change wort chiller, you will get higher bitterness.

There is also a factor for those of us who boil a partial batch and top up with water, also those brewing beer higher than 1.050.

$GA = (GB - 0.5)/0.2$ if $GB > 1.050$

$GA = 0$ otherwise

GA gravity adjustment
GB gravity of boiling wort
The formula for IBU is divided by $1 + GA$

This is from the 1990 special issue of Zymurgy.

Remember your mileage (utilization) may vary.

From: BMENK@ccr2.bbn.com

There are only two actual brew-pubs I know of in Minneapolis: one is called "Taps" and is located in the Riverplace center across the river from downtown Minneapolis. The other is called "Sherlock's" and is located in one of the western suburbs - Minnetonka as I recall. Sherlock's certainly has the better reputation, (and better food as well). I've only tried one of the beers at Taps, and found it merely adequate. I don't remember what it was called, but it was an average pale ale. They were in some financial difficulty last summer/fall and may have succumbed - I haven't heard.

There are some other brew-related things worth seeing there though. The Summit brewery on University Avenue in St. Paul offers tours and samples if you call ahead. They make a delicious pale ale and a porter, plus some seasonal brews as well.

In New Ulm (about 80 miles southwest of the Twin Cities), Schell's brewery is worth a visit. They make some excellent brews - both under their own name and number of "brewed under license for...." products.

The other small brewer in the state is called Cold Spring and is located in the town of Cold Spring, 15 miles south of St. Cloud. Last I heard they weren't giving tours or samples, but call to be sure. Some of their brews are alright, others have the virtue of being incredibly inexpensive.

>additive.

I have heard this before, but have also heard that you are just
as likely to find dried corn sugar in the dry malt extract as you
are to find liquid corn sugar in the liquid malt extract. Anyone
else with any evidence? The safest bet is to buy from suppliers
who tell you what is in the extract, such as with Yellow Dog.

Personally, I wouldn't brew without some dry malt extract in the
house, because I can use it in any quantity I want, whether for
priming or during the brew.

However, I really like the 6 lb. boil-in bags of extract. Every
so often I order a bunch, typically from Williams Brewing (they
tell you what malt went into the extract). I haven't bought a
can of extract in years (except for Yellow Dog).

I guess there has been plenty of discussion of this already. Let me just add that when I toured the Old Dominion Brewery, I asked about their yeast. He said that they were surprised to find that they hadn't had to stop re-using their yeast yet (at that time they had been brewing weekly for about 6 months). Every week or two they took samples and had them analyzed in a lab.

My only question would be related to the amount of "head space",
or air between the top of the beer and the cap. I leave about
1/4 to 1/8 of an inch between the top of the beer and the cap. I
used to be more haphazard, with about an inch of variation. This
seemed to cause uneven carbonation within a batch (more head
space, less carbonation).

Could the yeast involved make that much of a difference?

I'd like to add that most people also recommend that you crack the
grains first. If you don't have a grain mill you can do this with
a rolling pin. Try not to grind the husks into powder, as that will
result in astringency. (You'll probably get some powder from the
sugary innards of the grains, but that's of no consequence.)

Crystal malt will add color, sweetness, body, and a caramel note.
Cara-pils will add sweetness and body only.

I suggest that you consider steeping the grains at 168 degrees for
15-20 minutes rather than removing them immediately when the water
reaches that point. I have removed them by pouring the whole mess
through a wire mesh colander resting on a big bucket. The grains
end up in the garden, and tea gets poured back into the boiler.

I've not seen any recipes calling for as much as two pounds of
crystal malt. That certainly doesn't mean that they don't exist
and are not wonderfully tasty, but the ones I've seen all call for
a pound or less. Also, cracking two pounds of crystal malt with a
rolling pin will take you a long time -- I have found it to be a
rather tedious job.

Subject: Slow fermentation

In my first batch, I used Red Star Ale yeast. There was a steady increase in seconds per glub, and fermentation was complete in 6 days. My last two batches I used Whitbread Ale yeast. In both cases, fermentation was vigorous within 24 hours (about 1 glub per second), and it steadily slowed to about 1 glub every minute and a half. In both batches, however, it stayed at this rate for about two weeks before reaching a specific gravity low enough for me to bottle. Why is it getting "stuck" at this slow rate? Low yeast population? Or is this typical? All my brews have been partial mashes, all malt, room temperature for fermentation about 65-70 degrees. I think I am aerating the wort sufficiently before pitching the yeast, and I rehydrate the yeast before pitching. My fermentation lock is the S type if this helps in interpreting my glubs per second figures.

Subject: Lanny H's bottled water technique, CO2 techniuqe, Yeast repitching

Lanny (and others following this thread) be sure that those are *GLASS* carboys. If not I would not adopt this technique. Only certain types of plastic are rated for containing alcohol. Other types leach carcinogens in contact with alcohol. I am fairly certain that the plastic bottles used by many bottled water companies these days *ARE NOT* safe for storing alcohol. You should either use only glass, or contact the FDA or BATF to determine which types of plastic are safe for alcohol storage and then investigate as to whether the carboys (if they're plastic) are safe.

I'd sure hate to see someone inadvertently poison themselves with homebrew.

>I recently kegged up a batch of wheat beer in my new draft system.

>later when I tapped the keg it was nearly flat!

Gee that's so scientific. I usually just chill the beer down to 35-40F and hit it with 25-30 lbs CO2 till you hear it stop flowing. Unhook the CO2 shake it up like 40-50 times, toss it back in the fridge. I do this 2 or 3 days in a row, then let it sit in cold store for another 3-10 days (depends on my mood and how low I am on homebrew). Never had a problem this way, no messy charts to consult :-)

CR says> I've never investigated the minimum time required to carbonate, >but I've applied gas on Thursday and had fizzy beer on Friday.

I'd watch out though. I did this once and all my fittings weren't quite sealed (not me, on my kegs) This resulted in leaking away a whole tank of CO2. Remember one thing, we're talking about dissolving a gas into a liquid so rates of dissolution (sp?) apply here. The rate is temperature dependent. My technique puts a higher pressure of CO2 over the beer, one that exceeds the equilibrium pressure at the beer temp, thus the excess CO2 will dissolve into the beer over time. The lower the temp (up to freezing) the higher the rate at

which the gas will get absorbed into the liquid. By hitting the tank up 2
or 3
days in a row I replace the gas that has dissolved (thus lowering the CO2
pressure over the beer) with more gas and re-establish an overpressure.
There
is some practical saturation level at which the beer will cease absorbing
CO2.
The last thing I do before tapping is to yank the pressure release valve
to let
this overpressure off. Then I hit the beer with a normal dispensing
pressure
(say 7-10lbs).

I hope veryone understood that, or at least somebody understood that, I
mean
what the heck it works for me.

Just a not on yeast repitching. Before microbiology came into vogue the
standard technique was to pour the new batch of beer into the fermenters
over
the top of the yeast cake left by the old batch. While from a scientific
standpoint this may not be optimal it obviously worked well for centuries
(either that or the Brits and Germans were drinking cruddy beer until
Louis
Pasteur the Frenchamn came along hmmm.....).

Reply to: More Milwaukee Places
Just south of the airport, next to the Airport Lounge (local Strip Joint) is supposed to be the oldest continuously operating tavern in Milwaukee. I can not remember the name, but you can't miss the place if you find the Lounge next store. Last time I was there (1988) they had about 60 taps. Many imports as well as many micros, including 2 or 3 Sprecher brews (Black Bavarian is my favorite). The atmosphere can get pretty rowdy depending on what night it is. Generally tho, it is a pleasant place to try a variety of brews on most evenings.

If you are like most homebrewers, considering going pro at some point in the future, don't miss Sprecher's. Randy left Pabst (if memory serves) to do his own thing. He built his brewery from recycled equipment and is a very interesting guy to talk with. Beers are excellent also. Lakefront is another "seat of pants" operation. They were not open when I was in town last, but I have read many nice things about the guys behind the place as well as their products.

Hope this helps!

> this done? Or would something bad happen?

I dunno, Carl. Why don't you give it a try, and report back ...

Actually, something like this is frequently done in commercial brewing. The examples that come to mind are Pere Theodore's culture of 5 yeast strains in Chimay, and Whitbread's 3 strains, as described by George Fix in the "Yeast" special issue of Zymurgy ('89?). As I recall, two of those three strains acted pretty much as you describe, one being a rapid starter but getting "stuck" after the simple sugars were gone, and the other being a slow starter but quite attenuative. The role of the third strain seemed to be to flocculate cleanly, taking the other two with it.

This approach wouldn't be easy to translate into strains available at the local homebrew store, though I have read of folks making truly heavy barleywines who pitch an ale yeast first, and then a Champagne yeast a week or so later. The problem with pitching them at the same time is yeast's otherwise desirable trait of "taking over" its environment. Whichever strain established itself first might very well "off" the other strain.

>reproduction happens then (natural selection only works if the survivors
>reproduce).

Father Barleywine said better what I was trying to say. Your
argument is reasonable, but it assumes the only difference between
the two are the effectiveness of their mitochondria. If it were
also true, for example, that the respiratory-deficient isolates
budded more rapidly and survived more budding cycles under anaerobic
conditions than the "normal" strain, the model I presented would
more closely resemble the observed effect.

>Even if r were more attenuative, that should simply mean that R
>would go dormant first---you might get different ratios in different
layers

>but most of the recommendations seem to start with stirring up all the
>sediment and saving some of the resulting slurry.

>From what I've seen, what changes with successive repitching is not
the total attenuation, but the RATE of attenuation for a (roughly)
constant pitching rate, which I assume to be due to a smaller yeast
cell concentration in the early stages of fermentation, due to the
slowed reproduction rate.

> As a tangent to this, I'd note the opinion/experience of several Wort
>Processors that single-cell cultures tend not to be as attenuative as
their

>sources until they've gone through a couple of repitchings---suggesting
a

>positive correlation between respiration and attenuation?

... Or an adaptation to the conditions under which the culture is used. The commercial literature mentions this effect.

Subject: Weizen extract question

I've got a can of the Ireks Weizen extract (6.6 lbs). One set of directions calls for 1 lb of corn sugar (for 5 gal) which, of course, I don't want to add. I also do not want to add any dry malt as it may imbalance the intended amount of wheat to barley. I have a 3.5 gal fermenter and was wondering if anyone thought it would be better to make the smaller amount? Would it end up too strong? Weizens, if I remember correctly, should probably have a starting gravity of 1.032 - 1.035. Am I better off making a 5 gal batch (with no additives) or a 3 gal batch (with no additives)?

Subject: Thanks, Catamount Porter and Carolina Bio.

First, many thanks to all who send me copies of the digests 62 and 63. I got four or five copies, and all were sincerely appreciated.

Second, I picked up a sixer of Catamount Porter yesterday. Had one last evening ... delicious! I am not experienced in many different types of beer, and am learning slowly. Is this a good example of a porter? Is it generally regarded as a good beer? I loved it, but that might be inexperience speaking. The flavor seems rather complex, going through several stages in the mouth. The lingering bitterness is very satisfying.

The store had some Sam Adams Doublebok, but my wallet was empty. Is this good stuff?

Third, I received my catalog from Carolina Biological on Friday. Wow! This is the mother of all catalogs. There is plenty of lab stuff that I am going to order, and a lot of stuff I didn't even know I could get too. My wife wants to spend about a thousand dollars from it. (Maybe I'll send the bill to the person who mentioned it in the first place, [grin]).

The only disadvantage is that culture tubes come in quantities of a hundred odd. I could probably use a dozen or so, but I don't think I'm going to have a hundred different slants. Ah well, at least I can order an organic chemistry modeling set, (otherwise known as organic tinkertoys).

Subject: bottled water

wrt lhoff@acc.stolaf.edu's suggestions

1. Bottled water can vary widely. It usually has less chlorine than tap water, but I'd ask the bottler to be sure. Also, if it really is spring water (instead of municipal water that's been filtered and dechlorinated--

-- an association of municipal waterworks says that's a common stunt) the mineral profile will be different from tap water, so you should get a complete analysis if you're thinking of adding minerals.

2. The prices quoted are rather high. I can get 5 gallons of bottled water at the local supermarket for \$3 (in recyclable plastic containers) ; I

would expect Mpls to be cheaper than Boston, so you're probably paying (in

effect) at least \$2 "rent" on the carboy each time in addition to the \$6 tied up in the deposit. At this rate, \$20-25 for a carboy you own is good if you think you're going to keep brewing for more than a few batches.

Subject: % fermentables

Is there any info. available regarding the percent of fermentable sugar in different types of malt? I never use "recipes", so I don't know what the FG will be beforehand, but I was thinking there may be a way to calculate it.

Let's say you have an OG of 1.100, just to make the math easier, and a type of yeast that will attenuate to 75%. Then you should get a final gravity of 1.025 . But the yeast will really only eat the fermentable sugar. So if, let's say, 80% of the gravity, or 1.080, is fermentable sugar, then the yeast will eat $(.75 * .080) = .060$ of the gravity, which leaves a final SG of 1.040.

So, if you know the attenuativeness (?) of the yeast, the percent of fermentable sugar, and the original gravity, you should be able to calculate the final gravity. The actual % of fermentable sugar is the only missing variable. Any thoughts?

Subject: New Brewery in Buffalo

Howdy all!

Any of you heading to Buffalo sometime? Just in case you are and you get thirsty for good beer, visit the Buffalo Brewing Company in Lackawanna. It's owned by the guy who owns the Buffalo and Rochester Brewpubs, which have been making extract-based beers for a while. The new brewery makes all-grain beers using only German malt. Right now they have their flagship "Buffalo Lager", which is a version of Munich Helles, plus a Pilsner, a Weiss (in the Bavarian Weizen style)

,
and a Bock. All four are really nice, well-made beers, and you can get them at stores in the area or at the brewery, which has a restaurant/bar attached.

To get there, take I-90 to the Lackawanna exit and take Ridge Rd west ~1 mile. At the light for Abbott Rd, make a left (south) and go ~1 1/2 miles. The brewery is on the left, 1830 Abbott Rd, just before the road goes under the viaduct. Awesome beers; well worth the trip. Ask about good Buffalo chicken wings while you're there; why the hell not?

I recommend the Anchor Bar, but have heard that Duff's is great, too.

Enjoy,

STEVE RUSSELL

Subject: Goofy wort chiller / advice?

In trying to get the most efficient chill possible, I rigged up this for a wort chiller, but I have some minor questions to people using this. Sorry if this one has been hashed recently, but I picked up HBD with #574, haven't got around to the archives, and feel I should contribute SOMETHING, dammit!

An immersion chiller should be more efficient with a constant flow of water for heat exchange, plus, I had heard about people doing this. What I did was straighten out about a 20' length of copper tubing, and shove it inside about 23' of garden hose, starting at the end I cut off of the garden hose. Then I cut a hole in the garden hose about four feet down from the connector end of the hose, pushed the end of the copper tube through, and made sure there was about 6" sticking out of the end of the hose and also through the hole I cut. Then I sealed the hole with RTV silicone, and coiled the whole mess back up again. Here is a simplistic diagram:

The concept is, to run the syphon right from a lauter-tun (or strainer in a bucket), through the copper tubing, while running cold water through the garden hose to achieve a REAL fast chill. Also, you can easily regulate the output temperature simply by running more or less tap water through the hose. I just got done inaugurating this device, and here are my observations:

- 1) This thing does NOT need 20' of copper tubing. Maybe an immersion cooler might need that length, but I was barely running the tap water, and getting wort out at ~60F. I would think 8-10' would suffice. I may split mine into two wort chillers.
- 2) My question: Everybody I know who uses a device like this uses a counterflow, that is, cold tap water running in an opposite direction to the wort flow. However, it just made intuitive sense to me to send both in the

same direction: The hottest wort will exchange the heat with the coldest water and some sort of equilibrium will be reached by the time you reach the end of the chiller. Why would the chiller be more effective with counterflow? Which method makes it easier to regulate temperature? Enquiring minds just GOTTA know!

thanks,
-dr.d

Subject: Broken carboy

Last Saturday (the 6th of April), I brewed my first partial grain-mash batch. That was fine, but Sunday night I was bringing up laundry from the basement and checked the carboy with its blowout tube. It was bubbling merrily away. Five minutes later, I came down to get another load of wash and smelled wort. Beer was all over the floor. (Praise Florian and Gamrinus that we have a drainhole in the basement).

There went the rest of my evening, cleaning tub.

Upon inspection, my NEW carboy was cleanly broken, leaving the base as a lip-disk. I had tempered the wort by having two gallons of cold 40-45F H2O in the carboy so the glass would not crack.

Should I assume I just got a bum carboy? Has this happened to any one else?

I do not think this was a pressure problem because blowout was functioning perfectly five minutes before.

Comments?ts?

> // |----- <-- copper tubing
> |-----|-----
> ^-- garden hose
```

This has to be about the best character schematic I've seen :-). For anyone considering this design, another option in lieu of slicing into the hose is to go out and buy one of those Y type hose adapters for each end of the garden hose, so that the copper tubing can come out of one of the ports on the Y. Regardless of the length of copper tubing you use, you'll probably have to adjust the length of the garden hose (there are adapters for this again at any hardware store). Make the cut close to one of the ends, so you can already have the Y screwed into the small piece of hose before joining the hose together. That way, you don't have to keep bending the copper in a circle to screw on the Y. Now, the other advantage of using a Y is that you no longer need to use silicone sealer. Get a hose nipple which has an ID larger than the OD of the copper and which has hose thread, so it will screw onto the end of the Y. Then, a small 3" section of vinyl tubing that fits over the hose nipple. Get successively smaller pieces of vinyl tubing that fit in the big one concentrically until the ID of one matches the OD of your copper. Secure the whole thing with hose clamps and wa-la, you have a seal that would even

hold up to pressure (sometimes there is pressure in my chiller, since I have installed a cooling water control valve at the outlet end).

> 1) This thing does NOT need 20' of copper tubing. Maybe an immersion cooler
> might need that length, but I was barely running the tap water, and getting
> wort out at ~60F. I would think 8-10' would suffice. I may split mine into
> two wort chillers.

While certainly true in some cases, this is NOT a good general rule. The length of tubing needed is greatly dependant on the diameter of the copper being used. I agree that for 1/4" OD copper, 10' is probably a good guess, but I think you'll really have to rush the water through if you go with 3/8" OD. Another variable is the ID of the garden hose. The water flow rate will be either faster or slower depending on this as well. I don't doubt the measured results of the author, but, as they say, mileage may vary, and I've had experience now with two of these chillers. Anyone wanting more detailed descriptions of how I built mine, I can email them to you if you're really interested. There is no "right" way to build one. My comment about diameters and flow rates is based on the fact that your flow will most likely be laminar, with well developed stream-lines. When this is the case, the wort near the edge of the copper tubing will lose heat quickly, but it must carry heat from the center streamlines outward, which is not an instantaneous process in laminar flow. Same goes for the cooling water. And as far as 1/4" tubing, anyone thinking about it...think hard, because you may run into very long cool times.

> 2) My question: Everybody I know who uses a device like this uses a counterflow, that is, cold tap water running in an opposite direction to the wort flow. However, it just made intuitive sense to me to send both in the same direction: The hottest wort will exchange the heat with the coldest water
> and some sort of equilibrium will be reached by the time you reach the end of the chiller. Why would the chiller be more effective with counterflow?
> Which method makes it easier to regulate temperature? Enquiring minds just
> GOTTA know!

If your outlet wort was at 60F, and you were using a mere trickle of cooling water flow, your water must have been quite cold. If you used parallel flow, both in the same direction, then the cooling water cannot have exited at a

temperature above that of the wort, that is, as soon as the wort and water come to the same temperature, the wort can be cooled no further. Unless you have a very fast flow rate, with such a system, the wort can never reach the temperature of the water coming out of the tap. However, with counter-flow, the outlet wort is in "contact" with water at tap temperature, allowing the wort to reach that temperature (again, depending on lengths, rates, etc)

Again, I am not trying to flame the original author as I'm sure what he/she measured is fact, but building one of these things is nothing to be totally blase' about. You can end up wasting a bit of money with a failed attempt... I know :-). There are a lot of variables to think about.

Subject: Airlock contents

I read about using vodka in airlocks and it has more to do with the fermenting wort bubbling up through the lock and getting contaminated then with bacteria making their way down through the lock. Also with a plastic sealed primary the airlock water can be sucked into the fermenter if you lift it to move it. Perhaps it better to add a little vodka to the beer then some bacterial unknown.

Mark Roleau writes:

> I've not seen any recipes calling for as much as two pounds of
> crystal malt. That certainly doesn't mean that they don't exist
> and are not wonderfully tasty, but the ones I've seen all call for
> a pound or less.

I tasted a beer that a friend of mine made a while back, an extract/
grain
beer. It was delicious. It tasted much more like the ordinary bitter I
drink by the gallon when in England than nearly all homebrews I have had
over here. I asked for the recipe and was astonished to find out that
five
gallons called for *three* pounds of crystal malt, and if that weren't
enough, it also used Cascade hops. It didn't taste anything like an
oversweet West Coast ale.

Also, about a year ago I made a lager with pale malt, Munich malt, and
Bullion hops. It completely lacked the harshness that one would expect
from Bullion hops. It came out incredibly smooth in flavor, a crystal-
clear
bright red in color.

Does anybody else have any counterintuitive recipes?

> Also, cracking two pounds of crystal malt with a
> rolling pin will take you a long time -- I have found it to be a
> rather tedious job.

Not as long as cracking 9 pounds of 2-row with a rolling pin does. I
used
to start two days in advance. Now I use a meat grinder with a sort-of-
Corona-
like blade, and it does quite a good job.

From: "John E. Lenz" <JELJ@CORNELLA.cit.cornell.edu>
Subject: Greetings

I have been on the distribution list for about a week now and though it about time that I weigh in with some comments and a subject for discussion.

First the comments (all on items in today's release, Apr 10):

>Jeff Shelton asks "Why do people use green bottles?"

I guess the snide response would be "to contain their beer," but seriously, I don't think the color of the bottle is much of an issue if you keep your beer out of direct sunlight. I have bottled in brown, green, and clear bottles and have never detected any significant differences in the end product. If you are able to keep your beer in a cool dark place I don't think that you will experience any problems. I have a few bottles of Weizen which are about two years old and showing no signs of any lightstruck character.

>Craig (flowers@csrd.uiuc.edu) asks about the typical OG for Weizen

I think that the 1.032-35 stuff is probably the Berliner Weisse, all the info I've seen regarding Bavarian Weizens indicates that they are of a more respectable OG, on the order of 1.045-50. I too would be loathe to add corn sugar to my Weizen, though if the Ireks extract is straight wheat you might consider combining it with a can of something like Alexanders Sun Country light extract, which I believe is an all-malt extract made from 2-row Klages and is the lightest available US product.

>Dave Beedle writes about the hydrogen sulfide odor of his fermenting beer,
>and the sweetness of his barley wine.

Dave, I wouldn't worry about the odor, it seems to be a common thing, I've experienced this with several brews while they were fermenting but have never noticed anything remotely like it in the finished product. As to the Barley Wine, if it is truly a Barley Wine (with an appreciable OG) it is certainly well under the age of consent if it is only two weeks in the bottle. This stuff is meant to have (in fact requires) a lengthy fermentation and aging in the bottle for at least 6 months before being consumed. I'm not familiar with the kit you mention, but if it is a high gravity brew you should sit on it for several months, as it will certainly improve with age. I'd keep a close

eye on those bottles, if the caps start bulging you may consider recapping so as to blow off the pressure in the head space (in fact you might have to do so several times). I hope you went light on the primings.

And finally, I'd like to kick off a discussion on dry hopping. I made a Pale Ale on Sunday and plan to dry hop it with an ounce, or more, of Goldings leaf hops when I rack it into the secondary. I would be interested in hearing of other brewers' experiences with and procedures for dry hopping. I'm planning to simply put the hops, which are in compressed half-ounce plugs, into the carboy and rack the beer onto them. It seems to me that letting the hops have unrestrained contact with the beer should achieve the best result in terms of extracting the desired compounds. Will they eventually sink to the bottom? Or am I opening myself up to a racking nightmare at bottling time? I eagerly await your responses.

Cheers,

Dr. John (jelj@cornella.cit.cornell.edu)

to me, since bacteria cannot travel up a loop anyway. Has anyone >done
this
and noted any different results from just using water?

I always use straight vodka in my airlocks. I buy a bottle of the
cheapest I
can find and keep it in the basement with my fermenters. Bacteria should
not
be able to get through, or survive in the high alcohol level. The
advantages
to using vodka over water or some anti-bacterial solution include the
fact that
if for some reason the contents of your airlock should contact the brew,
nothing will be imparted to the batch (either bugs, toxins, or flavors)
which
would cause a problem. Any high alcohol solution will do but vodka is
cheap,
easy to use, and clear which makes it easy to monitor. I use a bleach
solution
for my blow-off hose airlock. I don't worry about sucking up that stuff
since
I use 4' of 1" tube.

Subject: Dry Hopping

Hi,
The lager that I am making is in the primary in the fridge. I want to dry hop it and was planning to add about 0.75 oz hops to boiling H2O in my erlynmeyer (sp?) flask, quickly cool it in an ice bath and add this to my secondary before I rack in the beer. Is all of this necessary? Do I take a risk with infection if I simply add the hops directly with out the boiling H2O?

Anyone familiar with Triple Rock Brewery in Berkley? Their beers generally have a very hoppy nose and taste that I really enjoy. Do they dry hop their beers? I just can't seem to get the same kind of flavor and aroma by adding the hops after the boil.

Thanks Doug

Subject: Ireks and Weizen

Craig Flowers asked about Weizen extract, specifically Ireks...

I have used Ireks before and I seem to remember that it is 100% Wheat Extract. So, using a little dry malt wouldn't really change the ratio of anything. Adding some barley extract would actually be better in creating a more traditional Weizen recipe.

As for the gravity of Weizens, all the recipes I have seen come in at around 1.050. One can of Ireks in 5 gallons gets me around this point.

From: kswanson@casbah.acns.nwu.edu (Kurt Swanson)
Subject: Re: Weizen Extract

Craig, (flowers@csrd.uiuc.edu), has a can of Irek's Weizen extract (6.6 lbs), and would like to make 5 gallons of Weizenbier, w/o adding corn sugar. This can be done. While the extract is all-wheat, it has approximately the same amount of fermentables as an all-barley malt extract. Thus, considering 2 normal size cans of barley malt extract in 5 gallons of beer yields an OG of around 45, he should have no problem. But one thing Craig should worry about, is the fact that Irek's extract is ALL-WHEAT --- no barley. Personally, I'm about to make a Weizenbier using Ireks, but plan on using a bunch o' crystal malt to balance the wheat. Note that it has already been discussed that commercial Weizenbiers contain ~1/3 barley malt.

Kurt.

Subject: A Canadian Sending Beer to USA

Hi all. My brewing partner and I decided that we would enter the AHA contest this year. There is only one problem: How to get it there. I realize it is now probably too late for suggestions, but here are the problems we were having. We went to UPS. Unfortunately, they demanded

that they know *exactly* what was in the package for customs. This meant that we had to tell them it was beer. Despite our insistence that it was alright to send it for analytical purposes, they refused to ship it. We next tried Canpar. They had no trouble with shipping it, but said that they will only ship things to the US if you have an account with them.

We next tried Federal Express, but they wanted about \$80 for the two packages that we wanted sent. Finally, we went to Canada Post, but apparently they can't ship alcohol for any reason. Furthermore, the customs officials mentioned that even if you send it by courier, you have to clear the package with US customs before you send it. So, are there any Canadians out there who have successfully sent an entry to an American competition? How did you manage it?

Thanks,
Mike

Subject: Brewpubs in Minneapolis/St. Paul

Bobb Menk wrote a fairly complete article on this subject in #612, but I must add my comments.

Taps is, indeed, out of business, so don't even try to go there.

Sherlock's Home (Sherlock's in his article) is a wonderful place with wonderful beer and wonderful woodwork behind the bar. Overall I would say that the place is pretty nice:-).

Summit Brewery has put its tour schedule on hold for a while. I talked to the guy who runs the place and he said that they are doing some construction and won't be giving tours for another few weeks. If you are in Mpls, however, find a sixer of their porter (Great Northern Porter) and enjoy. I will post when they resume touring, as it is very interesting and the free beer is plentiful, fresh and very tasty.

There is another micro in town. James Page Brewing also gives tours, but only on the first Saturday of each month. His is an interesting approach since he uses wild rice as an adjunct in his brews. Tasty.

Good luck, and welcome to Minneapolis/St. Paul.

Subject: Brewpubs in Minneapolis/St. Paul
Clarification time.

In Digest #611, I wrote in suggesting that people look into using bottled water. I found a place in MPLS which deals in both plastic and GLASS for spring and distilled water. Of course, the obvious choice is to get a glass carboy, and that is what I did. JaH (J. Hersh, I believe) pointed out, and rightly so, that we should only consider glass. I had said that before, however.

Another submission in #612 suggested that I could get bottled water cheaper at the supermarket. This is very true, but the added convenience of getting a clean carboy (i.e., doesn't need to be sanitized->No POSSIBLE worries) for only \$1.50 is a steal in my book. (to recap: I could go out and buy bottled water for only about \$3 at the store, in the carboy it costs \$4.55)

As to the quality, all I can say is that the spring water from the bottlers tastes, smells, and even looks better than tap water. The beer I have made from the bottled water has also been excellent. How can you argue with success?

To summarize: bottled water offers quality and convenience at a low price. I challenge anyone to find a GLASS carboy for less than \$6, and I am sure that nobody has ever worried less about sanitation in his/her fermenter.

Thanks,
Lanny Hoff

From: troby@carl.org (Thorn Roby)

Subject: Rotokegs going flat

I've brewed something like 20 batches over five years in three Rotokegs and I think only two have gotten through the keg without needing additional carbonation. I keep upping the priming corn sugar (lately I've been using about 12 oz, about three times the recommended amount) and the initial pressure is great but it only lasts about half way through (over a two to three week period). Typically I add two or three little CO2 cartridges to get the rest out. Still, at a carbonation cost of about \$1 a keg, I'm reluctant to do anything more serious about pressurizing. Anyone know any intermediate solutions short of a full CO2 tank? Seemed like it was going to cost me about \$80 to do that.

One of the things they recommend is to use a mixture of vodka and water in the airlock.... Has anyone done this and noted any different results from just using water?

I use gin in the airlock. But I don't think it makes any difference. If I add a little more gin after bubbling through for a while, I notice the Schlieren patterns which tell me the liquid in the airlock was no longer gin (probably mostly water).

(Description of tube-in-a-tube wort chiller)

> 2) My question: Everybody I know who uses a device like this uses a
> counterflow, that is, cold tap water running in an opposite direction
to the
> wort flow. However, it just made intuitive sense to me to send both in
the
> same direction: The hottest wort will exchange the heat with the
coldest water
> and some sort of equilibrium will be reached by the time you reach the
end
> of the chiller. Why would the chiller be more effective with
counterflow?
> Which method makes it easier to regulate temperature?

I started to write the long answer, but my fingers started to hurt, so
briefly:

Countercurrent heat exchangers are more efficient in certain ways, most
notably coolant utilization; it takes less water to reach the desired
temperature. Unless you live in a drought region, though, this isn't a
big
consideration for homebrewing.

The gist of it is that in countercurrent operation, your coolest beer
(exiting) meets your coolest water (incoming) and so can match its
temperature. In co-current operation, the coolest beer sees the warmest
water. In order to get the beer as cold as the incoming water, you have
to
use a very high flowrate of water.

You're starting with an imbalance, if you have the same type
of Ireks Weizen extract as I did. On my can, I believe it said
the only ingredients were Malted wheat and water. This would
be 100% wheat.

>I have a 3.5 gal
>fermenter and was wondering if anyone thought it would be better to make
>the smaller amount? Would it end up too strong? Weizens, if I remember
>correctly, should probably have a starting gravity of 1.032 - 1.035. Am
I
>better off making a 5 gal batch (with no additives) or a 3 gal batch
(with
>no additives)?

I made a 5 gallon batch with nothing but 1 oz of Hallertauer pellets
in the 60 minute boil and 1 more oz of Hallertauer pellets for the
last 5 minutes of the boil. The result was strange. I think that
I may have burned the malt (damned electric stove, damned enamel
brewpot!) because it came out dark red, like a dunkel lager. The
flavor was definitely burnt, but mellowed out after a month in the
keg at 45F. I suggest you make a 5 gallon batch. My intuition
says: "6.6 lbs of liquid extract in 5 gallons of beer should result
in an OG of 1.042 to 1.050" since Papazian says 1 lb of liquid extract
per gallon gives you 1.032 to 1.038. I used Wyeast Bavarian Wheat
yeast.

Please post how it turns out and what you ended up doing.

Al.

Subject: Green glass

In HBD #612, Jeffrey Marc Shelton <js8f+@andrew.cmu.edu> writes about green bottles. Do they let the nasty green light through?

Well, it is green light that causes the "skunkification" (that's a technical term) photochemical reaction of the iso-alpha hop acids. But you can't tell just by looking at a bottle whether it transmits or blocks green light, unless the bottle is clear. Even a brown bottle may be blocking no green light. A green bottle may be transmitting either green light or equal portions of yellow and blue light. Your three-color visual system can't tell the difference: both look green. The only way to know for sure is to use a spectrometer.

Since most of us don't have access to spectrometers, I'd suggest just keeping your bottles, whatever their color, in a dark place. I even have a couple clear bottles, and they've never skunked up, because I keep them in the dark. This doesn't mean I keep them in a light trap. I keep them in a closet while they carbonate and in a fridge thereafter. The brew gets consumed fresh enough that photochemistry is never noticeable.

Subject: Re: Brewpubs in Cleveland ? (YES! A really good one)

Jeff Chambers [motcid!red!chambers@uunet.UU.NET] writes Brewpubs in Cleveland?

Yes. I recently returned from Cleveland, my 2nd trip there in less than a year, and my 2nd visit to the Great Lakes Brewing Company confirmed that this place has some truly great beer! Here's some details:

Great Lakes Brewing Company
2516 Market Street, Cleveland
771-4404

"Located across from the West Side Market
West 25th Street and Lorain Ave"

It's close to Cleveland Municipal Stadium (the big round stadium seen off the Cleveland Shoreway/Rt 2). On the map look for Rt 42 and the intersections of this road with Rt 2, Rt 90, and/or Rt 71. It's close to either of these intersections.

The beer there is German style. 2 weeks ago I sampled the Einbeck (a 'special' single or double type bock typical of a sweet malty German style bock beer) and the Heisman (a regular beer there, Dortmunder style - nice and hearty sweet finish).

I rank the GLBC either #1 or #2 for the best microbreweries in the Northeast, in competition with the Cambridge Brewing Co for the #1 slot. I've never been to any places on the left coast, nor anywhere south of Ohio, but this place is a must visit. The Brewmasters Pie washed down with a Heisman made my day *-)

For bottled beer, Erin Beer, made by the Cleveland Brewing Co, is also very good if you can't wait till you get to the GLBC.

From: nolan@lhevax.DNET.NASA.GOV (Tom Nolan)
Subject: Stuck Fermentation?

A friend of mine brewed his first batch of beer last week. He used one can of Laaglander "Irish Ale" kit (3.3 lbs) and 3 lbs of light dry malt extract. He didn't take an initial gravity reading. As far as I can tell, he did everything right, aerated the wort before pitching the rehydrated yeast. The fermentation peaked at about 48 hours after pitching, at only about 1 "glub" every 3 seconds. Three days later it stopped. The final gravity is 1.028, steady for four days now. He used the yeast that came with the kit.

So is this supposed to be a sweet beer? Or might it benefit by another yeast addition to try to bring it down to what I would figure the normal range should be (1.012 or so)? I guess that would mean it should be re-oxygenated.

Any advice would keep us from worrying too much.
Thanks
Tom

From: ralph@ecn.purdue.edu (Ralph L McCallister)
Subject: Ireks, green bottles, dry hopping, DME priming...

Ireks, green bottles, dry hopping, priming with DME:

I promise to keep this short.

Ireks, Dave Miller states that when brewing a wheat beer you should use a 2:1 ratio of wheat to malted barley. This year I made a wheat beer using 6.6 lb. can of Ireks and 3.3 lb. can of MF light malt extract. I also dry hopped with an ounce of Saaz as well as about 2.5 oz. of boiling hops. This turned out to be a very pleasant surprise. I really like this beer and would recommend using this ratio, either with grain or extract. I would like to add about a lb. of cara pils next time and an extra half ounce of dry hops. I would NOT add any corn sugar to this recipe. This is a semi-sweet brew with a nice flavor and after taste. Try it, you'll like it!!! I highly recommend Ireks for your wheat beers.

Green bottles, I bottle in clear, green, and brown bottles. I keep them out of the sunlight while in storage. I have never had any problems. If you bottle in clear or green keep them covered. If light cannot get to your bottles, they will never know the difference!

Dry hopping, it can be a pain, you will lose a little more brew when you rack from the secondary to bottling bucket or bottles, but it is well worth the effort. I think that an ounce or two depending on the alpha acid content, added to the secondary will give that little extra spark to a beer. I add mine after I am done racking, I don't know about adding them before racking. They float on the top and after 5 weeks in the secondary they did not sink to the bottom. I would be interested in knowing how it turns out when they are added to the bottom.

Priming with DME, I thought I read that DME has about 70% of fermentable sugars. A 1:1 swap with corn sugar should work. I think that you could even go with about 30% more DME than sugar and be alright. I had a friend of mine split a batch, priming 1/2 with corn sugar and the other with DME. The one visible difference is that the ones primed with DME are a bit more cloudy, this may work out in time. Other than that I could not taste any difference and the heads on both samples seem to be about equal.

A great plus about brewing your own, is that you can try anything you want!!!
Ain't it great!!

Ralph McCallister ralph@ecn.purdue.edu

....Something going to happen..What's Going to Happen..something wonderful..

From: "John E. Lenz" <JELJ@CORNELLA.cit.cornell.edu>
Subject: bottles

I noticed in HB Digest #613 (today's issue) that I neglected to mention that the 2-year-old Weizen that I mentioned was in green bottles, perhaps the comment will make more sense now.

>Kurt Swanson asks (in #613) about using a coffee grinder for crushing malt.

I have done so in the past, you will need to set it for the coarsest grind it will make. Depending on the type of grinder you have this may or may not be adequate for malt milling, be careful not to pulverize the husks too much. You may also want to check with your local food co-op to see if they carry a Corona grain mill, or some other brand. I got mine at the Moscow, Idaho co-op for just over \$30, as compared to the \$45-50 price tag this item typically carries in the Homebrew supply catalogs.

>Gene Schultz (also in #613) asks about West Coast suppliers of malt extract

You might want to check out Great Fermentations, there are two, one in Santa Rosa and one in Marin, Byron Burch owns one of these. I used to order from them and recall that they carried a bulk extract syrup, though I'm not sure what they had in the dry category. As I recall their prices were quite good and the service was excellent. I think that I dealt with the Santa Rosa outfit, but am not sure, though I know that it was the one that Byron does not run.

A general comment regarding brewpubs, breweries, etc.. Michael Jackson has a brand new edition of the "Pocket Guide to Beer" which is an excellent reference with very good coverage of the brewing scene in the U.S. as well as the other major brewing nations around the world. I highly recommend this to anyone who is travelling and needs good information on what brews they can expect to encounter, or should be looking for, along the way.

As to airlock contents, I have been using Wild Turkey lately, seems that a malt-based distilled product shouldn't hurt the beer if it comes in contact with it.

And lastly, Ted(TSAMSEL@ISDRES.ER.USGS.GOV) you have my sympathy on the demise of your carboy and the loss of your beer. Had you ever subjected the carboy to

a physical shock of any sort? If not you probably just got a defective one. I try to handle my carboys very carefully, I have some plastic milk crates (the kind that half-pint cartons are delivered in) and find that these are just the right size for both 5 gal and 25 litre carboys and provide some protection when setting them down, especially when they are full.

Cheers,

Dr. John

From: BIOSCTH@UMCVMB.MISSOURI.EDU
Subject: dry hopping, Evanston, IL

Hello Homebrewers --

On dryhopping ... I've had great success with a no-worries approach. I just dump pellets or fresh/whole hops into the secondary and rack the beer onto them. They settle out after 10-14 days. If the secondary fermentation is particularly vigorous I sometimes add another dose of hops after the bubbling slows down -- I don't want all those wonderful aromas carried off by the CO₂. I wouldn't recommend boiling the *dry* hops at all. The aroma-causing compounds are very volatile and some of them will be lost in even a short boil. The brew's EtOH, pH, and the hops themselves seem to be enough to keep rogue microbes from getting established.

Brewpubs in Evanston ... Not likely. Evanston is the home of the Women's Temperance League -- the teetotaling biddies that were largely responsible for swinging public sentiment in favor of Prohibition. Although things may have changed since I lived in the Chicago area, Evanston used to be the only *dry* town in Illinois. When I was in high school it finally became legal to buy beer & wine in restaurants. The only good thing I know about Evanston, beer-wise that is, is that it's on the northern border of The City of Broad Shoulders. Get a cab and go to the Goose Island Brewery.

From: russo@carlos.sps.mot.com (Russell L. Oertel)
Subject: 1st attempt at lager beer

I've learned alot reading this forum over the past two months, and now I think it's time I make my first posting. I've been brewing since last July, and am presently working on my 6th and 7th batches.

I decided to make my first attempt at a lager beer (an American-style bock, actually) and I don't have any experience as to the timeframes required to make a lager. At the moment, I don't have the resources to keep 5 gallons of beer chilled to 45-50 degrees, so I am making a 1-gallon "experimental" batch. What has surprised me about this batch is the length of time it has sustained very active fermentation. It took a couple of days for it to get started, but it has been very active (15-20 glugs/minute, but remember, this is only 1 gallon) for more than a week. How long can I expect this to go on? I'm not worrying, just curious.

The other thing I was wondering about is how long should I age it? I was planning, once the fermentation is basically done, to put the gallon jar in the fridge with the lid on, loosening the lid every day or so to relieve any pressure that may build up. Before I do this I plan to make sure that the fermentation is going **very** slowly. Is this not a smart thing to do? With my current setup, I don't think I have many other options (not until I can get my dedicated fridge). Maybe I should just bottle it when the fermentation slows down?

Thanks for any advice,
Russ Oertel

I used to use a coffee grinder with my hand drill to provide power.
It was slow (about eight minutes per pound) and didn't do a good job.
I didn't know how bad it was till I bought a Corona mill. The
Corona takes a minute or two per pound and is much more uniform.

My advice - get a Corona and don't waste time with a coffee grinder.

I tried dry hopping in exactly this way on my last batch o' pale ale.
I put 10 grams of Freshhops Mt. Hood hops into a carboy and racked
three gallons of beer onto it. I did not attempt to sterilize the hops
in any way, I just dumped them into the carboy. It all floated to the
surface and looked like swamp scum. It didn't sink in five days, at
which time I racked it and bottled. The hops rinsed out of the carboy
easier than I expected. The resulting beer is excellent.

The only complaint I have is that there is too much crud in the
yeast cake making it unsuitable for repitching.

Subject: sanitary airlocks and carboy handles

In HBD #612 Dan Graham writes:

>One of the homebrew mail order catalogs I have adds a lot of advice
along
>with their product listings. I have found some of the advice to be
good,
>and some pretty bad. One of the things they recommend is to use a
mixture
>of vodka and water in the airlock. This seems like overkill to me,
since
>bacteria cannot travel up a loop anyway. Has anyone done this and noted
any
>different results from just using water?

If there is anything that abounds in the world of homebrewing, it is
overkill;
as the readers of this digest well know. On the other hand, advice for
overkill is not bad advice, just unnecessary.

However, using vodka in the water might be a good approach to dealing
with a
problem I have from time to time - getting water sucked from the airlock
into
the carboy. This will happen when there is very little fermentation
going on
and the temperature drops. It happens to me under two conditions: 1)
when I
rack a lager, I let it sit for an hour or two to allow the sediments
stirred up
by moving it to the kitchen counter to settle. In the process it warms
up and
get warm gas (potentially air but I usually charge the new carboy with
CO2)
above the beer so that putting it back in the fridge cools the beer and
gas, causing a temporary lower than atmospheric pressure in the carboy for
a
short time. 2) I like to bulk age my meads in the carboy for 6 months or
more;
I think it speeds up the aging process and makes for a better final
product.
Since I brew a lot of melomels during berry season (e.g. warm months) the
temperature in my brew storage area drops before I bottle them and after
the
fermentation is complete.

In any case, I get carboys that suck water out of the airlock. This is
not a
good thing, although it's not necessarily a bad thing. I always just use
tapwater and don't worry and get excellent results. However, Byron Burch
points
out in his book that not all tap water is as forgiving as mine is. Also,
some
posters to this digest have complained of getting fruit flies in the
water of
their airlocks. Under such conditions, you would definitely want
something to

kill off anything that gets into the water of the airlock if there is a chance that it will get into the carboy.

Also, Marc Rouleau relates a message from John DeCarlo:

>> The carboy was shipped to me via UPS, in a very nice styrofoam container. This container is invaluable in storing and carrying the carboy. I would hesitate to use a neck-handle on a full 7 gallon carboy, but find it very easy to use the handles on the styrofoam container to move it about even when full.

The first thing I do when I get a new 7 gallon carboy is to put a neck handle on it. I ferment in the crawl space under my house which is reached by a trap door in a closet. The floor of the house is about 5 feet above the floor of the crawl space. If not for the handles I almost certainly would have dropped a full carboy by now. I use the handles to carry full carboys to the closet or out to the garage where my lagering fridge is located and have never had a problem. I did, however, mount the handles as low on the neck as I could get them which meant stretching out the ring that goes around the neck and getting a longer bolt to hold the handle on.

Subject: Re: Dry hopping / aromatics

From: "John E. Lenz" <JELJ@CORNELLA.cit.cornell.edu>
Subject: Greetings

It seems to me that letting the hops have unrestrained contact with the beer should achieve the best result in terms of extracting the desired compounds. Will they eventually sink to the bottom? Or am I opening myself up to a racking nightmare at bottling time? I eagerly await your responses.

One time, I left the hops bag of aromatic hops (added at end of boil) in the primary fermenter. After fermentation kicked off, the bag ended up floating on top of the krausen - effectively minimizing any further contact with the beer.

I'd like to found out if anyone has figured out how to get the kind of floral aromatics which Sierra Nevada has.

Subject: Midwest Brewpubs

There have been some recent requests for info on brewpubs in Illinois and Ohio. Things change quickly, and my records may be out of date, but here's what I've found:

There are unfortunately no brewpubs in Evanston. There are five brewpubs in Illinois, three in Chicago, one in Berwyn, and one in Champaign.

Cleveland boasts the Great Lakes Brewing Company (2516 Market St., 216-771-4404). There are also brewpubs in Columbus, Dayton, and Strongsville (?).

I haven't had the pleasure of visiting any of the above, so I can't say much more about them. If you make it to any of them, please let us know what you find.

Enjoy,
CR Saikley

Subject: Wheat Extracts

There has been alot of talk about wheat malt extract and wheat/barley ratios etc. The consensus seems to be that Ireks is 100% wheat malt. That raises a question.....

How do they do that?

The reason that wheat beers are usually at least 1/3 barley is that the barley is necessary. Wheat malt is low in enzymes, so tthe added barley compensates. Also, wheat malt lacks husk material which is needed to form the filter bed. Anchor Brewing has gotten their wheat content up to something like 72-73% in Anchor Wheat, but they don't think they can go higher.

Now maybe Ireks is able to get away with more since they are making malt extract and not beer. I suppose that they could add lots of gibberellic acid to get the starch->sugar conversion. They would also probably have to develop a specialized lautering system. This is conjecture; does anyone out there really know ??

Eagerly Awaiting,
CR

>I suggest that you consider steeping the grains at 168 degrees for

Well actually I would suggest using a slightly lower temperature, say 145-155F as the higher temps can also result in greater extraction of tannins and astringency.

>have the smell of rotten eggs (hydrogen sulfide) coming from my beer!
The

What kind of yeast are you using?? I have brewed Lager beers in the past and had H₂S odors come off the carboy. I found however that the smell and flavor did not remain in the beer. Depending upon the yeast strain and brewing process a lot of sulfur compounds can be produced. Depending upon the amount produced the yeast will reduce them. This chemical reduction can result in the release of H₂S. It is actually a good sign that H₂S is being produced as this means the sulfur is being eliminate from the beer. Of course at some point the release of this should cease. If it persists past say 10 days, then it is likely your beer has so much Sulfur in it that the yeast simply can not reduce it all, otherwise the smell should wane as the level of Sulfur in the wort drops

> I'm planning to simply put the hops, which are in compressed half-ounce plugs,
> into the carboy and rack the beer onto them.

Yeah this works real well, some people rig up devices to prevent the hops from cloggin up the racking tube. I did sort of the opposite, I chopped the hops up and put them in one of those mesh boiling bags, put it in the carboy first then racked the beer onto it in the secondary.

Subject: Tubing and "Psuedo" Beer

Two rather disparate items:

A friend showed me an ad for "Tygon" beverage/food tubing. According to him, this stuff was originally designed for the ice cream industry, and won't promote bacterial growth. He made the obvious connection to homebrewing. According to the ad, "Tygon B-44-3 tubing is odorless and taste-free, so it won't alter your formula for success." Tygon (a registered trademark) is made by Norton Performance Plastics. The ad concluded "For details, call 216-798-9240." At this point, I haven't called them, tho my friend did send in one of those circle-the-numbers-for-more-info type cards. Anybody out there familiar with this stuff?

A few HBDs ago, there was some discussion of non-alcoholic beers. I happened across a case (empty - I haven't tried any of it - I like alcohol :-)) of "Marke Clausthaler Non-Alcoholic Malt Beverage", and couldn't resist writing down the info on the case - thought it might contribute (late, I realize) to the previous thread. For the record, this stuff is brewed by Binding-Brauerei A.G., Frankfurt, West Germany. Per the box (direct quote) "Brewed from pure water, barley malt, hops and yeast in accordance with the German Beer Purity Law of 1516". Hmmm, no doubt, tho I'll bet the law doesn't cover removing the alcohol you tried so hard to create. Unfortunately, the blurb on the box made no mention of how they removed the alcohol. For what it's worth...

<to my secondary before I rack in the beer. Is all of this necessary ?
<Do I take a risk with infection if I simply add the hops directly with
<out the boiling H2O?

Dry hopping is certainly the way to get hop aroma into your beers, but
there is the nagging question regarding infection. Unfortunately, boiling
the hops long enough to ensure sterility also ensures that the hop aroma
has dissipated. The shorter the boiling time, the more hop volatiles
remain,
and the more critters survive. Fortunately, the critters typically found
on hops don't like a yeasty, anaerobic, low pH environment, which allows
dry hopping to be successful. I've dry hopped many beers, and this has
not caused any infection problems.

Last February, I took a homebrewing class from Dr. Lewis at UC Davis. He
said they had studied the problem, and concluded that tossing in hops 2-
3
days into fermentation is basically safe, and that no added precautions
were called for. (Correct me if I'm wrong Russ.)

<From: "John E. Lenz" <JELJ@CORNELLA.cit.cornell.edu>

<bottom? Or am I opening myself up to a racking nightmare at bottling
time?
<I eagerly await your responses.

I've found that pellets generally work better than whole hops. The half
ounce plugs will separate into whole hops in the carboy. They do sink for
the most part, but are easily disturbed and tend to clog the racking
tube.
Pelletized hops break up into very small pieces that are less easily
disturbed. If you do pick them up, they will pass through the tube into
your priming vessel painlessly, where they have another opportunity to
settle.

Hope this helps,
CR

From: hplabs!bnr-vpa!bnr-rsc!crick (Bill Crick)
Subject: Rotokeg, carbonation

I had a Safron Superkeg, plastic keg for about 4.88 years, which split, and the store that sold it replaced it with a Rotokeg on the 5 yr warantee, as they no longer sold the superkeg. I've had the Rotokeg for about three years.

I have found that one has to be very careful to clean and lubricate all the seal joints if you don't want them to leak, and yield flat beer. Even if you are careful, sometimes a beer will suddenly go flat. On the other hand

I've had some batches in these kegs for 8 months with no problems. If you put a five gallon batch into the keg, you will most likely have to add CO2 cardtridges to get the last half out of the keg.

What I have been doing lately with good succes is the following:

I take a five gallon batch, and add two cups of sugar. I then bottle 24 bottles of this, and put the rest (3.5Gallons) into the Rotokeg, and seal it up. This is way more sugar than they recommend. You must have a relief valve of some type. My Brewcraft injector has one. The keg pressure

increases to the relief valve pressure, and then starts venting quite a bit of gas. This gas that is vented purges a fair amount of the air that

was in the large headspace in the keg, which helps reduce oxidation problems.

Because there is a large headspace filled to maximum pressure, there is enough gas in there to dispense most or all of the beer without any cartridges

SOMETimes it takes a cartridge to get the last 1/2 gallon or so out.

Note that I have often served the bottled version, and kegged version of the same batch to friends one after the other, and most like the bottled version better. Some won't even believe they are the same beer!!!!

The Rotokeg has the tap at the top of the keg with a pickup tube. The superkeg had the tap at the bottom. I found the Superkeg hard to get beer

out of. You either get a glass of foam if you crack the tap, or 90MPH beer flying around if you open it wide. With the small diameter pickup tube

in the Rotokeg, there is enough restriction in this tube, to open the tap wide, and still get beer coming out slow enough that you can keep it in the glass.

Even so there is lots of ofam. I'm thinking of making the pickup tube either

smaller diameter, or longer so the pressure drop is spread out more gradually, so the flow is lower, and the tendancy to foam less.

I once had someone who works for a beer company tell me that in there draft setups, if the keg was less than a certain distance from the tap, they added a small coil of small pipe between the tap and keg to reduce foaming.

He called this coil a "restrictor coil".

Bill Crick Brewius, Ergo Sumfoam!

Subject: brewing stoves

For anyone who cares, I found a rather nice looking brewing stove in a Bass Pro Shops catalog (1-800-227-7776). It is stainless steel, 136000BTU, has a stove-top-like burner, and stands waist high. It comes with a 3 gallon stainless steel pot and lid with a large frying basket too (it's really for fish frying). The guy on the phone assured me that it was quite sturdy and that their return policy was very liberal. I have it on the word of an avid fisherman that they are a good place with which to do business. The price is regular 139.97, on sale till June 18 for \$99.97. I just ordered yesterday and have not yet recieved it, so no comment yet. Just thought I'd let anyone interested know so they could call for the catalog (which takes about a week or 2 to get there). They also have less elaborate 2 and 3 burner units.

If anyone is interested in how mine looks, email to me and I'll let you know when it gets here.

Mike Zentnerof to sample some bock....

Subject: Thanks and kegging...

Hi all! First thanks to those folks who told me not to worry about the hydrogen sulfided oder in my latest batch. It does seem to be going away and I am not worrying! The yeast, BTW, is Witbred Lager yeast (dry, 14g).

Yesterday I picked up a small (2 1/4 gallon) Brewcraft pressure keg. In the literature it mentions an "Auto injector"? I assume this is a CO2 set up of some sort. Keeping the pressure up seem like a good idea to me since I don't plan on drinking the whole two gallons in one sitting ;-). Just what, exacly, is this critter and where can I get one? Are there alternatives? Thanks!

Quick note to those who want to drive their Corona with a power-drill. I
smoked my Black-and-Decker VSR drill after grinding about three batches
worth of grain. My suspicion is that the drill is designed for high speed
and low torque, and that unless you can gear it down, you'll melt the
winding insulation like I did.

My solution? Hook up my Skil Hammer Drill to it. It has a lower speed but
much higher torque. Of course it costs \$100, which drives the cost of the
grinding system up... :-(

Have any of you build a roller mill? My brew store owner had one, and it
was great, but I think he said he spent over \$1000 on it!

Subject: Dry hopping

A quick note on dry hopping. I tried it once for a holiday ale; It was your basic American pale ale, with (Wilamette?) hops added to the secondary. It tasted pretty good. I told people to drink it quickly, as I was afraid that the dry hopping would introduce an infection that would show up in a month or so.

Well, one of the people I gave it to stored it in his refrigerator for months. I was at his house the next summer, and he pulled one out. I never save my own brews for that long! Anyway, it tasted twice as good as it did when fresh brewed! No infection at all. Better than Anchor Liberty Ale!

The moral of this story is - don't worry too much; just do it!

From: BAUGHMANKR@CONRAD.APPSTATE.EDU
Subject: Head retention; Dry hopping; Straining

These remarks go back several issues:

Dan Needham asked about carbonating in kegs.

I've been artificially carbonating my beers for several years. I've found it necessary to *really* overpressurize the keg (50 or 60 PSI) for 2 or 3 days. Don't shake or roll the keg else you'll get big fish-eye bubbles instead of the smaller ones that result from letting it sit. Also, the colder you can get the keg while doing this the better. Cold beer absorbs CO2 better than warm beer.

Since the beer is overpressurized, it'll take a while to settle down to 8 PSI after you tap the keg. I usually depressurize just prior to pulling a beer. You'll have to do this for the first 8 or 10 beers.

Dan Strahs asked about adding maize for head retention:

Flaked maize is not the best way to go for head retention. Ditto the other remarks about Cara Pils, Crystal and Wheat malt. I've used all with good success.

Several other factors could be causing the thin head on your beer:

Did you wash any of your equipment with detergent? If so, you have to rinse, rinse, rinse to make sure none of it is left. Detergent breaks the surface tension of liquids and the head of your beer along with it.

Did you use sugar in your recipe? If so, shuck the sugar next time and use an equivalent amount of dried malt extract. All malt beers are thicker and more likely to exhibit good head retention than are sugar beers.

I usually add a cup or two of crystal malt to any and all extract beers. Crystal malt adds unfermentables to the wort which end up giving the final beer an all-grain character and more mouth-feel. This also helps with head retention.

Bob Clark wanted to know how Sierra Nevada gets those aromatics in their beer. I asked Ken Grossman that last year while touring the brewery. He dry hops and likes to use "gummy hops".

I haven't dry-hopped in a while but I've always been disappointed by the aromatics (rather, the lack of) from finish hopping. I built a modified hop back last year for use with my BrewCaps. In one batch I used Cascades, the other Chinooks (a nice gummy hop). The Cascade batch had no aromatics (just like old times). The Chinook batch was wonderful! Conclusion: If you're not dry-hopping, try a really high alpha hop for finishing to increase the aromatics. Low alpha finish hops are a waste of time and hops. If you are dry-hopping, try high alpha hops but go easy on the quantities. 1/4 to 1/2 ounce per five-gallon batch should be plenty.

And finally, a quick reminder of the pot-scrubber-in-a-mesh-bag technique for separating hops from your boiling wort/dry-hopped beer. Tie a copperwound pot scrubber around the end of your pick-up tube. Tie a fine mesh hop bag (No-See'um netting from a camping store works well,

too) around the scrubber, in effect putting the scrubber in a bag.
Suspend the bottom of the pick-up tube several inches above
trub/sediment and siphon. A painless, efficient technique.

Subject: Lies, damn lies and Guinness

Gee, I was so happy to get this visiting faculty position at Northwestern, but when I hear the way you folks dump on Evanston, it makes me glad I'll be leaving in a few months :-)

First, the outright lie. Graig Flowers says:

Craig> Evanston, including Northwestern University, is dry.

Then, BIOSCTH@UMCVMB.MISSOURI.EDU says:

BIOS> Brewpubs in Evanston ... Not likely. Evanston is the home of the
BIOS> Women's Temperance League (sic) -- the teetotaling biddies that
were
BIOS>
BIOS> The only good thing I know about Evanston, beer-wise that is, is
that it's
BIOS> on the northern border of The City of Broad Shoulders. Get a cab
and go
BIOS> to the Goose Island Brewery.

Just the facts, Ma'am: There are no brewpubs in Evanston, and the Goose Island is your best bet; it's about \$15 by cab, easily accessed by the CTA and the beer is good and fresh.

Evanston WAS a dry town, until 1971. Now, there are about as many pubs as you would expect in a suburb of its size, at least in "downtown"; I suppose the periphery long ago accustomed itself to drinking in the neighbouring townships. Most pubs serve Miller and have sports on TV, but there's one good pub. It's called Tommy Nevin's, 1500 Sherman Ave., right across from the Holiday Inn. They have half a dozen imports on tap, always fresh, and they know how to draw a pint of Guinness. The ambience is pseudo-Irish, there's no TV and the food is decent. It's associated with the Davis Street Fish Market, a restaurant where the fish is superb and the beer list closely approximates Tommy Nevin's.

And, no, the campus isn't dry. However, the majority of American campuses I've visited in the last year were. (Just as well I didn't get that job at Eastern Washington U. :-)

The Women's Christian Temperance Union is indeed headquartered here, but are a much bigger force, e.g., in Toronto (part of which is STILL dry; a referendum was held just a few years ago and that's what the RESIDENTS of High Park want). Nowadays, the WCTU doesn't lobby against drink but instead does charitable work on real causes: hunger, homelessness, child abuse, etc.

Perhaps they've decided it's easier treating the symptoms.....

Subject: Homebrew from Canada, Lots-o-repitching: evaluation

I have an idea for the person(s) having trouble sending homebrew to the US.
Maybe you could do a relay thing where you ship the beer to somebody on the Canada/US border, and they cart it across to a place where they could ship it to the AHA. You could call it "the Underground Aleroad" :).

This dead horse has been beaten to a pulp, but since I have two cents to add, I figure I might as well. I met Father Barleywine this past weekend at a homebrewers club meeting, and he had several fine beers with him, which he claims were brewed with his repitching technique. If anyone has forgotten, it involves something like tossing new, cooled wort on top of the yeast from the last batch. The beer was *very* good.

Now let's be pragmatic about this. Despite all the hoopla about yeast mutations over "generations" of beer, it would seem that repitching works, at least for this individual. I would say that the real proof of a brewing technique is in the finished product. If you can handle the volume (repitching this way requires that you brew often), then give it a try. I intend to do so, as soon as the opportunity (i.e. money and time for brewing) presents itself.

Subject: Rare Trappiste Ale

After reading of the many exploits of Digesters travelling in Europe and all over the US, I never thought I would taste anything others haven't already posted about. As luck would have it, I have had the opportunity to taste one of the rarer Trappiste Ales.

A recent acquaintance travels to Belgium a few times a year for work. He brought back a Trappiste Ale and said the only place you could get it was at the Abbey. It came in a brown bottle and had no label. The cap is marked: Trappistenbier Westvleteren ABT. I looked it up in Jackson's book (the first edition) and found it was made by one of the 6 Abbeys that can lawfully call their beers Trappist. The abbey is run by the St. Sixtus Brothers and is referred to as the Westvleteren Abbey. They brew beer mainly for the brothers and will sell to visitors. The beer is not available away from the Abbey, although a local brewery brews another beer under the Brother's direction. This was about all Jackson had. Could someone look this up in Jackson's latest edition to see if there is any other information?

For the truly curious, the side of the cap reads: ST. SIXTUSABDIJ V.Z.W. B-8983 Vleteren. I don't know if Vleteren is town but that's what I would guess. I don't understand the ABDIJ connected to St. Sixtus nor whether B-8983 is in any way significant.

The beer is 11% alcohol by vol (also marked on the cap) and was very sweet and suprisingly well balanced. Definetly a sipping brew. It had plenty of yeast that was flocculating in clumps in the lower quarter of the bottle. It was impossible to pour even half the beer without any yeast. I noticed no yeast bite, but I suppose it could have been masked by the high alcohol. The color was a deep, clear brown. I really liked it and was suprised it survived the trip in such good condition. I have no idea how much it cost.

I am attempting to culture the yeast. I know of no practical way to share it with anyone, unless, of course, you live nearby, in which case you're more than welcome to a sample of the recultured yeast.

It's probably a bit too much for my Dunkel Weizen, huh?

Won't promote bacteriological growth, but probably won't prevent it either,
and if it does I don't want that antiseptic in my beer. I've seen this
stuff in Cole Parmer (big lab supply vendor) catalogs. They also have
lots of fancy tubing for handling corrosives, solvents, and other less
benign liquids than beer. The cost for these was in the few dollars per
foot range -- talk about overkill! I go for the cheap (\$.27/foot) FDA
clear vinyl hose from the local hardware store for siphon hoses, etc.
where the exposure time is low. For service lines from kegs the standard
beer tubing is equally cheap and maintainable. When they accumulate
enough
gunk and become slightly opaque I simply replace them.

I usually add a bit of crystal or other flavoring malt to an extract
brew,
and always use my 'cheap' little coffee grinder. It's the motorized kind
with twin blades that rotate horizontally at about a zillion rpms.

One does need to take care, as it can turn the malt grains into a fine
powder
in about 10 seconds. I usually grind 1/3 cup at a time in small bursts
until
it looks ok. It doesn't get em all, and grinds some too fine, but it's
preferable (to me) than a rolling pin.

Subject: SAM ADAMS

re: Varieties of Sam Adams (TSAMSEL 8/12)
I have found five varieties of Sam Adams at my local Safeway in the DC area (Fairfax, Virginia). However, only the Original and Lightship are continuously stocked. These five are:

- Original
- Lightship (a Light Beer - 1/3 less flavor than regular)
- Boston Ale
- Winter Lager
- Double Bock

My personal taste is that the original is far superior to all but the Winter Lager. The Double Bock is interesting for a change of pace.

P.S. - No success brewing a replica of Sam Adams original (although not one of my homebrew goals), yet I find many people compare much homebrew to Sam Adams, as it is the only domestic premium they have previously tried. Thanks for the Cooper's Australian recipe, I will give it a try.

Subject: RE: Sam Adams Double Bock

On Pitching yeast while hot:

I always make a "1-hr starter bottle" by taking a little bit of wort at the start of the boil, then add cold tap water to it to cool it down, then add the yeast and shake.

I've pitched yeast at anywhere from 80F to 105F. Anything over 100, and it seems to start slowly, possibly indicating that I've killed a significant portion of the yeast. 95F works fine - It usually starts off within 6 hours - I try to shoot for 85F, though.

I think the highest temperature you can get away with without killing the yeast will stimulate it, and get it going faster. The wort is usually cooled to near its final temperature within the next few hours - There isn't time to produce an appreciable amount of "off flavors". As long as you don't kill off much of the yeast, I don't see how it could be "damaged".

I usually do the "sparge hot wort into cold water method", so the aeration is in the cold water, not the hot wort. I seem to remember Papazian saying something in TCJOHB about not aerating the wort until it has cooled completely.

On airlocks:

If you use an S-shaped double bubble airlock, a vacuum in the carboy will not pull water back into the wort. I always use them for the first few hours in the carboy, where the cooling wort may create a vacuum. Once when I attached a blow-off tube right away, I had it pull water through 3 ft. of hose back into the carboy - never again. Now I make sure that CO₂ is being produced before removing the S-airlock and attaching the blowoff tube. After it's done spurting its stuff, I'll attach any old airlock (always an S-shaped one on a plastic fermenter - It was previously noted that a vacuum can be created when picking them up) The S-shaped airlocks clog more easily than the econo-locks, so you have to watch out.

On explosive Carboys:

If the tube is 1/4" ID, then it has $\pi/16$ sq. in. cross-sectional area. If you have a, say 14" in diameter carboy, then the area of the bottom is $\pi * 49$ sq. in. If the level of liquid is below the neck of the carboy, then there is ~ 800 times as much total pressure on the bottom of the carboy (plus the pressure from the weight of the wort!) as there is against the blow-off

My apologies for being an asshole in digest #614.

Subject: Brew On Premises

Can anybody point me to a homebrew club anywhere between Toronto and Buffalo? I found the "Sensitive Hombrewers" in Hamilton, but they seem to be inactive as a club right now.

None of the homebrew shops around here (Burlington-Hamilton) carry liquid yeast cultures. Does anybody know of a supplier near Toronto? How about mail order houses? Who is near enough that the yeast would survive the trip? Is ordering liquid yeast this way advisable (possible)?

On a slightly different note, the latest thing around here is "Brew On Premises" facilities. They provide the equipment, sell the supplies, and do the cleanup. You mix up the extract and hops, and boil it up in their gas fired kettles. They run it through a heat exchanger to cool it, you pitch it, and leave it to ferment for 12 days. They then filter it and carbonate it, and you bottle it (they sell screw top bottles).

They provide for extract brewing only, with recipes posted right on the wall, and helpful staff on hand to direct you. They seem to be aimed at the "cheap beer" crowd (advertising proclaims 1/2 price beer!). A brewing acquaintance has tried a couple of these, and likes them. I tried

one of his, that was supposed to be a Newcastle Brown clone. It was a nice clean tasting brown ale. It certainly wasn't Newcastle Brown.

A recent batch of stout had a F.G. of 1.020, a bit higher than usual for this recipe. It foamed like mad (a problem I haven't had since you all straightened me out on pressure and opening the tap fully). Has anybody seen a correlation between F.G. and foaming with kegged brew?

Subject: Re: sanitary airlocks and carbonation

Re: alcohol in the airlock.

My molecular bio roommate guesses that the alcohol content of the liquid in an airlock should be at least 80%. I didn't query him at length, but he said that alcohol is not nearly as good at destroying things quickly, and a higher concentration of it is required to be useful....

A question: why use either CO2 from a bottle or prime the beer to generating carbonation in the keg? Does it take a lot of CO2 to carbonate? Is it worth it to avoid the yeast sediment? Is there something inherently different in these two processes?

It would seem to me that CO2 carbonation is ideal, since you don't waste any beer.

Hi,

I'm looking at ordering some hop rhizomes and would like some information. The types that are available to me are:

Cascade
Hallertauer
Williamette
Tettnanger
Nugget

I was thinking of ordering Hallertauer, Tettnanger and Nugget. The thing is I've never seen or used Nugget. So could someone give me an idea what it is like?[I'm basically looking at has a high alpha bittering hop]

Since I'm supposed to have my order in my the middle of next week I would appreciate email responses.

The second question I have concerns priming. I don't use corn sugar so I would like to prime with normal white table sugar. Does anybody know how they relate in terms of amounts to add?[I've used the fact that cane sugar is supposedly 45degrees extract/lb versus 35/lb for corn sugar but this gave me flat beer :-(] Since priming is normally my only sugar addition I'm not worried about it affecting the taste.

Thanks
Nick

From: hplabs!bnr-vpa!bnr-rsc!crick (Bill Crick)
Subject: Barley wine from mash

I tried to post this last week, but it bounced?

In my post of the other day about all grain barley wine, I suggested using the first run runoff to get a high gravity 1/2 batch. In that article, I presented it as if I meant to use no sparge water. This of course would probably compact the filter bed, and wreck it. This is not what I meant to say. What I meant was recycle the wort until the runoff is clear, to set the bed, and then add sparge water slowly to the top, as you runoff the high gravity wort. By knowing how much wort is in the bed to start, measuring runoff gravity, or watching for a color change, you can predict/detect when you hav ranoff all the initial wort, and are starting to get the sparge water coming through. This is when you will get a fairly sudden drop in the gravity of the runoff, and should consider your barley wine wort complete, and save the rest of the runoff for the lower gravity, or extract beer.

Hope this makes more sense??

Subject: Re: St. Florian

Kris Weiss (love that name!) asks:

>Now wait a second here. Is this the same Florian that contributes to
this
>journal? Is Florian the Dreamer also Florian the Holy?? I dunno -- the
guy
>always struck me as some kind of troublemaker...

I was named after my uncle Florian, who was in turn named after St.
Florian.

St. Florian is the Bavarian Patron Saint of the Fire Brigade. A couple
of
years ago i was in an outdoor shop in Munich (one of the biggest sport
shops in the world). It was converted from an old grand house, you know,
the kind with the square cedar beams that are about 500 years old. In
this house were examples of the old lamp stands that were built into the
wall. This is a concave notch cut out of the wall where they put a
candle in the old days. The concave acted like a parabolic mirror, to
reflect the light out into the room. In these concave areas, they used
to paint a picture and write something witty, for orneriness. One of
the areas had a painting of St. Florian hovering in the clouds above
a burning building (probably a brewery), and had an inscription written
in Bayerish which translated something like,

"Dear St. Florian, protect this house...burn another..."

Florian is an extremely Bayerish name. In the middle of Garmish-
Partenkirchen is a town square called "Floriansplatz". This is, many
Germans argue, the most beautiful place in all of Germany. I was there
in 1986 on a perfectly clear blue day. With the Zugspitze in the
background, I had a beer in "Florianstuberl", in direct earshot of
the Floriansplatz fountain. The beer was so perfect, it was like
no beer I have ever tasted since. Pity that we home brewers can't
duplicate it exactly. The stuff that memories are made of.

Florian, the not-so-holy.

The **ONLY** grades suitable are USP (suitable for use as pharmaceuticals) and FCC (suitable for use as foods). I glanced at an old Carolina catalog after I read Dan's message: anything that's USP or FCC is clearly labeled as such. For example, they have many grades of Calcium Chloride. The one Dan should buy is labeled Reagent **AND** USP. If it just says Reagent, or just says Lab grade, STAY AWAY FROM IT. This is really something you don't want to mess around with- non USP/FCC grade stuff is frequently purified with some truly nasty stuff. Some off the shelf Calcium Chloride in our lab had heavy metals measureing in the parts per million range- the FDA limit is somewhere in the low parts per BILLION.

Let's be CAREFUL out there!

Subject: Florida Brewpubs

There was a recent request for info on brewpubs in Florida. So once again I dug into the archives, expecting the brewpub scene in Florida to be similar to its neighboring states'. WOW - Was I surprised!!! Florida is blessed with 12 brewpubs (ahhh, the joyous decadence of Spring Break). It ranks third behind California and Oregon in total number of brewpubs, and is tied for fourth in number of microbreweries and brewpubs combined.

Here's what I found:

Clearwater - Hops Grill and Bar #1

Ft. Meyers - Kidder's Ale House

Ft. Lauderdale - River Walk Brewery

Gainesville - Mill Bakery, Brewery and Eatery #1
- Market Street Pub

Miami - Florida Brewing Co.

Pensacola - McGuire's Irish Pub and Brewery

Sarasota - Sarasota Brewing Co.

Tallahassee - Mill Bakery, Brewery and Eatery #2

Tampa - Hops Grill and Bar #2
- Tampa Bay Brewing Co.

Winter Park - Mill Bakery, Brewery and Eatery #3

Interested parties can email me for addresses. If anyone knows of new openings or closures :--<, please let me know.

Cheers,

Rob Bradley (bradley@math.nwu.edu) slipped in a shot at Eastern Washington U. in #615.

Well Rob, having moved from WSU (in Pullman, WA) just a year and a half ago I can tell you that there are be worse places to be employed than Cheney. Pullman for one, though it does have a good pub called Rico's. Cheney is close to Spokane, where Jim's Homebrew Supply is located. In my limited experience with homebrew shops this is quite a good establishment. Tom (the current owner) stocks quite a wide variety of extracts, grains, hops, yeasts, and wine stuff, as well as all the usual brewing equipment. His prices are quite competitive and he is a good guy, always willing to talk homebrew and give advice when asked for it. In addition he has a liquor license and stocks an incredible selection of micro and import brews. I noticed recently that he is advertising as a mail order supplier now and would encourage those of you who are looking for such to contact him for a catalog. By the way, he is the sponsor of the Rauchbier catagory for the AHA national competition. If anyone needs the address he has an ad in the 1990 special Hops issue of Zymurgy, or you can e-mail directly to me and I will supply the information.

Ein Prosit,

Dr. John

Subject: Claening copper

This talk of pots to span two elements made me think of a copper "boiler" I have in the basement that would span two burners, and should hold 10- 15 gallons. The only problem is that it is fairly oxidized from about 20 years of sitting in basements. Any idaes on an easy way to clean it? I seem to remember you could remove the axide off of copper with an acid, but forget which one? Nitric? Muriatic? any ideas?

Subject: lab grade chemicals

Date: 12 Apr 91 13:49:00 EDT
>From: "DRCV06::GRAHAM" <graham@drcv06.decnet@drcvax.af.mil>

In perusing my new Carolina Biological catalog, I have found some chemicals that would be useful in tailoring the mineral profile of my water. My question of any lab types out there: Can I assume that a reagent grade chemical will be safe to use in my beer, (providing that the chemical is not poisonous in the first place).

STOP! I would suggest not using lab grade or reagent grade chemicals. Although they may be pure, you don't know what the trace elements are. If you can, select pharmaceutical grade or USP-grade. Lab/reagent/ACS grades are good for lab work where one is not consuming them. A prime example is 100% ethanol. This stuff is pure, but to get it to 100%, they use benzene (or something like that), so there is a trace of benzene left in the ethanol. (It turns out that 95% ethanol is safer, since simple distillation will get you to 95% from ethanol-water mixtures.)

From: DAVIDSOND%AC%CSC@CSC.ISU.EDU
Subject: sm/sntp&

We've just started two batches of mead/metheglin:

One is 5 Lb. dark honey to 2 gal water & 1 quart raspberries (et. spicetera)

The other is 12 Lb. light honey to 5 gal water (ibid.)

FIZZ TRICKS for MEAD:

The batches are our first attempt at mead, so we're unfamiliar with how Montrachet yeast and honey coexist/mingle. Since we're interested in the drinks

having some fizz/carbonation when opened, I would appreciate help or tips on handling it. Specifically, Cheri Feinstein (some months ago) said that

one seals at a late stage in fermenting (how late?!) then 'kills' the yeast

with everclear or vodka and bottles it. Since my experience has been that

pouring carbonated drinks (or siphoning them) tends to agitate enough to let

a hefty share of the CO2 out... and since the yeast is hopefully (regrettably)

quite dead upon arrival in his/her/its new glass house (and thus unable to make

life fizzy for me)... I suspect this leaves a very mild effervescence, no?

Other postings seem to suggest one consults Specific Gravity ratings, or other

mystic help at 'guessing' the correct time to bottle. Since we'd prefer to

use caps, and since this is a first experiment with mead, complete with a very unique fermentation cycle compared to any of our limited experiences...

can someone either repost good estimated SG's for a recipe of 12lb. honey to five gallons water (estimated)... or Jeanne Dixon's toll-free number.

Well, that also mentioned the other option I've been handed: corks. That way

seems to allow options other than bottle-grenades... but we aren't equipped

with corker, corks, or any clue for that approach.

RACKING MEAD for clarity/speed/etc.

Also, regarding racking: Monday (Taxday) is day two, and I'm left with an impression that every few days I should be racking into clean containers.

This is for (what?) clarity? taste? speed to maturation?

SPEED MEADing

Finally, if I want to 'nudge' this toward an early maturation, someone said that

strangling the yeast early with grain alcohol added will help. Right? Wrong?

which? Oh-oh, the sysop's kicking me off!

Please, if any responses are 'time sensitive', post to me directly!!! The newsletter seems to take two days delivery here sometimes.

Subject: Root Beer

I just finished mixing up a batch of Root Beer (My wife doesn't drink beer, and wanted to play brewer with me.). As I was bottling it, I started to wonder, what stops the yeasti-beasties from eating all that unfermented sugar, and blowing bottles all over my kitchen. I thought that the yeast stoped working when either the sugar was gone or the alcohol reached some high amount (~14%?). I just gotta believe that my brew supply store wouldn't sell me a home bomb making kit.

The word "abdiij" is Flemish for "abbey". The "8983" is the zip code.
It is customary in Europe to precede the zip code by the country code,
so you don't have to write the name of the country on the envelope.
"B" is Belgium, obviously. Vleteren must indeed be the town, then.

I don't know what the abbreviation "V.Z.W." stands for.

Bill Crick mentions a
> copper "boiler" I have in the basement that would span two burners,
sounds like a laundry tub to me.

I would have a care and check just how this tub is constructed,
I would not be surprised to find that the seams are soldered
with a lead solder which would be fine for doing laundry, but
appreciably less than terrific for making acidic food or drink.

If the seams are rolled instead of soldered and show no grey metal,
you may well have something useful there.

Good Luck,

Carl

Only food grade chemicals should be used in brewing. Such chemicals will be marked "USP" or "FCC". I don't know what your supplier means by "reagent" or "lab" grade; USP and FCC chemicals have to meet well-defined standards of purity.

A friend in the chemical supply industry tells me that one DOESN'T want to take chances with non-food grade additives. They can and often do contain dangerous levels of lead, arsenic, cadmium, etc.

Subject: Spokane WA

In HBD 616 John E Lenz rises to the defense of the Eastern Washington region.
I would like to add that Spokane is also the home of the Fort Spokane Brewing Company. I was there last summer and I was very impressed. I forget the exact address, but it is located right in the downtown area. When I was there they had four of their own beers on tap, and Guinness and a few others. I was in a hurry (I had to meet someone at the train station) so I only sampled one. If I remember right, it was called "Red Alt" and I thought it was very good, although it was served too cold in my opinion. I can't remember what the other choices on the menu, but they looked intriguing and I regretted not having more time. (The selections were written on a chalkboard, so I assume they vary). The atmosphere was great. Also, in Couer d'Alene, Idaho (about 20-30 E of Spokane) there is the CdA Brewing Company, also known as TJ Fischer's Brewpub. As of last summer, they were brewing Centennial Pale Ale (I wasn't that impressed, but it won a gold medal at the Great American Beer Festival), Summer Weizen Light (which has a wonderful bready wheat flavor and aroma -- the only beer I've found which my wife will drink), and a bock (I forget the name, but I liked it) and a stout, which I haven't tried yet. The beer is available at several area restaurants and in bottles at local stores. The owner and staff are very friendly and will give tours if you call in advance. I'm headed out that way again this summer, and I would appreciate hearing if there is anything else in the area that a beer hunter should know about.

Subject: Foam

From: rob@maccs.dcss.mcmaster.ca (Rob McDonald)

<A recent batch of stout had a F.G. of 1.020, a bit higher than usual for
<this recipe. It foamed like mad (a problem I haven't had since you all
<straightened me out on pressure and opening the tap fully). Has anybody
<seen a correlation between F.G. and foaming with kegged brew?

There is a correlation between FG and foaming in bottles, and may be in
kegs depending on your carbonation method. The high FG may indicate that
the yeast isn't really finished yet. The beer then goes into its package
and finishes. If you're priming the green beer with sugar, malt extract,
wort or whatever, then there is more sugar present than the priming
addition would indicate. Hence more carbonation and foam.

If, on the other hand, you are artificially carbonating, timing may be
the key. One possible scenario goes like this.

1. Transfer to keg and seal
2. Pressurize beer to x psi
3. Wait n days
4. Tap

In step 2, the keg is pressurized to the level required to achieve the
desired carbonation. During step 3, the beer continues to ferment,
thereby increasing the pressure in the keg, and carbonation in the beer.
Again, it all depends on the timing.

I've had problems with high FG's and over-carbonated beer. It also seemed
to correlate with those fermentations that dragged on endlessly. I've
been working on a system that should alleviate this and other problems
that have plagued me. I'll follow up with the details after it comes
together.

Cheers,
CR

From: Crawford.Wbst129@xerox.com
Subject: All-grain troubles

I have been attempting all-grain brewing and have run into a problem. In three attempts I have ended up with extremely husky tasting brew. It is so bad that the beer is undrinkable. Here is a quick rundown of my process:

- I use pre-crushed, two row english pale malt from Great Fermentations.
- Infusion mash in a coleman cooler with the slotted copper pipe drain in the bottom
- Pre-heater water (about 170 deg) is added to the grain at a ratio of 1 quart/1 lb of grain, in a 5 gal kettle.
- Heat is added (via a gas stove) until the target temp. is reached (about 152 deg).
- PH is at 5.5
- This is then transfered to the pre-heated coleman cooler until conversion is complete.
- The drain is opened for the sparge. Sparge water is 165 deg at PH 5.5.
- Sparge is terminated before the PH of the runoff reaches PH of 6.0.

I believe my problem is directly heating a mash that is too thick. What grain/water ratio do you all-grain pros use? Do you boost temp only by adding heated water? Can you boost the temp. from sacccrification temp. to mash-out temp (or protein rest to sacccrification) by just adding hot water? Or is mash-out at 165 really necessary?

Any help would be appreciated before I screw up another attempt. Please hurry,
I might start worrying...

Subject: All-Grain Barley Wine

With the recent talk of all-grain barley wines, I thought I'd put in my two cents.....

A friend of mine, who is a professional brewer, made a batch of barley wine at home last month. Having a penchant for excess, and access to grain at \$0.23/pound, he used *70* pounds of grain, mostly pale malt. The mash was as stiff as he could get it (don't know the specifics), and no water was added after mashing in - no mash out, no sparge, no nothin. After draining the mash tun and boiling, he ended up with 7 gallons of wort at SG 1.120!!! (Don't try this at home kids! ;-]

It will be quite a while before we know the final results. Until then, we can only salivate.

From: hplabs!bnr-vpa!bnr-rsc!crick (Bill Crick)
Subject: Brewcraft injector

I have been using a brewcraft injector for years. First on a Safron Superkeg, and now on a Rotokeg. This injector fits onto the keg, and server to add CO2 to the keg to keep the pressure up in the keg by replacing the volume of the beer removed with pressurized CO2. The source of CO2 is the little soad siphon cartridges that are about \$0.50 ea. My five gallon keg uses up about 2 per batch. There are several cartridge injectors availble for plastic kegs. Most of them dump the whole cartridge in at once. If there is not enough room in the keg to hold all of the CO2 without exceeding the pressure relief valve pressure, the excess CO2 is wasted. The brewcraft injector contains a pressure regulator, that only fills the keg to a certain pressure, and shuts off. From there on, when you draw off beer, and reduce the pressure, it adds enough gas to restore the pressure. This gives more even carbonation through the life of the batch, and saves on the cartridges. The regulator works on the same principle as the regulators used with regular draft setups, using a spring, a diaphram and a valve to add the gas. The Brecraft regulator is a bit more Mickey mouse, and doesn't maintain teh pressuere as evenly, due to stiction in the piston that is the diaphram. Overall, it works quite well.

NOTE: when I go tmy injector, the little clear plactic piston (a disk about one inch in diameter) was cracked! When I returned it, the sotre had a whole box of cracked ones, and we had to sort through a box of new ones to find a good one. It eventually cracked, and a friend made me one from aluminum which has worked fine since. Several weeks ago I looked at Brewcraft injector in a store, and the piston was a green plastic that seemed more resiliant, so they may have solved the problem, but it may be worthasking the store if they get many back?? The original piston was hard, brittle, clear plastic.

The injector will also work as a relief valve. It the pressure gets high enough, the piston gets pushed far eough that gas will escape past it. NOTE that the pressure it relieves at is fairly high, and is higher than the relief valve that was in the lid of my superkeg. I have been using the injector as my relief valve on teh Rotokeg, with no problems for two years now, and I routinely add too much priming sugar so the extra CO2 gets vented, and purges some of the air out of the keg.

Alternatives are: Injector that adds whole cartridge; Refillable aerosol cans of CO2 that you use to "give the keg a shot by hand when needed"; CO2 tanks and regulators setup; Not filling the keg as much (I bottle 24 bottles from a 5 gallon batch and put the rest in my 5 gallon keg),

with lots of priming sugar (2 cups/5 gallons: YOU NEED A PRESSURE RELIEF VALVE!!)
the extra gas in the large head space will dispense most or all of the beer without adding any gas.

Bill Crick

I talked to a friend who is a Belgian national to see what he knew
about
this beer/place. He did not know the beer but he did know of Vleteren.
It
is not a town but rather an area of the Flemish part of Belgium. His
guess as
to the significance of the other letters and numbers on the top was that
it is
the address of the abbey. His parents, who still live in Belgium, are
coming
over for three months in October and his father has offered to bring me
up to
six beers of my choice (that he can obtain relatively easily) from over
there.
He is also going to try and bring several glasses and/or mugs including a
Chimay one if he can get it. He will also be bringing a somewhat larger
quantity of Jupiler for his son as it is his favorite beer.
Unfortunately,
Jupiler is not the best example of the finer Belgian beers. I have
another
Belgian friend who is a rabid fan of the Trappist ales and he probably
would
know more about this particular one as he hails from the Flemish section
of
Belgium. I have been unable to contact him as of yet.

How much sparge water do you use?? How far do you sparge (ie till the
liquid
runs completely clear)?? Perhaps you are oversparging, thus taking extra
astringency otherwise left in the grain bed along into the wort. This is
a
typical problem.

Grain/Water ratios vary with brewing technique, grain used and recipe,
though
the number I'm familiar with is 1qt. per pound of grain.

I used to have an Edme pressure Barrel, I spent \$40 on the thing and it
never
really carbonated properly, even when using CO2 capsules to inject extra
pressure. Today I wish I had just gone all the way and gotten the
Cornelius
System like I have now and not wasted the \$40. IMHO the 3 or 5 gallon
Cornelius
System is much more reliable and durable and produces much better
results, and
the extra cost was well worth it for what I consider a permanent piece of
equipment.

Subject: Root Beer, Jackson, Database

Ken Flowers asked why root beer doesn't turn into soda bombs:

Yeast need not only sugar but also nutrients in order to proceed with their fermentation duties. Since cane sugar has hardly any nutrients, the yeast quit working even though there is plenty of sugar left to munch on. Thus a sweet soda pop that is naturally carbonated.

Rob Caton, the Jackson book referred to is The World Guide to Beer, by 'Sir' Michael his rotund self. Available at a Walden's or B.Dalton's near you. A magnificent resource. Pictures and descriptions of damn near every beer in the world. Highly recommended to all homebrewers and a must for those preparing for the BJCP exam.

John Melby's idea of putting together a database of pubs, breweries, and homebrew shops is a great idea. I'd suggest sticking it in the archives. Beer travelers of the world could search there first before departure. We could get the information we want directly and immediately and save our fellow brew-buddies the task of writing the rather lengthy exposes of such and such a place, many times repeating a discussion from a few months past.

Subject: Water, water everywhere; and all the drops did stink.

Brewing with the Derry air is fine, but the Derry water is the pits!

First off, much thanks to all who put up with my novice questions. The first couple of batches of homebrew turned out very good. The problem is that our city water has a rather strong chlorint taste, plus some other off tastes and odors. I can identify these impurities in the beer, so I want to get a water purifier. I'd rather start with very pure water and add back the minerals necessary for a good brew than continue using this city hydrobilge.

I am confronted with three basic types of water purification units: Distillation, UV/carbon block and reverse osmosis with pre and post filters. I've ruled out distillation because they are more expensive and use a lot of electricity. Between the other two I can't decide. Each claims that the other type is no good, or not so good. What are thoughts on these devices?

The carbon block with UV sterilization seems very good to me, but the reverse osmosis people claim that the carbon won't remove the metallic ions from the water. The carbon folks claim that reverse osmosis is wasteful and no better than the carbon blocks.

I want the water to be as pure as possible. What do various of y'all think? If you email to me directly, I'll post a summary to the net.

Dan Graham, WA6CNN
Beer made with the Derry aire, and unfortunately, with the Derry water.

Subject: Home brewed pop

> As I was bottling it, I started to wonder,
> what stops the yeasti-beasties from eating all that
> unfermented sugar, and blowing bottles all over my
> kitchen.

The explanation given to me is that the soda mix doesn't have enough nutrients for the yeast to do much. Unfortunately, this is wrong, and I ended up with some very highly carbonated ginger ale when I tried it. Though there may not be enough nutrient for a good fermentation, your soda will slowly but surely gain pressure.

You must put your soda pop in the refrigerator when it reaches a good level of carbonation, or it will (really) pop!

Subject: RE: Homebrew Digest #617 (April 17, 1991)

Ken Flowers asks about root beer.

The yeast in root beer will have a harder time growing than the yeast in regular beer, due to the lack of yeast nutrients. However, root beer still has copious bomb-making potential. I made one batch of ginger beer in Pepsi bottles and came home one day to find a sticky slush of ginger beer and glass, and splinters of glass embedded in the wall at eye height.

After your root beer has gone the minimum amount of time needed to carbonate it, put it in the fridge. I've found that at Florida temperatures, 12 hours is sufficient to carbonate. Drink it within a week or so.

Subject: Root Beer

Ken Flowers says:

> I just finished mixing up a batch of Root Beer
Thanks, you goaded me into finally posting something I've been
meaning to write for a long time.

> As I was bottling it, I started to wonder,
> what stops the yeasti-beasties from eating all that
> unfermented sugar, and blowing bottles all over my kitchen.
Precisely the question I asked myself, and of course the answer
is "Nothing". Unless of course, you have a spare fridge to house
all your bottles at near freezing temperatures or dump something in
to kill off the yeast after you magically devine that the bottles are
sufficiently carbonated..

> I just gotta believe that my brew supply store wouldn't sell me
> a home bomb making kit.
Unfortunately they have. I always follow recipes religiously the
first time before modifying them. So when I mixed up a batch of
root beer from a Hires extract, I somehow forgot everything I had
ever learned about brewing. I did get a bit suspicious of the mumbo jumbo
in the recipe about adding more or less yeast depending on the
temperature.
Adding yeast is essentially a binary process. Either the yeast
grows or it doesn't. And it doesn't stop until it runs out of sugar.
The recipe calls for over NINE cups of sugar. Just think what your
beer would turn out like if you primed it with that much sugar.
I spent every evening for a couple of weeks opening bottles to release
the pressure. Then I had to add more sugar before serving for sweetening.
My kids didn't get to the point of staggering around, but
they did swear it was the best root beer they ever had :-)

The recipe I came up with (and works well for me) is:
Use one cup of sugar at bottling time (5+ gallon batch).
Before serving, put 1/4 to 1/3 cup sugar per 750 ml of liquid
(depending on your sweet tooth) in a clean bottle, pour in one bottle
of root beer, shake.
Adding the sugar directly to the root beer doesn't work well
because it foams all over the place.

Subject: Soda Pop, Weizen yeast, Grainy beer

Ken Flowers talks about rootbeer:

> what stops the yeasti-beasties from eating all that
> unfermented sugar, and blowing bottles all over my
> kitchen.

NOTHING!!! This is very important. I have exploded more than one batch of rootbeer in my time. I have, however devised a fairly safe way to make soda pop (using yeast to carbonate it). First, use only plastic bottles (and only new ones to boot). Plastic bottles will make a mess when they explode, but won't usually kill people. Secondly use a yeast that is fairly temperature dependent (an ale yeast is good -- bread yeast, lager yeast, champagne or wine yeast are all out). After you bottle, squeeze the bottles periodically until they are hard. Put them in the freezer. When they get cold enough (almost frozen), take them out and decant the liquid off of the yeast. rebottle and store the bottles in the fridge. I have found that this method gets rid of most of the yeasty taste and will give you much more control over the carbonation level. It's well worth the extra work.

Marty Albini asks about a pure Weizen beer yeast:

MeV sells one. I can't remember the number, but it is mentioned in the Zymurgy special issue on yeast.

Greg asks about husky tasting yeast:

Your method basically looks OK, but I can see a few places where you might be going wrong. When you are applying heat (and adding hot water) to the mash, make sure you stir like crazy. As long as you get no hot spots above 168 degrees F, you will be OK as far as huskiness goes. Also, I recommend a mash out as this will make your sparge go a little easier. The next possibility is that you are oversparging. A final pH of 6.0 is a bit high. Fix mentions that the industry standard is around 5.8 (Warning: possible faulty memory on this point :-)). The two batches I have tested have a final pH of around 5.5 (I usually get very good extraction)

Finally, you may be getting grains in the boil. I recommend recirculating your sparge until it starts to come clear (although, watch that final pH, you don't want it to get too high). You also have to watch out for leaching stuff out of the grains that will adversely affect head retention. As long as you keep the recirculation below 2 gallons, this should be no problem.

From: bliss@csrd.uiuc.edu (Brian Bliss)
Subject: mead

I just made a 6 gallon batch of orange ginger mead:

15 lb clover honey
juice from 1 orange (because I had no citric acid)
6 oz grated ginger
1 oz halletauer hops

combined above ingredients, brought to a boil.
took out a little wort, cooled down, added champagne yeast
and shook. boiled the remaining wort 30 min.
added another .5 oz halletauer hops. boiled 30 min.
turned off heat. cut 4-5 lbs of oranges in half, and squeezed
into the wort. Threw the halves right in after squeezing.
let sit 15 min. sparged into cold water, while removing the
orange halves and squeezing the last bit out (with clean
hands - very hot - ouch!). added yeast starter when cool.
I got a S.G. of 1.088 at 85F. It's been fermenting like
a mad dog for almost a week now. I'm not going to rack it
to a secondary until I slows down a little - Nothing's
settled out (except for a little bit of yeast) with the
rapid fermentation constantly stirring it up.

Anyway, hope this helps anybody who wants to try making
mead get the S.G right. btw, I practically had an orgasm eating
the last bit of fruit out of the hot, honey-soaked orange
halves after I was done.

From: Bob Devine 17-Apr-1991 1328 <devine@cookie.enet.dec.com>
Subject: Invasion of the Yeast People???

For the second time recently, after I gave a beer novice a bottle of my homebrew, they became very interested in brewing for themselves.

Now that got me thinking. If anyone ever read "The Selfish Gene" by Richard Dawkins, it may explain the reason for a sudden desire to be a homebrewer. In the book, Dawkins posits that it is really the genes that control everything and human beings are nothing more than a gene's way of making more genes.

Therefore it seems entirely reasonable that the yeasts used in homebrewing have mutated to control our very thoughts. Right now there are millions, nay, trillions! of yeasts inside your body telling you to MAKE MORE BEER!

On the other hand, maybe they just liked my beer....

Bob ;-)

From: Eric Rose <rose@aecom.yu.edu>
Subject: Cider Making

Howdy everyone. I'm new both to this list and to homebrewing.

When I was in England a while back, I tried several different brands of hard sparkling cider, and loved them all. The only brand name I remember was "Strongbow." They were all very very dry, and really tasty.

I'm writing to inquire whether anyone has a recipe for such stuff, or, even better, has made it themselves. Around September here in the Northeast, you can get excellent freshly-pressed apple cider from local orchards, so I thought I might try making some then.

Peace,
Eric Rose.

<So what I want to do is create a more formal database that I can query
<asking things like
<what pubs are in San Jose
<what microbrewerys are in San Francisco or in the 808 area code
<what beer stores are near Tulsa
<and so on.

<I already have a large amount of semi-formatted data (around a 100K
<annotated list of pubs including notes and comments from the net).
<Has anyone else already got such a program? Would anyone else be
<willing to contribute their list of pubs for such an effort?

Sounds like a great idea, John. I'd be happy to give you access to the
Celebrator's records. We've talked about creating such a database, but
thusfar it's only talk.

But alas, we stray from the topic of homebrew. So I pose a question :

Does S. Delbruckii have oxygen requirements similar to
standard brewing strains, like S. Cerevisiae and S. Uvarum ??

I'll be making a wheat beer soon, and would like to learn more about the metabolism of S. Delbrucki. If I use a mixed strain, will lots of O2 favor one strain over the others?? Can a pure strain of S. Delbruckii be used satisfactorily?? Any input would be appreciated.

A friend recently returned from Munich with a bottle of Amertaller Weizen which is unequivocally the finest libation in the Universe (beats a Pan-Galactic-Gargle-Blaster hands down!!). So I plan to culture the dregs. The brewery is very tiny, so I doubt they filter out the Delbruckii and then add a different strain to bottle condition. This is how the large German breweries make HefeWeizen (according to Dave Miller - me thinks).

Cheers,
CR Saikley

Subject: Pub Database

> We could get the information we want directly and
>immediately and save our fellow brew-buddies the task of writing the
>rather lengthy exposes of such and such a place, many times repeating
>a discussion from a few months past.

There is a benefit to these things being reposted (as Pat Baker of Crosby
&
Baker, & The Beer Bar Atlas fame can attest) regularly. That is that the
Brewpub/Beerbar industry is rather fluid :-). If a database is made, it
needs
to be updated. That can be a bit of work. Repostings have the advantage
of
being kept up to date in a distributed manner (ie lots of people doing
it), and
probably have broader coverage. Now I'm not against the idea, just
pointing out
some of the cons (since people have already mentioned the pros).

I personally have just made a directory where I keep a file for each
geographic
area, and concatenate new info onto the old files. If this thing does get
going
I'll gladly send you what i have to date.

Good Luck, keep us posted.

Subject: Eastern Washington is great, honest!

My sincere apologies to any Spokane/Coeur d'Alaine area residents who may have taken offence at my my crack about EWU in #615. For the record, I really liked what I saw of the area, Spokane seems to be a truly fine town, I really liked the Fort Spokane Brewery (I even bought the sweatshirt :-) - their Red Alt is very scrumptious indeed, and I actually do wish I'd got the job.

Craig Flowers - who has written me personally and apologized; his information was not so much false as long out of date - claimed that Northwestern is dry. Not only is that false, but I somehow felt that, being piggy-backed with the statement about Evanston, it was being held up as something out of the ordinary.

In the 19 months I've lived in the USA, I've visited a lot of universities to attend conferences, give talks and, most recently, interview for permanent faculty jobs. Every state school has been dry. EWU is only distinguished by being the only one of this number that I visited for reasons of a job interview.

The drinking age is 21 in the USA, and many (most?) undergraduates are less than that. I guess the dry schools see this policy as a way to limit their liability. It certainly doesn't curtail the drinking itself any more than Prohibition did.

As I understand it, different states had various drinking ages from 18 through 21 until quite recently, but were forced to toe the line at 21 by some recent federal legislation that predicated federal money for highways on a drinking age of 21.

The way I figure it, 19 and 20 year olds are going to find a way to drink no matter what the law says. I'd rather they could do it in pubs where they just might walk or take public transportation than have them doing it at tailgate parties which essentially guarantee drinking and driving.

I've lived in Quebec (drinking age 18), England (17? 18?) and Ontario (19). Being foreign parts, the moral standards were of course quite low :-) Nonetheless, I would be surprised to hear that the drinking and driving statistics are any worse there than they are in a typical State of the Union.

What do you suppose motivates the legislators in this country?

Rob Bradley
(bradley@math.nwu.edu)

P.S. I never received a copy of #615 (Monday). Could some kind soul out there send me a copy? Thanks a lot. Rob

From: Dave Sheehy <dbsh@hprnd.rose.hp.com>
Subject: Re: Soda Pop and exploding bottles

As we have seen in the last several posts the general consensus seems to be that making soda pop is an exercise in demolitions manufacture. My experience however has been to the contrary. I have some bottles of home made soda pop that have been sitting at room temperature (which can range up in the high 70s in the summer) for over a year. Why do I not have the problems that many others have had? I've thought over my procedure and think that I may have a reasonable hypothesis. My procedure is:

1. Put the required quantity of water (4 gals.) in my brewpot and heat. I may or may not bring this to a boil depending on how patient/distracted I am that day but the temperature definitely gets into the sanitation range (> 165 F).
2. Start the recommended amount of yeast (1/4 tsp) separately in a bowl of warm sugar solution.
3. Add the entire quantity of sugar (8 cups) and soda extract to the water. Dissolve the sugar into the water and allow the solution to cool to, oh say somewhere in the 80s.
4. Add the yeast starter to the soda solution and mix well.
5. Bottle immediately (do NOT pass GO, do NOT collect \$200 :-).
6. It commonly takes 3-4 weeks to carbonate. It's really much better after several months in the bottle. The flavors blend or something, it's a very noticeable effect.

Why does this procedure not cause problems? Here's what I think may be going on. The commonly offered explanation for why bottles of soda pop do not overcarbonate and explode is that the yeast is limited by available nutrients. I think this statement is true but that it is only part of the answer. In my procedure I heat the water up to a high temperature driving off any dissolved oxygen in the process. This limits the aerobic phase (and therefore the reproductive stage) of the yeast. This limits the effective population of yeast. With a limited population of yeast you are less likely to overcarbonate. In this scenario, the pitching rate becomes a factor. If you pitch a large initial population of yeast, you will get overcarbonation. In fact, the only time I've had bottles explode (and they blew up in the vegetable crisper of my refrigerator by the way) was when I exceeded the recommended pitching rate of

1/4 tsp. Therefore, I disagree with the poster who maintains that pitching is a binary function. I believe pitching rate is significant in this situation.

I got a whole load of pretty vehement email about exploding bottles about a year ago when I posted about an experiment in making psuedo low cal soda pop (I still haven't tried it but it involves using fructose which is 80% sweeter than sucrose, I think you can figure out the rest of my plan). Since I hadn't had the problems that these people had I've been thinking alot about my procedure and why I don't have the same problems. This is what I came up with. So, what do y'all think?

What I have is: "The Simon&Schuster Pocket Guide to BEER", by Michael Jackson. I got it when I bought his "Beer Hunter" videos. It claims to be "the connoisseur's companion to over 1000 beers of the world". It's a quick guide to a lot of beers, with a pretty decent index at the end. I like it very much. ISBN for it is 0-671-66225-2.

names,
>and two phone numbers

They are very strange. The proprietress is a Cuban-German woman who reportedly looks for asexuality in her staff. Zum Alten Fritz is the over-priced german restaurant. She opened the brewpub about a year or year and a half ago, and was immediately shut down for serving beer before the arrival of the license... The "Garlic Grill" is adjoining, and serves, obviously, nothing but foods with garlic. It opened a couple months ago.

Subject: Wiezen yeast

Re; the request for wiess beer yeast S. Delbruckii:

Mev does a pure S.Delbruckii culture, Mev 033. I've got a batch of FrancenWiezen brewing with it now. It definitely gives a clove tang to the beer.

The Yeast Special issue of Zymrgy mentioned the Wyeast 3056 as being a blend, and the Mev 033 as being pure delbruckii. They also mentioned ONE of the following, but I forget which: Wyeast has a pure Delbruckii culture, OR Mev also has a blend.

As far as getting the Mev yeast, they do have a US distributer, but I don't know who. I Canada, they presently don't have a distributor.

Mev's address is: P.O. Box 123
Waterloo, Ontario,
Canada.
N2J 3Z9
Phone 519-742-7227

Note they are moving in a month or so to a bigger facility.

I get my Mev yeasts from: The Hop Stop
1661 Montreal Rd.
Ottawa Ontario
Canada
K1Y 6N6

613-748-1374

Hop Stop will do UPS mail orders if you want.

Hope this helps.

Greg: Re the Husky flavor: I don't think heating the thick part will hurt, as

decoction mashing biols the thickest third of the mash
In may not be the mash? Too hot a temperature removing
tannins results in an Astringent taste. Is that what
you mean by Husky? I know the Zymrgy troubleshooting
issue lists a taste specifically as "husky"> I forget
what the cause is. I believe they list Astringency
as a separate flavor characteristic.

Looking at my own posts, I notice a lot of character reversals that I don't seem to notice when I proofread. Blame ti on being left handed! If you can't understand some words, try flipping character pairs around. Os there a Unix spel checker? How do I use ti?

Well, I can't recommend a kit, but I've had success making a Salvator-like doppelbock in the past. I wrote an article for the Maltose Falcons newsletter a while back, and since I still have it lying about, here it is (sorry about the length, but...)

Thinking About Beer:
More About Recipe Formulation
by Darryl Richman

Brewing the 1st place Bock beer wasn't a slap-dash effort. It's the second bock I've attempted, and the first was a disaster. Let me lead you through the development of the recipe for this beer, in a qualitative rather than quantitative way. You don't need the specific numbers for this and that if you understand why you need to do something.

First, let me tell you what I want to make: Paulaner Salvator. See, I have a goal in mind. I like that beer because, although it is big and malty as a doppelbock should be, it isn't overbearingly so, like EKV 28, which I find to be cloyingly sweet and unbalanced. Salvator actually has a reasonably dry finish, and a hint of hops in the aftertaste to keep you from getting tired of it. The beer is dark brown, but not opaque. There is no hop aroma, and very little flavor from the hops in the mouth.

My first approach was to look at the beer and say to myself "it's dark..
.
add some black malt. A little bit of Munich malt as an adjunct. And throw in lots of that klages malt to get the body that we need." But all of that malt needs a lot of sparge water to get the full extract from the grain. Lots more volume than I can fit into my boiling pot. Barleywines are made from only the first runnings, and what's left is used to make low gravity Mild. Finally, I thought, "only use boiling hops-we don't want any aromatics."

So I made a big, black lager beer. It wasn't opaque, as I had wanted, but it wasn't the right color, either. It was malty, but it didn't have the right malt character to it. It had that black malt bite that wouldn't smooth out with aging. In short, it was very little like Salvator.

What was wrong? I turned out a fine beer. It was clean and malty. But I had shot far wide of the style. Clearly, I needed to understand the style better before I could make my beer.

What malt is used to make a bock? The style comes from Bavaria; the Paulaner brewery is one of the big six in Munich. I had used a bit of

Munich malt--about 10%--as an adjunct. But Munich malt is a natural, local malt for a brewer to use there. It is also darker than the very pale 2 row klages, although not by a lot. Munich malt is noted for its toasty character, and that toasty aroma was precisely what my beer needed. Clearly I was onto something here: try to make the beer with more of the indigenous ingredients.

I was not displeased with the hopping in my first attempt. It was the only thing about the beer that seemed to be right. I had used exclusively Hallertau hops, and that seemed to be right. It's best not to mess with things that work.

Fred Eckardt, in his "The Essentials of Beer Style," said that I needed an original gravity in the mid 70s. I had done that by using enough malt to make a 90s gravity beer, if all the extract could have been pulled into the required volume. Of course, barleywines are special beers, made only occasionally. Bocks and doppelbocks are much more frequently made, and I reasoned that the thrifty brewer wouldn't waste valuable extract on a regular basis.

Well, if I couldn't get the needed extract into less water, I would have to remove some of the water afterwards, by boiling. Hmmm, a long boil would definitely caramelize some of the sugars and darken the beer. Bingo! By reducing the beer in the boil, I could get the extract and darken the beer to the right color, while controlling the volume. The pieces of the puzzle fit into place.

So that is what I set out to do. Here is my recipe for 15 gallons of all-grain Bock Aasswards:

24 lbs. Munich malt
6 Vienna malt
6 2 row Klages malt
1.5 80L Crystal malt

I treated my medium hard water with 18 grams of Calcium Bicarbonate. I mashed in with 10.5 gallons of water, which is about 1 1/8 quarts per pound--pretty thick mashing! This was dictated by the size of my mash tun, which I filled right to the brim. I followed a mash program of 0:50 at 50C, 0:20 at 58, 0:40 at 65, 1:30 at 70, and a mash off for 0:15 at 77.

I sparged for almost an hour and a half, collecting 19 gallons at the end. I determined the end point when I could no longer perceive any sweetness in the runoff (at about 1.010 gravity).

At this point, I had to boil in two pots. I boiled for a total of 3:20, until the volume was down to about 13 gallons. As the volume decreased in my regular kettle, I added back the wort from my other pot. Getting down to 13 gallons was also dictated by my setup, as I cannot get a good whirlpool at the end of the boil without 2 gallons of headspace. I added my hops (200 grams of Hallertau pellets) about 2:00 into the boil, not being quite certain how long the boil would have to continue. The result of this was a beautiful brown wort with lots of red highlights.

I pitched this with a 2 liter starter I had retrieved from a batch of lager I had just made with an AB yeast strain. This wasn't my intent, but the starter of Bavarian yeast I had made didn't smell right. The AB yeast likes relatively warm conditions (50-55F), but I held it down at 48 for the primary. The original gravity, adjusted to 15 gallons, was 1.075. After three weeks I racked it and topped it up to 15 gallons, and brought it down to 36F.

I bottled 5 gallons 6 weeks later with 130 grams of dextrose with a final gravity of 1.022. That yields a beer of about 6.5-7% v/v, which is perfect. Then I put the bottled beer back into my thermostat-rigged chest freezer and held it up to the present at 36F. The other ten gallons went into two kegs, which I carbonated by overpressuring.

I'm not going to claim that this is the way to make an authentic bock. In fact, I'm not going to claim that this is at all authentic, because I don't know. What I do know is that I was able to reason my way to making what I think is an authentic-tasting bock beer, and the 2nd round judges at the AHA National Competition seem to agree.

Subject: Spokane red

In addition to Fort Spokane Brewery and Jim's Homebrew (now of course run by Bob) Spokane also has a wonderful tavern with over 20 beers on tap, most of them from microbreweries in the Northwest. It is the Viking and is only about six blocks from downtown. The only thing we can't find beerwise is a good homebrew club. We moved down from Anchorage last year and the Great Northern Brewers, the club in Anchorage, is sorely missed. In addition to the places mentioned above Hale's Brewery will be moving from Colville, Washington to Spokane sometime this year so another beer attraction will be available.

Well, maybe not the simplest recipe, but I made 'potlatch doppelbock'
from The Complete Joy Of Homebrewing. This is a partial extract
recipe.

I had a lot of trouble with temperature control with that batch. The
temp was all over the map, back and forth, too hot and then too cool.
None the less, the beer was one of my best batches ever! Well ballanced,
smooth, and rich. Try it!

Subject: Water and brewing, a summary.

Firstly, many thanks to the many who emailed me directly about water treatment and purification. I've also read, (had read to me ... I'm nearly blind ...), some relevant literature on water. I also had a long conversation with a water chemist at The Water Test Corp., in Manchester, NH.

What I've learned is that the water purification scene is confusing and there are contradictory claims aplenty. These seem to be the main kinds of purification and filtering methods: Boiling, charcoal filtering, carbon block filtering, UV sterilization, reverse osmosis, distillation and deionization.

A lot of the people who wrote to me said they boiled their water before using it to brew. This can be useful if it is boiled for an hour and allowed to sit until cool so there can be a "cold break" and an opportunity to get rid of the sediments on the bottom of the boiling vessel. Boiling also gets rid of most of the chlorine and a good portion of the volatile organics like benzene and phenol. The problem with the organics is that once out of the water, they are in the air, thusly, in your lungs.

The simple charcoal filters like the Teledyne, and others that attach to the faucet are only so-so. They do remove chlorine and some organic stuff, but wear out very quickly and once worn out, tend to release all that stuff they caught at first.

The carbon block filters are pretty good if the water path through the carbon is long enough, say fifteen to twenty inches. These will not remove the light metallic ions like sodium and potassium. They do remove lead and other heavys, all organic matter and virtually all nasty chemicals. They produce a very good tasting water. Since they do not remove all minerals, they may leave the water just right for brewing, or some additional minerals may need to be added. The good carbon blocks filter down to .75 micron. Most mineral ions are in the 5 nm to 80 nm range so they can't be removed by any type of filtering.

The ultraviolet light idea is used in high grade lab purifiers to sterilize the water. Sears and Electrolux market carbon block filters with Ultraviolet lights. The water passes by the UV light both before and after being filtered.

The reverse osmosis devices do produce very pure water. The water is nearly of distilled quality in terms of total dissolved solids and mineral content. Since distilled water isn't much good for brewing, these units

probably produce water that is too pure and would need additional minerals in almost all brewing cases. While this is fine as far as I am concerned, they are very pricy. Unless you want to pay in excess of \$1,000, you can only get three to six gallons a day, which is not always adequate. The carbon block filters are high volume, a gallon per minute is normal. The RO units also tend not to be very portable, while a countertop carbon block unit is easily moved for brewing at a friend's house.

Distillers are good if you want mineral and substance free water ... except for volatile organics which most non laboratory grade stills transfer from the source water to the distilled side intact. Good distillation units are in the \$1,000 to \$1,500 range, so out of my range.

The deionizers are the ultimate in mineral removal. They must be coupled with some other method, however, to get rid of the organics and bacteria or viruses. They tend to be expensive, but one day, I'll probably spring for one to piggyback on my UV carbon filter ... the best of all worlds.

As was obvious, I have decided on the carbon block unit with the ultraviolet light sterilizer. I wonder what would happen if I modified the unit to use just the UV light and passed the wort by it on its way to the fermenter ... hmmm ...

Well, that's a thumbnail sketch of what I found out. You can spend as much or as little as you wish to get pure water. One thing I did find out was that most bottled water isn't worth a tinkers damn. There are virtually no regulations on the water. You could bottle some water from your pipes and call it "jerry's super duper spring water" in most places and there are no laws to stop you.

So, I'll be getting my unit on Monday, assuming it passes my wife's palate, she has a very sensitive water taster. (She still thinks of the carbon filters as fish tank filters, even though there aren't any fish.)

I hope some of this is useful to people. Water is a very important factor in beer and I want to eliminate all the potentials for disaster that I can do without spending the earth.

Dan Graham, WA6CNN
Beer made with the Derry air and the filtered Derry water.

From: BAUGHMANKR@CONRAD.APPSTATE.EDU
Subject: Sterilizing, cleaning copper in chillers

Darren Evans-Young hypothesized that the sterilization method he was using for his counter-current wort chiller was the source of the recent infection of his beer. This is a subject dear to my heart because I've been using (and selling) counter-current chillers for about 8 years. I had always stored my chillers with a mild solution of clorox and water (1 teaspoon clorox per 1 gallon of water) in the chiller between brewing sessions. Since this worked for me-never an infection in 8 years-I recommended the same to my BrewChiller customers.

Then a friend in the plumbing business pointed out that they use copper to sterilize swimming pools when they become real funky. It seems that copper has anti-bacterial properties. Added to that were the comments that the clorox caused little blue flakes to form inside the copper tubing. I've never worried about the blue flakes because even though blue, they were sterile, and didn't seem to affect the taste of my beer in any way.

Still blue flakes were a recurring comment and I began to consider doing what Darren did, use boiling water to sterilize my chiller instead of storing it with the clorox solution in the tubing. And so far so good, but I still do a quick 30 minute clorox soak prior to brewing. I'm a paranoid at heart. :-)

To insure that boiling water sterilizes the copper tubing, one must siphon it through the tubing when the chiller is dry, that is, no water in the "cooling chamber". This must be done both after a brewing session and before the next one. So my question to Darren is: Is that they way you handled your sterilization procedure? If so, given what my plumber friend said, I'd be surprised that the chiller is the source of the infection. Still I'm not a chemist and I'd be interested in what the net has to say about all of this.

While we're on the subject:

A few digests back, someone pointed out that new copper has oils which must be removed before first use of a chiller. That's absolutely correct. I think they use silicone oils when extruding the copper tubing. I've always recommended doing a couple of clorox soaks (1 Tablespoon clorox to 1 gallon of water, for 30 minutes) before using copper chillers for the first time. Following up or interspersing it with a couple boiling hot water rinses is a good idea as well.

Cheers,

Kinney | Beer is my business and

Subject: Re: Pub Database

KRB> John Melby's idea of putting together a database of pubs, breweries,
KRB> and homebrew shops is a great idea. I'd suggest sticking it in the
KRB> archives. Beer travelers of the world could search there first
before
KRB> departure. We could get the information we want directly and
KRB> immediately and save our fellow brew-buddies the task of writing the
KRB> rather lengthy exposes of such and such a place, many times
repeating
KRB> a discussion from a few months past.

Yes, Yes, Yes! A few months ago I tried to motivate the same thing.
(Even discussions on removing repetitiveness are repetitive)

Remember the HBD FYI?

As for local brewpubs and good bars: I suggested an individual in each
area
of the country write up a few page article on what's happening in their
area. Upon completion this would be posted to the digest for review by
the
masses. In it's final draft it would then be put on-line with the
archives.
Then as it grew out of date the author would revise it and repost to
digest
and finally back to the archives.

This could also work for basic homebrew subjects. For example, An
article
on 'Dry Hopping for the Homebrewer'. This would work for many repetitive
topics on the digest. All that's needed are motivated individuals who
feel
that they know a lot about a particular area of brewing to write up a
comprehensive article on their area of interest. Of course the author
would have to be willing to take into account other people view and
techniques. However, as long as the topics are on basic brewing
practices
there shouldn't be much controversy.

The last time I brought this up the general opinions I received were
good
but nothing much happened. A brewpub/bar guide may be a good place to
start to get people motivated.

Personally I feel Boston is a good place to start, seeing as how this is
the largest metropolitan area near to this years AHA National Conference.
I would be willing to put together a list of what's happening in
Massachusetts. Anybody with an opinion or list could send it to me and I
will incorporate it.

Anybody for Vermont, Maine, Florida, ... ?

Subject: Re: Infected Batch

>I've got a batch of bitter in my secondary that has what looks like
>white strings on the surface. You have to look closely or with a light
>to see it. I suspect the lactobacillus bug has got me.

I had a batch that had a greenish "pond scum" sort-of on top. I say sort of, because it wasn't floating -- it was just below the surface. I tried to photograph the scum in the carboy before racking to the keg, but was unsuccessful. When I racked, I tried to leave it behind, but I think that was unsuccessful also. The flavor was just a tad on the sour side, but not overpowering. I primed the keg and let it sit at 68F for 3 weeks. After the three weeks, it tasted normal. Actually, this was part of an experiment. I brewed two batches of extract brew (1 can M&F Old Ale Kit + 1 oz Hallertauer boil + 1 oz Hallertauer finish) under the same conditions (except 1 week apart). In one I used Wyeast (I don't recall which but I have it in my notes) and in the other, I used the Muntona yeast provided with the kit. The Montona batch had the pond scum. After the three weeks, the only obvious difference was in a slight phenolic taste, but I wasn't doing a formal evaluation, so I don't recall which had the phenolic taste. I will do a formal evaluation (blind taste test with crackers & water between, etc.) eventually.

Back to your question. I suggest you ignore it. If it really is lactobacillus, I suggest you call it a pseudo-lambic and enjoy that.

On a semi-related note, this is my second request on this point, if I don't hear from anyone on this topic, I will assume I imagined it: About a month ago, CNN had some story on a link between bread mold and cancer. Does anyone have any more info on this? This probably doesn't affect us brewers because the alcohol, hop oils and lack of oxygen probably make beer an uninviting environment for bread mold. Right?

Al.

Subject: Re: Jackson book.

>What I have is: "The Simon&Schuster Pocket Guide to BEER", by Michael
>Jackson. I got it when I bought his "Beer Hunter" videos. It claims to
be

I too got the videos and the book came with them, however, two weeks ago
I received the new 1990 edition and it has a lot of new beers in it.
The pictures and text up front have been cut out. He now starts directly
with the first region (England, Belgium, etc.). At the same time I
bought
the other book by Jackson (the name escapes me). This one is hard cover
and has lots of photos, labels, etc. Each has its place. The only
problem

I had with the pocket guide was that while my friends just picked beers
by curiosity (from the extensive list at Winekeller in Skokie, IL - near
Chicago) I was still matching the book to the list. The price of obscure
taste is high: \$8.00 for 12 oz of Mort Subite Kriek (Sudden Death Cherry
Lambic)! I think the Lindemann's was \$8.00 also.
Al.

Subject: Cooking with homebrew

I suppose that this isn't 100% in tune with what this list is for - my apologies. But, has anyone else done any cooking with homebrew? My wife and I recently made a loaf of beer bread (using a simple supermarket beer bread mix). The recipe called for 12 oz. of "premium American beer". Since I rarely buy commercial beer anymore, all we had was various batches of homebrew, so I used a bottle of ale. (Well, to be honest, she had some Coors Light, but I couldn't imagine how that would be any better than using water...) The ale was rather hoppy, and I was curious how that would affect the bread. As it turned out, the bread had a subtle hop taste that was great, IOHO.

If anyone has any good recipes for that call for beer/homebrew, I'd love to see them. Please email and I will write a short summary for the digest.

Cheers,

Ken

From: Paul Bigelow <bigelow@waterloo.hp.com>
Subject: Re: Root Beer question

> Is the only purpose of yeast and fermentation to carbonate the root beer?

Yes. It's just a question of economics. A pinch of yeast and a cup of sugar amounts to pennies. A carbonation system requires a major capital investment.

> Since I have a keg system, couldn't I just mix up the appropriate amounts
> of sugar/syrup/water/?? and carbonate it artificially?

Yes. Most keggers use systems originally designed for making soda pop.

I have only a soda syphon, which requires one CO2 cartridge per bottle of root beer. I can buy commercially made root beer for the cost of the cartridge. That's why I use yeast to carbonate.

From: Jim Anderson <andersj@jacobs.CS.ORST.EDU>
Subject: too much body

When attempting our second batch of homebrew, my friend Aaron came up with the idea of adding crystal malt to the wort. Since Aaron's ignorance of homebrewing is only slightly less abysmal than mine, I didn't object when he decided to put two pounds of the stuff into our 5 gallon batch. Later Aaron finds out the purpose of crystal malt is to add body. Let me tell you, we DEFINITELY have body.

Can anyone give me a suggestion as to how to remove some of the sediment before we bottle it? Direct email is fine, unless you think this would be a question of general interest.

Thanks in advance.

From: hplabs!mage!lou

Subject: chilling wort

I finally broke down and made an imersion wort chiller (I lucked into another homebrewer who wanted one and we got a box of 50' of copper tubing for 40% less than the regular per foot price).

I used to chill my wort by putting my brewpot in cold water in the sink (constantly being replaced with running water) and stirring the wort to speed cooling. This time I put cold water in the sink, put my brewpot with the chiller in the water, and used the output of the chiller to refresh the water in the sink (after it started coming out cool). After about 10 minutes, the pot was still too hot to touch. I swirled the chiller around to stir the wort and the pot immediately cooled and I poured the wort into the fermenter a minute later.

The point of all this is, I never heard or read of anyone using their chiller to stir the wort but it certainly made a big difference when I tried it. In fact, using my usual method of pre-chilled fill water my initial temperature was 50F and I don't know if my yeast will survive the shock.

From: rtidd@ccels2.mitre.org (Randy Tidd)
Subject: Water water everywhere

I've been thinking more and more about the water I use to make my beer. I've made about 6 or 7 batches that I thought were pretty good -- but when I helped a friend make his first two batches, I noticed quite a difference in the way the beer tasted. The stuff made at his house was "cleaner", with a crisper taste and no excessive bitterness nor off-tastes that I sometimes find in my beers. Since we both used the same kit for our first batches, i've decided it's the water.

In my supermarket I see both distilled and "spring" water for sale for somewhere between \$0.69 and \$0.99 a gallon -- not too bad. I assume the spring water would have some stuff in it (i.e. minerals) but that the distilled water would have virtually none. What minerals, if any, would I have to add to this water? I've seen a lot of recipes that call for Burton water salts or gypsum. What results can I expect if I use only pure water, malt, yeast and hops?

I do mostly extract brewing, with no more than 1-1/2 lbs of specialty grains per batch (usually) so I don't think I have to worry about water pH or anything that you mashers need to worry about. Is this true?

Thanks! Please send e-mail unless you think this should be a new thread.

From: Doug Dreger <dreger@seismo.gps.caltech.edu>
Subject: Dry Hops

I've added about 3/4 oz of hops to the secondary when I racked, and now I have hops just about everywhere with the most at the surface. My question is, do the hops at the surface and those that seem suspended within the beer drop out? I suppose it doesn't matter whether they're at the surface or the bottom as long as they're at one end and not suspended.

I added them about 2 days ago now, and plan on leaving the beer in the secondary for 2 weeks. But I am interested in hearing of others' experiences.
Please Email responses.

Thanks
Doug

The fact that blue flakes were coming out indicates that there was a layer of blue stuff inside that had formed and was flaking off...not necessarily that all of the corrosion was washed out, though. In industrial applications, this stuff is very important, because fouling reduces drastically, in many cases, the efficiency of heat exchange. I don't suspect it matters much in a home-application, though. I am still pretty sure I wouldn't want it in my beer, for no real scientific reason, just because I'd "know" it was there.

Sorry to keep harping on this subject, but I think it's VERY important. Bleach will have very little effect in dissolving oils. Hot water may "soften" the oil enough that some will float out, but it will not get the thin layer off the edge of the copper. You need one of two things which interact either chemically or physically with oil to remove it: Either something with surfactant properties (soap) or a solvent (alcohol will work). I really tried about everything possible running through my chiller to get this gunk out, and nothing was effective. I ran hot soap solutions through it, propanol, and even pine sol (this worked a little bit). Simply rinsing with this stuff was not effective. It actually required physical agitation to get the oil out...which meant uncoiling the darn thing and fighting with it half a day with stiff wire and cotton balls.

The easiest reliable way to know if you have oil in there or not is to actually dip a cotton swab in rubbing alcohol and stick it in, rubbing it around. If it comes out black, that's grease or oil. After you wash it out, test it again, inserting the swab to a different depth, so you don't test the same area you swabbed clean earlier.

The other option is to say, "I can't taste it, so who cares?" It just depends on what kind of person you are. Just knowing it was there was too much for me to relax about.

From: "Andy Wilcox" <andy@eng.ufl.edu>
Subject: MeV German Alt Yeast

Has anybody brewed with this yeast before? Here's my situation. I started the yeast in a two-quart malt solution. From this, sterile agar slants were inoculated. The original starter was then used to brew a batch of beer. This fermentation was slow to get going, but then produced a slab of light brown material covering the top of the glass fermenter. There is a strange odor to this brew - not "bad", per se, but strange. It's improving significantly with lagering (1 month now).

Now, the slants. They were my first. Not knowing what a healthy slant should look like, I assumed these were good. They were not "pure creamy white" as described in the Leistad book, but more like light creamy tan. (One of the slants did become infected with some green goo. I *knew* that wasn't right :-). From this slant, I made a 100ml starter, and then pitched this in 1000ml and then 2000ml. This was pitched in wort. This fermentation is behaving exactly the same as the original, except it started much faster.

Is this "normal" behavior for this yeast? I'm dissapointed that it seems to need so much aging. I *really* like the german Alt style, and would like to have it mature sooner.

Subject: Yeast for Lambics

Hello all,

I have just added cultures of *Brettanomyces Bruxellensis* and *Pediococcus Cerevisiae* to my culture collection. These are the two main yeasts which give Belgian Lambics their distinct characteristics.

Both of these cultures are from a 'reputable lab' which wishes to remain anon. These are pure cultures, not sludge from the bottom of a bottle.

If there is sufficient interest, I will make them available in liquid cultures. What I need to know is if there is sufficient interest.

If you're interested in obtaining subcultures or just getting on my mailing list please contact me at msharp@cs.ulowell.edu or (508)441-2220.

(if your e-mail bounces try msharp@hawk.ulowell.edu)

I'll be using the mailing list to keep net-folks up to date on the availability of special yeasts & bacterias as well as equipment and techniques for making pseudo-lambics.

FYI, I can probably start subculturing in about a month or by special arrangement prior to that. (I'm running some test batches at the moment)

Subject: re water purification

Some thoughts on a couple of water purification messages in HBD #620:

Dan Graham said:

>As was obvious, I have decided on the carbon block unit with the
>ultraviolet light sterilizer. I wonder what would happen if I modified
the
>unit to use just the UV light and passed the wort by it on its way to
the
>fermenter ... hmmm ...

I don't think this would be a good idea. We all know what certain wavelengths of light can do to hop components; while I've never heard of UV being implicated, it wouldn't surprise me if there's something in your complex soup that could get re-combobluted into something nasty smelling/tasting after getting hit by UV.

Randy Tidd sez:

>In my supermarket I see both distilled and "spring" water for sale for

>that call for Burton water salts or gypsum. What results can I expect
>if I use only pure water, malt, yeast and hops?

You'd probably be okay using spring water, but you might run into problems with using only distilled. Yeast require a bunch of bizarre minerals at very low concentrations which wouldn't be in distilled water, and wouldn't be added with gypsum or burton salts. However...

>I do mostly extract brewing...

So what I said is probably moot. The trace minerals extract adds back are probably sufficient, and would probably allow you to get by using distilled water plus burton salts.

From: John Mireley <mireley@horus.cem.msu.edu>

Subject: re water purification

Greetings. As a newcomer to the art/science of homebrewing I have several questions concerning glass ware. I recently purchased, at a garage sale, the glassware of a fellow that made wine. I got two five gallon carboys and a half dozen glass jars. The glass jars and one of the carboys seem to have been made by the same company as they all have the same sort of pattern on their bottoms. All but one of the jars is three or so gallons. The odd jar looks like it will hold five gallons. All have a threaded wide mouth and a wire/wood handle. The bottoms have a random pattern of lines that look like the patterns in cracked mud. I would guess they are there to increase the strength of the bottoms. They are marked on the bottom with an "I" in a diamond and an oval. What were these jars made for? All the jars and the carboy have, what appear to be small curved cracks in the bottoms. The 5 gallon jar has a small crack in the side. Do these cracks represent a problem? Could the 5 gallon jar be used if I wrapped the jar with, say a fiberglass, tape?

Can a wort that has been pitched and does not start fermenting be reboiled and repitched?

I bottled my first batch of beer a week ago. We ran out of beer Saturday and money on Friday so my wife wanted to start drinking the green beer. I objected but she insisted. She says she likes it better than anything that we have been buying. Are there recipes that are designed not to be carbonated?

When using hopped extract, I have 6lbs of M&F amber, do the producers assume that you will be mixing it with some amount of unhopped extract or other sugar source? Can I just use all six pounds to make a batch or will it be too heavily hopped?

John Mireley

Subject: Long Term Physiological Effects of Beer Drinking

Does anyone have any hard information regarding long term physiological and/or psychological affects of drinking (home brew) beer at the rate of 5-6 pints a week? What about 8-10 pints a week? What about abstinence and binging?

I consider 6 pints/week to be moderate. My wife, who works as a statistician in the medical community, typically considers more than three bottles of beer a week "problem" drinking for classification purposes.

I take popular medical recommendations with a large grain of salt. They seem to change every six months. So the current fad of near abstinence is pretty suspect. Info, or pointers to info, names of researchers, etc would be helpful.

From: "John E. Lenz" <JELJ@CORNELLA.cit.cornell.edu>
Subject: Random(?) notes

A few comments regarding items in HBD #621:

Chris Hudson asks: ...but has anyone out there tried quart Mason Jars rather than bottles?

I'd recommend that you save the Mason Jars for the output from your still
Chris. If you are planning to carbonate your beer the Mason Jars will probably not withstand the pressure.

Andy Wilcox asks about the MeV German Alt yeast,

I haven't used this particular one, but have used one of the Wyeast German Alt cultures with good results. Don't worry too much about the color of the yeast growing on your slant, as long as it looks clean and uniform. If you haven't seen it, there is a good article by Farnsworth in the Zymurgy special yeast issue. One of the things that he recommends is cooking up your slants and letting them sit at room temperature for about 5 days to ensure that no unwanted organisms have taken up residence in the tubes. If you like the ALT style and remain disappointed with some aspects of the MeV culture I would recommend trying one of the Wyeast Alt cultures (I believe that they are marketing two different Alt strains now).

John Binkley in responding to Randy Tidd's query about using distilled and spring water says he thinks spring water is ok.

Probably, but check the label to see if it has an analysis. Some of the spring water I've seen being commercially marketed contains very high levels of bicarbonates, which you probably shouldn't be putting too much of in your wort regardless of whether it comes from a mash or extracts. Also, the popular press has lately run a lot of stories about unscrupulous operators who are labelling and selling just about anything as spring water, seems that there isn't much regulation in this area, or if it is it isn't being enforced too vigorously. Caveat emptor.

John Mireley asks about glassware, lightly carbonated beers, and hopped extracts.

Given the recent posting (I can't remember the issue) from the poor soul who had his carboy expire during a fermentation I'd be mightly hesitant to use those carboys that look like they are already cracked. After investing the time and effort required to produce a batch of beer it would be a crying shame to have the carboy crap out on you. An being new to the hobby you might even find yourself in a situation where you don't even have a beer to cry into.

I claim no particular expertise on the topic of lightly conditioned beers, but do remember reading that many of the styles of beer served in the pubs in southern England are quite lightly carbonated. If this is what tickles your (and your wife's) fancy then you should make your beer that way. After all, isn't producing beer precisely as you like it what brewing your own is all about?

As to the hopped extracts, I wouldn't worry about having an overhopped beer when using these as my sole source of fermentables. These extracts might be considered to be balanced, though if anything they are probably conservative in their hopping rates both for reasons of economics and mass marketing (if I may apply the term to a homebrew product). You may find that you want to add some bittering hops to the worts you produce from such products.

Finally, I don't think I've "publicly" thanked all those who so kindly responded to my question about dry hopping, both here and directly to me. I added the hops to the carboy before I racked the beer into the secondary, they are now floating in an inch-thick mass at the top of the beer. I'll be bottling the stuff later this week and will report on it when it is ready to be, and has begun to be, consumed.

Cheers,

Dr. John

That's what you get for living on the health-conscious west coast :-)
No, seriously, I can't quote you figures, but under that definition
I would bet that 85% of the adult populations of Germany and the UK
count as "problem drinkers". If we extend it to the equivalent amount
of alcohol consumed in wine, add 98% of the populations of France and
Italy. In any case, add 99% of the readers of this newsgroup.

What makes a person an alcoholic is not quantity per se, but the
extent to which alcohol controls their behavior (eg interferes with
work and play, impairs their ability to operate heavy machinery, is
necessary for them to feel good etc). My own consumption runs between
3 and 6 pints a week, at a rough guess, depending on how much evening
work I'm doing. Much above that I start to notice that I'm putting on
weight, and cut back. I think that's moderate; I don't think I'd
enjoy drinking a lot more than that. I could well believe that a
large person could handle more without technically being a lush, though.

Someone more knowledgeable than I will have to talk about health
effects. I'm sure that at 7 pints a week they are measurable,
and that somewhat fewer is somewhat better. I bet that the difference
is small, however. Special exception for pregnant people: I think
the best evidence is that anything beyond one or two beers a week
has significant negative effects on fetal health, and that none at
all is considered safest.

Subject: CLEANING COPPER TUBE

Greetings,

With all this talk about cleaning copper tubing I can't help but add my noise to the net. I've spent a lot of time cleaning tubing (usually stainless steel, but...) and I have a suggestion that might not be practical (or even advisable, depending on how conservative one is). For getting grease out of tubing acetone (major ingredient in nail polish remover) works pretty well. There are better things like trichloroethylene, but that's quite unhealthy. Even with a powerful solvent I have found that either scrubbing or agitation is necessary. If you have access to acetone you might also have access to an ultrasonic agitator; that combination works pretty well.

About removing the acetone from your tube (acetone is not very good for you either), an alcohol rise followed by lots of water should work well. I've used such a process (starting with TCE) to clean components of a gas system and it turned out clean at a level of parts per billion. That should be clean enough for beer.

My disclaimer: I'm not suggesting that anyone actually do this, I'm just thinking out loud at my keyboard.

Good luck,
Joe

On a related note... I've made some **very** authentic tasting
pilsners using light extracts, saaz hops, a quality yeast,
and ~4 (FOUR) gallons of a U.S.P. water. Boil with your
carbon filtered tap water (for the mineral component), and
then add the (agitated) USP water to your fermenter.

This works well here in Florida, where our water is a bit
on the hard side. Your mileage may vary.

Obviously, this is horse-crap. I got this same dogma when I had to go
through a alcohol awareness class.

Now if this were true, the Germans, French, Italian, Czech, etc, who
drink
beer and wine with their meals must *all* be alcoholics. I mean, gosh --
even their *kids* drink the stuff!! :-)

When will the neo-prohibitionists wake up?

PS: at least the people from countries who treat beer/wine as a food (eg:
quality and consumption rate) grow up treating it more responsibly
than
the folks in the US. Here, the two main rites of passage are a
driving
license and the ability to drink. Oh, yeah, and sex, which seems to
be
inextricably wound up with the previous two.

Subject: Re: Yeast for Lambics

Mike Sharp advertised *Pediococcus* cultures recently. I'm curious about how closely related this type of *Pediococcus* is to the *Pediococcus* that scares the bejesus out of commercial non-Lambic breweries? I suggest folks explore this before letting this bacteria into their homes.

I hate like hell to mention this and feel Mike's offer of slants is a great idea. Hopefully I'm wrong and this is a "friendly" *Pediococcus* and not the one that is hard to kill and which can permanently infect brewing environments.

Speaking of mailing slants, I've found that cutting a block of styrofoam and drilling it allows for a well insulated, light shipping package that can be reused many times.

I have a pint with dinner, and a few more on the weekends, so I guess that puts me in the 8-10 per week range, at least the 5-6. So just ask anyone who knows me (in person or via my long term presence on this digest) what the psychological effects of long term consumption are :-))!!

I do remember one discussion regarding a symbiotic bacteria that causes flatulence. Seems that this bacteria consumes dead yeast. It occurs naturally in beer in small amounts. It ends up in your body when you drink the fresh beer and ends up consuming the yeast in the homebrew, and excreting methane at a fairly high rate, causing increased flatulence. If I recall the discussion yeilded the cure of abstincence for a several week period to starve the creatures.

The only other physiological indicators I know of are the oft quoted studies that moderate consumption of 1-2 oz alcohol per day (your glass of wine, or pint with dinner) can help reduce risk of heart disease.

I have found that too many people use a number to define what is the difference between acceptable drinking and overindulgence. This is total *BS*. If you use the numbers AA tells you, the whole couuntry of Germany is full of Alcoholics. Basically these numbers ignore the manner in which one drinks, physiological and psychological dependencies, lifestyle, manner in which you were raised, and a host of real, important factors that effect your attitudes. Of course I'm often told by these same people that these are smoke screen issues I cite to conceal my drinking problem (ie end reasonable discussion).

A personal observation is that the friends I have who have grown up in households where moderate drinking (for religious or social purposes) was done (ie they gained exposure to responsible alcoholic consumption at an early age) have *NEVER* had problems with alcohol. I have known others who grew up in households with either relatives with drinking problems, or no exposure to

responsible enjoyment of alcoholic beverages. These people tended either not to drink, or to drink to excess.

I consider the viewpoint of a large portion of the medical and rehabilitative communities to be an intemperant load of garbage. I am partly of German descent, and strongly favor the view they have of Beer (and other alcoholic beverages) as part of the daily diet, not some aberant evil thrust upon us. Guess I'm just a radical though.

Pour it out of the bottle and serve it in the jar.
Mason jars are not pressure vessels, and their lids probably
won't work either (this is good, as it would be a shame to
start a tradition of ducking glass shrapnel in northern
Alabama).

Subject: re Mason Jars

I have one suggestion: DON'T!! Canning jars in general are not designed to withstand any internal pressure. The type that uses a 2-piece lid (one flat with rubber edge, and a ring to hold it in place---the only ones I've seen recently were made by Ball) can take some external pressure (it's how they seal), but I wouldn't assume that you can seal them tightly enough to get the beer to carbonate---and if you did, you'd probably get an explosion before carbonation. The type with a one-piece(plus-sealer-ring)lid (the lid held on with a wire hinge/handle) //might// take the pressure but I wouldn't care to bet on it. Seeing as you're safely out of range, would you like to try it? :-)

The alcohol that comes in jars all over the rural south (at least by tradition) is mostly corn whiskey at up to 150 proof, so it's not likely to carbonate. Your neighbors (e.g., the Atlanta Worldcon bid committees) have discovered a manufacturer of (you'll pardon the oxymoron) legal moonshine--- as a marketing gimmick it's sold in something like a jar (rather like the bad sherry that was sold in a drawstring bag (=sack)).

Subject: Re: MeV German Alt Yeast

The first time I used this yeast, the result was a *wonderful* amber ale. The only new recipe variable was the yeast, so I sing it's praises. I have not encountered the unusual activity mentioned in the other posting.

The second time the yeast never took off. The packet still sits on my kitchen counter somewhere. We ended up making an emergency steam beer with an MeV lager when the alt yeast didn't puff up after 2 days. Still, this is only two data points and any brewer worth his salt perseveres.

Subject: beer cooking K long term

Date: 23-Apr-91 Time: 12:48 PM Msg: EXT00931

Hello,

in HBD 621 Larry Barello asks about long term effects of drinking beer. There was an article recently in Glamour magazine about drinking beverages with tannin in them (beer, wine, coffee, etc) and tooth decay. It seems that researchers have discovered that tannin adheres to the teeth and inhibits the bacteria that cause tooth decay. However, the article said that more research was needed. This may not be what you were asking about, but it is health related. Also in the magazine was a short take on that "love beer". No verdict on its taste.

in HBD 620 Ken vanWyk asked about cooking with beer on Homebrew Digest. There is a nice recipe for Cheddar Cheese soup that has beer as an ingredient in the first cookbook by The Frugal Gourmet (a PBS show). I don't have it, but it is in print, and your local library might even have it. I used to have a nice recipe for quick beer bread, but I never wrote it down. I think it was 3-2-1: 3 cups flour, 2 eggs, 1 bottle beer, but I can't remember for sure. I never saw a recipe that specifically mentions homebrew, but no doubt using better beer will make for better food.

Subject: immersion vs. counterflow

I hope I don't start a war here, but all this talk about cleaning out the inside of copper tubing reaffirms that I made the right choice in choosing to build an immersion chiller. It helps me not worry when I can see the condition of the surface that will be touching my wort. Also, it's much easier to clean the outside of the tubing than the inside. The water out of the tap here in Palos Hills, IL is plenty cold year round and last week I got the wort down from boiling to ~70F in about 20 minutes. I probably used about 10 gallons of water altogether. I have a long translucent white plastic (not vinyl - PVC would melt) hose on the output side of the chiller which I use to fill the carboy and sanitation bucket with ~180F water (the first couple of gallons) for sanitizing solution.

Just for the record (all from Ace Hardware): 50 feet of 3/8 inch O.D. new copper tubing, 10 feet of 3/8 inch I.D. clear PVC tubing, 10 feet of 3/8 inch I.D. translucent white plastic tubing, three small hose clamps, brass fittings to go attach the PVC to the faucet (slop sink, garden hose-type fitting). I used a compression fitting with a plastic ferrule and a flanged brass reinforcing sleeve (on the inside of the PVC hose end) but a barbed hose fitting and another clamp would have probably been better.

Cripes! More than 3 bottles a week constitutes 'problem' drinking,
now?
I wonder what ~8 beers/week means to the meds now, should my friends
start
renting refrigerator cartons? (No offense intended).

> I take popular medical recommendations with a large grain of
> salt. They seem to change every six months. So the current fad
> of near abstinence is pretty suspect.

I agree. I have studied some psychology, and the more-or-less-current
know-
ledge holds that individual differences in psychological drug tolerance
are
primarily due to genetic factors and biochemistry. Interesting, huh?

Regardless, from my own personal non-empirical observation, it depends
on
the individual. I've known people who IMO are heavy alcohol drinkers (~
12
beers/night on occasion, not as easy to monitor the booze drinkers)
suffer no
short-term physical, psychological, or lifestyle effects other than the
occasional hangover. Mind you, these folks maintain ~3.8 GPA, or decent
jobs
and families. Not a hint of dysfunctionality. I've also known people
who
down 2 beers, lose all inhibitions, and habitually black out. Not a good
scene, these unfortunates seem to be predisposed to drug _abuse_, not
use.
I don't know any homebrewers in the latter group.

I realize that I'm not providing anything other than personal
observation,
but I naturally have an elevated opinion of my observing skills.

You should research the effect of heavy beer consumption for
people in East Europe. Germany, Austria, Belgium, Poland,
Czechoslovakia, etc are countries that consume lots o' suds.

I just saw in an article detailing the problem Czechoslovakian
hop farmers are having with finding enough workers to string
up the hop vines now that they can't just get students that
the average per capita Czech beer consumption is 100 quarts/year.

That works out to a little less than a beer per day.
The only demonstratable effect is that one day you will wake
up and attempt to change the government! ;-)

How about some not quite anecdotal evidence: I filled out a questionnaire
for my wife's company's insurance about my health and habits. I
indicated
that I consumed 8 12 oz. beers in a week. The computer printout that I
got returned indicated that this was considered "moderate" drinking.

As far as I can tell, the latest fad is to say that abstinence is best,
but
then whisper that moderate drinking (about 1 ANSI drink/day, +/- 0.5) is
best. Apparently there is a dip in the curve for heart attacks at this
point. Above 3/day, the curve starts going way up. Seems that a nip is
good for a stress reliever, but when you thoroughly abate the stress,
it's
bad for the other organs. ;-)

Subject: please remove me from homebrew mailing list.

Goodbye everyone.

Although I found the homebrew digest interesting, reading and participating for several months, I have not had time to read it in 3 months, and so am requesting that I be removed from the list, so that network bandwidth is not wasted.

I wish that the digest were a newsgroup, so that I could participate on an occasional basis without having it appear in my mailbox every day. I believe that the fears of flames (the usual reason given for not having a newsgroup) are unjustified---none of the newsgroups I read have any flaming on them. I know that there are newsgroups with violent personal attacks, but these newsgroups generally lack either a focus of discussion or rational participants. I believe that rec.homebrew could be as successful as the current digest.

I anyone wants my mead recipe, send me e-mail.

From: hplabs!bmr-vpa!bmr-rsc!crick (Bill Crick)
Subject: Mason Jars? NO!

Someone asked about bottling in Mason Jars. I would suspect that the tops of the jars wouldn't be able to stand the pressure, and would either leak, or buckle. I also wonder if the glass is strong enough. Mason jars are designed to have a small negative pressure inside which is achieved by capping when contents are near boiling, and the partial pressure of the water goes down when it is cooled, and some of the water vapour condenses.

What do I know?

Subject: Jars, M.eV.'s address, & abstinence

Some answers to some of John Mirely's questions:

The wide mouth glass jars with handles are old pickle jars. If they're old enough and you soak them in a strong solution of clorox and water, they should be fine for making beer. I used to use them as primary fermenters for my wine and ciders. Chuck the cracked jar. You not only may lose a batch of beer but could severely injure yourself if it broke at an inopportune moment. Besides, the crack could harbor bacteria.

I see no problem with reboiling wort that hasn't started fermenting. It may not be common practice but of such experiments the joys of homebrewing are made.

End of HOMEBREW Digest #622, 04/24/91

Date: Wed, 24 Apr 1991 8:01:14 EDT
From: TSAMSEL@ISDRES.ER.USGS.GOV
Subject: Pulque and Broken Carboy (Redux)

I have had the pleasure of drinking fresh pulque while in Mexico. If you can still find them, the pulqueri'as have lurid murals on the walls and are a step back in time for a home brewer. (Not grain/malt but you get to watch the fermentation as you drink).

This was nearly 20 years ago but we stopped in a pulqueria called "Los Tigres" (the tigers) somewhere between Saltillo and San Luis Potosi. The walls were emblazoned with tigers playing baseball. We brought in our cups, bought a gourd full and drank. Very weird and yeasty. We filled a couple of gallon milk jugs and put them in the ice chest and continued on our journey, venting them every hour or so. Other than moderate flatulence, no ill effects were perceived.

Broken carboy II:

After acquiring a 15 gallon carboy, a friend made several batches of (yech) raisin wine. The final batch occurred when a raisin made its way into the blowoff tube, obstructing the vent. Thus a 15 gallon raisin jack bomb. Luckily no one was in the house at the time.

I've recently tried a couple of recipes using beer. One was a cheese
soup,
which called for ale, the other a beef soup with a thin broth that just
said
beer. In the first case, I used Hood River Golden Ale, in the second
case a
pale ale of my own. Both soups were excessively bitter. My wife, who
believes
the only good use for malt is in milkshakes, found them to be
unpalatable, and
even to me, a born-again hophead, they were unpleasant. My guess is that
the
heat accentuates the bitterness. I'm seriously considering trying
American
industrial swill next time, since the hops in most of these seem to exist
in the
imagination only.

I'd like to believe that "better beer will make for better food", but
maybe not.

Subject: CULTURE AND IT'S EFFECTS ON ALCOHOLISM

FIRST OF ALL, WHAT IS ALCOHOLISM? THE BEST DEFINITION I CAN COME UP WITH

IS THAT AN INDIVIDUAL:

- 1) CAN'T CONTROL THE AMOUNT HE OR SHE DRINKS
- 2) FAILS TO YIELD WARNINGS OF FRIENDS AND FAMILY ABOUT HIS OR DRINKING
- 3) ALLOWS ALCOHOL TO BECOME MORE IMPORTANT THAN HIS OR HER COMMITMENTS

SECONDLY, I REMEMBER READING A STUDY THAT STATED THAT THE LEADING CAUSES OF ALCOHOLISM IS THE SITUATION IN WHICH AN INDIVIDUAL IS RAISED. THE COUNTRIES WITH THE HIGHEST RATES OF ALCOHOLISM ARE THOSE WHERE THE PEOPLE

ARE ECONOMICALLY AND POLITICALLY OPPRESSED (SOVIET UNION IS A GOOD EXAMPLE) OR

WHERE DRINKING IS NOT CONSIDERED A CULTURAL OR FAMILY ACTIVITY.

AS A COLLEGE STUDENT, I HAVE SEEN THAT THE PEOPLE WITH THE GREATEST PROBLEMS WITH ALCOHOL ARE THOSE WHO USE ALCOHOL TO "FORGET ABOUT ..." OR "JUST NOT TO FEEL ANYTHING".

THE PROBLEM IS THAT WITH THE DRINKING AGE (21) ALCOHOL IS FIRST INTRODUCED TO THE INDIVIDUAL AS SOMETHING TO HIDDEN AND KEPT SECRET. IF INDIVIDUALS WERE INTRODUCED TO ALCOHOL AS THEY ARE IN WESTERN EUROPE, PROBLEM

DRINKING WOULD MOST LIKELY DECLINE.

I was under the impression that the benefit is because the alcohol
thins the blood (the same reason that I've heard a doctor suggest
to elderly persons to take one aspirin per day). Maybe the stress
relief is part of it too, though.

Hat's off to Bob Devine, the only person to put Belgium in their
list of high-consumers. An article in Zymurgy in 1988 or 1989
listed the amounts of beer per-capita for various countries.
West Germany was #1 and I'm almost positive that Belgium was #2.
This was before I had tasted Belgian beers... now I question why
the Belgians are not #1!

Personally, I abstain on weeknights and drink at a German pace on
weekends (although I'm Lithuanian ;^).

Subject: beer bread

My landlady routinely makes bread with whatever I have leftover after bottling (e.g., partial bottle at end plus contents of hydrometer (which various sources say not to put back in the tank)). The results vary with the intensity of the beer; a good ESB or stout can give great results in a part-wheat (10-25% whole wheat flour) mix. Weaker-flavored beers tend not to affect taste because you use several cups of flour for each cup of beer, but it might be interesting to try a good lager in an all-white sourdoughesque bread. If your yeast cakes reasonably well you can also pour off what's left after you rack from the fermenter; this will give a faster-rising dough but even the pre-bottling beer will do the job if you're patient.

Note that because the yeast is already suspended in liquid you have to use a sort-of-sponge method; add flour to the beer until it's almost as thick as molasses (or batter from a cake mix), then make dough from that when the yeast is going vigorously. (And that's about the limit of my knowledge concerning bread making.) It's not a quick operation, but that just means you can make the starter when you're done bottling, then work on the dough the next morning.

In HBD 622, a bunch of people write about how many beers a week constitute craven dereliction, based on larryba@microsoft's statistician wife's contention that more than *THREE* bottles of (presumably American light Pilsner) beer per *WEEK* constitutes "problem" drinking.

I guess we hit a nerve. ;-)

Political disclaimer: I believe people should be free to make their own personal decisions as long as they don't screw things up for others by, e.g., running them down with an automobile. I also think the War on Drugs and Alcohol is really a War on Liberty. Nuff sed.

As someone who does research that involves the use of statistics, I know how easy it is to do bad science. That's why one must remain skeptical and ever vigilant against error. I wonder how much of the "alcohol will kill you if you get within a mile of it" research has a hidden axe to grind. Here's one error that I suspect may be embarrassingly common and would be widely known except for the rampant scientific illiteracy in these United States:

Consider the cutoff criterion cited by Mrs. larryba@microsoft: 3 per week. Now consider an epidemiological study where people are asked how many beers they drink per week (or even a garbological study where you count the dead soldiers in their dumpsters). Then you partition the sample into two groups: those who drink fewer than 3 and those who drink 3 or more per week. Then you do some kind of medical history on them all. You do an ANOVA or t-test, and, surprise, surprise! There's a significantly higher incidence of bad stuff in the 3-or-more group. This is BAD EVIL NASTY science, because the granularity of the partition isn't fine enough. The 3-or-more-per-week group includes the 24-per-day people. Alcohol's effects are dose-related, so the dosages you pick for comparison are critical to the scientific validity of studies. Without having read the actual studies on which some of the public pronouncements are based, I just don't believe what I read in the newspaper. Again, nuff sed.

Write your Congressman and Senators. Tell them what you think the War on Drugs and Alcohol. Don't wait until they start introducing bills to ban homebrewing to appease noisy neo-prohibitionists.

Oh, and by the way, you don't really think that homebrew was what was studied, do you?

Subject: Re: Mason Jars? NO!

My dad tell me when he was a kid. One of his friends put some dry ice into a mason jar, which blew up and sent shards of glass threw his neck, killing him dead.

I don't know if the pressure of a homebrew is anything near what dry ice would be, but I wouldn't wanna be around to find out.

Does anyone know the final pressure in a typical homebrew?

Subject: UPS sucks

As a businessman, I have been hosed by UPS so many times I should be blase by now, but they did it again.

Yesterday a neighbor told me they had a package for me from UPS. They mentioned they had it for a week, why didn't I get it earlier? Well, UPS had left no note at my address indicating that my neighbor had a package for me. This didn't surprise me, it has happened about a dozen times in the last few years.

What surprised me was the package itself. It was our entries for the national competition which we had sent over a week ago. Affixed was a large yellow sticker proclaiming "no alcohol through UPS". The packaging didn't mention alcohol, the package was sent from the local UPS center and no mention of alcohol was made. How did they decide there was alcohol?

I called UPS this morning, all they were willing to do was take a complaint about the lack of a message. I explained that the yeast samples were a time sensitive shipment and I wanted to know how they decided to return them. The answer, "we opened the box and saw beer bottles". They weren't even apologetic and suggested it was my fault for not writing "yeast samples" on the package. They also reminded me that they are not responsible for perishable goods.

Well I am sure none of this is news to anyone who has dealt much with UPS, but I felt it was worth posting as a reminder and a warning. My policy for the last couple of years has been to use FedEx for shipping anything important, but my brewing partner decided to save a few bucks. I recommend sending competition entries by FedEx overnight. It costs more, but your beer is in their hands less than 24 hours, and actually arrives at its destination.

Subject: Re: Homebrew Digest #622 (April 24, 1991)

Greetings fellow beerbrewers:

Just thought I'd add to the list of micro's.

I live in the Davis/Sacramento area of central California, and although I am by now means an expert on the microbrewery scene, there are two breweries around here that make pretty good stuff.

Sudwerk's is on Pole Line Road and first street in Davis CA and serves German beers and good food--try the french fries, they are excellent. The beer is sometimes excellent, but usually very good.

Dead Cat Alley is on Main Street in the downtown section of Woodland CA, about 10 miles north of Davis, and 20 minutes west of Sacramento

on Interstate 5. It's a more traditional bar, and serves stout, amber and

a lager beer. The stout and amber are quite good, but sometimes have a few peculiar flavors. Not bad, just unusual. Give it a try if you are in the area.

Also check out the Crown City Brewery in Pasadena CA down in the Los Angeles area. It is a block from the Amtrak station (which is how I discovered it) It has excellent beer, as well as offering a multitude of world beers to choose from. It's the best micro I've been to.

Let me know if anyone knows of any others in my general area.
Adios.

This isn't directly related to home brewing, but this story about "legal moonshine" reminded me of a friend at Virginia Tech -- he acquired a jar of "Georgia Moon" whiskey. It is sold in a mason jar, with a label that reads "guaranteed to be less than 30 days old!". It was horrible stuff -- he had one shot, then kept it around to de-ice the locks on his car. It does a great job...

Subject: Mason jars, I've tried it.

The results were uninspiring.

The jars I used were NOT the old kind with the wire holder and the rubber ring, but a sort of two part metal lid. One part a circle rimmed on one side with a rubbery/foamy edge, and fitting into the other threaded part.

In any event, none of the jars reacted dynamically to any pressure buildup, because there was little or no such buildup (ie. the beer was flat)! The lid simply didn't seal tight enough.

I was a bit disappointed, as these jars would be easy to clean in a dishwasher, (substituting B-brite for standard dishwasher fare, mayhap?) but alas I deemed it a failed experiment.

Subject: Re: Long Term Effects

Wow! thanks for all the personal and digest responses. I guess people are getting bored with the intricacies of cleaning copper pipe :=)

First, let me say that my wife doesn't personally believe that 6 pints/week is a problem. She just uses three drinks a week for classification purposes in statistical analysis. She has to set the limit low enough to catch all potentially problem drinkers. Her main problem with my drinking is that she is pregnant and can't share. Also, I tend to lose my "work ethic" (gosh not too surprising) after a pint.

I have relatives in Italy. They have wine with Lunch and Dinner. They never get intoxicated and they are mildly embarrassed by the drinking problem of Italy (drunk driving and attendant death rates - plus the more chronic problems of alcoholism). The people I met in France seemed to share the same viewpoint. Of course, my sample was small and highly educated (like this digest).

The kind of hard data I was looking for was of the medical, personal health, life span variety. For example the tannins and tooth decay. There is a book called "The Life Extension Handbook" that was popular in the mid 80's. It had a section on alcohol and its affects and how to mitigate them (Papazian hit the major ones). Unfortunately the book is full of semi-pseudo-research references. I was hoping to get a lead to some reputable, peer reviewed research or pointers to medical centers doing real research.

I read in the wall street journal that moderate drinking was associated with lowered cholesterol levels and a more favorable HDL/LDL ratios. This was about a week or so ago with regard to a woman who inherited two copies of the methuselah gene and had *radically* low LDL and extremely high HDL levels. She also had a drink a day for the last thirty or so years.

Keep those letters coming. I am interested in pos & neg personal testimonials. Send them to me direct and I will try to summarize next week.

Personally, I am a "Born Again All Grain HomeBrewer", hence the increased consumption! I find that all grain adds about 1.5 hours to my brew (4 hours start to finish), cuts the costs in half and the results are always just great. Plus mashing smells so good. I also like to bake bread. Hmm.

Subject: Biostatistics and Beer

I am a first year medical student and let me tell you, one of the most common lines you will hear from any first year about the course load is "When am I ever going to use this basic sciences crap in my career? If I wanted Biochem I would have never graduated from college. Well, as it turns out, one of these courses is Biostatistics, which the department says is important in teaching us Young Doctors in Love how to interpret data presented in medical literature. Finally a practical application: health risks/benefits of beer/alcohol.

Perhaps the greatest source of hidden error in research data is a phenomenon nicknamed "The Great Confounder". This represents apparent cause/effect relationships when there are none, but instead the "cause" is only closely associated to the true cause, but not the effect. Example: An apparently well designed study identifies a correlation between number of matches in one's pocket at any one time and the risk of lung cancer. All the data supports it. People who never have matches in there pocket almost never get lung cancer, or many other respiratory and cardiovascular diseases. So what is it about matches that causes cancer? Well, of course, you say, people with matches smoke cigarettes. Well maybe beer drinkers smoke more cigarettes, too. Think about it.

I'm sorry I'm running on, but I get so few opportunities to practically apply my limited knowledge.

Subject: UPS returns HOMEBREW COMPETITION entry's

Friday, April 19, 1991, I had returned to me, my homebrew entries. Reason, UPS does not violate Federal Law of Interstate Transport of Alcoholic Beverages across state lines. When the package left Maryland, somehow the UPS distribution center in Pennsylvania decided to check my package. They decided that it was really beer, although it was not marked as such. They informed me that they "know" all of the tricks and are watching for packages marked: beer, yeast, vinegar, malt, "Zymurgy". They also know of the competition, it's locations and dates.

I was instructed to cease and desist my attempted shipping of alcohol across state line, or they would report me to the BATF. note: the entries were shipped from Baltimore MD, on April 10, 1991. Package was marked: "Liquid in Glass, Yeast Cultures".

We need to find a solution to this problem!!

I
> discovered it) It has excellent beer, as well as offering a multitude
> of world beers to choose from. It's the best micro I've been to.

I wasn't as enthused over their beer, although I must admit that at
times
it was great! I don't know if there were different brewmasters or what,
but
going to Crown City fairly regularly revealed a lot of variance in their
brews. Sometimes the stout was a bit too flat and thin for my taste. I
do
like their Mt. Wilson Ale, though. The food is good as well, although a
bit
too pricey (like everywhere else near Old Town Pasadena).

When in Pasadena, get to the Loch Ness Monster Pub (north on Fair Oaks,
I don't remember the address). Center of the infamous Doo Dah Parade,
this
is a nifty little pub without their own brew, but they do have Bass,
Watney's
and Guinness on tap, and loads of other stuff in the bottle. Good bands
on
the weekends, with a fairly cheap cover.

In L.A. proper, I recommend Goriky's. There's one downtown near the
Museum
Of Contemporary Art and Little Tokyo, and I think they opened one up in
Hollywood where the old Tick Tock Diner used to be. Goriky's is
insufferably
gimmicky (with their "Soviet Socialist" theme), but it is lots of fun to
go
to and hear bands. Don't know too much about their food. Lots of artsy
types in and out, nothing like the yuppified atmosphere of most brewpubs.
I like Goriky's amber and dark brews in particular, these seemed more
consistent
than the Crown City brews (to me, anyway).

And Fred Condo <CONDOF@CGSVAX.CLAREMONT.EDU> sez:

ever
> vigilant against error.

Regarding statistical analysis, one thing my Applied Psychology
professors
always pounded into our skulls was the very important concept:

Correlation, In And Of Itself, Does Not Imply Causation!

To demonstrate the importance of this rule, we were given the raw data for a study of birth order and the effects on intelligence. The class analyzed this data using common statistical methods, and came up with a very valid and significant conclusion. Something like firstborn children most definitely tend to have higher intelligence. Mind you, our analysis was not flawed, according to the professor. Chuckling, he handed us the data for parental involvement, and very quickly showed us how this neglected component completely invalidated our previous conclusion. The correlation was present and the causation implied, yet with more information, poof! no causation! Powerful stuff, and I'm never able to read anything statistical in the newspaper without thinking "what's wrong with this study?"

Science is most definitely politicized, and the neo-prohibitionists are among the worst misusers of statistics. Remember that as you down your fourth homebrew for the week ;) .

> the bejesus out of commercial non-Lambic breweries? I suggest folks
> explore
> this before letting this bacteria into their homes.

As for the relationship of this *Pedio.* to the one which has been
known to inhabit breweries -- yup, this is the one. Be careful
folks.

I doubled checked this with the lab that supplied the original
cultures. There is no problem using this strain of bacteria
PROVIDED that all fermenters, utensils, racking tubes, etc
are sanitized with the usual bleach solution. This assumes
that you are starting with something that can't be sanitized to
being with (i.e. NOT wood). In other words, do what you always
do (or should) and you won't have any problems.

I'd go further than this and also avoid soft plastics just in
case. This means either a glass primary/secondary, or, if you're a
fanatic like me, a special oak one.

The problem that breweries have is due more to their size than
anything else. *Pedio* is hard to kill in a brewery because it can
hide anywhere in your ten story building. The standard homebrew
5 gallon setup doesn't have this problem. If you want to be
extra sure everything is dead you can put it in a tube full of
bleach -- commercial brewers can't put their whole plant in a
tube of bleach.

> I hate like hell to mention this and feel Mike's offer of slants is a
> great idea. Hopefully I'm wrong and this is a "friendly" *Pediococcus*
> and
> not the one that is hard to kill and which can permanently infect
> brewing
> environments.

This was a good question so don't worry about it. Since I'm
brewing only Lambics its something I've never worried about.

Finally, part of my testing of this prior to sending it out is to
see if it causes infection problems for two volunteers. Getting
these results will take a little while, so if you're nervous I'd
wait for an announcement of the results (probably around the end
of June).

Subject: Re: Alcoholism

In HBD 623, James Zuniga (ZIGGY) Writes:

- > WHAT IS ALCOHOLISM?
- > 1) CAN'T CONTROL THE AMOUNT HE OR SHE DRINKS
- > 2) FAILS TO YIELD WARNINGS OF FRIENDS AND FAMILY ABOUT HIS OR
> DRINKING
- > 3) ALLOWS ALCOHOL TO BECOME MORE IMPORTANT THAN HIS OR HER
> COMMITMENTS

In the military, people can be involuntarily referred for alcohol rehabilitation if they drink so much that:

- 1) they neglect their job
- 2) they neglect their responsibilities
- 3) it's hurting their family
- 4) their health suffers

Most people are unaware (or unwilling to admit) these effects are occurring;

that's why it's important for friends to be bold enough to let someone know they appear to have a problem. Alcohol, you see, can dull your perception of the things on my list; so #2 on Ziggy's list is everyone's responsibility to those they care about. If a person says they're irritated by friend's warnings, this is a clear signal of alcoholism. Worse--most alcoholics deny their problems (much less their illness). So be careful...we all love beer, but we're playing with fire.

Date: Fri, 26 Apr 91 07:56:06 EDT
From: "John E. Lenz" <JELJ@CORNELLA.cit.cornell.edu>
Subject: HB Digest no. 624

In # 624, Jean Hunter writes

>. . . is searching for a Hunter Energy Monitor. Having read the brief
> recent posting, so am I.

Well, I can't resist. Jean, is this for personal use, or are you really going to use it for fermenting?

On a more serious note, Ken Weiss asks about adding a fresh dose of yeast prior to bottling a batch that has been in the secondary for 8 weeks.

Well Ken, I guess the definitive answer is "It depends." If this has been an 8-week cold lagering I'd definitely add some active yeast. On the other hand, if it has been at "room temperature" (whatever that is) there may be enough yeast in suspension to do the conditioning without adding more, even though the beer appears clear there may indeed be some active yeast in suspension. In either case, adding some fresh yeast shouldn't hurt, unless of course the yeast is some of that infected dry stuff I've been reading about lately in Zymurgy, and will probably speed up the bottle-conditioning process.

Lastly, Ron Rader, Jr. writes:

> . . . one thing my Applied Psychology professors always pounded into our skulls was the very important concept:
>
> Correlation, In And Of Itself, Does Not Imply Causation!

They told us that in econometrics as well, but to read the literature you wouldn't know it. Economics, being a non-experimental discipline, too often results in models being concocted on the basis of how some economist thinks the world works with the results being presented in causal arguments which really only have there basis in correlations. All too frequently the above advice seems to be forgotten, or, worse, ignored. So you can, if you haven't already, add economics-related items to the list of things could be hazardous if taken at face value.

Subject: Hardy's trip to Germany

I have a hard copy of Norm's 6 (?) part series on his trip to Germany. I thought there was some talk about extracting it and posting it to the archives by itself. Was this done? It would be a good idea.

The series is great to read because (in my opinion) he doesn't clog it up with too much description of tastes. He describes the atmospheres of the different establishments to give a nice overall view of the experience. Coupled with the homebrew hints, it makes a nice reference piece. I really hate discussions about wine where people describe mouth feels, tastes and aftertastes that apparently never made it into my glass.

Subject: Re: Can I forfeit the deposit and use the Busch keg?

Well, you can certainly forfeit the deposit :-)

We've got 3 `half kegs' (15 gallon) and a couple pony/quarter kegs (7 gallon). The deposit was \$10, so it was easy to justify.

We've turned one into a barbecue grill (turn on it's side, cut longways -
-
it'll never rust like the overpriced Webers). The other, we cut a large hole in the top and use it as a brew kettle. The third, we've figured how to remove the valve so we can clean it, and are thinking of doing a 10 gallon strong batch, diluting to 15 gallons, and serving at a party.

To remove the valve, you remove the spring-clip, then just pull up the valve; it's a little harder to get it back in, but a rubber mallet will help. Your/our biggest problem will be fermenting 15 gallons (3 carboys? an other keg?), but one guy I talked to just used a 15 gallon plastic trashcan!

You can get the CO2-fired taps from Foxx -- I can't remember the cost, but it's not too bad. I think you can do better than a \$40 deposit, but if you're going to be making a kettle out of it, it's still a hell of a lot cheaper than buying a 10 gallon stainless pot from Rapids (\$100).

WARNING: If you're making a kettle (or grill), cutting through the stainless is a bitch. Forget jigsaws, and even a Sawzall doesn't cut (sorry :-) it. Use an abrasive wheel (like for concrete) and a circular saw. It makes a *lot* of noise, too...

Ciao!

On Apr 24, 11:24am, microsoft!larryba@cs.washington.edu wrote:
> I find that all grain adds about 1.5 hours to my brew (4 hours
> start to finish)

Really? Only 90 minutes extra? Can you explain how much time
you spend

- (a) measuring
- (b) grinding
- (c) mashing
- (d) sparging

It takes me about 30 minutes to get everything measured and ground,
another 1-2 hours to mash, and an hour to sparge. And that doesn't
include the extra half hour or so it takes me to bring the larger
quantity of wort to a boil. What am I doing wrong?

While I'm talking, I'd like some advice on a problem I'm having with
extraction. I've calibrated my thermometer against a fever thermometer.
I check pH at mash-in and at the start of the boil and adjust with
gypsum when necessary. I'm careful to stir the mash pretty frequently
to equalize temperature. I sparge with 160-168 degree water acidified
to pH 5.7 as recommended by Dave Miller in TCHOHB. I let the mash go
on ridiculously long (also Miller), and I use the temperature ranges
specified in Miller's recipes. The specific gravity at the end of
sparging is always very near 1.000. Once it was even below. Oh yeah,
my water is damn close to distilled:

- >Calcium 11.2 (probably 16-17 from tap)
- >Magnesium 1.3
- >Sulphate 11.5
- >Chloride 8.2
- >Bicarbonate 17
- >Carbonate 0
- >Sodium 3.2
- >Iron 0.06
- >pH 6.85-7.2

The problem is that my extraction rate is about 75% of what Miller and
a number of you folks are getting. The only reason I've come up with
is that I might be measuring specific gravity at a different point from
everyone else.

After the boil (I use 1/4 to 1/2 tsp Irish moss at the end for a good
hot break) I chill the wort to 70 degrees with an immersion chiller and
strain it into a big bucket. The strainer catches virtually all of the
trub, several cups' worth I'd say. I say "all" because there's never
more than a 3/8 inch layer in the bottom of the 6.5 gallon carboy I
use as a fermenter. Then I add cold water to the bucket to bring the
quantity of chilled wort to a bit over five gallons. I let it sit for
a while to let any remaining trub settle. Then I let it drain noisily
from the spigot on the bucket into the fermenter, which already contains
the yeast. When half of the wort has drained I capture a sample in
the SG measuring tube -- the SG of that is what I note as my original
gravity.

Using these methods, which are very close to Miller's (although he's

rather vague about measuring SG), I'm getting 26 points of SG per pound of Klages (or English pale ale) instead of the 35 that Miller claims.

Any ideas? Do I have to get Noonan's book and start decocting? :-)

Subject: 2-liter bottles

I have heard from relevely reliable sources (master of my brewing club) that the plastic 2-liter bottles which are used to contain carbonated beverages are not appropriate for storing alcoholic beverages (such as home-brew). The issue is that the alcohol causes some of the plastic bottle to be dissolved into the drink, making the drink slightly poisonous. I do know that there are various kinds of plastics and that they are graded (classified) for their use in the food and beverage industry. For instance, I have seen plastic bottles used for liquor (Scotch in a plastic bottle - how unasthetic!).

REMINDER: THIS IS ONLY A QUESTION! I DON'T HAVE ANY FIRST HAND KNOWLEDGE!

The reason I raise this question in this public forum and risk the nasty rumor business :-(is that I've been reading "homebrew digest" for a few months now, and I find the high level of intelligent discourse very pleasing. (Apart from the usual "my pub's better than yours" :-) discussions! - let me tell you about the ones in Boston!)

I am sure there are people on this network who have more knowledge than I do about plastics and their interactions with alcohol, and I would appreciate a summary or some pointers to reference material which will allow me to resolve this question for myself (and my brewing club).

Thanks in advance.

> to ensure carbonation?

Nah. I made a pilsener that sat from Christmas to March, and not only did it carbonate fine, it was the best beer I ever made. I just last weekend bottled a brown ale that had been "resting" for six weeks, and it's carbonating OK as well. (It also tastes really smooth and nice...I'm beginning to notice a trend here. I wonder if my interpretation of the data is correct :-)

Now I need to buy more carboys so I can age everything a couple of months before bottling.

From: zentner@ecn.purdue.edu (Michael Zentner)
Subject: Bass Pro Shops brewing stove

A few people asked me to post my experiences with my brewing stove from Bass Pro Shops after I had a chance to play with it a little bit.

It came 7 days from ordering, using a credit card. Yesterday was the first chance I had to get out and get a propane tank, hence the delay. In appearance, it is quite comsmetic, since the whole thing is stainless steel. They do an amazing packing job getting it all to fit in the box, so some assembly is required. The assembly directions were lousy, but it really doesn't take too much to figure out from the schematic how things fit together. The 3 gallon stainless steel pot that comes with it is large diameter, thus somewhat "flat". Everything is included except the propane tank. You even get a hose with valve and 50 psi regulator.

There are two heights for this thing, depending on whether you put on the extender legs or not. With the legs, the book says do not put more than 50 lbs on it. This translates to about 6 gallons of water, minus the weight of your kettle. I put on 5 gallons, and the thing still felt very sturdy, like it could go at least 2 more gallons. With just the short legs, the book says 150 lbs is OK, which ought to be more than sufficient (18 gal!) for most homebrewers.

If you are expecting to buy one of these things to use in your kitchen, I'd advise against it. This is the second different "type" of high output propane burner I've seen, and neither would I use indoors unless VERY well ventilated. The legs on the model I have do not get hot, so burning your floor would not be a problem.

I brought 5 gallons of water to boil (VERY strong rolling boil) in about 35 minutes on a very low setting. By very low, I mean the point where the flames were just barely licking out from under the pot. There certainly was a lot more heating ability if you turned the thing up higher, as verified by opening up full throttle in the absence of a pot. I'm not sure I'm impatient enough to try it on a real pot, though. These things will leave some black soot on the bottom of the pot, but that comes off of SS easily enough. I wouldn't use it in your favourite Calphalon stock pot, though :-). Again, if you really want to crank up the heat, you'll definitely have flames going up the sides of your pot (it takes a good amount of fire for a 170,000 BTU burner).

And, as always, be safe with propane. The lady at the store was sure to remind me of the article in the paper that same day about the family out camping who stored the tank in their tent, and did not wake up the next day.

All in all, for me, I think it was a worthwhile investment. I'll be doing my boiling mostly in the evenings, either in the garage or the back patio.

Mike Zentner, who feels like he better just mention the keywords "copper tubing" just for kicks :-).

Subject: LA BP's / Pitch yeast at Priming

On the Subject: Los Angeles Pubs
I agree about CrownCity. It is variable.

>When in Pasadena, get to the Loch Ness Monster Pub (north on Fair Oaks,
>I don't remember the address).
This is a good place to go. It is now called something like the
Old Town Pub and is located on the northeast corner at
Fair Oaks and Union. Another place to go is the John Bull located on
Fair Oaks (South of Del Mar). This is a decent place with good food
and a different selection of beer than the Old Town Pub, featuring ESB
Newcastle, Devonish, Fullers and a special ale that changes from time to
time.

On the Subject: bottling after long period in secondary

I often lager my beer and found that it does take longer to carbonate
if you don't pitch a yeast to prime. I added yeast once at priming at it
noticeably changed the character of the beer. To a friend that brews
lagers
I recommended not adding the yeast and patiently wait. After a month the
beer was very nicely carbonated and had the character it had at bottling.
As for myself I now keg all of my beer and force prime it. The long
lagering
period is especially nice in that there no sediment dropping out after the
beer is kegged.

>> WHAT IS ALCOHOLISM?

>> 1) CAN'T CONTROL THE AMOUNT HE OR SHE DRINKS

>> 2) FAILS TO YIELD WARNINGS OF FRIENDS AND FAMILY ABOUT HIS OR
>> DRINKING

>> 3) ALLOWS ALCOHOL TO BECOME MORE IMPORTANT THAN HIS OR HER
>> COMMITMENTS

>Most people are unaware (or unwilling to admit) these effects are
>occurring;

>that's why it's important for friends to be bold enough to let someone
>know they appear to have a problem. Alcohol, you see, can dull your
>perception of the things on my list; so #2 on Ziggy's list is everyone's
>responsibility to those they care about. If a person says they're
>irritated by friend's warnings, this is a clear signal of alcoholism.
>Worse--most alcoholics deny their problems (much less their illness).
>So be careful...we all love beer, but we're playing with fire.

You should beware of circular reasoning here. Say someone has 1 beer
per week. Some well meaning Temperance Union zealot tells him he has
a problem. He says "Get stuffed! One beer per week is NOT
excessive!"

Now the poor sot is rejecting suggestion of a problem. Plus, in the
eyes of some, he drinks excessively. To top it off, he can't control
his drinking (actually, he is not willing to change his habits just to
please some whacko who really thinks ANY alcohol is immoral).

While a "true" alcoholic may practice denial, isn't that
a REASONABLE action for a non-alcoholic? In short, while you should
recognize the tendency to deny a problem, denial itself isn't an
indicator of the problem.

Subject: Re: Kegs (Toufic Boubez)

Dude,
If the keg and apparatus are CO2 go ahead. If its the hand pump variety, forget it you are just asking the dormant bacteria to start breathing. Also, you may find it difficult to clean and fill. Some companies like Hamms (I think, maybe Old Mil) have a rubber removeable bung that can be removed with a cork screw and replaced at a buck a shot.

I just sank \$70 (probably a bit steep) in a party ball plus CO2 cartridge tap plus adapter set up; It actually pays for itself in a couple of brews if I rate myself at \$5/hour for cleaning and filling, since the whole process takes less than 20 minutes. And it holds upto 5 gallons which is a typical batch.

I just do a second ferment in the beer sphere and let it sit for about two weeks for flavor. The pressure usually lasts for a couple of drinking sessions, then I have the option of either adding more sugar and waiting over night, or injecting 8 grammes of CO2 vi cartridge through the tap (made by EDME). I'm pretty satisfied with it except that my first batch had a Lactobasilus (sp?) infection halfway through due no doubt to opening and closing while trying to figure out the right way to screw on the damn adapter.

None the less its a neat idea, so if you were inclined to forfeit \$40 for a heavy metal keg plus I-don't-know-how-much for the CO2 tank, regulator, adaptor and tap, you might want to look into the Beer Sphere setup instead.

The only place I know of that supports its distribution is The Fermentation Settlement in Saratoga, California (they should pay me grain for advertisment now!)

Have a blast, man.

Subject: Fermentation rates for small batches.

Last Wednesday, I put in a two gallon batch of Irish Stout. Using a Whitbread ale yeast, fermentation was off to a good start in just a few hours. By Saturday, the glug rate in the airlock had dropped to about two a minute. By this morning, (Monday), it had dropped to about one every three minutes. I would expect a five gallon batch to take a couple of weeks or more to drop to this level of carbon dioxide production. This is the first time I have made a small batch. Is this normal for a small batch. Obviously, there is less material to ferment and less yeast doing the work. Have others with small batch experience had this same result, or is this yeast just not particularly attenuative.

Dan

From: bradley@dehn.math.nwu.edu (R. Bradley)
Subject: Fermentation rates for small batches.

Numerologists take note: 625 is 5 cubed. In any case, it's a great milestone for the HBD.

In #625, Chris shenton, talking about a 15 gal. Busch keg, says:
> ... The third, we've figured how
> to remove the valve so we can clean it, and are thinking of doing a 10
> gallon strong batch, diluting to 15 gallons, and serving at a party.

Augh!!!! The dreaded practice of high-original-gravity brewing, bane of the Canadian brewing industry (and American I suppose? Anybody know?) since the mid-seventies. Another example of the triumph of accounting over sound brewing practice. It increases the throughput of a brewery, but adding water (carbonated, in the case of the Canadian biggies) means raw, watery beer and oxidation.

Chris: do evrything you can to remove the oxygen from the water you'll be using to dilute the beer. Heck, just drink the true beer, strong and free :-)

Yet another entry into the 'long-term effects' fray: I find all the preaching about alcoholism chafing as well. However, consider the following: if you drink 24 beer a day, you will undoubtedly suffer long-term PHYSIOLOGICAL effects (as in 'body'). If you drink 1 per week, you undoubtedly won't. Who's to say that the cut-off isn't three per week? No, I don't believe in 3 either. If you eat right and exercise, it's undoubtedly much higher. But let's not kid ourselves, at some point the body has trouble processing the poison if it's going to be coming in >300 day per year. Maybe the livers of our Czech cousins look pretty bad by age 60.

Cheers,
Rob

>
>Any ideas? Do I have to get Noonan's book and start decocting? :-)

>
> -- Marc Rouleau

I have experienced the very same trend in my first few mashes so this past weekend when I mashed my first original recipe I boosted the grain content to account for poor extraction efficiency. My recipe was:

5 lb. pale ale malt
3/4 lb. cryatal
1/4 lb. black patent
1 lb. corn sugar
1 cu. molases.

Per Miller's book this should have yielded an OG of around 45. I added a sixth pound of pale ale malt to compensate for poor efficiency. The result: an OG of 52! This time I replicated Miller's extraction almost exactly. The only deliberate change in my procedure this time was to avoid temperature overshoot when adjusting the mash temp. In the past, I had set the mash temp and when I returned to stir I'd found the temp to actually be higher than before. I think this time by avoiding overshoot and stirring regularly to maintain uniform temperature (as Marc does) I avoided de-activating my enzymes prematurely.

Just one brewer's experience.

Subject: Cooking with beer/health issues

First, let me say I just *love* this subscription!!

Next, on to cooking. I love to use a good pale ale as a marinade for most any kind of beef. Take a roast, pour an ale (or two) over it, season it with a little seasoned salt or the like, some fresh pepper and let it sit for a couple of hours. Put it all (liquid too!!) in a roaster, cover it and put it in the oven on about 350 for a couple of hours. Remove the meat when it is done and make a gravy with the remaining liquid by cooking it on the stove and adding a tablespoon or two of corn starch. Add a little little water if you want more liquid. You probably won't need to add anything else to the gravy -- I don't because I like it just like that.

Another favorite from back home (Wisconsin) was beer batter trout. I will need to get the recipe from my brother if anyone is interested.

Finally, health. Just for your statistics and since I didn't read anything coming from the female portion of our reader populace, I drink 1.5 to 2 pints per night and slightly more on weekends. It doesn't seem to have had any affect on my ability to hold a job (I've changed jobs twice in the last ten years) and I am a wife and mother too. I like beer and I especially like our homebrew although we have only been brewing for about two months.

Keep up the great correspondence, I love it.

Later, Diane

> an 8-week cold lagering I'd definitely add some active yeast.

I've never brewed a lager, so maybe this question is silly. Instead of
adding new yeast, why not stir up some of the sedimented yeast in the
secondary fermenter? Seems to me this would avoid the risk of
infections
being brought on by adding new yeast.

Sort of like the old brewer's trick of using the yeast from one batch to
pitch the next.

Subject: Beer Hyper Card Stacks

There's been a lot of discussion of late about wort chilling. Well, this past weekend I tried something. I started with 5 gallons of bottled water. I refrigerated 3 gallons while allowing the other two to stay at room temp. I used one of the room temp. gallons for my boil. When I was ready to mix everything, I remove the 3 chilled gallons from the fridge, poured them into my primary, added the remaining gallon of room temp water and then poured in the boil. A couple of stirs of the resulting wort gave a temperature of 85 degrees F. All I had left was to test the gravity, pitch the yeast, put on the lid, and install the fermentation lock. The total time to do all this was 5 minutes from the time I poured in the first gallon of water. In about 10 hours it was bubbling away...no unusual odor and hopefull no infection. I'll keep the list posted as to the outcome.

Subject: yeast at priming, time to mash

To the person who had beer in carboy for 8 weeks, and is wondering about adding yeast. I regularly have beers in secondary, or tertiary carboys for several months, and often at low temperatures. I've never had a problem with priming. I don't think you need to add yeast. It may take a bit longer to carbonate, but it should carbonate just fine.

Re: 1.5hr mash??? How do you do it? It takes us at least three hours, not including heating the water for the protein rest which is in parallel with breakfast. This also doesn't include roasting or grinding which we usually do the night before.

It takes almost 1.5 hours to sparge? say 45 minutes of recycling to set the bed, and 45 minutes to sparge, and run it off.

Mash 45 minutes or so, and protein rest of 30 minutes??

Bill Crick Brewius, ergo sum!

Hmmm, most of my 5 gallon batches drop to that level of CO2
production in about three to four days. Maybe I just ferment too
warmly, though. IMHO, your experience with 5 gallon batches
seems more unusual than your 2 gallon batch.

I suppose it depends on the yeast, the temperature, and the
amount of unfilled space in the fermenter (I do the
primary ferment in a 7 gallon acid carboy).

In reply to Matthew B. Harrington's request for a source for LARGE beer mugs, steins, etc., try a mail order company by the name of "Crate and Barrel". I do not have their address, but you could try 1-800 information, or look in your phone book to see if there's a local store. We receive a catalog every month or so, showing a wide selection of kitchen ware, including beer mugs of varying sizes and shapes. They even have the "dimpled" English pub mugs! I bought a large (18 oz. capacity) glass mug last year, which has the all important large handle which keeps my hand from warming the beer. I'll post the address etc., if there's any interest.

Subject: Mac brewing software

Kieran's (IOCONNOR@SUNRISE.ACS.SYR.EDU) posting yesterday reminded me that

I've been remiss in not passing along my recipe formulation spreadsheet for Excel on the Mac. I built this a couple years ago and almost turned it into a product for sale. But I decided that I needed to do a lot more with it to turn it into a commercial product, and grinding Excel macros is definitely not for me. I long ago uploaded it onto CompuServe, but I'd like to post it into one or more of the ftp sites. How? Thanks in advance! Just to whet your thirst, this spreadsheet allows you to select what units you use (grams v ounces, kgs v lbs, etc.) and then has a water adjustment calculator, beer color and extract estimator, and a hop bitterness feature. There are adjustable fudge factors like your brewery's extract rate and pellet and leaf hop utilization. Color is estimated based on the length of the mash. There are tables of grain characteristics which you can update or add new entries to. Included in the package are the macro sheet, a blank worksheet, a half-done manual, and a couple sample spreadsheets. If only someone would email me the way to upload this...

Subject: More questions about plastic bottles.

With regard to the recent question (#625) about using 2-liter plastic bottles for beer:

>I have heard from relatively reliable sources (master of my brewing
>club) that the plastic 2-liter bottles which are used to contain
>carbonated beverages are not appropriate for storing alcoholic
>beverages (such as home-brew). The issue is that the alcohol causes
>some of the plastic bottle to be dissolved into the drink, making the

>drink slightly poisonous.

In addition to information about the above, I would also like to know:

Does any significant amount of CO2 diffuse out of the bottle and conversely can O2 diffuse into the bottle?

Are there any differences between the 2-liter, 1-liter and 16 oz. bottles (other than the amount of beer they will hold)?

I have been using these bottles for about 6 months with no obvious effects or loss of pressure, but would be very interested in hearing from someone in the know.

Hello -

Cooking with Beer - The current issue (June) of Playboy has a section on cooking with beer that calls for varied types of beer. One recipe is for ice cream made with porter or stout. They also have an interview with MacNeil and Lehrer (Plug Plug:)

Alcoholism and Beer - This is a really touchy topic. The amount of alcohol that would make me sick drunk would be a drop in the bucket for someone else. I am small, female and have an hereditarily low tolerance for alcohol or other intoxicating substances (thanks mom). My friend drinks at least four bottles of beer (homebrew or good micro/import stuff) on weeknights, and more on weekends. He is a father and husband, around 6' 1" and stocky, and recently passed a big exam and received a promotion in his job (mechanical engineer). Maybe I'm being naive, but I think those people who make beer or wine have a different type of personality than those who have addictive (alcoholic) personalities.

Nuclear Carboys - My boyfriend is a grad student and works in a medical research lab. They use both HCl and radioactive materials. He has no idea what those messages on your carboy meant, they resemble nothing he has ever seen. There is no danger from any HCl itself, it is in your stomach, Coca-Cola, etc. He did not know if perhaps some other ingredient (like Benzene, etc) was or was not used to purify your HCl.

Subject: Problems getting Beer to AHA (wrt: USPS/UPS)

Last week there were a couple articles from people who had their beer returned by UPS or the USPS. I'd like to get `reprints' and follow-up information on these and any other cases you know of.

If the USPS won't send beer, I'd like to push the folks in government to change that. I live on Capitol Hill [sic] and a neighbor (and recent convert to homebrewing) works with the powerbrokers. Between the two of us, I think we could get things changed.

If it's just ignorance of the legality of shipping beer by the USPS, then maybe we can get a copy of the law, photocopy it and tape it to boxes which are being sent to competitions, etc.

If it's UPS who won't send it, then there's not much we can do except to petition them.

Any and all comments appreciated. Comments on the legality and policy of the USPS and UPS should ideally be backed up by references or somesuch, rather than speculation; I'd hate to talk to these people without sound facts...

Thanks.

Subject: Re: wort chilling

Mark Andrews writes:

>There's been a lot of discussion of late about wort chilling. Well, this past weekend I tried something. I started with 5 gallons of bottled water. I refrigerated 3 gallons while allowing the other two to stay at room temp.
>I used one of the room temp. gallons for my boil. When I was ready to mix everything, I remove the 3 chilled gallons from the fridge, poured them into my primary, added the remaining gallon of room temp water and then poured in the boil. A couple of stirs of the resulting wort gave a temperature of 85 degrees F.

I used to do something just like this before I built my wort chiller. I have several additions to your procedure, Mark. I pre-boiled four gallons of tapwater (Palos Hills water tastes pretty good out of the tap), poured it into gallon plastic jugs and chilled overnight. In the morning, I took one of the four jugs and put it in the freezer. That evening, I would brew using 1.5 gallons of tapwater in the kettle. The freezer jug water was used to get a good cold break after the boil (sometimes I would have to crack up a layer of ice that had formed in the jug). The three refrigerator jugs were splashed into the primary. The final temperature was somewhere in the 70-75F range.

Several things to keep in mind: 1. boiling the water will kill or otherwise beat-up-on any nasties in your water (yes, even bottled water has nasties), 2. boiling drives off chlorine your water dept. adds, and 3. boiling drives off oxygen (which means you need to aerate your water or finished wort before pitching).

So why use a wort chiller? Well, if you are doing all-grain, you have little choice. If you are doing extract, then there are still some advantages: 1. better cold break, 2. better hop utilization (a higher gravity boil will give you less hop utilization), 3. if using my above mentioned procedure, you don't raise the temperature of the inside of your fridge to 60F with four gallons of boiling water (I had noticed a correlation between spoiled milk and brewing sessions). By the way, better cold break is another argument for immersion versus counterflow chillers.

I wrote:

>better cold break is another argument for immersion versus counterflow

What I meant to say is that if you use an immersion chiller, it is easier to dispose of your cold break trub -- you just leave it in the kettle as you transfer to the primary. A counterflow chiller will still give you the same cold break, but you have to filter it out of your wort somehow.

Subject: glassware

Matt Harrington asks about glassware. I can suggest a couple of things. (Note that my interest lies in beer-brand-name or brewery-name labeled glasses and to some extent mugs.) Call distributors of beers for which you'd like glassware. You might try Merchant du Vin in Seattle. Manneken-Bruxelle in Austin used to exist, and had a lot of Belgian glassware; they may not anymore. Sierra Nevada also sells some nice glassware.

If you're ever up in the Bay area, there are a couple places you might want to check out. First, there's Harry's Bavarian Deli in San Jose. Harry has an amazing collection of German glassware for sale. Must be seen to be believed. In Morgan Hill, there's Let's Brew, a homebrew supply/pub/cookware/coffee/tea shop, and they carry a small but nice selection of glassware (got my gold Chimay glasses there).

On a recent vacation in Munich, my wife suggested that we look for glassware. "Right" I said; I speak little useful German, and I figured it would be impossible to track down anyplace in a city the size of Munich. I mocked her mercilessly for having such a silly idea as we were strolling about west of Marienplatz, when we turned a corner and came across the (a?) "Glaswerk" store. Lots and lots and lots of glassware. Amazing.

From: cjh@vallance.HQ.Ileaf.COM (Chip Hitchcock)
Subject: more on carbonation after long fermentation

I have a doppelbock waiting to reach drinkable age. It was fermented eight weeks in primary (it took that long to get below ~30 sec/glug, then quit) and bottled. I tried a bottle at one week and it had a // wonderful// head.

I suspect that carbonation depends less on time per se and more on two other factors: sedimentation rate of the yeast and (which affects this) presence of clarifying agents. I made the mistake last fall of putting the recommended amount of Polyclar in a batch of stout (to get it to blow off CO2 to flush O2 out of the secondary---stouts aren't supposed to be clear); it was a few days in primary and a week in secondary, and it still has NO head at all. I asked both my suppliers what I could do about avoiding this and they basically went fmfuh-fmfuh-well-you-could-add-yeast. (Note that a number of German bottle-conditioned beers, e.g. "hefeweizen" do this after deliberately filtering out the fermenting yeast).

If you're really worried, you could try mixing a sample with a 1/4-tsp or so of sugar in a bottle; put on a fermentation lock and see whether it starts bubbling in a day or so. Even this may be too pessimistic an assessment, because you'll probably scoop up some yeast when you rack.

From: eisen@kopf.HQ.Ileaf.COM (Carl West x4449)
Subject: Fermentation rates for small batches.

About two weeks ago I finally got around to drilling a one inch hole in the bottom of the side of a one gallon jug (a story in itself, if there's interest I'll try to describe it). This was so I could insert a stopcock, the idea being that I would be able to draw off samples from the fermenter without compromising the 'bio-seal' (not worrying, just trying to be careful). I then started a one gallon batch using Whitbread's Ale Yeast. Within 28 hours of pitching the whole 14gm package, the yeast was beginning to settle. That seemed pretty quick. Five days later, the batch was down to less than a blub a minute so I bottled it, it's still aging and has yet to clear. Before bottling, I cooked up another gallon of (low SG) wort, poured it off into a clean jug to cool and settle the trub, and in the morning siphoned it in on top of the yeast and 1/2" of beer from the last batch and shook it up good. Before I was done with breakfast I was getting about a blub every two seconds. By the time I got home that night the Krausen had risen and fallen (it left marks) and the yeast was beginning to settle. This time I'm going to let it settle 'till it's clear before I bottle.

By my limited experience, yeah, small batches go faster, It probably has more to do with pitching rate than size though.

Date: Tue, 30 Apr 91 11:32:56 EDT
From: hersh@expo.lcs.mit.edu
Subject: Fermentation rates for small batches, etc..

> I would expect a five gallon batch to take a couple of
> weeks or more to drop to this level of carbon dioxide production.

fermentation rates are batch size independent, Think about this,
otherwise it
would take places like Anchor N times longer to produce a batch than a 5
gallon
homebrewer, where N is the ratio of their batch size to the homebrewers.

Things that effect fermentation times are
1) pitching rates, how much active yeast you add at the start
2) proper aeration, how much oxygen is present to allow the yeast to
undergo
aerobic fermentation which produces more energy thus allowing for
reproduction,
which utilizes a lot of energy, and greater yeast concentration
3) presence of proper trace minerals for yeast health
4) temperature at which fermentation occurs
5) attenuative ability of the yeast, how much alcohol it can produce
before it
poisons itself.

Most ale ferments take on the order of 3-14 days ,independent of batch
size,
but dependent on the above factors.

Relax, don't worry.

To Bill Thacker,
primary yeast is much better than secondary yeast. It tends to
be more vigorous, since it has been dormant for a shorter period. Most
everything I've seen on repitching says use yeast fromn the primary...

To Mark Andrews:
The thing is you don't boil *ALL* your water. Many brewers like to do
full
boils, thus necessitating wort chilling. I used your method in the past,
but
now that I do full boils I use an immersion chiller, 15 miinutes is not
so long
to wait...

JaH

PS Sure seems like a lot of people in the military have taken to
homebrewing.

From: bliss@csrd.uiuc.edu (Brian Bliss)
Subject: Re: Fermentation rates in small batches

I don't think the size of the batch affects the fermentation rate per se, assuming you use proportionately as much yeast, same temperature, etc.

As for your beer finishing in two days, I find this normal for a stout. My favorite beer is to follow the guidelines for "Dark Sleep Stout" in TCJOHB, doubling or tripling the grains and hops, adding 3 extra lbs of dry dark malt extract, and starting with 6 gal. instead of 5, so that I have 5 left when transferring to a secondary. I usually get an initial S.G. of ~1.070, or slightly less. The beer ferments completely in 2 days! I started a batch last tuesday, and it was practically done fermenting thursday night. I gave it until saturday to settle, racked it to a secondary, and then bottled it last (monday night). by tomorrow it should be carbonated and ready to drink. 8 days total. Anybody know of anything faster? (P.S. I've only tried this with munton & fison ale yeast - perhaps that has something to do with it)

I find it interesting that you get much less of a stout flavor when you add the third bag/can of malt extract. (even if you cut the roasted barley proportionately.) The weaker stouts taste stoutier, the stronger ones taste more like a cross between a porter/bock/stout, more to my liking, - I can't stop licking my lips the whole time. (but quite volitate to your digestive system)

Saturday night I tried to brew an oatmeal stout. I cooked the oatmeal separately, used a lot of water, and strained the finer oat particles into the boil. They certainly made the wort thicker, but did not add much S.G. to it. I started with 42 oz. oatmeal, and probably threw 75% or it down the drain, getting about 2 gallons of the finer particles in the boil. Same basic recipe as above, with only 2 cans of malt extract, no dry. initial S.G. 1.053, final S.G. 1.027. There was 5 inches of oatmeal sediment in the bottom of the fermenter - it all settled out. Perhaps one needs to start with cracked oats, not oatmeal.

Subject: Hunter, extraction temps

Does anyone know where to pick up a Hunter Energy Monitor in the Bay Area/

Don McDaniel writes:

The result: an OG of 52! This time I replicated Miller's extraction almost exactly. The only deliberate change in my procedure this time was to avoid temperature overshoot when adjusting the mash temp. In the past, I had set the mash temp and when I returned to stir I'd found the temp to actually be higher than before. I think this time by avoiding overshoot and stirring regularly to maintain uniform temperature (as Marc does) I avoided de-activating my enzymes prematurely.

Last week I completely screwed up a batch by mashing at 170 F, because I was using a friend's thermometer and was used to the C scale. Anyway, I tried to save it by lowering the temperature and adding a little more grain, but I only got 1036 out of 10 lb of grain. I'm bumming. I used to mash at 70 C, because of the quick conversion times. But I always seemed to get really shitty extraction rates like 25 pts/lb. Is it possible that a lower mash temp would improve things? What kind of temperature/time combinations are people using to get good results? I'm thinking of switching to a 90-120 min mash so I can sleep in class while starch is converting.

From: "John E. Lenz" <JELJ@CORNELLA.cit.cornell.edu>
Subject: HB Digest No. 626

In today's (4-30) digest Dan Graham asks about the attenuative abilities of the Whitbread ale yeast.

I've seen this referred to as an unattenuative strain (at least in its dry form) but have just recently used the Wyeast Whitbread culture and don't feel this is so. The original gravity, on a Pale Ale, was 1.058, and after a one-week primary and a two-week secondary fermentation the terminal gravity on this batch was 1.010. Seems like a reasonable attenuation to me. CO2 production can be somewhat misleading at times, specific gravity seems to be a more reliable indicator of what activity has taken place, though with a two gallon batch I understand if you are unwilling to "waste" very much of it on specific gravity readings.

Bill Thacker asks about using the yeast drop from the secondary in lieu of pitching fresh yeast when bottling.

Seems like a reasonable approach, why don't you give it a try and let us know how it works out.

Matthew Harrington is looking for a mail order source for beer steins.

As I recall, Jim's Homebrew Supply, in Spokane, WA (address was posted recently) had a catalog from which these could be ordered, at least this was the case a couple years ago when Tom was the proprietor.

A general comment regarding the extract levels that Dave Miller claims to get, 35 points per pound per gallon seems a bit high to me, but then Dave may have been brewing long enough to have optimized his procedures and processes. Something in the 28 to 30 points per pound per gallon range seems like a reasonable expectation to me. One thing I remember from some reading I was doing a few years back is that beyond some point (which I don't recall) the relationship between pounds of grain mashed and points of extract starts to show some diminishing returns (i.e. the relationship isn't simply linear).
If anyone has some more detailed knowledge on this subject I'm sure that some of us would appreciate a posting on the subject.

Lastly, do any of you have any experience with the Wyeast Bavarian Wheat yeast culture? I'd like to know what the lower end of the temperature range at which this one will actively ferment is.

Ein prosit,
Dr. John

From: IOCONNOR@SUNRISE.ACS.SYR.EDU
Subject: Pitching

Hi,

This is my third batch. I have two bottled and one in the secondary fermenter. Due to the fact that I live in an apartment, I brew in the kitchen and ferment in the living room. My apartment is about 75F constantly, and sometimes gets to 80F. Here's the question: when I pitch, the fermenter bubbles for no more than 2 days--max. When I move it to the secondary, no more bubbling occurs.

What am I doing wrong? Most literature I've read here and in the brewing books talks about 7 days--what's up? BTW, the first two batches ended up with ending gravities of about 1010, and starting gravities about 1042, so it is fermenting. The first batch tasted ok.

Second quick one--would taking a gravity measure with the scum from the bottom of the bucket, i.e. mostly yeast, be completely inaccurate. I haven't done this, but was wondering.

Keep on Brewin'!

Kieran

Subject: Small batches, beer spheres, brewpubs

A couple of quick comments on recent postings:

Re: Small batches ==> Fast fermentations

We do our ales in standard 5-gallon batches, at about 70 deg F., in a large plastic primary. Our rule of thumb is that four days is sufficient for the fermentation to be slowed enough (i.e., several minutes between glubs) to rack into secondaries. On the other hand, our hard cider is fermented in its original 1-gallon jugs, but takes >2 weeks to reach a similar level of fermentation rate. I realize that the cider has more fermentables, but not THAT much more. We make ciders of differing strengths, but they all take roughly the same length of time. All of the batches, ciders and ales, use dry ale yeast (usually M&F) that has been given a head start (an hour or so in warm sugar water).

My point is not that small batches imply long fermentations. As the recent statistical discussions point out, coincidence does not imply causation. My point is just that small batches do not necessarily imply short fermentations either. For whatever that's worth.

Re: A source for beer spheres

There will probably be a lot of replies to this, since I got my original info from Zymurgy. A company called Marc C. Fritz, Inc., in Potsdam, NY, sells what they call a Batch Latch system for reusing party balls as homebrew kegs. Prices for different systems range from \$29.95 to \$185.00; individual parts are available also. If you're interested, call them at 1-800-762-2560 and they'll send you a free info package in a month or so. I don't work for them, I just think it looks like they have a good setup and am considering it myself. If we go through with it, I'll post a summary of the results.

Re: A new topic

My brewpartner and I have recently been thinking quite seriously of going commercial, in the form of a brewpub. It just so happens that both of our lives have a sort of opportunity for this right now. ANY information from

knowledgeable types (preferably someone who's done this before) would be greatly appreciated. Please e-mail directly to me or my brewpartner (MC2331S at the same node); if I get a lot of good stuff, I'll post a summary. Thanks!

Hello fellow brewers.

I've been quiet about this beer in plastic bottles thing because I felt that someone with more experience than I would interject, but I just have to open my big mouth. I'll just add one data point about beer in plastic.

I'm 6 months into an 18 month assignment in London. With all those pubs, why should I be concerned about beer in plastic bottles, you ask. Well, I do have to shop for groceries and so have perused the beer section at my local supermarket (a Safeway of all things!). British beer is available in 2, 2.5, and 3 liter amber plastic bottles. The plastic looks very similar in color to that used for the Matt's Party Ball, but the beer is much better :-). The bottles are typically labelled with a Best Before Date about 3 months in the future (of when I find them in the Safeway). Several brands are available, my favorite being the Samuel Smith's Old Brewery Bitter in the convenient 2 liter bottle. Costs about 3 pound, versus about 1 pound 60 pence per pint (20oz.) at the few Samuel Smith tied houses I know of.

So, other than bragging about having so much beer to choose from, what does all this mean? Well, the beer seems to keep pressure for months in proper plastic bottles, proper plastics do exist, and some very good beer is put into them. I won't mention Matt's anymore :-).

Personally, if I ever run out of new pubs and beers to try, I plan to bottle in used plastic beer bottles. But with only about 12 months left to go, I don't have much chance of running out of new adventures!

Oh, and they sell homebrewing supplies at the local Boots, the Chemist.

Cheers!

Subject: Beer in plastic bottles.
Subject: Pale Bock yeast?

Greetings!

I just got back from spending a week in Ft. Collins, Colorado at Hewlett-Packard trying to port our device driver to the new HP 9000 Series 700. My technical support person was none other than our very own Homebrew Digest coordinator, Rob Gardener! Unfortunately I did not get a chance to taste his "Hacker Brew", but I did get around to all of the Brewpubs in Ft. Collins.

I picked up an assortment of microbrew at this HUGE liquor store in Boulder and one of the brews I brought back was Sierra Nevada "Pale Bock". It says on the label that it is "Bottom-Fermented", so I am assuming that the yeast they used is a Lager yeast and is different from the "Chico Ale" yeast that they use in all of their other Ale-type brews. Does anyone out there know what variety of yeast they used? There seems to be some yeast in the bottle, so I am going to try to make a culture from it. Hopefully, I will be able to get a culture from this and be able to make a "Steam" beer. Is a Bottom-Fermented Pale Bock the same type of style as the trademarked "Steam" beer from Anchor Brewing?

Thanks.....

Bruce Hill

Subject: glassware and england

Two questions for the gallery:

1) The talk about glassware and the recent addition of "yards" to the Cambridge Brewery's serving menu got me wondering again, "where can one get these yard glass things"? Anyone know? I'd particularly like to get my hands on a few half yards as they are a little more wieldly. Yards would be a fun way to serve up homebrew to friends! (and myself)

2) I'm going to be in England for three weeks at the beginning of June. I'd like to include a few brewery tours. Can anyone recommend some "must-see's" ?

Thanks,

-Jim

Subject: Repitching

Jay Hersh wrote:

>fermentation rates are batch size independent, Think about this,
otherwise it
>would take places like Anchor N times longer to produce a batch than a 5
gallon
>homebrewer, where N is the ratio of their batch size to the homebrewers.

Another way to look at this is, "How does the yeast know if the little
bit
of brew it's sitting in is surrounded by one gallon or a million?"

However, it is worth noting that for those of us whos fermentation
temperature is at the mercy of our household thermostats, large batches
will take longer to adjust temperature to match the surroundings, so will
be less sensitive to periodic fluctuations in room temperature. This can
affect fermentation rates, but unless your fluctuations are really
extreme,
I wouldn't think the amount would be great.

> To Bill Thacker,
> primary yeast is much better than secondary yeast. It tends to

> everything I've seen on repitching says use yeast fromn the primary..
.

Now you've got me confused. "From primary" to me would mean getting some
yeast out of the primary fermenter (obviously requiring that you have
another batch working when you bottle the first). I'd agree that the
yeast
there is more "awake."

The article I was replying was (I *thought*) about throwing in a fresh
package of yeast at bottling time. In this case, I'd argue that the
yeast
from secondary would be a better choice. It didn't just get thawed or
rehydrated, for one thing. For another, we're constantly told to aerate
the wort before pitching yeast to provide enough oxygen for reproduction,
but you definitely don't want to aerate at bottling time.

John E. Lenz wrote:

> Bill Thacker asks about using the yeast drop from the secondary in lieu
of
> pitching fresh yeast when bottling.
>

us
> know how it works out.

I have, actually. The last batch we brewed was a porter, and we didn't
get
around to bottling it until it had been in the secondary for about 4
weeks.
(We had racked off the primary as soon as fermentation was done, knowing
it

would be a while until we could bottle.) Our previous batch had seemed a bit slow in carbonating, so we kicked up a little bit (*) of the yeast in the bottom of the secondary while siphoning into the bottling bucket. It did carbonate a bit quicker -- about a week and a half -- but based on one batch, I certainly can't claim that the theory is proved.

(*) - about a quarter cup of the "cake." Which brings up a question. I've heard of the dangers of yeast autolysis in fermentation, but what about bottling ? Will an "excessive amount" (?) of yeast autolyze in the bottle ? I certainly don't want my yeast driving around in little autos, burning up all the alcohol and polluting my beer with exhaust fumes ! 8-)

Sterling> systems range from \$29.95 to \$185.00

Geez, for \$185 (or less, maybe) you can get a complete soda-keg and CO2
tank setup (from Foxx or from American Brewmaster, maybe others). Just a
keg will set you back about \$30. My 5# CO2 cylinders lasted about 6
months,
and may last another at the rate of about 20 gallons/month.

This beer-ball thing seems too expensive to me.

From: "John E. Lenz" <JELJ@CORNELLA.cit.cornell.edu>
Subject: HB Digest No. 627

Chip Hitchcock writes about his doppelbock which has a wonderful head after only a week in the bottle.

I'd monitor this pretty closely, I had an all-grain Maerzen which was of a similar nature after a week in the bottle. Unfortunately, after 3 to 4 weeks in the bottle the stuff was damn near unmanageable in that it produced a pitcher full of head with very little liquid left at the bottom when it was poured. For those of you who are thinking "Aha, an infected batch," I don't think so, I still have a bunch of this stuff (now 2 years old) and once the head turns back into beer it is quite tasty. Turns out that it wasn't fully fermented when bottled (after about a 2-3 week primary and a 2-month cold lagering) and dropped about 7 points !! in the bottle. Needless to say, I've since become quite conservative in my priming.

Ken Johnson asks about the effects of temperature on extraction rates.

There is definitely a relationship here. According to my calculations your 70 degree C mash temperature is 158 degrees F. Mashing at this high a temp. will produce a very dextrinous wort, in a relatively short time to boot. I have read that mashing at 150 degrees F is generally believed to produce a very well-balanced (in terms of dextrans v.s. fermentables) wort. Mashing below 150 degrees F will produce a lot of fermentables at the expense of dextrans, and will take much longer to convert. I generally try to maintain a mash temp. of about 150-152 F, 2-3 degrees higher if I want some residual sweetness in my beer. My extraction rates aren't on the order of those which Miller gets, but I usually get about 38-30 points per pound per gallon which I find quite acceptable.

mbharrington@UCSD.EDU writes about his batch which has been 16 days in the fermenter, and seems to want to speed things up.

I'd say you might be better off simply waiting for things to proceed at their own pace. Within reasonable limits you might try warmer fermentation temperatures, though you will likely get increased ester production (not too desirable in a lager).

mbharrington also asks about taking samples out of the carboy for hydrometer

readings.

I have a rather large plastic "wine thief" which I use. It is a 3-piece thing which is easily sanitized in bleach solution. I usually have to draw out two portions of beer with it to get enough for a reading. A lot of homebrew suppliers sell these things, and also some made of glass. The glass ones are really too small to be of much practical use, at least the ones I've seen.

Cheers,

Dr. John

>1042, so it is fermenting. The first batch tasted ok.

The drop in S.G. tells the story... You're not doing anything wrong.

Warmer

ferments go faster. I'll bet you're using dry yeast, too, which takes off very rapidly, as a rule. Stick with ale yeasts, and heartier recipes that will cover some of the esters and potential off flavors from a warm ferment, and enjoy.

>

>Second quick one--would taking a gravity measure with the scum from
>the bottom of the bucket, i.e. mostly yeast, be completely
>inaccurate. I havent done this, but was wondering.

Yes, it would be inaccurate. If the S.G. of the stuff at the bottom was the

same as the S.G. of the stuff at the top, it wouldn't settle out.

Consider

an extreme case, like a mixture of oil and vinegar...

Bill Thacker asks about reusing yeast from the secondary fermentor.

I have done this three times now, with very good results. I brew and bottle on the same day. While the new beer is in the boil, I bottle the previous batch. Then I swirl up the sediment from the secondary fermentor and use it to pitch the new beer. The biggest problem I've had is the resulting acceleration of my brewingschedule, and deceleration of the rest of my life, as I try to drink the beer faster than I'm producing it...

Subject: More fun in Pasadena!

To all the folks who replied to my post regarding pubs in Pasadena, CA, thanks! I'm very VERY sorry I forgot all about the John Bull, I would definitely recommend it to anyone going to the area. Fair warning: if you want to kick back and relax at the John Bull or the Loch Ness Monster (did the name actually change?) DON'T go on a weekend night. Late weekday evenings are bad for relaxing as well. You see, the John Bull is faithfully frequented by the South Pasadena rich suburban kids, and it gets pretty loud and rowdy at times. It's still fun, but not if you want quiet reflection. Ah, growing up in L.A. ...

The John Bull is definitely on S. Fair Oaks (~6 blocks south of Del Mar), and definitely catty-corner from Gerlach's Liquors. I'd tell you the name of the cross street, I can vividly see it in my mind's eye, but I can't remember the name.

The Doo Dah Parade definitely started at the Loch Ness Monster.

Subject: wyeast Bavarian wheat beer yeast(s)

> From: "John E. Lenz" <JELJ@CORNELLA.cit.cornell.edu>
>
> Lastly, do any of you have any experience with the Wyeast Bavarian
Wheat
> yeast culture? I'd like to know what the lower end of the temperature
> range at which this one will actively ferment is.

It's actually two yeasts: *S. Delbruckii* (the estery one) and a top fermenting ale yeast (the boring one). If you fool with temperature, you will favor one over the other. My own experience indicates that lower temperatures will favor the ale yeast, making the clove aroma characteristic of wheat beers disappear.

The reason they mix yeasts is that they were afraid the pure *S. Delbruckii* would be too intense for most people. Mixing yeasts seems like a poor approach to me; I would rather ferment down to some level of gravity and change yeasts, but then I'm a fanatic.

Pure strains of *S. Delbruckii* are available from

MeV
PO Box 123
Waterloo, Ontario, Canada
N2J 3Z9
(519) 742-7227

There's also an outfit in Tennessee that stocks it, but my order is two weeks old now, and still no yeast, so I hesitate to recommend them.

Wyeast will sell you a package of pure *S. Delbruckii*, but this is not a retail product; they sell it to brewpubs and the like. They quoted me \$14 for one packet!

Go ahead and try the Wyeast; I've had excellent wheat beers made with it (as well as bland beers with little detectable wheat character), so I know it's possible. The straight stuff is proving almost as hard to *get* as it was to *find*.

Subject: Fast fermentations, oats

In HBD #627, Brian Bliss writes:

>I started a batch last tuesday, and it was practically done
>fermenting thursday night. I gave it until saturday to
>settle, racked it to a secondary, and then bottled it last
>(monday night). by tomorrow it should be carbonated and
>ready to drink. 8 days total. Anybody know of anything faster?
>(P.S. I've only tried thried this with munton & fison ale yeast
> - perhaps that has something to do with it)

Munton & Fison is indeed a speedy yeast. I was really surprised the first time I used the stuff. At 60 degrees, it fermented a stout out in 5 days -- done, kaput, not another glub out of it. My previous experience with Whitbred dry ale yeast is very different. At the same temperature I've had the Whitbred continue fermenting for over three weeks.

Also, regarding the use of oatmeal.

>I started with 42 oz. oatmeal, and probably threw 75%
>or it down the drain, getting about 2 gallons of the finer
>particles in the boil. Same basic recipe as above,
>with only 2 cans of malt extract, no dry. initial S.G. 1.053,
>final S.G. 1.027. There was 5 inches of oatmeal sediment
>in the bottom of the fermenter - it all settled out.
>Perhaps one needs to start with cracked oats, not oatmeal.

You've got to mash oats otherwise none of the starches will convert. If you just boil the stuff, all you get is goo. Steel cut oats will work best. If you decide to try it: 1) don't use much more than a pound of oats and 2) be aware that oats are very sticky -- it's quite easy to get a stuck run-off.

From: csswingley@ucdavis.edu
Subject: Cheap sparger

Howdy,

Just thought I'd pass along my cheap sparger idea. Being a graduate student and homebrewer often come in conflict due to the expense of the hobby. I had wanted to try an all-grain recipe, but didn't want to spend the money (typical for me) to get all the equipment.

The sparger I now use is made out of an old Culligan 5-gallon water jug. One can go to a Culligan water distribution center and buy "defective" water jugs for 50 cents. All I did to convert it to a sparger was cut the top off, cut a hole in the bottom, and attach a piece of plastic pipe to the bottom. A simple plug serves to stop the flow of liquor when more water needs to be added. I suppose a spigot could also be used, but the plastic pipe pieces I used were very cheap, and serve the purpose well.

The only difficulty in converting the water jug is cutting it up. I don't have any tools save an electric drill, so I had to drill umpteen holes and crack the top off. Perhaps a hack saw or pipe saw would work more quickly, I don't know.

Anyhow, just thought I'd pass the idea along for those who want to try all-grain brewing (an hour and a half!!) but don't want to buy several buckets and all the stuff Burch recommends in Brewing Quality Beer. I should also add that cheesecloth does not serve well as the sparge bag that holds the grains--the cheesecloth just fills with grain and plugs up the pipe at the bottom. Nylon is really the only thing I've found that works.

Also, any advice on brewing during the summer? It gets pretty` damn hot out here in central Ca over the summer. Burch recommends a water jacket to cool the fermenting beer. Any other ideas? Does the water jacket idea work? Let me know. Thanks.

Adios.

From: Brew Free or Die! 01-May-1991 1444 <hall@buffa.enet.dec.com>
Subject: Brew Free or Die Homebrew Club of New Hampshire

Here's a reminder/pointer to anyone interested in being a member of a homebrew club in the southern NH/northeastern Mass area.

The club that started at a brewer's home in Pembroke, NH some months ago has really gotten off the ground. We call ourselves the Brew Free or Die Homebrew Club of NH. We meet from 3-6 PM on the second Saturday of the month on the 3rd floor of the building that houses Masi Plumbing and Heating Supply and The Grainery Restaurant, at 36 Otterson Street in Nashua, NH. This location is fairly central for both NH and Mass brewers, and it is offered gratis by one of our members and our /berbra|meister, Ed Boisvert (made famous recently in an article about home brewing and Jasper's Home Brew Supply printed in the Nashua Telegraph and another in the Manchester Union Leader). There is a large meeting room, several small rooms (one with a fridge), and a bathroom. All the conveniences of somebody else's home. 8^)

We've already gotten a logo designed (shows the Old Man of the Mountains hoisting a frosty mug), and will be printing up T-shirts both for ourselves and to sell at a table we have reserved at the AHA conference in Manchester. Dues are \$10/year, and \$2/meeting, which will be used for mailings, and put towards possible club trips, holiday dinners, or a summer barbecue.

So far, we've got about 20 regular members, with a fair mix of men and women, and several all-grain brewers. We've been in contact with the AHA regularly, and in fact, Charlie Papazian has agreed to speak at Ed's Rotary meeting, and several club members will be in attendance. I invite anybody interested in joining the club to get in touch with me. Your friends are welcome too. The more members, the merrier. We are a *very* informal club. I will scan and email the first three newsletters and a map to anyone who requests.

The next meeting is May 11 at 3 PM, and if you're interested, the Beer of the Meeting is Brown Ale, though any beer is welcome, including commercial products. Last time, someone brought Catamount's new Ethan Allen Ale. Now I know I don't need to waste my money. IMRHO, the first bad product Catamount has produced, and they did it in a big way - truly wretched!

See you there!

-Dan

From: microsoft!larryba@uunet.UU.NET
Subject: Re: Four hour brews...

Ok, so there is some doubt about my claims. Well perhaps I slipped a few minutes here and there... This is the letter I sent to Marc. My appologies for the length, in advance.

I get my grain measured and crushed at the local supplier. I bought a grain card so all I do is walk in with my recipe and walk out with a sack o grain 5 minutes later. I guess I don't count this in the brew time... I do a loose rendition of single step infusion mash and typically get 105% efficiency compared to miller. Conversion at 150deg takes about 1/2 hour - but I let it go for 1 hour. I sparge with 175deg water. I use a mash/sparge bucket with a home made screen on the bottom (polycarbonate laboriously hand drilled) and an insulite wrap. I overlap starting the boil with sparging (spage into the boiler, on the heat) I use a counterflow chiller and it takes about 8 minutes to chill 5.5. gal.

I don't have much fine control over the process, however simplicity makes the process quick. The resulting beers are pretty consistent. I am happy just to be able to calculate IBU's and control that aspect with confidence. Use of carmel malt or other high kilned malts (munich, etc) seem to make the biggest difference in the quality of the brew. If I were a micro brewery and wanted to use dirt cheap klages for the bulk of my brews, then fine control over mashing technique would be more important. I am certain that I will get more anal about the process as my skills and tastes improve. Below is a log of a brown lager I made this weekend:

11:00am start heating 8.5qt water + 2 tsp burton salts (Seattle water is soft)
Fill carboy, racking tube, chiller with bleach solution (2oz/6gal)
11:30 water @ 172deg, put in bucket, measured at 170
mash in at 145deg (6lb Pale Ale, 8oz Xtal, 4oz Chocolote)
11:45 Mash stabilised at 150, start heating ~4 gal of sparge water.
11:50 Add 1qt of boiling water to mash, bring temp back to 150??
Periodically recirculate 2 qts of wort and check with iodine.
12:30 Conversion done (mash temp still around 150) Start sparging.
12:50 Boil Heat on at around 3 gal of sparge
1:10 Sparge Done. Add 1qt of water to bring total to 6 gal
1:40 Boil started, mash bucket & kitchen cleaned
1:55 pitch hops (16 grams of Chinook - ~7aau) start draining carboy/
chiller
2:40 Heat off, pitch 1oz of Cascades, swirl hard. final rinse of
carboy.
2:50 Chilling done, wort at 60deg, pitch yeast, SG = .043
3:00pm Carboy wrapped and in refer, boiler cleaned, wort chiller rinsed.

There was some fooling around so my mash water was about 5 deg hotter than usual. I was trying to mash at 160, but goofed. I still don't know what went wrong.

P.S.

The reason I wanted to mash at 160 is due to the highly attenuative yeast I got from a local microbrewery. 163 is the temp they mash at in order to get decent body. I have brewed with Klages using the above technique and obtained essentially identical results (klages tends to be more fermentable). I use a hot water heater fire ring to preheat my water. Another technique is to simply crank the temperature of your hot water

tank to 180-190 the night before brewing (and all through the house...) I use pellet hops. I don't worry too much about bleach in my beer. I toss the first pint or so from the wort chiller before turning on the cold water. I let the chilled beer splash into the carboy. For an ale I chill to 75 deg, for the lager I chilled to 60. I make extensive use of gravity to speed the chilling. I put the kettle on a bucket on the counter and the carboy on the floor. The sparge bucket also goes on top of a bucket so I can sparge directly into the kettle. I use a tube on the spigot so I don't splash the wort into the kettle. Aside from preheat, everything is done on my electric stovetop. Because I overlap so much stuff, I find the four hours to be pretty busy. Usually I have a half hour to eat lunch between the hops pitch and the final rinse of the carboy. The bleach takes that long to drain because there is essentially no head between the carboy and the sink.

There, I have told all. The lager was my 7th brew since switching to grain.
I hope this answers all your questions... For additional details send mail direct to me. Thanks.

Subject: Re: Four hour brews...

OK, OK. 625 is 5 to the 4th power. Had to be one of those positive integers, didn't it? This is all further indication that a mathematician doesn't need to be any good with arithmetic (there's always some student in the class who'll correct it for you).

What I really want to find out about is diacetyl and other unpleasant by-products.

During the course of some 160 or so batches in my Toronto years, I had three significant flops. They all had an off-taste I referred to in my log book as "clinical". It reminded me of that antiseptic/solvent smell you notice in hospitals, clinics and doctors' offices. The first two I was foolhardy enough to bottle and pray, but they never got appreciably better. The third one I pitched out; it also had a strong banana aroma, which I seem to recall hearing about in the HBD about a year ago. BTW, that last one was an experiment with lots of flaked rice, and a dried lager yeast with room temperature fermentation.

I had heard about diacetyl here and there, but the term "butterscotch" was frequently used.

Fast forward to December 1990 in Evanston. I had a batch of pale ale, bottled less than two weeks from brew-up, with an unmistakable "butterscotch" nose and palate. Strong, even over-powering, but not entirely unpleasant. I even kind of liked it. Kind of, and only one at a time. After about a week in the bottle, the old "clinical" flavour started to develop, so I put it all into the fridge, and nothing much changed from then on.

So I'm beginning to think that "clinical" is just what happens to diacetyl after long aging. Either it actually mutates chemically, or it's just a secondary characteristic that develops with time.

About two months later another batch of pale ale, almost identical to the December batch. At two weeks it's showing only "clinical", and strongly so.

So here's where the tinkering begins. Diacetyl is an intermediate product, right, somewhere between the $C_6H_{12}O_6$ and the C_2H_5OH that's supposed to get produced and consumed, right? Trace amounts are normal, large amounts an indication of unhealthy fermentation, right? So I throw the whole mess back into a primary with a pound of dextrose dissolved in water, a vigorous oxygenation and a new pitch of dried yeast (M&F, same as I'd started it with). A new fermentation got going, sure enough, but the results four days later were no more or less "clinical" than they'd started out being.

Oh, well, chalk up another one to empirical science. :-) I flushed the whole batch away.

3 bad batches in 160 isn't too bad. 2 out of a dozen is awful. A few months back, someone suggested the following way to get rid of trub: pitch the yeast into a primary with trub and all, rack 12-24 hours later when the trub has settled and the anaerobic has yet to begin. I tried it three times: the first with great success, the latter two being the above-mentioned batches. You can bet I won't be trying that trick again.

So, answers and/or opinions, please. Is the "clinical" thing mature diacetyl, or something diacetyl turns into? Is this kooky method of racking after (typically) 16 hours likely to cause diacetyl problems? Could the whole thing be explained by infection?

BTW, which issue number will be the next prime power?

Subject: Alcoholism again

In HBD #625, Don Perley writes:

>You should beware of circular reasoning here. Say someone has 1 beer
>per week. Some well meaning Temperance Union zealot tells him he has
>a problem. He says "Get stuffed! One beer per week is NOT
>excessive!"

I suggested that a FRIEND's warning should be heeded. There aren't any
Temperance Union zealots on my Christmas card list! But if a person
whose opinion I generally respect tells me I drink too much, I'll
listen. I don't give a damn for the "drinking is immoral" crowd. Does
anyone in this audience? It's not circular if you consider the source.

>Now the poor sot is rejecting suggestion of a problem. Plus, in the
>eyes of some, he drinks excessively. To top it off, he can't control
>his drinking (actually, he is not willing to change his habits just to
>please some whacko who really thinks ANY alcohol is immoral).
Those criteria I listed in HBD #623 are what the military uses to find
problem drinkers--do they sound reasonable to you? Anyone whose life,
family, job, and health have crumbled has problems, if you ask me.
There are no acceptable criteria for a specific volume being "too much."
One beer a week is not enough, if you ask me. Even a case a day may
not be "too much" for some people.

>While a "true" alcoholic may practice denial, isn't that
>a REASONABLE action for a non-alcoholic? In short, while you should
>recognize the tendency to deny a problem, denial itself isn't an
>indicator of the problem.

Roger. Denial itself indicates nothing. However, you seem to
believe in a "true" alcoholic...what is that, exactly, and would
you tell a friend if you thought they were? Hypothetically, you
do so, and they say "stuff it." What are you going to think then?
"Time to join the Temperance Union?" Or maybe "it's more
serious than I thought?"

If you still want to argue, lets take it off the net;
HBD isn't a debate forum, after all.

>to speed it up a bit?

You can raise the temperature, but you will be defeating the purpose of brewing a lager. You can brew an ale with any yeast (ale, lager, bread, etc.) but lagers are more elusive. The primary difference between a lager and an ale is the amount of esters (fruity flavors). Ales, in general, are fruity and lagers are not. At what temperature are you brewing? If you are brewing at 70 or 75F and it's taking 16 days, then I don't know... maybe you have a bacterial infection (some bacteria can digest complex carbohydrates that most yeasts leave behind). If you are brewing at 40F, then buy some good micro beer or import beer to take your mind off the homebrew -- it will take longer than 16 days at that temperature.

Al.

to 65F is good
for ales and will produce enough esters. Some ale yeasts will tolerate 50F or even lower. Also, some yeasts will produce less esters at 70F than others do at 60F.

Subject: Miller on special malts

Hi all - I was at my brew supply store this evening, and I finally broke down and bought a copy of Dave Miller's "The Complete Handbook of Home Brewing". My first impressions are very good. I did see one thing that confused me a bit, so I thought I'd ask the group.

In chapter 8 (Special Malts), Miller says (any typos are undoubtedly my own), "One point that must be emphasized is that all roasted and crystal malts contain residual starch, and should be mashed with a diastatic malt in order to convert that starch and extract their full flavor and color."

This is contrary to what I've always believed. Even many extract recipes that I've seen call for crystal malt. I've never heard of mashing crystal or roasted malts. I've always mashed my [pale|klages] malt and then tossed in the specialty malts in with the sparge, leaving some time for them to steep at about 170F. Perhaps I should be mashing. What do other folks do?

A related question - won't mashing a dextrin (cara-pils) malt convert some of the dextrose into maltose during the maltose (~155F) phase? Do you all mash your dextrin malt?

Thanks,

Ken

It arrived the afternoon I posted this. To make up for
impugning their reputation, here is a plug:

Brewhaus
4955 Ball Camp Rd.
Knoxville, TN 37921
(615) 523-4615

I mentioned in this article that I thought lower
temperatures would work against the S. Delbruckii strain in
the Wyeast packet; the MeV packet says "ferment below 20 deg
C" on it, which is pretty cold for an ale yeast. I'm going to
bite the bullet and make the international phone call today to
get the straight poop. Byron Burch recommends a warm ferment
for the Wyeast to get lots of esters, and I'm confused (but
not worried!).

Tell them the current laws are anti-competitive, and
are inhibiting a potentially lucrative industry. Jobs is a
good argument; I don't think anybody in the legislature would
be sympathetic to "I'm sick of bad beer!" If the process of
regulating alcohol is as corrupt in TX as it is in CA, the
megabreweries will have an easier time suppressing competition
than the public will encouraging it.

Simply pointing out the absurdity of a law doesn't
seem to help much either...

Subject: cara-pils; diacetyl; mash-time

Greetings All:

The U.S. Open Homebrew Competition was a success. We judged 90 beers. The guys who judged Best of Show had an awful time deciding which deserved the "Big Blue" but in the end it went to the Pale Ale, from a homebrewer in Texax (sorry, I didn't write down his name). This was the first competition to participate in the Southeastern Homebrewer of the Year Award program, an award to the homebrewer from the Southeast who accumulates the most points in a year from all the competitions he/she enters.

Being the judge director, I didn't have the privilege to judge a category :-(. But the most interesting beer I sampled was a raspberry/clove mead by Jeb Sturmer from Durham. A MOST interesting beverage. A little heavy on the cloves otherwise it might have taken first in the meads. In case anyone wants to try something different...

A question arose so at the competition so I pass it to the group:

How do they malt Cara-pils so that it doesn't have any convertible starches?

As for diacetyl in beer:

It's my understanding that diacetyl can be produced by racking too quickly to a secondary fermenter. There is a diacetyl reduction period just after primary fermentation when the beer needs to sit on the yeast cake for a day or two. Diacetyl is what they use to make margarine taste like butter (check out the ingredients on the side of the package sometime) so "butter" is definitely what you should be tasting if diacetyl is your problem. "Medicinal/clinical" probably relates to another defect. I'll have to check some of my sources to nail it down.

As for the time it takes to make all-grain beer:

I find that most of the time involved in making all-grain beer is used up waiting for the mash to convert, sparging, and then waiting to finish the boil. I wrote an article for the All-Grain special issue that outlines a procedure whereby you brew two beers at once and "stagger" the steps. Sparge #1 while you're mashing #2; Boil #1 while you're sparging #2; Cool #1 while you're boiling #2. It takes some advance planning. I grind the grains, weigh out the hops and sterilize the carboys the night before, because once the process begins, it's non-stop! The net effect though is two batches of all-grain beer in just a little more time than it takes to brew one. The drawback is that it takes two brewpots. I'm a Bruheat fan and use two Bruheats. Whatever you use, if you can borrow the extra pot and mash tun from a fellow brewer for a day, then you don't have to drop the coins on the extra equipment.

From: Douglas Allen Luce <dl2p+@andrew.cmu.edu>
Subject: Styro-Mead

Last September, I decided to try making a small batch of mead. I used a recipe from the list calling for ginger, tea, and orange peel in addition to the honey. I ended up with a one gallon batch (heated for 45 minutes with scum-scraping, no boiling) dubbed "Feynstein Troublemead."

It has had pretty much the same taste since the fermentation (with Red Star Champagne yeast) ended. Very sweet, no real taste of alcohol, and a horrid composure of styrene!

Yuk. I've never heard about this taste before; what could be causing it? The stuff came out of my stainless steel boiler into the glass fermenting vessel and glass conditioning jug, never making it's way through coffee cups or anything like that. I've only racked it once after the primary fermentation, and there's a few wisps of yeast left at the bottom; could this have anything to do with the taste? Is this something that might go away? It seems as strong as ever.

Goofy stuff.

Subject: diacetyl, clinical flavor

In HBD 626, R. Bradley asks about diacetyl and 'clinical' flavors:

From what I've read, diacetyl is naturally produced during the yeast's aerobic reproductive phase. And during the anaerobic phase, diacetyl is reduced by the yeast. I believe the amounts produced and reduced can vary in different strains of yeast. Also, reintroducing oxygen during the anaerobic phase will restart diacetyl production, sometimes producing more than can be reduced. You sound like an experienced brewer, so I hesitate to suggest this, but are you being very careful not to oxygenate the wort when racking off the trub? To me, this seems like the most likely cause of your diacetyl problem. I wouldn't say that diacetyl is the product of an unhealthy ferment, but rather an improperly controlled ferment.

As for the clinical taste deriving from diacetyl, I don't think that could be true. Some commercial brewers purposely try to produce some diacetyl (Samuel Adams and Samuel Smiths come to mind) and it's a desirable attribute in stouts and porters, where it stays in the background. I think the 'clinical' flavor you're describing is known as phenolic. I usually associate this with contamination problems. I know, you've done 160 batches with no problems, but a small change in procedure can sometimes cause problems. Myself, I made good beer for two years, then, all of a sudden, every second batch was going bad. I realized (after doing a lot of reading) that I had just started using adjunct grains in my extract beers, and since I wasn't doing full wort boils, the dust from the cracking of grains was contaminating my brew water. I started cracking outside, and no more problem. It sounds like you've changed your procedure, slightly. Try to determine if you've increased the contamination risk, or tell us more.

kg.

> be mashing. What do other folks do?

You'll find that Byron Burch, author of "Brewing Quality Beers" is an
advocate
of mashing adjuncts, as well. What do I do? When I make extract beers, I
use
primarily dry malt extract, which is almost complete fermentables, so I
use
crystal to add both flavor and body. Therefore, I don't mash it, but just
steep it. When doing all-grain, however, I'm using the mash process to
control
body. So I go ahead and mash the crystal (and other adjuncts) with my
pale malt.

As to Miller's claim that mashing adjuncts must be done to "extract their
full
flavor and color", I think he might be over-stating things, especially
color. I
haven't done any extract-with-mashed-adjunct beers to support my opinion,
though. As it has been noted here before, crystal makes extract beer so
much
better, almost every brewer will keep increasing it and end up with a
beer
that's too sweet. If you were to mash the crystal, you could increase the
crystal without your beer becoming cloying. When I mash a pale ale, I use
1 lb
of crystal for 5 gallons. In an extract recipe for 5 gallons of pale ale,
1/4 lb
of unmashed crystal is about the limit (IMHO, of course) before causing
over-sweetness.

Subject: Weizen Yeast

Hello. I've got a quick question for all you out in homebrew land. I am an intermediate extract/speciality grain homebrewer with an interest in making an attempt at producing a Weizen this summer. I was hoping to do something simple with a wheat malt extract and a traditional top fermenting Weizen yeast. Here's where the question comes in. My girlfriend and I managed to get these bargain basement tickets to Germany and are going to vacation in Bavaria, alias Beer Heaven. I would like nothing better than to grab a couple of bottles of Weizen mit Hefe (wheat beer with yeast) to bring home in order to reculture the yeast for my Weizen. The problem is that according to Papazian in the Spring 1990 issue of Zymurgy, most Bavarian Weizen beers are filtered in order to remove the yeast used during fermentation. The yeast is then replaced with a lager yeast which flocculates better. Does anyone know of a Weizen brewer that does not do this? If so, do you have any advice on reculturing from bottle conditioned beers? Thanks in advance.

Subject: Quicker Brewing

From: dinsdale@chtm.unm.edu (Don McDaniel)

>I'm with Marc. I've recently gone over to all-grain brewing
>(except when I'm desperately low on brew and don't have time for
>mashing) but I find it takes me the better part of EIGHT HOURS
>to brew a batch. It's not a total write-off since I can use some of
>the dead time to get chores done around the house, but it does
>control my whole day. I'd really like to know how it can be done
>in four hours!

I made the move to all-grain about three years ago, and have been refining my brewery and technique since then. In the last six months, I have gotten my brewing time down to four hours. A full blown description of my technique would be rather tiresome, so I'll limit the discussion to a few hints and caveats. First the caveats.

This style of brewing is not for everyone, for at least three reasons.

1. Managing time efficiently. To brew that quickly, you must streamline your process. There are usually several things happening simultaneously, which must be executed with precision. Even if you know what you're doing, it can get kind of harried. Often I would rather take 5-6 hours, which leaves more time for relaxing etc.
2. Equipment. The brewery set-up must be easy to use, and must do its job quickly. Setting this up can consume hundreds of dollars and infinite amounts of time. It helps to love brewery building as much as brewing!!
3. Flexibility. If you really want to brew in four hours, you'll probably have to forgo protein rests, low temp saccharification rests (<157F), roasting your own grains, longer boils, whirlpooling, etc. A high temp, single step infusion mash, followed by a one hour boil limits your flexibility, but speeds up your brewing.

And now a few hints.

1. Concentrate on the "critical path". Know exactly what you will need when, and have it ready at that time. Use periods of lesser activity to prepare and clean. Examples, a) sterilize equipment during the mash; b) drain and rinse carboys during the boil; c) clean mashtun while chilling wort (saves water too!). By thinking carefully about the process, you'll be able to see things that can be done in parallel.
2. Use pre-cracked grains. If you get your supplies on brewing day, or the day before, have your supplier crack them for you. It beats spinning the handle of the old Corona, and should give you a better crush too (assuming your supplier has a 2 roller mill).
3. Get a high output burner. This is a great way to shorten brewing time that causes nothing to be compromised. The kettle is used to heat mash water, heat sparge water, and boil wort. Depending on

your set up and schedule, all 3 of these may be on the critical path. Anything that you can do to shorten the critical path will reduce the time spent brewing. My 125,000 BTU burner can boil 15 gallons in 10-15 minutes, and has shortened my brewing time considerably.

4. Use hot tap water. Part of your work is already done for you.

5. Brew outside. If you've got a high output burner, you'll want to do so for safety reasons. Furthermore, you'll never have to mop another floor again!! (A word of caution, sanitation can get trickier outside.)

6. Shorten mash times. According to Dr. Lewis at UC Davis, nearly all of the conversion takes place in the first 5 minutes of the mash, provided that you use enzyme rich American malt (2 row Klages is excellent), and mash in at 158-160F. Marin Brewing Co is now mashing for about 35 minutes (it takes that long to get the sparge water up to temp), and one sip of their beer is enough to convince most skeptics. I've mashed for as little as 1/2 hour at 158F, and been very pleased with the results. Because of the high mash temp, the finished beer will be full bodied and rich in unfermentables (yummm).

7. Use a hot liquor back. This is an insulated tank that stores heated sparge water. By freeing up the brew kettle, you can begin heating the runoff before sparging is completed. You must exercise caution, however, to avoid scorching the high density first runnings.

8. Limit the boil to one hour. One hour is sufficient to extract & isomerize alpha acids, sterilize the wort, and get a good hot break.

9. Clean up as you go. If you do this, you will minimize the amount of drudgery after the fun part is over. By the time I've got cooled wort and yeast into the carboy, there are only two things left to clean : the brewkettle and the heat exchanger.

Naturally there are times when you wouldn't want to use some of the above techniques. If, however, minimizing brewing time is a priority, you might want to try them.

Subject: Federal law?

According to wolfe@zeus.WEC.COM (braumeister)'s account, "UPS returns HOMEBREW COMPETITION entry's," ...

> Friday, April 19,1991, I had returned to me, my homebrew entries.
>Reason, UPS does not violate Federal Law of Interstate Transport of Alcoholic Beverages across state lines.
> I was intructed to cease and desist my attempted shipping of alcohol across state line, or they would report me to the BATF.

Balderdash! UPS may elect not to ship the Demon Alky-hol across state lines, but they have no right to tell you that you're a law-breaking malefactor. There is NO federal law that forbids interstate shipment of alcohol, except specifically by the U.S. Postal Service, and that's a postal matter, not in BATF's bailiwick. Call the BATF agents in your own home town and they will be happy to confirm this.

Most UPS agencies are quite willing to look the other way when you ship "processed barley" via their system. In this case, while acknowledging that they have the right to deny your shipment, I think I'd have a little talk with your agent's supervisor about his attitude problem.

I think that UPS' problem, other than a galloping case of neo-prohibitionism, is that there's a patchwork of STATE laws governing shipment of alcohol IN, and a relative minority (Texas is said to be one such) are fairly aggressive about enforcement. This is generally not because of prohibitionist sentiment as because the states like to collect excise taxes. UPS, among others, finds it easier to decline to accept the shipment than to keep track of the paperwork.

Try Federal Express or Greyhound Package Express. And tell UPS that you don't intend to send ANYTHING on the big brown truck until they get their act together.

From: <CONDOF%CLARGRAD.BITNET@CUNYVM.CUNY.EDU>
Subject: Diacetyl & "clinical" odor

bradley@math.nwu.edu (Rob Bradley) asks about diacetyl and a "clinical" odor/flavor.

Diacetyl is short for diacetyl ester, $\text{CH}_3\text{COCOCH}_3$. It has a sweet or butterscotchy or buttery flavor/odor, depending on who you are. In low amounts, it can be quite pleasant. It's present only in young ales, because the yeast will eventually digest it, even in the bottle.

According to "Principles of Brewing Science," by George Fix, high levels of diacetyl can be generated by a bacterium, *Pediococcus* sp. These bacteria also produce lactic acid, and I believe they are used on purpose in Lambics. In other brews, they're considered disastrous.

Other sources of diacetyl, again according to Fix: minor metabolic pathways of yeast, "petite" yeast mutants, spontaneous decomposition of alphaacetolactic acid, too much oxygen in the wort, too little valine in the wort.

Correction: above I said it's diacetyl ester. That's wrong. It's diacetyl KETONE.

As for the "clinical" odor, I suspect you mean a phenolic character. The compound of interest, again according to Fix, is 4-vinyl-guaiacol. It is produced by superattenuating wild yeast (*S. diastaticus*) in high quantities. It is produced more by ale (*S. cerevisiae*) than by lager (*S. uvarum*) yeast, and it is produced by *S. delbrueckii*, the Bavarian wheat beer yeast, in which it is considered desirable, as in low quantities, it provides the "clovelike" character of those beers.

>So, answers and/or opinions, please. Is the "clinical"
>thing mature diacetyl, or something diacetyl turns into?
>Is this kooky method of racking after (typically) 16 hours
>likely to cause diacetyl problems? Could the whole thing
>be explained by infection?

The "clinical" and diacetyl flavors are caused by quite different compounds produced by quite different pathways. The "maturing" of diacetyl to "clinical" is caused by the disappearance of the unstable diacetyl. The prevalence of phenol could be explained by infection by *S. diastaticus* or its presence in a contaminated dry yeast source, for example. Very high levels of diacetyl could be explained by infection by *Pediococcus*.

According to Fix, *Pediococcus* loves maltose, so incomplete or slow-starting fermentations are most susceptible. If you're not getting short lag times after pitching, this could be something to look into. Of course, thorough sanitation is necessary. Fix says the bacteria can live even in scratches in glass, and plastic is a great haven for them. Consider replacing all your plastic equipment.

Hope this helps.

Subject: Re: brewing software

[Darryl Richman's post on Mac brewing software reminded me of this.]

In the 1989 or 1990 special issue of Zymurgy (the one on "Beer and Hops"), there is an article by Jackie Rager (sp?) that gives a formula for calculating IBUs given a hop's alpha content, boiling time, etc..

Can anyone tell me how accurate it is? I programmed the equations and data table into my HP 48SX calculator, and noted that, using the example in the article, an error of one minute roughly translated into an error of one IBU. In other words, if the wort is boiled for an extra five minutes, the IBU changes by 4-6 IBUs (I've forgotten the exact number). Given that the IBU value can change rapidly with time, how do you take into account wort cooling time, or is this already reflected in the equation? Perhaps the bitterness extracted from hops decreases rapidly with wort temperature?

Subject: new reader's questions

Gooday from Australia,

I'm a recent subscriber to this digest and think that it's great. What follows is part of an article that I posted to rec.food.drink a few weeks ago. Two homebrewers kindly mailed me details of this list. Some of my questions may provoke some discussion?

I've been homebrewing for several years now with results ranging from the usual undrinkable failures to some that were 'few-cents-a-bottle' masterpieces.

I started with kits, made extract brews, then graduated to grain brewing - [poetic waffle about joys of brewing deleted].

Since moving to a four acre block in the hills North-East of Melbourne and starting to owner-build our house there isn't much time for brewing (*HOME* brewing on a massive scale). I've made a few extract brews to keep up a supply but with mixed results. Here are some comments and questions:-

We're now on tank water, currently a 2000 gallon galvanised main tank. Are zinc ions known to affect yeast performance? When the house is habitable we'll have a 15000 gallon concrete tank - some calcium carbonate to harden the water - looks like I'll be brewing pale ale!

I believe that yeast quality has a large affect on flavour. One of my best beers was made with a lager yeast that came from the US in a liquid culture via the president of the local brewers club. I grabbed one of his empties and got the sludge to start. My beer was all grain, hops and water and had clean malt taste with beautiful yeast complexity and balanced bitter finish. I wish I could make it again! Any comments on yeast quality, sources, methods of culture etc?

I've just sent off a cheque to AHA to subscribe and ordered the 'Yeast' and 'Extract' back issues, also, am about to invest in a glass carboy for a primary fermenter (my plastic fermenter is getting old and I'm not sure how well it cleans up these days). All in the cause of more consistent, cleaner tasting brews.

Cheers... David Taylor

That's a generous upper limit! (I remember when Anchor was at about 30,
000
barrels/year; where are they now?)

>...Debate
> is ongoing, so I ask: in my letter to my representative, what arguments
> should I include? My local supplier suggests tourism, but I cannot back
> this up with any facts. Is local color enough of an argument for
passage?

Tourism is a minor issue. I'd suggest two possibilities:
- Moderation: Microbreweries tend to make beer which has more
flavor and body. People drink less of a flavorful, full-bodied
beer than of thin beer. (It takes a little work to write it all
out in convincing style, but "less filling" really means "more
intoxicating".) They also drink less of good beer than of hard
liquor. Therefore, microbreweries encourage those who drink to
drink in moderation.
- Local control and local economic benefit: A local beer employs
local people, is locally controlled, generates more local tax
revenue, and doesn't ship our dollars off to them damn furriners.
(Apologies in advance; I'm sure there are "damn furriners" in the
audience! No ill will intended. We're trying to help a fella
get local breweries by speaking to the issue in terms that will
be understood in his locale.)

Subject: Where to brew my Ale?

I have been fermenting my lager beer in the basement. The temperature has been 61 and hasn't changed more than a degree either way. I want to brew my first batch of ale. I'll be using a Muton and Fison Olde Ale kit.

Should I do the fermenting upstairs where it will be warmer but the temperature is likely to vary more (5-10 degrees) or keep doing it in the basement at a steady 61 degrees? My inclination is to do it in the basement and be patient.

Subject: rootbeer revisited

Does anyone have a recipe for rootbeer that is "from scratch"
using the actual plant parts that make the syrup?

I just saw such a posting in rec.food.drink (see, they're good for
something :-) and saved it, on the off chance that someone here
might once again ask the question. I think the rootbeer and the mead
question comeup once a year. However is keeping archives could have
special mead and rootbeer files just for those times... :-)

The first recommendation is to use the bottled extract (Schilling, or
McCormick, or Hires [I don't think Hires sells their extract anymore]).
But you say you want more... shameless picked up somewhere on the Net:

From: Dave Sheehy <dbsh@hprnd.rose.hp.com>
Subject: Re: Soda Pop and exploding bottles

As we have seen in the last several posts the general consensus seems to be that making soda pop is an exercise in demolitions manufacture. My experience however has been to the contrary. I have some bottles of home made soda pop that have been sitting at room temperature (which can range up in the high 70s in the summer) for over a year. Why do I not have the problems that many others have had? I've thought over my procedure and think that I may have a reasonable hypothesis. My procedure is:

1. Put the required quantity of water (4 gals.) in my brewpot and heat. I may or may not bring this to a boil depending on how patient/distracted I am that day but the temperature definitely gets into the sanitation range (> 165 F).
2. Start the recommended amount of yeast (1/4 tsp) separately in a bowl of warm sugar solution.
3. Add the entire quantity of sugar (8 cups) and soda extract to the water. Dissolve the sugar into the water and allow the solution to cool to, oh say somewhere in the 80s.
4. Add the yeast starter to the soda solution and mix well.
5. Bottle immediately (do NOT pass GO, do NOT collect \$200 :-).
6. It commonly takes 3-4 weeks to carbonate. It's really much better after several months in the bottle. The flavors blend or something, it's a very noticeable effect.

Why does this procedure not cause problems? Here's what I think may be going on. The commonly offered explanation for why bottles of soda pop do not overcarbonate and explode is that the yeast is limited by available nutrients. I think this statement is true but that it is only part of the answer. In my procedure I heat the water up to a high temperature driving off any dissolved oxygen in the process. This limits the aerobic phase (and therefore the reproductive stage) of the yeast. This limits the effective population of yeast. With a limited population of yeast you are less likely to overcarbonate. In this scenario, the pitching rate becomes a factor. If you pitch a large initial population of yeast, you will get overcarbonation. In fact, the only time I've had bottles explode (and they blew up in the vegetable crisper of my refrigerator by the way) was when I exceeded the recommended pitching rate of

1/4 tsp. Therefore, I disagree with the poster who maintains that pitching is a binary function. I believe pitching rate is significant in this situation.

I got a whole load of pretty vehement email about exploding bottles about a year ago when I posted about an experiment in making psuedo low cal soda pop (I still haven't tried it but it involves using fructose which is 80% sweeter than sucrose, I think you can figure out the rest of my plan). Since I hadn't had the problems that these people had I've been thinking alot about my procedure and why I don't have the same problems. This is what I came up with. So, what do y'all think?

From pepke@gw.scri.fsu.edu Tue Apr 23 11:49:15 1991
From: pepke@gw.scri.fsu.edu (Eric Pepke)
Subject: Re: ginger beer/ale, root beer

Here is the recipe I usually use for ginger beer.

Ingredients:
3-4 oz. fresh ginger
2 lemons
2 cups sugar (sucrose or brown sugar or both)
1 gal. water
Yeast

Peel the ginger and slice into 1/8 inch slices. Mix the water with the sugar and put in the ginger. Boil an hour or so. Slice the lemons, add to the boil, and boil for about 15 minutes. Allow to cool to room temperature. Add yeast. Let the yeast grow overnight. Bottle in very strong bottles. Let sit at room temperature for about 12 hours to carbonate. Put bottles in the fridge. Open very carefully.

Notes:

Every time I did not peel the ginger, the yeast did not multiply properly.

There may be a causal relationship.

The more you let the lemons boil, the more bitterness will be extracted from the peels. For a result a lot like Canada Dry's Bitter Lemon, increase the number of lemons to 4, let the lemons boil for about 1/2 hour, and cut back on the ginger. If you don't like the lemony flavor at all, substitute about 1 tsp. cream of tartar for them. I don't know what it's supposed to do, but it's better with than without.

I first started making this when I was a teenager and knew nothing about homebrewing. I always used baking yeast and didn't really sanitize anything. It worked fine. Now I brew all-grain beer with fresh yeast, but I still use baking yeast for this recipe.

I have a number of recipes for root beer as well, but (1) they require some ingredients which are difficult to find even in well-stocked yuppie granola-head stores, (2) most of them include sassafrass bark, which is no longer legal to sell for human consumption, and (3) none of them produce results that taste much like the modern extract-based root beer that we're used to. I will try to put my hands on them if there is any interest.

I have recieved several requests for root beer recipes. Here are some from a 19th century book, which has long since been nicked from the library.

Most of these recipes contain sassafras bark, which is illegal to purchase for human consumption because it contains small amounts of a toxin. So, don't make root beer with sassafras. Instead, go out and buy a whole carton of unfiltered cigarettes and smoke them all at once. That's legal.

Root Beer--1.--To 5 gal. of boiling water add 1 1/2 gal. of molasses. Allow it to stand for 3 hours, then add bruised sassafras bark, wintergreen bark, sarsaparilla root, of each 1/4 lb., and 1/2 pt. of fresh yeast, water enough to make 15 to 17 gal. After this has fermented for 12 hours it can be drawn off and bottled.

2.--Pour boiling water on 2 1/2 oz. sassafras, 1 1/2 oz. wild cherry bark, 2 1/2 oz. allspice, 2 1/2 oz. wintergreen bark, 1/2 oz. hops, 1/2 oz. coriander seed, 2 gal. molasses. Let the mixture stand 1 day. Strain, add 1 pt. yeast, enough water to make 13 gal. This beer may be bottled the following day.

3.--Sarsaparilla, 1 lb.; spicewood, 1/4 lb.; guaiacum chips, 1/2 lb.; birch bark, 1/8 lb.; ginger, 1/4 oz.; sassafras, 2 oz.; prickly ash bark, 1/4 oz.; hops, 1/2 oz. Boil for 12 hours over a moderate fire with sufficient water, so that the remainder shall measure 3 gal., to which add tincture of ginger, 4 oz.; oil of wintergreen, 1/2 oz.; alcohol, 1 pt. This prevents fermentation. [Yeah, right--EMP] To make root beer, take of this decoction, 1 qt.; molasses, 8 oz., water, 2 1/2 gal.; yeast, 4 oz. This will soon ferment and produce a good, drinkable beverage. The root beer should be mixed, in warm weather, the evening before it is used, and can be kept for use either bottled or drawn by a common beer pump. Most people prefer a small addition of wild cherry bitters or hot drops to the above beer.

Subject: chlorine as sterilizer

My local water utility is in the process of building a new water treatment facility. The reason given is that new EPA guidelines on trihalomethanes can only be met if ozone rather than chlorine is used as the primary disinfectant in water treatment. That has me wondering how good an idea it is for us to use bleach in disinfecting/sanitizing brewing equipment. My uncertainty on this is even greater since I have seen such wide variations in recommended concentrations of bleach in water to use. Are bisulphites or B-Brite safer?

Subject: Re: Maybock

In digest #629, <hannan@gnpike.enet.dec.com> asks
>> Anyone know the definition of May bock beer, or bock in general ?

"Bock" means "male goat" in German, and you often find a picture of one on the bottle. However, the name of the beer has nothing to do with that. Bock beer was first brewed in the town of Einbeck, and got its name from that. The Einbeck beer was extra strong and became well known for that, even outside the immediate area. Other beers could not be transported well in the olden days; they spoiled in transit. (We are talking oxcarts over dirt roads, here, with the beer in wooden kegs).

Today, Bock beer just means any extra strong beer. Many breweries in Germany make one of these for Labor Day (May 1 in most countries except for the USA), so that is Maibock.

The traditional Labor Day activity in Germany is to take a hike in the outdoors, to enjoy the coming of spring, until you run into one of the beer tents set up all over the place. This is where Maibock comes in.

Subject: Re: Cheap Extract

>What's the cheapest source of malt extract (canned or dry)
>available? Please list distributor, price, and address

It seems to me that the folks that sell their malt extract in the plastic bags (that can go right in the boil) offer the best prices.

The best price I got was last year when Williams Brewing in CA had a sale on English Light--\$10 for 6lbs. I just recently ordered some from American Brewmasters in NC. In quantity, the cost goes down to \$6.08 for a 3.3lb bag.

As Chris Shenton pointed out to me, if you include shipping charges, your effective price will vary on distance, so shipping from NC probably saves me more anyway.

It would seem likely that buying the 55lb pails of extract would be the cheapest, but it never goes below \$2/lb, so it can only be cheapest by including the shipping charges, which are typically included in the price.

Subject: Brewpubs in Texas and pub database

I have heard that out club president, Mike Leonard (also runs one of the local home-brew stores) has been down to Austin to testify to the legislature to legalize brewpubs. Usually the first real hurdle is to make it into the legislature as a real issue, as opposed to something the politicians ignore.

I believe we have made it this far. The real opposition now is the very strong beer distributors' lobby (which wants to keep the 3-tiered system).

On another note, v1 of my pub (and brewpub and microbrewery) program is running. It has about 640+ entries (181 brewpubs, 77 microbreweries). The README file is 8k so I'm not posting it here, but I'll send it to anyone interested. The program is in C++ for a Sun/4. The db itself is currently 126k.

Anyone having listings of brewpubs, microbreweries, or bars you can recommend please talk to me.

Subject: Miller's homebrew book

When ZYMURGY reviewed this, the chief rap was that the book was very opinionated, taking vigorous positions on matters that brewers disagree on without backing them up with solid research. This is certainly true; consider -"iodine testing for starch conversion is a waste of time"-. Miller also disdains extract brewing; most of his recipes are for full-mash brewing, with partial-mash versions appended. It's definitely a book that would scare away most beginners.

On the other hand, the book notes many of the advances in basic homebrewing technique. All recipes specify AAU's of hops (Papazian specs ounces, which is much less precise), and he covers a very wide variety of styles with both recipes and discussions of what defines the style, and without cute names or distracting and inaccurate descriptions. I've used his recipes to figure what to add to light extract to make various styles (this is Papazian's weakest point---his recipes and his table of style additives show an excessive fondness for black malt, which I am now //very// cautious about using at all). It's well-organized (technique in brief, technique in detail, recipes), discusses chemistry in useful detail, and has an index.

I'd say it's still not the ideal book, but it's much better than any other general homebrewing book you can find (e.g., there are some pretty good English books that cover fewer styles and call for ingredients that are either unavailable or strangely named). NB: the cover varnish on my copy shrank even without exposure to sunlight; a nuisance, but I don't think this can be fixed (somebody should tell Miller he has a cheap publisher) and it doesn't spoil the book.

Subject: Re: I'm sick of bad beer

Marty Albini commented on Brian D. Moore's input to the Texas legislature:

> Tell them the current laws are anti-competitive, and
>are inhibitting a potentially lucretive industry. Jobs is a
>good arguement; I don't think anybody in the legislature would
>be sympathetic to "I'm sick of bad beer!" If the process of
>regulating alcohol is as corrupt in TX as it is in CA, the
>megabreweries will have an easier time suppressing competition
>than the public will encouraging it.

The trouble is, having microbreweries legal isn't any guarantee that the beer quality will improve. In fact, here in Oregon there are several breweries producing ale of such poor quality that if I had made it in my own kitchen, I would have poured it out. Some of this stuff **should** be illegal!!

Rarely do I purchase microbrewery beer out of bottles on the grocery shelf. But recently, I made a trip to Portland, then Corvallis on a weekend. Being away from my own brew, I took the plunge and bought some bottled micros from two grocery's. In PDX I bought Portland Ale, Full Sail Amber, and some European standby's. In Corvallis I bought Sierra Nevada Pale Ale, Sierra Nevada Bock, Bridgeport Coho, and Coors. Of all these, I could only stomach the Sierra Nevada and Coors. Here is a little miniature beer judgement:

- 1 Portland Ale. Muddy, floating debris, autolyzed, a rotten egg buried under a chicken coop for 10 years, unbalanced bitterness, of interest only to Philistine swine.
- 2 Bridgeport Coho. Murky, stale, bitterness akin to quinine without the redeeming medicinal quality, "sweet bile", aroma of rotting manure, bathtub odor. The weekend drink of desert oil-drilling equipment mechanics.
- 3 Sierra Nevada Bock. Clean, well-balanced, satisfying, good aroma, professional.
- 4 Coors. Clean, neutral, thirst-quenching, unoffending, nearly worth the cost.
- 5 Corvallis tap water. Dark, moldy, floating boulders, aroma of rotting fish, reminiscent of Portland Ale, but with the aminic stench of Bridgeport Coho.

But hey, it's only my opinion.

Subject: diacetyl -/> Phenols, S. Delbruckii, mit hefe,maibock

Diacetyl, and phenols:

Diacetyl can be created by the yeast, or by contamination. I've also heard that too much adjuncts can contribute.

I don't think diacetyls can change to phenols? I have intentionally brewed high diacetyl ales, and stored them for long periods with no evidence of phenols.

Source of phenols? Most likely is residue from Chlorine bleach creating chloro-phenols. These have flavor thresholds in the parts per BILLION!! Note they have medicine like, plastic like flavor. Like chewing an old bandaid?

You did chew bandaids when you were kid?

Have you changed your cleaning methods lately? Started using bleaches?

A cleaner with chlorine based ingredients? Decided to really get it clean by using concentrated (> than 1oz/5gallons IE:a teaspoon in a gallon)

bleach to "really nuke it"?

Temperature, and S. Delbruckii:

I have a batch going with Mev 033 Wheat beer yeast, which is supposed to be pure S. Delbruckii. They list 16C to 20C. At 16C its going pretty slow (can you say 7weeks, and still fizzing?),so depending what the other yeast is,

I'd suggest that at 16C teh S.Delbruckii won't be doing too much attenuation,

but I don't know what its secondary flavor activity is at this temp.

Maibock:

Although several friends have brought Maibock home from Germany, I've never seen it described in any beer books? HOW come? How popular is it?

Subject: extract prices by the barrel?

Howdy Folks,

Some of the homebrew supply stores I've been to, have 55 gallon barrels of malt extract syrup. You take your own bucket and fill it with the amount of extract you need, and they charge you by the pound. (Last time I did this is was about \$1.69).

(From my inquires, I've found that a barrel is about 700 pounds of extract.)

But the owners always are a little touchy about how much they paid for it.

(One said he'd sell it to me for about \$1.20 per pound).

So my question is,

"How much do thos 55 gal barrels of malt extract syrup cost the homebrew supply stores?"

And if I had a sudden desire to make 583 gallons of beer, could and where would I procure it?

I'm just curious; I live in a one bedroom apartment, and a barrel would take up half my living room. :-)

Subject: off tasting mead

Date: 03-May-91 Time: 11:53 AM Msg: EXT01012

Hello,

Doug Luce in #629 asks about off-tasting mead from September. When I made my first two batches of mead (winter 86-87 and 87-88) I tried 2 recipes. One was the tea, ginger, orange & honey variety, one was from Acton & Duncan (powdered acids & honey). After a year (and I think 3 rackings) the stuff still smelled and tasted off, not quite like formaldehyde, but a similar sweet chemical taste. I chalked it up as a loss and stuck the gallon jugs in a dark corner of the basement. And forgot them. For two years.

In 1989 I moved and found them. I decided to bottle them and ask more experienced brewers what I did wrong. Surprisingly, both tasted great! We're talking superb, dry, wine-like meads. I suspect that if you give your mead a while longer to age, it will get better. I know people who make drinkable mead in 2 months, but they usually do not add any acids. Mead and wine take longer than beer to mature. Relax. :)

Subject: off tasting mead

After reading the latest zymurgy I'm confused. The vast majority of the digest posts stress the point to remove the wort from the cold break. This is contrary the zymurgy article on "The trouble with trub" (sorry can't remember the authors name) which stated for most type of beers the cold break trub is actually good for a limited time (you would not lager on trub).

He further stated that the hot break precipitates are detrimental to the flavor of the beer. The problem is I did not see an easy way to separate these small (80 - 100 micron) precipitates from the wort. The idea of siphoning from the side of a whirlpool does not seem practical and since these precipitates are so small settling may take forever and siphoning may stir them up again anyhow.

Any comments on how to eliminate hot break trub from the wort and why the digest and Miller say to separate the wort from the cold break??

Subject: Some questions from a novice

Hi folks,

Now that my third batch is relaxingly burbling away in my carboy, I have a few questions about some of the techniques I attempted in my last brewing session. The last place I ordered ingredients from included some directions for new ways of doing things, but there's a few things I'd like to understand better.

The first new process I used was preparing a yeast starter from a liquid culture. I boiled 1c water, 3Tbsp malt extract, and one hop pellet for ~20 minutes, cooled, and transferred into a sanitized bottle topped with a fermentation lock. When a nice foam had formed I brewed and pitched the entire contents into my 5 gallon batch. Am I right to assume that I could have perpetuated this yeast by preparing another wort like above, and placed some of my yeast in it to make a new starter? If so, how much would I need to use in the starter? I guess I'd really like to learn more about yeasts. Is the Zymurgy yeast issue a good source?

I'd also like to try reusing the yeast by adding my next batch on top of the yeast left from this batch in the carboy. I've seen mention of something called "washing" the yeast, but no explanation of how to do this. Could someone please fill me in? How soon after siphoning off the first batch must I pour in the new one?

Thanks for any help.

Tom Quinn

From: dinsdale@chtm.unm.edu (Don McDaniel)
Subject: Starch conversion in specialty grains

I'm looking for some experiences with converting the starches in specialty grains in all-extract batches. The recent mention of Miller's comment that the color and flavor is fully released only in mashing reminds me of these thoughts.

I have seen a couple of products in brew catalogs (sorry, I can't remember which ones) which should allow an extract brewer to get sugars from his special grains. One was DMS: diastatic (sp?) malt extract. That's extract with enzymes. The other product was a liquid containing concentrated enzymes. The description said it was used in the production of sake. Add a small amount, adjust the pH and temperature, and full conversion would take about 15 minutes.

It seems to me that one could steep the crushed grains in a grain bag, add the enzymes and let it go for 30 min. Then dissolve the extract and continue as usual. This would add no extra time as you need to steep for color and flavor anyway. It would let you get the sugar from the grain and might result in more color and flavor. Miller says specialty grains yield 25 points per pound per gallon (somewhat more for crystal). For a five gallon batch then, you'd get about five points out of a pound of crystal (common amount for a pale ale).

Has anyone tried any of these products? How do they work? Do you see any reason they might not work?

>My brew partner wants to brew our next batch with unhopped
>extract and add no hops. I think this will not turn out very
>good. Has anybody tried this and how did it turn out.

I would tend to agree with you. Hops are very beneficial to beer, so
use 'em :-D

The Anchor Brewing Co made a special Sumerian Brew. The recipe allegedly
came from the inside of a cave in Sumeria (sometimes referred to as Iraq!
).

The mash was made from loaves of bread and dates. The "wort" was heated,
but not boiled. No hops were used. It was not your everyday drink, and
was
enjoyed by some yet decreed vile by others. I put some in my cellar to
see
how it would develop. It went off very quickly. This brew had the
shortest
shelf life of any I've known.

Moral of the story : Boil your wort and add hops.

Hoppy Brewing,
CR

llbock, but is nonetheless a heavenly
brew. Maibocks can vary in color, I've seen them range from golden to
amber. For a domestic Hellbock that does its Bavarian brethren proud,
look
for Sierra Nevada Pale Bock, the proverbial nectar of the gods.

From: kevin vang <MN033302@VM1.NoDak.EDU>
Subject: bock definition, starch in spec. grain

"Bock" means "goat". One of the charming traditions of German brewers is the brewing of special seasonal beers to be drunk at various times of the year. Oktoberfest beers being one obvious example. Bock beers were traditionally brewed by monks to be drunk during lent (Salvator, brewed by the Paulaner order, is the archetypical example). Either the season when bock is brewed or served (I forget which, I'm not up on astrology) occurs during the sign of Capricorn, the goat, hence "Bock bier". Bocks are traditionally stronger than usual brews, and one which is extremely strong is a "Doppelbock" (double bock). A "Maibock" would be a bock intended to be drunk in May. "Helles" means light (color, not calories) and "Dunkel" means dark, so a "Helles bock" is a light colored bock. (bocks are typically dark, so you wouldn't say "dunkelbock"). Incidentally, most bock beers will have a picture of a goat somewhere on the label. I was amused by two domestic bocks. Augsburg bock (if I remember correctly) has a picture of a sheep on its label, and Kessler bock, brewed in Helena, Montana, has a Rocky Mountain goat.

Specialty grains -- The purpose of mashing is to convert non-fermentable starches into fermentable sugars. Crystal malt has been soaked in water and then kilned, which process converts the starches to sugar. Thus crystal can be added at any time, and does not need mashing. Cara-pils (dextrine) malt is similar to crystal except (I think) that it is kilned at a lower temp, so it has less color, and it has some starches; so it should be mashed. Roasted malt, black patent malt, and chocolate malt are added purely for color and flavor, and thus don't need to be mashed. Munich malt, wheat malt and adjuncts (rice, maize, flaked barley, oatmeal) have only unconverted starches, and therefore must be mashed.

From: "Dr. John" <JELJ@CORNELLA.cit.cornell.edu>
Subject: Maibock, etc.

A few comments regarding postings to HBD #629:

Ken <hannan@gnpike.enet.dec.com> asks about the Maibock style,

According to Michael Jackson, in "The Simon & Schuster Pocket Guide to Beer"
Maibock is "A bock beer of super-premium quality. Usually pale. Made for the end of April and beginning of May to celebrate spring." I have had this particular beer (Ayinger Maibock) a couple years ago and don't recall it as a particularly bitter, perhaps they have changed the formulation.

Bill Boyle asks about making a hop-free beer with unhopped malt extract, I don't think that this would produce anything that I'd personally want to drink, haven't tried it and don't plan to.

Darryl Okahata asks about Jackie Rager's IBU formula in the Hop issue of Zymurgy,

Guess I'll have to play around with the formula a bit more to look into its apparently extreme sensitivity to the time of the boil. One thing I did notice in the presentation is that the formula as presented, if used strictly as presented, produces different numbers than the example which follows it later in the article. Seems that Zymurgy could use a good technical editor; this is not the first time that they have had articles with mathematical formulae which don't give the answers that subsequent examples produce. Caveat emptor. As to additional extraction of bittering compounds during the time between the boil and when the wort is all chilled, I personally wouldn't worry about it too much as a good rolling boil is required to isomerize the alpha acids.

Mbharrington@ucsd.edu asks about Miller's book

In my opinion this is a good book that picks up with a lot of topics where Papazian leaves off. It also doesn't suffer from the cutesiness that Papazian was so fond of (he seems to have toned it down somewhat recently, and thankfully, though I guess the true test will be the second edition of "The Complete Joy of Homebrewing" which is reportedly due out this fall.)
The only caveat I would place on my recommendation for Miller's book concerns

those who have no interest in mashing, if you are among this group you may not find the book to be all that useful. If, on the other hand, you are thinking about dabbling with some partial mashes, or jumping into all-grain brewing, then this is the book for you.

Is anyone out there planning to take the Beer Judge exam at the AHA conference next month? I know we have at least one beer judge on the forum (Darryl Richman), any others? If so, do you have any study/exam-related advice for those of us aspiring to judgeship? Any and all comments would be graciously accepted and appreciated.

Cheers,

Dr. John

From: David Lim <limd@sulu.Colorado.EDU>
Subject: Culturing Paulaner hefeweizen yeast

Hi. I'm interested in knowing what kind of experiences people have had in culturing Paulaner hefeweizen yeast. I realize that it's a lager yeast that they add to the bottle after fermentation (i.e. not the yeast they use to do the "primary" fermentation - which I'm assuming would be one specifically needed to produce the classic wheat beer phenolics, esters, etc... such as *S. Delbruckii* (spelling?)). What I'm interested in is how good of a yeast this bottle yeast is for lager fermentation.

It doesn't seem to be a very flocculant strain, as shaken bottles of Paulaner hefeweizen seem to stay cloudy for quite a long time - maybe this is intentional on Paulaner's part to make sure that the drinkers know that they're getting "real" yeast (hefe) in their brew. (I hear that some breweries in Germany actually have dispensers of yeast slurry for customers to *add* to their glasses of beer!) I do have the ability to culture my own yeast colonies on agar slants and plates, so I'm looking to expand my "collection" with other samples. If anyone has successfully used this yeast for fermentation of lagers, what's it like? Is it attenuative? Does it have any "quirks" like having the need to raise the fermentation temperature during the final third to reduce diacetyl? Is it "stable" enough for home culturing?

Yes, I could just as easily start from some "known" strains such as those Wyeast provides, but that's not as fun.

Thanks!

From: dworkin@habitrail.Solbourne.COM (Dieter Muller)
Subject: siphoning

OK, it's ignorant beginner question time once again....

How do you start the siphoning from a fermenter? The problem, as I understand it, is to pull enough of a vacuum in the siphon tube that the liquid fills the tube. You then get whatever pulled the vacuum out of the way (preferably replaced by whatever you're siphoning into), and let gravity do the rest of the work. Is there some convenient vacuum pump available, or does everyone just suck on the tube? The latter approach seems pretty much guaranteed to contaminate things....

Thanks.

Date: Mon, 6 May 91 08:59:37 EDT
From: rtidd@ccels2.mitre.org (Randy Tidd)
Subject: Lagering lagers

I'm on my 6th or 7th batch of homebrew now, and wanted to make a lager. I decided to use Papaizan's recipe for Rocky Raccoon's Honey Lager with slight modifications; I used 4 lbs of light extract (Alexander's) and 3 lbs of clover honey. I brewed it and pitched a liquid bavarian lager yeast. Once the fermentation got going, I put the fermenter in the fridge at about 40F. The fermentation went real slow once it cooled down, then stopped after about 3 days. I decided it was too cold, so I warmed up the fridge a little (from 'E' to 'C' on the little dial inside -- wonderful gauge, that) and racked the beer to a secondary. Now it's been going for about 4-1/2 more weeks! The lock has been glubbing about once every 20-30 seconds the whole time. Now the beer is clear enough that I can see little bubbles inside as it ferments.

Will this beer be ready to drink anytime this year? This is taking much much longer than I expected. I was hoping to have a homebrew to celebrate graduation with, but it looks like I'm gonna miss my mark by about a month. I was going to make another lager that was slightly richer (6-7 lbs of extracts + specialty grains), but if this supposedly "light" beer is taking 5-6 weeks to ferment, I hate to think how long a richer beer would take. Is this normal?

I'm not worrying, i'm just thirsty.

Subject: Oatmeal, Frank Jones

I've got 2 lbs. of steel-cut oatmeal, and plan to make an oatmeal stout. I understand that the oatmeal needs to be mashed, something I have never done. Does oatmeal have enough enzymes by itself, or do I need to include some pale malt in the mash?

I tried some Frank Jones Reserves Extra Special Bitter this weekend. It tasted **very** much like Sierra Nevada Pale Ale. Delicious! It is contract brewed by Catamount brewery in VT., for the Frank Jones company based in Portsmouth, NH. F.J. had a **big** brewery at the begining of the century. (I lived in his house for awhile; there were 3 apartments and an insurance company in the building. Big house.) Anyway, there has been a Frank Jones Pale Ale out, also made by Catamount, that's good, but nothing super. The ESB is great. I've only seen in it NH liquor stores. The store tag says it has 12% alcohol, but that's wrong. They must mean 12 proof. Tom Hardy Ale is listed at 10.3% alcohol, and Corsendonk Monk ale was 7.9%, and the ESB was not as strong as those. But I still highly recommended it, even at "only" 6% alcohol.

>creating chloro-phenols. These have flavor thresholds in the parts per
>BILLION!!

Not exactly. Chloro-phenols are a special type of phenols. So you can have a problem with phenols in your beer and not have them be chloro-phenols. As for chloro-phenols having flavor thresholds in the parts per BILLION, that's exactly right. I made a beer that suffered from chloro-phenols once. WOW! It was like drinking chlorine! Nowhere close to "clinical".

Geoffrey Woods writes:

>"The trouble with trub" (sorry can't remember the authors name)

Though others probably have opinions to the contrary, I would agree that fermenting on cold break trub is O.K. I've been doing it for years. I am the BrewCap man, though, so the cold break gets drained away relatively early in the fermentation process, doesn't sit around for a couple of weeks, and I've noticed no adverse flavors as a result. Racking to a secondary is probably a good idea if you're not using something like a BrewCap. Cold break is protein. And we all know what protein does if left at room temperature for a couple of weeks!

>Any comments on how to eliminate hot break trub from the wort
>and why the digest and Miller say to separate the wort from the
>cold break??

As for separating hot break trub from the wort, after the boil, stir, stir, stir the wort in the kettle creating a whirlpool. Let this settle for about 10 - 15 minutes. The whirlpool will force all precipitate matter to a cone in the bottom of the kettle. Then siphon, don't pour the wort into the fermenter. By siphoning, especially if you hold or suspend the pick-up tube close to the top of the liquid as you go, you will get the cleanest possible run-off. Never pour your wort into a fermenter, not even through one of those fine mesh bags, if you're worried about getting hot break into the fermenter. And you should be worried about that.

Tom Quinn asked about washing yeast:

Yeast is washed by shaking it in an acidified solution (tartaric acid, phosphoric, or sulphuric). It is generally not recommended, even in commercial breweries, because of all the variable factors involved- the choice and concentration of the acidifier, and the length of time the yeast is in contact with the acid. In addition, while it may kill some of the bacteria present, it also has an adverse effect on the viability of the yeast. In short, don't wash. Just be your normal, careful, sanitizing fiend when handling the wort after the boiling stage. Most micros reuse yeast 5 or 6 times without worrying a great deal.

Dieter Muller asked about starting a siphon:

Stick a short length (2 ") of copper tubing in the end of your siphon hose, suck on the copper and remove it before the wort comes. If you hold the end of the siphon hose *above* the top level of the beer when you do this, the wort will never rush into your mouth. Pinch the hose when the wort is a couple of inches away from your mouth, remove the copper tubing, drop the hose below the top level of the beer in the fermenter and you're off and running.

Studying for the BJCP exam:

You'll be quizzed on malt (the different types, how they're made and used in making beer), hops (the different kinds, alpha levels, how they add to the flavor and stability of beer, which kinds are used in which styles of beer), yeast (the different types, ideal fermentation temperatures, which type for which style of beer, characteristics, etc.), and sometimes water (water treatment for different styles of beer). There are usually several questions on beer styles (difference between ales and lagers, name and describe several ale styles, name and describe several lager styles, describe a couple of Belgian style ales, etc.) You might get a question on how to brew a particular style of beer and give a 5-gallon recipe. You usually get some off the wall question concerning an obscure commercial beer: name two breweries in Czechoslovakia, four breweries in Japan, two breweries in Scotland, the strongest beer in the world, the strongest beer in America, what's a Steinbeer?, etc.) Sometimes a question that zeroes in on some aspect of the brewing process (why boil beer, why add hops to beer, why an ale instead of a lager yeast, why Munich malt instead of crystal malt, why soft instead of hard water...) There's always a question on the BJCP program (how are points assigned in a national or regional competition, what are the different levels one can attain...)

You'll be asked to judge 4 different beers and judge them as you would in a competition. Some will be commercial beers, some are homebrewed beers, and there's usually a problem beer in the midst as well.

You have three hours to take the exam. The test is quite a bear! Your answers need to be precise and concise, yet thorough in order to get it finished and do justice to all the questions.

The written portion is 70% of your score. The evaluation of the beers is 30% .

As for how to study...Get a copy of The World Guide to Beer by Michael Jackson and absorb as much of it as you can for the beer style questions. Read something like The Big Book of Brewing by Dave Line, or Brewing Lager Beer by Greg Noonan, or The Complete Handbook of Brewing by Dave Miller for discussions on the technical side of brewing, recipes, etc. And get the latest copy of the flyer that describes the BJCP program and memorize it. (I have some copies and will send one to you if you send me your snail mail address)

Hope this helps.

Subject: Siphoning Method

In hb 630, Dieter Muller (dworkin@habitrail.Solbourne.COM) asked:

>How do you start the siphoning from a fermenter? The problem, as I
>understand it, is to pull enough of a vacuum in the siphon tube that
>the liquid fills the tube. You then get whatever pulled the vacuum
>out of the way (preferably replaced by whatever you're siphoning
>into), and let gravity do the rest of the work. Is there some
>convenient vacuum pump available, or does everyone just suck on the
>tube? The latter approach seems pretty much guaranteed to contaminate
>things....

I siphon twice with every batch, once from the primary fermenter (food grade plastic) to the secondary (glass carboy) and once more from the secondary to the bottles. I start the siphon by sucking on the tube. I always clean the tube before each use. Even though the end of the tube is inside your mouth, you can prevent it from touching the inside of your mouth, so the only point of contact between your mouth and the tube will be on the outside of the tube where it will not contact the beer.

With very little practice, you can start the siphon and pull the tube out of your mouth before the beer actually reaches the end of the tube. This is even easier with a clear plastic tube because you can see the beer start down the tube. My early experience in siphoning was in siphoning gasoline through a non-transparent hose, so I learned quickly how to start the siphon without getting a mouth full of gas. Since the hose was not the cleanest (or even tastiest) this was also where I learned to keep the contact between my mouth and the siphon tube to a minimum.

Once I start the siphon for bottling, I am careful not to break the siphon, and with practice it can be done. When a bottle is nearly full I move it to about the level of the beer in the carboy, stopping the siphoning action as the bottle becomes full, but not far enough to break the siphon.

I am probably more careful than I have to be about sanitation since at the bottling stage the beer is already fermented (except for the little bit that carbonates the beer in the bottle) and any bacteria that got on the tube from your mouth and subsequently into the beer should be taken care of by the alcohol.

What have I learned from this? Siphoning beer is more desirable than siphoning gasoline, but the principle is the same for both!

>IMHO Beer w/o the bitter would be like Chocolate w/o the sweet. Though
>I'm sure that history would provide some precedence for such a brew, I
>>wouldn't recommend it.

Nonsense. Beer was brewed without hops for a long time. Many of the
Munich
styles use very low hopping rates. This simply will give you a beer with
a full
sweet palatte. In most beers the hop bitterness offsets the sweetness,
but in
some styles (say Munchener Helles) a sweeter, lower alcohol beer is the
mark,
though typically some hops are always used, just not enough to impart any
substantial bitterness or aroma.

Florian, about those beers you tasted, quit pulling punches, tell us what
you
REALLY think of them :-) :-)

> I know we have at least one beer judge on the forum (Darryl Richman),

Subject: Wort straining

Time:01:37 PM Date: 5/6/91

Subject: Wort straining

I recently bought a glass carboy to replace my plastic food-tub for single-stage fermenting. I also have a rather large funnel with a metal screen near the bottom to strain the wort as I pour it into the carboy. Well, I tried it for the first time last night, and when I went to pour the boiled wort into the carboy, I found that the screen got clogged almost instantly from the hops. Not really knowing what to do, I just ran the wort through a regular kitchen strainer to get the big stuff out, and poured the rest into the carboy through the funnel without using the screen (gee, I hope I didn't end up contaminating the wort in the process...). My questions then, are this:

- 1) Why sell me the stupid little screen in the first place (I doubt most homebrew stores are out to rip anyone off)
- 2) As long as I bottle as soon as fermentation stops, do I need to strain the wort at all? I've brewed a few batches before without straining at all, and they seemed ok. But, then again, maybe they could have been better.

Thanks,

Bob Hettmansperger (reply to, bobh@twinkie.bellcore.com please)

P.S. The clear glass carboy is the way to go. Imagine, all those other batches where I couldn't see all the cool stuff going on inside the carboy!

> that
> would scare away most beginners.

As author of the review that appeared in Zymurgy, let me say that I
always
recommend Miller's book over CJoHB because I feel that one is likely to
produce a better beer, even at first, using Miller. I wish he (or his
editor, whom he indicted in a reply letter in Zymurgy) had picked
a different title, one that was not reminiscent of CJoHB, and one that
better described the contents. I agree that his recipes and style
descriptions are superior; I use them in talking to a BJCP prep class
we give, to help people learn how ingredients and process make styles.

I have grown to dislike CJoHB for its sappy humor and approach that
says "this isn't a serious hobby". Perhaps I'm just too serious.
Anyway, Miller is often on my desk when I'm working up a recipe, but
Papazian rarely is. I like it a lot, and I now wish that I hadn't been
as strong in my review about the book's problems, because it clearly came
over as a negative review. But, for me, my conclusion is still true: I
use Miller along with Noonan consistently.

> forum (Darryl Richman), any others? If so, do you have any study/
exam-
> related advice for those of us aspiring to judgeship? Any and all
comments
> would be graciously accepted and appreciated.

I'll give you my standard advice. The test is not trivial, and passing requires a good knowledge of the field. The test is composed of 10 short essay questions and 3 or 4 beers to judge.

The essay questions cover ingredients, process, styles, and faults. Expect questions like "What is the lifecycle of yeast?" or "Describe each of the following malts, how they are made and what they are used for: a) chocolate malt, b) crystal, c) Munich, d) Cara-pils". Be sure to study up on beer styles, they've been asking more questions (e.g., "Describe the Altbier style") about styles on recent tests. I think that it is important to be able to answer the questions succinctly. Clearly, one could write a book (some have!) in answer to these kinds of questions. However, a shorter answer that includes all of the pertinent details demonstrates breadth and depth of knowledge more than an extended one. There is always a question about the program itself, so get a copy of the booklet and read through it.

The tasting portion is very similar to what you'd get in a real judging. You are presented with the beer and told what category it was entered into. You have a judging sheet to fill out. Perception is, of course, important, but so is neatness, tact, and feedback to the brewer regarding any faults or tuning. It is likely that at least one beer will have a noticeable fault.

The written portion counts for 70%, the tasting, 30%. The test runs for 3 hours, but that should be more than sufficient.

florianb@chip.cna.tek.com reviews some local (to me) brews in the bottle he bought at a grocery store:

>1 Portland Ale. Muddy, floating debris, autolyzed, a rotten
> egg buried under a chicken coop for 10 years, unbalanced
> bitterness, of interest only to Philistine swine.
>
>2 Bridgeport Coho. Murky, stale, bitterness akin to quinine
> without the redeeming medicinal quality, "sweet bile",
> aroma of rotting manure, bathtub odor. The weekend drink
> of desert oil-drilling equipment mechanics.

Florian:

You really should've visited a brewpub instead of a grocery store. The stuff available on tap here is great. I've bought many a bottle of Portland Ale w/o ever a problem. The stuff is light, moderately hoppy, and has a nice clean finish. Most local beers 'round here have chill haze (I prefer to drink 'em warm enough to eliminate it) but it doesn't affect the flavor.

My wife bought a six pack of the Coho and it tasted kinda fishy. Perhaps it's supposed to -- after all, it's named Coho. I haven't tried it on tap yet.

But the owners always are a little touchy about how much they paid for
it.
(One said he'd sell it to me for about \$1.20 per pound).

So my question is,
"How much do thos 55 gal barrels of malt extract syrup cost the
homebrew
supply stores?"
And if I had a sudden desire to make 583 gallons of beer,
could and where would I procure it?

Some friends and I recently purchased some 60-pound, 5 gallon buckets
of malt. We paid wholesale prices, and picked it up it directly from
the processor. Our price was \$50.00/bucket, with a minimum purchase
of three (or maybe it was five). That works out to \$0.83/pound, which
we were quite pleased with. Unfortunately this was a one-time deal
that I don't think we can repeat, but it does give you an idea of what
a supply shop must pay.

From: Dale Veeneman <devl@gte.com>

Subject: Comment/Two questions: temp. and dark grain boil

A while ago, there was some discussion on the viability of yeast after a long secondary storage. I thought I would relate this:

Around last Thanksgiving, I brewed an IPA with Irish Wyeast (1084), and bottled around Christmas (4 day primary, 3.5 week secondary). Unfortunately, my cellar (where the fermenters are) got pretty cold around then (low 50's), so after bottling, I left the bottles upstairs for a couple weeks, then everything went back into the cellar where there's more room. The beer never carbonated. Occasionally, I would try a bottle but it was always flat. This spring, as the weather warmed, I tipped both cases upside down and shook. Now, a few weeks later, upon opening and pouring, there is a beautiful creamy head and the nicest carbonation you'd ever want.

Which brings up my first question (also related to some recent discussion): if you could pick any temperature to ferment an ale, what would it be? It most likely would depend on the strain - does anyone know for different Wyeast strains, for example?

Second question (also related to recent discussion): I know that dark grains have no fermentables, so there is no need to mash. However, Papazian recommends cracking all speciality grains, put in the cold water, bring to boil, and then remove, while Burch says to put uncracked dark grains directly in the boil for the whole time. I've done it both ways, and while I haven't noticed strong tannins with Burch's method, I still wonder what's really better?

Yes, just suck on the tube.

>tube? The latter approach seems pretty much guaranteed to contaminate
>things....

That depends on what you had been sucking on prior to transferring your
wort or beer.

I have read in and heard from various sources that this practice can
lead to contamination. But I can't find any scrap of evidence that
that is the case. I used to take a swig of whiskey before sucking
on the racking tube, but that got expensive, since all I have
around the house is Bushmill's, and it tasted so good one swig
wasn't enough. I stopped being paranoid about tube sucking and just
did it anyway. Somehow, there are a lot more important factors
in good brewing to consider than this one.

Procedes to bash excellent breweries like Bridgeport, Portland etc.....

I suggest that the problem was that you got your beers in a grocery store. Microbrewed beer should be enjoyed fresh, but unfortunately, grocery stores often sell stale beer.

If you are interested in checking out these beers, find one of their many draft accounts at the very least. Of course, for the best brews, go to the breweries themselves. The cask conditioned ales at Bridgeport are truly wonderful.

And now an approximate quote :

"Bridgeport serves the finest examples of cask conditioned ales I've had in America."

> I recently bought some Ayinger Maibock (May Bock) beer from West Germany. It is a very bitter very heavy very strong delicious brew which I had never heard of. Apparently "bock" doesn't mean dark, as this brew has a basic dense, golden color.

Anyone know the definition of May bock beer, or bock in general ?

Aying is a pleasant little town just outside of Munich. I had the pleasure of touring the brewery in 1982, and they do make some fine brews. Seek out Ayinger Ur-Weizen, it's wonderful stuff.

In Germany, a bock is defined as a brew that starts at a gravity of over a certain amount (1.065 I believe). If the gravity is 1.075 (?) or more, then it is christened dopplebock. This nomenclature is not adhered to in the US.

If it doesn't specify otherwise, a bock is typically a dark brew. In general, a pale colored bock is a Hellbock, but is nonetheless a heavenly brew. Maibocks are usually pale, although they can vary somewhat in color.

For a domestic Hellbock that does its Bavarian brethren proud, look for Sierra Nevada Pale Bock, the proverbial nectar of the gods.

Subject: safety of bleach as sterilant

The problem with chlorine in your drinking water is that you drink it (unless you boil the water first); ozone is much more unstable, so it tends to sterilize the water and dissipate. Homebrew sterilizing is a two-step process: soak in sterilant, then rinse //thoroughly// in hot water; you shouldn't be consuming any significant amount of bleach. B-Brite is a nasty substance too---I wouldn't say you're any safer drinking it.

Note also that the chemistry is somewhat different---water plants use chlorine gas instead of sodium hypochlorite (although I can't guess which is more likely to yield THM's).

> Moral of the story : Boil your wort and add hops.

I visited the Anchor Brewing Co specifically to find out more about their sumerian beer. I did get a taste from their bar (he had a few bottles left) and it had already gone south.

Their explanation for the short shelf-life is twofold:

a) No hops. To brew commercial beer in the U.S., you are required to brew beer with hops. They had to get a special permit to make the sumerian beer without hops. Hops has specific anti-bacterial activity which is one of the reasons it was added to beer to begin with.

b) Flash-pasturize. Anchor normally only heats their finished product to 140 deg for 20 seconds to get a shelf life of six -to- nine months (if I remember correctly). For the Sumerian Beer, they didn't do even that since it was a one-batch item intended for a conference (Micro-Brewery Conference in S.F.).

The bottle I tasted had definite signs of having gone sour, but I did still taste the dates and the grains used to brew it. It was a neat experiment and I hope they continue to do specialty brews. In fact, I hope they make the sumerian beer again - I want a "fresh" bottle.

The Anchor Brewing Co. gives great tours and very fine samples at the end of the tour! :-)

61 deg. sounds fine for an ale. I think of most ales fermenting at
celler tempature and lagers fermenting at 'fridge temps.

Subject: Belgian Lambics mailing list

Hi!

Just wanted everyone to know that the Belgian Lambics mailing list is up and running. This has started as a relatively technical forum so may not be for everyone. Currently most of the articles center around two test batches, the techniques used to make them, and the behavior of the specific bacteria/yeast.

Anyway, my point for posting this was to let everyone know the new addresses:

lambic@cs.ulowell.edu for submissions
lambic-request@cs.ulowell.edu for administrative junk

Don't forget that most shops can't pick up those 60-pound pails
directly from the processor so their prices reflect an appreciable
shipping charge.

What do you want the book for? I think that Miller's book is
more useful for brewing technique than Papazian's. Papazian has
some interesting recipes, especially for us extract brewers. I
also like Byron Burch's Brewing Quality Beers as a concise
description of brewing.

Once you get into it, there are lots of other books on specific
topics.

Anyone have a Brewing/Beer Book Bibliography on-line?

OK, let me say that I have not had any problems with
contamination, but I may be lucky in what resides in the air and
dust in my house. On the other hand, I love to *taste* the beer,
as fresh as I can. *Therefore*, I start the siphon with my
mouth, and drink a little bit of it, before transferring the
siphon to the container. I do this when racking to the secondary
and when racking to my priming bucket before bottling. Now,
I don't know what I would do about tasting the beer if I changed
methods, and wouldn't want to give that up.

I use this method (though I plan to try the whirlpool and siphoning someday) and equipment. You need to keep a spoon or something to stir the hops around so they don't clog up the funnel. Every so often I stop and dump the hops into a pan and continue on. The hop bed on the strainer helps get more of the hot break particulates from getting into the fermenter (I am told). It works best with two people, but my funnel fits nicely and stably in the carboy neck, so I can manage it myself.

Oh, and you can try a hop bag to keep your hops in if you want to make the hop cleanup easier. Then you can put the bag on the screen and pour through that without causing any clogging.

Subject: Re: Removing Cold Break

I went back and read the _zymurgy_ article, "The Trouble with Trub". Let me quote a few portions:

"Hot break and cold break should be removed before fermentation to create easy access for the yeast to the nutrient base, as well as to delete negative flavor components."

Followed later by:

"The consensus on cold break influencing the flavor of the beer is mixed. It is well-documented that total removal of cold break creates negative attributes for the fermentation cycle and the final flavor spectrum. ... However, the advantage of cold-break removal is apparent with respect to vitality of the yeast reuse."

So, my interpretation was to remove as much of the cold break as you can, but not **all** of it. Though it isn't discussed, presumably the oft-used methods we homebrewers use **don't** remove all the cold break*. So I decided not to worry.

Subject: Re: Homebrew Digest #630 (May 06, 1991)

Davin Lim asks if a microwave oven would be any use in sterilizing. No, because they heat so unevenly that you might melt one part of your plastic hose while another part barely warmed up. The microwaves themselves do not have sufficient energy to disrupt the DNA of contaminating bacteria. Micro waves are like radio waves; they have a wavelength longer than visible light. You would need UV light or the even shorter wave X-rays to decontaminate your equipment. The only use I know for a microwave in brewing is to warm your sterile stock of malt extract agar before pouring out some new slants. Or to pop some popcorn to go with that great home brew. --Cheers, Jean

Subject: a non-beer related cooling question

Get those flamethrowers ready -- this is a non-brewing related query!

A net.correspondant of mine has a 300 gallon marine aquarium. The intense lighting and high capacity pumps needed to support this monster are raising the water temperature to an unacceptable level. For about \$1400 she could buy a stainless steel thermostatically controlled chiller to maintain 75 degrees. She's looking for a lower cost solution.

It occurred to me that the participants in HBD might have some good suggestions on a cut rate way to maintain a mass of salt water at a set temperature. I thought of using a stainless coil inside a small refrigerator, with a Hunter energy monitor to maintain the temp. Any other/better ideas? Design parameters:

Must achieve about a 10 degree drop from ambient temperature.
Must maintain temperature +/- 1 degree F.
Must be non-corrosive and non-toxic (i.e. copper tubing is probably out)
Must cost less than \$1400

Thanks for your consideration. Since this is non-brewing related, please direct all replies to me at krweiss@ucdavis.edu, and I'll summarize if anything comes in that looks like it would be of general interest.

Joe,

I run my bottles through the dishwasher as I drink 'em, and keep them in a kitchen cabinet until I'm ready to bottle. No sanitizing, no nothing. I keep them right side up and uncovered. I have (please don't strike me down for hubris, Lord!) never had a problem with contamination. I think you'll be reasonably safe, assuming the bottles are clean to begin with.

Subject: Carapils

From: BAUGHMANKR@CONRAD.APPSTATE.EDU

>How do they malt Cara-pils so that it doesn't have any convertible
>starches?

Carapils is made very much like crystal malt. It goes thru the same steeping and germination periods that all malt does. After germination, pale malt, Munich malt, chocolate malt and black patent malt are dried and then roasted to the desired degree.

Crystal malt and carapils are not dried. They are raised to saccharification temp while still moist, allowing starch->sugar conversion in the hulls.

Crystal malts are then raised to a still higher temp to allow caramelization of the newly formed sugars. This is why crystal adds residual sweetness, the caramelized sugars taste sweet, but are not fermentable.

Carapils is dried at a lower temp, so it does not go through the caramelization that crystal does. The amount of dextrin in carapils is controlled by the temp during starch->sugar conversion. If you mash with carapils, you can convert these dextrins into simple sugars, thereby losing those elements that the maltster so painstakingly provided.

Given that the conversion takes place in the uncracked grains, I don't think that it's accurate to say that carapils has no convertible starches.

Here is an attempt at ascii graphics :

Hope this helps,

Subject: Re: Homebrew Digest #631 (May 07, 1991)

I'd like to second Martin Lodahl's impressions of the west coast first round of the national competition. Anyone who sent a beer to San Francisco owes a debt to Russ Wigglesworth, Brook Ostrom, and Paddy Giffen. I salute you for the best run competition I've experienced. We also owe thanks to Anchor Brewing for allowing the use of their excellent facilities. Behind the scenes, Russ had all of the entries on his computer, and the results were tallied within an hour of the collection of the last judging sheet. I think that the biggest flight tasted was 11 beers, the average more like 7 or 8. With 35 or so judges this weekend, three judges per flight, and two flights per day, this was a most professional event. I hope that the other sites can carry on in this Grand Tradition in the making.

Subject: Fermentables in Dark Malts

in HBD 631, Dale Veeneman says:

```
>  Second question (also related to recent discussion): I know  
>  ^^^^^^  
>that dark grains have no fermentables, so there is no need to  
>^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^  
>mash.  However, Papazian recommends cracking all speciality  
>^^^^^  
>grains, put in the cold water, bring to boil, and then remove,  
>while Burch says to put uncracked dark grains directly in the  
>boil for the whole time.  I've done it both ways, and while I  
>haven't noticed strong tannins with Burch's method, I still  
>wonder what's really better?
```

I'm not the sage that some of the more experienced contributors to this digest are, but I am an all-grain brewer with ten batches of experience. (So much for establishing credibility) I feel compelled to respond to Dale's highlighted statement which, judging from other recent postings is a common misconception.

Dark grains have no enzymes with which to convert starch to sugar. Enzymes are produced in the sprouting or "malting" process. They are naturally produced to allow the seed to convert its starches into sugar which can be metabolized (wrong word for a plant I'm sure) in the growth of the plant shoot. The sprouting of the grain is then stopped by the maltster so that we brewers can use the enzymes and starch at our convenience. Dark grains are kilned at high temperatures. This roasting caramelizes some of the starches and de-activates the enzymes. There ARE still starches which may be converted to sugars if the grains are mashed with pale malts which have excess enzymes. Miller's figures for extract are 24-25 points of gravity per pound per gallon for dark roasted malts. This compares with 35-36 points for typical pale malts.

In my recipe formulation I account for the fermentables in dark malts and my OGs have been coming in very close to my calculated expected gravities. So, if you want to get the most of your malts...MASH.

Subject: Cheaper extract.

In 630 comment was made about not finding liquid extract for less than \$2.00 per pound. In #631 a brewer fell into a deal of less than a dollar per pound. While this is not likely to be repeatable, I have found \$1.33 to \$1.50 per pound at several mail order shops if you purchase a five gallon bucket, (60 lbs.) of extract.

Alternative Beverage, 800 365-BREW, sells a "Concentrated Wort" which is, they claim, pure extract, in 5 gallon buckets for \$91.25. This is just above \$1.50 per lb. The Homebrewer's Store, 800 TAP-BREW sells their own extract, Premier and Telford's extracts in the 5 gallon buckets for \$75 to \$80. This is as low as \$1.25 per pound. My local supplier, also a mail order shop, Jasper's Homebrew Supply in Litchfield New Hampshire, don't know the phone, will sell extract at \$80 per five gallons.

Now, these prices don't include shipping, and shipping on a 66 pound net package can run as much as \$25 from coast to coast. I suggest you use the one nearest you, and call others for the bulk prices. Many places don't carry the 5 gallon buckets, but might if the demand goes up.

There is another issue here; will it spoil. If you get pasteurized extract, probably not, if it's unpasteurized, it will grow alien life forms in several months if it's unused. There is a cure for this. If your extracts grows, put it in a large pot, your wort pot will do, and bring it to pasteurizing temperature, about 158 F. Hld it there for a few minutes and ladle off the surface scum and mold, or whatever grew. This should reclaim the extract and render it perfectly useful. This is a trick maple syrup folk have used for years should their syrup develop mold.

Even pasteurized syrups will grow on you if they are left long enough. The above procedure will work for them, too. If this is at all unsafe, I would appreciate the word of a qualified commenter.

The moral is: Brew a lot, or buy with a friend and split it up. This business of \$9.95 for 3.3 lb. cans is far too expensive for my taste.

Subject: SN culturing question

I'm attempting to culture the yeast from the sediment from a bottle of Sierra Nevada Pale Ale. I poured off (and drank :) all but the last 1/2" of beer, flamed the lip of the bottle, and added about 1/2" of weak sterile wort and sealed up the bottle with a fermentation lock.

I figured that keeping some of the beer involved would help keep the bacteria down, and what better place to grow a yeast than where it's been surviving nicely (I hope/assume) 'til now.

Everyday I shook it up to aerate the wort and stir up the sediment/yeast. About four days later I added about another inch of weak sterile wort. I've continued the shaking routine. There has never been a `head' on the wort, but there have been a few bubbles and the fermentation lock looks like it might be glubbing about once a day. The liquid has always been clear, whatever's in there settles very quickly.

A week and a half later there is about an 1/8" of sediment in the bottle. SOMETHING is growing in there. Is there any test short of brewing a small batch that'll tell me if I got it? Those of you who've had success with this sort of thing, does this sound like a success so far? This is my first attempt, so I have no idea.

Carl

From: David Lim <limd@sulu.Colorado.EDU>
Subject: Re: Oregon Brew Bashing

I understand where Florian (florianb@chip.cna.tek.com) could have easily found some less-than-ideal local micro-brews at the groceries. Sigh.... the one thing I miss the most about leaving Portland (even above the fantastic windsurfing in the Gorge) was the abundance and variety of brewpubs. I lived in the neighborhood of NW Portland (the artsy, eccelctic, increasingly yuppie, but-still-a-whole-lot-better-than Beaverton, part of town) and was easily within a three miles of about *six* brewpubs - Bridgeport, Portland Brewing, McMenamins (I could never spell this right) Tavern and pool, the Blue Moon (another McMenamins), Widmer (really the Heathman Deli), some other McMenamins in a hotel on 23rd. Talk about a *real* pub crawl... There's now probably a few new establishments since I left - almost two years ago. My favorites were Bridgeport, Widmer's, and Portland Brewing. They had the most consistent products and the cask-conditioned Blue Heron Ale at Bridgeport was heavenly. The McMenamini products are not so consistent, but can be excellent on occasion.

Anyway, I *do* feel that having microbreweries WILL eventually make for better beer all around. I just don't buy the line that Bud, Miller, Coors, etc... shouldn't be knocked because they're "extremely consistent and If any homebrewer who tries to make them would understand how difficult it really is, blah, blah, blah..." Consistency and repeatability do NOT make a beer great. Clean and refreshing are adjective that can well be applied to water as well as beer. As more communities become exposed to a wider variety of beers at a *LOCAL* level, and understand that fine beer can be made right next door (as opposed to some bohemian castle in a long-lost land, far, far, away...) the demand for such products will only grow. I seem to recall that micro-brew beer consumption in the Portland metro area (yes, even Beaverton) is approaching the levels of consumption of mass-marketed beer. With education comes appreciation (of fermentation? sorry...) Even if there are example of less than perfect-beer, it's still a whole lot more fun than seeing Hamms, Bud, and Blitz as the only choices on the menu (oh, I forgot the import Corona.) As the micro and pub brewers begin to mature, it *is* inevitable that the product quality *must* improve - otherwise they will drop by the wayside.

-Davin Lim (now a Colorado resident and trying to support the local brewpub and microbrewery businesses as well as I can.)

IMHO, Dave Miller's book is wonderful! However, keep in mind that I was asking myself a similar question (i.e. I have been using TCJoHB as my bible for extract brewing, now where do I go for more info and an INTRO to mashing?)

One thing was clear to me after joining a local homebrew club; the all-grain brews tasted better than most extract brews (my opinion). Miller's book is letting me dabble with partial mashes now. I am not geared up equipment wise or mentally prepared for truly all-grain mashing, instead Miller's book will give you great instructions for your first partial mash. Once you have done a partial mash then you can be the judge and decide if your brew has inched up the quality scale.

Miller does have some chapters (e.g. the chapter on water) that are a bit to detailed for me but I will come back to those details when I am ready. What really sold me on this book is Miller's common-sensical approach to brewing. His book is just littered with neat tips. For example stuff like: (1) to calibrate your thermometer, use a mercury fever thermometer as it is accurate to 2/10 of a degree, (2) draw your brewing water from hot tap water at 150 degrees as chloroform boils and chlorine gasses out in a few minutes, (3) an easy way to maintain a partial-mash temp of, say, 150 degrees is to put your covered kettle in the oven -- if you can set your oven to a temp that low, (4) AAUs explained (very helpful), (5) use the dry heat cycle on your dishwasher to sterilize bottles. etc. etc.

Last but not least, Miller takes the time to explain every brewing term he uses; and for the most part the definitions are easily understandable by the above average beginning brewer. Furthermore you can later find his definition in the body of his book because he has a decent index (which is lacking in Papazian's book).

Sorry to go on so long here but as you can see, I would recommend this book for the brewer who has 8-10 batches under his belt and is looking for more

homebrewing information, tips and/or challenges.

Ken Weiss says he keeps his clean bottles in a kitchen cabinet and simply uses them as needed.

Ken, might I suggest that you turn the bottles upside down while storing them, though you have had no problems to date you probably have indeed tempted the gods by posting your info. If you have the bottles upside down they may find it harder to put any nasties in them. Otherwise, it does seem unlikely that anything could live for long on clean dry glass.

C.R. Saikley provided a graphic of barley derivatives.

C.R. are you sure you want to put roasted barley where you have? Your chart implies that roasted barley is roasted flaked barley, and interesting concept but one which I have yet to encounter (all the roasted barley I've seen, and bought has been whole corns). Perhaps the roasted barley should be on its own branch?

Carl West relates a tale about an attempt to culture from a Sierra Nevada bottle.

Carl, sounds like you have an old bottle there. I personally wouldn't use it to pitch a batch of homebrew, think about how bad you'd feel if it fermented a whole batch as weakly as it appears to be fermenting the small amount of wort you have introduced into the bottle. I would want to see an active ferment, with a good head, after a day or two if I were going to consider pitching yeast from an experiment such as this. But, these are only my personal opinions, do what you like.

Matt Harrington asks about the Great Fermentations "33 gallon" brewpot.

Planning to brew some big batches Matt? I think that you probably meant to say "33 quart." I bought one of these, from this source, about two years ago, for about a dollar a quart as I recall. The only thing I would caution you against is lifting the pot by its handles when it is full of wort. The handles aren't strong enough for this task, mine has some small chips on the inside of the pot from doing this once (I never lift it when it is full any more). The price seems reasonably good, but if you can get by with whatever you are using and save your pennies for a while you might be further ahead waiting till you can afford a 10 gallon stainless steel pot, I wish I had done this but I too was a "starving" grad student (and thirsty too) when I bought the

afforementioned ceramic on steel pot. This is a serviceable piece of equipment if treated with care and used within its limits.

Matt also asks about sanitizing bottles from a questionable source.

I'd go ahead and immerse them in a bucket of bleach solution for a good long soak. In addition to cleaning the insides good this will loosen most paper labels, I personally find it more aesthetically pleasing to put my beer into bottles which are clean both inside and out. And, make sure that you get rid of any gunk inside the bottles before you soak them, use a brush or a pile of BB's (didn't you have a BB gun when you were a kid?) to scour the insides of the bottles. The BB's work rather well, just dump in a small handful of them along with a bit of liquid and swirl them around till they have loosened the deposits.

I'd like to thank all of you who responded to my query about the beer judge exam. The information should all be useful in my attempt to achieve the highest possible score the first time I take the exam.

It seems, from several recent postings, that there is more than one variation on the Hunter Energy Monitor (perhaps going by several names). Does anyone have the lowdown on this thing (these things)? What is involved in getting them installed and usable? Are these the same type of gizmo that some homebrew suppliers (Williams in particular) are selling (i.e. the type of thing that plugs into the outlet, and you plug your fridge or freezer into, and has a thermocouple that controls how much current your fridge gets to run its compressor)? A somewhat detailed discussion would seem to be in order if anyone has the knowledge and the inclination to share it.

Good brewing,

Dr. John

Subject: Dark/Black grain fermentables

In my previous posting where I asked about mashing vs. boiling dark grains, I guess I should have said BLACK grains used as adjuncts. Burch says, "Unlike the lighter grain malts, black grains do not have to be mashed, as all the starch has been effectively burned out during the kilning, and they consequently have little effect on the amount of fermentables in your wort." What I was wondering about is the possible effect of tannins or whatnot due to boiling (as Burch recommends).

Subject: Hard Cider

Hello everyone.

I'm a New England native that loves hard cider and wants to try getting some batches up starting in apple season. I know that this board is more geared to beer, but there has to be someone out there that has at least tried since the same equipment can be used (the carboy anyways).

I've done a little reading on the topic, but I was wondering if anyone out there had any tips on either (or both) of the following:

- 1) How to control how dry or sweet the end-product becomes.
- 2) The legality of selling it at roadside stands.

I have read that the Federal Government allows New England natives to sell limited quantities of hard cider from roadside stands - not even requiring a license or taxes! But I'm not sure if this law has any provisions - and then there's the state. I'd love to try selling some, but not at the expense of spending a weekend in jail.

Thnx

Subject: Reccomendations

Hi folks...

My mother is going to France in a month or so and I have a couple questions.

First, what are the prospects of shipping (relatively) large quantities of beer from France to US? Possible? Costly? What carriers?

Second, can anyone reccomend brews that would be readily available and tasty to have her send? I am interested in Belgian brews, mostly lambics, and also would like to get some Dutch Trappist brews as well. I'd prefer brews from smaller breweries and will want to try to get some yeast cultures (if the yeast in the bottle is the 'real' yeast).

Any suggestions about shipping procedures and specific brews to buy will be much appreciated. Thanks...

Subject: Room temperature lager

My brother and I are making a steam beer for batch #5, roughly based on the "The Sun Has Set On Time Steam Beer" recipe in Papazian. That recipe describes its product as "a lager beer fermented at ale temperatures". Since I don't have enough refrigerator space for my carboy but wanted to try a lager anyway, I got some MeV high temperature lager yeast for the experiment. The package says that the yeast works best between 10 and 16 C; my basement stays around 18 C. Papazian assures us that perfectly good beer can be made with lager yeast at those temperatures but that we might sacrifice some smoothness. Does anyone have firsthand experience with room temperature lagers? Will it take longer to ferment than ale? And is racking to secondary necessary at higher temps?

Secondly, when substituting dry malt extract for the liquid, I've been using 80% as much dry as I would liquid, on the assumption that the liquid is 20% water. Is this a good estimate?

Last, there was a discussion some weeks ago about spruce beer. We made a batch of this using the recipe for Special Red Bitter; we tossed a pint cup (loosely packed) of the smallest spruce twigs into the wort for the last 10 minutes of the boil, then removed them. We thought this would be safe; it's far less spruce than is called for in the Kudmis Island Spruce Beer recipe in Papazian; but in the first few bottles we opened, the beer tasted like puree'd pine tree. After aging in the bottle for five weeks, though, it has mellowed and is pretty good (though the pine taste is still too strong). A few more weeks of aging might be all it needs. I'd still advise using about 1/4 what we used and working up from there.

Thanks,
Jim Buchman

you'll
>be reasonably safe, assuming the bottles are clean to begin with.

I'm sure Ken knows this, but for a beginning brewer it might be
important. There may be nothing wrong with this as long as you use
some common sense. For instance, consider what else you do in your
cabinets/bottle storage area. My wife was fooling with sourdough bread
starters for a while, keeping them open-top in the cabinets. Point is,
just make sure the area you propose to use is free of obvious
contamination sources (ie microbes, pets, pests...). As Ken suggests,
keep them washed as soon as you're done with them. If there's nothing
in them that bacteria like, chances are it won't thrive in there.

>for \$36.95 + shipping/tax. Seemed like a great price to me. Anyone
>have comments or suggestions for a better place to get a brewpot on
>a starving student's budget? Thanks in advance...

A couple of things worth looking into. First, I assume you mean 33 quart, not gallon. Anyhow, I found a 5 gallon stainless steel pot for \$20 (on sale from \$30) at a store called Venture. I've also been told by another person that one can get a 6 gallon SS pot at Service Merchandise for between \$30 and \$40. I just recently ordered a 10 gallon SS pot from a place called Rapids that Marc Rouleau posted a blurb about from Chris Shentons mail order summary. This is what Chris had to say:

-> Rapids Inc: 1011 2nd Ave SW; P.O. Box 396; Cedar Rapids, IA 52406;
-> 800-553-7906. Restaurant wholesale equipment. Most interesting: 10 gal 20

-> gauge stainless pot: \$80; matching lid: \$20. The pot is quality, and it's

-> a good company with which to do business. [chris@asylum.gsfc.nasa.gov]

The pot is now \$90. They sent me the lid, but the pot was on backorder. After

seeing the heavy duty construction of the lid, I can hardly wait to get the

pot. Having used both ceramic on steel and SS now, I am glad I never spent

any money on a c-o-s pot specifically for brewing. SS pots seem easier to

clean up (after mistakes) and they don't chip. Also, it doesn't seem like I

scorch as often on the SS, but maybe that's just because I'm being more careful

these days.

Re: your bottles....for peace of mind, I'd soak the whole bottle instead of

just filling them up. When I sterilize my bottles, I always soak the whole

bottle, (especially considering that my dog or cats may have snuck a lick while

I wasn't watching:-).

I agree with this, but I still use a microwave to sterilize. What I do is add a small amount of water to whatever it is (usually yeast starter jars), cover but don't close it (e.g., saran wrap), and run them in the uwave until most of the water has steamed away. I like to use boiling water as my sanitizer, and steam is pretty good too. This technique does require that you watch what's happening somewhat closely, because running the uwave dry could result in the replacement of the magnetron bulb (and they're expensive, I'm told.)

That's a pretty average price, from what I've seen in the catalogs.
You're not getting rooked; might as well buy it from Byron. I found
one of these kettles for somewhat less in an aging hardware store,
but that was clearly a fluke. They're good kettles, wide enough to
cover two burners on the average stove, a factor you will definitely
appreciate when boiling the full wort volume.

Subject: Hop growing

I'm growing hops this year and have read a book (don't know the name offhand) from the catalog found in Zymurgy.

>In all the descriptions I've read about growing hops,
>they describe trellises that are 12 to 20 feet off the
>ground. Is this to avoid some sort of pest? Or does it
>make the whole project more convenient somehow?

Hops grow like crazy (up to a foot in a day) and are a vine. That's just how it is. According to the book I read, if you don't let them vine (can that be used as a verb too?) you will get a diminished crop. They will grow horizontally as well. Someone on the net was going to try to grow them near the ground in a horizontal manner. Maybe they can comment on how it's working.

>Also, in the planting instructions from Freshops it says
>that rhizomes of the same kind may be planted as close
>together as three feet, but different varieties should be
>at least five feet apart. Anyone know why?

All hop plants look alike. A sprout can break the surface a good foot or more from where the rhizome was planted. If they are too close, it's possible to get confused which variety is which. Also don't forget about the root system that they develop. They will spread rapidly in a few years and become mixed with a nearby variety if you are not careful. (They won't create a new variety because they are all females. By mixed I mean you won't be able to tell which variety a particular sprout is.)

Finally, there was a useful picture in the book which showed hops planted too close together. The result was said to be reduced harvest. I have no experience with this part.

> make the whole project more convenient somehow? (hard
> to believe). Maybe it's to keep vines from running into
> each other?

I suspect it's really in keeping with the natural proclivities of the hop vine. What's happened in my hopyard in the last few days seems pretty typical: one of the Mt. Hood shoots had gotten long enough for me to begin twining it around a cord. In the two days since then, it's nearly doubled in length, while the other shoots seem listless, by comparison. Hop vines climb; that's just what they do. This is to our advantage, as we can train them in ways that enhance our access to the cones at harvest time.

> Also, in the planting instructions from Freshops it says
> that rizomes of the same kind may be planted as close
> together as three feet, but different varieties should be
> at least five feet apart. Anyone know why?

Two possible reasons come to mind. First, the vines grow like bloody 'ell and will climb anything in sight, including each other. So, if you want to have any idea what kind of cone that is you're pulling from the impenetrable thicket of intertwined hop vines, it would behoove you to keep the varieties some distance apart. Second, the reason Freshops has rhizomes to sell is that the hops crown vigorously sends out these underground stems looking for a new dunghill to colonize, and so in subsequent years shoots can appear a considerable distance from the crown. If the hills are too close, you could have Cluster shoots cleverly masquerading as Saaz ...

Because plants grow this tall and sometimes much taller. My Cascades are
19
feet tall right now (in central North Carolina). Since the vines can't
climb
air, a trellis or twine is needed to accomodate lots of vertical space.

>Also, in the planting instructions from Freshops it says
>that rizomes of the same kind may be planted as close
>together as three feet, but different varieties should be
>at least five feet apart. Anyone know why?

Because the plants spread and after a few years you will not know what is
growing from where unless you can use other clues like leaf shape.

Are you sure it's not a 33 quart brewpot???

If it's truly 33 gallons, then it's a very good deal. However, you'll need a burner that can boil 33 gallons - stove tops are right out.

Another alternative is making a kettle out of a Sankey keg. It takes a bit of time, but can be had for little more than the price of a keg deposit (\$15).

Once you've got the keg, cut a 12-14 inch diameter hole in the top using a Milwaukee Sawzall (or a plasma cutter if you've got access). Cut a 1 & 1/16 inch hole near the bottom. A drill with a hole saw is fine for this. Then get a stainless steel coupling, and weld it in the hole at the bottom. You can then attach plumbing to the coupling : nipples, elbows ball valves, etc. When all is said and done, you've got a 15 gallon stainless steel kettle with a valve at the bottom for cheap.

There is still the burning issue of how to boil 15 gallons. Broken hot water heaters are a pretty good source of cheap burners. It's another project, but the spirit of homebrewing can easily spill over into home brewery building.

It's really pretty easy to do this stuff. I knew absolutely nothing about metal working until I built my kettle, and it works like a charm. I've left out many of the details. If anyone is interested in more info, respond via email. Also, Buffalo Bill Owens wrote a book on building a home brewery in which he talks about using a keg for a brewkettle.

Subject: Cultural Exchange

From: eisen@kopf.HQ.Ileaf.COM (Carl West x4449)

>I'm attempting to culture the yeast from the sediment from a
>bottle of Sierra Nevada Pale Ale.

A noble pursuit. I've brewed several award winners with yeast pilfered from Sierra bottles. There are several ways to do this, here is the one that works for me.

1. Brew about one quart of lightly hopped, low gravity (1.020 or so) wort. Cool and transfer to a sterile 48 oz jar fitted with an airlock.
2. Add the dregs from 3 or 4 bottles of Sierra, flaming tops as you go. Be sure to drink the beer ;-D. If there are any off flavors, don't use the sediment.

If your source of Sierra is fresh, your starter should be in high krausen in 3 days. I usually make a starter on Thursday, and brew on Sunday. It's that easy. There are those who insist that autoclaving is necessary when making starters, but that hasn't been my experience.

>A week and a half later there is about an 1/8" of sediment in the
>bottle. SOMETHING is growing in there. Is there any test short of
>brewing a small batch that'll tell me if I got it?

Yes there is. One of the niceties of making starters is the quality checks you get along the way. The simple test is to taste a small amount of the starter. If it tastes like very green beer, then you're probably OK. If it's off, don't use it.

>yeast. Once the fermentation got going, I put the fermenter in the
>fridge at about 40F. The fermentation went real slow once it cooled
>down, then stopped after about 3 days. I decided it was too cold, so
>I warmed up the fridge a little (from 'E' to 'C' on the little dial
>inside -- wonderful gauge, that) and racked the beer to a secondary.
>Now it's been going for about 4-1/2 more weeks! The lock has been
>glubbing about once every 20-30 seconds the whole time. Now the beer
>is clear enough that I can see little bubbles inside as it ferments.

I'm going to guess that you pitched the yeast from a packet into room temperature wort. Then you cooled the wort and shocked the yeast. It recovered after three days and intended to do its job when you racked it and shocked it further.

>month. I was going to make another lager that was slightly richer
>(6-7 lbs of extracts + specialty grains), but if this supposedly "light"
>beer is taking 5-6 weeks to ferment, I hate to think how long a richer
>beer would take. Is this normal?

A beer with "specialty" grains shouldn't take any longer to ferment than the pale beer, unless you are using lots of 80L crystal or something like that. The 5-6 weeks isn't normal fermentation. In any case the present stage is fermentation, not lagering. Please let me go into some detail to develop this by giving an example of how I brew lagers.

First, I prepare a yeast starter by pitching the packet into a solution of 1/8# dry light unhopped extract in one quart water, which has been (I mean the solution has been) boiled 20 minutes, then cooled to about 70 degrees. I do this two days before brewing. On the brew day, I prepare the wort, then chill to about 50 degrees in a large tub fermenter. I pitch the yeast starter, stir like hell, then put it into a 48 degree fridge. Here is where temperature control is extremely important. After two days, it is fermenting bodaciously. When the foam head has dropped, I transfer to a carboy quickly so that the temperature of the wort doesn't change much. Then I jam it back into the fridge at 48 degrees for about 12 more days. The fermentation should be just about over by then.

At that point, I do one of two things. Here are the two options.

(1) I rack it once more and put it back into the fridge. I lower the temp gradually over one week to 35 degrees. Then I leave it for 6-8 weeks. After that, I carbonate it. I then store it at 48 degrees for one week to carbonate it, then lager it once more until consumption.

(2) I keg and prime it. The I put it in the fridge at a temperature of 48 degrees for one week. Over a week's time, I lower the temp to about 36 degrees. Then I leave it for 6-8 weeks.

In either case, the lagering occurs after fermentation is complete. It is optional whether to carbonate before or after fermentation.

Most likely, if the beer is requiring 5 weeks to ferment out, the culprit is temperature. The one and only real good alternative

is to use a temperature controller on the fridge.

I hope this helps. The most important things are to (1) stay cool
(2) don't worry, (3) stay in school and graduate (4) keep brewing.

Subject: looking for keging suggestions

As I bottled last night, I thought about how nice it would be to have a Cornelius system, in that it would be so much less effort than washing all of those bottles. It is a bit pricey for me though, about 1/3 of my tuition here! Papazian's book shows a keg that looks like it would be a lot cheaper, but I havent been able to find one in a catalog. Not the actual keg, but the bungholes, etc. Have these kegs been phased out? Does anyone still use them?

Also, I was thinking that it was a lot easier, but if I only had one keg, I could only have one type of beer at one time, right? And, it wouldn't be economical to drink some beer and age some for a while. I gather that many readers of HBD use a keging system and I'd appreciate your comments.

What really made it a pain in the rear was that many of the bottles that I set aside to use couldn't be capped with my capper, which I believe is called a Universal capper made in Italy. The capper I have needs a bit of an angle on the neck of the bottle, and the neck can't be too thick as in champagne bottles. I found out the hard way as the first champagne bottle shattered into itsy bitsy shards of glass.

Is it possible to use a Bud/Miller/etc. keg from my local store to brew
? I'd just give up the deposit...

Thanks,

Matt Harrington

>What is a spaten?

Spaten is indeed a spade, and Spaten is also one of the bigger braueries
in
the Munich region. The spade is the brewers spade, used to turn the
grains in
the malting/mashing process.

On a recent trip to Germany, I was suprised to see how many breweries
have
the spade, fork and a hop cluster in their logo. Also of interest was the
brewer's star, which was a star of David. Anybody know what the
background
on that is? How did the symbol of Judaism become associated with brewing?

Subject: Re: Hunter Energy Monitor - The right one

Two friends and I just received Hunter energy monitors picked up for us by a fellow IHD subscriber. We have the model 42205, H.E.M.-AC, which is meant for use with a room air conditioner and will handle a 115-V power source. Presumably the 24-V model referred to in a recent HBD is the one that connects to a home thermostating system. My new HEM plugs into the wall, then the fridge plugs into it. It has a thermocouple (thermistor?) plug at the end of a 4' cord, which goes inside the fridge to measure temperature. It is microprocessor based and can be programmed for a weeklong cycle with four temperature changes/day on weekdays and two on weekends. Temperatures are set digitally in a range from 40 - 90F. The dead zone is 1 degree above to 2 degrees below setpoint and there is a 4 minute minimum delay between power-off and power-on to protect the fridge compressor. The H.E.M. is made by Hunter Fan Company, 2500 Frisco Avenue, Memphis TN 38114. Their customer service line is (901) 745-9222, M-F, central time. Enough? No one has ever accused me of brevity. Cheers - Jean

Subject: more questions about hops

All this talk about hops has me wondering a few things, and I'm curious if it would be productive to try to cultivate my own.

I live in N. Fla., very hot and humid, and a few freezing nights in the winter. I've got a fairly limited space of full sun with most of my property pretty well shaded. Can I cultivate hops in these conditions? If so, can someone list the address and numbers for Freshops or any other good sources for rhizomes?

Also, is it too late in the year to get them started? How soon can one expect to harvest after planting?

Thanks...

This is my regular summer brew (it's called "The Sun
Has Left Us On Time Steam Beer," btw, after a quote from
Thomas Edison). I have gotten good results with both Red Star
lager yeast and William's dry lager yeast.

If you brew at the temperature mentioned, you are
not brewing a lager, you are brewing a steam beer. A
different animal, and quite enjoyable in its own right. I have
been able to improve the smoothness of this recipe by lagering
the secondary, and doing the primary ferment at room
temperatures, but as you point out, this requires a LARGE
fridge. Even doing both at room temperature makes a fine
beer.

> Secondly, when substituting dry malt extract for the liquid, I've
> been using 80% as much dry as I would liquid, on the assumption that
> the liquid is 20% water. Is this a good estimate?

Yes, by weight. This makes TSHLUOTSB an easy recipe:
five pounds of dry malt extract and half a pound of crystal
malt. Try dry hopping with Cascades as the finishing hops.

Don't mess with it. Soda kegs are cheap if you know
where to shop (you're local, so give me a call) and you don't
mind reconditioning a used keg. The rest of the hardware isn't
bad, and can be found used as well. Figure a hundred bucks to

get started with used stuff, twice that with new. Another thirty bucks per keg additional (used).

Well, I have more than one keg 8<:^) (anybody who's been to my house can appreciate the humor). I store my beer in five gallon kegs and refrigerate and serve from 2.5 and 3 gallon kegs (they fit the fridge better). I use a transfer hose to move from one to the other. I only use bottles when I need a "single serving" package for some reason (my annual Christmas beer distribution, for instance).

Subject: Four Comments on Four Topics

Subject: AHA First Round

I echo Jay Hersh's positive comments about the East-coast first round judging. Everything went well. We spent one full weekend and one evening unpacking and registering our ~400 entries. We expected lots of broken bottles, but received only one. We had about 15 entries from wrong categories sent to us by mistake - these were re-shipped to Boulder. We received about 20 bottles with imprinted or raised lettering - illegal bottles!

We ran 5 judging flights, held over 3 days. Most flights had between 8 and 10 entries. IMHO, most beers were excellent.

Is there any news from the Boulder judging crew?

> In general from the results on either coast it seems like the
> distribution of labor was a total success. Too bad it took so long for
the

> timers recall our long past discussion of the tiered competition
system).

I agree. I see this year's experiment as the first step to the tiered competition system. If the AHA sets up more first-round sites, and allows each site to judge all categories, then we will have a regional "tiered system".

Subject: IHMO

> This may be a stupid question, but it's starting to drive me

I use a 5 gallon cylindrical Coleman cooler. It works fine - I use it as a one-step combined masher/sparger. For sparging, I wrap a stainless vegetable steamer in a nylon bag and place it on the bottom. It fits just above the valve. Oh yes, I've removed the standard push-to-dispense spigot and replaced it with the usual draining valve.

Subject: spaten

The Spaten Brewery is in Munich and makes many styles of beer. Spaten means shovel/spade in German, and they use a spade as their logo. BTW, they used to call their Dobbblebock "Doppelspaten" and put two shovels on the bottle.

Subject: first batch of ale

After brewing three batches of lager I've brewed my first ale. I used the expeditious ale recipe from tcjohb. It sure is expeditious. I've been getting 14 or so day fermentations with the lagers. This batch went from an og of 48 to 18 since Monday evening. I used both yeast packs from the Old Ale kits and I would guess that this contributed to the quick ferment. I figured if I racked it into the secondary fermenter Thursday morning I wouldn't have any blow off through the fermentation lock. I did it to quick on my last batch and wound up putting the boil off tube back in. Anyway, the fermentation slowed to one glug in 50 seconds and the specific gravity was down to 18 when I racked it. Did I wait to long? Is this rate to slow to drive off the air in the carboy? Is this quick ferment typical of ales or just this recipe? I would be inclined to use a single stage fermentation if this is typical. Would pitching just one packet of yeast help? Should I bottle this now or is there enough CO2 to drive out the oxygen and keep it from going bad.

John Mireley

P.S. I would like to brew a Southern Brown Ale for my next batch. Can someone recommend a good extract recipe?

I'm a bit confused now, what is the "proper" way to use Cara-Pils?
If steeped before mashing, I would expect the extracted dextrans
to be broken down into fermentables during mashing. After mashing
and sparging, everything is too hot. Should Cara-Pils be steeped
separately, and then this dextrin soup added to the kettle after
sparging and boiled with the full-volume wort?

Subject: Last word on Hunter

I finally got my Hunter Air Stat and it works great. For those of you who will be getting beer fridges or just thinking about getting beer fridges pay close attention. Hunter is a ceiling fan company that also makes thermostats. The Hunter Energy Monitor is too loose a term, because it applies to almost all of their stats (including the regular house heater/AC stat which I unknowingly bought the first time). What the brew wants is the Hunter Air Stat, an air conditioner thermostat that plugs into the wall. You plug your fridge into the Air Stat, put the remote temperature sensor in the fridge, set the stat, and away you go. This model goes down to 40 F, which is plenty low. If you want to get cooler, just put the stat on manual and control the temperature with your regular fridge stat. The energy monitor feature allows one to read how long the unit has operated on the current day, the previous day, and a running total. For those of you who don't know where to buy one, look in your phone book, or call Hunter at 901-745-9222. A warning about calling them: no one ever answers the phone. It may take you several tries to get through. Cost retails around \$40 (I think).

Bay Area: buy yours at Home Depot, because they're on sale for \$19.95. Look in the air conditioning dept.

Midwest: check Builder's Square for the ~\$20 price.

To make sure you are buying/have bought the right one, the model # is 42205.

good luck
kj

>I've done a little reading on the topic, but I was wondering if anyone
out

>there had any tips on either (or both) of the following:

> 1) How to control how dry or sweet the end-product becomes.

This is decidedly non-trivial. As a beginner, I wouldn't even try - just
ferment it and decide how you like the result before getting fancy. The
key is

how attenuative your yeast is (are you using the natural yeast in the
fresh-pressed juice or are you pasteurizing and adding yeast? If so,
what

kind?). What is your original SG? You can add sugar (actually I'd
recommend

honey, but then, I'm a mead-head) to a level where there will still be
some

sweetness after the yeast dies off. On the other hand, you can add
Everclear or

vodka to kill the yeast before the fermentation is done. Anything you do
to try

to control it is going to be tricky.

I've fermented out and bottled cider. My opinion is that just pouring
the

juice in a sanitized carboy and adding an airlock works as well as the
more

sophisticated techniques of pasteurizing and adding yeast that I've
tried.

My preferred way of having hard cider is to just leave the jug open at
room

temperature for 2-4 days and then serve. You get a little bit of
fermentation

and the result is short on alcohol but long on taste. Of course, you
can't

bottle it and serve it next July this way but I think this way has the
best

taste.

> 2) The legality of selling it at roadside stands.

>I have read that the Federal Government allows New England natives to
>sell limited quantities of hard cider from roadside stands - not even
>requiring a license or taxes! But I'm not sure if this law has any
>provisions - and then there's the state. I'd love to try selling some,
>but not at the expense of spending a weekend in jail.

Reading this makes me wonder if you live in the same United States that I
do.

The federal government not requiring taxes on the sale of alcohol????? I
strongly recommend that you ask the nearest office of the US Bureau of
Alcohol, Tobacco, and Firearms and the state Liquor Control Board and get

permission in writing before trying this.

This is purely speculation and not based on fact or even rumor, but my guess is that the Feds are tolerant if the roadside stand's cider ferments slightly and contains traces of alcohol when it is sold since it is very difficult to prevent this from happening. I suspect that they take a very different opinion of someone deliberately fermenting cider and selling it without paying tithes to Uncle. don't expect to spend a weekend in jail if you're caught; think in terms of years and \$K.

The answer is a very definite maybe. Some lager yeasts take longer than others. I haven't tried steam beer with that yeast. Racking may or may not be necessary depending on how long the fermentation goes. Try it and find out.

> Secondly, when substituting dry malt extract for the liquid, I've

Subject: Grain Brewing, Cleaning Equipment, Kegs, etc.

Why does everyone act like grain brewing is hard and that beginners shouldn't attempt it? Although I did extract brews for years (with mediocre results) and my anxiety levels were very high for the first grain batch, the results were good and the process was pretty easy and forgiving. Stick to simple, single infusion mashes (ala miller or Papazian), get a sparge bag, wrap your mash/sparge bucket with a towel or two and most of all "Relax, have a homebrew". The equipment requirements for a good mash are really pretty low tech. I just added a barrel tap to my old plastic fermenter and voila: mash & sparge bucket!

The proof is that a friend of mine did his first three batches ever as all grain and had very nice brown ales to show for it.

- ---- Cleaning Equipment

Try plain old Washing Soda (in a blue box at your supermarket) It is just Sodium Carbonate (main ingredient in your dishwasher detergent). A chemist friend of a friend claims Soda doesn't etch your glass ware (the phosphorous in detergent is the culprit) and rinses out very easily. Also, the stuff strips off beer labels and the gum very quickly. This doesn't sanitize and shouldn't be mixed with bleach. Etched glassware is a haven for bugs and harder to clean/sterilize.

- ----- Kegs

I got used Firestones for \$30/ea. I spent around \$220 for CO2 bottle, regulator, hoses, kegs, taps for three kegs. It was a lot of money, but the kegs are pretty convenient. I also bottle (from the keg) when I want to give someone my beer or take some on a picnic. Unless you can find a supply of used kegs real cheap you probably won't get setup this cheap. The place that set me up (Brewers Warehouse, Seattle) doesn't carry used kegs anymore... The only problem I have with kegs is that I am limited to how many beers I can have on tap - this gets even worse now that I am playing around with lagers and a keg is tied up for a month or so before I can start drinking!

Anyone have a pointer to a supply of cheap used pin lock kegs?

Subject: Beers from France, Miller

In HOMEBREW Digest #633, David Poore asked:

> First, what are the prospects of shipping (relatively) large quantities
of
> beer from France to US? Possible? Costly? What carriers?

I can't answer this one. I started looking into the question several years ago, and at the time, the complexities involved with the shipping plus the BATF and ABC red tape made me finally give it up. Unless you're willing to be an honest-to-goodness importer, it just doesn't seem to be worth it. I hope someone else has a better answer than that ...

> Second, can anyone recommend brews that would be readily available and
> tasty to have her send? I am interested in Belgian brews, mostly
lambics,
> and also would like to get some Dutch Trappist brews as well. I'd
prefer
> brews from smaller breweries and will want to try to get some yeast
> cultures (if the yeast in the bottle is the 'real' yeast).

Where's she going? Many Belgian beers are available in Paris, including many lambics. My brother-in-law lives next to a tiny, completely unremarkable neighborhood store in the 20th Arrondissement, and it carries such delicacies as Leffe Trappiste, Mort Subite kriel & gueuze, and Jenlain biere de garde. A couple blocks away is an ordinary liquor store that has Orval, the three major Chimays, St. Sixtus, Timmerman's gueuze, kriel, and framboise, and many others. In short, if she's going to Paris, she should have no trouble at all finding things you'll like. To the best of my knowledge there's no practical limit on the quantity she could bring back in her baggage, but excess baggage charges make it not practical politics to bring more than a case or so, and she'll be charged duty on anything over 2 liters.

The question of culturing from the bottle is a real "gotcha", for exactly the reason you've stated. There's an additional problem with lambics: due to the the complex nature of the fermentation, only some of the organisms lying in that heap of rubbish at the bottom of the bottle are likely to be viable, and of those that are, some reproduce very slowly. So, if you manage to culture something from a gueuze bottle and use it to make beer, that beer probably won't taste much like gueuze.

On an entirely different subject: I wholeheartedly throw my support behind the Miller book (The Complete Handbook of Homebrewing). I agree with Darryl's reservations concerning the title, but it's always the first place I look when I'm considering brewing a new (to me) style of beer. I personally believe it belongs in every homebrewer's library.

>first champagne bottle shattered into itsy bitsy shards of glass.

Two-handled cappers are traps for the unwary. Frankly, I can't imagine why retailers sell them. Actually I can, but just wish I couldn't. I had exactly the same problems, and sent many a perfectly usable bottle off to be recycled, before my wife found a bench capper at a yard sale for \$3. For a few batches I bravely tried to go on using that two-handled glass smasher on those bottles it seemed suited to, but I finally gave up on it and just keep it in case of the (unlikely) failure of my bench capper. Do yourself a favor, Matt, and start setting a little money aside each month for a good capper. They're lots cheaper than Cornelius kegs.

Subject: Fresh beer?

Something I have been wondering about: Several new small breweries around here date stamp their beer, and go to great lengths to explain that they do all sorts of things to make sure you get "Fresh beer"?? Why? The last thing I want is fresh beer? I go out of my way to hide freshly brewed beer where I won't be tempted to drink it until it has aged. I consider a few months to be minimum, six months better, so what is it with the "fresh beer"??

Of course this is mainly for cool/cold fermented beers. When I throw a bitter into the keg, I figure I deserve a glass right away for washing such a big container;-) It's amazing that in five minutes, there is enough gas produced to ooze that first glass out of the keg. But IMHO, even warm flat ales taste better after aging.

>glubbing about once every 20-30 seconds the whole time. Now the beer
>is clear enough that I can see little bubbles inside as it ferments.
>Will this beer be ready to drink anytime this year? This is taking much
>much longer than I expected.

One point to remember is that honey takes a long time to ferment. I recently bottled a Mild Ale that contained 4 pounds of amber DME and a bit less than a pound of honey, and used Wyeast ale yeast. Normally, I would expect this to be done fermenting in about a week at 65 F. With the honey, it took 3-4 weeks! And for a good portion of that time, the fermentation lock was going at 5-6 glubs/minute (constant). By the way, this stuff turned out great - it will make a wonderful summer beer. When it got down to the area of 1 glub/min, I bottled with my normal prime - 3/4 cup corn sugar. This stuff is *carbonated*, as the honey wasn't completely fermented out - but I like it that way for a light summer beer.

Also in HBD #631, Dave Huyink writes:

>I siphon twice with every batch, once from the primary fermenter (food
>grade plastic) to the secondary (glass carboy) and once more from the
>secondary to the bottles. I start the siphon by sucking on the tube.
>I always clean the tube before each use.

I use a turkey baster to start the siphon. It works reasonably well. The area that causes difficulty is where the soft plastic tubing fits over the hard plastic racking tube. This increase in diameter plus the occasional air leak at this point sometimes breaks the flow.

In HBD #632, Matt Harrington writes:

>I'm about to sanitize my bottles for my first batch of homebrew. Some
>of the bottles came from the recycling bin in my dormitory (sp?) so I
>can't
>vouch that the people that drank from them were healthy. Should I soak
>the
>entire bottle under water+bleach overnight? Or is filling the bottle
>sufficient? Help! I can't relax and have a homebrew knowing that I
>could
>get hepatitis or something...

Bottles I have just received from elsewhere (a liquor store, etc) are some

of the grossest things I've ever laid eyes on. I'd say over 50% have large, nasty mold colonies growing in the bottom. I've found cigarette butts and even *live* bugs in the bottles. So, my routine for these "new" bottles is (1) fill about 2 inches with *strong* (1 oz. per gallon or more) bleach solution. Soak overnight - this should loosen the mold colonies. Then, I put them in the laundry tub and soak them inside *and out* in another bleach solution of 2 oz per 5 gallons. Rinse thoroughly.

Now, I don't go nearly this far once I've used the bottles. I rinse them well right after drinking from them. Before using again, I soak the insides only in a weak bleach solution and then rinse thoroughly.

I have a book on making cider called "Sweet & Hard CIDER, Making It,
Using It &
Enjoying It", by Annie Proulx and Lew Nichols, published by Garden Way
Publishing, Pownal Vermont. It is copyrighted in 1980, but in its fifth
printing in 1990; I don't know if it was revised in the mean time. It
has a
chapter called "Cider and the Law", which says the following about the
Feds:

The Federal law reads:

Sec. 5042. Exemption from Tax. (a) TAX-FREE PRODUCTION. --
(1) CIDER. -- Subject to regulations by the Secretary, the
noneffervescent production of the normal alcoholic
fermentation of apple juice only, which is produced at a
place other than a bonded wine cellar and without the use
of preservative methods or materials, and which is sold or
offered for sale as cider and not as wine or as a
substitute for wine, shall not be subject to tax as wine
nor to the provisions of subchapter F.

However, before you start siphoning off jugs of your cellar's best to
sell to passing cider lovers, check with your state officials --
either the Department of Liquour Controls or the State Attorney
General's office for the laws and regulations of your particular
state that govern the manufacture and sale of cider. These laws vary
considerably from state to state...

The book also mentions that "surprisingly few farmers and apple growers
in the
US take advantage of this exemption". Too bad :-(

Subject: mash tun design; fresh beer

Chip Upsal requested hints on how to improve his mash tun design:

A small point. You don't have to solder anything with that type of design. Just fit the copper caps onto the open ends of the tubing. You want it to leak. That's the whole purpose.

Bill Crick asked about fresh beer::

I made the same mistake, Bill. There was a time when I wouldn't touch my homebrew until it had 'aged' three months. That was in the old days of marginal extract and I thought the extract 'tang' would go away if it aged longed enough. Hogwash. The objectionable extract 'tang' will never go away. Use good ingredients and when the beer tastes good, drink it. Most pubs serve their beer when they're only 1 week old. I don't recommend drinking it that young but I have had some beers that peaked in a month, held for a month, then started going downhill by the time they were three months old. By going downhill I mean the hop character started degenerating.

The rule of thumb here is the more hops and the more alcohol in the beer, the more the benefits from a little ageing. Light bodied lagers, bocks, sweet porters, viennas, etc. can be drunk rather early on.

Relax, don't worry, and quit waiting. Have a homebrew!

From: flowers@csrd.uiuc.edu
Subject: Some basic hop information

Hops grow best above the 50th parallel which is why Washington and Oregon are hop country. That's not to say they WON'T grow anywhere else. It's always worth a try.

Hops like lots of sun. At least a half day of sun is required.

Hop rhizomes are usually only available in the spring but a place like Freshops might still have some. You won't get much harvest this year starting so late, but you'll be all set for next year. (First year harvests are usually poor anyway.)

Hops are very hardy, being able to stand freezes and constant cold weather.

They can be planted in early March without much worry. Indeed, established rhizomes are already sprouting at that time.

Harvest time varies with variety. Some are ready by late summer, others in the fall.

I received my hops from Nichols Garden Nursery. I don't have the number or address on hand but they usually sell out by late fall. (They may even get their rhizome supply from Freshops because my directions came with a reference to Freshops.) Anyway, Nichols is an excellent company and guarantees their products. When my hops didn't come up last year, they placed a reorder for me at no cost with no questions asked. Of course, I had to wait an extra year to receive the hops. I'll post their address if there's interest. I don't know the Freshops address. BTW, Nichols carries several (4 I think) varieties and include good directions.

Once again we see the assumption that more is better. Randy I suggest
you
try a lighter bleach concentration even with these 'new' bottles. It
can't
hurt to try it once and you might be suprised at how effective 3
tablespoons of bleach per 5 gals of water can be.

When your clothes are really dirty, do you add an extra cup of bleach to
the washer? Why do it now? (Admittedly though, 1 oz per gallon may not
be
THAT bad, just as long as it doesn't turn into 1/2 cup per gallon.)

Subject: kegs, CO2, Old P - book, filter

After four years of grad school and homebrewing in England I've just move back over the Atlantic last October. I've been reading with interest for the past few months and figured maybe I'd make a few comments and questions that might be of interest to some readers:

1) kegs (or pressure barrels in the UK). Why do plastic pressure barrels cost so much over here?? They cost about 15 pounds (\$25) in England and here they ask \$70 here! Anyone have a source for less expensive barrels? I brought one over on the plane and I use it with a very cheep CO2 system. There are two kinds you can get. The first uses an automatic injector that takes the small cartridges that are normally used on seltzer bottles (the injector is made by Edme and I've seen it for sale at Barley, Malt and Vine 617/327-0089); the second uses a manual injector (I think Edme or Boots, UK makes them - but I've never seen them over here) that takes a much larger CO2 cartridge that is intended for a SodaStream drink maker (they are 12" high and probably 30x more CO2 than the small ones).

SodaStream drink makers are small carbonation systems that are very popular in England (sold at all Boots chemists and Tesco's food stores). To my great pleasure I found an American supplier that sells the drink makers (about \$20), many soda extract syrups (all Schwepps products), and, most importantly, the CO2 refills (for only \$4 each with free shipping over \$12!! - they don't even take a deposit on the cartridges!) The company is:

Schwan's Sales; 115 W. College Drive; Marshal, MN 560258
1-800-282-2244 ask for the Cap-Your-Own division.

Unfortunately, they don't sell the connectors that go onto the pressure barrels - anyone going to England can get one for ~\$17 at any Boots. or maybe someone knows where to get one here??? The only problem I see with this type of system is that you can't monitor the pressure - but don't worry - it works just fine.

2) Anyone know a recipe for Old Peculier (Theakston), Bishop's Tipple (Gibbs Mew), or Skullsplitter (Orkney) (three of my favorites). I once saw a book in England called "Making beer like those you can buy" but I haven't been able to find it since (there or here)... any help? I know Old P is some kind of Brown Ale using Molasses, but I don't know the recipe.

3) To filter out the hops and stuff I use one of those large flat circular screens that are intended to keep spattering fat from hitting your face when frying up bacon. The large fine surface doesn't clog as easy as those stupid funnel screens. Warning: better get your own rather than steal someone else's.

4) you people worry more than my mother! I never even heard of anyone using a fermentation lock for beer until I came here! A loose lid always did the trick for me in England. Are there different bacteria here or is it just paranoia?

Cheers,

Paul Hubel USQUE AD MORTEM BIBENDUM

From: Steve Dempsey <steved@longs.LANCE.ColoState.Edu>
Subject: Re: AHA First Round

The East/West-coast folks report that the AHA first round judging was a resounding success. I wish I could be as enthusiastic about what transpired in Boulder.

There was no major snafu as far as I know, but once again there were too many beers and not enough judges. Eight sessions held over four days were not quite enough to judge 900+ entries. Most flights were a full 12 entries. Depending on how many entries were received, the last flight in some categories ended up with 11 or 14 beers. A few similar categories were combined in a flight. I judged four sessions on four days: Munich Helles(12), Fruit lagers(5)/ales(9), Bavarian Pils(11), and Fruit ales(12). Some of the judges worked two sessions in one day, with an hour or two break between; these folks were showing definite signs of fatigue half way into the 2nd session. At the conclusion of the last scheduled session on Saturday afternoon, there were some 35 entries remaining to be judged. A few judges were recruited to finish them off at one extra session the following Tuesday.

The minor problems included misplaced entries -- beers showing up in the wrong categories. This could have been the entrant's fault in specifying the wrong class, or a handling error. Some of the specialty beers were not labeled as to their unique ingredients. Melomels, fruit lagers & ales, herb beers, etc. were identified only by category. This was probably an omission on the entry form as most entries clearly listed special ingredients. Four of the fruit beers I judged were not labeled. A few of them remained unidentifiable even after the evaluation!

Everyone got a good laugh when during the last session on Saturday, Charlie Papazian opened an entry with a loud POP! Everything within five feet was doused and foam gushed violently. Charlie stood up and said "we're judging still meads". There was not really enough liquid left in the bottle to judge it and the score sheets were drenched. The cover sheet remained and a comment was recorded: "Please do not ever enter a sparkling mead".

I can hardly wait for the second round and the conference!

From: kswanson@casbah.acns.nwu.edu (Kurt Swanson)

>Has anyone out there ever tried using rye in brewing? Besides
>barley, I've heard of wheat, oats, corn and rice being used in
>brewing, what about rye?? What other grains am I missing?

I have never used rye myself, but I have tasted a rye beer. A friend of mine is a professional brewer who still finds time to brew at home. He tends to get pretty experimental at home and does things that may not go over well at the brewery. One of his experiments was a rye beer.

The beer was pale in color and big in flavor. It was high in alcohol, had lots of body and was relatively lightly hopped. These attributes helped to bring out the character of the rye. Both the aroma and flavor had spicy and bready elements. It was somewhat reminiscent of a loaf of pumpernickel (no - really!!). If you can get ahold of the raw materials, it's definitely worth checking out.

This brew was made with both malted barley and malted rye, which is *extremely* difficult to find. Great Western (a large American malting company) made an experimental batch of malted rye, and my friend managed to get 10 pounds. They do not make it on a regular basis. Malted rye is made in Scotland for the distilleries, but to my knowledge no one has started importing it. The demand just isn't there. You could try using unmalted rye, but the results would surely be different. Mashing would get trickier also. Unmalted rye has no enzymes, so you'd probably have to use a lower rye/barley ratio. Depending on the temp at which rye starches gelatinize, you may have to cook the rye before mashing. It may also tend to gum up the mash, making sparging more difficult. Nonetheless, it would be worth a try if you're interested in alternative grains.

On a similar note, the Capital City Brewing Co in Middleton Wisconsin makes a wild rice beer. It's quite good if fresh and not light struck (green bottles :-Q). Don't know much about how they make it though.

I've been formulating a recipe using blue corn in the mash. Don't quite know what to expect, but the color should be interesting.

From: Darren Evans-Young <DARREN@UA1VM.UA.EDU>
Subject: chlorine removal, stout kits

Using a chlorine test kit designed for swimming pools, I tested tap water and water that was being boiled. To my surprise, even after 30 minutes of vigorous boiling, there was still a substantial amount (4-5 ppm) of chlorine left. The original level was 5-7 ppm. However, testing the water the next morning revealed no remaining chlorine. This is the second time that I have done this test with the same results. My next batch I'll be more scientific with the timings to see how long one should boil.

I have two John Bull stout kits (3.3 lbs) and looking for a good stout recipe. I've found the "Mega Stout" recipe in the archives, but it uses Munton and Fison's stout kit. Can I substitute the John Bull for the M&F?
Are they close in flavor/strength? I've heard that there is a big difference between stout kits.

From: hersh@expo.lcs.mit.edu
Subject: Cider Sales

Can't speak for the Fed, but in NYS the ABC laws do allow for sale of hard cider at roadside stands. I think this is cause the cider tends to go hard naturally and the provision was put in to prevent cider makers who sell their product from being prosecuted from inadvertantly selling alcohol when they were selling went hard. Cider sales are a pretty big seasonal business in some parts of NY.

I do disagree with Lou C. about certain aspects of cider making. I've been doing this for a few years, and while it has required some tuning I don't think it's all that complicated and would encourage others to give it a try.

E-mail to me (hersh@expo.lcs.mit.edu) and I'll try to put together a how to do it mailing. You best wait for the fall though as you will find much better and fresher cider to start with then.

>Two-handled cappers are traps for the unwar
I've had the 2 handle Italian capper for years. Never had a problem. I oil the joints once a year and it works like a charm, makes me regret I've gone mostly to kegging :-))!! Oh also the one I have has these little metal plates that make it the right height for beer bottles, but pivot back to work on champagne bottles (American type), have a closer look at your capper, perhaps you've overlooked this feature on yours (I did for the first 2 years I had mine :-)

>start setting a little money aside each month for a
>good capper. They're lots cheaper than Cornelius kegs.
Ah but nowhere near as much fun as drinking right from the keg tap :-)) :
-)

From Bill C.

>I consider a few months to be minimum, six months better, so what
>is it with the "fresh beer"??
Bill did you used to drink a lot of imports?? Perhaps you've just grown accustomed to that stale beer taste. Urban Myth has it that someone once did a taste test with fresh imported beer, and imported beer bought through retail outlets (ie OLD) and the consumers preferred the old stuff since it was what they were used to. Sigh....

We've been through this before, but in general beer is a fresh product that undergoes spoilage. Now the big CAVEAT is that certain styles are brewed to require aging. On the ale side those styles typically have high alcohol content, or as someone else put it "big" body (ie higher residual sweetness). On the lager side, well lagering is typically part of the brewing process and is done before bottling, but for homebrewers this can often be done in the bottle, but basically aging for lagers is a COLD storage process which avoids spoilage through temperature control.

Now I do cold condition my ales, at 35F for 2-4 weeks and it has an excellent effect, but I would never dream of aging these same beers at room temp.

From: dbreiden@mentor.cc.purdue.edu
Subject: Re: fresh beer

Bill Crick was wondering about the fresh beer fanaticism he's seen. A relevant issue was beaten to death in rec.food.drink recently; some people got to wondering about the shelf life of homebrew which got people preaching about when beer is best, etc.

Of course, it is simply a matter of taste. Personally, I think the fun part is trying to detect the change in beer over time and to decide if that batch got better or worse. As far as stamping dates, I like it because it's nice to know. With Bud, I have no idea how old it is. With freshness dating, I can drink a beer and say, "Wow, and that was bottled last Christmas!" or whatever.

Fresh, young, old, whatever. We all will drink the stuff when we want to, but it is nice to know just how old the stuff is.

From: rtidd@ccels2.mitre.org (Randy Tidd)
Subject: Making wheat beers from extract

I know this thread came up a month or two ago, but I can't remember what came of it. My local brew shop just got some wheat extracts in and I want to make a wheat beer. The extracts are 3.3lb cans of all wheat extract. Does anyone have any recipes for making a wheat beer from extract? What I was thinking was 3.3lbs wheat extract, 3-4lbs light extract, maybe 1/2# Crystal and 1/4# Chocolate malt. I'm not sure about the hops. Do I add extra hops to compensate for the sweetness of the wheat? Also, what sort of yeast should I use? I don't think my brewshop had any special wheat-loving yeast, but I could order some. Please reply via e-mail to rtidd@mwunix.mitre.org.

BTW I made "Toad Spit Stout" from Papaizan's book a while ago and was sort of worried after tasting it at bottling time -- I went a little crazy with the specialty grains (1/2# each Black Patent, Roasted Barley and Chocolate) and 3oz of high-alpha hops gave it a very bitter edge. But after aging in the bottle for 5 weeks, it's looking like it's going to be really good! I've gotta learn to be patient! I'm going to make it again in a few months, but this time i'll try to add soured beer to it according to the method posted to rec.food.drink. What is it, something like 3 or 5 percent soured beer in the fermenter?

Regarding the recent discussions on growing hops. I have some plants (Ringwood Special, a bitter variety) that have had a rough time over the last few years. Originally the root cuttings came from an established and spreading hop garden belonging to a long time local home brewer. I planted them in our suburban garden and got a small crop the first year.

To dry the flowers I fastened flywire over the end of a tall cardboard carton and used a fan heater blowing warm air in at the bottom. After running overnight the aroma in the room was glorious! I noticed the fresh hops had the yellow aromatic resin (lupulin?) all over them - far more than the whole flowers bought through the usual supplier.

The flavour carried through to the grain brew made with them. It had a fresh hop character and perfume that I haven't achieved since.

As for the plants - when we moved to rented accomodation I dug up the roots and potted them, where they suffered our poor care and lack of water for two years. Last summer (too late) I planted them into permanent beds. Two vines valiantly struggled up to about 5 feet then faded with the coming of colder weather. I've been told that you can't kill hop plants! I'm holding out great hope for next season.

By the way, in Victoria, Aust. hops are a declared noxious weed so growing your own is not encouraged!

Cheers... David Taylor

Subject: fresh/aged beer

I think there's something to be said for both. It depends on the brew. I've had a keg of amber ale from the Commonwealth Brewery in Cambridge, MA that was explosive in its "fresh-baked" (like bread) aroma and flavor. That beer needs no aging, and it shouldn't be aged. But it was professionally made. My own ales tend to improve with a few weeks of 60 degree aging, and what they lose in freshness is more than offset by the gain in smoothness. I think this has been said before on the list...If you make the brew "correctly", it should be drunk fresh. Aging will help to cover up the mistakes.

Now as for old beer, I had some Red Star Ale, from *East* Germany, so it was made before the unification. It still tasted very good. No off flavors. Did East Germany prescribe to the Rheingesbot, or did they allowed preservatives? It might have been Red Star lager....

I notice clove flavor/aroma in all German beer, not just wheat beer. Even in Becks. Is this just a case of taste-sensitivity, like the aluminum (oh no he said it) debate, or does the "standard" German yeast produce clove esters?

From: mcnally@wsl.dec.com
Subject: rye

In HBD 635, C. R. Saikley mentions that rye is malted in Scotland for whiskey, but no-one imports it here. That seems mighty strange to me, since I was under the impression that American whiskies are made with rye while Scotch whiskey is made from barley. It may be that the Scots use rye as an adjunct, but I'd think that the quantities use would be dwarfed by American whiskey production.

From: (Mark Stevens) <stevens@stsci.edu>
Subject: Wheat beer

In Homebrew Digest #635, Randy Tidd (rtidd@mwunix.mitre.org) asked about brewing wheat beers with extracts.

On the issue of adding extra hops: Probably not a good idea. Wheat beers are generally not real hoppy, and most recipes either omit or go very light

on finishing hops.

On the issue of yeast: Yes, there are special wheat beer yeasts. The Brewers

Choice line from Wyeast Labs has a liquid culture (I believe it's either #3026 or #3056) called "Bavarian Wheat". This is a very good choice for a wheat beer, although I've also had reasonably good results from their European Ale yeast. [Your mail address looks like it's in the D.C. area, in which case, you can get the Wyeast liquid cultures from BrewMasters in Rockville.]

Okay, now a recipe:

This turned out so good that I brewed two batches, the first was called "Jihad Better Have a Beer" [named by Karl Lutzen---thanks Karl], and the second was dubbed "Casual Dunkelweizen".

3.3# Northwestern weizen extract
3.3# Northwestern amber extract
1/2# crystal malt (crushed)
1/2 cup black patent malt (lightly crushed)
1 tsp. gypsum
1/2 tsp. Irish moss
8.6 AAU hops (I used 2 ounces of Mt. Hood at 4.3%)
Wyeast Bavarian Wheat liquid yeast

The black patent was *VERY* lightly crushed (I just ran a heavy rolling pin over it a few times) because I just wanted a light brown beer---not a black beer. The grains were steeped to just before boil and strained out. Add extract and all of the hops. Boil 60 minutes. Add to cold water in fermenter and pitch yeast.

Cheers!

Subject: More on Rye

From: kswanson@casbah.acns.nwu.edu (Kurt Swanson)

>Has anyone out there ever tried using rye in brewing? Besides
>barley, I've heard of wheat, oats, corn and rice being used in
>brewing, what about rye?? What other grains am I missing?

A couple of pubs near where I was living in England were selling a beer called Rogen around the end of last year and beginning of this year. It is made by the Bavarian brewer Thurn & Taxis, and the pubs also sold their

Hefeweizen (wheat beer - also widely available at Tesco supermarkets). The label claimed it was the first beer to revive a style not brewed for decades (I forget the exact number, but could easily have been over 100 years). Written in German, it said something about it not surviving a particularly bad succession of rye harvests.

Like the weizen, the Rogen came in half litre bottles and they supplied the tall weizen "vases" to drink it from. It was much darker than the weizen, a deep, reddish brown, and was also much smoother. Poured correctly (up-ending the bottle and shaking to get the last dregs out) it had the same massive head, but held it better than the wheat beer (the glasses probably hadn't been rinsed too well, which didn't help). Taste-wise, it was delicious: reminiscent of the better English mild ales, sweetish and smooth. It rapidly became a favourite for when I was feeling rich; at 1.75 pounds it was considerably more than a pint of bitter (around 1.25 to 1.35).

The pubs are both owned by Brent Walker. They are the Tap and Spile, Crouch Hill/Stroud Green Road, near Finsbury Park, London (part of a themed chain specializing in constantly varying selections of independent brewers real ales) and Fat Harry's near the Sobell Centre, also near Finsbury Park. I won't guarantee either still has the Rogen, but both carry a rewarding selection of ales.

Let me know if anyone finds this in California!

Subject: Sanitation

All this talk of starting siphons with one's mouth and not sanitizing bottles before bottling makes me feel that I should comment. I feel that these two procedures should not be recommended as being okay. I'd like to point out that if you drink the entire batch within two weeks of it being carbonated, then you could probably not boil anything and ferment in your toilet bowl. However, I have four homebrews on tap at all times plus a couple aging, so that sometimes a beer will take two or three months to be consumed. In my experience, if I cut one corner in my usual sanitation procedure, I get (probably) a lactobacillus infection after 8 - 10 weeks. I suggest following the usual procedures recommended in the texts and sticking with them. Once you make a habit of them, they don't get in the way and don't increase brewing time that much.

From: "Dr. John" <JELJ@CORNELLA.cit.cornell.edu>
Subject: HBD No's 635 & 636

In HBD #636 C.R. Saikley mentions a wild rice beer.

Just to set the record straight, this is brewed by the Capital Brewing Co., Madison, next to Middleton, is the capital city of Wisconsin, but the brewery name doesn't contain "City." I have yet to taste this brew, though all the other products I've had from this brewery have been very good.

Just to add my empirical evidence to the two-handled capper discussion, I have broken the tops off of a few bottles with mine. Haven't done so since I received a Colona(?) single-handled capper for Christmas a couple (3?) years ago (probably due to the fact that I retired the 2-handled job then :-)) . The Colona capper is capable of capping some types of bottles I couldn't cap with the 2-handler, and also speeds up my bottling considerably.

In today's digest, Rob Derrick asks about "God is Good"

I believe this is a term that was used for yeast, in the period before its importance in brewing was understood. There were other terms, I believe "barm" was one of them though am sure someone will correct me if I'm mistaken :-), that were used in that period also.

Good brewing,

Dr. John

Subject: ?'s

A couple of them: I've seen a couple of people mention putting black patent malt into wheat beers. Is that a common practice? Every wheat beer I've had/made was light colored and flavored, with no call for black patent. I don't see how it would fit. Also, I think you *should* use a good amount of aromatic hops (Hallertau works very well) in a wheat beer. It may not be "in the style", but the combination of the big head and the light flavor makes a lighter AAU hop very noticeable. Try it.

I guess that's only one ?.

Hello,

1) if you grow hops be prepared; they take over and may strangle your other plants. Put them in a separate area or use that plastic stuff you bury as an underground fence.

I'm planning to start a batch (extract only) in about 2 weeks.

2) Are Grolsch type bottles ok to put homebrew in?

3) What effect on my beer will a small vibration have? The only place to put the fermenter is near the washers on the cement floor. Bottled beer will be upstairs, so any sediment will be able to settle out in the bottle.

Subject: mead ferment times

I was wondering how long before the activity of the yeast slows down in this mead. I bought 15 lb of honey for 5 gal. It's been fermenting for about five weeks right now. OG 1100 SG 1060 right now. If it will finish near 1000, how long is this going to take before I can bottle? The yeast was Red Star Champagne, and the ingredients were water and honey. Should I add some yeast nutrient next time?

Subject: Hops & NY, Gingered Pale Ale at AHA Conference

My understanding was that upstate NY and Western Mass. were big hop growing regions, but shortly after the opening of the West (in a commercial sense) in the late 19th/early 20th Century more hops began to be grown out West.

I was told that the final nail in the coffin of Eastern hop growing was a nasty fungus which destroyed the commercial viability of the crop in this region.

Hops acreage now is tightly controlled by the USDA and one needs to be registered and/or licensed to grow hops. This has to do with some type of bidding system to insure an adequate supply for commercial breweries. Sounds like restraint of trade to me though...

And a warning to all planning to attend the AHA conference. I am brewing up a batch of my soon to be infamous Gingered Pale Ale (4 oz chopped ginger, 2oz Eroica + some Sticklbract), talk about a beer with a bite. Look for it at the AHA club night or the Wort Processors Courtesy Suite.

Subject: rye in beer

For the benefit of the person who inquired about using rye in brewing.

I have used rye with good success in the past. I purchased the rye by the pound at a nearby feed store. I cracked it along with my other grains (I brew all grain) and mash it along with the malt. The recipes I have dreamed up use maximum 1 pound of rye, but there is no reason why more could not be used. According to Papazian, it converts readily in a normal mash, even though it has no or very little enzyme. The enzyme is provided by the balance of the malt.

I have used it in both lager and ale. It imparts a flavor which I can only describe as "pointed." It appears to accent the bitterness of hops, the dryness of pilsener, and the statement of strong ale. If these words are insufficient to describe its flavor, I'm sorry. For better information, you could try it yourself.

Another grain I've had delightful results with is triticale. I buy rolled triticale at the local giant food store out of the bulk bins. I add it in the amount of 1/4 to 1/2 pound per batch of beer, again all-grain recipes. It goes in right in the mash in the beginning. Note that I do a protein rest at 122 degrees F for 30 minutes. This grain seems to impart smoothness to the brew.

BTW, rye will not add cloudiness to your brew; in fact, it may help clarify the beer. Don't ask me how.

From: greg@cemax.com (Greg Wageman)
Subject: Re: Sanitation

I just have to stick my two cents in after reading all the postings saying, "I don't worry about sanitation, and have only had X bad batches out of Y...".

First of all, depending on where you live (and how often you clean), the number and kind of flora in the air differs tremendously. I've brewed in a basement condo in southern New Hampshire, and now do so in the S.F. Bay area.

Both areas have two things in common: dampness (in the form of humidity here, drought notwithstanding) and a propensity for mold. Mold spores are present in the air constantly in humid areas, and will settle and grow on virtually anything the least bit damp (for example, the inside of rinsed, uncovered beer bottles). Needless to say, sanitation is of the utmost importance in this kind of climate, otherwise homebrew tends to develop a grey-green head in the bottle. Not a pretty sight, and even worse for the flavor.

The human mouth is another wonderful repository for bacteria of several kinds. Most will happily grow in your homebrew. This is why starting a siphon with your mouth is a bad idea. If you are siphoning from the secondary, it will take longer for the bacteria to get started, but if you lager or age in the bottle for any length of time you *will* see an infection. The bacteria will digest sugars that yeast will not, leading to drier and drier beer, gushers and grunge.

Yuck.

Secondly: I don't know about the rest of you, but I find brewing to be a fair bit of work. Like most people who work for a living, I don't have a whole lot of free time to waste, so if a little bit of extra care in sanitation is going to save me from having to toss the product of several hours labor and ~\$30 worth of materials because of an infection, I'm all for it.

So, I guess the point is this: if you can get away with poor sanitation because of where you live, or don't mind dumping an occasional batch, good for you. But don't mislead others into thinking that this is a desirable or even acceptable practice for anyone else. Many beginners look to this list for good advice, and you're not doing them any favors by downplaying the importance of sanitation.

Subject: Capping Bottles

I saw a show about wine bottling the other day. They say to lean bottles of wine on the side to keep the caps moist and the cork therefore expanded. While I realize that most don't use cork caps, would there be any benefit to laying your bottles on the side, or would any advantages outweigh the fact that the sediment will be all over the bottle?

Second question--I have a bag of caps with cork in them--anyone have any experience using them? I got them as a gift--but don't want to ruin a batch if they will screw up the brew. Would it be to my advantage to age a brew capped with *these* caps?

Subject: Varia

1. God is Good (indeed!) refers to the yeas Back in the old days they didn't understand microorganisms as we (but not I) do now.
2. Hop growing is best in WA and OR (and Idaho too) because of the seasonal temperature differences (not TOO extreme). Heck, even in Latte-land Seattle my hops are 10 feet up to the trellis and very hardy (hearty?) despite a coospringtime here in America's most overrated city.
3. Czech Budweiser Budvar is not to be compared to the #1 selling A-B product. T real thing is 5% alcohol by volume with an OG of 1.048 which is clearly printed on the bottle. Better on tap though, it is smooth and malty with a tawny color and non-threatening hop character. The bitterness is just right for the malt. Let me know when an authentic recipe for Klages is available.
4. Age and beers: recently during a brewing drought I was forced to start consuming some ancient brews as old as 5 years. I was surprised by the way most all the brews kept their flavor and in some cases got better; by which I mean smoother. I store the bottles on the basement floor which fluxuates between 54 and 62 during a year's time. Cleanliness in the handling of the beers seems to be a very important consideration.
A few of the beers were gushers but had little flavor loss once the foam died down.
5. AHA question: did the number of entries to the competition (1600+) exceed the projected number? Did the price increase affect the number?

Hmmm...have things gone so far downhill at the conference that a gingered
ale is once again a threat? Especially with only 4 oz ginger, a mere
pittance!...or was this only a 2-gallon batch?!? (In '84, our amber
gingered ale took a first in Specialty. We used 9.5 oz ginger in 5 gal.
Try it; you'll like it.)

Seriously...I wish Jay the best, and I wish more people would try ginger
for specialty beers. It's a wonderful addition. In particular, the
combi-
nation of a gingered, well-hopped pale ale with good Chinese food (Hunan/
Szechuan), or with barbecue, is a match made in heaven.

Subject: gingered ale

Having recieved a *considerable* number of requests for recipes for Bishops Tipple and Old Peculier, I have decided to send the recipes and quoted method to HBD. This is quite a lengthy message and I apologise to those who have the book. For those who haven't, however, the details are:

Brewing Beers like those you buy
- David Line
ISBN 0 900841 51 6

It is/was published in GB by The Standard Press (Andover) Ltd., South St, Andover, Hants, England and is an Amateur Winemaker publication. I don't think it has been released in the states.

It contains *many* recipes for Lagers, Light Ales, Pale Ales, Keg Beers, Brown Ales, Stouts, Barley Wines and Strong Ales. Most beers included are British, although there is a section on Beers of the World, including Chimay, Pilsner Urquell, Grolsch etc. Best though, is the Real Ale section with *43* recipes - many of which are authentic, that is to say they have been adapted from the true recipe and techniques used by the brewery. I have brewed several of the Real Ales, and can verify in most cases that results are good, and occasionally better than the original:-) Most are all-grain brews.

Old Peculier - Theakstons, Masham, N Yorks (Approx 6% Alcohol)

15Litres of water treated for 'brown ale' brewing (although it is not a Brown Ale!)
2000g Dark malt extract
250g Crushed roast Barley
250g Crushed crystal malt
1000g Soft dark brown sugar
60g Fuggles hops (or extract)
5 Saccharin tablets
60g Brewers Yeast
100g Black treacle ;-)

Boil extract, malt grains + hops in water for 45mins. Strain into bin and sparge the grain and hops with hot water. Dissolve sugar in hot water and add to bin. Top up to *25* litres with cold water. When at room temp, pitch in yeast and saccharin. Ferment until activity dies down and rack into secondary. Fit airlock. After 7 days rack into a barrel primed with treacle. After seven days conditioning it should be ready to sample:-)

Bishops Tipple - Gibb Mew, Salisbury (OG 1066)

3500g Crushed pale malt
500g Crushed crystal malt
15g Crushed black malt
15 Litres of water treated for 'strong ale' brewing
5ml Irish moss
750g Golden syrup
60g Molasses
100g Goldings hops
5Saccharin tablets
60g Brewers yeast

15g Gelatine
60g White Sugar (for priming)

Raise water to 60C and stir in crushed malt. Stir continuously raise temp to 66C, retain at this temp for 1.5 hrs. Contain mashed grain in a grain bag to retrieve sweet :-) wort. Sparge grains with hot (~70C) water to collect 20 litres of extract. Boil extract with hops for 1.5 hrs. Dissolve molasses and sugar in some hot water and add during boil. Pitch Irish moss. Strain clear wort into bin and top up to *20* litres with cold water. When cool add yeast and saccharin. Ferment until sg 1020, rack into secondary, add gelatine, and fit airlock. After 10 days rack into primed barrel. Sample after 10 days.

These are Lines recipes and method, not mine, and *should* be experimented with, for example to capture cold break or to replace unavailable ingredients. Suggested improvements would be welcomed.

I would appreciate hearing from anyone who has a go at these recipes, and will answer brief queries. Much arm-twisting would be required, though, if I am to release any more recipes. I am, however, compiling a recipe and method database and will send to anyone interested. Contributions of course are welcome.

Finally I am glad to hear of your healthy loathing of American Bud.

Ade

Subject: Dutch Trappist Ales

I got some good advice on Belgian beers available in France to have my mother get for me this summer (thanks Martin!). However, no word on Dutch Trappist Ales. One of the Beer Hunter episodes had a bit about these brews and breweries which left me in a bad state: rolling around on the floor drooling. Most unattractive. Can any one help me out? What brand Dutch Trappist Ales (if any) would be available in Paris?

Also, re: the cantilever cappers. I also ditched mine in favor of a bench capper. Broken bottles etc. The problem I had with it is that it wouldn't work on all bottle types (even with the adjustable collar) and it didn't mash the caps on completely. The bench capper works on everything and is much fast and safer. They can be had cheaply and easily by haunting a couple flea markets or garage sales.

From: Mahan_Stephen@lanmail.ncsc.navy.mil
Subject: Grolsch bottles

Lee Katman asked about the suitability of Grolsch bottles. They work great. Check the gaskets before starting bottling and replace those that are questionable.

I usually bottle using both 12 oz. (IBC root beer) and 16 oz. (Grolsch) bottles. The 12 oz. bottles are good for giveaways, as my family consumes enough root beer to keep up the supply. The Grolsch bottles are MINE. I can bottle in Grolsch by myself in one pass, running the bottle filler with one hand, and capping and filling the case with the other hand. Conventional capping usually needs a helper or two passes, putting caps on as I fill and then crimping after all bottles are filled.

On the same topic:

>I like to use the Grolsch re-sealable bottles for bottling. The are
>16 ounces and they are re-sealable. Capping is a breeze! The problem
>however, is getting them. Does anyone know where I could get a lot at
>a reasonable price? I know I can get the gaskets, but the bottles?
>Or similar ones?

I found a German bar locally that saves them for me. I get about a case every week or two at no charge. I'm currently stocking up for myself and two or three brewing friends. Zymurgy usually has an ad from some people that sell Grolsch-like bottles (at an unknown price). They are:

E.Z.Cap Bottle Distributors
4224 Chippewa Road N.W.
Calgary, Alberta, Canada T2L 1A3
phone: 403 282-5972

I see the Grolsch bottles occasionally at the flea markets in small quantities, but the asking price is around \$1.00 per bottle. You could also make the sacrifice and buy and drink a few cases of Grolsch beer.

Subject: Black patent in wheat beers

I'm not a purist, so I have no moral indignation at putting black patent in a wheat beer. However, it is almost certainly not what German brewers do to make Dunkelweizenbier. More probably, they use a Vienna malt. Dunkelweizens are generally pretty sweet, with no tannic bite.

One of the best dark wheat beers I've ever had was a Weizenbock called "Aventinus". I had it in Munich. It's produced by a brewer that's relatively big but unknown in the states; I don't remember the name. Aventinus is really a fabulous beer, and it's served in the niftiest weissbier glasses I've ever seen.

Subject: We wuz HAD! A Cautionary Tale ...

I'm passing on an experience our club had last night, to put you all on your guard against being duped as we were. The observations and opinions that follow are mine and mine alone, and don't necessarily represent those of even a single other member of my brewclub. And please forgive the length, but I believe this to be important.

A long-time member (and local pub brewer) contacted another long-time member and past President (and M. D.) to give a talk to the club about responsible drinking and the effects of alcohol. So far, so good. Part of the talk was to be the ritual demonstration of getting a few "designated drunks" plastered, after assuring they wouldn't be driving, to demonstrate the effects of various levels of blood alcohol content. To provide a consistent means of testing this, and to "sharpen the point" of the demonstration, a representative of the California Highway Patrol was invited. I don't know who invited Channel 13 News.

The lead story on the 11PM newscast was on DUI (it must have been a slow news day), the anchorperson fairly trembling with indignation and righteousness, and our club serving as unwitting shill for neoprohibitionist extremism in an amazingly crude form. Certainly none of us had ever imagined the footage would be used in this way. Fortunately, the name of the club was never mentioned, nor was anything said about its being a gathering of homebrewers; it's possible the "reporter" (who stood very much aloof, at the meeting) was unaware of the type of gathering the CHP officer was addressing.

We are under attack, and must be very careful of the image we present, how we present it, and to whom.

Subject: Recipe Book

Are you tired of searching through the Homebrew Archives trying to find just the right recipe? Have you ever wanted to have a nicely formatted book of recipes from the Homebrew Archives? Well, then keep reading, because Mark Stevens and Karl Lutzen are proud to announce the release of their Homebrewing Recipe book, 'The Cat's Meow'. In it you will find a collection of recipes taken from the Homebrew Digest archives. After many hours of filtering through the archives, many more hours of editing, the book is now ready for public consumption. Rush right out via FTP to the homebrew archives, mthvax.cs.miami.edu, and change directories to homebrew/recipe-book. Here you will find the 15 parts of the book in compressed format. Please do not forget to set type binary before transferring the files! After the files in your machine and are uncompressed, you will have PostScript formatted files ready to go directly to your Laser printer. (Please note: A plain ascii version will be available upon an email request to Karl Lutzen at lutzen@apollo.physics.umr.edu. It should be ready in about 2 weeks).

So rush right out and get your copy of 'The Cat's Meow' today!

Subject: Barm and Rye

Various and sundry comments:

Dr. John:

I always thought that 'barm' was the clean, 'hot', recently deposited yeast in the secondary.

Florian:

A cautionary note. I've been told to be wary of grains bought in feed stores. Being fit for animal consumption doesn't mean being FDA approved for human consumption. They have all sorts of fertilizers, chemicals, etc. floating around in the air in those warehouses for one thing. For another, they spray all sorts of fertilizers and chemicals on grains while they're growing. They may or may not clean them if they're destined for the grain hopper in a barn somewhere.

There's no advantage to laying beer bottles on their side as I see it. It's necessary to keep corks damp in order to insure an air tight seal. The crimping of the crown around the upper neck of a bottle does the job for capped beer.

Cheers!

Kinney

From: David Lim <limd@sulu.Colorado.EDU>
Subject: Re: mead ferment times (HBD#637)

Ken Johnson asks about mead fermentation times...

Ah, the mysterious world of mead. I've made three batches of mead, and I've yet to discover what **really** makes them tick. The first batch was a plain still mead (no fruit or stuff.) I used a little acid blend (to get pH around 3.5) a little yeast nutrient (about 2/3 tsp for 5gal) and some Lalvin K-1 wine yeast. The K-1 yeast is one of the so-called "killer" strains which produces a substance (enzymes, i believe?) which kills off, or at least inhibits the growth of other competing micro-organisms. This batch took a few months to ferment from an OG of about 1.100. It stalled at about two weeks at about 1.060. I added some more nutrient and some more yeast - this time a more attenuative strain of S. Bayanus made by Lalvin. I wasn't sure if this yeast would take hold since there was the K-1 killer yeast already in the fermenter. However, it did go to completion (about 1.002 on my hydrometer) in a few months. My guess at why it took so long to ferment was that I didn't aerate the mixture enough prior to pitching.

My second batch, a raspberry mead, had only a slightly lower OG (1.090) and was aerated **thoroughly** prior to pitching. Same S. Bayanus yeast, no yeast nutrient or acid blend (I figure the raspberries would take care of this for me.) This batch had a very active fermentation - I had to attach a blow-off tube to the fermenter! This was **not** the classic lazy mead fermentation. The mead reached a final gravity of 1.000 in 1 1/2 weeks! It's still a beautiful deep red! Can't wait until it's a year or so old in the bottle.

Moral of the story: Aerate the cooled honey mixture! I don't have enough experience to make real scientific claims, but if you don't supply enough oxygen for the yeast for the respiratory phase, it only makes sense that the classic slow, possibly stalled fermentation could result. It needs enough O2 to form a large enough population to handle all that food.

Though aeration of a batch under fermentation is not a good thing (oxygen is bad after in the anaerobic phase of the yeast life cycle), I did it anyways with the first batch to see if I could kick start it. It did eventually go to completion and tastes fine. Not award-winning, but entirely enjoyable.

Good Luck!

>branch?

Sorry for the confusion. I didn't mean to imply that roasted barley was
made
from flaked barley, but that neither roasted or flaked barley went
through
the malting process.

If roasted flaked barley sounds interesting, you could try roasting it
yourself. It would probably be most suited to a stout. Dave Miller talks
about roasting your own grains. He makes it sound very hard. The
transcripts
from the 1990 AHA conference contain another discussion about roasting
grains. I think the talk was given by Randy Mosher. He makes it sound
easy.

Subject: Strange hoplike herbs

Well recently I was judging the fruit/herb beer category at the Southern New England homebrewing competition. One of the beers was a chamomille/marigold beer brewed by the very noteworthy Ron Paige. I personally didn't like it cause of the marigold flavors, but it was a well brewed beer and many others liked it.

Ron is part owner/operator of the brewers of Atlantic Amber, I think they're called the Connecticut Brewing Co. and are located in Norwalk Conn., though I'm not 100% sure of the breweries name.

> If you are siphoning from the
> secondary, it will take longer for the bacteria to get started, but if
> you lager or age in the bottle for any length of time you *will* see an
> infection.

Nonsense! I have been tasting bottles from last Fall and last Spring, all siphoned by mouth-starting, and have had //no// gushers---maybe your "any length of time" is over a year? The bacteria in your mouth aren't wimps, but they aren't guaranteed to get a foothold from the minimal contact of mouth-starting, especially in finished beer and/or if you avoid sucking the beer right into your mouth (I use a long enough tube that I can suck it about half full, then work the air out of the rest of it by gravity).

You're right that it's not good to be casual about sanitation; you don't know when something's around that's going to be a problem, and it would be a shame to ruin a batch that's cost a lot of time. But there's a limit to how fanatical you want to be; if you use water to start your siphon, do you boil it? I sanitize everything (10-60 minutes in std bleach solution) and have had only one spoiled batch, which had two vulnerable periods: >3-day lag, probably from dead yeast (I repitched after ~2), and 1 day in closed racking bucket because I found after racking that the spring in my filler had been corroded by overexposure to bleach, and I couldn't replace it immediately (as a dex 3 I didn't even consider trying to bottle with a pinch siphon).

> weeks right now. OG 1100 SG 1060 right now. If it will finish near
1000,
> how long is this going to take before I can bottle? The yeast was Red
Star
> Champagne, and the ingredients were water and honey. Should I add some
> yeast nutrient next time?

Red Star Champagne is a pretty good yeast, highly attenuative. But 15
pounds should have put your OG well above 1.100, probably closer to 1.
120.

I have consistently had OG 1.100 using only 12 pounds, which usually
works
out to exactly one gallon of honey per 5 gallons of mead. Most champagne
yeasts will attenuate about 100 SG points before the alcohol kills them.
Using 15 pounds should finish above 1.000 in the medium-sweet range.

What temperature is your primary? Unless you pitch a healthy quantity of
yeast and ferment fairly warm, things can go fairly slowly. I know guys
who do meads at 80F and complete primary in 7-10 days.

Nutrients are important in meads because there's not much in honey except
sucrose/dextrose. It's also very easy to overdo the nutrients and end up
with an unpleasant, bitter chemical mess. I'm down to 2 tsp nutrient per
five gallons and have gotten rid of the nutrient flavors. The aroma will
come through in some of the drier meads but I'm working towards medium
and sweet meads and this problem should work itself out.

Unless you want to wait 6 months for this thing to attenuate, my advice
would be to boil up 1 tsp nutrient in a cup of water throw it in.
Activity
should pick up for a while and maybe even complete. If it slows down
again,
another dose of 1/4 or 1/2 tsp nutrient may get it going once more. Or
just
relax and wait for it to finish on its own; as long as you can perceive
that
it is still active, it should be just fine (some day).

From: polstra!norm@uunet.UU.NET (Norm Hardy)
Subject: Miller's book

Starting to brew in 1985 I read Papazian's book and was led by the hand by the wit and knowledge of the author. Even today the book is used as a reference for some of the charts on mashing or style recipes.

I grew weary of the light-hearted banter, accentuated by similar recipes and articles in zymurgy. It seemed that Charlie was intent on keeping the extract makers in business and the *serious* homebrewers making mediocre beer. Still, I read the book and the articles.

What attracted me to Miller's book was the attention to detail and the answers to many questions I had. I find Miller to be a little too serious at times and abit off at other times (like his stand on bleach for instance). But, by and large, I picked up MANY tips to improve my homebrewing, and they worked. At the same time that liquid yeasts became easily available, my brews took a quantum leap in quality.

Now, being a bit jaded and a little burnt out, I brew less often (maybe once a month) but make the best beer yet. Miller's book was a definite step upward for me.

Who wants to talk about Fix's book or Noonan's book? Is it true that Noonan now runs an ale brewery?

From: dinsdale@chtm.unm.edu (Don McDaniel)
Subject: Pilsner Urquell Recipe

I tried a Pilsner Urquell this winter (I called it Ersatz Urquell). It was my first partial mash batch and was unquestionably the finest brew I had made. I then tried the same beer in extract form. Again fine results. Unfortunately neither was an Urquell. The hop character just wasn't there. At the time I didn't know about the gravity adjustment for high gravity boils and I had Saaz pellets of questionable history.

The yeast I used produced a very clean, clear beer and I'd recommend it highly. It was the Wyeast Bohemian Pilsner yeast. If you haven't gotten into liquid yeast cultures yet, do it for this batch. The difference is tremendous. I did a two-stage fermentation. Primary, secondary and bottle conditioning were all done at a steady 50 F (that's where my cellar was during Dec and Jan).

Here's my extract recipe. I just took Miller's partial mash and calculated how much dry malt extract would be needed to get the OG of his recipe. I've also adjusted the hop rate upward by 20% for the gravity adjustment (I didn't account for that in my attempt).

4 lb. can Alexander's Pale malt extract syrup
2-1/3 lb. light dry malt extract
Saaz hops
 5 AAU 60 min boil
 5 AAU 30 min boil
 5 AAU 10 min boil
Wyeast 2007 Bohemian Pilsner yeast
OG ~1.050
FG ~1.010-1.008

I feel the key to success here are:
1. The lightest extract you can find
2. Fresh hops or pellets packed in Nitrogen
 (onlyonly Saaz will do)
3. Liquid yeast fermented at a steady low temp.

Happy brewing.

Must have been that wimpy store bought ginger. Mine was dug fresh off the trail
and smuggled back from remote tropical Islands :-) :-)

1000 Humble Kudos to those brave souls involved, Mark Stevens and Karl Lutzen.

>My second batch, a raspberry mead,
How many raspberries?? I've made blueberry meads, and Strawberry Blueberry, and Orange Cinammon, and Raspberry Cider, but it's always useful to get the amount (lbs or pints) per gallon from others to compare.

Oh yeah I've gotten a few responses on the Cider starters offer. I'm just waiting for the last few stragglers before sending something out. Perhaps if there is sufficient interest I can set up an alias and mailing list here for cider, but I'll hold off on that for a while.

> Dave Miller talks about roasting your own grains
I think that's just a tendency Dave has in his writing style. I've roasted grains myself before and it's not that difficult. There was some sort of chart in a past issue of Zymurgy about temperatures and times for roasting your own grains, I'll try to find the issue.

>Is it true that Noonan now runs an ale brewery?
Greg runs the Vermont Pub & Brewery located in Downtown Burlington, Vermont.
A truly wonderful place, (well it helps that I'm friends with Greg having met him at many a competition while he lived in Williamstown Mass, and I was just over the border in Troy, NY.) with a nice atmosphere most of the time (occasional the UVM college types over run the place and it gets a little like a Frat party). The beers there are pretty good. I especially like the smoked Porter that he's been making for a while. From what I understand he now has someone else working for him doing most of the brewing, but on my last foray there I couldn't notice the difference.

Subject: Malt Vinegar.

Well, I didn't get any ideas about how different beers make diff. malt vinegars, but a few people did want to know where they could get the mothers for making their own malt vinegar. Several of the mail order homebrew suppliers carry vinegar mothers, they come in jars. I called to check, and Alternative Beverage, 1 800 365-BREW has them in stock. In fact, they have mothers for five different vinegars. I think they said the cost was \$4.50 or something like that.

You can use the mother many, many times so the cost is minimal. Making vinegar is a little stinky, so do it in the basement or attic, or anyplace that is well ventilated. Vinegar likes about 85 degrees to work, and takes about three months to complete. What happens is the bacteria in the mother are converting the alcohol to acetic acid. You don't want more than about six percent alcohol at the most, so if you use a XXX stout for your malt vinegar, cut it with a little water.

Ah, will the practical uses for homebrew never end!

Subject: leaf hops vs. pellets

>Hi. I'm wondering about the difference between leaf and pellet hops. Is
>one type the "standard"? If a recipe says "2 oz. Cascade", which type
are
>they referring to? Assuming that I can figure out which type they
intended
>how much of the other type should I substitute?

I've heard that 1oz. of leaf hops is equivalent to 1oz. of pellets,
and I've heard from other sources that leaf hops are up to 4 times
stronger, by weight. Personally, I believe that leaf hops are only
marginally stronger, when they are used as boiling hops.

I would use nothing but leaf hops for finishing, though.
If you add them right as you take the wort off the heat,
You can immediately sparge into cold water or remove them
by some other means, but the important thing is that their
aromatic qualities are immediately imparted to the wort
and that the wort is cooled immediately before they have
a chance to disappear. Pelletized hops need to be boiled
at least a little in order to break them up; by this time
the aromatic qualities have degraded significantly.

In my last batch of stout, I added only 1/4 oz hallertauer leaf
hops for finishing, mainly because I wanted the leaf filter bed,
and could definitely taste the difference (even through
2 oz. of fresh, nearly overpowering, bullion leaf boiling hops.)

When I follow a recipe, I use the weight of hops is called for,
be it pellets, or more often, leaves.

> barn somewhere.

After spending 3/4 of my life on a grain farm, I wouldn't have any qualms about using grain from the local elevator. They handle the grain that goes to make your cornflakes, flour, corn chips, etc., and you might as well but directly from them what you can instead of paying 5000% markup. Any fertilizers or pesticides are applied sufficiently early in the growing season, with ample time for rain to wash the plant, and besides, the end product (seeds) have yet to form. The only disadvantage of buying animal food is that there's no one to sue if something does get contaminated, which is just as likely with human food.

From: David Lim <limd@sulu.Colorado.EDU>
Subject: Wort Aerator Question

I recently read in a back issue of Zymurgy a aeration device based on a little pump which pumped air through an aeration "stone". The "stone" emitted air bubbles fine enough to efficiently aerate the wort. The test by someone on the Zymurgy staff concluded that this gadget produced a better result (i.e. shorter lag time) than simply shaking the fermenter to aerate.

I presume the pump was an air pump for a fish aquarium, similarly the "bubbler-stone" (I don't know the proper name) came from the same pet store. There was also a filter in the hose between the output of the pump and the stone. This filter supposedly filtered out any airborne contaminants before it reached the wort.

Here's my questions: What type of filter is this? Is the claim of filtering out any harmful airbornes valid? If so where can I get one of these filters?

I have the pump and can easily buy a bubble stone. I need to know if the filter is for real.

Thanks!

Subject: re: various topics

I had fallen behind in reading HBDs and did not want to comment until I was sure that these topics had not been covered by others in subsequent digests. So here goes (sorry about this being a bit late and that I've lost the original poster's names):

Bock - Yes, goat in German - originally brewed for consumption under the sign of Capricorn (Dec 22 - Jan 19) i.e. X-mas holidays. Beyond that, I don't know for sure: I suspect that a similar style brewed for spring consumption gained the name Maibock. I second the praise for the German tradition of seasonal beers (although I'm not very fond of beers that lean too far on the malty side of hop/malt balance like the Oktoberfest style).

"the enzyme used by rice wine brewers for conversion" - I believe it's called "koji."

"3 or 5% soured beer in the fermenter [for more-authentic Guinness]"
I'd just like to add "PASTEURIZED soured beer"

"It is optional whether to carbonate before or after fermentation." - I suspect the author meant to say "before or after LAGERING." In other words, either you can prime+bottle (or keg) then lager or lager then prime+bottle (or keg). I don't have enough experience in lagers to comment on which is better -- I would like to hear what others recommend.

"Did I wait too long to rack to the secondary?" - I contend that using a secondary is unnecessary for beers that ferment out in a week or two. I used to transfer to a secondary after the krauesen fell (2-3 days at 65F) and then bottle after two or three weeks in the secondary. I stopped using a secondary for ales quite a while ago and did not notice any change in flavor. I did notice a decrease in infections, which may or may not be attributable to the one less racking. The primary reason for using a secondary is to get the beer off the dead yeast before it begins autolysis (where the yeast cell walls begin to break down). Although it is temperature and yeast-health dependent, I only go to a secondary after a week in the primary if I don't plan to keg or bottle within 6 weeks (lagers/high-gravity beers/scheduling conflicts).

>they referring to? Assuming that I can figure out which type they
intended
>how much of the other type should I substitute?

There is no such thing as leaf hops. You are referring to "loose" hops, which are the pressed cone flowers. Pellet hops are cone flowers that have been munched up and compressed into pellet form. The use of either is determined (as far as I can tell) by individual brewer preference. Pellet hops are easier to deal with since they won't plug up your transfer tube, and for this reason, some people swear by them. Others swear at them, claiming that fresh cone hops are the only way to go./ Some of the European hops are only available in pellet form, for obvious reasons. The issue on which to use has been settled by two famous brewers, but their conversation takes place in the restaurant at the end of the universe. So unless you have time travel or can wait 6 billion years, you will have to decide for yourself which is better.

Substitute amounts by alpha equivalent content. For example, if you have on hand both types, and both have the same alpha acid percentage, then substitute equivalent weights. If the two types have different alpha acid percentage, then substitute amounts by taking the product of the weight and the alpha acid percentage.

...And hey! Enjoy yourself! -- Welcome to the neighborhood, Steve!

yes, I agree. But I was unable to find whole rye anywhere else. We have only one or two very poorly stocked health food stores in Central Oregon (where?). I haven't given up trying to find the rye elsewhere. Funny that triticale is in the grocery store, but rye isn't.

While we are on the subject of alternate grains, let me (how can you stop me?) talk about corn. I have been using corn in lager for a while now. It produces a cleaner, clearer, dryer lager, and this is just fine for making pilsener. I was using corn out of the feed store for a long time, but this year I grew and dried my own. I simply planted an overabundance of sweet corn, and left some on the stalks about 4 months into the winter. Then, I picked the mature, dried ears, hulled it, and stored it in a plastic bag. Before brewing, I measure out the grain, grind it in my Corona mill and gelatinize it. The gelatinizing is done the day before brewing in a large kettle. I use 1.5 gallons water to 1 pound cracked corn and boil it 1-1.5 hours. The next day, I add this porridge to the usual mash. For the specific application of pilsener, I am really pleased with the outcome.

There aren't any hard and fast rules. Papazian suggests that to retain
"beer character" you add honey in amounts less than 30%. That figure is
by
weight in an extract beer - for your 1050 OG that would be a bit less
than 2 pounds of honey. That would produce a fairly potent beer - I
would
guess in the 6-7% alcohol by volume range. I prefer to use only enough
malt for an OG of about 1040 (or less), and about a pound of honey. The
honey produces a pleasant dryness in the beer. Yes, the fermentations
get
quite extended - 3-4 weeks for a honey ale at 65F, and of course longer
for a lager fermented cold.

End of HOMEBREW Digest #639, 05/17/91

Date: Fri, 17 May 91 8:36:22 EDT
From: "Justin A. Aborn" <jaborn@BBN.COM>
Subject: Beer in 2 liter plastic bottles

I called the Pepsi Cola consumer information hotline (800-433-2652) to ask about whether the plastic bottles they use are "alright" for beer. They directed me to the "Plastic Bottle Institute" in Washington D.C. (202-371-5200).

The nice man at the PBI said that the 2 liter bottles used for soda are made out of PolyEthylene Terathalate (sp?) or PET. This used for liquor and beer bottles in Japan and the UK. He thought there were no worries. Who knows...

From: "Dr. John" <JELJ@CORNELLA.cit.cornell.edu>
Subject: Copyrights, etc.

In today's digest (#639) Kent Forschmiedt suggested that by posting recipes from Dave Lines book to the digest we are blatantly violating copyright laws.

Well, it seems to me that if proper credit is given, as it has been, there probably isn't much of a problem. As to reparations to Dave Line, that might be rather difficult as he is no longer among the living. If buying his books helps to support his wife and child I'm all for it, in fact I own both the "Big Book of Brewing" and "Brewing Beers Like Those You Buy" and find them both to be very interesting.

As to the possible copyright infringement again, it seems to me that one of the main reasons for the digest is educational, and I beleive the copyright laws allow copyrighted material to be photocopied for educational purposes.

And lastly, this gives me an opening to broach a subject that has been bothering me for some time. To my knowledge, Dave Line was the originator of the alpha acid units concept. Now, for those of you who read Zymurgy, have you ever noticed the striking similarity between Homebrew Bittering Units and alpha acid units? (a rose by any other name . . . :-)) I am open to arguments against my position, but I currently think that Zymurgy has shamelessly ripped off Lines concept here, and have never seen him given the credit I think he is due. It doesn't seem to me that it would be that much trouble for Zymurgy to add on stinking little credit line to the sidebar to the recipe column and properly credit the man who discovered this concept.

I apologize if this seems like flaming to some, but it has been sticking in my craw for some time now. Any information on the subject will be gratefully, and humbly if necessary, accepted.

BTW, if anyone is interested in obtaining a copy of "Brewing Beers Like Those You Buy" and can't find one, e-mail me. Our local brew shop has a few copies and I'd be glad to arrange to send them to interested parties (supply is somewhat limited and I don't know the price right now).

Good brewing,

Dr. John

Date: 17-May-91 Time: 09:57 AM Msg: EXT01152

From Thursday's New York Times:

Albany, May 15 (AP) - A State Senator who wants to ban the sale of non-alcoholic beer to minors said today that it was a "training beverage for the real thing."

Several brands of non-alcoholic beer on the market look, smell and taste so much like real beer that people under 21 should not be allowed to drink it, said the Senator, Thomas Libous, a Republican of Broome County.

"We spend millions of dollars annually educating young people throughout New York about the negative consequences that result from alcohol abuse, yet we

allow access to a beverage that is brewed, packaged and marketed as a beer substitute," he said, adding that it was "sending conflicting signals."

His bill had no sponsor in the Assembly as of today, but it was supported by several groups fighting drunken driving, as well as by the New York Parents and Teachers Association.

Beer companies that also produce the non-alcoholic brew oppose the bill.

Subject: Hops Plugs

Well with all this talk about pellets and loose hops, I figure I should jump in with a recommendation for a new form of hops - plugs. The hop plugs are hops that have been compressed, but not so much as a pellet.

The plugs come in vacuum sealed foil pouches. I have been using these for my last several batches and I am quite impressed. Storage is a problem with any type of hop, pellets store better, but they still have problems (unless you get them in vacuum bags also).

I had been unhappy with the quality of hops that I could obtain when the homebrew store I use got in the plugs. I gave them a try and they are just amazing. When you add them to the boil, they fluff up into loose hops again. FRESH!

If you can get them, I strongly recommend the hop plugs!

Subject: wort aerating machines

Davin Lim asks about filtering air that will be used to aerate wort.

You can home build a very effective air filter. Get a 12" length of 2" or 3" PVC pipe, and a couple of endcaps. Drill small holes in the endcaps and

attach very small hose barbs, or just use silicon gunk and glue airline tubing right to the caps. Attach one cap to the PVC pipe. Put a small wad of acrylic filter floss in the bottom of the pipe. Fill most of the pipe with activated carbon. Add another wad of filter floss, and cap the other end. Just friction fit the cap on the other end, and tape it for an airseal. This filter will remove 99% of airborne crud, and will last about

six months in continuous operation. For a homebrewer, it will probably last a lifetime.

BTW, if you're going to pursue this idea you might try to locate ceramic airstones. These can be cleaned by heating with a propane torch -- a handy

way to ensure that the airstone is sanitary./

Subject: ginger beer

There's lots of talk on Gingered beer, so here's my 2 cnets.

The last beer I brewed was an all grain Pilsner, using all pale malt. After a few weeks of fermenting, I racked off some and added fresh ginger. This was a great way to try a little ginger. I made only 6 bottles and got to try something different. Here were my steps:

1. Racked off 6 pints of wort from the secondary into a clean 1 gallon jug.
The wort OG was 1.040 and was 1.009 at this point.
2. Grated up a bunch of fresh ginger from the supermarket. I added 1/2 teaspoon to 1/2 cup of boiling water (hopefully to kill off the bad guys without losing the ginger flavor).
3. Added to the jug and attached airlock.
4. Bottled two weeks later. SG 1.007.

Its been in hte bottle for a month now adn I just had my first one yesterday.
My observations:

1. Too much ginger for a pilsner. This ginger rate might do for a medium ale.
2. The ginger seemed to add some additional bitterness.
3. No infection problems.
4. Good ginger aroma and taste.
5. The head went away. The remaining Pilsner has the best head of any beer I've made. The ginger version has none.
6. This method of trying out a new thing was great. Same base, change only one variable, compare results, lose 6 beers if it doesn't work.

My question for those that have made ginger beers with good balance, what kind of final gravity did your beer have? You know, how much sweet to balance the ginger?

Subject: Re: Leaf vs Pellets

There does appear to be differences between bittering abilities of pellet and whole hops. Two references, "The Practical Brewer" and a late issue of Zymurgy indicated about 20% greater bittering power of pellets (~32% vs 27% isomerisation of Alpha Acid) over whole leaf. The difference seems to be due to the complete rupturing of the resin glands in the pellets. Of course, if the pellets were stored improperly, then this works against you. The Zymurgy issue had a table of isomerization rates/boil time but didn't distinguish between pellets and whole leaf hops. As for aroma, fresh pellets sure smell good and do a good number on my beers. I use whole leaf for dry hopping.

I'd be most concerned about sterilizing the stone. All of those tiny
little pores sound like the perfect environment for critters to hide
from bleach or boiling water or whatever you use to sterilize. Dropping
this into your cool, fertile wort at its most vulnerable time sounds
risky at best.

Hello,
several people have sent me e-mail about brew pubs in Manhattan and surrounding areas. I only know of one, Manhattan Brewing Co. 40 Thompson St. 212-219-9250.
I also called the Brooklyn Brewing Co. (Brooklyn Lager) 318 2 St. Brooklyn 718-768-2346 to see if they gave tours. Brooklyn Lager is brewed upstate in Utica. The Brooklyn location is only a distribution center. Bummer. If anyone is interested in Philadelphia brew pubs (they have TWO :) or bars with good selections in Philly, I'll e-mail you the "Philadelphia Magazine" article on the subject. On that note, apparently NRI is having trouble with their Internet to MCI Mail link. If you get a bounce from my address, try again in a day.

>of these filters?

I know that the "stone" part is right... can't say about the "bubbler"
part. I've heard stones are used to carbonate the finished beer in
some breweries.

Anyway, I got a good laugh when I read this review in Zymurgy. Whether
the manufacturer doesn't understand biology or wants to "pull one over
on us" or the reviewer made this up, I would expect a Zymurgy staffer
to know better than to write that a filter "STERILIZED" the air!
I assure you that no filter can sterilize air. Even sanitization
is probably impossible (I'm not a biologist either). At best, the
filter will remove large airborne particulates, which (when you think
about it) is better than simply sloshing your beer around to aerate it.

>There is no such thing as leaf hops.

I've always called them "leaf hops" to distinguish from pelletized hops. I use pelletized hop for boiling and finishing and use "leaf hops" for dry hopping. I use hop bags (fine, polyester mesh bags) so the transfer tube part is a mute point. I've read (and verified empirically) that hops in the pelletized form stay fresh longer.

Subject: The Cat's Meow

Gooday

Thanks to Mark and Karl for compiling 'The Cat's Meow'. My copy was FTP'd between several nodes before arriving in Postscript form on a Macintosh - then it was dumped to a Laserwriter. Some of the chapters were a few pages short but we put that down to Apple's PS interpreter.

More importantly, the recipes were terrific and give a clear picture of the types of brews being made in the US. There's a lot of experimentation going on with fruit and spices, honey etc. I've gained enough ideas to keep me brewing for a long time!

Almost all recipes did not use cane sugar (those that did were of UK origin). I'm weaning my own brews off cane sugar (commonly used and argued about by Aus. homebrewers too) and with Wyeast liquid cultures am hoping for excellent results.

Our commercial brewers seem to be able to handle cane sugar well, producing beer devoid of body and flavour yet with 5% alcohol. When I try to make a similar strength brew without sugar the malt comes through strongly. So... why don't *you* use cane sugar?

Cheers... David

I'd better put the disclaimer in this time! MINE! MINE! MINE!

Subject: Re: Copyrights, etc.

>As to the possible copyright infringement again, it seems to me that one of
>the main reasons for the digest is educational, and I believe the
>copyright
>laws allow copyrighted material to be photocopied for educational purposes.

Not really. The Copyright law grants exclusive rights to a work to the owner of the Copyright. The owner may then relinquish those rights as they so desire. Allowing short excerpts from a work to be printed as part of a review is an example of this. Educational use is sometimes permitted, but not always. The Copyright notice in the book sometimes lists the exemptions that have been granted, or you can contact the publisher for more information.

One aspect of the law that I'm not clear on is how long the Copyright remains in effect after the death of the holder. I think it's 50 years, but I'm not certain of this (I am certain that it's not 0).

Conclusion: it's probably illegal to send recipes from Dave Line's book (or any homebrewing book, for that matter) to the Homebrew Digest. In practice it seems unlikely that any legal action would be taken against you (or your employer if you sent it using a computer at work, or Rob Gardner, or Rob's employer, all for permitting the violation) but that doesn't make it legal.

/Don

Subject: weekend spree

Well, I cleaned up this weekend. I picked up a Lindemann's Frambroise Lambic, an Orval Trappist Ale, an Aass Pilsner from Norway I think, and a Sierra Nevada Pale Ale, Porter, and Stout. I also had some Long Trail Ale (made in Vermont): supposed to be a pale ale, but it was amber, and had an "over-bitter" character to it, as if it had too much pellet hops (I know the flavor well...). Nice malt aroma, but the malt flavor got lost in the bitter, and it had little hops aroma. An ok ale, but

I also had another VT made ale on tap, but can't remember its name. It was made in Bridgeport (?). It was also a pale ale. It *was* pale, a little cloudy, and light. Little maltiness, little hopiness. A nice yuppie beer. Actually it would be nice on a hot summer day. It seemed "cleaner" than the Long Trail, but maybe that's 'cuz it was on tap (at 3 Dollar Dewey's in Burlington, VT. Great place, about 15 different beers on tap, from local VT brews to Spaten Bock!).

I also picked up 2 food grade 4.5 gallon containers. The plan is to turn them into a Zapap later tun. If anyone has done this and has some suggestions or things to avoid, I'd appreciate the info.

Now, Belgium (Flemish?) beer: What should I expect from the Lambic and the Orval. I've never had either before. The Orval is dated Feb 1990. Is that too old to culture the yeast? What temperature should the Lambic be served at?

Any info on the Aass pilsner?

All in all, a succesful (and expensive) weekend.

These 2 litre (and 1 litre and even half-litre) PET bottles are also used in another strange, foreign land: Canada. Many micro-brewers have chosen to use them. Also, you can buy them in homebrew stores, where screw-on caps can also be purchased. There are two types: the re-usable ones seems more attractive on cost considerations, but they don't work as reliably as the one-time jobs that have a ring around the bottom which breaks when the bottle is breached.

On an entirely different note, I finally found a job. I'll be working at Adelphi University in Nassau County, Long Island, come September. Another lonely posting for "un Canadien Errant". Does anyone have information on local clubs, homebrew stores and brew pubs (I stress the "local" in the last point, as Manhattan brewpubs have recently been discussed...Adelphi is in Garden City and I'm told that nearby Hempstead is a nice town).

Thanks,

Rob

Subject: Contents of various whiskeys

Chip Upsal writes:

> Does anybody know what goes into what type of wiskies?

As I understand it:

Scotch: Malted Barley (Blends may use some others)
American/Canadian Whiskey (Seagrams, CC, Crown Royal): Rye
Bourbon (Only in Kentucky): Corn Mash
Sour Mash (Jack Daniels): Corn Mash

As for rye being malted in the US, I beleive that the House of Seagram is the largest single consumer of rye in North America. I doubt that they buy malted rye though, they probably do it themselves.

Bittering Units
> and alpha acid units? (a rose by any other name . . . :-)) I am open
to

Actually, HBUs are not the same as AAUs. HBUs are not as useful a unit,
because they aren't volume neutral. (For those who don't understand
what I'm getting at: 1 AAU = 1 oz. 1% alpha acid hops/1 gallon.
1 HBU = 1 oz. 1% alpha acid hops. Therefore, any information that
quotes an HBU level must also specify the batch size, or else it's
useless. That's not true for AAUs.) Papazian "simplified" AAUs
because "everyone" makes 5 gallon batches.

I like Dave Line's Big Book of Brewing a lot and still refer to it.
It has got its drawbacks: for USians, the English volume units
can cause trouble; he specifies saccharin for several recipes because
his equipment did not allow him the temperature control he needed to
get a good, high dextrin mash, and once again for us, he calls for
a lot of sugars that I have not seen in the local Safeway. But
especially
considering just how long ago the book was written, it is a milestone
work. And it is a good reference when investigating English styles. His
bedtime story for enzymes is still not surpassed ;-).

From: mcnally@wsl.dec.com
Subject: whiskey ingredients and beer stuff

When I said rye is used in American whisky, I should have said "some American whisky is made with rye." Like, maybe, "rye whisky".

Here's a brewing note: I've been using the technique suggested a few digests back of rinsing chlorine residues with cheap beer. I'm very satisfied with the results, which are mostly that I worry less (i.e., I'm not sure I've tasted any difference in the beer). At about \$3.69 a twelve-pack, Blatz is the best deal around here. (As an aside, I was struck by the pronounced yeastiness of this stuff. I didn't try any, just smelled it.)

Another brewing note: I got a notably higher extraction rate from a mash this weekend. I was thinking about life and mashing and stuff while I was in the recirculation phase (lauter tun->stovetop->lauter tun) when I decided that recirculation of some sparge water might be a good idea. I figured that the whole point was to extract as much soluble sugar as possible. Since a single pass through the grain bed is unlikely to fully exploit the solvent capabilities of the water, I figured I can give it a better chance by draining off some wort, adding some sparge water (maybe a gallon), then recirculating for a few minutes. I realized that I might be risking greater extraction of husk polyphenols, but I decided it was worth a try; besides, my sparge water was acidified to about pH 5.5. The result was an extract rate of about 31 for my mix of 7 lbs. 2-row, 1 lb. wheat, and 1 lb. mmedium crystal. We'll see how it turns out. . .

Finally: anybody who's thought of building a RIMS for mashing, but has been daunted by the complexity, I'd like to share ideas. Complete lack of understanding of thermodynamics, mechanical engineering, and fluid dynamics hasn't stopped me from planning various simplifications to the original plans (which came from Zymurgy? Somebody faxed them to me...) Anyhow, drop me a line if you want to share ideas.

Here here, I second that recommendation. These things are very convenient, and are available in a few varieties, which will probably increase as they catch on.

I toss one or two into hop boiling bags. They seem to break up nicely in hot wort, but I suggest you break them up if you're dry hopping with them.

Subject: feed store grains

Sorry to beat an almost dead horse, but I've been off the net for a while.

To Florian & Kinney:

Before I gave up all hope and became a computer weenie I was a pre-vet student at Michigan State. Other posters to the Digest have stated that you really don't have to worry about pesticides and the like in the grains you buy from feed stores. This is true as long as it is intended to feed animals that are to be used for human consumption. Lots of nasty things are allowed if the animals will never be served up.

What you do have to worry about is enzymes and hormones.

Both of these are often added to feed grain to increase/improve milk & meat production. Fortunately nothing in life (or feed stores) is free. Thus you have to pay extra for these wonderful chemical additives. Ask the people running the feed store if either of these are in what your buying. If they ain't there you should be OK.

Oh, another thing often added to food for ruminants (cows, horses, ect.) is nitrogen. It helps the bacteria that live in their stomachs (the bacteria are what actually digests the food). The nitrogen is often added in the form of urea (yes this means that they spray the grain with urine).

So buy your grain at feed stores and don't worry, just ask.

Subject: Returning to the digest

Hi there!

I've been out of touch for quite a while, due to an extended illness, and have just finished reading a s--tload of back homebrew digests. So, please pardon my commenting on a "dated" thread.

A number of people were asking about mead a while back; I wasn't able to retain the various questions. So: my "quick 'n' dirty, 3-week mead" recipe is available to those who would care to request it. Any other questions may also be addressed to me directly, rather than taking up bandwidth here.

Other than that, in dig 629 Douglas Allen Luce <dl2p+@andrew.cmu.edu> said:

>Last September, I decided to try making a small batch of mead. I used
>a recipe from the list calling for ginger, tea, and orange peel in
>addition to the honey. I ended up with a one gallon batch (heated for
>45 minutes with scum-scraping, no boiling) dubbed "Feinstein
>Troublemead."

>It has had pretty much the same taste since the fermentation (with Red
>Star Champagne yeast) ended. Very sweet, no real taste of alcohol,
>and a horrid composure of styrene!

>Yuk. I've never heard about this taste before; what could be causing
>it? The stuff came out of my stainless steel boiler into the glass
>fermenting vessel and glass conditioning jug, never making it's way
>through coffee cups or anything like that. I've only racked it once
>after the primary fermentation, and there's a few wisps of yeast left
>at the bottom; could this have anything to do with the taste? Is this
>something that might go away? It seems as strong as ever.

First of all, sorry you had any trouble with this recipe. But remember:
it
is meant to be a "quickie" recipe, with fermentation halted by
artificial
means (addition of grain alcohol or vodka).

Second, it is *meant* to produce a sweet (as opposed to a dry) mead, and
if I
remember correctly so states.

As to the off-flavor you're experiencing: presuming from the phrasing in
your
posting that you allowed fermentation to proceed until it ceased by
itself,
then you've probably got a mead that will need to age 2 years before it's
drinkable. One to two years are very typical mead aging times. Such is
the
case, for example, with the pyment I did last summer.

If that isn't the problem, then I would assume that the stainless steel
pot is

the culprit. I do *all* my brewing-type boiling *only* in enamel. As Papazian and others point out (if I remember correctly), metal can chemically interact with a boiling wort, with undesirable results.

Again, sorry you had trouble. Hope this helps.

Really glad to be back,

Cher

From: Pete Soper <soper@encore.com>
Subject: sterile filtration, AHA Nats

It is possible to sterilize air by filtration, just as beer is commonly sterilized by filtration in many commercial breweries.

I played with some Cole Parmer L-02915-34 50mm nylon filters (\$27.50 for ten, 800 323 4340, credit cards welcome). These have a 0.2 micron pore size which will block darn near everything that is likely to cause infection. They come in sterile packages, have hose barbs on both ends and pass air very freely when driven with something like an aquarium pump.

I was not interested in reducing lag time but instead wanted to "turbocharge" yeast starters involving small dabs of yeast from slants. I hoped that by forcing a prolonged aeration period I could keep the yeast in a respiration phase longer and get more buildup of cells. After what looked like good results (which I ranted about privately), I set up an experiment, running sterile air into starters with two original gravity values while also running two starters without more than the usual "shake it up" aeration at the start, with matching gravities. There was no significant difference in apparent speed of onset of turbidity, sedimentation rate or amount, clarification speed, etc. In other words it was a great deal of trouble for nothing.

This was just one data point and probably says nothing about potential use for shortening lag in a larger volume of wort; I just wasn't interested in this application.

I got my judging sheets back from the pale ale and dry stout I sent off to Boston for the Nats. These were two just-OK beers and the judging forms went a long way toward showing me all that was wrong with them. I take issue with a few comments (of course) but overall think the judging was *VASTLY* improved over last year and for these two beers was a great help to me for understanding some brewing mistakes. It was a real treat to open bottles of the beers in question and sip them, reading the forms and saying to myself "Yes, yes!, yes, maybe, yes, yes!", instead of "Say what? Which planet did these guys fly in from?" :-)

>employer, all for permitting the violation) but that doesn`t make it legal.

No. No. No. We've had this discussion throughout the various cooking newsgroups and Fidonet echos. Recipes ARE NOT COPYRIGHTABLE!!! A recipe is a formula or process, neither of which can be copyrighted. A formula can be patented ("Our patented fire-brewed process...") but is specifically excluded from copyright since it is merely an idea.

A cookbook can be copyrighted under a compilation copyright which protects the total collection of recipes as a book from being reproduced. But, you can take out a recipe, retype is exactly as is, and put it in your own cookbook with perfect legality. Now, reproducing the page exactly, with pictures and all, probably is not legal, but here in the digest the format must have been retyped and is never substantially the same as the original.

Do you think that Papazian or Miller or Line all have completely original recipes in their books? Really!

You should have no qualms whatsoever in typing in your favorite recipe into the digest.

Sorry I don't buy it. You're not going to get off flavors from Stainless
Steel.
Stainless is not going to chemically interact with the boiling wort.
Almost every commerical brewer in this country uses Stainless (except
those
that use Copper). I have Stainless Surgical Steel implanted in my body,
Stainless Steel is pretty resistant to chemical reactions, particularly
oxidations.

I will personally stake a large quantity of my Mead that the source of
these
poor persons (HBD 629 Douglas Allen Luce) off flavors is *NOT* Stainless
Steel.

And no, I don't have any money invested in the Steel industry.
I just don't want to let you start propagating misinformation, the
Aluminum/Stainless debate is bad enough.

They used to have beer in that area, in the Sumerian Empire days about four or so thousand years ago. Anchor recently put out a limited edition of a beer made to a Sumerian recipe, which I hear didn't keep well due to lack of hops. Since modern Iraq is an Islamic country, I doubt you'll find any alcoholic beverages sold there legally. (I assume you were kidding)

On a related subject, an archaeologist recently found the oldest wine yet discovered at a site in Iran, between ancient Sumeria and the Caucasian mountains. She found pottery fragments from 3500 BC, and intact bottles from 3000 BC, which still contained traces of wine. Her colleagues were skeptical at first--they didn't think man knew how to make wine until many centuries later, and were sure that her samples were just paint. Now they are all rushing back to test their own collections of pot shards :-)

This wine was definitely "mature" after aging for fifty centuries, but unfortunately it had dried out and was not drinkable. Does anyone know the record for the oldest wine that's still sloshing around in the bottle and theoretically drinkable? Last I heard, it was >2000 year old wine found in intact amphorae by Jaques Cousteau at the bottom of the Aegean. He actually took a swig from one of the bottles and said it was pretty good.

I didn't catch the archaeologist's name, but she says her next project is to discover the oldest beer.

Subject: Is pale ale pale

Yes I know I made a mistake. I described Long Trail pale ale as not being pale, but as being amber. Well I know that pale ale **is** usually amber. But the Long Trail ale had this orange/reddish glow sort of color; it struck me as a strange color. Maybe it only looked strange because of the lighting in the house, or in comparison to the other pale ales I was having, or because I just plain had too many pale ales.

When does a pale ale become a brown ale?

Russ

>3 Dollar Dewey's in Burlington, VT. Great place, about 15 different
^ Brattleboro? Or is there one in Burlington too?
>beers on tap, from local VT brews to Spaten Bock!).
yow!

Vermont brews on tap at Dewey's in Brattleboro are:
Long Trail from Bridgewater
Otter Creek from Middlebury
Catamount Golden, Amber, Porter from White River Junction
Dewey's own (or at least they *said* it would be ready by now)
from Brattleboro

The (cloudy pale) ale you describe sounds like Otter Creek.
As far as I know, there is one other brewery in Vt., the Burlington
pub and brewery, and one brewpub-in-the-making just around the corner
from Dewey's at the Latchis Hotel in Brattleboro.

As I haven't seen a reply posted yet, and happen to have the information
with
me:

The 1991 CAMRA (Campaign for Real Ale) Great British Beer Festival will
be
from 13th to 17th August at the London Arena in London's Docklands. This
is a MASSIVE venue and is convenient to reach from Central London.

Promised are over 300 cask ales, bottle conditioned beers, foreign beers
and
lagers, cider and perry, pub games, live entertainment and family room.
Opening times are Tuesday 5-10.30pm, Wed-Fri 11.30am-3pm, Sat 11am-10.
30pm.

Unlike the Great (sic) American Beer Festival, you pay for the beer, but
you
can drink it in larger than thimble-size quantities.

Unfortunately, I won't be able to make it there myself, owing to my
current
self-enforced exile.

Subject: styrene flavor in HB

Greetings.

Don't have all the editing capabilities of this system figured out yet, so forgive my paraphrasing rather than direct quotes.

In digest #641 Cheryl Feinstein commented on a posting from digest #629, in which Douglas Luce described making a small batch of mead with ginger, tea, orange peel and honey. The resulting brew tasted strongly of styrene.

Feinstein suggested that perhaps the use of a stainless steel brew kettle was to blame. (Again, forgive the lack of direct quotes.)

#641 was the first HBD I have received, and I hope that this thread hasn't been beaten into the ground, but I had a similar batch of beer last year. It was supposed to be a Christmas Ale, based on light malt extract (Munton and Fison) with some dark specialty malts to add character, and spiced with 1 pound of honey, fresh ginger, and orange peel. I used an enamel brew kettle, primary fermentation in glass, secondary fermentation in glass, and temperature control was good. However, the beer tasted *very* strongly of styrene. The flavor was sharp initially, and after some months was more subdued, but still made the batch undrinkable.

My techniques and ingredients were the same I've used in other batches, and produced at least drinkable brew, if not outstanding examples. After reading the ingredients for Douglas Luce's mead, and the similarity of the off-flavor (I mean it tastes like polystyrene smells) I wonder if using honey, ginger, or orange peel can produce this flavor.

Have other homebrewers encountered this particular phenomenon? I'm somewhat reluctant to attempt another "specialty beer" until I have some idea why the last one failed. If this topic has already been covered, could someone please e-mail me the consensus?

Thanks,

Subject: iraq

I was under the impression that Iraq wasn't an Islamic state, as Iran is. Of course, Moslems make up the majority, but there are approximately 800,000 Christians and even a few Jews. I remember reading in the paper during the Persian Gulf conflict about Iraqi beer. Something about it being stronger than American beer and our troops didn't like it all that much. Too bad we couldn't start IPA again, except substitute Iraq for India.

Uh, yeah, well it's probably a good thing I don't get over to Vermont very often. The town *was* Brattleboro (not Burlington). The cloudy (but not bad) beer *was* Otter Creek. And we've already covered the pale ale thing. But I did have a good time, I think.....

Some bad news: What used to be a good bar near where the AHA conference will be held is no longer as good. They had a reasonable good on-tap selection (Bass, Sam Adams ale, and other stuff), but they changed the bar around, made it smaller, and now only have American swill on tap. A real shame. It's called The Boston Trading Co. Still a lively place, but.....

From: tighe@inmet.inmet.com (Michael Tighe)
Subject: comments on "styrene" flavor

I am responding to the "styrene" mead flavor question that has been raised here by a number of people. I'm a mead brewer, and I've had my share of good and bad batches. Here's my \$0.02.

I usually make mead with honey, fresh ginger and orange peel (or lemon peel). My brew is highly praised and valued by my friends (they've actually contemplated torture to get me to make it more often :-). Some of my friends make honey-based beers as well, using similar spices. The "styrene flavor" is definitely NOT from the ingredients listed above, and I don't think its possible that the flavor comes from the cooking vessels.

Here's my classification of the "bad things" that have happened to me (and a few roommates who also brewed) and why I think they happened.

a) brew turned the color green during primary fermentation - I never even sniffed (much less tasted) this one, but two different brewers in the same house using different techniques had the same problem several times in a two-year period. We assumed the house or water was cursed. In truth, our yeast was probably contaminated, or the fermentation was run way too warm.

b) bitter final product with soapy aftertaste - After consulting various people, I figure this is the result of adding too much of the white part of the orange peel. That is, the "white meat" of the orange peel is very thick in some oranges and appears to be the source of this flavor. Some people find this taste very horrible (chalk on a steel chalkboard), whereas other people don't notice it. My guess is that this is the cause of the "styrene" flavor being referred to in other postings. My opinion is that the orange peel ingredient adds the oils which are in the orange skin, and that is where a lot of the aroma comes from. You can reduce the amount of white meat by using a knife to cut the skin off the orange in thin slices rather than peeling it off the orange.

c) formaldehyde flavor (or medicinal flavor) - This I usually associate with some off-yeast getting into the brew. Then I made a batch that had this really tart almost (but not quite) formaldehyde taste. I wasn't sure it was worth saving, but I let some trusted friends taste it. Their opinion was that it was GREAT - they like "dry" and I like "sweet", and this particular brew had high alcohol content and was very dry. This is the most subtle of the problems I've encountered. Apparently I am not the best judge of my own brew - I've taken to trusting the taste-buds of various different brewers when I have a questionable batch. One person's brew is another's waste-water.

d) bitter-sour flavor - This is caused by bacteria getting into the brew. I was clearly able to prove this to myself when I tasted another brewer's product (he was a professional brewer) which he used as part of a demo (brewery tour). His batch was definitely spoiled, although

you could still taste the separate elements of his experimental brew. He called it "bacteria" spoilage, and it was the same taste of some batches of mine that went bad.

I have never found any problems cooking my brew in either aluminum or stainless steel - I've only used enamel once, so I can't really comment on it, although I assume its just a cooking vessel so it has to work fine. Most of my friends and I do fermentation in one of three kinds of containers: stainless steel, glass or alcohol-grade plastic.

We did do an experiment once with a bottle of my brew - we held a taste-test where the only varient was the drinking vessel. We tried glass, pewter, aluminum, glazed clay, wood and horn. The best, universally, was glass. All the others added off-aromas or dulled the taste of the mead. Second best was glazed clay, so I now only drink from one of those two, and prefer to brew and drink in glass. The pewter added the most flavor, and it was a relatively bitter and astringent additive.

Good Luck, and may your yeast always have Zest!

Subject: Blueberry Mead Recipe, Styrene Flavors

Straightforward, simple, In my memory one of the best Meads I've made, and the first.

For 5 gallons

12 lbs Wildflower Honey (got mine at an apiary in Troy, NY)
2 tsp gypsum or water crystals
3 tsp yeast nutrient
1oz Hallertauer Leaf hops
1 tblsp Irish Moss
2 lbs blueberries
2 pkg Red Star Pastuer Champagne yeast

Boil hops, yest nutrient, water crystals for 30 - 45 minutes. Add Irish Moss in the last 15-30 minutes of the boil. Turn off the heat and add the honey and the blueberries, steep at 180-190F for 15 minutes minimum (30 is ok too).

Pour the whole mixture to a bucket or Carbouy (if you have a wort chiller then chill otherwise let it cool) add the yeast at the temperature recommended on the packet (85-90F I think). Let it ferment. Rack the mead off the fruit after 6-7 days (you can actually let it go longer if you like) I fermented for 4 more weeks in the secondary then bottled. Other people like to rack their meads at 3-4 week intervals and let it keep going in the carbouy. I don't think too much fermentation went on after the first 4 weeks (I made this in July so it fermented fast), so if you keepcracking you'll basically be doing some of the aging in the carbouy, otherwise it will age in the bottles.

This mead had a terrific rose color. It took over 8 months to really age, and was fantastic after 2 years. It had a nice blueberry nose to it, and quite a kick.

Enjoy.

Was the ginger peeled?? I have made orange-cinnamon mead, no off flavors. I have made ginger beers, again no styrene. I haven't mixed orange and ginger but have tasted fruit specialty beers that have. They tasted fine. If I had to make a guess I might guess that perhaps if you didn't peel the ginger that these flavors came from the peel. I have never heard of this

particular off flavor arising before. I'll try polling Steve Stroud, my local Organic chemistry consultant and coc-conspirator in Dr. Beer sessions. Perhaps these poor souls can give us a better description of how the ingredients were prepared, and the brewing process. This might help us some, otherwise maybe you'll want to consider sending a bottle for diagnosis.

I, too, have a batch of orange ginger mead going. Its almost two months old, and ready for bottling. I took a SG reading two days ago (1.000), and tasted it. It was kind of nauseating. I used 6 oz. ginger and 5 lbs of oranges (half of which was probably peel). My guess is that prepubescent orange ginger mead always tastes like styrene.

Let's both keep our fingers crossed and hope it improves with age.

Subject: Alcohol toxicity in common yeast strains

Yesterday I tasted the first bottle of my weizen batch, (extract, 2/3 wheat, 1/3 barley, OG 62, TG 20), and found it quite sweet. I was wondering if there was a problem in that since OG was relatively high, the high alcohol content killed off the yeast (WYeast 3056). I have to believe that certain strains are better than others at surviving certain levels of alcohol toxicity. Does anyone know of ball-park figures (in terms of OG or %alcohol), for various yeasts?

Subject: Shipping reg's; anecdote

Hi there!

Regarding the recent thread about shipping homebrew UPS, and the legalities of such (and especially to the gentleman with legislative connections, who wants to gather data): a couple of things occurred to me while thinking about the postings I'd read.

First, my own experiences in having to do legal research came to mind. I discovered long ago-- and *much* to my surprise-- that while much legislation is written in Legalese, much is also written in Plain English. Thus, it's worth one's while to go to a library and simply look up the requisite statutes. The worst that can happen is that the stuff's in Legalese after all.

The other thing is to politely write such government agencies as the BATF and request any literature they may have explaining their policies. Many government bodies are image-conscious, and have all sorts of pamphlets and things that they will cheerfully deluge you with. Often, these are helpful sources of information.

Totally aside from the above: recently, a Czechoslovakian blacksmith (an *extremely* talented and astute gentleman) visited my blacksmithing mentor, who is his pen-pal. Iaroslav brought with him a number of bottles of *GEN-YEW -WINE*, *homemade*, Moravian Slivovitz! Talk about quality hooch! After my second shot, the only thing I could say was "Cowabunga!"

It seems that, since Iaroslav was not a state-approved artist (under the now-defunct Communist regime), he needed to hold down a job to support his family. Thus, he and his brother-in-law work at the local power plant, which is water powered. The plant stands on an island in the middle of a river, and a good chunk of it is covered with plum trees. Iaroslav and his brother-in-law harvest approx. 1 metric *ton* of Moravian plums every year, with the slivovitz the end result. They keep a still on the island, and double-distill it, btw.

Another amusing side-effect for Iaroslav of not being a state-approved artist: after the Communist Party fell, a New York gallery solicited some of his work. Since Iaroslav wasn't listed as an artist, then it followed that what

he was shipping out wasn't necessarily art. So, he shipped his sculptures as "scrap iron" to avoid certain bureaucratic entanglements! Think about it...

Yours in Carbonation,

Cher

Well, this is nothing close to these ages, but when I went on
a tour of the Guinness Brewery in Dublin, they had a letter or told a
story from some arctic/antarctic explorers. It seems these guys had
discovered a cache of supplies from an earlier expedition. Among the
supplies they found were three bottles of Guinness (I believe the supplies
had belong to a British expedition). They brought one bottle back and I
think they gave that bottle to the brewery. As for the other two, they
"were put to good use". :-)

Subject: general questions on various & sundry yeast

All right, I realize fully that this question
a) will add to the general ongoing flame, and
b) has been asked and maybe even answered before (in parts), BUT
this hasn't seemed to stop anyone else on this digest, so here goes!

What, in general, are your impressions of the various yeast strains and varieties you have been using? The type of qualities I'm after are:

- 1) fruitiness in aroma and flavor
- 2) maltiness in aroma and flavor
- 3) other flavors/aromas, which may or may not be off flavors, like clove
- 4) temperature of usage, and how this affects flavor, attenuation, etc.
- 5) attenuation (how low is typical FG, and how does this vary w/ recipe?)
- 6) time until krausen, time of krausen
- 7) speed of fermentation (how long does it take to reach this FG?)
- 8) consistency
- 9) interactions among the above 8 items
- 10) anything else you feel to be of importance

I have the yeast issue of Zymurgy and I like it very much. However, I would like more information from you most educated digest types (stand back as I wipe my brown nose!!) as well as a larger sampling pool. Feel free to be as simplistic or as detailed as you'd like, but specifics are helpful.

Please, please, *PLEASE* send me responses directly and I will try to make a compendium of sorts and post it on the net (or distribute it individually, if this method seems to be more appropriate) in a couple of weeks, if there is sufficient response and sufficient interest. Of course, this could be biting off more than I can chew....

As Dr. John would say, "here's mud in your eye",

Subject: AAUs v. HBUs, revisited

I recently jumped into the discussion of the difference between AAUs (as presented by Dave Line in his "Big Book of Brewing") and HBUs (as given by Charlie Papazian). In that message, I indicated that CP's HBUs were different and less useful than AAUs and, as a part of the discussion, indicated that there was no real ripoff by CP of DL.

I wish to retract my previous statement.

I had opportunity to look back in the BBoB and discovered that AAUs are not volume neutral; they require an accompanying volume to be of any use. They are exactly the same as CP's HBUs.

In explanation of this goof (and as an attempt to extract my feet from my mouth), I will tell you that I don't use either, and that DL's explanation of AAUs involve working on a per gallon basis, before expanding them to the 5 gallon batch size.

I'm sorry if I led anyone astray,

Subject: Xmas ale

Here are two Xmas extract Recipes from "our" Recipe file, I have not tried either of these, but my next batch will be the first one (I have all the ingredients but I need time to make it). Hope you like them.

B^2

++++
+++

Subject: Xmas Beer Recipe

I just tried one of my ginger beers brewed following CP's recipe in TCJHB. Although only in the bottle a week, it was really tasty. It will make a nice spicy beer by Xmas. Here's the recipe,

3.3 lbs Northwestern light ME
2 lbs DME
2 lbs wildflower honey
2 oz Hertsburger (Spelling?) boiling
1/2 oz Goldings finishing
2 oz fresh grated ginger boiling
1 oz fresh grated ginger finishing
2 paks M + F ale yeast started

Start yeast in about 90F watered down wort. Boil malt extract, honey, hops, and ginger about 1 hr. Strain, then add finishing hops and ginger. Cool rapidly in tub, pitch yeast already started. SG=49, FG=14 after 2 weeks. Prime and bottle. This is a quite light beer with a nice ginger aroma and flavor.

++++
+++

Subject: Fleming's Christmas Ale Recipe

Ingredients for 5 gallons

3 1/2 pounds Munton and Fison Stout Kit
3 1/2 pounds Munton and Fison amber dry malt extract
3pounds Munton and Fison amber dry malt extract] ?? Typo ??
1/2 ounce Hallertauer hops (60 minutes)
1/2 ounce Hallertauer hops (5 minutes)
3/4 pound honey
53-inch cinnamon sticks
2teaspoons allspice
1teaspoon cloves
6ounces ginger root
6rinds from medium size oranges
Wyeast No. 1007 German ale liquid yeast
7ounces corn sugar for priming

*O.G.: 1.069
*T.G.: 1.030
*Primary fermentation: 14 days @ 61 degrees F.
*Age when judged: six months

BREWER'S SPECIFICS

Simmer spices and honey (45 minutes). Boil malt and hops (50 minutes).
Add finishing hops and boil (5 minutes). Cool, strain and pitch yeast.

MY COMMENTS:

The second call for 3 pounds of M & F amber dry malt extract is probably
a
typo in the magazine. 7 pounds of extract and 3/4 pound of honey would
give you an O.G. of around 1.069. 10 pounds of extract would give you an
O.G. much higher than that.

Hello,
in HBD abirenbo asks about making hard cider. I haven't done it, but a
friend
of mine buys that unpasteurized cider in the soft plastic bottles, drops
a
pinch or two of champagne yeast in it, lets it sit a few days (covered
with
towels in case it explodes), and then puts it in the fridge. Nice
sparkling
cider. We also had some cider "turn" on us. Just don't drink it all, let
it sit
a few weeks, and you'll probably get hard cider. No guarantees of quality

Subject: Culturing Yeast from Wheat Beers
Full-Name:

OK, I keep hearing that you can't get any of the choice S. Delbruckii
(sp?)
by culturing the dregs of wheat beers.

So, can anyone out there provide a counter-example?

Anyone know how Grant's handles their wheat beer and filtering of the
yeast?

Thanks in advance.

>bar around, made it smaller, and now only have American swill on tap.
>A real shame. It's called The Boston Trading Co. Still a lively place,
>but.....

I know the owner of the BTC. I have spoken with him on the topic of the AHA conference and he assures me that there will be a good selection of beer on hand during conference week. The problem he has had in the past in keeping "good" beers stocked is that his distributor charges him "import" scales for such locally brewed beers as Sam Adams, Harpoon, Catamount, Frank Jones, etc.

The distributors apparently have two different pricing structures; one for domestic, and one for imports. The only beers on the "domestic" structures are the products of the Big Three (Coors, A-B, and Miller)

He doesn't like getting ripped off, and practically the only people who drink "Good Stuff" (He DOES keep some Harpoon around and occasionally some Sam Adams, but you have to ASK for it) are myself and the rest of the Monday night dart crowd.

As for the bar changing around... It only appears to be smaller. They pulled it away from the wall and arranged it in a square in the middle of the room. The bar still has the same frontage, it just uses the floor space more efficiently now. This has allowed them to put in more tables. They also recently (2 weeks ago) opened up an outdoor patio area. Also, this week they FINALLY got a new pinball table in.

BTW, you can find me at the BTC on Monday nights throwing darts (or playing the silver ball between rounds of darts.) John, the owner, sometimes joins in. Once in a while he'll play us for a round of beers on the house, and he's not a very good dart player. But, he is a good sport.

From: zentner@ecn.purdue.edu (Michael Zentner)
Subject: Bock Recipe

Due to the stated lack of dark lager recipes in the excellent brew recipe compilation, I'm going to contribute a bock recipe that turned out very good.

BEAT ME OVER THE HEAD WITH A STICK BOCK

Ingredients:

- 6.6 lb John Bull light malt extract
- 3 lb Klages malt
- 1/2 lb chocolate malt
- 2.75 oz of 4.7% AAU willamette flowers (60 minute boil)
- 0.5 oz " " " " " " " " " " " " " " " " " " (2 minute steep)
- pick your favourite lager yeast (I used something from MeV)
- 10 g Burton Salts (for the partial mash (I've got soft water))

Method: partial mash---NOTE for those of you who generally skip a recipe without reading it when you find the word "mash" anywhere in the text...read on. The title of this brew comes from a friend of mine who would never try something, and when he did, his only thought was, "Why didn't you guys beat me over the head with a stick when I was so afraid of this...this is great!" I used to skip those recipes too, but it's real easy to do, and the taste is worth it.

OG: 1.072 FG: 1.021 (7%)

Procedure: I ended up with a lot of volume for the amount of grain used, but that's OK if you're just doing partial mashes.

- Bring 3 qt + 2 cups of water to 130 F.
- Add cracked Klages and chocolate malts (temp = 122F)
- Rest 30 min
- Add 7 cups of 200F water to bring temp up to 150F
- Rest 30 min.
- bring up to 158F with burner
- rest 20 minutes
- mash out at 170F

Sparge with 7 quarts of 170F water, recycling the first runoff. I did this step very slowly since the filter bed was quite shallow in my full size lauter tun and I didn't want to add sparge water too violently and disturb the whole bed.

Add malt extract and boil as normal.

Chill the wort and pitch. Aerate vigorously with a hollow plastic tube...there's no need to get fancy equipment here. With the hollow tube I can whip up a 3" head of froth on the chilled wort. Bubbling activity is almost always evident within 8-10 hours of pitching a 12-18 oz starter solution.

Ferment as you would a lager, or do it in a semi-cool room (my only option at the time). You can make a lager outside of a refrigerator, but it won't taste quite the same.

Comments:

Don't worry...give partial mashing a try. Before doing it, my biggest worry was how to keep the temperature constant. During each phase of the mash, I only had to add heat once to keep it within a degree or so.

Variation - Add ale yeast instead and call it a porter.

Finally, don't worry about extraction rates, points, etc... The point is, you can make a beer distinctly different from anything possible with straight extracts by using a mash. Hook yourself on the idea first, worry about details after you're convinced it's not as hard as it sounds.

From: Bruce W. Hoylman x5806 <bruce@patton.uswest.com>
Subject: ?? Brew head retention techniques ??

I'm a basic "green" extract brewer type of guy, to give you folks a frame of reference. My question is:

What methods/ingredients/drewid chants are useful if I want to create a brew that has a good head of foam when poured (cold or warm) ... definitely one that is thick and creamy (or otherwise)? I'm looking for some input as to ways to toy with the head retention properties of brew, so if you could phrase your responses in the terms of "This method does this to brew head" and "This ingredient produces this type of brew head" and "This chant on this day with this animal draped about your shoulders produces this type of brew foam ..." these would be ideal.

I ask this because my last batch, although the flavor was tremendous (ask me ... I'll tell you ...) after two weeks in the bottle, it had sort of a sparkling nature to it. Any head which formed while pouring quickly dissipated, sort of like a soda does when you pour it. I'll admit, the head has slightly improved since then (age has an effect?) but I'd like to be able to control this quality of a beer myself or at least have an idea as to what causes/effects it while brewing.

My local brew supply dude suggested a ration of crystal malt be steeped into my next batch (which is to be a John Bull stout derivation). I'm looking forward to trying this additive. Do yeast varieties have any effect on brew head? How about fermentation times or bottling techniques? Anyway ...

Thanks. Either post to the digest or email and I can post a summary.

Subject: Recipe book troubles

Hello all,

(Dr. John, You were right!)

1) Barm, n, a peculiar kind of dance.

2) Barm, n, yeast; froth; nonsense; foolish talk;

-v. used of the mind: to work; to fret; to mix wort with barley to cause fermentation; used for money; to grow with interest. (side-note: the term "barming" is used for interest accrual)

Barmy, adj. volatile; flighty; passionate; irascible

(sound like anyone you know? You can also be barmy-faced! Too much bock, I

guess, see below :-)

The terms are as defined in "Scots Dictionary" circa 1911. (**wonderful*

book, that.)

btw, the same Dictionary defines Bock: v. to retch; to vomit. (Which I don't

think is the meaning the Germans had for it!)

disclaimer (there is that word again) No, I have nothing against German

beer... I even drink Maibock on occasion. I grew up in Germany (army-brat)

and IT is responsible for my inability to palate most domestic beers, thank goodness.

- - - - -

While on that subject (bock, not disclaimers) The term Bock is used for some

male stock animals eg, goats, sheep and deer... "Buck, derives from the old

english Bucca, german has a similar root. Which has little to do with the beer of that name, but 'tis interesting.

Anyway, (ah-ha, a point!) anyone have a mash recipe for a McEwan taste-a-like?

Send direct or general delivery if you think it apropos.

Russ Gelinias in #631 writes:

From: Pete Soper <soper@encore.com>
Subject: AAU

>From: darryl@ism.isc.com (Darryl Richman)

>I had opportunity to look back in the BBoB and discovered that AAUs
>are not volume neutral; they require an accompanying volume to be of
>any use. They are exactly the same as CP's HBUs.

Sure the AAU must be used with volume to be of any use. However the AAU
itself
is volume neutral. An AAU is 1/100 ounce of alpha acid, period. No
volume in the definition at all. This is clearly spelled out in Line's
definition of the AAU on page 82 of BBoB. ("One Alpha Acid Unit is
represented
by 1 percent of acid in 1 ounce of hops.") I agree that volume must play
a
part in any practical application but disagree that AAUs are exactly the
same
as HBUs.

But to paraphrase Byron Burch (in his newsletter a couple years ago),
it's
time to move to on IBUs. For my money AAUs are just a step better than
"Add three ounces of hops" and HBUs not much different (so I'm agreeing
with
you in principle).

But just what is an IBU and how can Digest readers make use of this unit?

For the past couple years I've been refining a spreadsheet I wrote to run
with a
customized version of the public domain Unix spreadsheet program named
"sc".
Among other things I use this to calculate hop bitterness since it
incorporates
isomerization data from Burch's wonderful little book and a bit of
refinement
involving what others have reported about utilization as well as
adjustments
for the gravity of the boiled wort. This has given me a great deal of
predictability as far as basic bitterness goes.

You've been doing similar things, haven't you Darryl? Perhaps you could
give
us a taste of what you will be talking about next month at the
conference.

From: prcrs!link@uunet.UU.NET (John S. Link)
Subject: Final Gravity Calculation

How does one figure what the final gravity should be when your are not following a recipe which provides this info?

This is my third batch. I've kept away from brewing for over a year due to non-impressive results from the first two. I've been reading the HBD to learn more.

Here is the highlights of what I've done:

5/18 - Made yeast starter. Boiled 2 cups M&F Pale DME in 2 quarts of charcoal filtered water with 8 cascades hop pellets. Added water as needed during boil. Added 1/3 pack of yeast nutrient/heading salts after boil. Quick Cooled, added 14 gr Whitbred Ale yeast and placed in gallon jug with air-lock.

5/20 - 3 1/2 gallon boil with charcoal filtered water and

- 2 tsp Water Salts (gypsum)
- 2 tsp water crystals (calcium and magnesium sulfates)
- 1 tsp Irish Moss
- 3 lbs John Bull Amber liquid malt extract - hopped
- 3 lbs M&F Amber DME
- 1 cup M&F Pale DME
- 1/2 oz Clusters pellets at start and 1/2 oz again 30 min.
- 1/4 oz cascade pellets at end.
- last bit of yeast nutrient/heading salts.

- Quick cooled to 78 degrees in 35 min.

- Original gravity was 1.046 adjusted to 1.048 for temp.

5/22 - Siphoned off primary into secondary. I hope the bubbles which were forming inside the tube were CO2 and not O2 so oxidation is not a problem. There were enough bubbles to stop the siphon 4 times. I'm sure I kept the primary end of the tube below the surface. I also kept the secondary below the surface to minimize oxidation. The gravity reading at this time at 76 degrees was 1.022 adjusted to 1.024. It has a slight cidery taste with a lingering bite (hops?).

What is a reasonable final gravity for this and how do you figure it out? Please feel free to critique, I need it.

Thanks,

John S. Link

Subject: Supply info for a new brewer

Hi All!

I just started getting this news group, and hopefully you guys can answer a few questions for a rookie brewer. I'm in Dayton, OH and I'd like to start up a homebrew operation. Does anyone know of a supplier of brewing equipment as well as ingredients in SouthWest Ohio (Dayton-Cincinnati-Columbus)? I'd also like any information you have of mail-order type places for supplies. There are sure to be more questions as I get started, but a friend of mine has convinced me that homebrewing is a very rewarding hobby. Thanks!

From: semantic!bob@uunet.UU.NET
Subject: Prelude to Release 1.0

Well, I've finally got it together...

Release 1.0 of "Points of Interest for The Beer Enthusiast (Eastern Massachusetts)" is completed!

This is a list of Brewpubs, Breweries, Beer Bars, HomeBrew Suppliers and Beer Stores in the Boston Area/Eastern Massachusetts.

There are only two Brewpubs and two Breweries so these sections were easy to put together.

The Beer Bar list I limited to only bars with a decent selection of interesting beer. I purposely left out many bars with "a nice atmosphere and a good pint of Guinness". This was to keep the list short and concise for the visiting tourist. Those establishments marked with a (*) are favored by most local beer lovers.

The section on HomeBrew Suppliers is a complete list of shops in the 508 and 617 area code, to the best of my knowledge. Every brewer has their own favorites and I will make no distinctions as to which stores are preferred.

The Beer Store list is what slowed me down. Obviously there are many stores that sell a moderate selection of beer. The list that is presented was taken from the suggestions of local area homebrewers. I have first hand knowledge of only a few of them so I did not make distinctions as to which might be the best to visit. Any of them will surely lend to an armful of interesting malt beverages. The list is surely not complete and is primarily centered around Boston.

To enable me to get the first release out as soon as possible I limited the contents to basic phone book information and hours of operation.

Ideas for Release 2.0 can be found at the end of page 4. Any comments on contents or layout for future releases would be appreciated as well as input on your favorite Beer Bars and Beer Stores.

I would like to release a revised version of 1.0 before the AHA conference, so your timely input would be most appreciated.

Enjoy....

From: "Dr. John" <JELJ@CORNELLA.cit.cornell.edu>
Subject: Digest No. 644

Greetings,

A few comments regarding the contents of today's digest (#644) seem in order.

John DeCarlo asks about culturing yeast from bottled weizens

I can't provide any counter-example, all that I've heard and read indicates that, at least the German Hefe-Weizens, are filtered and then pitched with a bottom fermenting yeast prior to bottling. As to Grant's weiss (sic) beer I think that they do indeed filter it prior to bottling, if there is a sediment in it I think it may be something other than yeast (I may be wrong here but I don't think Grant's does any bottle-conditioned beers).

Bruce Hoylman weighed in with an interesting question regarding various factors which may affect head formation/retention.

As to the druidic chants, we can only hope that Martin (if it's good enough for Druids . . .) Lohdahl can provide some help. As to the more mundane approaches, crystal malt is reputed to help out head retention, but will definitely sweeten, and add a caramel note to, your brews if used in any appreciable quantity; this is definitely not appropriate for some of the drier styles. If you are willing to do a partial mash you could use a couple pounds of malted barley augmented with a half-pound of either cara-pils or malted wheat (either of which should help out in the head department).

Are you using sugar in your brews? Too much sugar is detrimental to head formation and retention, all-malt beers generally produce a good and reasonably long-lasting head.

I'm sure that the temperature of the beer at pouring has an effect, as more CO2 is held in solution at colder temperatures; but I'll leave the full explanation of this phenomenon to the more erudite correspondents.

You might consider priming with wort rather than sugar when bottling, in my experience this makes for a creamier head (composed of tiny bubbles which seem to last longer).

For your stout you might consider using some flaked barley (1/2 pound or so) in a partial mash. The proteins in it add to the heading qualities and any haze they might create would be unnoticeable in a stout.

Well I've rambled enough, and I'm sure that any misinformation I've imparted will be corrected by others.

Frank Jones asked about a mash recipe for a McEwan clone,

If you get one I'd sure appreciate a copy, presuming you are talking about the dark, faintly smoky, delicious stuff we get in the bottle here in the U.S.

Pete Soper asks "what is an IBU"

As of May 7 it is the "Ithaca Brewers Union" as we changed our club's name, but I presume you are referring to International Bittering Units, and you will find articles on the subject in the Zymurgy special issue on hops. In particular, there is an article in this issue by Jackie Rager which gives several IBU-related formulae. If you consult this source beware, a close examination of the examples is required in order to make some transformations to the general formulae so that they give the desired results. It isn't always clear just what units (and how they are measured or transformed) are required when you read the conceptual presentations of the formulae. Sorry to keep ragging on Zymurgy, but it seems that they need to pay a bit more attention to technical detail when they have equations and formulae in their articles. Thankfully, there are usually examples in these technical articles which give enough computational details to allow the interested reader to make the necessary corrections to the notation necessary to arrive at the desired results. But it would be nice to be able to use the stuff as it is presented and get the right sorts of answers the first time.

Cheers,

Dr. John

In digest 644, <C08926RC@WUVM.D.Wustl.Edu> (Rob) asks

>> Well, my in-laws have gone to Europe, but they couldn't find the beers
>> I requested, so they're bringing me some Jaegermeister. I've heard
>> various rumors regarding the ingredients of this; could someone shed
>> some light on the subject?

Jaegermeister is a sweet herb liqueur. The exact ingredients are probably secret, unless you can find some on the bottle. The main ingredient is definitely sugar, followed by many, many secret herbs and spices.

I have seen it sold in this country, too, in several places. It is quite good in small doses, if you like liqueurs, but don't ever get drunk on it. I got the most vicious hangover from it that I have ever had. Twice, actually; I should have known better after the first time.

There is absolutely no relation between beer and Jaegermeister, other than that they both contain alcohol.

"Jaegermeister" means "master of the hunters". The bottle has a deer with big antlers on the front.

Subject: Another looking for brewpubs

Howdy folks,

After seeing the posts for just about every city in the US, I haven't noticed one for the Washington D.C./Baltimore MD area. Do any brewpubs exist in this corridor? While we're at it, how about Philadelphia, PA?

There are a few places where you can get decent brews; the Brickskeller in Washington has a good selection, but it's been yeeeeeears since I've been there. The Olney Ale House in Olney, MD has a variable but good selection of beers, and Guinness, Oxford, and Genessee 12-Hourse (for hot summer days) on tap. Also, Oliver's Saloon in Laurel MD has an Oliver's Lager on tap which is pretty good (brewed somewhere in NY state). Any other suggestions?

Subject: Head Retention Methods

I know of three ingredient factors that will improve head and head retention:
All malt brewing (and that means no corn sugar, even for priming)-Leads to

to tiny little bubbles (in my beer...makes me happy...makes me full of cheer...), which will make a creamier head.

Crystal malt-I believe the residual, unfermentable sugars from crystal make the

beer more sticky or viscous or something, but tends to develop fairly slowly. Mine take about 1 month to fully develop.

Hops-Some component in the hop oil gives the beer head retention. Some kind

of detergent, coming from oil I would guess some kind of phospholipid.

All these attempts will be futile if your apparatus from brew pot to bottles

is not very clean. Any oils will kill the detergent action of the hops (try drinking a big head beer with greasy potato chip lips), and other forms of

detergents (like Cascade or Ivory liquid) will counteract the hop action. I have good success with these simple techniques.

Subject: mold, head

Someone mentioned haveing to throw out a batch because it got some mold on it before he pitched. You don't necessarily have to toss it. What have you got to lose by fermenting it? I had a batch that had some mold on it once. I skimmed it off, and went ahead with it. The beer tasted good, and forgetting about the mold, I entered it in a tasting. It won!!!!!! It was only when I went back to my book to supply info on the beer to the tasting participants, that I found the reference to the mold. I forget whether I told them about it, but I think i did;-)

Finding good head, and making it last a long time. -> Think about baseball;-0
Seriously, adding a bit of malted wheat, wheat flakes, or shredded wheat can improve head formation, and retention. The wheat has more of the head forming protiens that barley has.
Most heading liquids, or powders are basically edible soap? :-P
IF you try some, use it in moderation. I once tried some heading powder, at about 1/8th of the recommended dosage, and the effect was pretty dramatic.

>

I've had real problems with head retention as well. Here are a few
pointers

I have found out in my search for improving head retention. I'll leave
out the stuff about protein rests and mashing in wheat since you are
an extract brewer.

1. Use only FRESH leaf or compressed hop plugs. These types of hops
apparently help promote head retention. If you can't get good
hops locally, then I suggest mail order (Freshhops is good for
the limited supply they carry). Also high alpha acid hops are
supposed to be best for head retentive qualities (more hop resins).
2. Ferment at a low temperature. This sounds a bit iffy to me, but
Terry Foster mentions this in his book "Pale Ale" and looking back
at my brews I do note a reasonable probability for correlation.
3. If you are adding specialty grains, make sure they are taken out
before the boil starts. This is because you may leech out tannins
that will cause the medium weight proteins and albumins to
precipitate out. This can cause lack of head retention.

That's all I can think of right now (actually I'm surprised I can think
at
all after the day I've had). Anyway, I hope this helps. I should point
out
that I'm still searching for the perfect head, so perhaps the above is
not really worth looking at. Then again, I guess it can't hurt.

May 26, 1991

Greetings.

I am new to the digest, and this is my first letter. Please forgive what the

ASCII transfer to E-mail does to its format.

I have brewed a Guinnessesque brew that turned out so well that I must share

it. I call it Mach Guinness and it has soured ale in it, so I will give you

both recipes.

Mach Guinness

5 lbs pale 2 row British malt
1 lb rolled barley
1 lb roasted barley

2 lbs lighth dry malt extract
2 cups corn sugar
2 Oz bullion Hops (1.5 boiling, 0.5 finishing) (preferably whole)
1 pkg Whitbread Ale Yeast
2/3 cup corn sugar

Mashed 5 lbs 2-row, rolled barley and roasted barley

Mashed in at 132 deg F.

Protein rest 30 min

Starch Conversion 2 hours at 153 degrees

Mashed out 15 minutes at 168

Sparged with 4 gallons 172 deg water

Add the 2 lbs dry ME and the 2 cups sugar. Bring to a boil. Add 1 1/2 oz of

hops. Boil 1 hour. Add 1/2 oz of hops, turn off heat, and let stand for 15

minutes. Cool wort to 72 degrees, strain into fermenter, and pitch yeast.

(note: I personally cool the wort in the boiler and then pour it through a

strainer to oxigenate it and remove the hops, as apposed to straining it hot, which oxidizes it)

S.G - 1.066

T.G - 1.016

Ferment 7 days. Rack and settle 6 to 9 days.

one to two days before bottling, sour two bottles of ale. To do this, pour

two bottles of ale into a steril glass container. Cover with a clean cloth

secured with string or rubber band. Put in the cupboard (or somewhere relatively dark and warm) and let stand one to two days. It should sour, but

not mold.

At bottling time, put 2/3 cup corn sugar in the sour ale, and boil for 10 to

15 min. Add this to the bottling container, and siphon wort into it. This

gives a good mixture without having to risk stirring it. Bottle and try in

two weeks. The flavour changes week by week and levels off after 6 weeks.

This stout is creamy, but not as heavy as some, with a head that takes almost 30 seconds to form, lightly bitter, with that back of the throat

sourness from the soured ale.

Now, the beer I soured is a unique ale, and you dont have to use it, but it

is also very good, and I know it worked:

Ides of March Ale:

1 cup brewed Kenya AA coffee
.25 lb Black Pattice malt
.25 lb chocolate malt
.25 lb 40 deg crystal malt
1 lb rice syrup
1.5 lb light dry malt extract
1.5 oz Willemette whole hops
1 can Coopers Ale Kit
1/2 cup corn sugar - bottling
?? finings (follow directions)

In three gallons of brewing water, put Black Pattice and Chocolate malt. Bring to a boil. After boil just starts, strain out grains. Add coffee, crystal malt, rice syrup, dry ME and 1.5 oz willemette hops. Boil 45 min.

Add Cooper Ale Kit, and continue to boil 3 to 5 min. (much longer and the finishing hops in the Coopers kit make the brew bitter)

Cool and pitch with Ale yeast from the Cooper Kit.

S.G. 1.046

T.G. 1.012

Ferment 7 days. Rack and add finings (or polychlar). When settled,

bottle with corn sugar.

Hope someone trys these and has as much luck as I had. Later - kls

Subject: malty ale recipes?

Hi folks,

I was wondering if any of you had successfully brewed any beers that resemble malty British pale ales such as Fuller's ESB and all those various, wonderful Scotch ales, and what were your recipes? Since someone recently had requested a McEwan's recipe, I thought I'd chime in.

It seems to me that such a maltiness in aroma and flavor could be achieved using German malts such as Munich, but as this is probably not the actual ingredient in Fuller's (since the British use British malts and the Germans use German malts), I'd like to know how to achieve that maltiness using British ingredients. For all I know, this "maltiness" could be accomplished by some combination of sugars like demarara or treacle, which I have never used myself due to their lack of availability in my area.

Of course, part of the freedom in homebrewing is making German beers using British ingredients and vice versa, so *any* recipes you have would be most gladly accepted.

Thanks,

STEVE

From: IOCONNOR@SUNRISE.ACS.SYR.EDU
Subject: Getting "Bombed" on Homebrew

OK, so you thought by my header, that I meant drunk when I said "bombed." Well I got you to read this.

This weekend i got bombed by my own beer bottles. Luckily I wasn't there when it happened, but it could've been pretty bad. One bottle exploded in the case containers I keep my bottled brew in. So I cleaned all the bottles and set them on the counter to dry. When I returned, two more exploded and put glass everywhere. I'm really glad I wasn't home!

A couple of weeks ago I asked about ending SG's of 1026 for an extract ale. I used M&F premium to make this brew, and I added only crystal and spray malt to it. My friend said that it tried to ferment more in the bottle, and this caused them to explode. I waited almost two weeks to bottle, so it should have stopped fermenting. What gives?

Any help would be appreciated.

If anyone wants this recipe to take revenge on someone, email me.

Kieran

Subject: Hops Question

My question pertains to hop growing. I planted two rhizomes in mid March. One was a Hallertau the other a Willamette. The Hallertau now has reached eleven feet, while the Willamette is six inches tall. I know that the Willamette is supposedly a slow grower but should it be that slow compared to the Hallertau? Both of them get direct sun and lots of water. For anybody in the San Jose area, is eleven feet good for first year growth of Hallertau?

From: (Mark Stevens) <stevens@stsci.edu>
Subject: D.C. area brewpubs

In Homebrew Digest #645, David Arnold (davida@syrinx.umd.edu) asked why he hasn't heard anything about brewpubs in the D.C. area.

The most likely reason is that there aren't any. About 2 years ago, plans were afoot to build a brewpub--tentatively called "Atlantic Brewing Co." in Alexandria. Brewpubs are legal in Virginia, and a use & occupancy permit was issued to the would-be brewers. I don't think they ever got further than that though, because there certainly isn't a brewpub in Alexandria today.

Would-be brewers are now trying to open a brewpub in D.C. on New York Avenue at the site of the old Greyhound depot (next to the convention center). John Ray of the D.C. City Council sponsored a bill to legalize brewpubs in the District, but I don't know if this was made into law or not, nor do I know how far along this brewpub is.

There are, however, two excellent brewpubs in Baltimore, if you're willing to make the 45 minute drive up the parkway. Sisson's, at 36 East Cross Street in the Federal Hill area, offers Cajun food and some very good ales (as well as a couple thin ones). Sissons seems to do best with its seasonal specialty beers. I was up there 2 weeks ago and had an excellent I.P.A.---very hoppy and sharp.

A few blocks away is the Baltimore Brewing Company (Albemarle and Pratt Streets). This is a cavernous brick place with huge copper kettles adorning the back bar. They serve up lagers here, with the most distinctive

being their pils, which is very hoppy and pleasant. I wasn't crazy about their light lager, but their dark lager was suitably dense and malty.

If you're just looking for pubs with a good variety of microbrews, try the Last Chance Saloon in Columbia (e-mail me for directions), which serves up dozens of different kinds of beer (last time we were in, they had 17 taps going, including Anchor Foghorn, Wild Goose, and Schlosser Alt...all at about \$2/pint. Monday is a good night because it's half price hamburger night.

Another good place is Heroes in Manassas. It's been a couple months since I've been out there, but last time was worth the trip. We loved their house beer, which is brewed by the Old Dominion Brewing Co. in Chantilly.

Happy Drinking.

Sacrifice is the answer. Animal sacrifice can cause trouble with the SPCA, and human sacrifice has been overdone lately, so I recommend the practice of sacrificing a bottle of a previous batch of homebrew early in the boil, and another after the cleanup is done, by straining the beer through the kidneys ... ;-)

> use? I've got a Gott picnic cooler mash/lautertun ...

No, I don't think I'd try a stovetop step-mash in a plastic cooler, either 8-). Using a single temperature does limit you to grains that have been pretty completely modified, such as English pale ale malt, as the basis of the beer. If the recipe calls for lots of adjuncts, the pale malt may not be rich enough in enzymes to convert the mash fully, so some recipes will simply be beyond the scope of your equipment. For those within the realm of the possible, however, conversion is a matter of comparing the mash extract in the recipe with what you usually obtain with your own methods and materials, and adjusting accordingly.

> ... I'm also wondering if it is feasible to do a
> step mash using this by simply adding different temp water or if
> it is necessary to have a heat source.

Possible, but complex. You could start out with a very stiff mash, and add enough boiling water at each step to reach the temperature you want. Obviously, this will change the thickness of the mash, which has all sorts of effects on the conversion. Equally obviously, if you overshoot the temperature you'll have to add yet more (cold) water, and if you overshoot again ... Some brewers use this method as a matter of course, with good results. Another option is to go to a decoction mash, where a portion of the mash is abstracted and boiled, then returned to the main mash to raise the temperature. This also has its partisans; I haven't tried it yet. A very good description of it can be found in Greg Noonan's "Brewing Lager Beer", which deserves a spot on every brewer's bookshelf, IMHO.

Subject: Oatmeal stout

Well I made an oatmeal stout this weekend, complete with a partial mash (my first mash). , an infusion. I used 3 lbs of English 2-row pale malt, 1 lb. of steel cut oats, mashed in 5 qts. of water, sparged with 2.25 gallons of water through Zapap lauter tun. The sparge took 20 minutes, which seems fast. I expected ~10 minutes/gallon.

Would the deeper grain bed of a full mash slow things down? The runnings were never clear. I did recirculate the first runnings. The OG of the sparge was 1.026 in 3.5 gallons. Somebody want to figure out my efficiency?

The grain bed was not at all sweet after the sparge, which I took to be "a good thing".

I added 3.3lb of dark extract and 3 lbs. of dark DME to the wort and boiled with 2 oz. of Centennial leaf hops (AU=11.1, total=22.2 WHOOPS!) Good thing I like hops. Finished with 1 oz. of Cascade leaf hops. (AU=5)

Pitched Wyeast Irish Ale yeast starter (#1084?), took 24 hrs. for active ferment. The Wyeast packet was dated Feb 1991, (I got it cheap). The pouch

was started on Thursday, by Saturday it was nearly fully puffed. I made a started on Saturday night with it, by Sunday night it was at high krausen, and by Monday night it was happily eating oatmeal.

So, other than overhopping, it all went well, and the mash was alot easier and enjoyable than I expected. But now I need a bigger brewpot; I was right up to the edge on this one.

Subject: Durango Brewpubs (an answer not a question)

I made a quick trip to Durango Colorado this weekend to race in the Ironhorse Classic bike race from Durango to Silverton. I wasn't thinking of microbrew when planning the trip, but being ever vigilant I was able to seize upon the opportunity to sample some of the local beverages.

I drove up from Albuquerque with a friend Friday afternoon and headed straight for Pronto's Pizza and Pasta for the usual biker's carb-load dinner. They have a fine buffet there. Naturally the place was packed with cyclists and there was a 20 min wait. I asked if we could be seated at the bar and we were ushered right in. I looked at the taps and saw Durango Lager nestled between Bud and Miller. Naturally I ordered a Durango. I expected some light innocuous lager and was pleasantly surprised with a rich dark brew. I can't do the beer justice in words. I'll just say that it was a satisfying, hearty dark lager with plenty of body and flavor. It was clear and had a good lingering head. I had a second mug even though I was racing in the morning. Cost was \$2.50 per mug (10 or 12 oz.).

I asked the bartender if the beer was brewed in town or if it was a contract brew. She told me it was local and that there was also a brewpub in town. I immediately knew where I'd be having lunch the next day after the race.

The next afternoon we found the Carver Brewing Company. It's a very small, plain restaurant with accompanying bakery and brewpub. The pub didn't open until four so we ate in the restaurant. Of course they featured their fresh breads with soups and sandwiches. I had a turkey Reuben that was very good except for the out-of-season tomato. The beers offered were a honey lager, a pale ale and a stout. I was very interested in trying the stout, but after racing needed something somewhat more refreshing. I ordered the pale. It was served in a nice pint pub glass (I just last week bought some for myself) for \$2.50. Although the waitress had described the ale as bitter, I found it underhopped for my tastes. It was also quite cloudy. In short, it was an adequate beer, but nothing any of my brewing friends couldn't easily match or exceed. I was unable to try any of their other brews as I had a 225 mile drive ahead of me.

Before leaving, I wandered back into the pub to have a look. It was surprisingly small, having only six tables and four barstools. Behind the bar was the obligatory glass window into the brewery. I saw a copper brewkettle, a stainless primary and two stainless secondaries (they were clearly labeled, making identification easy :-)). It was encouraging to see the small scale of this particular operation. Maybe there is hope for me. On the other hand, I expect this underwhelming operation may well have been unviable without the substantial bakery operation associated with it.

As for my race; I dropped my chain in the first mile, got it tangled in the rear derailleur and had to stop to fix it. By the time I got back underway, the pack was way down the road and I faced a headwind in trying to catch up. I slogged through the race alone and finished WAY down in the field. Bike racing can be frustrating, but it keeps me a skinny homebrewer :-).

Subject: Lager Eggs

I pitched a half gallon starter of cultured Sudwerk (Davis, CA) yeast into a fine batch of wort last week. After three hours there were six glubs/min. After four hours there was a three inch head on the beer. However, the smell of rotten eggs came out of the airlock. It wasn't overpowering, but very noticeable. I remember comments in the past about this activity. Is it normal? Will it go away? The fridge temp is set at 48 F.

I use the same set up and here is how i do it; I call it the modified decoction method.

for a proteen rest I heat water to 135F and add to grains -- one quart of water for each pound of grain. The temp stabilizes at about 125-130F.

After 30 min I add one pint of boiling water for each pound of grist to the mash tun. this stabilizes the mash at about 150F for about 20 min.

To further raise the temp I remove about 1/3 of the liquid in the mash tun via the drain on the cooler and bring that to a boil. Then I return the boiling liquor to the tun and stabilize the temp at 158. I hold that about 20 more min.

Of course you will have to play with the times and temps to match your system

K-Johnson's new lager batch stinks - well, Ken, I hope your spouse is more tolerant of off-odors than mine. Seriously, don't worry, relax, etc. Different yeast strains blow off different by-products, and if the odor is coming off the primary, it will be minimized in the final product. Using a dry lager yeast, your batch would smell like strawberry and pineapple. Evolution of hydrogen sulfide means that your batch has a very low redox potential (opposite of oxidized) and is slightly acidic, both OK. Is your UC Davis yeast strain available commercially? It sounds like a very fast starter. I would be interested in getting some if it conserves malt character and does not produce diacetyl. Let us know how it goes! -- Jean

From: microsoft!larryba@cs.washington.edu
Subject: Re: Oatmeal Stout, Mashing, Lager Smells.

On single infusion mashing: Klages is suppose to have enzymes equivalent to 6 row malt (Miller, The "Complete Handbook of Home Brewing"). I have had good results with Klages pale ale malt and 25% adjunct and single step infusion mash. It was a stout from Papazian, "The Complete Joy of Homebrewing", 6lb klages, 1 lb each, roast barley and flaked barley in 5 gallons.

I have had some good pilsners and made a couple of lagers (vienna, american bock and pilsner (still lagering)) that were all single step infusion mashed. Some were done with English and some with Klages pale ale malt.

- -----
For the fellow with the Oatmeal Stout, the extract rate per Miller is

Pale Ale = .035/lb/gal
Raw grain = .035/lb/gal (for barley, I assume oats are similar)

So you could expect $(.035 * 3 + .035 * 1) / 3.5 = .040$ (1.040). I don't think that 20 minutes is excessively fast. I typically spend less than a half hour sparging 7-10lb of grain for a 5 gallon batch. Your rates are probably small because of fixed losses in your system and the small size. If you did a full mash your rates would be similar to Millers. My first mash was similar to yours (a three gallon batch) and I got similar results. Subsequent batches have been a full 5 gallons and my rates are similar to Millers. My runnings are always cloudy. I think you just want to make sure you don't get any obvious grain or husk in your wort - not even an issue with a stout!

- -----
One of the defining characteristics of Lager Yeast is the rotten egg smell. I believe that the smell is suppose to be reduced by the yeast during the lagering period. That is what appears to happen in my lagers.

>> 10:1. Is there a pretty reasonable way to convert recipes using step
>> mash to infusion or am I simply limited by the types of grains I can
>> use? I've got a Gott picnic cooler mash/lautertun ...

> Using a single temperature does limit you to grains
> that have been pretty completely modified, such as English pale ale
> malt, as the basis of the beer.

This appears to be a central part of the cannon to any homebrewer who has ever read Papazian. I've been mashing for 5 years this summer, maybe 160 mashes, and I've rarely used anything but an infusion mash. Canadian malt, American and English, 2-row and 6-row, singly and in combination. Never a problem with poor enzyme levels, slow or incomplete conversion, or excessive chill hazes. At first, believing Papazian and dreading chill haze, I always used step mashes. When I learned that Upper Canada makes German style lager with Canadian ("under"modified) 2-row malt in a single-stage, I stopped worrying...

I sometimes got chill hazes with step mashes, I now sometimes get perfectly clear beer at fridge temperatures with infusion mashes. I don't think there's any correlation at all.

I would be willing to believe that a step mash is necessary if one uses substantial amounts of adjunct, and I can understand wanting to brew wheat beer in the summer, but otherwise, I don't personally have much use for rice or corn.

Speaking of summer, it's 90 degrees in Illinois these days. I live on the top floor of a three-storey house. Is there anyway I can continue brewing short of air-conditioning the place?

Cheers,
Rob

Hello all,

This is quoted from Seventh Generation's catalogue (they sell environmentally friendly stuff)

"When paper is bleached with chlorine, dioxins (some of the most deadly substances known to science) are formed along with other toxins such as furans and chloroform. Unbleached paper causes less pollution"

"When chlorine gets into the environment it forms unhealthy compounds like chloroform" (in reference to using chlorine vs. all-fabric bleach)

"Our water treatment facilities are overloaded and wastewater is being dumped directly into lakes and rivers. Therefore it's important to use cleaners

that biodegrade quickly and are as gentle as possible on the environment.
"

"to learn more about household chemicals, send \$9.95 for the Guide to Hazardous Products Around the Home to HHWP, S.W. Missouri State 901 S. National Ave. Box 108 Springfield, MO 65804"

I doubt that using 2 tablespoons in a gallon of water will be that bad for the environment, since chlorine is regularly dumped into water by the water authorities (I lived in Fort Lee, NJ and had to get bottled water, the chlorine odor was that strong). However, it couldn't hurt to use a less destructive chemical if there is one that will kill the bacteria like chlorine will. Hydrogen Peroxide breaks down into O2 and CO2 and is used for disinfecting cuts, would that do it?

Subject: Brewing Lager Beers

Hello everyone.

I am intersted in different peoples techniques and results in brewing lager beer. Recently I have been able to clear room in my refrigerator for a carboy.

Do people find they have better results by doing all the fermenting in the refrigerator including the carbonating in the bottles and then storing the beer at room temp (60F).

Or do people do the primary fermenting at room temp and then store the carboy in the refrigerator for several weeks and then bottle and leave the bottles at room temp.

Or do people find they have better results by doing all the fermenting at room temp and then place the bottles in the refrigerator for several weeks.

What effects does temp. changes have on the beer and the yeast.

If I get enough responses I will post a summary.

From: botteron@bu-it.bu.edu (Carol Botteron)
Subject: Chlorine + Wort -> Chloroform?

Steve Anthony brought up the subject of chlorine. I've been meaning to ask what is known about the effect of chlorine on wort.

In the processing of drinking water, a frequent problem is that chlorine reacts with organic matter in the water, forming chloroform and related compounds, some of which are carcinogenic.

Cambridge, Mass. (which has its own water system, mostly separate from the rest of the Boston area) has this problem; apparently the source of the organic matter is leaves falling into an open tank, so the tank is being replaced with a covered one.

A small biotech company in Cambridge got into trouble a couple of years ago because there was too much chloroform in their effluent water. The company didn't use any chlorine compounds, but the people there analyzed all their processes in an unsuccessful search for the source. Finally they measured the chloroform in the city water coming into their building....

Anyhoo -- wort has plenty of organics in it. Many people use chlorine bleach to sanitize equipment. If anyone has actual information on the effects of bleach on wort, probably quite a few people would like to read it. Meanwhile, thorough rinsing and draining sounds like a good idea.

Carol Botteron (proud descendent of Dionis Stevens of Newbury, Mass.)

From: darrylo@hpnmxx.sr.hp.com
Subject: Re: Final Gravity Calculation

In HBD #645, prcrs!link@uunet.UU.NET (John S. Link) asks about final gravity calculations. I'm under the impression that FG is influenced by the type of yeast used and the amount of fermentable sugars in the wort (e.g., dextrinous worts will have high FGs).

However, I'm curious as to how the OG is calculated. This should be a simple topic, but I've been unable to find a good explanation in either Papazian's or Dave Miller's books. Can anyone tell me if the following is correct (I'm going to use John's recipe as a guinea pig)?

John uses the following malts:

```
> - 3 lbs John Bull Amber liquid malt extract - hopped
> - 3 lbs M&F Amber DME
> - 1 cup M&F Pale DME
```

(I'm ignoring any SG contributions from trace minerals, hops, etc..)

In Appendix 10 of Papazian's book, there is a table that gives estimated SGs for different ingredients (this table is on the very first page of Appendix 10). Taking the "average" values we have:

In 1 gallon, 1 lb of: Will yield an SG:

```
-----
Malt Extract (syrup) 1.035 (Papazian gives 1.033-->1.038)
Malt Extract (dry) 1.040 (Papazian gives 1.038-->1.042)
```

Note that Papazian gives SG *ranges*. Here, I'm giving an exact value to make things easy (but not necessarily exact).

I'm going to assume that 1 cup of pale DME weighs 1/2 lb (I'm taking a wild guess at this).

I'm also assuming that SG can be calculated by individually calculating the SG contributions of each malt, and then adding them up to get the real SG value:

***** For the 3 lbs liquid ME:

```
  0.035(3)/5    = 0.021 <-- SG contribution of this liquid ME
  ^   ^   ^
  |   |   +-- 5 gallon batch
  |   +----- 3 lbs of liquid ME
  +----- "normalized" SG of 1 lb of liquid ME in 1 gallon
  (SG is relative to 1.000, so I subtracted 1.000
  from the value, to make it relative to zero).
```

***** For the 3 lbs amber DME:

```
  0.040(3)/5    = 0.024 <-- SG contribution of this DME
  ^
  +----- "normalized" SG of 1 lb of DME in 1 gallon.
```

***** For the 1 cup of pale DME (assuming 1 cup DME weighs 0.5 lb):

```
  0.040(0.5)/5  = 0.004
```

Adding these numbers, we have (can you really add SGs???):

```
0.021 <-- liquid ME
0.024 <-- Amber DME
+ 0.004 <-- Pale DME
-----
0.049 --> SG (OG) of 1.049
```

John says that the OG was:

>- Original gravity was 1.046 adjusted to 1.048 for temp.

This is close to the calculated value of 1.049. If you use the min and max values in Papazian's table, you get:

```
Min OG: 1.046
Max OG: 1.052
```

Is the above right, or have I had a few too many beers? ;-)

Also, in HBD #648, Matthias Blumrich <mb@Princeton.EDU> asks about dry ME to liquid ME substitution ratios. If the above is correct, then DME can be said to be about 14% "better" than liquid ME (I've also heard that DME is 20% more "efficient", whatever that is). To *estimate* the amount of DME needed given an amount of liquid ME, you would multiply the liquid ME amount (weight in pounds) by 7/8, or 0.875.

```

From: Alan Garvey <Garvey@CS.UMASS.EDU>
Subject: re: keg registration

A few digests ago Bill Thacker posted a message about a keg registration law in Green River, Wyoming. That reminded me about a law that the town of Amherst, MA passed a couple of weeks ago.

The new law requires anyone in possession of a container that is 5 gallons or greater and has any beer in it to have a keg license. A license is obtained by going before the town selectboard and paying a \$25 fee. It is not clear whether this is a one-time fee or a per keg fee. I read the exact wording of the law and it is incredibly unclear. The intention is to give police the authority to remove kegs when they are called to a party where beer is being served to minors. Apparently undergraduate partying here at UMass (aka ZooMass) has gotten even more out of control than usual and the residents of Amherst are upset about it. I sympathize with home owners whose lives are disrupted by partying students, but this law seems much too broad.

Homebrewers who keg their beer (rather than bottle it) certainly fall under the ordinance. Homebrewers who brew 5 gallon or larger batches in a carboy or bucket (that is, nearly every homebrewer), may or may not fall under the law, depending on whether you consider the product in the carboy to be beer before the brewing process is completed.

A friend of mine who is a member of the town meeting that voted in the law (and who voted for it himself -- pinhead) tells me that the police promise not to harass "ordinary" citizens and use the law only to control student parties, but I have a hard time believing police promises to not use the full authority that the law gives them. The law was conveniently passed just as students are leaving for the summer. It will be interesting to see the effects of the law when the students return in the fall.

From: mike_schrempp%42@hp4200
Subject:modified decoction

In HBD 648, Chip Upsal describes his "modified decoction" in which he removes and heats liquid from the mash. I've never tried any kind of decoction mash, by Noonan talks about pulling out the "thickest" part of the mash, by which I believe he means very little liquid. His claim is that the enzymes in the grain are quickly washed off the grains and into the mash liquid. Noonan also claims that boiling those grain husks will not deliver too many tannins to the beer (he had a reason, but I forget what it was). He claims boiling the liquid will reduce the enzyme potential.

Can't call that a data point, but there it is.

Now a question: I'm making batch 7, my first hopped extract kit (I know that's backward, but I got the kit as a gift so I used it), and it's been actively bubbling for almost two weeks. The kit is a "Draught Ale" from Newbegin Brewery in New Zealand. Has anyone had any experiences with this brand before? Is it slow (doesn't seem that way), or maybe just VERY attenuative (no SG check since pitching)? I'm not worrying, but all my bottled beer is nearly gone and I'm scared of a brew-drought.

From: FATHER BARLEYWINE <rransom@bchml1.aclcb.purdue.edu>
Subject: Impurities, Residues, and General Yuckiness

Hey Brewfreaks!

I've read many articles recently about the various molecules which can contaminate homebrew and what measures can be taken to avoid them. My big mouth and biochemical background have persuaded me to throw in my opinion.

The factor which most people tend to forget is the essential ingredient in brewing: yeast. If your water contains trace amounts of organics, if the copper coils lend a few molecules to your wort, the yeast you've pitched will generally suck this stuff right up. Few of us realize just how many cells are present in a completely clear glass of homebrew, much less the cloudy murk that reigns in early fermentation. The volume of water in your pitched wort is passed many times through yeast cells in the course of a days hard fermentation, and at each pass the water is effectively filtered (and, of course, effectively pissed in). Most toxic molecules have high affinities for components of living cells (which is often why they're toxic) and will bind strongly to them, and in the case of beer, be precipitated to the bottom during the inevitable die-back of the yeast population. Thus the yeast are going to clean up your starting materials.

This is not to say that beer is safe. During their life cycle, and particularly during anaerobic (no oxygen) fermentation, yeasts produce and excrete all sorts of questionable compounds into your beer. This is what makes your beer taste like beer and not malted hop tea. Alcohol is a great example (although this is a primary metabolite and not some wierd shit that yeasts have decided to make before dying) of a poisonous result of fermentation albeit one we have decided to take a liking to.

The conclusion is that you're more likely to die from eating the carcinogenic compounds produced by mushrooms and by drinking the secondary metabolites produced by yeasts than you are from the copper sulfate leached off from your old and crusty cooling coils. So sit back, pound down a few coffin nails, and reflect on the fact that people have been dying since the invention of reproduction by methods other than fission. Personally, I prefer sex and homebrews to living forever anyway.

Subject: Cream soda, siphoning woes.

My biggest concern with many authentic root beer recipes is that they call for many bizarre and hard to find ingredients. Of course, one can always get the extract, but that just doesn't sound like as much fun to me. Besides, I'm not that big of a root beer fan anyway.

What I would love to try is a cream soda recipe! Does anyone have an actual recipe for cream soda? I'd prefer one that starts "from scratch" rather than from an extract.

On brewing: I whipped up a hellacious black/brown ale last night. I still work from extract, and I don't have a wort chiller yet. My biggest hassle in brewing is getting the wort from the brewpot to the carboy. I'd prefer to siphon or use gravity feed, but my tubing always gets something in it to plug it up and make me restart the siphon. I'm concerned that one of these days I'm going to infect the stuff. I don't want to pour, as that tends to slosh the hot wort around a lot. Also, it seems that pouring wouldn't adapt well to the day when I finally make a wort chiller.

So, let me hear some advice on getting hot wort into a carboy (I use cold water in the carboy to absorb the shock). Many thanks.

Subject: Re: Brewing Lager Beers

MJ asks:

>What effects does temp. changes have on the beer and the yeast.

Drastic temp changes can shock yeast into dormancy or even death, but I think that what you need to ask is: "How does temperature affect the flavor of the finished product?"

I'm not sure what chemical reactions take place during lagering, however, the effect of fermentation temperature on flavor is, to put it simply, fruitiness. When yeasts perform fermentation at higher temps (60, 65, 70F, etc.), they produce more by-products such as esters. Esters are the chemical compounds that give fruits their flavor. Red Star ale yeast, for example, is known for "banana" esters. Cooler fermentation temperatures (50, 45, 40F, etc.) cause the yeast to produce less by-products, including esters.

Typically, ales are fermented somewhere in the vicinity of 60F, and then consumed shortly thereafter. Lagers, however, are traditionally fermented cooler, let's say around 45F, and then *lagered* (stored) for several months, also at cool temperatures, let's say 33F to 45F.

Maybe someone who knows beer chemistry better, can explain the effect of lagering temperature.

Subject: question on recarbonation with dry ice

Does anyone have any experience with recarbonating leftover keg remnants by putting dry ice into a 2 liter plastic bottle with the brew? I don't want a dry ice bomb, and am not about to try it with glass! We don't have the fittings for this odd little keg of smoked beer (yes, wonderful) from the other side of the country, or the CO2 equipment, but I can snag some solid CO2 from the biology labs fairly easily.

Either weight or volume results, by testing or calculation, would be interesting. My chem is a little rusty, and figuring out the solubility, etc., would take a while. Particularly since I have no idea what "good" levels of carbonation are in physical terms.

Thanks in advance for any replies. I'll post a summary and any experimental results.

Alan Garvey <Garvey@CS.UMASS.EDU> writes about a keg registration law:

...
> A friend of mine who is a member of the town meeting that voted in the
> law (and who voted for it himself -- pinhead) tells me that the police
> promise not to harass "ordinary" citizens and use the law only to
> control student parties, but I have a hard time believing police
> promises to not use the full authority that the law gives them...

Pinhead indeed! Alan's got it pegged: There's no excuse for passing laws which won't be enforced exactly as written, and if you think an existing law won't be used against you, you're at least optimistic and certainly naive.

The difference between "laws that exist" and "laws that are enforced" is a very dangerous ground; it should be as small as possible! That's the area where laws can be enforced selectively--where two people can do the same thing but only one gets prosecuted because he is black, is a longhair, lives in the wrong part of town, doesn't grease the right palm, etc.

If the law is unjust or unfair, bring focus on the law; get it repealed or rewritten. The letter of the law (and NOT what some transient council-creatures promise off-the-record, not-in-writing) is what matters. If the letter of the law is unconscionable, the law is unconscionable; don't take any excuses.

Subject: Beer in Raleigh (Mayberry on Steroids)

I had a chance to sample several beers from Greenshield's, which is a small brewpub in Raleigh, N.C.
The light wheat beer was very good.
The dark wheat beer was very, very good.
The pale ale was very, very, very nasty.

I will admit that the high quality of the wheat beers may have made a mediocre pale ale seem worse than it was. However, it tasted acrid and somewhat soapy. Can someone tell me what the most likely culprit would be for such a flavor?

Finally, I would like to know if anyone can add to the following list of N.C. Brewpubs...

1. The Loggerhead
2. Spring Garden Brewing Company (both 1 & 2 are here in Greensboro)
3. Old Heidelberg (formerly the Weeping Radish in Durham)
4. Greenshield's (Raleigh)
5. Dillworth's (Charlotte)

Have I missed any?

>Homebrewers who keg their beer (rather than bottle it) certainly fall
>under the ordinance. Homebrewers who brew 5 gallon or larger batches in
>a carboy or bucket (that is, nearly every homebrewer), may or may not
>fall under the law, depending on whether you consider the product in the
>carboy to be beer before the brewing process is completed.

This may not be entirely true. I am unfamiliar with this particular law
but when it comes to state regulations on the alcohol content of beer,
the
term 'beer' has a very strict meaning. It only applies to 'lager'. Here
in California there is a 4% limit on the alcohol content of beer, or
lager.
However, there is no limit on the alcohol content of ale, stout, porter,
malt liquor, bock, etc. As long as you do not call it beer or lager, the
alcoholic content can be anything. If the law mentioned above refers
to 'beer' specifically than homebrewers should not be affected. After
all
you can call what you brew anything you want.

I would be interested in hearing some other opinions on this because it
seems to
me that unless they regulate the brewing process, the ingredients, and
equipment, they could not require you to register the container you keep
it in.
You could always claim, "Hey, it wasn't like that when I put it in there."

From: "Dennis R. Sherman" <DRS%UNCVX1.BITNET@ncsuvvm.cc.ncsu.edu>
Subject: low alcohol beer

The July 1991 issue of Popular Mechanics has an article on how brewers are taking the alcohol out of beer. They say there are 4 ways to take the alcohol out of beer: vacuum distillation, where the alcohol is boiled out of finished beer, then things are added to the beer to replace the esters also boiled out; reverse osmosis, where the beer is pushed against a semipermeable membrane that only allows the alcohol molecules through; brewing with a yeast that only ferments part of the sugars available; and arresting fermentation.

Most brewers use vacuum distillation. Reverse osmosis is expensive, and is used by Anheuser-Busch to make O'Doul's. Birell and Utica Club NA use the "stupid yeast" (or maybe 'not hungry yeast') method. The arrested fermentation method is used by the three beers PM rated highest, Clausthaler, Haake Beck, and Sharp's.

Interesting article - worth tracking down for a quick look.

>you get "Fresh beer"?? Why? The last thing I want is fresh
>beer? I go out of my way to hide freshly brewed beer where I
>won't be tempted to drink it until it has aged.

Well, this is an age-old controversy, which is why I refrained
from replying until I saw what happened.

Good breweries only bottle when the beer is ready to drink. How
long it is aged beforehand depends on the type of beer, the
brewery, etc. For instance, Anchor Brewery stores their ales
cold (45? 50? 55? I forget) for awhile before bottling. IMHO,
good breweries don't use artificial preservatives (beyond the
yeast and hops). Therefore, you want to get their beer as
quickly as you can because it should be near the height of flavor
when bottled. [This does not apply to high-alcohol beers that
can age years.] Remember, the longer it is in the bottle, the
more likely it will be mishandled by being stored in hot
conditions or somesuch.

So, what about the beer you make yourself? After being on both
sides of the fence, I think that fresh is good, but not the
end-all and be-all of brewing. I store my beer in the basement,
not exposed to light or heat, fairly cool (roughly 60F all year).
So I have had good beer over a year old. Still, if I don't like
the taste at a week in the bottle, I figure there is something
about my brewing process that could be improved.

I have found that 1 week-old beer brewed with liquid yeast is
much, much better than the 1 week-old beer I made with dry
packets. I now regularly drink the beer young and enjoy it and
remark on the changes that occur as it ages. I like my beer both
fresh and aged, now that I think I am doing things more-or-less
right in the brewing process.

>your bottles 6 times), than necessary, by all means use this
>book as your bible. But really, Papazian has it all over this
>guy!

OK, here is another data point. Before having ever brewed (and, unfortunately, not knowing other brewers in the area), I read what I could find on the subject. Someone I talked to recommended avoiding older books on the subject, so I ended up with Papazian and Miller. I thought Papazian was interesting and informative, but not really very helpful for a novice brewer who wasn't really sure if he had all the equipment, etc. Miller tried to be very thorough, explain what equipment you needed and what you probably already had in your kitchen you could use. His procedure was very detailed and easy to follow. I knew if I followed Miller I would not miss any steps, so I could relax.

In other words, it sort of depends on your personality and such, but I think Miller is by far the best for someone who hasn't brewed at all before. Once you are comfortable with the process and equipment, Papazian then is more fun and has more interesting recipes. Miller does become useful again when you want to get beyond the basics of extract brewing.

>From: Jean hunter <MS3Y@CORNELLA.cit.cornell.edu>

>At the risk of reigniting an old controversy, (why) is aluminum
>a bad material for a mash tun or wort kettle? Color, flavor,
>aroma, my health, the yeast's health? Is there a brief answer?

Here is my relatively unbiased analysis of the situation.

1) Flavor. Some brewers can taste the aluminum-imparted flavor in beer brewed in aluminum. Some can't. Highly acidic liquids (wort is only mildly acidic) leach out aluminum (I know *I* can taste a metallic taste if tomato sauce is cooked in aluminum) from some types of pans. So, this is a human variable, at least.

2) Health. Current studies have established no link between dietary aluminum and any diseases. Also, other sources of dietary aluminum (such as plants grown in soil) far outweigh any possibility of aluminum from brewing.

3) Color? Haven't heard of any relationship there.

4) Aroma? Ditto.

Subject: Re: Homebrew Digest #650 (June 03, 1991)

Hi Al - Beer carbonation is generally expressed in volumes, that is how many volumes of CO2 at standard temp and pressure per volume of beer. Carbonation ranges from around 1 vol for "flat" British ales to nearly 3 volumes for a very lively beer like Anchor Steam. Going for two volumes, you'd need enough CO2 to make 4 liters at STP. From the ideal gas law, one mole of gas (44g of CO2) fills 24.4 liters at 1 atm. and 25 degrees C.

So you need $(4 \text{ liters}) * (44 \text{ g/mol}) / (24.4 \text{ liters/mol}) = 7.2 \text{ gm dry ice}$.
Let us know if it works - it is probably easier to deal with dry ice than with a whole keggings/pressure regulating setup. BTW, one caution, if you don't know how many volumes of CO2 are in the beer already, go easy on the dry ice. Happy bubbling, Jean

From: gschultz@cheetah.llnl.gov (Gene Schultz)
Subject: Samuel Adams Beer taste-alike

Several months ago I posted a request for a recipe for something that tastes like Samuel Adams Beer. Several of you replied, and I brewed a four gallon batch based on the collective wisdom of these replies. I used a 3.3 lb. Cooper's Ale kit, steeped one pound of Crystal malt for 30 minutes in 2 qt. of water heated to 170 degrees F, added it to the syrup from the kit and water, added 3/4 oz. of Saaz hops and boiled for 30 minutes, then removed the heat and added 3/4 oz. of Saaz hops for finishing. Although I am a fanatic for liquid yeast, I (grimaced and) added the dry Coopers yeast supplied with the kit to the cooled wort in the primary. I transferred to secondary after two days. All fermentation was at approximately 60 degrees F. I primed with 5/8 cup of corn sugar.

I tasted the beer for the first time two days ago. It was wonderful--very similar in taste, body, and color (where did the red come from?) to Samuel Adams, but just a hint of the flavor of Anchor Steam Beer. I'm going to try to brew the exact same thing again this weekend--the first time in over 30 batches that I will ever have tried to brew an exact replica of something I have brewed before.

Thanks to you homebrewing folks who supplied me with the good info.!

Subject: Soapy doesn't have to be bad.

In #651, Russell D. Shilling writes:

> However, it tasted acrid and somewhat soapy. Can someone tell me  
> what the most likely culprit would be for such a flavor?

Acrid could be one of many things, those more knowledgable than I will better be able to identify the source. A good fresh Goldings hop (particularly the British, as opposed to the British Columbian or Oergonian) sometimes has a soapy flavour. I remember noticing it for the first time in English real ale - a London brewer, a pale ale, but darned if I can remember which! - and being a little taken aback. I came to appreciate it with time, but was never able to duplicate it with the domestic Goldings I got in Toronto.

On a different note, I somehow suspect NOBODY RECEIVED #646!!!!

Cheers,  
Rob

Subject: soap taste, and sex?

<I mean, what the hell, the beer is way more important than the sex already...

and I thought I was the only one.

<I will admit that the high quality of the wheat beers may have made a mediocre pale ale seem worse than it was. However, it tasted acrid and somewhat soapy. Can someone tell me what the most likely culprit would be  
<for such a flavor?

I think the flavor comes from leaving the troob in the fermenter, the yeast eat-up the troob instead of the sugars, at least that is what I've been told

Subject: Original Gravity Calculation

In HBD #649, darrylo@hpnmxx.sr.hp.com was asking about OG calculations:

> I'm also assuming that SG can be calculated by individually calculating  
> the SG contributions of each malt, and then adding them up to get the  
> real SG value ...

Yes, that's correct.

```
> ***** For the 3 lbs liquid ME:
>
>   0.035(3)/5    = 0.021 <-- SG contribution of this liquid ME
>   ^   ^   ^
>   |   |   +-- 5 gallon batch
>   |   +----- 3 lbs of liquid ME
>   +----- "normalized" SG of 1 lb of liquid ME in 1 gallon
> (SG is relative to 1.000, so I subtracted 1.000
> from the value, to make it relative to zero).
```

This is right, EXCEPT that you made one very common mistake. You want to divide by the volume of wort at the end of the boil, and that's not 5 gallons. You may end up with 5 gallons of beer, but chances are you're starting with more like 5.5 - 5.75 gallons of wort at the end of the boil. You lose some of that during the remaining steps (e.g., some gets soaked up and thrown away with the spent hops, some gets left behind during siphoning, some goes out the blowoff hose if you use that method, etc.). This may seem like a fine point, but it makes a surprisingly large difference in the OG that you calculate.

It just so happens that I wrote an article about this topic for the most recent issue of my brewing club's newsletter. It describes techniques I've been using which allow me to decide what I want my OG to be, formulate a recipe, brew it, and reliably hit the target OG almost exactly. The article is aimed at grain brewers, but the methods would also work for extract brewing. If anybody would like a copy, I'd be happy to send one. Just send a SASE to me at this address:

Subject: RE: Keg registration

RE: Keg registration / license Amherst Mass:

A couple of comments on keg registration in Amherst Mass. The problem isn't that the law was passed after the students left, it was that most were not registered voters and could not vote on the issue. Your friend may indeed be a pinhead but he did register and did vote. Sitting on your ass relaxing with a homebrew will only produce sewage. Quibbling over the definition of beer isn't a solution either. If people are concerned about Neo Prohibitionism then they need to have their votes and voices heard. The sad thing about this type of law is the drinking problem it tries to address will not go away, people will make "party punch" in plastic buckets or buy Matt's Beer Balls (if they hold less than 5 gallons), and the law will still be on the books.

From: dbreiden@mentor.cc.purdue.edu  
Subject: Cream soda, siphoning woes.

My biggest concern with many authentic root beer recipes is that they call for many bizarre and hard to find ingredients. Of course, one can always get the extract, but that just doesn't sound like as much fun to me. Besides, I'm not that big of a root beer fan anyway.

What I would love to try is a cream soda recipe! Does anyone have an actual recipe for cream soda? I'd prefer one that starts "from scratch" rather than from an extract.

If anyone does have a cream soda recipe from scratch, please post it or email it to me as well...

As an aside, there are two types of 'cream soda' sold in North America. In the good ole' USA, we have 'Cream' or 'Creme' or 'Vanilla Cream' or something along those lines. What you get is a soda that is slightly golden colored and has the taste of vanilla - as in vanilla beans, or extract or ice cream.

Canada (at least Montreal and the southern part of Quebec province) has a soda called 'Cream Soda' or in French 'Soda Mousse'. This is a clear soda which tastes remarkably like cream (as in dairy cream) and has a long lasting head (for soda that is). The Canadian cream soda uses as an ingredient either saponin or quialla (sorry about the spellings) which is an extract from plants that is used to make soap - I guess just a bit in the soda makes for the wonderful head you get.

I have also seen in Montreal a 'cream nectar' type of soda, made by Canada Dry in Canada, which is similar in taste to the 'cream soda' we get in the US, but which also had the frothy head of the other Canadian 'cream soda'.

I would be interested in seeing if anyone does have a recipe for 'cream soda' and which one - US or Canadian?

For the US version, I'd think that a vanilla extract/sugar syrup mixture to suit your taste would be a good starting point, then make as any other soda.

Ihor

Subject: Thanks and a mead question.

Many thanks to those who sent me copies of issue #646. I hope I send on copies to all who asked me to send it to them if I got it.

Now, about mead. I'm starting a still mead which will probably require at least a year of aging after bottling. Is it best to bottle this kind of mead with caps, or corks. Since pressure isn't the issue, would corks be better to allow minimal oxygen transfer as in wine or should I use plain old crown caps and seal the mead away from the elements.

Thanks for your thoughts,

Dan

From: bates@noaacrd.Colorado.EDU (John Bates)  
Subject: Yeast repitching/conditioning

I know the Forum went around on the subject of repitching yeast a few weeks ago, but I have just had a very interesting experience. We are going through the spring/summer transition here in BOulder, and I decided to try one last lager before switching to ales for the summer. I made a Marzen recipe and used Mev high temperature yeast that I had started. The package was quite old (about a year, I hadn't caught the date at the store or I wouldn't have purchased it) and took about 5 days for the package to swell up. I then started it in about 16 oz a day before brewing, pitched, and had good fermentation in about 24 hours. After a normal fermentation, that batch was kegged, I repitched the yeast into two more different batches, and conditioned the first batch for about 2 weeks. Upon tasting the original batch, something wasn't quite right...not undrinkable, just not all it should be. Well I was supposed to bring this batch to our monthly club meeting...and did with some trepidation. Tasters there agreed it was probably the yeast, but the batch wasn't that off in flavor because the keg was empty by the end of the night. Charlie P. mentioned that they had biologists look at a number of yeast strains and MeV was noted for having some strange critters in the yeast.

Now the other two batches from the repitched yeast are ready to drink... and to my joy there is no longer an off yeast taste. Both of these batches are really quite tasty! So IMHO, yeast does improve after repitching once or twice. I know this is also the predominant view of the hard core homebrewers in our club.

From: Marc Rouleau <mer6g@fuggles.acc.Virginia.EDU>  
Subject: Mashing Crystal and Cara-Pils Malts?

This question has come up recently, and I've also seen it in the archives, but I've yet to see a really convincing answer one way or another.

Dave Miller claims in TCHOHB that you should mash all special malts to extract everything from them. He says that the processes that produce crystal and dextrin malts do not convert all of the starch. Merely steeping them wastes potential extraction and, because of the unconverted starch in the boil, reduces the clarity of the beer.

On the other hand, won't mashing convert all those dextrans into simple sugars that yeast like? If so, what happens to the rich mouth feel and sweetness that these malts are intended to produce?

I believe that I've had good results mashing crystal and dextrin malts, but I'm new to brewing and would like to hear about this from more experienced brewers. Can anyone confirm (or deny) Miller's view with a technical explanation? Has anyone tried it both ways?

From: Fritz Keinert <keinert@iastate.edu>  
Subject: Brewpubs in eastern Iowa

In digest #652, Mark Stroup <ms56+@andrew.cmu.edu> asked about breweries and brewpubs in eastern Iowa.

I only know of one brewpub in all of Iowa; they were only made legal a year or two ago. It is in Iowa City and is called "Fitzpatrick's". I was only there once, but liked it a lot. A second one in Des Moines is supposed to be in the works.

There are some more breweries I know of, but they all make typical American beer, in my opinion, anyway. This includes:

- A brewery in the Amana Colonies (called "Mill Creek", I think)
- The "Dubuque Star" brewery in Dubuque, which is so small that it brews from malt extract; they survive by putting various labels on their beer, so that pubs or restaurants can have their "house brand".
- A brewery called "Foecking", which is run entirely by women and aimed at the yuppie drinker. I am not quite sure where that one is; Quad Cities maybe.

Anyway, I would recommend Fitzpatrick's, but not much else.

John> I have found that 1 week-old beer brewed with liquid yeast is  
John> much, much better than the 1 week-old beer I made with dry  
John> packets. I now regularly drink the beer young and enjoy it and  
John> remark on the changes that occur as it ages.

By ``young'' do you mean ``1 week-old''? After one week, is the beer adequately carbonated? or are you doing more authentic (pronounced ``flat'') English-style ales?

What changes did you make to your brewing procedure -- or recipes -- which improved your relatively-young beer? Inquiring minds want to know!

As an aside, now that I keg, I find my beer lasts only a fraction of the time it used too -- not that it spoils, but my friends come over and hose it down in under a week! :-( I rarely have time to taste it changing.

Quialla [sic, but I don't know how to spell it either] extract is also in the heading liquids available for homebrewers - to increase the head retention, not to give it one in the first place. I've never used them so I cannot report on how well they work. Has anybody else tried them? Are they yet another foreign object to keep out of my beer?

From: rmm@apollo.hp.com  
Subject: sunlight and beer

I have a question... When does sunlight stop threatening beer? (especially homebrew). According to Papazian, strong sunlight can ruin the flavor of beer in a matter of minutes. For this reason, I make sure that my carboys stay out of the sun and I only use brown bottles. I noticed, though, that at least a couple of excellent quality beers like Newcastle brown ale, and Sam Smith's Oatmeal Stout come in clear bottles. I would guess that these people know what they're doing, and that they put their beer in clear bottles because it is not at risk. Can someone shed a little more light (ow, that hurt :-)) on this for me? Thanks.

From: srussell@snoopy.msc.cornell.edu (Stephen Russell)  
Subject: NY, NJ, PA, CT brewclub members???

Greetings again!

Our homebrew club (the Ithaca Brewer's Union) is organizing a trip to Vernon Valley, NJ, the weekend of July 27-28. We will be there for "Germanfest", one of their many summer activities, but of more importance for subscribers to this digest, we will be getting a tour of the Clement Brewing Company (formerly the Vernon Valley Brewing Co.) courtesy of owner James Clement. The brewery is one of the few in the world that uses wooden casks for fermenting.

Anyhow, James has said that the tour is open to all who are interested. I have been trying to get in touch with regional brewclubs, in NY, NJ, PA, and CT, and would like to hear from you if you are a member of a club in one of these states. However, I also wanted to let others know as well. I figure that we could have an ersatz "conference", simply meaning a friendly get-together or something for all the homebrewers who show up.

Well, let me know if you are interested (please e-mail directly).

STEVE

From: srussell@snoopy.msc.cornell.edu (Stephen Russell)  
Subject: malty ale recipe search

Tried to submit this in the missing #646, but here goes again.....

I would like to try and make a malty ale, such as Fuller's ESB. Do any of you have recipes I could use?? One common approach to making a beer maltier, in both aroma and flavor, is to use Munich malt. However, I assume that British brewers use British ingredients (pale ale, crystal, amber, chocolate, and black malts, roasted and flaked barley, adjuncts, and various sugars like Demerara and treacle) and therefore, Fuller's would be devoid of German malts like Munich. So I'm curious as to how they achieve it. Maybe the darker sugars come off as malty??? Or maybe using a certain yeast strain?

I am perfectly willing to try recipes that contain Munich malt, since one of the neat things about being a homebrewer is the freedom to make German beers out of British ingredients and vice versa. I just wondered how they do it.

Extract, partial mash, all-grain, whatever you've got will be gladly accepted.

Thanks in advance,

STEVE

From: Chris Carlisle <C24884CC@WUVMD.Wustl.Edu>  
Subject: Fresh Beer and Under the Influence

Our cat accidentally unearthed the last of a hidden cache of homebrew that my husband had forgotten about, made two years ago. It was great, but I don't think it had more than about six more months of life. It was almost too smooth!

The St. Louis Post Dispatch is running a series on Under the Influence all this week, with an excerpt per day. I've been reading it with great enjoyment. It's interesting to see which of the brewery's legends are false. It was also great to learn of the Busch's Prohibition-era pact with Al Capone, and to realize that what saved them was not their diversification into soda, health beverages, etc. as they claim when you take the tour, but their real estate. They owned a lot of corner saloons here in St. Louis and sold them off to gas stations. Read the book, it's fun!

From: eisen@kopf.HQ.Ileaf.COM (Carl West x4449)

Subject: Really fresh ingredients & alehoof (yes, more questions)

Having gotten my hops plants into the ground very late, I don't expect much of a harvest, certainly not enough for more than one batch. I understand that drying is necessary for storage, but is it necessary that I dry the hops before I use them? or can I use them straight off the vine? The weight will be different, but aside from that?

While on the subject of very fresh ingredients, what about putting just-germinated barley directly into the mash? crushing it should be fairly easy, it seems that it would squish without busting up the husk much at all. I assume that by skipping the kilning you'd lose some body and flavor, but if you're trying for something light...

Anybody ever used alehoof instead of hops? I'm told that that's what is growing all over my yard.

Carl

Date: Wed, 5 Jun 91 12:09:04 CST  
From: <@hpfcla.fc.hp.com,@cdp.igc.org:pals@inland.com>  
Subject: Alternate Beverage massive price increase

I am an extract brewer, and have always purchased my supplies from Alternate Beverage. Generally, I've been happy with them. Up to now, any problems I've had with them relate to their growing pains. Their selection has been good, and prices reasonable. Their extract recipe packages are also very convenient.

However, I just called yesterday to place an order for some extract recipes, and their prices have \*SKYROCKETED\*. Example: Brown Ale recipe, was \$17.95 in the fall/winter 1990 catalog, is now \$22.95! That's a 27.9% increase!!

The person I talked to on the phone blamed this largely on the U.S. dollar-British pound exchange rate, as the malt extracts they buy are British. Sorry, folks - it doesn't wash. Here is a table of the dollar-pound exchange rate over the last year, as quoted in the Wall Street Journal:

| Date           | How many U.S. dollars to buy one British Pound |
|----------------|------------------------------------------------|
| May 9, 1990    | 1.67                                           |
| Sept. 13, 1990 | 1.86                                           |
| Dec. 19, 1990  | 1.93                                           |
| Jan. 30, 1991  | 1.96                                           |
| March 27, 1991 | 1.74                                           |
| April 25, 1991 | 1.69                                           |
| June 3, 1991   | 1.69                                           |

So, exchange rates are the same as they were one year ago. Even in January of this year, the pound was only 16% higher than it is now.

Besides just to rant and rave, my purpose is to 1) see if anyone has other information as to what prompted this drastic increase, and 2) encourage other Alternate customers to let Alternate know how they feel about this.

Subject: Beer with real malt taste

>From: ml4051@mwvm.mitre.org (John DeCarlo)  
>Subject: Re: Beer with Taste???

>>From: David Taylor <DAVID@phillip.edu.au>

>>Our commercial brewers seem to be able to handle cane sugar  
>>well, producing beer devoid of body and flavour yet with 5%  
>>alcohol. When I try to make a similar strength brew without  
>>sugar the malt comes through strongly. So... why don't \*you\*  
>>use cane sugar?

>I didn't notice a smiley-face here. If I don't want any malt  
>taste, I drink root beer or lemonade. Why drink beer if it  
>doesn't have any taste to it? If you haven't had a wheat beer,  
>you might be surprised at how good it is without much malt  
>flavor.

I didn't phrase my query very well - what I meant was an attack on commercial brewers and praise for homebrew. Homebrewers here in Oz criticize the products of the large commercial brewers as being low in flavour while being high in alcohol. When we try to brew our own all malt beer to 5% v/v alcohol the result is very prominent malt character.

It is apparent that the big boys are using cane sugar or other cheap fermentables (brewery watchers have seen the sugar syrup tankers pulling up to the breweries). Labels are not required to list all ingredients so mention 'fine quality malt and hops' etc. I understand that one of the prominent American brands is honest enough to list rice on its label.

I am wondering how the commercials can use sugar and produce light but clean tasting, relatively high alcohol beers, when if I use sugar I often get estery cider flavours that cause me to tip the batch out. The major Melbourne brewer is very protective of its yeast strain which came from Carlsberg nearly a century ago and has been maintained and improved over that time. Apparently it is now characterised to ferment the part malt wort under slight pressure so would not be any good under homebrew conditions. The resulting mass market beer is excellent in its \*consistency\* and clean, slightly grainy, slightly bitter taste, though it doesn't suit most homebrewers who've tasted real malt and hops in a brew.

Aussie homebrewers have been mainly influenced by English publications - Dave Line, Winemaker magazine and a few others, who just about all use sugar in their recipes. Hence my comments which were prompted by reading 'The Cat's Meow' - most of the recipes from you lot are all malt. Those that use other sugars include honey, dextrose (which I believe ferments cleanly) or fruit. I love it! There's more variety and sheer INTEREST in TCM than in ten 'Brewing Beers Like Those You Buy'. I'm changing my ways as a result of seeing how American homebrewing has advanced - my sanitizing methods have improved, I'm leaving the sugar on the shelf, and I've been inspired with enough recipe ideas to keep me going a lifetime!

So, what I meant to ask was, how did you arrive at the all malt position? What bad experiences have you had with cheap fermentables? Or good ones?

John, I didn't say that I drink beer with no malt taste (unless someone else is buying!), as I said, once you've had a real, malty homebrew, there's nothing quite the same!

P.S. I didn't get HBD 646 either

Watch those boiling kettles![the above is the opinion of David Taylor]

>know the state of beer there -- bars, micros, etc...

We have three brewpubs. The first two are part of the MacMenamin (sp?)  
chain (big in the Portland area).

- High Street Brewery & Cafe

\*Beer Art: They carry a nice range of their own brews. The standard  
bearers are Crystal (self explanatory) and Terminator (industrial  
strength

stout). Usually one can find about 5 others, including some strange  
ones: Ruby (raspberry), blueberry, or rose petal. Their beers are  
pleasant

and not at all objectionable. As well, they will have about 10 beers  
on tap representing other Northwest micros.

\*Ambiance: An old house festooned with deadhead paraphernalia. Very nice  
patio in the back with tables under the maples. Great on a hot day  
(here >70).

- East 19th Street Cafe

\*Beer Art: As above.

\*Ambiance: Former submarine sandwich joint converted to a merrye olde  
englande pub by a group of new agers with florescent paint. In the  
student ghetto next to the track stadium. Our favorite for department  
meetings Friday afternoon.

- Steelhead Brewery

\*Beer Art: Rather disappointing, but since they're in their start-up  
phase I should withhold judgement. They carry the usual range - pale,  
amber, stout, plus a special (bock, etc.). Palatable, but a bit harsh.

\*Ambiance: Nice decor - woodwork and brick (nearly a fern bar). Fewer  
students than the other two; more interesting food.

>mead with caps, or corks.

I bottle mine with corks, but I don't think that it really matters. I've talked to the winemakers at a couple wineries about this, and they said that corks are used now days mostly because their customers associate corks with better wine. Crown caps are cheaper, and provide a better seal. I use corks for the same reason as the wineries - they look better.

Subject: Re: Mashing Crystal and Cara-Pils Malts?

In HBD #653, Mark Rouleau says:

> On the other hand, won't mashing convert all those dextrins  
> into simple sugars that yeast like? If so, what happens to the  
> rich mouth feel and sweetness that these malts are intended to  
> produce?

Yes, mashing can convert the dextrins in crystal malt to simple sugars.  
But it

won't convert the caramelized sugars, and that's part of the intended  
contribution of crystal malt, as well. So, what about mouth feel and  
sweetness?

They must be controlled with mashing temperature, which can be adjusted  
to

favor a dextrinous wort. Or, you can add the crystal after the mash, just  
like

you would in an extract brew.

From: <S94TAYLO%USUHSB.BITNET@CUNYVM.CUNY.EDU>  
Subject: Light Struck beer.

The problem with UV exposure of beer is that a photoisomerization of certain hop components occurs, producing a "skunky" aroma. In some beers on some occasions, it is VERY distinct. The worst I've had it was with a fifth of Steinlager (have you had one yet?) from New Zealand. It is bottled in green glass, which doesn't absorb very much in the high frequency wavelength. Brown glass absorbs very well in this range. Finally, to answer the question that was asked in #653, most breweries DON'T protect their beer in green or clear bottles, and it IS susceptible to skunk. Miller Brewing Co. chemically converts their hop components so that they can no longer be converted into the skunky aromatic, while still retaining its hoppy character.

Subject: Re: Homebrew Digest #652 (June 05, 1991)

On the subject of dry ice for beer carbonation I would like to post two comments that came in since HBD652. First, dry ice is not known for food-grade cleanliness, so anything carbonated with it should probably be consumed within a day or two to avoid the possibility of spoilage.

Second,

the formula I gave was for volumes CO<sub>2</sub> at room temperature, 25 degrees C. If you want to calculate volumes at 0 degrees C you have to use 22.4 liters

per mole, not the 24.4 that I gave.

So, Al, did it work? --Jean

Subject: UK beer festivals this summer

I just got this info in from a friend in England - sorry, I don't have anything other than dates and places. For more info try CAMRA, 34 Alma Road, St. Albans, Herts AL1 3BW, UK

At long last the boys have got around to sussing out prospective beer festivals this summer. The following might be of interest:

June 21-22 Surrey  
June 26-29 Greenwich (London)  
June 28-29 Exeter (Devon)  
July 2-6 Chelmsford (Essex)  
July 10-14 Derby (Derbyshire)  
July 12-14 Ashton (Manchester)  
July 13-14 North-Sussex  
July 13-14 Woodcote (near Reading)  
July 18-20 Kent  
July 27-29 Wynchcombe (Cotswolds/Gloucestershire)  
Aug 13-17 London arena (the big one! - CAMRA GBBF)

happy festing,

Is this James Clement the same one who (I believe) owns the Chapterhouse,  
and who briefly ran a brewpub near Syracuse University called "Clement's  
Brewpub" (which has since reverted to being "Hungry Charlie's")? I  
always  
try to visit the Chapterhouse whenever I'm in Ithaca, and I've been  
wondering about the "story" behind the Chapterhouse's origins and the  
owner's plans for expansion of his brewing enterprise.

Also, how widely will the products of the Clement Brewing Company be  
distributed? And does anyone know the story behind the rise and fall of  
"Clement's Brewpub" in Syracuse?

By the way, I'm glad to see that Michael Jackson has paid a visit to the  
Chapterhouse; a favorable entry for it in one of Jackson's books will  
make  
for excellent publicity for an otherwise (in my opinion) too little-  
known  
establishment.

From: mike@ranger.bison.mb.ca (Mike Charlton)  
Subject: Mashing High Dextrin Content Malts

I don't really have any proof for my explanation of why mashing crystal leaves dextrins, but I think it is fairly reasonable. Basically, the reason that the complex sugars are not reduced to more simple sugars is that the enzymes work at a certain rate. They convert starch into complex sugars and convert those complex sugars into simpler sugars. The typical mash leaves a certain amount of complex sugars in the wort simply due to the fact that the length of the mash was not long enough to convert all the complex sugars. That being the case, when we increase the level of complex sugars at the beginning of the mash (by adding crystal malt, etc.) that level is still present at the end of the mash (although, probably not derived from the crystal malt itself, since that would have been converted right away). Anyway, you can get a fairly good idea of the dextrin content of your wort by closely inspecting your iodine test. Starch will turn iodine blue and simple sugars do not change the colour appreciatively. However, complex sugars will change the colour of iodine to a fairly dark brown. By inspecting the colour of the iodine test you can fairly easily get an idea about the fermentability of the wort and can adjust the length of time you spend mashing accordingly.

I've used crown caps on large beer bottles, and plastic champagne style  
corks on -- oddly enough -- champagne bottles. Both worked just fine.  
Since  
I \*thought\* I was making a sparkling mead, I tied down the champagne  
corks  
with champagne-cork-wire-thingies: kind of a pain-in-the-ass to do, and  
unnecessary, cuz it came out still anyway.

I'd guess caps would be easiest, but make sure they fit your bottles.

From: dbreiden@mentor.cc.purdue.edu  
Subject: Use of sugar

David Taylor (I think) asks what good and bad experience we've had with using sugar in our brews. Here's my bit:

I've had mediocre experience, and striking experience. The mediocre stuff was beer that wasn't half bad, but not quite as good as what I make now. The best thing about homebrew is that one's first efforts are really good even if the recipes use a lot of sugar -- the freshness must compensate.

One very stiking batch was a pale ale. My brew-partner and I used a fair amount of cane sugar in the batch. The stuff was awfull for quite a while. I think the yeast was partly to blame, but the stuff smelled and tasted almost like apple juice for a good 5 weeks. But once that went away, and it did, what remained was a clean, refreshing, beautiful beer.

People have come forth and admitted to using sugar in their brews with good results. It just creates a beer with different characteristics -- and isn't that what homebrewing is all about?

From: peterson@ddd.prepnet.com (Mike Peterson)  
Subject: Trouble with trub, crystal malt

Hi. I've got a couple of questions for you gurus out in homebrew land. I am an intermediate extract/speciality grain brewer who has been making some tasty (IMHO) brews for a while but needs some pointers on technique so that I can completely RELAX! I am having a bit of trouble removing the trub and hop bits before adding my wort to the primary. I typically add 1/2 tsp. of Irish moss 15 minutes before the end of the boil to aid the hot break and cool the wort by placing my brew pot in a sink full of cold water. The funnel I use for transferring the wort to the carboy has a fine screen in it for catching particulate matter. Upon pouring the wort through the screen, the screen becomes immediately clogged and I spend 20-30 minutes transferring the wort as I must continually pause to scrape the the screen clean. Though I'm not worried, I am concerned about exposing my wort to the air for so long. I also find I am getting lower starting gravities because so much wort is caught up in the trub and hop bits. Is there a simple way around my problem?

I am thinking of building a simple immersion wort chiller as I've seen dicussed in this digest, in the hope that more effcient cooling will precipitate trub better. I am also thinking of placing my hop pellets in a homemade hop bag made from some cheese cloth. Will this be alright? Does using a hop bag decrease hop utilization? Hop aroma? Enquiring minds want to know!

On a different matter, does anybody know the approximate degrees Lovibond (sp?) rating of crystal malt. The stuff I have been using is making my beers darker than I like and I was wondering if I got a bad batch or something?

Sorry if any of theses questions have been previously discussed. Thanks in advance for the advice.

Mike Peterson

Subject: Mashing Crystal and Cara-Pils Malts?

On Wed, 5 Jun 1991 11:12:21 EDT,  
Marc Rouleau <mer6g@fuggles.acc.Virginia.EDU> said:

Marc> Dave Miller claims in TCHOHB that you should mash all special  
Marc> malts to extract everything from them. He says that the processes  
Marc> that produce crystal and dextrin malts do not convert all of the  
Marc> starch. Merely steeping them wastes potential extraction and,  
Marc> because of the unconverted starch in the boil, reduces the clarity  
Marc> of the beer.

Marc> On the other hand, won't mashing convert all those dextrans  
Marc> into simple sugars that yeast like? If so, what happens to the  
Marc> rich mouth feel and sweetness that these malts are intended to  
Marc> produce?

I got interested in this during the last discussion, and  
did some more reading on it. I should probably go back  
and read some more before I open my mouth (for fear of  
sticking my foot in it), but here goes ...

I think there are a couple of things that keep you from  
converting "all those dextrans" into fermentable sugars.  
First of all, mash temperature will have a lot to do with  
how fermentable your wort is. A higher temperature mash  
will leave you with more unfermentables, as the enzymes  
are denatured by heat over time. I think the beta(?) -amylase  
(Papazian's "nibbler") stops working at a lower temperature,  
and I would think that this is the enzyme that makes most  
of the fermentables. (sorry if I've got alpha- and beta-  
amylase mixed up, go check Papazian). This is why a hotter  
mash will give you fewer fermentables, and a fuller bodied  
beer from the unfermentable dextrans.

Also, (here's where I get hazy) I think there are dextrin  
configurations that alpha- and beta-amylase cannot break  
down. I think these "limit dextrans" are different for  
each of the enzymes. So while you're mashing, you've  
got a couple of things keeping it from going too far:  
some of the dextrans get in a configuration where the  
a- and/or b-amylase can't do anything to them, and the  
heat is destroying the capability of the enzymes to break  
down the dextrans that they CAN still work on.

Subject: heretic again

Dave Taylor wonders:

-  
>I am wondering how the commercials can use sugar and produce light but  
>clean tasting, relatively high alcohol beers, when if I use sugar I  
>often get estery cider flavours that cause me to tip the batch out.

In particular he wonders about how the can use cane sugar. My bet: they don't. I bet they use corn sugar (or corn syrup, which I believe contains the same sugar). This mailing list has a strong phobia about using sugar in homebrew. I don't. I use it in every batch and I never get cidery flavors.

I owe this to two things:

NEVER USE CANE SUGAR (or beet sugar) because this contains sucrose which is only partially fermentable. A friend made his first batch using sucrose -- very cidery. Corn sugar is dextrose (which I believe is just a commercial name for glucose) which is fully fermentable.

Ferment cool. I ferment at about 60 degrees F. I did notice some very off tastes when I fermented at 80F. Chest freezers with Hunter AirStats do wonders!

CAVEAT: I can only speak for extract/adjunct brewing, but I really don't see why mashing would be any different with respect to sugar.

In the UK we can buy a bag for sparging and boiling. It is tough enough  
to  
stand the heat even if touching the element, and large enough to permit  
good movement of hops when boiling. It fits over the rim of the boiler  
providing an effective inner liner. The trub gets filtered out in the  
spent  
hops leaving a completely clean wort before cooling. I imagine something  
like this must be available in the USA.

I was at the Germanfest last year and got two tours. The first was with  
a group of people from the festival who knew very little about beer and  
then  
later on my wife and I got an individual tour. The staff was friendly and  
answered all my questions on how to improve my homebrew. It is definitely  
worth the trip. I enjoy their beer, which are all lagers, and the  
opportunity  
to drink from the lagering tanks was great. My wife drove home. :8^)

The beer is fermented in oak vats that were made in Czechoslovakia. As I  
recall they had at least four of them and probably more. I think each one  
held 50 hectoliters which is about 1320 gallons. The person who built  
this  
brewery spent a lot of money. There are three rooms, each at a lower  
temperature  
but I forget the time the beer spends in each room and also the temps.  
From  
an article I read in a local paper a while ago, James Clement bought the  
brewery a while ago and it makes beer primarily for upstate New York  
brewpubs. It was available in bottles in Northern New Jersey about  
6 years ago but since it was bottled the way us homebrewers  
bottle this didn't last too long. I keep asking them if I can  
bring over my siphon and some bottles... (:^). I do know the beer is  
available in Hoboken N. J. and at a bar in Morristown. If anyone  
wants more information let me know and I'll post a follow-up.

Subject: First All Grain Experience

Another HBD reader (hi Dave) and myself brewed our first all grain batch two days ago and had a wonderful time. Here is a debriefing of our best lessons.

We made the "ordinary bitter" recipe out of Miller's TCHOHB.

Mashing was easier than we expected, sparging was harder than we expected. One innovation we tried that worked out well was to wrap the mashing vessel in an electric blanket that I never use anymore. We held it on with some surgical tubing I had around and set it to its highest setting. Starting from 150 degrees F, the temperature dropped to 145 during the two hour starch conversion. We never needed to boost the temperature.

We also used the compressed hop plugs rather than pelletized hops. This had the unexpected side effect of making the transfer to the primary \*much\* easier. The larger size hop flakes were kept under better control by our hopping bag, and thus the funnel filter did not clog nearly as badly.

The raw wort tasted wonderful. We can't wait.

Millstream. Not typical American beer in my opinion. Their lagers are to be enjoyed for what they are, not swilled. Their wheat beer is their "light" concession to the American taste; their Millstream and Schild Brau labels are all-barley lagers with good flavor. Millstream's process is interesting for the age of their yeast; they have recycled it since day one. It must be nearing ten years old now. Remarkable for a microbrewery.

> - The "Dubuque Star" brewery in Dubuque, which is so small that it

> on their beer, so that pubs or restaurants can have their  
> "house brand".

Dubuque Star has a very well-deserved bad reputation for piss-poor beer. The scuttlebutt from employees is that this is because the former owner shortened the brewing cycle drastically to improve profits. This led to loss of sales and eventually the owner sold the brewery. The new owner and brewmeister has (have?) taken the skunkiness out of the beer, but the current generation of Dubuque drinkers may never drink it again.

Actually, at student drinkers. Imagine a cheap bottle'o'Bud with "Foecking" scrawled in lurid pink on the label. Great for those dorm beer parties. "Hey, gimme a Foecking beer."

I see. Mashed crystal malt will color beer red and add some caramel  
flavor, but you should use the mash temp to control the body.

I suppose this means that there's never any reason to mash cara-pils  
malt, right? If its only purpose is to add dextrins to the wort,  
you might as well do it by mashing at a higher temp.

Lovibond  
> (sp?) rating of crystal malt. The stuff I have been using is making my  
> beers darker than I like and I was wondering if I got a bad batch or  
> something?

The answer is "only your supplier knows for sure". Ask your supplier.  
There are lots of grades of crystal malt. One catalog I have lists three  
grades of crystal - 10 Lovibond (light crystal), 40 Lovibond (amber  
crystal), and 110 Lovibond (Dark crystal). My local supplier specs his  
"dark crystal" as 38 degrees Lovibond. My experience is that my 38  
Lovibond is very dark - a little bit goes a long way - I hesitate to  
use  
more than one half to one pound in amber beers.

From: darryl@ism.isc.com (Darryl Richman)  
Subject: re: Trouble with trub, crystal malt

Mike, crystal malt comes in a whole range of color ratings from 20L through 120L. Around here all of the crystal malt has a lovibond rating with it so you always know what you're getting. Of course, 2 lbs of Crystal 20 isn't the same as .5 lb of Crystal 80, even disregarding the difference in extract potential. The flavor changes as the malt gets darker. The lighter malts tend to leave a sweeter, grainier flavor behind, while the darker crystals move towards a drier, caramelly flavor that also brings with it a slight sour tang that can be interesting in a complex, estery bitter pale ale, or old ale.

To better separate your trub and hops from your wort, try whirlpooling. After the boil is finished, stir the pot round and round without splashing to avoid aeration. Do it for a solid minute, then cover and cool in the sink as you are doing now. When cool, siphon from the side of the pot into your fermenter. The whirlpool has the effect of piling up all of the solids into a cone at the center of the pot.

From: darryl@ism.isc.com (Darryl Richman)  
Subject: re: heretic again

Geoff, sucrose IS completely fermentable. It works just fine, for example, to prime your beer. I, too, have noticed the strong tendency against using sugar in homebrew, but there are MANY commercial producers that use it. It is widespread in the UK, and many of the Belgian brewers use it to beef up the alcohol without adding a tremendous body--after all, their beer has got to last a couple years.

However, your are right on the money as far as controlling the temperature. The presence of high levels of single sugars can actually turn the yeast off of fermenting double and triple sugars, and create stuck fermentations and large amounts of by products. At cooler temperatures, the yeasts' metabolic pathways are held in check.

One place that sugar is not prevalent is here in the USA. I suspect that that is mostly because we pay tremendous price supports for sugar, amounting to as much as 6 times the going world rate.

transferring  
>the wort as I must continually pause to scrape the the screen clean....  
>I am also thinking of placing my hop pellets in a homemade hop bag made  
...

Hop pellets seem to leave more solids in the wort than whole hops.  
If you're going to the trouble of a home made hop bag, consider  
whole hops. Besides, they look more, well, natural.

My local brew store had three different types of screens: course,  
medium, and fine. The fine screen is practically unusable - it  
plugs up too easily. For most of my brews, I've used the course  
screen - makes for a nice chewy brew :)

Subject: Re: Trouble with trub, crystal malt

On Jun 6, 5:28pm, Mike Peterson wrote:  
> I am having a bit of trouble [ using a small screen ] removing the trub

I have a fine-mesh straining bag that I bought from Alternative Beverage (1-800-365-BREW) and a stainless steel kitchen strainer with a handle. I fit the bag inside the strainer and rest it atop a 7.5 gallon bucket. Then I use a small SS pot to dip 70-degree wort out of the boiler and into the strainer until it's mostly clogged. I wait for most of the wort to drip through (it never clogs completely) and then remove the mesh bag from the SS strainer. I squeeze the bag to force out the rest of the wort and then dump the trub and rinse the bag. One more iteration always suffices to finish the job. All told, straining into the bucket takes me about five minutes, and minimal trub ends up in the fermenter (a 7 gallon glass carboy).

As a matter of fact, I've been reusing the yeast cake on the bottom of the fermenter for several months (five batches) without cleaning the carboy, and there's very little trub mixed in with the spent yeast.

While I'm talking about this, I'd like to say that I took the discussion about excessive sanitation from a few months back to heart. For these five batches I have used no bleach or any other special sanitary measure. I just clean stuff to ordinary kitchen standards. I rinse my bottles with tap water three times when I empty them and three times before I fill them. I routinely top off my chilled wort with tap water to make five gallons. I don't even worry about the dry brown stuff that sticks to the carboy after a fermentation is over. I rinse most of it off with fresh wort when I drain it into the carboy.

The yeast in my carboy are descendents of a Wyeast 1007 (German Ale) packet that I used in November. I've brewed 10 batches with it and have no intention of stopping. I have not experienced any problems whatsoever. If anything my yeast are more vigorous than ever.

Now I haven't kept any homebrew around for longer than 3-4 months, so maybe I have all sorts of subtle nasty slow-moving infectious bacteria infesting my brew ... but I've seen no evidence of anything wrong.

Anyway, if/when I get an infected brew I promise to 'fess up to the HBD. Until then I'll post a "this is still working and it's great!" message every few months. :-)

And thank YOU, Father Barleywine, for sharing your experience regarding sanitation and repitching. Brewing is A LOT more fun now that I've learned to trust my killer yeast! :-)

I've seen Crystal malt from 10 to 120 Degrees Lovibond. Ask your  
supplier what you've been using. If you want to get the dextrines  
of a Crystal malt without the color (and caramel flavor) try Dextrine  
malt (also called Cara-Pils, which I believe is a trademark of Breiss  
(sp?) Malting Company, somewhere in southeastern Wisconsin).

From: microsoft!larryba@cs.washington.edu  
Subject: Re: Trouble with trub, crystal malt

In yesterdays Digest, Mike Peterson asks about how to efficiently get hops and trub out of his wort before it gets into the primary fermenter.

I use a counter flow chiller and pellet hops. When I turn the heat off and the boil stops I get the wort going in a vigorous whirlpool. By the time my counterflow chiller is set up (about 5 minutes) the whirlpool has stopped and almost all the hot break and hop pellet junk is in a heap in the bottom. Since my racking tube is off to one side, it doesn't pick up much gunk. This works very well in a boiler with reasonable height to diameter. For huge fat canning boilers it doesn't work as well.

If you use an immersion chiller, before swirling, you should get most of the cold as well as the hot break. After swirling, cover and let sit for 10-20 minutes so everything has time to settle down.

The nice thing about counter flow is that you can avoid most air contact with wort and the wort is still hot enough (>180f) to stay sterile until it is in the bowels of the chiller.

The bummer with counterflow chillers is cleaning them out. I have never figured out a satisfactory solution for the kitchen brewer. Commercial microbrewers use nasty corrosive chemicals and lots of very hot water. I just rinse well after each use. Before the next use I drain all the bleach solution used to sanitize my carboy through the chiller before draining the hot wort through it into the carboy. I also toss the first pint of wort to make sure no bleach gets into my wort. Probably draining a couple of gallons of boiling water through the chiller w/o chilling water would work as well as avoiding bleach.

> "Clement's Brewpub" in Syracuse?  
>

Hungry Charlie's has existed for eons. It was there when I  
grew up in the area and when I went to school at Syracuse University.  
It had always been a big beer hall for underage drinkers at S.U.,  
until neo-prohibition starte setting in, and the city started  
arresting the bartender (pitcher server, actually). Thus, in order to  
remain open, Chuck's (as it is affectionately known), had to refuse  
entrance to anyone under 21, effectively killing ~75% of there  
business. Therefore, in order to make any semblance of a profit, it  
had to go "upscale." Previously Chuck's premium beer was Molsen  
Golden, but the big favorite was Piel's. Now it started selling  
imported bottled beers of high quality (for about the same price as a  
pitcher of Piel's used to be), and started brewing it's own - hence  
Clement's brew-pub became the new name. It's own brew I've admittedly  
never tasted, (I no longer live in the heart of central new york), but  
I don't think, from my friends comments, that it would have rated more  
than one star from Michael Jackson. This was still much less  
profitable than the original beer hall, despite not having to have 4 or  
more large bouncers constantly evicting drunks who vomitted on the  
floor. Thus, once the city had cooled down a bit, it returned to being  
Chuck's, and has even returned to the age-old daily specials it used  
to have. I do think they still brew, as architectural changes were  
necessary to convert it.

Subject: Brewing in the summer.

Rob Bradley asks about brewing in Illinois in the summer. There's always the "wet t-shirt" method (carboy in washtub full of water, t-shirt over carboy dipped into water). I've never tried this, but I know it worked for others on the net. However, I would suspect that your efficiency would be poor (maybe only 5F drop in temp) since it is very humid in the Chicago area in the summer. Also, you would increase the humidity in your room unless you had very good ventilation (oh, the sacrifices we make for our loved ones (yeast)!).

Subject: Iowa Info.

Greetings! Just a couple of notes to answer Mark (Stroup) et al; Here's the scoop on Iowa -

Mark, First of all, Welcome! Mount Vernon is a very pretty place. Congrats!  
Not too far from any of the following:

1. Fitzpatrick's Pub, Iowa City (Gary Fitzpatrick, brewmaster). Tasty products available only at this, Iowa's first, brewpub. Three staples: (pale) ale, (light) lager, stout. Gary is also having fun with various seasonal brews. He is there much of the time; Introduce yourself and ask him for a tour.

2. Millstream Brewing Co., Amana (Larry Schantz, brewmaster). A very tidy microbrewery. You'll find there three products around Iowa, bottled and on draft (all unpasteurized!): a light lager (simply called Millstream), an amber lager ("Schildbrau" - gold medal winner, '89 GABF, my favorite), and a wheat beer (gold medal winner, '90 GABF).

3. Dubuque Star Brewery, Dubuque. This is a sad story. This brewery has changed hands several times recently. Sad because it is the only surviving brewery after prohibition (Iowa had 138 commercial breweries before the turn of the century!). I, currently, can't recommend any of their products: Zele, Foecking, etc.

4. Heartland Homebrew Club. Let's finish on a positive note! We have an active AHA club here in Iowa. It currently has around 35 families from all over Iowa involved, from Allerton to Ames, West Des Moines to Iowa City. The club is based in Grinnell, but our monthly meetings rotate at member's homes. We, of course, do a lot of road trips too: Annual Fasching/Bock Beer Festival in New Ulm, MN (Schell's Brewery); Great Taste of the Midwest - Madison, WI; Great American Beer Festival (CO); AHA regionals and nationals. We have won a number of ribbons at the Iowa State Fair (21 last year alone!), and have taken a few at the AHA nationals too. Hey, we like good beer. The two brewmasters above (Gary and Larry) are in the club, and we get some nice tours and lots of info. from their commercial establishments.

I'd better get back to work. Drop me a note when you get settled. I'll send you an invite to our next meeting.

For better beer,

Craig Olzenak  
Heartland Homebrew Club  
1030 High St.  
Grinnell, IA 50112  
515/236-4033

Subject: Mach Guinness

I am afraid I sent this submission to homebrew digest requests. Sorry about that. I am re-submitting this, hopefully to the right place this time.  
kls

Greetings.

I am new to the digest, and this is my first letter. Please forgive what the ASCII transfer to E-mail does to its format.

I have brewed a Guinnessesque brew that turned out so well that I must share it. I call it Mach Guinness and it has soured ale in it, so I will give you both recipes.

Mach Guinness

5 lbs pale 2 row British malt  
1 lb rolled barley  
1 lb roasted barley  
  
2 lbs lighth dry malt extract  
2 cups corn sugar  
2 Oz bullion Hops (1.5 boiling, 0.5 finishing) (preferably whole)  
1 pkg Whitbread Ale Yeast  
2/3 cup corn sugar

Mashed 5 lbs 2-row, rolled barley and roasted barley  
Mashed in at 132 deg F.  
Protein rest 30 min  
Starch Conversion 2 hours at 153 degrees  
Mashed out 15 minutes at 168  
Sparged with 4 gallons 172 deg water

Add the 2 lbs dry ME and the 2 cups sugar. Bring to a boil. Add 1 1/2 oz of hops. Boil 1 hour. Add 1/2 oz of hops, turn off heat, and let stand for 15 minutes. Cool wort to 72 degrees, strain into fermenter, and pitch yeast.  
(note: I personally cool the wort in the boiler and then pour it through a strainer to oxidize it and remove the hops, as opposed to straining it hot, which oxidizes it)

S.G - 1.066  
T.G - 1.016

Ferment 7 days. Rack and settle 6 to 9 days.

One to two days before bottling, sour two bottles of ale. To do this, pour two bottles of ale into a steril glass container. Cover with a clean cloth secured with string or rubber band. Put in the cupboard (or somewhere

relatively dark and warm) and let stand one to two days. It should sour, but not mold.

At bottling time, put 2/3 cup corn sugar in the sour ale, and boil for 10 to 15 min. Add this to the bottling container, and siphon wort into it.

This gives a good mixture without having to risk stirring it. Bottle and try in two weeks. The flavour changes week by week and levels off after 6 weeks.

This stout is creamy, but not as heavy as some, with a head that takes almost 30 seconds to form, lightly bitter, with that back of the throat sourness from the soured ale.

Now, the beer I soured is a unique ale, and you dont have to use it, but it is also very good, and I know it worked:

Ides of March Ale:

- 1 cup brewed Kenya AA coffee
- .25 lb Black Patten malt
- .25 lb chocolate malt
- .25 lb 40 deg crystal malt
- 1 lb rice syrup
- 1.5 lb light dry malt extract
- 1.5 oz Willemette whole hops
- 1 can Coopers Draught Kit
- 1/2 cup corn sugar - bottling
- ?? finings (follow directions on bottle)

In three gallons of brewing water, put Black Patten and Chocolate malt. Bring to a boil. After boil just starts, strain out grains. Add coffee, crystal malt, rice syrup, dry ME and 1.5 oz willemette hops. Boil 45 min.

Add Cooper Ale Kit, and continue to boil 3 to 5 min. (much longer and the finishing hops in the Coopers kit make the brew bitter)

Cool and pitch with Ale yeast from the Cooper Kit.

S.G. 1.046  
T.G. 1.012

Ferment 7 days. Rack and add finings (or polychlar). When settled, bottle with corn sugar.

Hope someone tries these and has as much luck as I had. Later - kls

....

p.s. A lot of people want info on head retention. I have found that a lot of times they have a fine brew which gives good head, but the glasses it is served in cause it to de-head. Whenever I serve a beer to guests, I always do a hot water rinse to remove dust, a cold water rinse to recool the glass, and then dry with a paper towel. It only takes a second and presents your beer in the best possible state.

Subject: Brewery Tours in Britain

A friend and I are going to Britain for a few weeks in August (hopefully catch the CAMRA beer festival) and I was wondering if there was anyone out there who could recommend any brewery tours. We will be going all over the place, so we could theoretically hit anything in Britain. Also, I've heard that it's best to contact the brewery ahead of time to find out when tours are happening. That being the case, could someone give me a pointer to the addresses of likely breweries so I can send them a letter.

Thanks in advance,  
Mike Charlton

Hey Brewfreaks,

I read a interesting book..its called "Making Beer" by William Mares I am fairly new to homebrewing..anyway a section in his book told the story of Fritz Maytag (the heir to the Maytag fortune) and how he purchased the Anchor Steam brewery on a whim back in 1965, my question is this, has anyone been able to come close to duplicating anchor steam at home? What I know about it is that it requires sanitary conditions beyond belief.

From: R\_GELINAS@UNHH.UNH.EDU (Russ Gelinias)  
Subject: High FG, BFD info

Mr. Ed's Oatmeal Stout is finally in the bottle. I was hoping the specific gravity would fall a little more, but it's done at 1.026, down from 1.062. I think the cause is a partial mash (3 lbs. pale 2-row and 1 lb. oatmeal) at too high a temp. The strike water was too hot, and I didn't want to add too much cold water. It spent too much time in the high 150's. Have I made a reasonable deduction?

Brew Free or Die members: What was discussed at the meeting on Saturday?  
I'd appreciate an e-mail overview if you were there. (7.5 month pregnant wife + 2.5 year old daughter = .not.BFD meeting). Thanks.

From: Jean Hunter <MS3Y@CORNELLA.cit.cornell.edu>  
Subject: Re: Trouble with Trub (HBD #655)

To add to the anti-trub arsenal: I use leaf hops in a cotton mesh bag to finish, generally adding them as I'm turning the heat off under my big canning kettle. After the immersion chiller has done its work I fish out the bag and lodge it atop the fine screen in my big funnel. Then I siphon off the wort through the hop bag. Not only are extra hop flavor/aroma compounds extracted out (I think!) but the bag and pad of hops act as an effective filter aid to catch trub and fragments of pellet hops. After all the wort has gone through, I press down on the bag with a big clean spoon to squeeze out the last drops.

Another decent alternative is to leave the last quart of wort and trub in the boiling kettle. After pitching, come back and filter out the trub with a coffee filter, then freeze the wort. Next time you want to make a starter culture or some agar slants, you have known-quality wort all set to go with only a brief sanitizing boil needed before use. Oh, you can also add your O.G. sample to it unless you're a confirmed wort sipper (yum). -- Jean

Either you've been lucky or I've been unlucky. Like you I just used to give everything a good wash out, often with boiling water. Notice the past tense though!! I got away with it for about ten batches. The last time I did this (about two years ago) I noticed fermenting bin was getting a bit brown and made a note to use a chlorine cleaner before the next brew. I was too late! It fermented messily all over the floor. It looked foul and slimy; it stank. I tried barreling it anyway in the hope it might come right. It didn't and I had to throw it away. It then took \_ages\_ to get the taint out of the barrel. It only takes one bad batch to change your mind.

A small selection straight off the top of my head:

Hook Norton, Banbury, Oxon.  
Wadworths, Devizes, Wilts.  
Youngs, Wandsworth, London.  
Fullers, Chiswick, London.

There are hundreds of others. CAMRA may give you a more complete list.  
Mail  
me for their address if you do not have it already.

Come to that, a tour of the whisky distilleries in Scotland can make for  
a  
glorious hazy holiday.

From: keng@ic.MENTORG.COM (Ken Giles)  
Subject: Cleaning counter-flow chillers, try TSP

In HBD microsoft!larryba@cs.washington.edu says:

> The bumper with counterflow chillers is cleaning them out. I have  
never  
> figured out a satisfactory solution for the kitchen brewer. Commercial  
> microbrewers use nasty corrosive chemicals and lots of very hot water.

I've had good success with TriSodium Phosphate (TSP). TSP is not so  
corrosive to  
be dangerous (gloves are recommended but I often get it on my arms with  
no ill  
effects), but acts like a corrosive cleaner. I tried an experiment. After  
I  
rinsed and ran the usual bleach solution through my counter-flow chiller  
until  
it ran clear, I ran a solution of TSP through, and it came out yellow and  
eventually ran clear. The TSP was able to clean beyond the power of the  
bleach  
solution alone. No real surprise. TSP is also great for dissolving the  
gunk out  
of your blow-off hose.

TSP is available in the paint section of most hardware-type stores. It's  
used  
for preparing surfaces for painting. I've heard that some homebrew  
suppliers sell  
a dry bleach/TSP combination called tri-chlor. I don't use this because  
I'm  
typically only cleaning afterward (with TSP) or sanitizing beforehand  
(with  
bleach).

Stay clean,

kg.

Yes.

Empty- the state I prefer to leave mine in

:-) :-)

> Because I have on several occasions had a Miller go skunky on me within  
> a matter of seconds of exposure to direct sunlight  
The sunlight-hop reaction takes more than seconds. I seem to remember the  
number of 30-45 minutes as being right to convert a sufficient quantity  
for the  
skunkiness to breach the threshold for human detection. Of course you  
could  
have an amazingly sensitive palate to this substance..

From what I've heard/read Miller has a patented process which they use to  
treat  
the hop oils (they don't add whole hops) that they add to their beer.

gallons  
>of boiling water through the chiller w/o chilling water would work as  
well  
>as avoiding bleach.

Maybe commercial brewers use nasty corrosive chemicals but many  
brewpubs use boiling water or wort just like we do. My technique is  
this:

Follow a chilling session with a gallon or so of boiling water through  
the coils after draining the chiller body of its water, to cut the  
malt sugars from the copper. Usually I follow that up with some of the  
sterilant (I use 1 T. clorox per 1 gallon of water) that I've been  
using for that session, until the sterilant runs cool from the coil  
(since high temperatures destroy the disinfectant effects of clorox).  
Drain. Store dry.

Prior to the next session of brewing, I will usually fill the chiller  
coils back up with the sterilant solution and let it sit for about 20  
minutes. Drain. When I begin the chill routine, I run the boiling hot  
wort through the chiller prior to filling the chiller body with water.  
The boiling hot wort will sterilize the coils for sure. Toss the first  
few ounces of wort that comes through since some clorox will be in it.  
Let a quart or so of wort run through then return it to the boiler.  
Fill the chiller body with water and let 'er rip.

The boiling wort through the coils is what really does the trick with  
this routine just like it does with immersion chillers. So why do I  
still use the clorox solution? It's simple. It only takes a minute  
and I'm paranoid as hell!

The most effective means for straining wort into the fermenter  
discussion has popped back up so here again is my pot-scrubber-in-a-  
mesh-bag technique for filtering hops:

I've never been a fan of pouring wort through a filter because filters  
clog and you're bound to pour at least some trub into the fermenter.

Buy a copper wound pot scrubber and a fine mesh hop bag. Also get a  
rather thick rubber band. It also helps to have a copper pick-up tube  
if you're going to siphon hot wort into your fermenter. If you're  
cooling it first, one of those plastic pick-up tubes will do the trick.

Tie the pot scrubber around the bottom of the pick-up tube (the end

that's going into the wort). Then tie the fine mesh hop bag around that, in effect putting the pot scrubber in a bag. (Oh, yes, "No see-um netting" from a camping store works well, also.)

Tie a small 1/4" overhand loop in one end of the rubber band. Loop the other big end around and through the handle on your boiling pot. Now slip the pick-up tube through the small end of the rubber band. If you've tied the small loop small enough, the rubber band will grab the pick-up tube at whatever position you want. Suspend the pick-up tube a couple of inches below the top level of the wort. Start your siphon. The mesh bag/pot scrubber combo will effectively filter out all the hop leaves and particles. By siphoning from the top level of the wort, you'll always be siphoning off the clearest portion of the wort. As the level of the wort recedes, slowly inch the pick-up tube down accordingly, always keeping it an inch or two below the surface. This technique will give you the cleanest possible run-off into the fermenter without clogging the siphon.

Others have commented on the effect of whirlpooling the wort before starting the siphon, so I won't comment on that.

Cheers,

Kinney Baughman  
baughmankr@conrad.appstate.edu

Date: Mon, 10 Jun 91 15:21:02 PDT  
From: Martin A. Lodahl <pbmoss!malodah@PacBell.COM>  
Subject: Trub Removal, etc.

Ah yes, trub removal. The method I use seems to alarm some people, but the only trouble I've ever had with it is when it works too well.

I use an immersion chiller. At the end of the boil, I immediately begin chilling, and keep going until the temperature differential between the tap water and the wort is about 20 degrees F, or so. I use the hot water this generates for cleanup. Then I attach a pump, and recirculate ice water through the coils until the temperature is near freezing. I then do the whirlpool thing, and rack into a sanitized carboy, which I cap and leave overnight to settle. In the morning the wort is very clear and there is a generous layer of previously-suspended trub on the carboy floor! I rack into my fermentor (7-gallon acid carboy), and pitch.

In a sense, I was better off before the chiller, when I was doing mainly partial-mashes. Since I was boiling only a part of the total volume, I could use ice directly in the wort to chill. I usually boiled the water first, but not always. Never a problem, and some of the best cold breaks I've ever had.

The concern seems to be sanitation. While I can't go as far as Father Barleywine (having tasted altogether too many contaminated homebrews and microbrews, and since I culture *Pediococcus damnosus* and *Brettanomyces bruxellensis* for use in making imitation lambics), I have to say that I've never had a hint of infection using this technique. I live in a microbiologically relatively benign climate; your mileage may vary. The only problems I've ever had with it are when I've sacrificed too much wort in the interest of keeping trub absolutely out of the ferment. There seems to be some interaction between trub and yeast in the aerobic phase, and feeding the yeast just a little of it seems to start the fermentation a bit faster. I can't quantify this; it's altogether an impression. Also, a trubless brew can end up "too clean", especially after the wild originality of your first few batches.

I was surprised to hear Dr. Michael Lewis say that they'd researched the effect of fermenting with varying degrees of trub in the brewing lab at U. C. Davis, and had found it made much less difference than they'd expected. It made a rather large difference in my beer, I can tell you!

Date: Mon, 10 Jun 91 18:16:13 CDT  
From: Darren Evans-Young <DARREN%UA1VM.UA.EDU@hplb.hpl.hp.com>  
Subject: Trub removal,cleaning copper,reusing yeast,cleaning counterflows

Trub removal:

When I first used leaf hops, I followed the suggestion from the HBD and used a copper pot scrubber with a muslin (cheesecloth type) bag wrapped around it and secured to my siphon tube. I got all of my wort out and left behind the trub which stuck to the leaf hops. This worked so well that for my next batch using hop pellets, I did the same thing. I got a very small amount of trub in my primary. As the mass of shredded hops moved toward the siphon pickup, it acted as a sort of filter. I was amazed how well this worked for pellets and it is now a part of my brewing procedures.

Cleaning copper:

Whenever I use copper for the first time, whether tubing or a pot scrubber, I always boil it with some vinegar. This removes any oxidation off the copper and leaves it shining bright...also sanitizes it inside and out...Rinse well!

Cleaning counterflow chillers:

I simply run hot tap water through mine for about 5 mins after use. Before my next usage, I again run hot tap water through it, then use a weak bleach solution for 5-10 mins, then run hot tap water through to rinse. Works well and I've never had a contamination problem.

Reusing yeast cake:

I thought I'd give this a try. Boy does it work! I had fermentation going within 15 minutes of pouring in my new wort. By the next morning, I had blown the top off the fermentation lock in a 7.5 gallon carboy and foam was oozing everywhere! Is this normal for reusing the yeast cake in a primary? I'd definitely NOT do this again without using a blow-off tube. Seems like this method of reusing yeast is overpitching and causing the yeast to skip it's reproductive stage. How will this affect flavor?

Darren

Subject: RE:Info About Scotland Needed

In HD 645 Lars Nilsson posted a request for information on the Scottish beer scene, demonstrating a keen grip on the importance of good planning for a successful vacation. Well Lars, it's your lucky day. As it turns out

I have friend in St. Andrews who was willing to E-mail some information. The following is a synopsis of his communication:

\*PUBS\*

- i) Glasgow (Downtown)
  - :Horseshoe Bar (Drury Lane)
  - :Imperial Bar
  - :Bon Accord (Charing Cross)
  - :Zutz
  - :The Scotia Bar
  - :Blackfriars (jazz on Thur/Fri/Sun)
  - :Vale of Clyde (Queen St. station)
  - :Brahms & Lizst (near Odeon Cinema)
  - :Gordon's Bar
  
- ii) Glasgow (West End)
  - es Bar (back of Kelvin Hall)
  - :The Halt Bar (Woodside Rd.)
  - :Usage Breethe (Woodside Rd.)
  - :Chummy Chengs (Gt. Western Rd.)
  
- iii) Glasgow (Pollokshaws)
  - :Hergathy's Bar
  - :Titwood Bar
  - :Allison Arms
  
- iv) Edinburgh
  - :Cafe Royale (behind Scottish records office)
  - :Hebrides Bar (near Waverly Station)
  - :Greyfriars Bobby
  - :various pubs on Rose St. and on the Grassmarket.
  
- v) Stirling
  - :West End Bar
  - :Cairns
  - :Cross Keys
  - :Porters Bar
  - :Birds & Bees

Although Scottish beers are not in great abundance (in terms of variety) they are available along with a plethora of British ales. Some of the brews you can expect to come across are:

Tennent's Lager (Are you ready?), McEwan's Lager, McEwan's Export, Sunderland (Draught Bitter), Newcastle Brown Ale, (Take Up) Hemeling (Lite Lager), Carling Blacklabel, Camenoris Strongarm (The Mightiest of Beers), Federation Brewery Lager, M&B Brew XI (Have a pint of the Midlands),

Norseman Lager, Camenoris Best Bitter, Courage (Light Ale), Bank's (Traditional Draught Beers), Courage Beer, Theakston Ales (150 Years of Tradition), The Royal Silver Jubilee, Whitbread Shandy, Lion Lager, 70p, 80p, Tartan Sp.

As far as homebrew shops are concerned, there is one on Main Street in Stirling and there is one in St. Andrews. I couldn't get any information on breweries that offer guided tours, but I'm sure a few well placed phone calls will get you the help you need once you are in Scotland.

Good luck and happy drinking! I hope that this posting will be helpful to any HD subscribers who may find themselves in Scotland some day...it certainly has wet my appetite! Cheers.

re Brewery tours...

I am planning on Sam Smith's Old Brewery in Tadcaster (Yorkshire), and Hall and Woodhouse in Blandford Forum (Wiltshire) on my September trip. For me, these are on the "must visit" list.

Cheers...Gary

Subject: Punts

> My question is:

> Why is there a punt?

Haven't spent my honeymoon last summer in Napa Valley sipping a wide assortment of wines, I have heard a few explanations for the punt. The most common (and reasonable IMO) is that the quality of glass used to be unreliable at best. Glass is weakened by expansion, and strengthened by compression. The pressure from the champagne compresses the punt, thereby greatly increasing the probability that the bottle will survive the aging and transportation processes.

The glass bottles built today probably don't need punts, but punts don't hurt, and there's a tradition now.

I've also been told that the "proper" way to pour champagne is by sticking your thumb in the punt with your fingers cradling the lower side of the bottle, pouring with one hand by tipping your lower arm. It's easier to do than it sounds. You get really good balance and control. I recommend that you practice a lot at home before trying it at a party.

Subject: Mashing Dextrin Malts

I realize there has been much written on this in the past weeks, but I have not heard a complete explanation, ala Dave Miller, at least not the way I understand it. Many subscribers have written the pros and cons of mashing crystal and dextrins malts, asking whether the enzymes in the mash break down the dextrins added for body into fermentable sugars.

The way I understand it, and please correct me if I'm wrong, is the principle enzymes active in the starch conversion are alpha and beta amylase. These work by breaking the long strings of glucose molecules in a starch into shorter strings (in different ways, but that is not pertinent to this discussion). The catch is that these amylases are only capable of breaking 1-4 links in the glucose chain ( a bonding structure creating a linear chain of glucose ). The dextrins in malt also have side branches off the linear chains, which are connected by 1-6 links, which can only be broken by another enzyme, dextrinase (which is present in malt but very temperature sensitive, and therefore eliminated in the kilning of even light malts). The result of this is that glucose chains or molecules are broken off the ends of a dextrin until a 1-6 branch is reached, at which point the amylases are unable to break any more bonds. The resulting dextrin is called a limit dextrin because the amylase enzymes can break it down no further. For this reason, there should be no problem with mashing crystal or dextrin malts because the body and head retention enhancing effects should result from limit dextrins which remain even after an extended starch conversion rest.

Sound about right folks? Please e-mail me directly with any more valuable insights into this process.

From: Matthias Blumrich <mb@Princeton.EDU>  
Subject: Starting yeast

Hi. The last time I made a lager I filled a beer bottle with sediment from the primary and stuck in in the fridge with an air lock. That was about a month ago. I want to make a porter now and I'd like to reuse the yeast. I got some dry malt extract so I can make a little wort. My question is, how should I go about doing this? I have large (24oz) beer bottles, so should I make like 15oz of wort and then add some of the sediment? Or is that not enough? Papazian mentions culturing in beer bottle size portions, so I think it should be ok...

From: marcs@SLC.COM (Marc San Soucie)  
Subject: Brewery Tours in Britain

Mike Charlton asks:

> A friend and I are going to Britain for a few weeks in August  
(hopefully  
> catch the CAMRA beer festival) and I was wondering if there was anyone  
> out there who could recommend any brewery tours. We will be going all  
> over the place, so we could theoretically hit anything in Britain.  
Also,  
> I've heard that it's best to contact the brewery ahead of time to find  
> out when tours are happening. That being the case, could someone give  
me  
> a pointer to the addresses of likely breweries so I can send them a  
letter.  
>  
> Thanks in advance,  
> Mike Charlton

Desmond Mottram replies:

> A small selection straight off the top of my head:  
  
> Hook Norton, Banbury, Oxon.  
> Wadworths, Devizes, Wilts.  
> Youngs, Wandsworth, London.  
> Fullers, Chiswick, London.

Another brewery tour most highly recommended to American visitors is at  
the  
Samuel Smith brewery in Tadcaster, Yorkshire. I've taken the tour once  
and  
missed it by a day once. In neither case was I disappointed, because even  
if  
you cannot do the tour, the Angel And White Horse pub next door, owned by  
the  
brewery, offers one of the most lavish and sumptuous English lunches  
imaginable, washed down, of course, by fine Samuel Smith ales and stouts  
(emphasis on the plurals).

The tour that I took some years back occupied about two hours of the  
early  
after, and encompassed the entire brewery, from stables to bungs. The  
brewery  
is a marvel to behold, as they continue to use a few pieces of equipment  
from  
their early days in the late 1700's. There is nothing sterile and  
over-modernized about this place. It speaks volumes about its gradual and  
thoughtful evolution from a tiny backwoods brewery to its current status  
as a  
tiny backwoods brewery with an international reputation. There were also,  
you  
might imagine, some fine free samples at the end - I recall being regaled  
with  
a pair of pints, and purchased a set of engraved SS pint glasses to bring  
home  
with me - pride of the collection.

Their brewing practices are fascinating, the building is gothic in its peculiar suitability to the task, and the very town of Tadcaster, for most people a dull semi-industrial backwater, is itself a monument to beer and brewing, sporting besides Sam Smith a John Smith, Magnet, and Bass brewery. And all within 4 hours' drive of London. Call ahead and schedule your trip around this tour. You will be rewarded handsomely.

From: kscoles@pnet51.orb.mn.org (Kevin L. Scoles)  
Subject: Primitive Brewing

Greetings again.  
I belong to a living history organization (Clann Tartan Scottish Pike Troop) which performed at a 1730s Theme Park. For my part, I mashed out 6 gallons of

all grain beer ... Over an open fire.  
All equipment had to be in the period of 1630 to 1730. For kettles I used enameled canners. For a sparge tun I used a new nail cask and a muslin sparge

bag (from the U.S. Treasury). Regulating a wood fire to 152 degrees for two

hours is a bit of a task. And the ashes were sure to cange the pH.  
Flies?

What flies?

I guess the only reason I am even sending this is because it was a good time.

My character would not have been able to afford a hydrometer (if they even

existed back then (thank goodness thermometers did)) so I didn't even take a

specific gravity. It was fun to answer peoples questions on how I cultured

the yeast by soaking grapes in a malt medium, and showing them how to crack 7

pounds of 2 row malt with a rock on a plank. It was also neet to see the knowing looks from all the old timers (since Minnesota has a long brewing history).

The beer is still in the primary, but when it is done, I will write again.

So if you want to put the troubles of dry hopping and trub and keg laws and

all that stuff out of the way, you might want to do an out doors mash and get

back to the basics just for the fun of it.

Later kls

From: JWHITE@maine.maine.edu (Jim White)  
Subject: All grain brewing ?

I've read much discussion, in this digest, regarding various chillers, mashing tubs, temperature control ..... etc, related to all grain brewing.

I'd like to solicit some opinions about whether or not it's worth the (seeming) effort involved.

- Is the final brew, in general, superior to an extract brew? If so, why?
- What kind of time commitment are we talking about to wort creation?
- How much more water do we use? Do we have to condition the water?
- How about \$\$ investment in equipment (minimum required) ?
- Is the final per bottle cost less, or more?

I'm relatively new to the list, and I suspect this subject has been discussed many times in the past, but I'd like to know, 'Why do you brew how you brew'?

>effort, btw), Papazian, nor HBD (from #577 to date) discuss  
>strawberries as an ingredient in beer. Why? Any recipes or  
>brewing suggestions?

Basically because strawberries don't have a very strong flavor.  
I have used raspberries and blueberries. While I normally  
consider blueberries to have a strong flavor by themselves, they  
didn't add all that much flavor to the beer in proportion. The  
raspberries did fine, though. I would suspect you could put 8  
lbs. of strawberries in and still not notice the taste when it  
finished. But what do \*I\* know?

John "BTW, when I printed the PostScript directly from my Unix  
machine to the Apple LaserWriter, it came out 'Catus Meow'. When  
I transferred to the Mac and printed it out, it came out  
properly. Anyone else notice this?" DeCarlo

-----  
d, I  
believe, but his book is pretty old as well.

What you mostly see in the U.S. is a reaction against the  
old-fashioned type of recipe you still see on some kits. You  
know, "Empty the can in a bucket, throw in a bag of sugar, toss  
in the yeast, fill with water, and enjoy delicious beer in a  
week." Yow! This is not to say that you can't ever use sugar  
(one of my best bitters was one I primed with brown sugar), but  
that people like myself avoid it because it has a tradition of  
overuse. Plus, the German beer purity law, the Rheinheitsgebot,  
has become sort of a way of knowing the beer is good for some.

>So, what I meant to ask was, how did you arrive at the all malt  
>position? What bad experiences have you had with cheap  
>fermentables? Or good ones?

Like yourself, many of us have gotten cidery tastes from too much  
sugar. Plus, all the old recipes called for it in large  
quantities, and many people remember an "Uncle Ted" who made  
homebrew and the bottles exploded and people got sick from  
drinking it. So maybe we overreact in avoiding sugar nowadays.

>John, I didn't say that I drink beer with no malt taste (unless  
>someone else is buying!), as I said, once you've had a real,  
>malty homebrew, there's nothing quite the same!

Plus, as you mention here, the all-malt taste can be quite addictive.

Subject: help a poor vaxman reach the archives, and anyone in CT?

Greetings,

I have been reading the digest for some time now and I've seen some discussion about using the archives. However, I still have not seen anything that I can understand. I'm a Vaxman and I get this digest through bitnet. If there is anyone out there who understands how to use the archives from a Vax (I'm especially interested in getting the Cat's Meow) could you please send me a tutorial? The only networks that I have direct access to are bitnet and decnet. If interest is expressed, I'll post a summary of any info that I get.

By the way, is there anyone in the vicinity of New Haven, CT, out there? Does anyone know of any homebrewing clubs or microbrewerys? Here in New Haven we have the New Haven Brewing Company that puts out some pretty good beer--Elm City Ale and a nice stout called Blackwell Stout (I think). Brewpubs are still illegal in CT I believe, but the NHBC has been working against that.

Thanks,  
Joe

P.S. I think that I just sent a message with no text by mistake. Sorry.

Subject: HBD vs. Usenet

In HOMEBREW Digest #657, Joe Kagenski asked:

> alt.brew is now showing up at our site, Does anyone know if this  
> group is new?

Yes, it's new, created this week by someone with more enthusiasm than judgement, in my opinion, who apparently found the process of creating a brewing newsgroup in the rec.\* hierarchy exasperating.

> Also, has any consideration been given to combine/cross-feed this  
> with the other?

Yes, much consideration has been given to it. This comes up a couple times a year, and the answer is always overwhelmingly the same: DON'T DO IT. A part of the magic of HBD is its excellent signal:noise ratio, its relative freedom from pointless personal attacks and content-free postings, which are regular "features" of Usenet, especially in the alt.\* hierarchy. HBD works because of a (usually) tacet agreement by its members to maintain its excellence. The alt.\* hierarchy, on the other hand, prides itself on irresponsibility, and serves a reader community with very different tastes. Creating a crossfeed between the two would, in my opinion, be worse than pointless.

**Subject: Punts**

Another explanation for the "punt" at the bottom of wine bottles is that it makes production of hand blown bottles faster and cheaper; obviously a desideratum for bottle producers. The reason is that the depression provides a greater ability to withstand the stresses that build as the glass cools after the bottle is blown and knocked off. This allows the blower to anneal the bottle simply by burying in sand (for instance) instead of having to process it through an annealing oven of some kind.

The added ability to withstand the compression load from champagne is an additional explanation for why most champagne bottles still have a punt.

> rest.

I haven't noticed any loss of sweetness when I mash crystal malt  
(but then again, I use more when I mash than when I don't), but  
have noticed significantly poorer head retention when I mash.  
This is only from my limited experience; I offer no explanation.

Now a question: what is the best original S.G. for a yeast starter  
bottle?  
Does it matter? I just made a starter for Wyeast english ale this  
morning, and the wort couldn't have been denser than 1.010.

From: microsoft!larryba@cs.washington.edu  
Subject: Re: Dextrin Malt and Mashing

Y'all should re-read Miller again on this subject. Per Miller, ref DeCleric, Dextrins have little/no effect on body, mouth feel and head - these are all due to medium weight protein molecules. So, regardless of limit dextrins and how you add your carmel malt, etc. It is the proteins, not the sugar, that determines body. Apparently Cara-Pils is malted and kilned to produce a large amount of the appropriate proteins (read high degree of modification - same as Carmel and English Pale/Mild Ale)

Therefore, if you put in a bunch of Cara-Pils and then have a long protein rest (low Ph helps) you will overcleave the proteins and screw up the head and body of the beer anyway. The protein rests and all those steps are intended to get the appropriate ratio of low weight molecules, for yeast nutrients, and medium weight for body and head retention.

Sometimes I mash at high temperatures simply to get a high TG and low alcohol content while still retaining that All Malt Character that I enjoy so much. Since I always do Single Infusion Mash (even for lagers), I rely upon the skill of my maltster (whoever that is) to modify the grain and kiln properly for reasonable head/body.

Read, Read and Read some more: that is what improved my beers the most!

-----

Date: Wed, 12 Jun 91 12:47:59 -0700  
From: carl@ism.isc.com (Carl Hensler)  
Subject: punt

The concave bottom of the champagne bottle, the punt, is that shape to prevent the development of a bending moment in the glass under pressure. If the end is the correct shape, the material is only in tension or compression, with no significant bending. Cylindrical pressure vessels always have concave or convex ends for this reason. It is intuitively obvious why the champagne bottle does not have a convex end.

Subject: Re: Homebrew Digest #657 (June 12, 1991)

I think that I made this entry once before but it went into #646 (or whatever it was that it seems nobody received)

Concerning British Breweries: My experience has been that you do need to call ahead. Every place that I've visited has needed an appointment.

My favorite trip was a visit to the Theakston Brewery in Masham, Yorkshire. In my opinion, it has the smoothest XB in the UK. The Brewery doesn't offer tours every day of the week, but the tour they give is educational as well as historically interesting.

At the end you get a free bottle of OP - they don't currently have a Hospitality House. I think they were in process of doing something on that.

If you do go, take the time to visit all three local pubs that carry the brew. I had a hell of a time tasting the XB and making the rounds. It's a short stint from York proper and very much in the Yorkshire countryside. The trip back to Lancashire that day provided some of the most breathtaking scenery my frazzled memory contains.

From: polstra!norm@uunet.UU.NET (Norm Hardy)  
Subject: Zymurgy / Urquell / Richman

The latest zymurgy magazine came today and I was very impressed by the article of the Pilsner Urquell brewery done by Darryl Richman, who is probably reading this now. He toured the brewery and gave wonderful detail about the brewery, the process, and the result.

For those who want to duplicate Urquell (good luck, but who doesn't?), the description of the triple decoction was worth the price of the subscription.

I do have a question however: at what temperature is the wort when the yeast (one of three interestingly enough) is pitched? The article did mention 41f as the fermentation but didn't state the pitching temp.

Date: Thu, 13 Jun 91 14:23 EST  
From: David Taylor <DAVID@phillip.edu.au>  
Subject: Re: Jackson's Beerhunter

Gooday homebrewers!

Happily for those of us in Australia, our Special Broadcasting Service has started to show Michael Jackson's 'Beerhunter' series. The first episode featured the beers of Belgium. It was great, presenting a fascinating account of the tradition and culture of beer in Belgium.

A few interesting points:-

No-one has ever pronounced LOM-BEEK to me before, I always thought it was Lam-bic (as spelled).

Jackson commented that paintings by the old Flemish masters show beverages being poured from jugs. It has been assumed that this was wine, however, he asserts that the peoples' drink has always been beer, and this is what is being poured.

Scenes around the Lindemanns Brewery were shown, including the uncovered fermentation vessels surrounded by cobwebs and the open windows to allow entry of the wild yeasts. I wouldn't try that at home!

Hops used are aged for three years to reduce their aromatic contribution, and the wort is boiled for \*FIVE\* hours in a coal fired kettle - it must take great skill to regulate the heat.

A brewer is shown adding cherries to a barrel to provoke a secondary fermentation to produce Kreik. They were straight out of a box. I hope he followed them with a handful of Camden tablets!

Many beers were shown and I recognised a lot of the names - I've tasted only a few of them - how does a bloke get a job as a 'Beerhunter'?

Subject: Re: Jackson's Beerhunter

I have a couple things that have been a problem now that I'm "kegging" my beer...

I've set up a Cornelius tank tapping system, two taps, no waiting. The following problems have arisen:

1. I've tapped two tanks now, a dark amber and a variation to the Rocky Raccoon honey recipe, both were relatively flat! In analyzing what could have gone wrong, I suspect that there was too much B-brite left on the interior of the tanks when I racked into them and primed. The residual chemical could have zapped my yeast, right? I've been told I should rinse with clear water after using B-brite to sanitize, is that true? The other possibility is the tanks leaked at the seals in the poppets or the main lid gasket. I used Papazians suggestion of purging the air and pressurizing to 5 lbs. with CO2, then I checked for leaks and had none (at that time). Is there a recommended way to guarantee a good seal on these things?

2. After these two tanks came up flat, I artificially carbonated them. I was having company over in a couple days specifically to taste some home brew and didn't want to try re-pitching at room temp. again and letting it sit for a couple more weeks. So I ran the CO2 up to 35+ lbs for 2 days and then brought it back down. The beer is somewhat carbonated now, but DAMN do I get foam city when I draw a glass from the tap! Is this inherent in the Cornelius system when tapping beer? Since the beer has to travel up that thin tube from the bottom of the tank and then go through some turbulence to get through the quick-disconnects at the poppets? I wonder if I get the conditioning problem solved will I have this extreme amount of head? The beer is definately not over-carbonated once I get enough collected in my glass, but I have about 75% foam in my glass trying to draw one. Does artificially carbonating beer add to this foam problem? FYI - I'm running 3/16" tubing from the quick-disconnect fitting (Pepsi style tanks) up to the faucet (through wall mount) all of about 1 foot in length. I'm running 5/16" tubing from the CO2 tank outside the fridge about 4 feet to the tanks.

This is my first submission to the digest, I hope I didn't over do it. Thanks for any replies.

Stan

why?

Unquestionably. I brewed from extract for years because it was cheap and easy. I still do sometimes if I'm short of time. But I never achieved beer to match the quality we love and know so well. So I plucked up courage and invested in the gear for full mash. It's been great!! Now I can brew beers that can match the best available commercially.

Extract beers have off-tastes and lack flavour, body and aroma. Mashed beers, even light ones around 1030 OG, are full of hop and malt tastes, and character.

There is no doubt IMHO that mashed beers are vastly superior to extract, but you do have to be keen as they require more effort and initial expense.

> - What kind of time commitment are we talking about to wort creation?
