Due to equipment limitations I pitch my lager yeasts at 70f and then stick the primary in my refer to chill down to 48f. That seems to work fine. I have never worried about shocking yeast with moderate temperature differentials (48->70f) - of course, I might be damaging my beers without knowing it. Someday I will chill the wort to ferment temp, rack off the trub and pitch active yeast just to see what, if any, is the difference.

I have made only 4 lagers so far (all grain). The last (the vienna) was lagered in the secondary for two months (see above). It tasted great as soon

as I kegged and carbonated it. I presume it will taste better over time (if it lasts).

The previous lagers were fermented, kegged and carbonated and then lagered. They all had a distinct DMS smell that dissipated quickly after pouring. I am guessing that the lagering in a vented container was what allowed the DMS smell to dissipate from my latest effort.

Also, I ferment, lager and deliver my beer at 48f - I only have one refer!

From: gjfix@utamat.uta.edu (George J Fix)  
Subject: Re: Lager Questions

I have been asked to post a brief review of my experience with dry hopping.

For better or worse here it is!

Let me first say that I have a very high regard for the practice. There are

to be sure certain styles where it does not work. Some Belgium beers come to mind where hop flavoring of any kind is unwelcome because it would interfere with other characteristics deemed to be more desirable in these styles. Continental lagers (light, amber, or dark) are perhaps another class. Here the "kettle hop flavor" (taste and aroma) is presumably more appropriate than a "dry hop flavor". With these two possible

exceptions noted, I feel dry hopping can be used to advantage in just every thing else. A fact that is often overlooked, but one that is well documented in historical references, is that dry hopping was extensively used in turn of the century brewing in the US. According to one reference (Zimmermann) the practice was essential in rescuing American lagers from what otherwise would be a "unforgiving blandness". While popular taste has changed since then, the reaction systems which are capable of rescuing a beer from blandness have not!

The first practical point to be made is that our hops are loaded with microbes. In a recent study the folks at Cal-Davis have identified over 100 strains of yeast and bacteria in hops that are potentially aggressive to beer. They also examined the effects from these microbes when hops are added "as is" to fermenters. In all cases they found no effects. There was usually 100% mortality within the first 48 hours of active fermentation, and even with heavily infected hops the microbes were too weak to become metabolically active before their demise. They concluded that the addition of unsterilized hops to the fermenter is a safe practice. My experience is compatible with these findings. I have, however, been disappointed in the results with this particular method

for reasons that may or may not

be relevant to others. My biggest complaint is the instability of the hop aroma so produced. It tends to disappear after the beer is served, and losses intensity with age (in either bottle or keg).

Because of this I feel the storage tanks are the best place to dry hop. The extra contact time helps with the stability of the aroma, and valuable hop volatiles are not scrubbed out with CO<sub>2</sub> as they tend to be in the fermenter. Another bonus is the mellowness of the hop bitter that is extracted. All of the harsh bitter constituents (iso-betas and other resins) are insoluble in beer at storage temperatures. Given time they will precipitate out.

Infections will not automatically result if hops are added "as is" to storage tanks. My experience is that infections will occur at most 10% of the

time. The suggestion of sterilizing hops by soaking them in a 80 proof spirit (mentioned in an earlier Digest) is imaginative, and surely will cut down on the number of times infected flavors arise. However, it has been my experience that such spirits are not a complete sterilant. Beer spoilers can not grow in such media, but they can survive the experience. To

get a complete kill one may have to go a 180-200 proof spirit, something as a matter of personal preference I would not like added to my beers in even

small amounts. I have been working with steam sterilization as an alternative

to "as is" addition. There will be a loss of hop oils, but if the steam can be kept dry, this can be held to a minimum. For example, if the hops are

suspended in a pressure cooker(which will give moderately dry steam),  
then  
only five mins. at full pressure is needed for a 100% kill,and the loss  
in oils  
is only around 50%.Thus,if your recipe calls for 1/2 oz. dry hops, one  
need only double this amount to achieve the desired effect.  
One final point--and by a wide margin the most important--is that oxygen  
has deleterious effects on every aspect of hop flavor.I have found a  
direct  
correlation between the stability of hop aroma and the mellowness of hop  
taste with the following:  
    (i) amount of dissolved oxygen in storage(This is normally zero)  
    (ii) oxygen pickup in transfer  
    (iii)amount of air trapped in the final container at fill  
As any of these are increased ,Ihave found the hop aroma tends to become  
more unstable and the hop taste becomes harsher.  
Mike:I hope this is what you were looking for.

>I pitched the alt 2 weeks ago and the fermentation lock is still  
bubbling  
>away. Since i am going in for surgery Friday and will not be able to  
lift  
>a carboy for a week, would the Wyeast Alt be Ok for another 10 days?

The "Dictionary of Beer and Brewing", compiled by Carl Forget says the following:

ATTENUATION. The percentage reduction in the wort's specific gravity caused by

the transformation of contained sugars into alcohol and carbon dioxide gas through fermentation. The fermentable sugars in the wort (which have a higher specific gravity than water) are converted into alcohol (which has a lower specific gravity than water) and carbon dioxide gas (which escapes as gas).

$C_6H_{12}O_6 \rightarrow 2C_2H_6OH + 2CO_2$

The percentage drop in gravity is measured with a saccharometer and calculated as follows:

Formula:  $A = (B - b) / BX100$

Example:  $(12 - 4) / 12 \times 100 = 66.6\%$

A = attenuation: % of sugar of the original wort converted into alcohol and carbon dioxide after or during fermentation.

B = original gravity in deg. Balling (or Plato) prior to fermentation.

b = specific gravity in deg. Balling (or Plato) after or during fermentation.

Yes, the Wyeast Alt yeast is slow, but I found the German yeast slow too. Don't worry about your beer. It will be fine for another 10 days. Your health is more important. Get well soon! I hope you'll at least be able to lift a glass after surgery. ;-)

From: jm@sead.siemens.com (Jeff Mizener @ Siemens Energy)  
Subject: Beer Related Trivia

I just returned from a business trip to Berlin (not exactly the brewery capital of the universe) and while there, I learned the following factoid, here revealed in the context of a story:

I was going out to dinner with a colleague in Berlin and his wife, and as we exited their apartment, I noticed hops growing outside his front door. Wow, I said, this is great. Germany is beer country, hops growing outside everybody's front door! Why, they asked, was this so interesting?

Well, said I, I'm going to start brewing my own beer, and some people whose writings I have read (in this digest...) are growing their own hops. How very nice, they said, to be able to brew your own beer. Why?

You see, it's illegal in Germany.

Why? Taxes, don't you know.

And even at the most high-priced store in high-priced Berlin (Ka-De-We), a half litre of Erdinger Hefeweizen (the best), costs only DM1.78. (About a dollar and 15 cents, Altenmuenster costs a bit more).

And I could get 4 of them in my briefcase.

Next time I'll take a bigger briefcase. The customs man said a whole case wouldn't bother him.

Relaxed,

Jeff

From: eisen@kopf.HQ.Ileaf.COM (Carl West)  
Subject: attenuation, spelt, bananas

Best I can tell from my reading, the sugars we are generally concerned with can be classed as single, double, triple, and quadruple. Bigger than that and they're either starches or unfermentable or both (shows how clear I am on the subject). Anyway, your wort has all these sugars in it. Some yeasts can only digest single and double sugars (low attenuation), some can digest those and triple sugars (medium attenuation), and some can digest all four of these classes of sugar (high attenuation). Where alcohol tolerance comes into play, I'm not sure, but I don't think it matters to most of us because the yeast runs out of food before it hits that limit (my theory). An extremely high gravity wort might be another story.

Spelt:

Spelt is probably being touted as healthful because it's chaff stays with the seed, more fiber!

Bananas:

You've heard of people smoking banana skins? Well apparently there's something to it, I'm told that sub-fatal doses of arsenic can cause hallucinatory experiences. Guess what gets concentrated in banana skins? Arsenic. Probably not a good homebrew ingredient. Peel 'em.

Head:

I'm still mystified about wanting a head on your beer. I understand that a well retained head indicates that the beer probably has good body, but I can determine that with my mouth. :) For me, a thick head just means I've either got to wait for it to go down or get it all over my moustache (tray swave and de-boner). I try to pour so I don't get much of a head, it's much less inconvenient. Just what am I missing?

From: hartman@varian.varian.com (John Hartman)  
Subject: Torrefied Wheat, Say What?

Hi All--

I'm an all-grain brewer who would like to try my hand at making a version of Young's ESB. According to "The Real Ale Drinker's Almanac", by Roger Protz, the recipe calls for Maris Otter pale malt (97%) and torrefied wheat (3%).

Does anyone have specifics on Maris Otter pale malt? Is it any different from ordinary English 2-row pale malt?

I'd like to use torrefied wheat but have been unable to locate a U.S. supplier. My understanding of torrefication is that it involves roasting unmalted grain (possibly under pressure) until it pops or puffs like puffed wheat. Does anyone know of a supplier of torrefied wheat or of a procedure for making it?

Thanks in advance,  
John (hartman@varian.com)

Subject: Oven sanitizing bottles

In HBD 731 Jeff Frane sez:

>>I HATE sanitizing my bottles.

Amen. I have found the simplest and most effective way to deal with this nagging problem (on advice from WYeast's Dave Logsdon). I put my clean bottles in an oven, turn the temp to 350^ and leave them for 1-1/2 hours, turn off the oven and let them cool down to be filled. This can be done the night before bottling or if I want to do it well ahead of time, I put little foil caps on each bottle before sterilizing, then put them back in their cases (with the caps intact) until I'm ready to bottle. No problem! This has made the whole concept of bottling \*much\* more palatable.

I too have used this method and it seems to work great but I have one concern. The same person who demo'd this idea at the local beer club meeting mentioned that after three or four times in the oven the bottles would become substantially weaker. Now if like me you have one set of clean, delabeled dark brown bottles that you use over and over, this seems like not such a wise idea. The person who put forth this information is a doctor and works in a lab sterilizing things etc. for a living so I'm inclined to beleive her but I'd also like a couple other opinions before I give up on this method because like Jeff said it makes bottling much more palatable. Anybody heard of Pyrex beer bottles!?

From: hpfcmr.fc.hp.com!hplabs!uunet!bnr-vpa!bnr-rsc!crick (Bill Crick)  
Subject: maibock, checkvalves, grain, and washers

4 Questions:

1. I have what I believe is a Corona grain mill. To get a good crushing, I have to loosen the bolts that hold the outer grinding plate to the point that its holder wobbles around a bit. I have thought of putting a 0.5mm washer in there(NOTE recent post about needing washers). This is with the bolt that pushes the spring loaded ball to put tension on the outer plate wound right out to no tension. IS this normal? What is the tension spring for then? If I tighten the two bolts holding the outer plate holder tight, I get far too fine a grind. COMMENTS?  
Note I've been using this mill like this for several years, and with the bolts loose, I get a good grind, but adjusting the grind is tricky.  
Also I wonder if the wobbling of the plate and its holder is the reason that about 5% or so of the kernels aren't crushed (mainly smaller ones).
2. For people running multiple kegs off of one CO2 cylinder, how do you stop things (deadly microbes say) from migrating from one keg to the other?  
Are there check valves between the regulator or manifold, and each keg?  
Also how do you clean or sanitize the gas lines? I've never seen anyone mention this in any procedures. If you got a contamination in one of the kegs, wouldn't it get into the lines? Or again is there a check valve I don't know about.
- 3.Regarding Grain prices, we just bought 100lbs of two row malt for \$36.00 Canadian from a place called Great Western Grain Supply. The malt was by Canada Malting. That's \$0.36Cdn per pound. It came in a woven plastic grain bag with a heavy duty plastic liner.
4. Does anyone have an all grain recipe for Mai Bock?  
Why don't the books that list beer classifications mention Mai Bock?  
Most seem to think BOck is always a dark beer?

To: HBD  
Fm: Jack Schmidling

RE: caa@com2serv.c2s.mn.org (Charles Anderson)  
Subject: Grain Prices

In an otherwise useful source testimonial, Charles presents us with the following MOMILY:

>Other Brewing grains that they have are Wild Rice (I was surprised to find out talking to James that wild rice is a member of the barley family, and is not closely related to the regular rice that A-B adds to bud.).....

Jack says:

This would surprise any taxonomist because it is totally wrong. First of all, there is no "barley family" and secondly because wild rice is more closely related to commercial rice than any rice is to barley.

ALL Cereal grains belong to Gramineae (Grass Family)

Hordeum vulgare 6 row barley  
Hordeum distichum 2 row barley

Oryza sativa commercial rice  
Zizania aquatica wild (Indian) rice

There is no question that wild rice has far more flavor than commercial rice and probably a more interesting adjunct to a beer.

His motivation is on target but the analysis is strictly from "mom".

> CO2,  
> resulting in a drier beer with a lower final specific gravity. Less  
> attenuative yeasts will leave more sugar unconverted, resulting in a  
> sweeter beer.

This is close, but obscures why yeasts are attenuative or not. The term actually refers to the *range* of sugars that the yeast will digest. A more attenuative yeast can handle more different types of sugars than a less attenuative one. Since a brewery wort is composed of lots of different sugars due to incomplete degradation of starch in the mash, a yeast that has difficulty with longer sugars will leave a sweeter beer. (And because adjustment of mash temperature can have a large effect on the make up of the wort sugar profile, this can also result in a sweeter or drier beer.)

There is a particular genus of wild yeast, *S. diastaticus*, that has the ability to break down longer chain sugars into simpler ones, and when you get this type of infection, your beer comes out very dry and thin (and smelling of phenols and DMS, since it is not a very refined fermenter...). One might say that *diastaticus* is ultimately attenuative.

If indeed it is a Corona mill you have, the addition of the washers is  
normal. That was the only way I could achieve the correct grind.  
Tension spring? There is no tension spring on my grinder but I have a  
10 year old model.

> If I tighten the two bolts holding the outer plate holder tight, I  
get

I presume that's because the mill was made to turn grain into flour  
for making bread instead of cracked grain for making beer.

Many long years ago, we made an alternative treat to popcorn, that we  
called  
"popped wheat". We ate it like popcorn, with butter and salt. Making it  
is  
really easy: Just cover the bottom of a heavy dry skillet with whole  
wheat,  
and place over fairly high heat. Keep the pan moving so the wheat  
doesn't  
scorch. A lid is a good idea, although the wheat doesn't explode  
violently  
the way popcorn does. It does "pop", sorta, and looks a lot like puffed  
wheat, but is much tastier (fact, not opinion %^/).

I don't know if this is the same as "torrefied wheat" or not. But if it  
doesn't seem right, just pour it into a bowl, add a bit of melted butter,  
a  
shake or two of salt, and serve with a glass of ESB.

Date: Fri, 27 Sep 91 09:50:06 PDT  
From: Bob.Clark@Eng.Sun.COM (bobc@wings.Eng - Bob Clark)  
Subject: Kegs, backflow valves, tap cleaning

For people running multiple kegs off of one CO2 cylinder, how do you stop things (deadly microbes say) from migrating from one keg to the other? Are there check valves between the regulator or manifold, and each keg? Also how do you clean or sanitize the gas lines? I've never seen anyone mention this in any procedures

I run a line from the regulator output to the manifold, with no check valve. On each output from the manifold I have a check valve, and on the end of the CO2 line to each keg is the normal quick disconnect. This setup:

1. Prevents one high-pressure keg from forcing back-flow to a low pressure keg
2. Allows me to have lines disconnected while keeping other kegs pressurized.
3. Forces all kegs to eventually be at the same pressure (the output pressure from the regulator).

I have never worried about contamination on the gas lines.

If I am going to leave the taps unused for some time, I will put a TSP solution in an unused keg, and with a little pressure use this to fill up the tap lines. I loosen the collar at the tap to get some flowing through the gap there, too (this is the collar where the tap connects to the beer shank - I've had 'em loose before and grow mold). When I want to use them next, I repeat the process, only using boiling hot water in the flushing keg instead of TSP.

From: Greg Roody <"whzguy::roody"@necsc.enet.dec.com>  
Subject: On a whim and a fancy.....

Someone asked about the thought process behind brewing, and I thought this may be an indirect answer. And yes, I have done a lot of cooking/baking; yeast is my life.

On a whim, I picked up two gallons of fresh sweet cider at a farmstand last night. I had the innocent thought of using up some dry yeast I had left over from beer making (I have since switched to liquid yeasts for beer). Then, things kinda got out of hand.

I wanted to retain some residual sweetness, so I figured I'd add some wort made from some crystal malt. Well, while I hand the grain mill out, I threw in some pale malt grain. Now, I figured I should mash this stuff and get some usable sugars out of it so I did a 1 hour infusion mash, sparged and boiled.

Next, I went back to the freezer to put away the grains, and I found some light DME; "oh what the heck" sais I, and I throws it into the boil.

So, now I figure I should pasteurize the cider, so I adds the hot wort to it and heat it to 180. While I'm heating this glop, I clean up some more, and find six pounds of honey I was saving for a mead.... "Hmmm, a little of this couldn't hurt... could it?"; I added all six pounds.

Now I'm about a gallon short of filling my carbuoy, so tonight I'll throw in another gallon or so of fresh (pasteurized) cider.

I have no idea what I have created, save that it will be STRONG (O.G. measured 1.110 at racking to primary)

The total recipe looks something like this: for 5 Gallons

1.5 # 10 degree crystal malt

1.5 # 6 Row Pale malt

=== grains were infusion mashed, sparged, and boiled

2.5 # light DME (boiled with grain wort)

2 Gallons fresh Cider

6 # honey

1 cinamon stick ground finely

1 packet EDME Ale Yeast

1 Packet Red Star Wine Yeast

=== yeast was started as a slurry and pitched immediately into cooled wort/cider

Plus 1-2 Gallons fresh cider added one day into ferment

I'll let ya know how it turns out (in about six months).

/greg

From: eisen@kopf.HQ.Ileaf.COM (Carl West)  
Subject: torrified wheat, weakened glass(oven sanitizing)

For torrified wheat I expect that you can use any unsweetened puffed wheat breakfast cereal. How about other puffed adjuncts? puffed rice, air-popped popcorn.

Whether oven sanitizing will weaken the bottles depends entirely on how quickly they are heated \*and\* cooled, if it is done gently (slowly) enough the glass will end up slightly more annealed than before. In general, the more annealed and therefore more stress-free the glass, the stronger it will be (the exception is tempered glass). If the bottles are heated and cooled too quickly, stresses will build up in them and they will be more prone to breakage.

Subject: Anchor Spruce Beer

There has been some recent talk of Spruce Beer, so I thought I'd toss in this tidbit :

Those wild and crazy guys at Anchor have done it again. The same folks who dared to brew a Sumerian beer, were perhaps the first American brewery to revive the Christmas Ale tradition (mistletoe and holly on Bud six packs doesn't count!), and who were a microbrewery before it was fashionable, have brewed a spruce beer.

It's a pale, crisp and refreshing brew made with a portion of wheat in the mash. Overall I thought it was quite tasty, my only complaint being that it could have been better balanced. The spruce was a tad overdone for my tastes. This will probably mellow with age - not that any of it is likely to hang around long enough to find out.

It is a commemorative brew for the 10th annual Great American Beer Fest coming up this weekend. It will be available there, and is (make that was) available in select outlets in San Francisco - not Oakland, not even Daly City, San Francisco. If you are fortunate enough to encounter some, by all means buy it.

No, I don't work for Anchor. I just like them alot.

From: tony@spss.com (Tony Babinec)  
Subject: guinness formulation/recipe

The recent HBD entries on Guinness led me to look at Eckhart's (sp?) book on beer style, along with Michael Jackson's and David Line's books.

"Essentials of Beer Style" says that Guinness has pale malts, crystal malts, about 9% roasted barley and 9% flaked barley. Starting gravity is in the 1050-1055 range, and Bitterness Units are in the 40-45 range. I believe Jackson indicates that Guinness is made to different starting gravities for export to different parts of the world.

So, a recipe for 5 gallons of Guinness-like stout might go something like this:

8 pounds pale ale malt (OR 6 pounds dry malt extract,  
(light,unhopped))  
0.5 pound crystal malt  
1 pound roasted barley  
1 pound flaked barley  
10-12 Homebrew Bitterness Units of bittering hop  
Wyeast "Irish" ale or "London" ale yeast

I might be tempted to add a small amount of chocolate malt, although this is not used in Guinness so far as I know.

Subject: attenuation

> The percentage drop in gravity is measured with a saccharometer  
> and calculated as follows:  
> Formula:  $A = (B - b) / B \times 100$   
> Example:  $(12 - 4) / 12 \times 100 = 66.6\%$   
> A = attenuation: % of sugar of the original wort converted  
> into alcohol and carbon dioxide after or during  
> fermentation.  
> B = original gravity in deg. Balling (or Plato) prior to  
> fermentation.  
> b = specific gravity in deg. Balling (or Plato) after or  
> during fermentation.

Actually, I think that its  $A \sim (B - b) / B * 5/6 * 100$

Since pure alcohol weighs about 5/6 as much as water, then  
for every percent alcohol that the wort is raised, the SG  
gravity drops by:

$P * .008$  due to loss of fermentables  
 $P * .01 * 1/6$  due to gain of alcohol  
=  $P * .0016666$

so the SG has actually dropped by .00966666

Since the hydrometer ready "Potential Alcohol", Multiply the  
difference between the OG and FG by .008/.0096666,  
or slightly less than 5/6, before finding attenuation.

Subject: 50K No Way

A couple of us participating in the Digest are not on any regular network but are receiving our copies through Compuserve e-mail, via Internet. Unfortunately, it appears that CIS has an upper limit of 50K; whenever the digest is larger than that--such as #732-- it gets stuck and will not read or download. I find this very irritating, and know that Robin Garr--who is one of the sysops on the CIS beer forum--loads it into the forum's library. When the digest jams, it sometimes takes many days before someone gets a copy to Robin.

Does anyone have any suggestions? There are several possibilities that occur to me.

1. Someone can help me figure out how to acquire an account (free?) on a network and figure out how to run this software (Waffle) I acquired from a BBS. This would solve \*my\* problem but not Robin's. Although Robin would certainly be interested in learning whatever I learn.
2. Someone could offer to .ZIP or .ARC large digests and mail them to those of us stuck on Compuserve. This would be a really nice gesture.
3. Someone a heck of a lot smarter than me can figure out another idea.

From: Jeff Frane <70670.2067@compuserve.com>  
Subject: On 733

To Greg Habel:

I'm not sure of the current situation, but Dave Logsdon visited the islands a few years ago. His advice: drink rum! He said the beer was \*awful\*.

To Bob Hettmansperger:

UC Davis means the University of California at Davis. I believe the brewing program is actually part of the Food Science school; chief instructor is Dr. Michael Lewis, guru of the west coast brewpub scene. (A wonderful fellow, \*very\* knowledgeable about brewing science, who as far as I could tell doesn't really like beer nor brewing; we disagree strongly on the function/output of a brewpub.) One of the other teachers is Jean Xavier Guinard, a thoroughly likeable Frenchman (really!) whose excellent book on lambic beers was published by the AHA. Anyway, you should be able to get information on Davis at any public library.

To Norm Pyle:

Someone explained to me the difference between college and professional rugby: in professional rugby they drink the beer \*after\* the game. Maybe it's true for volleyball as well.

To Peter Berger:

I'd say you were generally right about "canned" extracts, but perhaps you should check out my personal favorite: Alexander's light malt extract. It was developed by the above-named Michael Lewis, and supposedly was evaporated only to the point where no "canned" flavor would result. It's made from 100% Klages pale malt and I have had excellent results with it whenever I've done extract-grain beers. You will notice it's not as thick as most malts, because the evaporation process is halted early.

You would be well advised to steer clear of Red Star; in fact, as pretty much everyone will no doubt tell you, you should switch to liquid yeasts.// And yes, your retailer sounds pretty expensive. Try mail order; look for ads in Zymurgy.

To John Hartman:

A friend of mine visited the Young's Brewery in London, which brags about their "all-malt" beer. He pointed out pallets of sacked torrified barley and ? Well, hrmm, hrmm, we just add a bit of that for nitrogen [since, supposedly, British malt is low in nitrogen]. He and I were never able to find torrified barley in this country (something like puffed barley), but through experimentation discovered terrific results from substituting a small amount of flaked barley in ale recipes. Great head retention and lots of mouthfeel. It's possible that a flaked wheat would substitute nicely for you.

To Bryan Gros:

I looked at a copy of the New Complete Joy (or whatever it's called) the other day at a local homebrew store. There don't seem to be a lot of obvious changes from the previous edition, although there is now an index and a couple of supplements on things like lambic beers. I was appalled to note that the publisher had managed to find an even lower grade of paper to print it on--although it does offer the opportunity to read more than one page at a time.

As far as I can tell, the difference between Anchor's wheat and Munich-styles is that the latter have taste. Hard to believe that the people who brew Anchor Steam and Liberty Ale could make such a boring beer.

To Tom Hamilton:

On sanitizing in the oven> I haven't broken any bottles yet, although I guess your doctor friend would have more experience in sterilizing than I. Perhaps the pressure in her autoclave would add to the stress on glass; something that wouldn't be true in the oven. ???

Subject: happy buzz, Oktoberfest, Canned vs dry?

Regarding the question about the "homebrew happy buzz": Get some hop pellets of fairly high alpha content. Chew a few up and swallow the hops. You'll get quite a glow on. I did this one day while watching the sparge trickle, and got quite a glow off them that lasted about 45minutes.

I hadn't been drinking. Any ideas on how to grind them up fine enough to fit up the nose;-)

Oktoberfest:- Go early, there will be lineups.

- Beer and peppermint schnapps seems like a harmless combination  
IT ISN'T! Major puke potential!

- Don't pass out! They'll put you outside in the rain, and sell your seat to someone in line!

- Wear clothes that beer can be easily washed from.  
beer fights are common. Beer spills are garrenteed!

- Ziggy, ziggy, ziggy, ziggy. Hoi! Hoi! Hio!

Party, party party, party. OH! OH! Boy!

Don't trust canned extract? Well to get the extract conentrated down, they boil most of the sap out of it, and put it in a can, To make dry extract, they boil ALL the sap out of it and put it in a bag. Although both processes likely use low temperature vacuum boiling, I can't see why the can would be worse than the dry when the canned extract actually has less processing? I've used canned extracts for years, and have used a bit of dry extract. I've seen little difference that can be attributed to one being canned, and one being dry???

Date: Fri Sep 27 09:39:42 1991  
From: larryba@microsoft.com  
Subject: Re: Dry Hopping, Hops utilization and Checkvalves.

- ---- Dry Hopping

Re, George Fix and dry hopping: one technique I have used is to dry hop with pellets (in a fine weave bag - real cheese cloth, not the coarse stuff you get in the grocery store) - poured my boiling priming + gelatine water over it (in the bottom of my keg). I doubt I get 100% kill (love that term), but it gets to 180f which will kill most stuff. Leaf hops should work the same. Anyway, then I rack the beer into the keg. Seal, let carbonate and then drink away.

- ----- Hop Utilization Rates

The Hops issue of Zymurgy has some utilization tables. Apparently there is some disagreement between Byron Burch and the guy who made the tables in Zymurgy. In a nutshell it appears that around 45 minutes of boil the utilization takes a sharp increase so it is hard to predict utilization in that time frame. The general idea is to boil hops for an hour or 20 minutes to avoid that part of the curve. The numbers I use are: For 1 hour boil, the utilization is around 27% (leaf) and 34% (pellet), at 20 minutes, it is 10 & 12%, at 5 minutes it is 5 and 6% respectively. I figure IBUs as follows:

$$(\% \alpha * \% \text{Utilization} * \text{Weight (grams)} * 1000) / \text{volume (liters)}$$

A typical boil for me leaves 5.5 gallons or 20.6L. Just figure IBU for each hop addition and add them up for total bitterness.

Hop freshness, Alpha acid amounts, weighing accuracy, boil temperature, pot geometry (i.e. pressure/ temp at the bottom where the heat is coming in from) all will affect your results. Does anyone know how to measure bitterness in order to calibrate our home breweries? George?

- ---- Check Valves

I run three kegs off of one CO2 bottle. The "Brewers Warehouse" in Seattle (advertises in Zymurgy) sells a three way tap, with check valves, for \$10. It screws into the regulator in place of the check valve and your gas lines screw into it (with checkvalves).

From: larryba@microsoft.com  
Subject: Recycling Yeast Cakes + Xmas Ale...

I finally got a chance to try out the Farther Barleywine yeast cake trick. I racked an ale from my carboy and chilled an Xmas ale directly onto the yeast cake. Very impressive fermentation! I used a counterflow chiller and a wort aerator (ref HBD #681). I really liked not having to carefully collect the yeast and clean the carboy before reuse.

One thing I noticed: the resulting yeast cake is now twice as thick as before. Sure, there is added trub, but not that much. Is it possible that aerating the wort is unnecessary when recycling the yeast cake? There probably wasn't any need for more yeast growth. Mr. Ransom: what happens after your 4th or 5th ferment? Is there any room for the beer?

BTW my xmas ale recipe is tasting good. The green wort was pretty tasty. Like pumpkin pie made with Barley Malt instead of pumpkin. It had a definite bite of cinnamon and ginger (yahoo). Fermented out, the spicing was considerably lighter although that ginger heat was still detectable. In short, the spicing is subtle and blends well with the Malt rather than dominating it. If I were to do it again, I might substitute a pound of 701 crystal for some of the Munich malt, maybe punt the Munich all together and bump up the amount of Klages.

8 lb klages  
2 lb munich  
8 oz chocolate  
12oz Honey (added to the boil, not mashed!)

7 gallons of supply water + 8 gm gypsum (~85ppm of Ca++ in Seattle)

Step Mashed 30min @ 130f, 30 min @ 155f (Papazian technique)  
Sparge water @ 175f  
Collected 6 gal of wort

1 hour boil  
Final volume 5.5 gal

OG 1.068

1/2 oz Willamette (5.4%) for 45 min  
1/2 oz Willamette (5.4%) for 30 min

6 oz fresh ginger (peeled, diced)|  
zest of 4 oranges (valencia)|  
1 tsp whole clove -toss in with second hops addition.  
1 tsp ground allspice |  
5 3" cinnamon stick (crunched up)|

A little more than 5 gallons made it to the carboy. It fermented out in 36 hours @ 74f and has been sitting for another 4 days @67f.

TG 1.017 alcohol ~ 6.6 %v/v

I targeted the OG of the winning xmas ale described in this digest several months ago. If you want to do this as an extract use 9.25 lb of syrup (a porter style would be nice) or 8.5 lb of dry dark extract. I kept the hop rates pretty low given that the spicing would be best with a sweeter flavor.

From: rich@progress.COM (Rich Lenihan)  
Subject: Thanks; Honey Trubble

First, I'd like to thank all who responded to my last submission re: the use of "bottling buckets" and DME vs. corn sugar for priming. The general consensus seemed to be that I should use a bottling bucket. Well, I'm still not convinced but for the sake of homebrewing science, I'll try it when I bottle my current batch. I'll probably use DME to prime this batch since I think it'll be appropriate for style (basically, an ale with 6 lbs malt extract, 1 lb specialty grains, 2 lbs honey), but I'll continue to use corn sugar for most of my brews.

Now to my questions: in the above-mentioned batch, I boiled this for about an hour (maybe a little more). I pitched my Whitbread dry ale yeast (from a starter) and had really active fermentation in less than six hours which went at a frantic pace for 24 hrs. (I keep my brewing stuff in a closet off of the kitchen and even through a closed door you could hear the noises from the blow-off tube. It sort of sounded like the noises John Cusack was making at the end of "The Grifters"). Anyway, three days after putting it in the primary, I racked to a secondary (both ends of siphon hose submerged). I had this really gooey glop (RGG) at the bottom of the primary. It tasted a lot like honey, so I suspect that much of the honey I added to the boil fell out of suspension. Is this to be expected when using honey? (My first time) Or should I boil the honey longer. Since I've been told that bad things will happen if I boil my extract for more than 1 hour (momily or factoid?) )  
perhaps I should boil the honey for a while before I add the extract?  
Or will over-boiling do bad things to my honey, too?

Also, after a few days in the secondary, there appears to be more RGG forming on the bottom and the glug rate is down to .5/minute. Now, I'm worrying. Is my fermentation finished (the SG was 1.023 when I racked to the secondary but I'm not sure what to make of this if most of my honey ended up in the RGG) or does this reflect the usual slowness reported with using honey? I've had very slow ferments before but nothing this dramatic.  
Or has my yeast died or taken a nap? From what I've tasted, it seems a little sweet (and slightly vomity).

Another question: Since I'll probably rack this batch one more time (at least) before bottling, I was thinking of saving the RGG from the secondary for my next batch (which will probably be a more traditional all-DME batch). The RGG contains, among other things, yeast which I want and trub which I don't. So, is there a relatively simple method of separating the two? I'm not equipped for lab culturing, yet. Also, is there any chance that the honey from the RGG would impart an undesirable flavor to my next batch (other than a slight honey flavor)?

From: Donald Oconnor <oconnor@chemistry.UCSC.EDU>  
Subject: plastic carboys and grain bugs

There have been quite a few notes on bugs in the barley malt and the suitability of the apparently new plastic carboys as fermenters.

Bugs in the Malt: I recall that my grandfather would regularly shake sacks of grain in order to avoid the problem of bugs. I believe the idea behind this lies in busting up any bug eggs (larva?). My guess is that shops aren't doing this and may also be selling very old grain.

Plastic Carboys: Someone recently asked about the usefulness of the new hard plastic carboys apparently used by some water companies. Someone else replied that they had used them successfully as fermenters. I have not seen these yet, but if they are a clear and hard plastic, they are most likely polycarbonate (aka Lexan). Polycarbonate is indeed quite hard and more difficult to scratch than the usual water bottles. It can also withstand quite high temperatures, certainly above the temp of boiling water. Unfortunately, polycarbonate reacts to basic solutions, so you cannot clean it with TSP, lye (sodium hydroxide or potassium hydroxide) or even a weak bleach (sodium hypochlorite) solution which are all basic. These solutions will eat away at the polycarbonate. They are inert to acid so perhaps an acidic solution could be used for sanitizing. Beer and wine are acidic so they pose no problem.

Subject: Maris Otter Barley

From: hartman@varian.varian.com (John Hartman)

>Does anyone have specifics on Maris Otter pale malt? Is it any  
different  
>from ordinary English 2-row pale malt?

The following is from an ad placed in the October/November issue  
of the Celebrator Beer News :

WHAT CABERNET SAUVIGNON GRAPES ARE TO RED WINE,  
MARIS OTTER BARLEY IS TO ALE MALT.

(These folks didn't do too well on the SAT exams!-)

Maris Otter is a rare, old fashioned two-row barley, low in  
yield per acre and tough to grow. Seasoned brewers still  
insist on the delicious, rich, plump, nut-like character  
and the finesse that the variety gives their pale and brown  
ales, porters, stouts and barley wines. Crisp Malting Ltd.  
of Great Ryburgh continues to contract with Norfolk farmers  
to supply them this extraordinary barleycorn. Crisp maintains  
one of the few remaining traditional floor maltings in England.  
Their fine pale, crystal, and dark dark malts are now available  
to micro- and home brewers in the U.S. and Canada through Liberty  
Malt Supply Company and their retail agents.

CRISP MARIS OTTER WON 1ST PLACE IN THIS YEAR'S NATIONAL  
MALTING BARLEY COMPETITION.

Liberty Malt Supply Company  
1418 Western Ave  
Seattle, WA 98101  
206-622-1880  
206-622-6648 fax

Despite the advertising hype, it sounds like an interesting malt.

> anyone  
> mention this in any procedures. If you got a contamination in one of  
> the  
> kegs, wouldn't it get into the lines? Or again is there a check valve  
> I don't know about.

I think that there are check valves in my manifold that not only allow me to selectively shut off gas to a particular keg, but keep gas from flowing backward towards the regulator in case it is disconnected from the tank. But even so, I have always assumed that nasty beasts like bacteria can't survive in a high-pressure (10psi) CO2 environment, and hence would not be able to crawl from keg to keg. I am lucky, though, in that I have had very few bad batches so I can't say from experience that this is a problem or not. I have never considered cleaning the gas lines.

On other matters, I am currently in second stage fermentation with a beer brewed with Sierra Nevada ale yeast. I ferment in a fridge controlled by a Hunter Energy Monitor unit. Yesterday, when I checked on the beer, I noticed that I had inadvertently left the temperature probe outside the fridge. Because the ambient temperature was 75 degrees and the unit was programmed to hold the temperature at 68, the temperature of the beer dropped to around 40 degrees (I had left a thermometer in the fridge to check the accuracy of the Hunter unit). Question: I don't suppose that there is anything to do about shocked yeast but let the temperature return to normal and pray like hell that the fermentation resumes, is there?

From: Conn Copas <C.V.Copas@loughborough.ac.uk>  
Subject: Blow out tubes, dry hopping, fruity tastes

This question almost seems too obvious to ask, but we've heard recently that a blow out tube is a good means of removing fusel oil from the primary. Is this referring to volatile fusel oil or that which is bound up with the krausen in some fashion which escapes me. If the former, surely an air lock is just as effective, and an open ferment is more effective still ? If the latter, surely skimming the brew is more effective ? Do top and bottom ferments behave differently ?

One phenomenon I have noticed is that dry hopping increases the attenuation of the brew. I have proved this to myself by dividing the same brew in half and treating each half differently. I would be interested in any explanations for this reaction. Here are some tentative ideas : the hops introduce additional enzymes or microorganisms into the brew, they cause a mechanical rousing of the brew, or maybe simply opening the fermenter and introducing oxygen is the key factor.

My all-time greatest fruity brew occurred when making a standard extract ale, using standard yeast, at standard temperatures, with 4 oz Goldings bittering hops. It was not so much a case of 'subtle overtones of blackcurrant' as the sensation that someone had sneaked in and poured a bottle of Ribena cordial into the brew! Before you all leap in and tell me that I may have been using mislabelled Bullion hops, I wasn't. The hops looked like Goldings and behaved like Goldings as part of an aroma technique. The bottled brew was undrinkable for the first 2 months of its life, then the flavour vanished as mysteriously as it had appeared. Any ideas or similar experiences ?

>Also, would anyone be willing to venture ballpark alpha  
>acid percentages for these varieties to help me in working out the  
>mass of substitute hops I need.  
>(I realise that the alpha acid % is variable  
>from crop to crop but any typical values would be of help).

Alpha acids are comprised of 3 ingredients, humulone, cohumulone and adhumulone. The content profile of these is what makes the bittering potential different among hop varieties. Cohumulone seems to be the one that causes the more harsh bittering effect. Bullion has high ratio of cohumulone (comprises just under 40% of the alpha acids and I think the alpha content runs around 6%). Eroica, Southern Brewer, Comet, Cluster and Brewers Gold also have high cohumulone ratios.

Bullion has really poor storage characteristics and is fading from production, along with Brewers Gold. Those high alpha hops are being replaced by Clusters (runs about 7% alpha), Nugget and Chinook (runs 10-12%). Centennial runs around 10% alpha and is what I'm using now.

Among the 'noble' (mighty fine aromatic - finishing) hops, Fuggles (~3.5% alpha) is a good substitute for Willamette, Fuggles being the 'father' of the Willamette variety. I think Willamette is replacing it in terms of production. Willamette runs around 4.x% alpha, my current batch is 4.5%. I \*really\* like Kent Goldings, if you can get them fresh the aromatics are powerfully seductive (Alpha around 3.5%). Cascades don't store too well, but are popular in the U.S. and run around 5.5% alpha. Tettnanger has a nice finishing aroma and is about 4% alpha.

If I was making a classic stout I wouldn't go too overboard (as I typically do) on finishing hops, not quite true to style. You'll want the cherry aroma to be noticeable.

From: rcd@raven.eklektix.com (Dick Dunn)  
Subject: berries and bitterness

(I hope this gets out...I've been getting HBD erratically, compensated by several copies of the ones I get.)

There have been various comments about using berries vs long aging times to

get things mellowed out fit to drink. I've done a bit of experimenting with some meads which suggests a simple aid:

Get the leftover berries out of the fermenter asap.

As soon as you get enough of a krauesen to lift the berries to the top, skim them off. If you broke them up a bit when you added them, they'll mostly be done fermenting. You won't get quite as much color as if you leave them in for another week or two, but you'll also get something drinkable a lot sooner, and it will mature to a better mead.

I've had two recent meads bear this out--one raspberry/blackberry, the other boysenberry/raspberry. Both were quite drinkable (although still young-tasting) within a couple weeks of bottling. One is still/sweet, the other dry and slightly carbonated. This was quite a welcome revelation to

me, as I like the berry melomels but hate the long maturation times.

From: R\_GELINAS@UNHH.UNH.EDU (Russ Gelinias)  
Subject: wet hopping

Was that \*the\* George Fix? Anyway, my method of mixing hops with vodka (and water) to add to the fermenter, as a "wet hop" mixture, also included gently heating the mixture, and letting it cool overnight. How warm? I don't know, but \*not\* boiling. I'll measure the temp next time; it's heuristic right now (am I using that term correctly?). The combination of alcohol and low-temp pasteurizing should (hopefully) help eliminate infection. The heat should also help extract more of "the good stuff". The mix is also \*strained\* into the fermenter. What this does is allow you to re-use the yeast slurry from that fermenter, without having to deal with loose hops. Siphoning is easier too.

Now the caveat is that I've only done this 3 times. One time I let the hops/vodka/water mix boil by mistake for maybe 5 minutes, and most of the volatiles boiled away. The other 2 times were very successful. As they say, your mileage may vary.

From: srussell@snoopy.msc.cornell.edu (Stephen Russell)  
Subject: Grinding flaked barley, lager vs ale malt for dry stouts

Howdy, brewfreaks!

Seeing references to Guinness recipes and so forth brought some questions to my mind:

(1) When making stouts, recipes often call for the addition of 9-10% flaked barley. This being a pretty laminar substance, it often leads to slow sparges. A friend of mine who brewed a stout over the weekend did something fairly radical and (to my thinking anyway) creative: he dumped the flaked barley into his Corona grain mill and ground it up!! Not real fine or anything, in fact, at a slightly less fine setting than for the rest of the grain. Have any of you all done this?? What do you think of this idea?

(2) Along these same lines...I too noticed in Eckhardt's book that Guinness uses pale ale malt. Dave Miller in TCHOHB calls for \*lager\* malt in his Dry Stout recipe on the grounds that the proteins in flaked barley require breakdown by proteolytic enzymes that have been destroyed by the higher kilning of pale ale malt. What gives here? Is Miller being overly anal? If I use pale ale malt will those proteins remain in my beer and thereby result in a cloudy Guinness? :-) If I \*do\* use lager malt, will I cleave proteins that might have added to the creaminess of the beer?

From: srussell@snoopy.msc.cornell.edu (Stephen Russell)  
Subject: How to do a seminar on different hop flavors and aromas

I have volunteered to conduct a seminar for my brew club on the differences in aroma and flavor imparted by different hops. I do plan to serve some well-hopped beers but would like to boil up some "hop teas" for comparison as well.

My questions:

a) should I add any dried malt extract to these teas or just use H2O? also, how much DME, water and hops should I use? (leaf only)

--my thinking here is that this might be a more realistic emulation of beer AND that the extraction of hop oils might be different in wort than in water BUT that this might interfere with the hop aroma/flavor.

b) should I boil them at all? if so, how long?

--Jean Hunter suggested that we bring the hopped solution to a boil and then turn the heat off to compare aroma, then resume the boil for a while (10 min or so) and then turn it off to compare flavor.

If this is a stupid idea (or just not the best one), please steer me to a better technique for accomplishing my goals. Which are, simply put, to help members of my club (myself included) learn the distinctions in flavor and aroma of different hop varieties. I plan to have Cascades, Willamette, Fuggles, E. Kent Goldings, Hallertauer, Tettnanger, Northern Brewer and Saaz.

advTHANKSance!

From: larryba@microsoft.com  
Subject: Misc info regarding Hop bitterness

The following are some correspondence with George Fix regarding measuring Hop Bitterness. I thought it would be of general interest.

>From: George J Fix <gjfix@utam.uta.edu>

I am constantly amazed by how much kettle utilization varies among different brewers. In fact, I am amazed by how much my own KU has varied over the years with changing circumstances. As far as I can tell the following

are the most important factors:

- (i) The type of boiling equipment, and in particular the temp. and pressure that is maintained.
- (ii) The actual alpha-acid level of the hops that are added.
- (iii) The type of hop, i.e., cone, plug, or pellet.
- (iv) The hop contact time.
- (v) The wort SG and pH.

There are formulas out there which can be used to compute corrections, however in my brews the predictions they yield tend to miss the mark, often by wide margins. Darryl is working on improvements, and he can always be counted on for coming up with something interesting. In the interim I have been depending on direct measurement (described below).

To cite one example, last Jan. I purchased some Saaz plugs (Cosby + Baker) which were rated at 3.03% alpha. I had them measured and found that the actual alpha was 2.55%. I had them measured 4 mos. later and found that the alpha level had fallen to 2.51%. I used the two data points with linear extrapolation to estimate alpha levels until new hops were purchased.

Since I have never used plugs before I had the additional task of finding the KU I would get from them. To do this I did the following pilot brew last Jan. and had the iso-alpha-acids of the wort measured.

vol. of wort = 1 liter  
SG = 1.048  
pH = 5.2  
hops added = 5 grms. (Saaz) = 5000 mg/l  
hop alpha = 2.55%  
total alpha added = 127.5 mg/l  
contact time = 30 mins.  
BU (measured) = 26.8 mg/l  
KU =  $26.8 * 100 / 127.5 = 21\%$

It has been my experience that the 21% is a good KU for any plug so long as the contact time, SG, and pH are close to those cited. For different choices of these parameters additional measurements are needed since the KUs will likely change. In addition, separate measurements are needed for pellets and cones. I have had iso-alphas measured from wort samples of full scale brews and the predictions based on my KUs I have always been within 5% of the measured data.

I seem to lose around 4% of the iso-alphas in the fermentation. If oxygen pickup in storage and filling are kept low, then additional losses are minor. However, if oxygen pickup is not kept low, then major losses can occur.

The alpha assay for hops is simple. Hard resins are extracted with methanol; soft resins are then extracted with petro. ether; finally, alphas are determined by titration with lead acetate. Most hop dealers have the necessary materials to do the analysis. They will typically do it for free if you buy hops >from them or at a nominal cost otherwise.

The iso-alpha analysis of wort (or for that fact beer) is also simple but requires special equipment. It is a bit more expensive, but fortunately it does not need to be done often. As noted above the numbers can be used forever for any fixed combination of the parameters (iii) to (v) cited above. Siebels of Chicago will do the analysis for you. They first extract iso-alpha-acids with iso-methanol. The concentration is then determined by its absorbance with light. The iso-methanol will actually extract resins other than iso-alphas. That is why results are quoted as "bitterness units" than mg/l of iso-alpha-acids. These two numbers, however, rarely differ more than 2%.

I asked just what is "contact" time...

>From: gjfix@utam.uta.edu

Thanks for your e-mail. If it is not inconvenient, then I would be pleased to have you post our correspondence.

By contact time I meant the time the hops were boiled. You are right, however, the time at simmer after the boil is over and before the hops are removed is important. It should be noted for any sample that is going to be measured, for the KU will be affected.

I have found that the wort SG is a big issue for hop utilization. The correction factors in Zymurgy seem ok for the range 1.050-1.060. They, however, have proven to be highly erratic above 1.065.

The effect of pH is likely weaker, especially in the range 5.0-5.6. It could be a factor outside this range. For example, a 15% drop in KU was reported for worts made from a "sour mash" at pH=4.7 compared to wort at pH=5.2.

I feel that a good pH meter is a worthwhile investment. However, for most purposes the paper strips should be fine.

Best wishes!

Subject: annealing bottles

> Whether oven sanitizing will weaken the bottles depends entirely  
> on how quickly they are heated \*and\* cooled, if it is done gently  
(slowly)  
> enough the glass will end up slightly more annealed than before.

I doubt that a home dishwasher holds heat long enough or high enough to do any significant annealing. My recollection from touring several Swedish glass works last summer is that their annealing ovens cool the glass from ~1000 to ~500 F in ~24 hours. I'd say that anyone using a dishwasher as a sanitizer should plan to leave it closed at least an hour after the cycle is over and hope that the glass is cool enough that it won't be stressed by room-temperature air. You could try running just a few bottles with a load of dishes (the thermal mass of a full load is probably significant) and see whether they're warm if you wait .5, 1, 2... hours before opening, or you could run a probe---now that you've got a thermometer that reports to the outside on the temperature inside your refrigerator, want to try the same thing for your dishwasher?

Date: Mon, 30 Sep 91 13:27:55 CDT  
From: gjfix@utammat.uta.edu(George Fix)  
Subject: Hop stimulation of Yeast

Conn Copas' observation that dry hopping increases yeast activity seems to be both correct and interesting. I conjecture that a major mechanism comes from hop particulate matter serving as nucleation sites for CO2 evolution. It is known that CO2 counterpressure tends to restrain yeast growth and other metabolic activity. Having more of it removed, and at a greater rate, surely is stimulatory to yeast.

In the early 80's a large English brewing company(Allied)reported serious problems with their fermentations after changing over to a high gravity brewing system. They ultimately solved their problems by increasing the amount of oxygen in their chilled wort, and by increasing the amount trub carryover. They concluded that trub was a yeast stimulant.

In a later follow up study the Allied results were confirmed. However, it was shown that the major yeast stimulation came from trub particles serving as CO2 nucleation sites in a manner described above. Since the effect is purely mechanical, the second study concluded that any type of particulate matter will achieve the same effect. This has been my experience as well.

I have never been a fan of trub carryover, since it contains a large amount of fatty acids which can be big players in beer stalling. Letting particulate matter from hops serve as a stimulant(along with O2)seems like better option when the yeast we are using need extra stimulation.

From: pencin@parcplace.com (Russ Pencin)  
Subject: Re: Ice Chest Lauter Tun / Dumping All Sparge Water

Well, I waited to answer both of these requests because I didn't want to be redundant with other folks.

I have been using an Igloo Ice chest with slotted pipe for a Lautern for over a

year now ( 24+ batches ). The inside of my Igloo has buckled in many places,

but has never cracked and has not affected the process in any way. I sparge at

170 degrees and, as with Florian, I dump the entire 4 gallons of sparge water

in at one time. Now let me expand on my process so no one misunderstands.

Taking some advice from both Nancy Vinyard and Anchor Brewing Co., I first

carefully recycle the first runnings until I get a reasonably clear runoff into

a large glass jar, at the point that the run-off is clear I COMPLETELY drain

the first runnings from the Igloo tun into my boiler. I then block the run-off

hose, and pour the entire 4 gallons of 170 degree sparge water into the Igloo

Tun, then merrily stir the grains and water for about 3 minutes. I let this

sit for another 10 minutes to allow resettling. After settling, I begin the

glass jar run-off and recycle until I get very clear wort from the drain. At

this point I let the run-off go into the boiler.

Please don't ask me what "efficiency" I'm getting, I don't worry about such

things [sic], but I usually get around 1.054 for 6 gallons of wort in the

boiler for 10 lbs of 2 row kladges.

I'm very happy with this method, and never have had a stuck mash since employing it.

The wort is sparkling clear and there is no evidence of astingency from "over-sparging". If you'd like more info mail me directly. If there is enough

interest, I'll post the summary.

Russ

From: Conn Copas <C.V.Copas@loughborough.ac.uk>  
Subject: Fermenting fruit - LONGISH

Second time lucky ...I've noticed a few posts about problems with fruit beers recently, so given that it is harvest time, I thought I might hold forth. I have zilch experience making fruit beers, but thought a winemaker's perspective could be useful. Lambic gurus, please stand ready to correct as necessary.

An initial decision one faces with any fruit brew is whether to press the juice or ferment the pulp. White wines conventionally employ the juice only, whereas red wines employ the pulp method in order to extract the colour and tannin which are expected in that style. Some fruits are so difficult to juice that pulp ferments are the only option, even for a white wine style. When pulp fermenting high tannin fruits such as apples, pears or elderberries, no more than 2-5 days contact is recommended. Presumably, a situation analogous to sparging exists, in that sugar will be extracted preferentially before the tannin, but overdoing it can cause problems. Those fruits often contain enough tannin in the juice alone to give the wine sufficient 'bite' or 'zest', similar to what hops do for beer. The pulp is meant to be pressed gently for similar reasons. Incidentally, broken kernels from stone fruits can also cause odd flavours, as well as being a good source of organic cyanide I believe.

Winemakers necessarily ferment the fruit during the primary, because the fruit provides a large amount of sugar and nutrient. In a brewing context, I can also think of some good reasons for retaining this practice. First, pulp ferments benefit from a twice daily stir to wet the crust and promote extraction. Also, straining pulp from the brew invariably involves much sloshing about, and the brew may not recover from that degree of oxidation at a later stage. Second, pulp can decompose with age to produce off flavours, with the maximum recommended contact time in wines being 2 weeks. Third, if one is using a pectin digesting enzyme (which is a standard means of reducing hazes and aiding extraction in most fruit wines), it is inhibited by the presence of alcohol. Generally, I would add that it is good practice to establish the chemical environment of a brew at an earlier rather than later stage, with that environment partly being controlled by the duration of the pulp ferment. Whilst there could be concerns about loss of fruit volatiles during the primary, the alternatives are probably worse. Considering the fragrance of some rieslings or sauternes, the effects of the primary ferment can't be all that bad.

For the same reasons, oaking is probably best carried out in the primary. The directions that accompany my particular brand of granules claim that a smoother result is obtained when added sooner rather than later. I suspect that there is better utilisation in the turbulent conditions of the primary, even if the duration of contact is less than in the secondary.

There seems to be a bit of confusion regarding strong flavours which take a long time to mature out. The two main possibilities are tannic astringency and acidic sharpness. Tannin mellows with aging, and this process can be accelerated by fining with gelatine. As far as I know, there is no practical home testing system beyond the human taste bud. Acidity mellows less appreciably with age, so it is important to adjust it before bottling if necessary. Most berries and stone fruits contain a mixture of citric and malic acid, with human tastes being able to tolerate higher levels of the latter. It is occasionally possible for the malic acid to be converted to the less sharp lactic acid if suitable microorganisms are present, but don't count on it. Somewhat unintuitively, taste relates better to titratable acidity than to pH. That is, it is possible for fruit juice to have a large total acid content yet only have a moderate hydrogen ion concentration, due to the weakness of organic acids. As a general rule, the worse the season or the less mature the fruit, the higher the level of acidity and the lower the level of sugars. Most berries are highly acidic. Although tartness is often a desirable characteristic of fruit beers, it could still be necessary to reduce acidity by stirring in chalk or a solution of bicarbonate. Doing this scientifically requires a home acid test kit containing alkali, indicator, test tubes, etc.

Now for some controversy. Winemakers seek a limited amount of oxidation, obtained either through porous wooden casks or periodic racking. This encourages alcohols to form aldehydes and carboxylic acids. These substances may then form fragrant acetals and esters at a slower rate by further reaction with alcohols, usually in the bottle. Wines are said to take about 3 months to recover from 'bottling sickness'. How much these principles apply in the less acidic and less alcoholic environments of beer is beyond me.

Onto sterility. It's all been said before, but there are few alternatives to sulphiting. Heat destroys the fruit's natural digestion enzymes, sets pectin into a haze-forming gel, and increases loss of volatiles. In the case of apples and bananas, starch hazes are also possible. Freezing won't kill all bugs, (but is a useful means of softening up some hard fruits, however). Sulphite has the secondary benefits of preventing oxidative browning and increasing production of glycerol by the yeast. This a sweetish substance which increases body and masks the harshness of young wines. It is a forbidden additive according to the winemakers' equivalent of the Rheit@\*%! For those who are committed to organic brewing, I would advise selecting totally unmarked fruit and at least washing it in sulphite before rinsing with water. It seems to me that there must be a big difference between adding something which produces volatile sulphur dioxide in the conditions of a primary ferment, and adding preservatives at bottling time.

Lastly, for those who have not yet been adventurous enough to try brewing fruit beers, the students around here have come up with something just as bizarre. The drinks are known as 'purple nasties' and 'snakebites', and basically involve various mixtures of lager, cider and raspberry cordial. Match that, Belgium :-)

From: arf@ddswl.mcs.com (Jack Schmidling)  
Subject: NITROSAMINES

To: Homebrew Digest  
Fm: Jack Schmidling

#### NITROSAMINES REVISITED

I just had a very disconcerting conversation with Roger Bries of Bries Malting, aka Chilton Malting et al.

I had the feeling I was caught in a "Cross Fire" debate with the tobacco lady who claims there is no proof that tobacco causes cancer.

Every question I asked was responded to with a long sermon on everything from the dangers of airline travel to the differences between mice and men.

I was also to be put at ease because the nitrosamines in their malt rarely exceeds 2 ppm with a FDA limit of 4 ppm. As it was my nickel, I persisted in interrupting with "but what malting process does Bries use"?

When I finally got tired of listening to him and got downright rude, he declared that he does not divulge the actual process.

In a previous conversation with Mary Ann Gruber of the Chilton Malting subsidiary, she told me that crystal malt was made using the "indirect" process but the others were made with the "direct" process.

In my limited research, I have learned that sprouting grains produce a "nitrosamine precursor" that is turned into nitrosamine, when heated in an environment with combustion by-products. i.e. gas fired kilns or the kitchen oven. This is what is known as the direct process. The reaction is particularly vigorous in a moist environment such as used to produce crystal malt.

She also informed me that the grain cured in the direct process is "sulphured" before kilning. They are soaked or sprayed with sulphur dioxide. This, I have been told, reduces the nitrosamines to below the FDA standard.

In the indirect process, the grain is heated through a heat exchanger, steam or electric heaters and nitrosamines are not produced or are greatly reduced.

I went away from the conversations with Bries Malting, with the very strong impression that, if not the entire industry, at least Bries is trying to prevent a festering wound from turning to gangrene.

Switching from direct to indirect would require an enormous

investment and essentially put them out of business. It seems apparent that the nitrosamines in crystal malt could not be brought to "acceptable" levels without changing process but I assume that, as a specialty malt, the volume is small enough, that they could sustain the cost.

My guess is that the FDA limit was a negotiated number that took all of the above into consideration, with only minimal concern for the actual human health aspect.

The other side of the issue that indicates some hope is the fact that, in the 70's when nitrosamines were first found in beer, none were found in Coors. I believe that Coors uses the indirect process for reasons probably related to their expansion during the time when the new process came along and had nothing to do with nitrosamines. They just got lucky.

We were then told by the industry/media that the FDA jumped in and everybody changed their process to meet the new standards. We now know that, to most malters, this simply meant "sulphuring" their grain.

Well, that's as far as I have gotten to date. I am not suggesting the we start drinking Coors but I do think that we need to do a lot of poking in some dark places to find out who is doing what.

I would instantly switch to a malt brand that uses the indirect process and/or publishes the nitro content, at the expense of more money or inferior beer. At least, I would like the option to make that decision.

If anyone out there has any info or can help in this crusade, I would love to hear from them.

Jack

Subject: On 734

I only got to read HD #732 today, so this is late:

To Russ Gelinas, I checked on the cold water wash with Dave. He sez there isn't any problem about shocking the ale yeasts (actually, ale yeasts are only shocked by pictures of Jesse Helms). Viable yeast apparently goes into suspension because it is more bouyant than dead yeast or trub. He sez.

On #734

According to a lecture I sat through at Great Western Malting, bugs in the malt is not a good sign. (Oh, really!) What it is is a sign that the moisture content has gotten above the safe level. It is important to keep the grain well protected physically, but apparently bugs and molds aren't much interested in grain until the moisture content rises above 5%. At that point, look out! If anyone is getting buggy malt from their homebrew supplier, they should definitely take that as an indication of poor handling and shop for another source.

Did I mention here that Great Western is now selling both their pale malt (Klages) and their line of Hugh Baird British specialty malts by mail? I don't know what their prices are exactly, but do know that their Klages by the box is very hard to beat. Address is P O Box 469, Corning CA 96021. Number is (916) 824-3888.

As "grumpy" sez, Liberty Malt Supply in Seattle has an astonishing array of malts, including something like 5 different wheat malts. !!

To Ken Ellinwood:

Dave tells me that Sierra Nevada is a particularly cold-resistant yeast strain, even though it's a British ale yeast originally. I don't think you should worry unless the fermenter had been at that temperature for days. Did the fermentation actually cease?

Subject: Kegs, backflow valves, tap cleaning

For people running multiple kegs off of one CO2 cylinder, how do you stop things (deadly microbes say) from migrating from one keg to the other? Are there check valves between the regulator or manifold, and each keg?

I always thought that bacteria couldn't grow in a CO2 environment, but perhaps this is just a "momily". Maybe Jack will help us here...

From: Doug Dreger <dreger@seismo.gps.caltech.edu>  
Subject: Barleywine and Yeast

Hello,

I've just racked my barleywine into the secondary and it tastes great and is more filling, but I have a few questions. First, it only took 2 days to ferment (from 1.090 to 1.017 @80F). I used the american ale yeast because Great fermentations recommended it for a barleywine over a champaign yeast. Since the SG is so low I don't think the yeast has been killed off, but is it possible with continued aging the yeast will die? Second, is this the same yeast that Sierra Nevada uses in their Bigfoot Barleywine? Depending upon the consensus or experience based on the first question, should I bottle as usual, or add some yeast? I do have a keg but I am worried about tying it up. Maybe I should keg the BW and buy another used keg to keep my regular brews in.

Also I remember some discussion about counter pressure fillers and that there were some to avoid. Which is the recommended type and where can they be found ?

Doug

From: kla!kirkish@Sun.COM (Steve Kirkish)  
Subject: Re: Banana Beer, oh no

In HBD #732, Hans Lindberg writes about banana odors...

>Let me start by saying that I'm a beginner so don't laugh.  
>I read in HD#731 something about banana tasting beer, and that that means  
>the brew has gone wrong. That worries me, because I have my first batch  
>brewing right now, and it's been bubbling off a pleasant smelling  
>banana like scent from about half a day or so after it started bubbling.  
>It's an extract brew, Muntons Traditional Bitter. It said on the can  
>that it should brew at 18 to 21 deg c, but I had a hard time keeping  
>the temp down at first (I overlooked one radiator) but it never was more  
>than 22 degs in the room. From the second day or so the temp has been  
>around 20 deg c. Have I messed it up completely?

Well, I'm not much more than a novice at this game myself, but that won't stop me from putting in my \$0.02 worth. I've brewed two batches recently, one using Dry Malt Extract (DME) and one using "liquid" malt extract, but both used Edme Dry Yeast. Because it was getting \*very\* late both evenings, and because I still apply primitive cooling means, it was taking forever to cool the wort before pitching the yeast. Well, I ended up pitching both times around 78 degF and got normally wonderful smells from the fermentor, but no bananas. However, I wound up with a banana smell when I popped the cap off the bottle due, I believe, from the slightly higher pitching temp (I imagine it took a loooong time for the 5 gallons to cool further.) I understand that yeast will give off various esters at elevated temperatures, so that's probably the story.

So, what happened? Well, the taste wasn't really affected, and after a few weeks in the bottle, the banana scent is no longer noticeable. And, most importantly, the beer tastes great (not just IMHO :-). Moral, as always: Relax, Don't Worry, and give it a go!

From: Jim Grady <jimg@hpwald.wal.hp.com>  
Subject: Clean Chillers

I made an immersion chiller for my last batch and was wondering what you all use to keep them clean & shiny. Before I used it I gave it a cursory scrub but did not worry too much about sanitation since it would be going into the boiling wort. When I pulled it out of the wort, it was much shinier than when it went in & I shuddered to think of what I had put into my beer! The beer has an off-flavor but it is also the stuck batch that I wrote about earlier. I believe it stuck because of temperature so I don't know which is the culprit here.

The chiller is made from 1/4" I.D. copper tubing. Following some advice in these pages for cleaning copper pot scrubbers, I tried cleaning the chiller by putting it in a weak, boiling vinegar solution. That seemed to clean up the submerged part nicely - the part that was out of the liquid got worse. This also does not do anything to prevent it from oxidizing later.

Do I just need to do this each time I brew? Is there a better method? I have a 5 gal pot on an electric stove so bringing 3-4 gal to a boil twice in one batch is no small feat.

And, while I'm on the subject of chillers, I actually was more worried about infection with this last batch. The chiller is taller than the brewpot so even if I put the lid on, there is about a 2" gap between the lid and the pot as the wort is cooled through the temperature danger zone. When the wort was cooling in the carboy, it is sealed off from the environment even though it cools much more slowly. I put some cotton wool in the fermentation lock (as well as water) to help discourage nasties. What do people think? Am I worrying for nothing? Thanks in advance.

If your dishwasher has a "heated dry" cycle, which produces steam (mine does), it will do a very nice job of sanitizing them for you (they end up pretty hot, though!). Just start at the rinse cycle, since they are presumably clean already, and don't use any detergent.

Hmmm. Luckily, I haven't had this happen to my DME, but it has  
certainly happened to my brown sugar. The solution in that case  
is to simply put the block into the microwave and heat for a  
minute or three at high heat. It should come out nice and soft,  
for some chemical reason, I am sure :-).

May I ask a simple question? How did you sanitize the caps? A friend of mine had this happen to him, and he sanitized the plastic bottle caps with the bottles. He usually boils the regular bottle caps (as I do and suggested to him), but forgot this time.

Especially if your beer was foamy when you bottled, the caps could have infected the bottles.

Guess what, the literature is either *\*implying\** this or wrong.  
Homebrewing was only made legal on the *\*federal\** level in 1979.  
So it was illegal *\*everywhere\** in the U.S. before that.

However, some local jurisdictions have passed liquor laws that  
prohibit homebrewing. New Jersey is just one of those. Georgia  
is apparently another, judging from a recent issue of *\_zymurgy\_*,  
where there was an announcement of a new homebrew club, with the  
members names kept anonymous, and their eyes covered with black  
rectangles in the club picture.

Subject: Bottling Beer

OK, I hope to not be involved in any further flaming, but let me get a few thoughts off my chest about bottling beer.

- 1) I think it is Miller who suggests letting the beer settle in the bottles for ten minutes or so--long enough to produce some CO2 and drive off the air in the bottle--before capping. And, this is with the advocated very small headspace. Presumably, this is the yeast attacking the new priming sugar. Is there any possibility of the beer being partially carbonated in the fermenter?
- 2) I used to put that little red plastic cap firmly on the end of my airlock. But I never got any bubbles or glugging in the air lock. Turns out I was pre-carbonating my beer and not letting the CO2 bubble out through the air lock. I now either leave it off completely or balance it on top at a rakish angle. Any ideas what it is for?
- 3) If I use a bottle filler, with a spring that stops the flow when pressure is removed, it foams up quite a bit at the beginning, until it is under the beer. If I just fill from the tap on the bottling bucket into the bottle, it also tends to foam up a bit unless I am really careful and use a slow fill rate. So far, neither of these has resulted in a beer that is obviously oxidized, but I worry nonetheless (I have tasted a batch that was oxidized--yuck). Any suggestions?

From: j\_freela@hwking.cca.cr.rockwell.com (Joe Freeland)  
Subject: Low attenuating yeast

Greetings Brewers,

I have just recently begun home brewing, and also reading this digest. I have some simple questions hopefully someone can answer or has experience dealing with.

1. Has anyone ever tried brewing in old whiskey jugs ?  
The ones I have come across have no means of capping, it seems as though they must be corked. Would the fermentation process provide too much pressure for a cork to hold ? Has anyone ever done this or heard of it being done ? I have a variety of sizes ranging from 1 quart to 2 gallons. I read mention of brewing in smaller jugs in the New Joy book, but it doesn't get into it too much. The next question is somewhat related.
2. I have been wondering about brewing small quantities of a certain variations of a recipe i.e. making a five gallon recipe, making some minor "adjustments" and then individually fermenting in say 1 gallon jugs. Each jug would have a different "tweek" to it. This would allow a better A/B comparison for fine tuning the taste. Has anyone ever tried this or am I just thinking about this too hard ?

I also have a supplier I have been ordering some begginers supplies from, it seems like they have quite a selection. They are AGS or Alternative Garden Supply in Streamwood, IL. They have a toll number which is (800)444-2837.

If anyone has ideas and doesn't want to waste digest bandwidth, or if these questions have been dealt with before, you can email me at j\_freela@hwking.cca.cr.rockwell.com.

From: "Jon Sonntag (LutherNet)" <SONNTAJM@CRF.CUIS.EDU>  
Subject: Priming Sugar "foam up"

When I bottled my last batch of beer, I checked the air-lock to see whether it was still bubbling away. It appeared to be done fermenting. I double-checked this with the hydrometer which was below the spec. grav. listed in the recipe. When I added the half cup of priming sugar (which was dissolved in luke warm water) to the beer, it foamed up for about 30 seconds making quite a mess. Obviously, something went wrong. Did I bottle too early? Will all of my bottles be exploding in a few weeks, or will it be flat since the sugars were used up immediately in the big "foam up"?

(Yes, I'm new at this if you haven't guessed. My history of home brewing: Batch 1 was awful. Batch 2 was great but a little over carbonated. I'm waiting impatiently for batch 3 and just bottled batch 4 - the "foam up" batch.)

>there's something to it, I'm told that sub-fatal doses of  
>arsenic can cause hallucinatory experiences. Guess what gets  
>concentrated in banana skins? Arsenic.  
>Probably not a good homebrew ingredient. Peel 'em.

Since this forum is so "into" recipes, I could not resist posting.  
(Please send all flames to /dev/null)  
According to this article is not arsenic in banana peels which causes  
a hallucinatory experience. I for one however, would not be brave enough  
to find out what ingredient does cause the effects (arsenic or Musa  
Sapientum bananadine) or do I care.  
\*\*\*\*\*

Believe it or not, bananas do contain a small  
quantity of 'Musa Sapientum bananadine', which is a mild,  
short-lasting psychadelic. There are much easier ways of  
getting high, but the great advantage to this method is  
that bananas are legal.

1. Obtain 15 lbs. of ripe yellow bananas.
2. Peel all 15 lbs. and eat the fruit. Save the peels.
3. With a sharp knife, scrape off the insides of the  
peels and save the scraped material.
4. Put all scraped material in a large pot and add  
water. Boil for three to four hours until it has  
attained a solid paste consistency.
5. Spread this paste on cookie sheets, and dry in an  
oven for about 20 minutes to half an hour. This will  
result in a fine black powder. Makes about one pound  
of bananadine powder. Usually one will feel the  
effects of bananadine after smoking three or  
four cigarettes.

Subject: Racking to secondary...

Hi ho all! I've got my second attempt at a SNPA clone going right now and decided last night to try a couple of things I haven't done before. First, I racked to a secondary. Now, what is "normal" behavior (of the yeast) after racking? The ferment was going at a pretty good rate before racking. Now it is still bubbling the air lock several times a minute but the activity is not nearly so vigorous. I was careful not to oxidise and do other nasty thing to mah yeasties. Second, I tried dry hopping. After some experimentation I was actually able to get most of the hops (leaf) into the secondary, nothing the vacume can't handle! ;-) Anyway, just how much is a good amount to use? Another question I saw someone ask else where, do you use finishing hops AND dry hop or does one or the other do the job? If you do finish should the amount of hops be reduced in the finish or while dry hopping? BTW, I dry hopped with 1/2oz Cascades, and have 2 oz in the boil, another 1/2oz at 30 min, and 1/2oz at 50 min with a 60 minute boil.

Thanks!

TTFN

From: carey@alta.tivoli.com (Carey Jung)  
Subject: Stuck Fermentation??

Help!

I'm a novice attempting to brew my first batch of beer. I chose the simple route, buying a can of Cooper's Stout extract and following the Cat's Meow brewing instructions. I boiled the wort for about 15 minutes in about 3 gallons of water, poured it into a sanitized fermenting bucket, and added cool water to 6 gallons (the recipe size). The temperature was around 130 degrees, so I chilled it in my bathtub until the temperature was down to 90 degrees (specified fermenting temperature is 20-30 degrees Celsius), pitched in the contents of the yeast packet, stirred it, put the airlock on, and stuck it in the closet to ferment. That was Sunday about 2pm. Well,...it's been two days now and fermentation is still insignificant (about one bubble every 3-5 seconds out of the airlock).

Anyone know what the problem is? Bad yeast? (The store where I bought it doesn't refrigerate it.) Bad procedure? (I didn't make a starter.) What?  
I'd appreciate any and all help. Thanks.

Subject: brew pub

In HBD #735, Russ described a bad experience with a brewpub in Portland, ME. I assume you were talking about Gritty McDuff's since that's the only one I know of south of Bar Harbor. I was there once and had a great pale ale. Maybe I got lucky or maybe you didn't. Hmm, I think I was in there in the middle of winter. Maybe what they're serving now is what they have left after tourist season. It may be that in the summer they have trouble brewing their best beers; their production system may not be up to the demands of the tourists. Or maybe these were brewed/fermented during that really hot spell we had a while back.

I don't mean to sound like an apologist for Gritty's since I have no personal attachment, but this is the first time I've heard anything negative about it.

-Nils

Oh yeah, Ray Davies of the Kinks hangs out there when he's in Maine. I think he has a sister who lives in Falmouth.

Date: Tue, 1 Oct 91 11:57:49 CDT  
From: bliss@csrd.uiuc.edu (Brian Bliss)  
Subject: flaked barley

I brewed up a batch of all-grain stout, the other day,  
and used flaked barley:

8 oz roasted barley  
8 oz black patent  
3 lbs klages  
8 oz chocolate  
2 lb barley flakes  
2 lb pale malt (very light)  
3 lb pale malt (darker)  
2 lb vienna malt  
1 lb untyped malted barley

The flaked barley has no husk, so I saw no reason not to grind it finely. I mashed in at 130 F, and tried to adjust my ph with gypsum. I \*almost\* boiled the water, but I guess this wasn't good enough, because it required acid blend to adjust the ph. I was worried about this, but figured "what the hell", so what if it's a little sour from the acid - that's standard in stouts. The wort tastes fine now, but think I'll use distilled water at least for the mash-in from now on. (lesson #1) (Ph had been easier to adjust in previous batches where I boiled the water completely)  
btw. the grains had a head on them at mash time! presumably from the flaked barley.

I mashed at 150 for 115 min. The sparge was slow, but I had 14 lbs of grain in the plastic sparge bucket. I decided to divide the grain into two halves, and sparge them separately. worked great (but I ran out of sparge water to completely get one of the halves totally sparged - It wasn't as light as the other half when it was done.). lesson #2 - only put 6" or 7" of grain in the sparge bucket at one time.

I then let the spargings settle, as I always do. What seemed to be 3 or 4" of hot break settled out of the initial spargings! I had already learned lesson #3 (let you spargings settle), but had never experienced this phenomenon before. ususally it is pretty obvious that the sediment is husks (and there's usually less volume).

I boiled for 2 hours, and used the following hops (all leaf):

14 g bullion (not so fresh) 1:45  
16 g cascade (very fresh) 1:45  
10 g bullion 1:05  
14 g cascade 1:05  
4 g hallertauer finish

I didn't meant to terminate the boil about 20-30 minutes earlier, but then I spilled hot wort all over myself, resulting in a blister half the size of a golf ball on my foot. It took a little time to recover.

As with all my all-grain batches so far, the wort never boiled over. I came to a rapid boil (over 45 min), and convection currents agitated it nicely. All of my extract brews have foamed up like the dickens at the start of a rapid boil.

I chilled with an immersion chiller, and strained the wort through the hops. instead of the usual hot break completely clogging up the hop bed, the hops stayed clean & green - I guess all the proteins came out when I let the spargings settle, and there were none left at this point.

It made 5.5 gal of 1.068 wort. I had 374 out of 450 pt \* gals of possible extraction, so an efficiency of about 85%. It might have been higher if I had sparged the one half of the grains a little more (but I had more than enough volume to boil away, anyway) There was no evidence of hot break in the fermenter. I wonder if extra proteins from the flaked barley coagulated, and brought most all of the protein out of suspension when it settled.

I pitched a wyeast german ale starter. This is the third time around for the yeast. The first time I used it, the yeast I was planning on using went bad, so I even incubated it for an hour and pitched. It took a month to ferment (a similar extract stout). The next time, I just saved the glob at the bottom of the fermenter. It took 3 weeks to ferment (a bass-like ale - but better :-). I saved some glob from this batch, and this time added some fresh wort. This batch took right off, almost as vigorour as M&F ale yeast or whitbread ale yeast. lesson #4. Of course, It could be that there were several strains of yeast in the original packet, and that through repeated reculturing, I was selectively growing one similar to what is in the two aforementioned dry yeasts.

I stuck the fermenter in an ice water bath, and keep it at 65F or below. It been aroung 60 hours since pitching now, and the krausen has almost completely fallen. I might get to enjoy this one earlier than I had anticipated.

Subject: Hop seminar & wet hopping.

My background in herbal medicine and herb tea preparation may be of some help here. The rule of thumb is: If you can smell it, you wasted it.

For the hop seminar, I'd do this: Take each hop and divide in two. Bring one half of each hop to a boil in a weak wort solution to illustrate the aroma and, after awhile in the boil, the bittering. For the taste test, use distilled water that has been boiled. Place the dry hops in cups and pour the boiling water over them. Place saucers over the cups and let sit for seven minutes. More time than that and the flavors begin to get bitter. Remove the saucers and begin the tasting.

If you want to do some work ahead of time, you can save yourself some headaches. The aroma test can only be done with actively boiling hops, but the taste test can be prepared in advance. This part applies to what Russ Gelinas is trying to do, too. The most concentrated and potent way to prepare an herb, aside from eating the herb, is to make a cold extraction.

To do this, prepare a one hundred proof solution of Everclear and water, or use 100 proof vodka. Place a portion of the hops in a bottle with the alcohol, cover tightly and let sit, shaking daily, for two weeks. Strain out the liquid and you have a \*very\* strong cold extract. Cut this two or three to one with distilled water and pass around for samples of hop taste.

The hot tea will probably be better, no alcohol taste, but the extract will be very accurate in showing the differences among the varieties and, as I said, it may be prepared in advance.

Maybe you should pass out hop pellets of the different kinds and let people munch on 'em.

Dan Graham,

From: Gerald Andrew Winters <gerald@engin.umich.edu>  
Subject: dry hopping

Conn Copas <C.V.Copas@loughborough.ac.uk> writes...

>One phenomenon I have noticed is that dry hopping increases the  
attenuation  
>of the brew. I have proved this to myself by dividing the same brew in  
half  
>and treating each half differently. I would be interested in any  
>explanations for this reaction. Here are some tentative ideas : the hops  
>introduce additional enzymes or microorganisms into the brew, they cause  
a  
>mechanical rousing of the brew, or maybe simply opening the fermenter  
and  
>introducing oxygen is the key factor.

This is the first digest entry I've read that comes close to an  
experience  
that has puzzled me. I brewed a batch that was supposed to end up  
something  
like Sierra Nevada pale ale. It was an all grain batch and the whole  
process  
went very smoothly with no surprises. I follow Millers method were I get  
the  
wort to near freezing, let it warm up over night, and rack and pitch the  
next  
day. After a couple weeks I racked it off the yeast into another carboy  
to let it ferment out and to dry hop. The beer sat in the secondary at  
least  
another couple weeks before I added 2 oz. of cascade pellets. I took a  
hydrometer reading and was disappointed in getting a reading of 25. My  
taste  
buds also confirmed that the beer was a little too sweet. I pitched the  
hops  
anyway and closed the lid on my temp. controlled freezer (I keep the temp.  
between 60 - 65f). When I checked the batch a short while later I  
couldn't  
believe it -- my batch was fermenting to the point of forming an inch of  
krauesen on the surface of the beer. I felt somewhat ambivalent at this  
point.  
I was happy that maybe the gravity/sweetness could be reduced, but what  
the  
hell did I add to my beer? The beer behaved as if fresh yeast had been  
added  
and seemed to go through all the normal phases -- again. When I bottled  
the  
gravity was at 10 and tasted okay. Any explanations? Also, the hop nose  
I  
expected wasn't there. Could this be because the CO2 from vigorous  
fermentation  
kind of scrubbed the delicate aromas away? Or are some of the low alpha-  
acid  
hops not a particularly good dry hop variety?

From: Frank Tutzauer <COMFRANK@ubvmsb.cc.buffalo.edu>  
Subject: Wy is my Wyeast so Wyld?

I'm working on batch number 4, which is my first time using liquid yeast. I'm brewing a steam beer and using Wyeast 2035 (American lager). When I got the yeast, I fondled the cool foil package a little, and then popped it into the fridge. A couple of days later (Wednesday evening), I broke open the capsule. At that time, the package was six weeks old to the day, and I figured I'd brew on Friday or Saturday, depending on how quickly things progressed. The next morning, I expected to see some swelling, but there was very little. Ambient temperature was right at 70, so I put the package closer to the pilot light on my stove. A couple of days later, there was still very little swelling. I thought I'd get something the size of a nerf football, but this baby never even got an inch thick. If I shook the packet and put it next to my ear, I could hear the sizzle of carbon dioxide coming out of solution, but otherwise there was no activity. Saturday evening, I figured I had contrived to kill the yeast, said, "What the hell," and made up my starter anyway (4 tablespoons of amber DME, boiled in a pint of water for 15 minutes). When I split open the package, the remains clinging to the inside smelled and tasted, well, yeasty (duh...), kind of a cross between bread and beer. The air lock glugged for an hour or so as CO2 came out of solution, and then activity stopped. Sunday morning, nothing. So I went off to see the Bills beat the Bears, and when I came home, lo, there was the tiniest of kraeusens on the surface of the beer. The next morning, the yeastie boys were going great guns. I figured no way can I brew Monday or Tuesday, so I boiled up a half cup DME in a quart of water, dumped starter 1 into starter 2, and set it aside. Before I transferred containers, I poured off a little of starter 1 to taste. Unfortunately I didn't think to do so until after I had given it a vigorous shake, so there was a lot of yeast in suspension in my sample...which tasted exactly like apple juice. Well, starter 2 still is at high krausen (Tuesday afternoon). I've noticed that the yeastie boys aren't flocculating too well. Is this typical of all liquid yeasts, or just the American lager? Anyway, I'm not really asking what I should do--I'm brewing tomorrow afternoon, and any answers I get, particularly if they're posted in the digest, will be too late. On the other hand, I would welcome any comments on my techniques and/or experiences. One of the great things about this digest is that relatively isolated people like me get the wisdom of Those Who Have Been There Before.

I think I'll call the finished beer something like Wycked Wyvern, to commemorate my first use of Wyeast.

Subject: Re: Banana Beer, oh no

A note to novices:

There are those purists who will tell you that a banana flavor/aroma in your beer is a "bad thing." Don't believe them.

True that the ester which produces the banana aroma/flavor may be \*undesirable\* in many beer styles, but it is not an indication that the beer has gone bad. When brewing lagers or a nice bitter you probably don't want the fruity taste. On the other hand, certain ales really benefit from the character added by various fruity and buttery flavors.

For a wicked example of banana ester, pop open a bottle of Samuel Adams Wheat Beer. Is this beer true to style? Probably not. Is it delicious anyways? You bet.

(Of course, some purist is going to reply that he (or she) doesn't like it because it isn't true to style. My attitude is that I don't care what the style is, I either like the beer or I don't. I happen to find fruity flavors to be very appealing in \*some\* beers.)

Remember, the goal here is to RDWHAHB! (or another SAWB which is what I'm doing right now.)

From: Jeff Frane <70670.2067@compuserve.com>  
Subject: On #735

To Stephen Russell: I knew that Dave Miller had some odd ideas, but his contention "proteins in flaked barley require breakdown by proteolytic enzymes that have been destroyed by the higher kilning of pale ale malt" is fascinating. Also, from personal experience, poppycock. For easily two years I have been brewing batch after batch of ale using British ale malts and a handy portion (2 - 5 oz./5 gal.) of flaked barley. The result is a wonderful, dense head and extra creamy mouthfeel--and perfectly clear beer. I would \*particularly\* not worry about this if I were brewing a stout; in fact, I've raised the amount of flaked barley in stout with NO problems.

On hops: Fred Eckhardt has done tastings like this (look in the back of his book on beerstyles; isn't there something about this?). My memory is that the hop teas were simply steeped in hot water. It's not clear to me that you'll get particularly accurate representations of flavor, but should get excellent \*aroma\* comparisons with a 15-minute steep.

To Russ Gelinas: I've saved an empty bottle of what was one of the tastiest ales I've had, Geary Ale from Maine. Is it still brewed and is it still good?

To Jack Schmidling: That's Briess, with two "ss". Has your "limited research" gotten any farther than the notes I passed along from Great Western Malting? Before anyone goes reeling off to drink Coors (eeagh!) do remember that GW switched to an indirect process a number of years ago. They supply pale malt (primarily Klages) to virtually all the west coast breweries, both mega- and micro-. I \*know\* they use an indirect process because I've toured their Vancouver plant at least four times, and have a friend who works there.

To Doug Dreger: Your two-day fermentation is truly astonishing, although I note you're fermenting at 80^. Wow! I brewed a beer several years ago that started at 1.090 and dropped to about 1.020 (over much more than 2 days, but then I fermented at 65^). I racked it to gallon jugs and let it sit for 6 months. Although the beer had dropped clear by then it was still willing to ferment in the bottle! I kegged it and put a slight amount of CO2 on it, no more than 5 pounds. When I opened the first bottles two weeks later, I was amazed at how full the carbonation was. Probably the best beer I ever made.

From: DAVID KLEIN <PAKLEIN@ccit.arizona.edu>  
Subject: Mead

Yo, Mead brewers...

I've been brewing beer for a short while now, and have just tried my first mead (actually a pyment (sp?) (honey and grapes)) and got 'a question

The mead ended up at about 1.125 OG. this is a 15% potential for alcohol.  
I am using the red star wine yeast. But the yeast should poop out at around 12% alch.

So)

- 1: will the 3% remaining sugar be too sweet?
- 2: Since I want a bubbly mead, and assume that I should prime to do so (due to a beer bias) What do I do to get bubbles, when the yeasties get drunk? (i.e. do I add a bit of water when I prime (how much) or do I just guess when to bottle so that the yeast poops out at a good time (at what SG?))

I am at about 4 gallons, and can thus lower the gravity, but really have so little info on mead, that I don't know if I should....

Suggestions?

Dave

> fill rate. So far, neither of these has resulted in a beer  
> that is obviously oxidized, but I worry nonetheless (I have  
> tasted a batch that was oxidized--yuck). Any suggestions?

I use a siphon hose and a `bottling wand' (with the spring-loaded gadget you mention). Since the pressure that is seen at the end of the siphon hose depends on how far it is below top of the beer in the bin, here's what I do to avoid the foam:

I Raise the bottle and the `wand' when I start filling each bottle. The flow of beer into the bottle is slowed down, and no foam is created. Then, when the level of beer in the bottle covers the bottle filler (spring-loaded part), I lower the bottle and the wand to speed up the flow.

Subject: Non-jellying jelly

No, this is definitely not a Homebrew Digest topic. But then again, all the talk of Gals in beer commercials isn't either.

The answer to your sisters problem is pectin, the lack of. If you add com-  
mercially availble pectin, Sure-Jell (sp? I'm at work, can't look it up)  
,  
you will solved this problem. Now, if you want to do it the old-timers  
way,  
ya gotta cook that baby for a Loooooong time. I made some apple jelly  
according to my grandmother's recipe, and I ended up cooking the stuff  
for  
about an hour and a half. If a long string hangs down off of the spoon  
when you lift it from your concoction, it's ready for canning. Don't be  
surprised if the jelly takes a long time to set up. That particular  
batch  
of apple jelly took over two months to harden up. (didn't cook quite long  
enough, or didn't use enough GREEN apples). But it tasted great as both  
a  
syrup and a jelly. :-)

Also, some fruits don't have as much pectin as others. Green apples tend  
to be loaded with it, while Red Ripe apples don't have quite enough.  
Probably  
due to the moisture content of the apple. Some friends of mine made  
crab-  
apple jelly, and it took no time to set up. As soon as the liquid  
cooled,  
you had to scrape to get it off the pans and spoons. With anything,  
practice  
makes perfect...

From: Dances with Workstations <buchman@marval.dco.DEC.COM>  
Subject: Express bottle washing

There's been much talk lately about ways to beat the drudgery of sanitizing bottles before brewing. Lately it has been recommended that heat--either by baking in the oven or running the bottles through the DRY cycle of the dishwasher would work. SO I was wondering...

Is there any reason that microwaving the bottles for a couple minutes at high power wouldn't do the trick equally well? This would fry the little nasty contaminants directly and not unduly heat the glass ( I would imagine). It would be faster than heating /cooling in the dishwasher or oven, and you wouldn't have to worry about annealing the glass.

I'm going to check this out with my biochemist brother and botanist sister, but would appreciate the opinion of the brewing community. Since I rarely cook with microwaves I don't know whether this would do bad things to glass, either.

From: larryba@microsoft.com  
Subject: Great Western Malting mail order

I called GWM (1-916-824-3888) and got the skinny on their mail order malts:

Pale Ale (mainly klages, but not identified as such in case they want to substitute something else)

20lb @ \$.70/lb (\$14.00) + shipping  
30lb @ \$.65/lb (\$19.50)  
40lb @ \$.60/lb (\$24.00)

Shipping to Seattle from Sacramento is \$8.35

All specialty malts are \$1.00/lb and are from some english supplier.

I have used GWM stuff for about a year and have been pleased with the quality and uniformity of their products. At the Brewers Warehouse (seattle) I get a grain card (pre-paid) and the pale ale is \$.85/lb and specialties are \$1.00/lb. Since the brew shop measures and grinds for me it isn't worth going through the mail.

Now, GWM is willing to sell 2000lb pallets for \$.30/lb... They allow mixing grains on the pallet - specialties are around \$.36 to \$.38/lb - all pretty cheap. Shipping to my doorstep would add another \$.05/lb - Hmmm. Time to start a brewing coop!

Also the guy in Vancouver Wa (where the bulk orders would come for me) said the premium pale malt (what we all call klages) is really 55% harrington and 45% klages.

Interesting stuff...

From: STROUD%GAIA@leia.polaroid.com  
Subject: The Composition of Beer

Thought you all might be interested in this (it's from The Spectrum, Vol. 4, # 2, 1991):

The taste and the flavor of beer are determined by the combination of several hundreds of chemical substances. A typical composition of lager beer is represented in the table below. The energy value of 1800 kJ/kg is less than that of fruit juice, wine, or milk. The most important energy contributions in beer are due to ethanol (29 kJ/g) and carbohydrates (16 kJ/g). Beers with a low ethanol content (so-called alcohol free beers).....are not diet drinks unless the concentration of carbohydrates is below 10g/kg. Variations in the amounts of both ethanol and carbohydrates are found. An alcohol-free beer may even contain more carbohydrates than a lager beer, which detracts it from being light. On the other hand, the concentration of carbohydrates in a beer may be low, yet the ethanol content can be elevated. To avoid confusion, one should carefully consult the information on the label.

The composition of a typical lager beer (in g/kg)

|                  |        |
|------------------|--------|
| Water            | 920    |
| Ethanol          | 40     |
| Carbohydrates    | 30     |
| Carbon Dioxide   | 5      |
| Amino acids      | 1      |
| Potassium        | 0.490  |
| Phosphorus       | 0.225  |
| Magnesium        | 0.105  |
| Hop derivatives  | 0.035  |
| Calcium          | 0.035  |
| Sodium           | 0.030  |
| Vitamin B0       | 0.010  |

From: MEHTA01@UTSW.SWMED.UTEXAS.EDU  
Subject: Hops extraction and addition to BEER

Hi. Reading HBD#736, i realized that the Vodka/Everclear method of extraction is something i've thought about before and would like to try this time for the weizen i have fermenting. Do i just place hops in vodka for a week and then add vodka (sans hops) to fermenting weizen? Would that work (to give the taste and aroma?) or should i add both vodka and hops to fermenter?

Please reply to mehta01@utsw.swmed.utexas.edu

Also, since i mentioned my weizen, i would like to get YHO about WHAT HAPPENED. i did a bad mash, due to overconsumption of homebrew, and ended up protein resting for 8 hours (i just left it overnight) and then the conversion wasn't complete (as shown by the bloody iodine test :-0 ) and then, to top off this great beginning (which i named WUNDER WEIZEN before i started : -) ), i decided to use Bavarian Weizen yeast (Wyeast). The package swelled and the starter activity was a little low (little foam on top) but i pitched. Activity was seen (many bubbles/min.) after 24 hours. Fermentation was carried out at 10-15 C in my fridge. Now, after 1 1/2 weeks there is almost no activity, and the SG dropped to <1. Oh yes, i added some amylase after activity had slowed down, to clear the starch left over from bad mash (see above : -( ).

Also, a slight foam stayed on the top after the initial foamy krauzen had dropped. This is still OK, as i have had more perplexing things happen. The only problem is this pungent smell that came out of the airlock during teh slow activity period (before amylase and after) and most important the beer does NOT SMELL or TASTE ANYTHING like the smell when the WYeast packet was opened, or like a normal WEIZEN. !! ??

Please post YHO, any comments or suggestions, to mehta01@utsw.swmed.utexas.edu

Perplexed.

Subject: Small batches?

A friend and I have been discussing the possibility of brewing smaller batches of beer to help speed up our knowlegde aquisition process. You see I'm not a large consumer of beer, but very much enjoy the hobby of making my own. (Not to mention the significant taste/variety advantage over commercial stuff.) I'd like to be able to brew about a 1 case batch at a time. I do only extract and partial grain recipes and mostly want to be able to experiment with different styles. What adjustments to the standard ~ 5 gal recipes would be necessary? Would the standard issue 7 gal plastic primary fermenting vessel be okay for the initial ferment? We figured that a 3 gal glass carboy could be used for the secondary.

Subject: Liverwort

Last week I brewed a scotch ale. At the end of the sparge I had collected 9 gallons at SG = 1.050. Although I've used the same boiler for five years (a keg with water heater element welded inside), on this day the wort smoked and burned as it boiled. When my 1.5 hour boil (burn) was over, I opened the tap to drain the wort. Nothing came out. Looking inside, I saw a slab of liver clinging to the side of the boiler. Using my spoon, I found another clogging my tap, and many small specimens as well.

Summing up the courage to actually touch this strange and repulsive substance, I found it to be like a wet newspaper, and found it to separate into sheets. Naturally my first reaction was that the brewing Gods had sent down some gremlins to throw the liver of some errant homebrewer (who wouldn't heed their warnings) into my boil. Or perhaps an issue of Zymurgy.

But having kept a close watch over my boiler that day, I can't help but wonder if there is a scientific basis for this wierdness. Perhaps excess flour from the first runnings of the sparge which I did NOT recycle combined with the high gravity of the wort to make "wort dumplings"

I would like to hear from anyone who has had this experience or has any theories about what caused it. It gives me the willies. I would consider there to be safety in numbers, but if I stand alone, I may just heed the warnings of the brewing gods and hang up my apron.

MORE TECHNICAL INFO: At the end of the boil the SG was only 1.060. The heating element had a thick black crust on it.

Subject: siphon tube end caps

Hey now- You know those little red thangs that fit on the end of the  
siphon tubes? Does anyone know if they come in different sizes? When I racked  
to my bottling bucket last night, there was total yeast carnage at the  
bottom of my carboy resulting in more sludge than most superfund sites.  
I ended up sacrificing about a quarter-inch of brew to avoid sucking up  
the nasties. A longer end cap would have been helpful as I could have  
jammed it into the trub as normal without having the opening submerged in slime.

Subject: bottle caps from hell

Hey now- I had a pretty bad cap experience last night and thought I'd give a word of warning. The caps were over-runs, blue with "Clearly Canadian" printed on them. When I boiled them for sanitation, the rubber lining came off of every single one. At this point I had my beer/sugar in the bottling bucket ready to go, so I was a little peeved. I decided to try again- this time just bringing the water to a boil, turning the heat off, and dumping the caps in. Within like 3 minutes half the caps were peeling. I ended up having to drive to a friend's house to get more.

I plan on doing a little minor bitching to the place where I bought them, but in the meantime I figured I'd spread the word to avoid these Canadian caps from hell....

Subject: re: Geary's

In HBD #737 there is this comment:

>IN HBD #736 Jeff Frane asks about Geary's Ale.  
>Brewed and bottled in Portland, ME. It is by far the best beer I've  
ever had  
>from a microbrewery. Of course I haven't had nearly the range of  
opportunities  
>that you on the west coast have. I can however recommend staying away  
from  
>Wild Goose (from one of the Carolinas I believe).

It is interesting that you mention both Geary's and Wild Goose. The  
man  
responsible for the recipe development of both brews is Alan Pugsley.  
Alan  
is now Brewmaster at the Wild Goose Brewery in Cambridge Md. I believe  
both  
breweries have similar equipment and brewing styles also via Alan's  
participation in the setting up of the breweries.

It has been awhile since I have had a fresh Geary's ( I do remember  
enjoying  
it however), but I see (taste) no reason why Wild Goose should be  
recommended  
to stay away from. I bought a case fresh from Cambridge last weekend and  
still  
find it to be one of the most refreshing Microbrewed beers on the East  
Coast.  
It has a very HOPPY character but I doubt that should be enough for the  
bad  
review. Was the sample you tried bought out of Mid Atlantic region ?  
Maybe it  
was just an older bottle. Fresh is the only way to enjoy a brew, that's  
why  
we homebrew anyway.....Tim Ness

From: darryl@ism.isc.com (Darryl Richman)  
Subject: re: Express bottle washing

Nuking bottles \*may\* be a good idea. But nuking dry bottles is not, as this will burn out your magnetron bulb. If you want to sanitize with the uwave, add an ounce or two of water and then boil the water for several minutes to sanitize by steam heat. Unfortunately, this eliminates the advantage you mentioned of not warming the bottles. I've done this a few times in anticipation of bottling a few from the keg.

From: bliss@csrd.uiuc.edu (Brian Bliss)  
Subject: Munich Beer Recipe

on Barvarian Weizen:

Is the Wyeast a Weisse or a Weizen yeast? (I don't have a package around to check) If it is a Weisse yeast, then the beer should be quite sour, and I wouldn't be surprised with an weird smelling fermentation.

I have never heard of adding amylaze to already fermenting beer. A friend of mine mentioned it last night, and I thought that one would add it during the mash. How well does it work? (If this Batch has SG < 1, then pretty well) but does anyone else have any practical expeience adding it in the secondary?

- -----  
Recipes - heres my best so far:

Munich Beer:

10 lbs pale alt Malt  
5 lbs munich malt  
.5 lb dextrin malt  
1.5 lb amber crystal malt  
1 Oz gypsum  
.333 oz burton H2O salts  
5.5 g hallertauer 90 min  
1.5 oz cascade 60 min  
.25 oz cascade 30 min  
.25 cascade 15 min  
we yeast munich beer yeast

the sparge stuck, so i got out a big strainer and sparged individual 1 lb strainerfulls of grain. I let the stuff settle, and it cleared up. After the boil, I had 3 gal 1.077 S.G. wort. fermented 2 months @ 40F, added polyclar, racked and dryhopped with 1/4 oz hallertau pellets two days later, moved to room temp a week later, let sit for a week, and bottled. Finished the last bottle the other night.

You should get twice as much with a good sparge. The wort really needed to to be dry hopped longer - the pellets never really completely dissolved, and kind of filtered themselves out in the siphon.

Serve very cold or very warm.

bb

P.S. I had tried to post this recipe about a week ago, at 2:20 in the morning. apparently it got to rob just as the digests were being packaged for morning delivery, because it never would up in the next day's (or the next day's) digest, but the mail I sent 10 minutes earlier did.

I'm the (retiring) editor of "The Brews & News", the newsletter of the Maltose Falcons Home Brewing Society (in LA). We run a newsletter exchange program: you send us yours and we'll send you ours. Mail a copy of yours to The Maltose Falcons, 22836 Ventura Blvd. #2, Woodland Hills, CA 91364 and include a note about exchanging newsletters. We exchange with about 50 clubs.

There are a surprising number of newsletter editors on this digest. John Polstra of the Brews Brothers (Seattle), Doug Henderson of the Oregon Brew Crew (Portland), Russ Wigglesworth of the San Andreas Malts (San Francisco), I think that Russ Pencin of the Worts of Wisdom (San Jose), Martin Lodahl of the Gold Country Brewers (Sacramento), Dr. John Lenz of the IBUs (Ithaca, NY), and... and... well there must some more.

Also, there's a very active homebrew forum on CompuServe, sponsored by the AHA. Costs a bunch to get on and read it, but there's a very large and diverse population and a lot of interesting discussion. (How come nobody has mentioned Anchor's spruce beer here?)

I believe that there are discussion groups on Prodigy and Genie, too, but I haven't been on Prodigy in over 2 years, and I've never been on Genie.

From: adw3345@ultb.isc.rit.edu (A.D. Williams)  
Subject: Re: Homebrew Digest #737 (October 03, 1991)

Well, last night I opened my first bottle of my first batch of homebrew. The beer had a good head and a nice smell, and was definately alcoholic. However, it had a very strong hops taste and was watery. Also, it was dark and cloudy rather than pale yellow.

I used the standard malt-extract single stage fermentation method, which I found to be the simplest to start with.

How can I improve this batch? Should I let it age further, or was there something seriously wrong with the way I prepared it? Reading this mailing list, I think it was said that a watery taste is a result of using too much (corn) sugar. Is this true?

Thanks for any help, and I enjoy reading this mail group. Y'all are just so wonderful :-).

From: Marty Albini <martya@sdd.hp.com>  
Subject: weizen experiment results

A while back, I began the search for the elusive "wheat beer" character after brewing a batch that didn't have much. I decided to isolate variables, and turn the knobs all the way up on the ones under scrutiny. I brewed two batches: a "doppelweizen," 1.090 OG of 100% wheat, very little hops, a pure culture of *S. delbrueckii* (the bavarian weizen yeast) from MeV; then a barleywine (1.090 OG, same hops) which I poured onto the yeast cake in the secondary left over from the first batch.

The results were interesting, if not really drinkable. Both finished at around 1.030, indicating that *S. delbrueckii* is not a very attenuative yeast, and proceeded at a leisurely pace, starting slowly and behaving itself well (no blown-out stoppers or foam gysers). Both beers were cloyingly sweet. My guess is that another yeast tossed in after *S. delbrueckii* conks out would get these batches down around 1.010 or lower, and I understand this is the practice in Bavaria.

Why not mix the yeasts at pitching time? *S. delbrueckii*, I fear, would start so slowly and compete so poorly that an aggressive ale yeast would "eat its lunch," so to speak. I have sworn off the Wyeast mixed-species wheat beer yeast for that reason, as I noticed that very effect when I used it. I've also had excellent wheat beers made with it, so I suspect that the semi-random whims of Father Bacchus and temperature have a lot to do with it.

BTW, since MeV is out of business, and Wyeast wants \$15 for a bag of *S. delbrueckii*, I may have the only culture of this yeast in SoCal. If anybody wants some, come see me soon!

The all-wheat beer had the clove aroma and complex, fruity character I was looking for. It was quite pronounced, in fact, but not unpleasently so. The flavor was just sort of unbalanced, missing something that my untrained tongue can't identify. It also had a soapy aftertaste that I noticed with a couple of other 100% wheat batches I'd tasted, so I think we can safely chalk this up to the malt alone.

The barleywine had the same complex flavors the doppelweizen had, but much more subdued. I wouldn't think "wheat beer" if someone handed me a glass without telling me what it was; I'd think "wow, you fermented this much to warm and the yeast must have up and died on you halfway thru." There was such a rich mixture of strong flavors, it's hard to distinguish them, but you wouldn't mistake it for the doppelweizen. No soapy aftertaste, for one thing.

So it's not the yeast alone. It's not the grain alone. In fact, it's not the grain and the yeast together either; I think the flavor isn't complete without some barley malt. I guess when I get that figured out I'll start fooling with hops too, but I'm content to get the sweet stuff right for the moment.

That yeast cake is now fermenting its third batch

(thanks for the tip, Fr. Barleywine!) with a 2:1 mix of wheat and barley malts. When it finishes up, I'm going to pitch some Whitbread and let it eat (after the obligatory tasting and gravity measuring). I'll probably mix my two experiments and do the same, for a kickass wheat beer for the winter.

Which will probably be spent somewhere else. As of 10/15/91, I will no longer be employed by HP, and won't have access to this fine publication. So if anybody out there wants to get ahold of me electronically, beter do it soon! It's been fun, I've learned a lot, met some interesting people. Hope to see many of you again.

Subject: Hop ecstasy.

A few digests ago a poster observed that he got an extra kick from homebrews, even if they weren't especially high in alcohol. This is easily explained. Nearly every herbal medicine book will tell you that hops are classed as hypnotics. The lupulins are a great barbituate.

fHomebrew relaxes you as much because of the hops as for the ethanol. If you want to prove this, make some tea from a few hop pellets, plugs or dried cones. Sweeten it a bit and drink up. You'll probably be asleep in a little while.

Hops have been used as a soporific for thousands of years. They work even better if mixed with catnip, valarian and scullcap.

Hoppy Oktoberfest,

Dan

>nasty contaminants directly and not unduly heat the glass ( I would  
>imagine). It would be faster than heating /cooling in the dishwasher  
>or oven, and you wouldn't have to worry about annealing the glass.

It's my understanding that microwave energy requires moisture to generate heat (those bi-polar water molecules oscillating in the field, you know)

Dry, clean bottles wouldn't have any reason to heat up; the question still remains, would it disrupt the microbes? I don't know.

The reason some of us use the dishwasher is that it does the double duty of washing \*and\* sanitizing in one step. What I do is rinse the bottles thoroughly with hot water immediately after pouring the beer. This removes the yeast cake and prepares the bottle for storage. I then put the rinsed bottles back into the (originally empty) case.

When a batch is ready for bottling, I first clean the dishwasher. If yours has a screen for catching large food particles (some do; some grind it up), this must be cleaned first, otherwise you'll be bathing your bottles in the remains of last week's dinner. I usually run the thing through one wash cycle, empty, with a couple of tablespoons chlorine bleach, then allow it to rinse itself. Then I fill it with two cases of bottles, bottom rack first, overflow to the top rack. Repeat the above cycle: 1 wash with bleach, one rinse, this time with a hot dry cycle. (Now admittedly this may be overkill, but the one thing I \*hate\* is to have a batch ruined by an infection. It helps me not to worry.)

I find that if I start this before I begin the rest of the preparations for bottling (sanitizing another carboy for racking, boiling caps, etc.), the bottles have dried and cooled to the point where I can use them straight out of the dishwasher when I'm ready.

>To Jack Schmidling: That's Briess, with two "ss".

Thanks you. The bags at Baderbrau said "Chilton" on them and spelling isn't obvious over the phone.

> Has your "limited research" gotten any farther than the notes I passed along from Great Western Malting?

My apology for not crediting you as a source. Other than that, the "research is limited to what was detailed in the article. The insight in crystal malt came from Noonan as mentioned in another article.

I have also been told that Great Western sells malt made by other sources and would appreciate any info you have on them to the contrary.

>Before anyone goes reeling off to drink Coors (eeagh!) do remember that GW switched to an indirect process a number of years ago. They supply pale malt (primarily Klages) to virtually all the west coast breweries, both mega- and micro-. I \*know\* they use an indirect process because I've toured their Vancouver plant at least four times, and have a friend who works there.

The local brewshop seems to carry only Briess.

From: Jeff Frane <70670.2067@compuserve.com>  
Subject: Comments in General

>On the subject of oxidation and momilies, etc....

>Has Jack Schmidling never tasted oxydized beer?

ARF says:

As I have never tasted anyone else's homebrew and have been using the roundly condemned procedure all my brewing life, a no answer would prove my case wouldn't it?

Well, to be totally objective, I suspect that "off" taste that an occasional batch acquires, just might be what y'all are talking about. The problem was particularly persistent when I was kegging beer. (5 gal of beer in a 7.5 gal keg) It is entirely possible that all my beer was potentially bad but I drank it faster than it could oxidize. The "off" taste I have in mind took a month or more to develop.

>If that's the case, I would be happy to let him join us in judging homebrew at the Oregon State Fair next May; I'm sure we'll find him some good--well, bad--examples.

I suspect this would be of help to all home brewers. As with pictures, a taste is worth a thousand words. However, even that is misleading. I will give you an example:

The guy who criticized my billowing foam guaranteed that it will taste "cidery" because of oxidation. Never having tasted beer that tasted like apple cider, I brought him a bottle of my "off flavor" beer to see if that is what he meant by cider.

His comment: "nothing wrong with this beer, could use a little more hops though".

I have posted another article ("Plastic") on the beer actually made in the video.

.....

You can all ignore the article on "Plastic". Bad science. The last bottle was as yucky as the glass ones.

From: scarfer@qualcomm.com (Steve Carter)  
Subject: High Fermentation Temps

I've been battling the San Diego summer heat for my last two batches, and realized that I don't fully understand the enemy...

I understand that high temperatures during primary fermentation causes overactive yeasties and off flavors, but how about in the secondary, when most of the fermentation is complete? How about during aging in the bottles or keg?

On a similar note, how does changing the temperature affect the beer at these different stages. I've heard the conventional wisdom about not taking bottles out of the fridge, warming them, then returning them to the fridge, but is this really a problem? Such antics may become necessary for me soon when I buy a fridge for brewing: if I'm in the middle of lagering, and want to start another batch, I'll need to warm the fridge to 65 degrees for my primary for a few days. Will my lager be angry? What will happen if I'm keeping my finished, drinkable kegs in the fridge and bounce their temp up and down a few times? On the other hand, maybe I should just relax and wait for the winter ;-).

Subject: cleaning blow-off tube

i finally filled my carboy up to 5gal or more last time, and sure enough, lots of brown foamy stuff was pushed through the tube and into my mason jar of water. in fact, too much stuff, so i had to clean the wall and floor the first night...mason jars aren't big enough!

the question is, now my blow off tube is coated with hard brown stuff on the inside. how do i get this out? or do i need to clean it?

In all three batches so far, i have not removed the blow off tube to put an air lock on the carboy; i simply leave the tube on in a jar of sanitized water. seems like the same thing as an airlock to me. but the foam had a week to dry in the tube. surely you people that blow off krausen don't buy a new tube every time??

- Bryan  
bgros@sensitivity.berkeley.edu

p.s. so are there no homebrew clubs in the east bay? or in SF?

**Subject: lambic**

I was leafing through some back issues of Zymurgy and came across Pap's recipe for a sour-mash lambic (spring '91, i think). I'd like to know if anyone's tried this. Seems like a good way of adding some tang to our wheat beers. Also, is there a retail source for belgian yeast?

Subject: Using roto-kegs

I've heard conflicting reports about Roto-Kegs (i.e. they don't work, or they do). If one kegs low-carbonation pale ales (say, with about 1/3 cup priming sugar) in them, do they work? (One report is that the seal blows out if you prime the beer AT ALL). Or should I save my money?

night@mapme7.map.tek.com said:

Mark> Would every homebrewer who has brewed at least 10 batches post the  
recipe

Mark> of their ONE, and only one, FAVORITE batch?

Mark> Mark Nightingale night@tekig7.MAP.TEK.COM

Ok, here's mine.

Steam beer

9.5# Klages malt  
1.5# Crystal malt 40L  
0.5# Cara Pils malt

1.5 oz Northern Brewer whole hops, 6.9% 60 min  
0.5 oz Northern Brewer whole hops, 6.9% 30 min  
0.5 oz Northern Brewer whole hops, 6.9% 10 min  
about 35 IBU

Wyeast #2007

125F Protein rest 30 min  
155F Conversion 90 min

Sparge to collect enough that a 1 hour boil will still leave you  
5 gallons of beer (brewing -- art or science?).

OG = 1.054, FG = 1.015, pretty close to Fred Eckhardt's "Beer Styles"  
book, which was an excellent reference for this recipe.

Side by side with Anchor Steam, this beer was very close. The  
color of this beer was a bit darker, and the late hop additions  
gave mine a bit more hop flavor than Anchor. The bitterness was  
right on, but my water has pretty high sulfate content; if you have  
"better" water, you might want to bitter it a bit more.

From: Subhash Chandra Roy <roy@mcnc.org>  
Subject: Over-flowing primary

I've finished bottling my second batch, a weiss beer, but I had some problems with 'too happy' yeast. I used an all extract batch (the american classic wheat package from American Brewmaster in Raleigh, NC) and the WYeast for wheat beers. The yeast attacked the wort and in 2 days, started overflowing my primary, I had almost 2 quarts of overflowed liquid, is this normal with WYeast? My first batch used Whitbread dry ale yeast and the fermentation was not nearly as vigorous.

In-Reply-To: MAILSEQ:rdg@hpfcmi.fc.hp.com's message of 10-04-91 01:00

Since I have not gotten into brewing my own beer yet, I am still stuck with buying a keg at the local distributor. This limits me mostly to the domestic beers, Michelob and Michelob Dark in particular. I keep the keg in a refrigerator in the garage at 35 degrees on CO2 at 10 pounds. The hose from the keg to the spout is 4 feet. The beer pours and tastes great for a mass produced beer.

My question is how long can one keg be kept in the above scenerio? I have had a keg for three weeks and the last glass tasted fine.

E-Mail or post it here.

From: "John Reed in Waltham, MA" <johnreed@BOSTON.vnet.ibm.com>  
Subject: Samuel Adams

In HBD 738 Brian Smithey asks about Samuel Adams Boston Ale...Yes, it is bottled and available, at least here in the Boston area. Boston Beer Co. which brews Sam Adams, contracts at least 2 other breweries to brew their recipes. I think that the Stock Ale is brewed here in Boston, but may also be brewed at one or both of the other breweries (Ithica, NY and Pittsburgh, PA). I would think that it should be available out there on the left coast, too.

BTW, I enjoy the Stock Ale; it's got a great balance of spicey hop character and maltiness.

Has anyone tried this year's S.A. Octoberfest?

Subject: Sam Smith, etc.

I JUST returned from three weeks in England, during which time I toured three breweries and about twenty pubs, and sampled some of those brews fabled in story and song. A few notes...

re Sam Smith diacetyl - during the tour of the Old Brewery at Tadcaster (a private one, due to a fortuitous cockup of the dates by yours truly), we were shown how they "reinvigorate" the fermentation by sucking wort from the underfloor tank and spraying it through a flattened showerhead-like fitting directly into the yeast in the above-floor stone square. That would appear to be the answer to this question. I was surprised to discover that Oatmeal Stout, Nut Brown Ale, and quite a few others were ONLY for bottles, and most of them ONLY for export. I was equally surprised to discover that the recipe for the Oatmeal Stout was designed by their importer here (Seattle - Merchant Du Vin)! Could someone up that way possibly cajole the recipe out of them and post it?

Also toured Hall and Woodhouse and Heritage. The latter is now closed. Their contract with Everards is up, and they have signed with a micro to brew and dispense through a newly approved on-premises pub/restaurant. They expect it to be close to a year until opening. It will be sixty barrels a week until expansion is required. The brewery is a listed building, so they have to be careful about refurbishing to original characteristics (it is of Victorian age). While there, we sampled Thomas Sykes Old Ale (formerly brewed there). At 1100 OG and 10.2 ABV - WOW! It was only bottled - then only occasionally.

Highlights of the drinking part of the trip ( it WAS just a minor subagenda, after all 8') were Gale's HSB; Theakston's Old Peculier and XB (went through only the visitor center there); Sam Smith Museum Ale; Greene King Abbot Ale; Ash Vine Bitter; Murphy's Stout; and still one of my favorites - Badger Best Bitter by H&W. Went to one micro - Hop Back Brewery - and tried the Summer Lightning. It came second in the Strong Ale category at the GBBF this year, and was very good indeed.

General impressions are that Mild is definitely not something I would want under any voluntary circumstances, and most ordinarys are too thin for my taste. I guess that I confirmed that I really AM partial to the heavier brews as I had suspected all along. One other generalization - the Midlands is not the place to buy beer. Stick to the South(west) and the North. Now where is my asbestos suit...

Counting down the two years until next time, I remain

Soberly Yours,  
Gary

From: andy@wups.wustl.edu (Andy Leith)  
Subject: Re. Amylase

Brian Bliss asks if anyone has added amylase to the secondary.

For one of my first brews I tried a partial mash using flaked barley and crystal malt. A bad idea as there are no enzymes in the crystal to convert the flaked barley. As a consequence by the time the beer made it to the secondary it was still about as clear as mud. I added about a teaspoon of amylase powder (from pig pancreas) to the secondary. The beer cleared completely in about 24 hours. The final s.g was about 1.008.

From: worth@park.bu.edu (Andrew J. Worth)  
Subject: Re: Samuel Adams' Boston Ale

Brian> Has anybody seen Samuel Adams Ale in bottles...?

Yup, its readily available here in Boston. I don't know anything about where they will be shipping it. Probably wherever the gods of capitalism tell them to. They also have an Octoberfest and a Double Bock. At the ought-to-be world famous bar, Doyle's, in Jamaica Plain, MA, they pour a 50-50 mix of Sam Adams' Lager and Ale and call it a "J.P. Musty". 'tis good, and good for you!

BTW, does anybody know why Samuel Adams chose that name? I hear that Sam Adams was more of a rabble rousing radical than a patriot, and he effectively racked his father's brewing business into the ground.

Andy.

Yes, Samuel Adams Boston Ale is available in bottles. I've been seeing it (and drinking it) for about six months. It is sold all over NJ, NY and PA. I heard that it was currently being brewed in Boston but soon will be brewed in PA, also. I don't know if it is available on the West Coast. I do know that the Boston Lager has made it as far as Chicago (or maybe you already have it on the Out There).

Date: 04 Oct 91 20:44:49 EDT  
From: Robin Garr <76702.764@compuserve.com>  
Subject: CompuServe Beer Forum

In HB738, Darryl Richman writes:

>Also, there's a very active homebrew forum on CompuServe, sponsored  
>by the AHA. Costs a bunch to get on and read it, but there's a very  
>large and diverse population and a lot of interesting discussion. (How  
>come nobody has mentioned Anchor's spruce beer here?)

Darryl, thanks for the plug, but to clarify the record, the CompuServe  
Wine  
and Beer Forum enjoys a friendly, even symbiotic relationship with the  
gang  
at the AHA, but we are not sponsored by them (nor they by us), nor is  
there  
any really formal relationship. We welcome the AHA's participation in  
the  
forum and encourage them to use our forum libraries to post AHA materials  
of interest to the online brewing community. We've listed Charlie  
Papazian and Dan Fink as more-or-less honorary "assistant sysops," and  
we're happy to have their brewing expertise on line.

The forum, however, is an independent organization. Jim Kronman, a Los  
Angeles-based engineer and wine writer, started it in 1985 as a wine-  
appreciation forum. At the suggestion of the AHA, we added a beer and  
homebrewing section in 1989, and it now comprises about half of the  
forum's  
traffic. I'm Jim's associate, a writer (and home brewer) based in the  
extreme  
outer reaches of suburban New York City.

While we acknowledge that CompuServe isn't cheap, we try to make the  
forum  
worth the price; we also encourage the use of "autopilot" programs to  
maximize  
time and cost efficiency on line.

We'd certainly welcome Internet folks who would like to drop in and check  
us out, and I may be able to make a limited number of introductory  
CompuServe  
"starter kits" with a couple of hours free time available to those (first  
come, first served) who'd care to contact me via EMail. For those who  
already  
hang around CompuServe, if you haven't found the forum yet, your choice  
of GO  
BEER or GO WINEFO will get you there. SubTopics 13 (Technical  
Homebrewing),  
14 (General Homebrewing) and 15 (Commercial Beer) are devoted to the  
amber  
fluid.

Robin Garr | "I have enjoyed great health at a great age because

In Digest #738 Russ Gelinus writes:

> In my mailbox at work today: a bottle of Liefman's Kriek, direct  
from  
> Belgium! Yeehah!

Russ, I too have recently had the luxury of acquiring some rather fresh Belgian brews without leaving the country. A friend of mine is a Belgian national and his parents are in the U.S. for a visit. His father brought me 7 bottles (5 different "brands") of Abbey beers from the south of Belgium. (They live in Namur) I have Chimay blue ( 9% alc. ), Chimay white ( 8% ) , Trappistes Rochefort 8 ( 9.2% ), Trappistes Rochefort 10 ( 11.3% ), Leffe ( 6.6% ), Maredsous Blonde ( 10% ), and Orval ( 5.2% ). He also brought me 5 glasses from Belgium (he left with 6 but the Orval one got broken). I am going home tonight and try one or two of these. They also brought a 750ml bottle of "Blanche de Namur", a "white" beer brewed in their home town. It was corked and secured with a wire cage, much like champagne. It was light colored, crisp, and refreshing. The hop bouquet was very noticable and my wife said "It smells like flowers". I think perhaps this was a wheat beer. Yeehah indeed!!

Subject: VIDEO

To: Homebrew Digest  
Fm: Jack Schmidling

Subject: NEW VIDEO FROM JSP (ARF)

Jack Schmidling Productions is pleased to announce the release of our latest production.....

"BREW IT AT HOME"

An easy to follow how-to on making root beer, gingerale and beer at home.  
Our "Easy Beer Process", will change the way you look at home brewing.  
.....

This exciting new video will show you how to make your own delicious root beer and ginger ale with that old fashioned taste. We will also show you how to brew high quality beer and ale for a fraction of the cost of commercial beer.

We demonstrate how to make root beer from a commercial extract and ginger ale from fresh ginger root, with materials and equipment found in any kitchen.

Learn how to bottle home-brewed beverages with a simple process that, not only guarantees perfect carbonation but also eliminates the problem of exploding bottles, so common to home made beverages.

Commercial American beers contain up to 100 additives and so-called adjuncts that have nothing to do with beer. By definition and tradition, beer is made from barley malt but the major brewers have taken the liberty of substituting rice and corn for barley malt and if that isn't bad enough, they adulterate it further by substituting plain old sugar for much of the malt. This is precisely why most American beer tastes more like carbonated saki than beer.

Learn our Easy Beer Process and make beer so good, you will wonder why you ever liked commercial beer. Through the magic of time-lapse and micro-photography, we show you how barley is malted, how yeast produces alcohol and carbonation and why hops is essential to beer. We visit a dedicated home brewer who grows his own hops and a local brew shop with a

dazzling array of home brew products.

We then show you how to improve on Easy Beer with simple modifications to the basic process, as your brewing skill increases.

#### TOUR A COMMERCIAL BREWERY

Finally, we take you on a tour of very special commercial brewery. This is one of the only American brewers that adhere strictly to the German tradition of Reinheitsgebot, using only barley malt, hops, yeast and water.

"BREW IT AT HOME" (54 min VHS).....

Price \$29 + \$3 Shipping and handling

Illinois residents add 8 sales tax.

ONE TIME offer to HBD readers:

If you send money NOW, no questions, letters, flyers, previews, credit cards, stamps etc..... the price to HBD'ers is \$12 + shipping.

Send \$15 and a note saying "HBD", along with your shipping address and it's on the way, in time for holiday giving.

<mason@habs11.ENET.DEC.COM>  
Subject: A few more random comments on England...

I used the CAMRA Good Beer Guide, and discovered what we all have known from the computer business for years - GIGO! I tried Gale's HSB first at a pub in Yeovil, as recommended in the GBG. It was singularly unspectacular. We then went to a pub that served evening meals, and recounted the experience to the publican. He said "if you want to try a REAL HSB, have one from here". He pointed at his 150 year old French water pump, converted - with much time, effort, and pain - to a beer engine. It was spectacular! It was simply a matter of cleaning the pipes on a regular basis, and proper handling of the beer. So, the lesson is...the Guide is just a Guide, and subject to personal tastes. I found that I did as good a job finding good beer without it as with it.

Samuel Smith sells their exhausted yeast (all but about 10 per cent, which they use to ferment the next batch) to several folks, including Boots the Chemist. I brought back some Boots yeast sachets to try - perhaps I will find a flavor difference in the results.

Lastly, something very ironic. Due to the vagaries of world economics, one of the most traditional of English products - their real ale - is served, in what I guess to be eight out of ten pubs, in French glass! Arceroc is the name you peer at through your empty pint glass most of the time. The dozen I brought home with me, however, are decidedly British.

Cheers...Gary

Subject: LIVERYEAST

To: Homebrew Digest  
Fm: Jack Schmidling

From: RCARLSON@MAX.U.WASHINGTON.EDU  
Subject: Liverwort

> Looking inside, I saw a slab of liver clinging to the side of the boiler.

Using my spoon, I found another clogging my tap, and many small specimens as well.

What caught my attention in your article was the title because in addition to brewing beer, I have spent about 5 years trying to grow liverwort in my backyard garden, with only limited success.

Liverwort is a very primitive land plant that is thought to be transitional between aquatic and land and of great interest to evolutionary biologists.

It is hard to grow because it requires water for the sperm to travel to the female plant but drowns easily in too much water.

Now, to your "liver wort". Last week I racked my first batch of (commercial) all grain from primary to secondary and got exactly what you described (except for color) in the yeast sludge. I took the usual care not to disturb the yeast with the syphon only to find when cleaning the fermenter that I could probably have turned it upside down without disturbing it. It was just like a half inch sheet of (white) liver.

Not likely any connection between your liver wort and my liver yeast other than "mouth feel".

BTW, I have made all grain before but only with home-made malt. This may, however be the first time I get to drink it. All the home-made stuff was a disaster. I have since come to learn that what I was making was crystal malt and this does not good beer make.

From: Jim Grady <jimg@hpwald.wal.hp.com>  
Subject: Christmas Ale

The weather is starting to get cool around here so I thought I would brew the Christmas Ale that Kinney Baughman posted here last August (HBD #693). There has been some discussion about whether the second call for 3# of amber dry malt was a typo. I made yesterday it without the malt and the O.G. was 1.049, not 1.069 as the recipe stated. The carboy was full and 1.049 should make a respectable beer so I relaxed, didn't worry and was already having a homebrew. It is bubbling away and smells great! I think that next time I will add the extra 3# of malt.

Chris (sorry, I didn't save your last name) said that he had had the same experience.

Subject: Re: Sam Adams Beer.

Heck you can buy Samuel Adams bottled lager all over the place. But I'm afraid I know only of the midwest areas. Like Chicago area or Milwaukee.

As long as we're on the subject of microbreweries. I would like to recommend Sprecher to anyone travelling through or living near Milwaukee. While their seasonal Mai Bock is my favorite they also brew a most complex amber. Each sip of the amber is complete from the first wiff of hops to the fresh grain aftertaste.

Well anyway I hope you get your handss on the Bostonian lager. They dryhop with Hallertau. That makes it terribly tasty!

From: rcd@raven.eklektix.com (Dick Dunn)  
Subject: Anchor's Spruce beer

Contrary to an opinion in a recent HBD (which I can't find because I got overzealous in tossing duplicates and tossed originals), I think the balance in the Anchor Spruce beer (brewed for GABF X) was just right. The basic beer was relatively light, so as not to distract one's tastebuds, but the amount of spruce essence was just about right. It was definitely there, at the level of "yeah, OK"--without being either "there's a little something funny here but I can't tell what" or "jeez, that's strong."

It's not something I'm ready to sign up for drinking as an everyday beer (unlike Steam), but if this were the way beer were made, I wouldn't be put off it.

Maybe, if you find the spruce essence too strong, it's because you don't spend enough time among evergreens? (You might suggest that I spend too much time there; I'll remonstrate that I don't think that's possible.-)

I think this whole thing is getting way too commercial for HBD. Perhaps  
I'd feel better if arf were teaching standard homebrew practice, but the  
couple go-rounds we've had here suggest that he's putting iconoclasm  
ahead  
of basic teaching, and in the process he's getting us to help with the  
editing. Even if that were not the case, I'm not sure I'd like HBD as an  
advertising medium.

(Or can I start advertising here too?:-)

Subject: Re: Lambics

Andy Kurtz <ak35+@andrew.cmu.edu> asks:  
> I was leafing through some back issues of Zymurgy and came across Pap's  
> recipe for a sour-mash lambic (spring '91, i think). I'd like to know  
> if anyone's tried this. Seems like a good way of adding some tang to  
> our wheat beers.

I tried some sour mash beers at the last AHA conference. IMHO, the sourness was completely different than the lambic sourness. I've chosen to avoid this route in creating pseudo-lambics. Your mileage may vary.

> Also, is there a retail source for belgian yeast?  
As far as I can tell there are no retail sources for the yeast/bacteria yet.

I know that Wyeast is planning to market a trappist yeast this fall, but this is not suitable (at least not alone) for lambics. One of the reasons you can't get these cultures commercially is that they scare the s\_\_\_ out of most commercial establishments -- most of the yeasts and bacterias used in making lambics are considered fairly nasty contaminants.

I should note here that I have never had any rampant infections in the time I've been using these critters.

Sources for cultures as well as all sorts of helpfull hints are discussed in the lambic mailing list. You can join this mailing list by sending a note to:

Subject: Favorite Recipes

Favorite Recipes  
- -----

John's Raspberry Ale  
- -----

Ingredients:

6 lbs. Williams' English Light malt extract  
1/2 lb. crystal malt (unknown Lovibond)

2 oz. Hallertau hops (4.0 AA%) (45 minutes)  
1/2 oz. Hallertau hops (4.0 AA%) (5 minutes)

4 lbs. raspberries

Wyeast liquid yeast (can't remember which ale yeast  
was used, and the ink ran there when it got wet.  
I think it was the London ale, but not sure.)

Directions:

Prepared 1 quart starter two nights before. Didn't get a  
heavy krausen, just started to get a light foam covering  
at pitching time.

Purchased raspberries at farmers' market the day before,  
then tossed in the freezer overnight (to break down cell  
walls or something).

Pre-boiled some water. Cooled some and froze some.

Prepared wort as usual, steeping crystal malt in 150-160F  
water while the brew pot water was heating up and sparged  
into the brewpot. Boiled about an hour.

At the end of the boil, I just tossed all the raspberries  
into the brewpot and let sit for fifteen minutes. Wort  
was pretty cool by then.

The first scary part--I couldn't filter out the hops and  
trub without leaving behind raspberries. So I tossed  
\*everything\* into the fermenter. With the raspberries  
in there, I figured I couldn't get any S.G. readings, so  
didn't try.

In spite of everything, this came out very very well,  
with rave reviews from everyone.

the  
> malt and the O.G. was 1.049, not 1.069 as the recipe stated.

We made a batch of this ourselves Sunday, and measured the gravity at  
about  
1.050. I agree, the extra three pounds of dry extract is required to  
reach  
the stated gravity.

This was an awfully fun batch to brew, BTW. The aroma was just  
wonderful,  
and with the first cold autumn winds beginning to blow it really started  
to  
put me in a holiday spirit. In fact, at one point I thought I heard the  
prancing of 32 tiny hooves on the roof (but then, I was already pretty  
"relaxed," shall we say, at that point.) 8-)

From: tcm@moscom.com (Tom Maszerowski)  
Subject: Rotokegs and SA Octoberfest

About the Rotokeg... I had one and never had a successful batch with it. The first problem I had with it was with the pressure regulator. As the pressure would increase it would open as expected to vent the excess. But when the pressure decreased, it wouldn't fully close and all the pressure would be lost. I replaced it with a pressure gauge and manual vent system a friend set up for me. This worked until the seam by the filler opening split and I gave up. The one I had was the big ball and was made of two pieces, "welded" together. I gave up at this point. I now have the English brown barrel type of keg that I've never had problems with. I just received some info on the Batch Latch system that allows you to convert a beer ball to use as a keg. It looks interesting. Has anyone tried it?

About Sam Adams Octoberfest... I bought it this weekend and I was disappointed. Compared to some other fest beers I thought it was thin and lacked sufficient malt character. It seemed to me to be an attempt to appeal to the BudMiller drinker and not an emulation of a particular style. As a side note, Sam Adams Wheat Beer appeared in my local outlet in late Spetember and doesn't seem to be selling quickly. I've yet to try it as my thoughts have moved on ales ( it get cold early here in Western NY ).

Subject: Homebrew Digest #739 (October 07, 1991)

Ooops - I think I just sent two blank messages - sorry.

Anyways, John Reed asked if anyone has tried this year's S.A. Oktoberfest beer. I have, and I thought it was OK.

I can't be very scientific about this, but all I can say is that it tasted like a Sam Adams product (hop characteristics?) as opposed to the Oktoberfest brew I was drinking in the Paulaner Tent two weeks ago.

Still worth a chug tho. (In otherwords, it didn't taste like any German beer I've had recently).

Brost!

Subject: Pear Beer?

I have a pear tree in my back yard that produces prodigious amounts of fruit that I usually wind up throwing away. As a brewer, other possibilities come to mind...

Does pear beer sound good or gross?

I imagine I would wash the pears in a sodium metabisulfate solution, peel them, chop them up some, and toss them into the primary fermenter as soon as the yeast looks like it has taken control of the wort.

I plan to rely on the yeast to maintain sterility rather than pasteurizing the fruit by any boiling. I would not want to boil off any of the volatile aromatics of the fruit. These are what I like best about pears.

Has anyone had such a beverage?

Should I do it with a lager or an ale?

From: R\_GELINAS@UNHH.UNH.EDU (Russ Gelinias)  
Subject: stuff

First, I have heard that Sam Adams was actually a \*maltster\*, not a brewer, for what that's worth.

Those of you who sparge all at once in a big cooler, do you use a rectangular cooler or a cylindrical one? How did you cut the slots in the copper tubing?

Re. yeast slurry: Last night I pitched saved slurry dated 9/17/91. It was the 3rd batch for that yeast, originally Wyeast Chico ale. I saved myself from worrying by making up a starter with it, and by tasting the beer layer that was on top. The beer was fine, the starter was fast, and so when the 6 gallons of brew didn't start fermenting after 6 hours, I didn't worry. It was fermenting madly this morning.

A good way to enhance wort chilling is to have 2 chillers, connected by plastic tubing. The first is connected to the faucet, and sits in a bucket of ice, the other (bigger) one sits in the wort. Especially helpful if your tap water is warm.

Here's what I brewed:

Stout Stout  
-----  
10 lb. pale malt (2-row)  
1 lb. roasted barley  
1 lb. flaked barley  
0.5 lb. crystal malt  
1+ oz. centennial whole hops (at 10.1 AAU) (science or art?) boil 60 min.  
no finishing hops  
Wyeast Chico ale slurry  
  
Mash water: 3 gallons @ 170 degF  
Mash in: 153 deg F for 90 minutes  
Mash out: forgot to do it  
Sparge: 5 gallons @ 170 deg F

Don't know what the OG was, but it should be in the 1.050 range, or higher if you get better extraction rates. This one should be prime by Halloween.

From: Chris Shenton <chris@asylum.gsfc.nasa.gov>  
Subject: Father Barleywine's yeast reuse trick -- first attempt

A couple weeks ago I made up a double batch of basic weizenbier -- 13.2# American Classic wheat-beer extract (60% wheat, 40% barley), some hallertauer, some tettnanger, and finish with haller again. I pitched a 750ml starter of Wyeast wheat-beer yeast into the two carboys and fermentation was going in under 24 hours.

After a week I racked to secondaries, and a week after that began brewing another double batch, the same recipe as above but with 50% more extract and alphas. While it was chilling, I siphoned the beer out of the carboys and into kegs, priming with a gallon saved wort split between the two kegs.

I then dumped the new wort on top of the yeast in the secondaries, and the stuff took off in well under 8 hours, almost explosively! I came home to find the foam had gotten into the airlock, displaced the water, and was not happily bubbling out through the top, coating the carboy in gooey muck and dribbling all over the counter. I was delighted!

Now it's calmed down and the krausen looks great -- dense bubbles and so on. This technique is a winner. One question, Father: this is great for doing multiple batches of the same or similar beer (same yeast); what do you do if you want a different style, just start over with a new yeast?

A question for HBD-land: Wyeast wheat-beer is (unfortunately) a mix of S. Delbrukii a basic beer yeast. Do you think repitching like this would select for eventual domination by one or the other strain?

One other thing: I think F.B. pitches on top of the yeast bed in the \*primary\*. I understand his rationale about not having to clean stuff and worry about new sources for contamination. Mine was too full of muck for me to want to do that, hence the secondary.

Bis spaeter!

From: dinsdale@chtm.eece.unm.edu (Don McDaniel)  
Subject: My best recipe

My response to the request for tried and tested recipes:

Here's my best ever brew:

Don's Most Wickid Ale (A.K.A. number nine, number nine, number nine...)

6 lb. Pale ale malt  
3/4 lb. crystal malt  
1/4 lb. black patent malt

1 lb. corn sugar  
1 cup blackstrap molases  
(strong stuff. don't mess with any wimpy Brer Rabbit stuff.)

Wyeast 1028 London Ale yeast

10 AAU Northern Brewer, 60 min. boil  
6 AAU Cascade, steep

1/2 cu. corn sugar to prime

yield: 52 12-oz bottles (5 gal. batch)  
OG 1.052  
FG 1.010

Mashed grains in 10 qt. water at 150 F for 90 min  
mash pH 5.5  
mash-out 5 min. @ 168 F  
sparge with 5 gal. water @168 F

Disolved sugar and molases into runnings  
Boiled 90 min.  
Cooled. Let sit over night. Racked off trub and pitched yeast.  
Temp at pitching: 62F  
After five days in primary, racked to secondary. Left for ten days.  
Racked into bottling bucket with disolved priming sugar and bottled.  
All fermenting and conditioning was done at 60-65F.

Tasting notes:

Tasted quite smoky and bitter at bottling. Kind of like a Porter rather than the brown ale I had in mind.  
Four weeks later...WOW!  
Both the smokyness and bitterness had mellowed. The beer was very dark, very malty with a complex flavor from the molases and black patent malt. The malt was balanced perfectly by the hops. My best beer yet.  
Had a thick, rich, smooth and long lasting head.

I've tried to reproduce this beer. That effort has been bottle conditioning for three weeks now. I'll know soon how it turned out.

I'm not aware of any commercial brew with which this beer can be compared. It sits between the brown ales available and something like an imperial stout or Mackeson XXX.

Finally, don't Knock the use of a pound of sugar. It comes to only about 1/7 of fermentables, sugar is standard in British brewing

and most importantly IT WORKED!

Subject: Adding Amalaysse to Secondary

>Brian Bliss asks if anyone has added amylase to the secondary.

The last beer I made consisted of a partial mash of 1 pound of wheat flakes which I mashed by adding amalaysse extract to just the wheat and some water. Not knowing whether the amalaysse contained alpha or beta or both, I just held the "mash" at 150F for an hour. A few weeks later, activity in the secondary had stopped but the beer was still cloudy. So I said what the hell and tossed in a teaspoon of amalaysse. The next day, there was a krausen on top! Good thing I had left a fair bit of space or things would have been messy. It took about another 2 months for activity to subside enough for me to feel safe bottling it. It turned out great. Very clean taste, and as a friend said "hey, this stuff has absolutely no aftertase". After all, I essentially just did the same thing as the big breweries do to make dry beer -- use extra enzymes to get more complete fermentation. The next time I do this, I will mash at 135F for an hour, and add more hops by dry hopping. The long time in the secondary didn't help the beer's hop bouquet or flavour.

From: larryba@microsoft.com  
Subject: Shocking Yeast Story..

Just what is the symptoms of temperature shock to yeast?

Three days after claiming I never worry about minor temperature differentials when pitching lager yeast, I seem to have a dead batch. I pitched about 1 cup of dormant lager yeast at 53f, that had been very active two weeks before when "fed" a pint of .028 wort, into 5.5 gals of 1.050 wort at 73f. I then stuck the fermenter into the fridge at 48f. Now, two days later there is no sign of fermentation.

This is wYeast bavarian lager. It was very slow @ 48f for my Vienna Angst lager (tasty stuff, even if I did bite my fingers off waiting for the four week ferment to complete!). I thought, for sure, repitching a cup of the yeast would make the next batch o beer ferment much faster. The yeast did ferment out the pint of extra wort very fast (one day!) and the resulting beer (decanted off the yeast before pitching, tasted pretty good, if a bit green, being only two weeks old.

Subject: Microwaving bottles, etc.

First, I would like to second Tim Ness in his review of Wild Goose beer:

> ... , but I see (taste) no reason why Wild Goose should be recommended  
> to stay away from. I bought a case fresh from Cambridge last weekend  
and still  
> find it to be one of the most refreshing Microbrewed beers on the East  
Coast.  
> It has a very HOPPY character but I doubt that should be enough for the bad  
bad  
> review.

The brewery in Cambridge, Maryland, which produces Wild Goose also makes Thomas Point Light, which is not to be confused with "lite beer"; it is a tasty pale ale with just a bit less body and hops than Wild Goose. (TPL is named for a navigational marker well known to all who sail the Chesapeake Bay). I believe these guys also make Saint Michael's Nonalcoholic beer, which is the only example of this genre which I have actually enjoyed.

Brian Smithey asks:

> On a trip to Boston a couple of years ago I had some Sam Adam's Boston  
> Ale on tap at a restaurant. At the time I was told that it wasn't  
bottled,  
> only available in kegs; . . .  
> . . . Has anybody seen SA Ale in bottles, particularly out  
> on the West coast?

I drink Anchor Steam when on the left coast so I don't know if Sam Adams Boston Ale has made it there, but it is available in bottles in most decent beer stores in the Baltimore/D.C. area. We also see a decent variety of their limited edition beers, such as Wheat, Doppelbock, and Oktoberfest, at various times of the year.

And thanks to everyone who replied to my (feeble) idea to cut bottle washing time by popping your rinsed bottles into the microwave. Many folks pointed out that you can't heat a dry bottle (or a dry anything) with a microwave.

Darryl Steve Russell Richman had further good advice:

> Nuking bottles \*may\* be a good idea. But nuking dry bottles is not, as this  
> will burn out your magnetron bulb.

My hope was that, though the bottles are dry, the microbes which would infect the beer would have enough water to be scorched to harmlessness in very little time. My sundry siblings with PhD's in biochemistry and botany said this would be true for active bacteria and wild yeasts, but that spores don't have enough water in them to be acted on by microwaves; and spores are the primary source of infection. They recommended cooking the bottles at 500 F for 45 minutes. They're used to lab glassware so

they couldn't say what that would do to a beer bottle.

Btw, thanks to Father Barleywine for the repitching idea. My partner and I brewed a pumpkin ale using Bavarian Ale yeast, then poured the wort for an Oktoberfest beer onto the yeast cake. Fermentation was extremely vigorous within five hours (at 75 F). We're glad we used a gallon jug on the receiving end of our blow-off tube.

Subject: Anchor...

I am not certain about the origins of the name for Fritz Maytag's place, but there is an Anchor Brewery in Salisbury, Wiltshire, England. It brews under the name of Gibbs Mew PLC. I did not have a chance to sample them this trip (next time!), but they have several bitters and a barley wine in their suite. Just looking at the place makes me think it may be older than the US version.

Cheers...Gary

From: Doug Latornell <latornel@unixg.ubc.ca>  
Subject: UK Brews and Pubs

The recent spate of messages about UK brews brought back fond memories of my trip to the UK and Austria in August and I just can't resist posting something about the brews and pubs I enjoyed.

A week on the Isle of Skye, in Scotland, was rather unimpressive for ale, probably because the region is still strongly dominated by prohibition sentiments. However, our 1st night in Scotland was in Glasgow where we stumbled upon a wonderful pub, The Halt, just around the corner from the youth hostel. A free house, they had 8 brews on tap; 2 were "specials" which change regularly (the signs on the taps were hand written). That night the specials were Old Peculiar and "Cask #3 Ale". The former astounded me with its richness and mouth-feel; I had only previously had it bottled -- what a difference!. Didn't try the ale. Also available were Murphy's Irish Stout, Guinness, McEwan's Bitter and Lager, Harp Lager and one other lager. All of this served up to the sounds of a very good jazz quartet (Wednesday's are jazz, Thursdays are a folk jam). The Halt is no tourist trap; we were rubbing shoulders at the bar with folks who clearly had it as their local.

Later in the trip we were in Cambridge where I got hooked on Greene King Abbot Ale, the definitive heavy duty ale, IMHO! It was particularly enjoyably served with lunch at The Zebra. Honourable mention to The Royal Oaks in Barrington, a pleasant bank holiday afternoon's cycle ride outside Cambridge. Also worth a sip is Greene King IPA.

In Austria the August heat of continental summer caused me to revise my opinion of lager, particularly the hoppy Styrian varieties (from south-eastern Austria) served ice cold. I also very much enjoyed my first opportunity to try weissebier. The Styrian stiftbier and Wiener dunkelbier are dark, rich beers with little hoppiness and an almost molasses-like taste that took a little getting used to.

Travelling sure is a pleasant way to expand one's beer horizons...

From: KENYON%MOE.ERE-NET.COM@pucc.PRINCETON.EDU  
Subject: Cork Caps / Bulk DME Prices? / Kegging Presssure

1) I recall seeing bottle caps in a friends garage that were cork lined. The box they were in looked pretty old (from the 50's or 60's rings a bell). Has anybody ever seen or heard of these before, and if so are they still obtainable?

2) Does anyone know of any mail-order shops that have reasonable discount prices on bulk purchases of DME (55# sack), Laaglander in particular?

3) At what pressure should 5 gallon soda kegs be conditioned/served?

Thanks in advance ...

From: kensiski@nas.nasa.gov (David L. Kensiski)  
Subject: Samuel Adams availability and Octoberfest

In HBD #739, John Reed in Waltham, MA mentions that Samuel Adams...

> ...is bottled and available, at least here in the Boston area.  
> I would think that it should be available out there on the left  
> coast, too.

I can attest to the fact that it is, in fact, available over here on the left coast. In fact, it's all over the place. I've seen it in supermarkets (Lucky) and liquor stores - heck, even Pizzeria Uno restaurants here in Sillycon Valley have the beer on tap.

> Has anyone tried this year's S.A. Octoberfest?

I just happened to pick up a six pack last week while I was at a conference in San Diego, of all places. (Can't get much further from Boston than San Diego and still be in the conterminous 48 states!) The Octoberfest is quite a good beer with all the flavor and possibly even more body than found in Samuel Adams regular brew. It comes highly reccomended, at least by me!

From: cjh@vallance.HQ.Ileaf.COM (Chip Hitchcock)  
Subject: more on uwave bottle sanitizing

>Dry, clean bottles wouldn't have any reason to heat up; the question  
>still remains, would it disrupt the microbes? I don't know.

In theory, it would; microbes, like most living organisms, are mostly  
water.

However, the problem is hitting something that small with a microwave in  
a reasonable amount of time. Think of microbes as kernels of popcorn  
you're  
trying to pop, and consider that there are always unpopped kernels in  
microwave[d] popcorn, even the prepackaged stuff with the special bag.  
Skipping a technical explanation [read: I've forgotten most of it], the  
odds of hitting something the size of a kernel with a microwave (whose  
wavelength is probably larger than the kernel) is small; you can pop corn  
only by putting so many kernels together that a wave going through that  
neighborhood /has/ to hit one or another of them.

If you nuked a dry bottle long enough (hours? days?) you'd probably get  
the  
microbe population low enough for safety---but in the meantime, as Darryl  
points out, you'd burn out the microwave generator (because 99.99...% of  
the energy it's putting out isn't getting absorbed).

From: greg@cemax.com (Greg Wageman)  
Subject: Re: Express bottle washing

Jim Buchman writes:

>Is there any reason that microwaving the bottles for a couple minutes  
at.

>high power wouldn't do the trick equally well? This would fry the  
little

>nasty contaminants directly and not unduly heat the glass ( I would  
>imagine). It would be faster than heating /cooling in the dishwasher  
>or oven, and you wouldn't have to worry about annealing the glass.

<It's my understanding that microwave energy requires moisture to  
generate  
heat (those bi-polar water molecules oscillating in the field, you know)  
.

We have discussed this subject under sterilizing petri dishes and yeast  
culture stuff but the same applies here.

Although, I have not done the double blind experiments, it appears that  
a few  
drops of water and one minute does the trick. I have been sterilizing a  
hummingbird feeder bottle for several years by nuking it for one min  
with a  
few drops of water in it. It was regularly turning to vinegar before I  
started this procedure.

However, I believe that water is unnecessary because living organisms  
contain  
water and because micro-organisms are so small, they would be  
instantaneously  
exploded with a very short exposure to micro waves.

I do not know about the moisture content of spores but as it takes one  
hour  
of steam at 10 psi to destroy Botulism spores, normal sterilization used  
by  
brewers would not affect them anyway.

My guess is that wild yeasts and the "normal" spoilage bacteria found in  
homebrew, could be killed in a microwave oven without ever warming the  
bottle  
or harming the magnetron. If it makes you feel better, put a cup of  
water in  
the oven, not in the bottles. However, all it will do is absorb energy  
that  
would otherwise zap the microbes and increase the time proportionately.

I will try to devise an experiment to determine the validity of this  
hypothesis.

jack

NEVERMIND!!!!!!!!!!!!

Since typing this up, I did some experiments. the most telling is...

I placed .2 grams of dried yeast (Fleishman's baking) in each of (3) 10 ml glass bottles.

- # 1 control
- # 2 nuked for 10 seconds
- # 3 nuked for 30 seconds

Added 5 ml of sterilized sugar water to each and screwed on plastic caps.

One hour later they all appeared to fermenting vigorously and gas escaped when the caps were loosened.  
.....

Apparently, dormant dry yeast is dry enough to make it immune to microwave energy.

So, it appears that sterilizing bottles in a microwave requires enough water to generate steam and enough time to heat the bottle thouroughly. This makes it totally uneconomical for anything outhter than a couple of bottles or petri dishes and lab samples.

Subject: A Few Brew Questions

Hi folks.

I'm interested in finding out what it takes to set up a brewing operation, but I have a few concerns and questions. Here we go.

What is the production limit for an individual in Pennsylvania?

Can more than one individual pool funds to purchase production apparatus, and then combine their individual limits?

To what extent is the sale of the ingredients regulated, and is the purchase of raw ingredients considered the same as purchasing alcohol under the law?

After the initial capital outlay, about how much does beer cost, per gallon?

Where can I find out about how to start brewing?

A little more than curious,

From: Jeff Frane <70670.2067@compuserve.com>  
Subject: On #738 & 739

In Digest #738/To Ron Carlson:

First thing you should do is brew another batch of beer; get over this weirdness about warnings from the brewing gods. Without knowing anything about your beer but that it was a "scotch ale", I'm necessarily guessing, but I would suggest that the "liver" was protein. This past spring I brewed a wheat beer with a very high proportion of wheat malt, and discovered great grey pads of latex floating in my boil. I suspected they didn't belong there, since I'd never seen such a thing before, so I fished them out. The beer was fine. It's possible that some failure in the mash resulted in your wort containing some unhydrolyzable protein. Some of this probably scorched on your heating element, as well.

To Dave Ballard:

Do you rack your beer to a secondary fermenter? I started doing this a long time ago, partly to resolve the very problem you're describing. This process leaves a lot of mung back in the first carboy; when it comes time to rack from the secondary to the bottling bucket, there's very little yeast left to carry over. The little red thang works just fine then.

To Brian Bliss:

The idea of adding amylase \*at all\* is fairly bizarre; certainly I can think of no earthly reason to add it in the boil. The WYeast product is a weizenbier strain but I have found it difficult to consistently reproduce the clove flavor associated with these beers. Best result was when Dave used a combination of the weizenbier and a lager yeast with a relatively warm ferment (60^?). Purty good.

To Darryl:

We got ex-editors, too. Namely me, ex-editor of the OBC. Pleased as punch, by the bye, to hear that you're moving to the Northwest. Good choice. Under our new laws, of course, you'll need to find someone willing to \*leave\* when you arrive. Who have you chosen?

To Jack Schmidling:

I'm not concerned that you list me as a source, I'm concerned that you describe

the transcription of my notes on a five-minute telephone conversation as "research." I'm also somewhat nonplussed to hear that you've never tasted anyone else's homebrew. Howcum? The guy who suggested your beer would taste "cidery" because of oxidation has got it wrong. Oxidized beer generally tastes remarkably like cardboard, although in extreme cases the oxidation apparently imparts a sherry-like quality (haven't run across this enough to personally verify it). I was fortunate enough to taste a beer a long-time homebrewer brought into Steinbart's once. He'd been culturing his own yeast for 40 years, and made a remarkably clean beer from Blue Ribbon extract and lots of sugar. It was actually pretty tasty--if you like 7-UP; didn't taste much like beer. The cidery quality comes from an excessive amount of non-malt sugar.

To Steve Carter:

Like you, I've had to take beer in and out of the fridge many times; never had a problem.

To Brian Smithey:

Samuel Adams Boston Ale is available in Portland, OR. I believe that it is brewed in Boston rather than here at the Blitz Weinhard Brewery as the West Coast SA Lager is. Not sure about their specialty beers. We never did see the SA Wheat Beer that I kept hearing about on the CompuServe Forum. Their Oktoberfest should be out; last year's was really yummy.

On #739/To Brian Kush:

You're serving your beer too damn cold! The beer should last fine, just periodically (every time you change the keg) clean the lines and the tap thoroughly. A local supply store should have the proper cleaners.

And to respond to a request for recipes, here is my current version of House

Ale. Very simple and received with universal acclaim:

For 5 gallons

British ale malt 9#  
British crystal 1/2#  
Flaked barley 2 oz.

Mash with 3-1/2 gals. of water at 155°F (our water is very soft; I add 4 gr gypsum and .25 g epsom salts in mash; double that in the sparge water) for 90 minutes (sometimes much less; check with iodine at 45 min.).

Sparge to 6 gallons, boil 90 minutes. After 15 minutes, add 3/4 oz. Eroica. At end-boil, add 1 ounce Mt. Hood hops. Ferment at 65°F with WYeast American Ale yeast (in starter). Bottle two weeks later, drink one week later. Yummy.

Date: Mon, 07 Oct 91 21:37:12 -0400

From: gonzalez@BBN.COM

Subject: Neophyte's Impressions Of Boston-Area Suppliers

As we prepare to bottle our first batch, I thought I'd take time out to offer my observations on several local suppliers. I visited their stores as we prepared to get into this hobby, and at various times since.

Barleymalt & Vine 280 Worcester Rd. Framingham 508-820-3392

The Framingham store (in the basement of a store for collectors of records and baseball cards) is reportedly new; the original, which I've not visited, is in West Roxbury. Fairly extensive inventory of extracts, including Munton & Fison in bulk. Standard array of tools and books. The place looks sparse, but is actually well-stocked. Prices consistent with other shops. Ad says prices recently dropped, but cashier said prices actually went up a bit recently.

Boston Brewin' 75 Maple Street Danvers 01923 508-777-2337.

Homebrew and darts. Not as many extracts as other shops, but he picked the key ones. Prices compare favorably, except for the True-Brew kit, which is about \$15 higher than elsewhere. Definitely worth a visit when you don't care to drive into town.

Modern Brewer 2034 Mass. Av. Cambridge 02140 617-868-5580

My favorite, so far, and right around the corner from work. Second most-extensive selection of canned extracts, and one of only two selling bulk that I know of. Best selection of books and all the Zymurgy special issues. Lots o' yeast (two refrigerators - no waiting :-). Prices acceptable (better deals on gadgets than raw material), particularly on equipment kits (this is where we got our gear).

Wine and Beer Hobby 180 New Boston St. Woburn 01801 617-662-0872

Helpful hint: this is in the Woburn industrial park near the mall. The town fathers apparently decided to cut it off from the rest of New Boston Street, which is residential. Don't try to pick it up near the Purity Supreme and head north; get off at the Washington Street exit and head south.

Most extensive selection of canned extracts and chemicals, with slightly higher prices. Fair selection of books. Equipment kits priced a bit steep. Prices on new bottles highest of the four stores. Worth the trip to see the hot-tub-sized winemaking vats.

Hope this is of some use. Off to the kitchen now :-).

-Jim.

Date: Sun, 6 Oct 1991 13:48:00 -0400  
From: MIKE LIGAS <LIGAS@SSCvax.CIS.McMaster.CA>  
Subject: Article for New Homebrewers

Here's a little article which I wrote a year ago for a local homebrew club. I wrote it to provide basic information for newcomers to the hobby. The only point which is missing which should have been mentioned is the need for extreme cleanliness. All pieces of equipment should be cleaned thoroughly and sanitized with a mild bleach solution prior to use. Large pails and carboys can be soaked for 30 minutes in a mild bleach solution containing 1/2 teaspoon bleach per 5 gallons of water. They do not need to be rinsed but must be thoroughly drained before being employed. Everything must be cleaned well after brewing to avoid the growth of nasty microbes on brewing equipment during storage.

The article is written for first time brewers who will be using kits. The only reason this angle was taken was because the interested brewers wished to keep things as simple as possible for their first few batches. The procedure outlined in the article is one which will produce good, consistent results as simply as possible. Variations on the described procedure can no doubt be suggested (ie. length of boil, etc.) but simplicity was the objective.

\*\*\*\*\*  
\*\*\*\*\*

ARTICLE: BETTER BREWING WITH BEER KITS.

As you all know, brewing beer can be accomplished in various ways, from grain mashing, mash/extract recipes, extracts only, and from the use of prehopped 'kits'. You can brew excellent beer using any method as long as you pay attention to details, like thorough cleanliness, minimal use of adjuncts, healthy yeast, etc. Many new homebrewers start by brewing from kits and gain valuable experience this way. The quality and variety of kits available to homebrewers has improved drastically over the past few years and some folks brew exclusively from kits due to their convenience and tasty results. The choice to move into extract or mash brewing is a personal one, and is by no means necessary. Just do what suits you. Since many of you are new homebrewers and are using prehopped kits, we have prepared a step by step guideline to brewing beer from kits which will improve your results if you are currently employing the manufacturers suggestion of using corn sugar to raise the gravity of the

wort.

1. Bring 4 to 5 litres (1 Imp. gal.) of cold water to a boil in a stainless steel or enamel pot (NO ALUMINUM). Stir in 1.5 kg light (pale) unhopped malt extract (dried, syrup, or combination) and bring back to a boil. Boil for 15 to 20 minutes.
2. Stir in the contents of your can of kit beer and bring back to a boil. Boil for 5 more minutes. Remove from heat and pour into your primary fermenter. Top up to 22.5 litres (5 Imp. gal.) with cold water and stir well. If necessary, cool to 19-22C by immersing your covered fermenter in a tub of cold water and pitch yeast.\*
3. Ferment for 3 to 5 days and then rack into a clean glass carboy and seal with an airlock.\*\* Try to fill the carboy to 1 -2 inches below the bottom of the rubber bung. If the beer foams for a few days after racking, just put a tube into the hole in the rubber bung and immerse the other end of the tube into a pail of water. When foaming subsides, replace the tube with an airlock.
4. The beer will continue to ferment slowly for 3 - 10 days, and maybe longer for high gravity beers or slow fermenting yeast strains. When visible signs of fermentation are nil (very few rising CO2 bubbles) the beer is ready to bottle.
5. For bottling, dissolve 3/4 to 1 cup of corn sugar (Dextrose) in a small volume of water (1 - 2 cups) and bring to a boil. Cool until warm and pour the sugar solution into your primary fermenting vessel. Siphon your finished beer into the same vessel, being careful not to agitate and thereby oxidize your beer. Gently stir to ensure that the dextrose is evenly mixed into the beer and fill your bottle to approximately one inch from the top. Secure caps and let the bottles stand for one to two weeks at room temperature in a dark place and then refrigerate.
6. You can start drinking your beer at this point but a few more weeks in the cold will help develop smoothness and flavour. You may wish to hide a few bottles away for a few months just to see if the particular style of beer you have made ages well.

\* Yeast must be treated with respect if you want a healthy fermentation. If

you are not using a liquid culture, which is highly recommended, then you

should rehydrate the dried yeast which is supplied with the kit.

First, boil

some water in a kettle and pour about one cup into a glass and cover with a

plate. Let the this stand until the water temperature is between 35C - 43C.

Empty the dried yeast into the warm water and let the yeast stand for 5 to 10

minutes. Stir the yeast slurry and pour into your wort and mix well.

\*\* It is never necessary to suck on a hose to start a siphon. This is a common

source of contamination. Just fill your hose with water and clamp it shut so

the water stays in the hose. Immerse one end in the beer, place the other

end at a lower level in a cup, and open the clamp to start the siphon. When

the water has collected in the cup and beer is in the tube, clamp shut and

transfer to your pail or carboy and commence siphoning.

\*\*\*\*\*  
\*\*\*\*\*

Subject: Re: Various

Justin Aborn sasy/asks:

> I have a pear tree in my back yard that produces prodigious  
> amounts of fruit that I usually wind up throwing away. As a  
> brewer, other possibilities come to mind...  
>  
> Does pear beer sound good or gross?  
umm, in a word, YES!

I would suggest that you use these in either a wine or a mead.  
Of course this is only what I would do with them. Your  
mileage may vary.

and Chris Shenton asks:

> A question for HBD-land: Wyeast wheat-beer is (unfortunately) a mix of  
> S. Delbrukii a basic beer yeast. Do you think repitching like this  
would  
> select for eventual domination by one or the other strain?  
I don't know of a way to guarantee which would dominate (if one ever  
does).  
However, if your goal is a pure culture of S. Delbrukii you can 'plate  
out'  
the Wyeast culture. You will note that there are two different size  
colonies. I believe (someone who remembers help me out) the S.  
cerevisiae  
is larger in size than the S. Delbukii. So, you then take a culturing  
loop and grab up a bunch of these smaller colonies & grow them in ~5ml of  
starter solution. Then you perform the whole process again (plating,  
etc)  
until you don't seem to have any more S. cerevisiae. Of course it  
may just be easier to find someone who have already done this. Drop me  
a line in a week or two & I can tell you for sure if its the large or  
small colonies you want.

Peter Karp asks:

> Has anyone in the New England area had a taste of a contract brewed  
> beer called En Garde. It is said to be in the style of the French  
> Biere de Garde (eg. St Leonard, Trois Monts, Jenlain). Where can I  
> get some?  
Yes, I've had it, and I like it. IMHO, its a good biere de garde.  
Its similar to those you mention so it must be 'in the style' anyway.  
Its handled by 'Dark Cloud Distributors' somewhere in eastern MA.  
(in fact, I think they're somewhere near Tewksbury) I've seen it  
at most of the well stocked liquor stores in MA. Two that come to  
mind are Harrington's in Chelmsford, and Aubut's in Tewksbury.  
I wouldn't be suprised if both were running low now, I believe  
that this first run has almost entirly sold out now. Another  
should be on the way.

and Greg Roody - dtn 237-7122 <roody@necsc.enet.dec.com> says:

> So, how many people would like to see (even "non-profit") ads limited  
to  
> either 5 lines maximum or banned outright?  
I'll go for a limitation. I won't go so far as to ban a message outright  
because there are people out there who have useful products  
(lambic cultures:-). Provided that the ad is appropriate, in good taste,

and doesn't appear more than 1-2 times per quater I wouldn't mind greatly.  
I'd prefer the ads to be <5 lines and direct those interested to an e-mail address for a full announcement.

-or-

perhaps have an 'advertisements' issue every few months? I can think of a few people who having interesting toys they'd probably like to advertise.

(hi Darryl)

Finally, since this is a digest and we have a moderator, I'll leave it up to him to decide the issue.

I am planning to make a christmas ale so I was excited when some contributors mentioned a good recipe in digest #693. Alas, after searching through my local back issues, there was no 693 to be found. Could someone either email em or post the recipe. Thanks.

Also, I didn't notice a date on the Charlie Papazian book signing. Will it be any day in particular?

From: MIKE LIGAS <LIGAS@SSCvax.CIS.McMaster.CA>  
Subject: Advertising for No Gain

HD740 had quite a few letters which bring into question the use of HD as an advertising forum. One letter brought up the issue of discerning between ads for profit vs. ads for non-profit. Well, here's my two cents worth.

I have submitted many postings in the past which could have been interpreted as advertising. Examples include a plug for the Canadian Amateur Brewers Association (CABA) which is a non-profit organization resembling the AHA, a notification of an upcoming CABA conference and competition, an ad for an International Beer, Wine and Food Festival, and an as of yet to appear note on a Brewerianist show coming soon to Toronto (I sent this one last Sunday and I haven't seen it in HD yet). In no case am I attached to these organizations as a representative or potential profiteer. I simply posted these letters because I felt they would be of interest to homebrewers and beer lovers.

Still I felt somewhat put-off by the comments in HD740. Maybe a simple rule is for the person posting the letter there should be no monetary gain from the ad. Although this is a rather loose rule at least we won't be suppressing general communication on beer issues and confining ourselves to trading recipes and problem shooting, both valuable but tedious after a while. This is a homebrew forum which allows general reading on beer related issues and according to the "advertisement" for Homebrew Digest available through Seenet even wine and mead discussion is allowed. Let's not stifle free speech in the name of political correctness.

> Just looking at the place makes me think it may be older than the US  
version.

Sounds like we had a similar itinerary in the UK... ;-)

I visited Salisbury and sampled some Gibbs Mew beer. Good stuff but  
nothing  
extraordinary.

Bishops Tipple I believe is the name of the barley wine put out by Gibbs.  
When we went into a pub (one of those fern bars that CAMRA's Guide to  
Good Beer  
complains about ;-)) we asked the bartender what he recommended, and he  
said  
"So you want to play with the big boys huh?" and poured us Bishops Tipple  
at  
about 7.5% alcohol, thinking we wanted to get drunk quickly :-/. That  
stuff  
was TOO strong. Had a nice spicy hoppiness to it at first, with good  
malt body,  
but the aftertaste reminded me of cheap whiskey. Just too much.

Anyway, did you get to try some Foilenfoel ("feelin' fowl") from Wales  
over  
there ? GREAT brew!

From: "Jack D. Hill" <jdhill@BBN.COM>  
Subject: re: Le Garde

Le Garde (not En Garde) is brewed in White River Junction Vermont. I think it is contract brewed by WRJ (the same people who make Catamount) for another company. The stuff is fairly readily available in most respectable (and a few not so respectable) liquor stores in Massachusetts. I love French Biere de Garde and although Le Garde is very good, it doesn't quite hit the mark. Le Garde has that big, robust malty taste but it is not as smooth as the French. Also, the faint sourness that wonderfully balances off the malt isn't there. Still, this beer is definitely worth searching out. An interesting note, the people who make Le Garde also import St. Leonard, a wonderful biere de garde from France. They were at the last Brewers Offering (a beer tasting sponsored by public radio station WBUR) in Boston.

Subject: Apple Flavor?

I recently sampled my first attempt at "homebrew". I used a "Continental Light" recipe, and after waiting four weeks for the "aging", I was a little disappointed in that there was very little "head"/carbonation, and a definite apple-like aftertaste. Is it

possible that the beer merely requires more time to age, which might produce more carbonation and concurrently remove the sweet apple-like aftertaste? Does aging temperature have a significant effect on the end product?

Subject: ice chest lauter tun

> Those of you who sparge all at once in a big cooler, do you use a rectangular cooler or a cylindrical one? How did you cut the slots in the copper tubing?

I've got an 80 quart Coleman rectangular cooler. I've made 5 gallon batches in it that turned out just fine, although I must admit that I was prestty concerned that 8 lbs. of grain was not going to make a sufficiently deep bed to lauter correctly. I cut all of the slots in about 10 feet of tubing with a hack saw. (That's me, just an old hack.) Another brewer round here used a saws-all and ended up with a very professional looking job, with about twice as many cuts as I made...

Subject: Best Beer

My wife bought me a keggng system from Foxx for my birthday back in August and I've been producing beer like crazy ever since.

This hyperactivity has resulted in one of the best beers I've made in my 4 years of brewing and it's an extract recipe.

No, it's not 100% true to style, but I don't really care because it was a damn good beer and it was quick and easy to make.

"Brew Free or IPA" India Pale Ale

4 lbs. Munton and Fison light DME  
4 lbs. Geordie amber DME  
1 lb. crushed Crystal Malt

1.5 oz. Cascade leaf hops (boil 60 minutes)  
1.5 oz. Cascade leaf hops (finishing)

Wyeast #1056 Chico Ale Yeast (1 quart starter made 2 days prior)

O.G.: No idea (I didn't check), but I'd WAG it to be about 1.055  
F.G.: 1.012

Add the crystal malt to cold water and apply heat. simmer for 15 minutes or so then sparge into boiling kettle. Add DME, top up kettle and bring to boil.

When boil starts, add boiling hops and boil for 60 minutes.

10 minutes before end of boil I added 1 tsp. of Irish Moss.

When boil is complete, remove heat, add finishing hops and immediately begin chilling wort.

Strain wort into fermenter and pitch yeast starter.

Primary fermentation took about 4 days. I let the beer settle for another 2 days and then racked into a sanitized, primed (1/3 cup boiled corn sugar solution) and oxygen purged keg and applied some CO2 blanket pressure.

After one week in the keg the beer was clear, carbonated, and very drinkable although it had a very noticeable alcoholic nose.

After 2 weeks the beer was incredibly smooth, bitter, and wonderfully aromatic. Several friends raved about this beer including one who lived in England for a while said that this was one of the best IPAs he's ever had and definitely the best homebrew he's ever had.

After 2.5 weeks it was all gone because we drank the whole thing.

Subject: Greetings one and all...

Three topics today:

First off, I was bothered by the add for the homebrewing video. True, Jack was giving us a price break and he surely wouldn't be make much money from a price of \$12.95, or whatever it was. It bothered me because it was a misuse of this wonderful digest. But then again, isn't this message a bit off the topic of homebrewing?

Second, many thanks to all the people for submitting new recipes. With all of the recent submissions, there are almost enough recipes for Mark Stevens and I to start on "The Cat's Meow, Vol. 2". Keep sending in the recipes, because we want Vol. 2 to be a winner. Right now we are just compiling, but if there are any suggestions for us please e-mail me at the address below. But please, please, please, do not send me any "Send me a copy when it is ready" requests. All such mail will be appended to /dev/null. (I have enough to do without keeping track of these requests.)

Third, I am setting up an FTP account if you care to do direct submissions, get copies of "The Cat's Meow", or whatever (related to homebrew PLEASE)

The address of the machine in which to FTP to is: 131.151.23.29. Currently I am testing it and so far so good. But please be warned that this connection is going to unavailable on Friday of this week. (Have some other network rewiring to do). This will be an anonymous FTP account, so have fun...

Subject: Re: Papazian Book-Signing in Boston

Kevin McBride discreetly mentioned that I had neglected to include the date of the book-signing. It is to take place on October 26th. Sorry about that.

I'm undecided about attending the dinner. I've included the text of the description to help others to decide for themselves.

-Jim.

Begin excerpt -----

Ruggiero to Host Dinner in Papazian's Honor

Later that evening, David Ruggiero, reknowned beer judge and proprietor of BM&V will host a dinner and beer tasting in Papazian's honor at the Boston Fencing Club in Watertown, MA. A large selection of locally brewed commercial beers, as well as some choice imports will be served with a buffet dinner who's dishes have been prepared with beer.

Later that evening Papazian will provide his insight into six home brewed beers prepared especially for the occasion by local brewers.

Copies of The Complete Joy of Homebrewing may be reserved by contacting BM&V. Tickets to the dinner may be obtained at Barleymalt and Vine or by calling (508) 820-3392. Seating is limited so order early!

Date: Tue, 8 Oct 91 08:30:37 -0700  
From: darryl@ism.isc.com (Darryl Richman)  
Subject: re: A Few Brew Questions

> What is the production limit for an individual in Pennsylvania?

The feds limit individuals to 100 gallons a year; households with two or more adults to 200 gallons. A gallon of beer is roughly 10 12 oz. bottles. The individual states may have their own regulations. There are still a few that make homebrewing illegal, although the conventional wisdom is that if you don't flaunt it, nobody will notice. I believe (but have no proof) that Pennsylvania doesn't have any such nonsense.

> Can more than one individual pool funds to purchase production  
> apparatus, and then combine their individual limits?

An interesting question, but I've not heard of the test case being decided. Once again, let me urge you not to lose sleep over this, unless you're offering your beer to the neighborhood children.

> To what extent is the sale of the ingredients regulated, and is the  
> purchase of raw ingredients considered the same as purchasing alcohol  
> under the law?

The ingredients are natural foodstuffs. There are no limitations on the purchase of barley malt (it's a common ingredient in cereals and baking), hops (the flowers of a trailing vine) or yeast. The government has more interest when you put them together and they create ethanol, especially if you try to sell it.

For that matter, although the BATF may disagree, the product is a natural foodstuff. There is a theory gaining credence among archaeologists that beer is responsible for civilization. It's not uncommon in other lands for the population to obtain a significant amount of its nutrition from beer: lots of energy is available from ethanol and carbohydrates, the water content is pure, the yeast add a significant amount of vitamin B, and hops add a small amount of vitamin C.

> After the initial capital outlay, about how much does beer cost, per  
> gallon?

If you make it from scratch, as I do, your cost can be under 7c a bottle. If you buy extracts (where the mashing step has been done for you), the cost goes up significantly. I think it could be as much as 40c. Of course, these numbers reflect the cost of ingredients, excluding water and gas or electricity costs (which can be significant) and your time.

> Where can I find out about how to start brewing?

Get a book or two. I'd recommend "The Complete Handbook of Homebrewing" by Dave Miller (ISBN 0-88266-517-0) if you're a techie and/or "The Complete Joy of Home Brewing" by Charlie Papazian. There's a new edition of the latter just released. Sorry I don't have the ISBN, my copy is loaned out at the moment. But you can order either direct from the AHA at (303) 447-0816.

Another thing to do is join a club. This is probably better than reading a book. You'll get to taste others' beers and probably see a

variety of brewing set ups.

I agree that we ought to request commercial "blurbs" to limit themselves to minimal space. In general I'd prefer not to see advertising in the Digest unless there is some special offer to Digest readers. In your case Jack, the ending offer to the HD readers with about 10% of the descriptive text would have been better. Perhaps a short announcement of products and/or services, followed by "for more information contact (E-mail address, phone #, etc. ..)" would allow free enterprise to continue without increasing the S/N ratio too much.

Date: Tue, 08 Oct 91 09:04:26 -0700  
From: night@mapme7.map.tek.com  
Subject: My best recipe...

Okay brewmeisters and beginners... here is my best recipe, by far!...

Nightingale DoppleBock

7# Light Scottish Malt Extract  
1# Dry Dark Malt Extract  
1.5# 80L Crystal Malt  
6 oz. Chocolate Malt  
2 oz. Black Patent Malt  
8 oz. Dextrin Malt  
1/4 tsp. brewing salts  
2 oz. Perle Hops (bittering) alpha=7.6%  
1 oz. Hallertauer Hops (aromatic) alpha=3.9%  
1/2 tsp. Gypsum  
2 packets of Redstar Lager yeast  
2/3 cup corn sugar for priming  
Water to 5 gallons

Mash crushed Crystal and Dextrin Malts in a pan of water at 150F for 1 hour.

Strain through collander into main kettle and sparged with 150F water until it runs clear.

Add enough water to kettle to dissolve extracts (~3 gal.)

Dissolve extracts, salt and gypsum into kettle and bring to a ROLLING boil.

Stir in 1/2 oz. Perle Hops and boil 15 min.

Stir in 1 oz. Perle Hops and boil 15 min.

Stir in Chocolate and Black Patent Malts (UNCRUSHED!) and boil 15 min.

Stir in 1/2 oz. Perle Hops and boil 15 min.

Add Hallertaur Hops in the last minute of the boil.

Strain though a nylon meshed colander into Primary fermentor.

Top up to 5 gallons with cold water. Cool wort as fast as possible.

(I cooled it to 80F in 9 minutes.)

At 80F add yeast. (I put the dry yeast into a 1/2 cup of 95F water and let it

sit for 6 min. first)

My O.G. was 1.060

I placed the Primary in my garage surrounded by other containers of water to

keep the temperature more constant.

It brewed in the primary for 12 days at 40-48F.

I then racked it into the secondary and let it sit and ferment VERY slowly

for 1 month. (Temp ranged between 32F and 40F) (Visible fermentation stopped

after only 10 days in the secondary.)

I then racked it again into my primary. Boiled 2 cups of water with 2/3 cup

of corn sugar and added. When bottling, top bottles to within 1/2" of top.

I then lagered for a full month at 34F.

The final gravity was 1.025.

This brew is not quite as strong as a traditional Dopplebock. However, the resulting beer was none less than excellent. It had a good shot of malt flavor (esp. the chocolate!). The head quite creamy. The hopping was perfectly balanced. It is the smoothest homebrew I've ever had.

I would love to tell you a brew that it compares to... but I can't. All of the Dopplebocks I've tasted are German varieties which are much higher in alcohol than this... It seems that we on the West Coast have a severe lack of good Lager breweries. The abundance of lager microbreweries are on the east coast. Thus... I make my own dopplebocks!

Enjoy!!!!!!

Date: Tue, 8 Oct 1991 14:12:21 -0400 (EDT)  
From: Peter Glen Berger <pblp+@andrew.cmu.edu>  
Subject: Great Stout!

Ok. My recipe rules after 2 weeks, and is tasting better every day.

Thanks to all who helped. Here it is:

"Bitch's Brew" Oatmeal Stout:

6 lbs. dark dry malt extract  
2 lbs. amber dry malt extract  
1 lb. crystal malt, cracked  
.75 lb. roasted barley, cracked  
.50 lb. black patent malt, cracked  
2 oz. Bullions hops (boiling)  
.5 oz Willamette hope (finishing)  
2 cups Quaker Oats  
2 pkgs. Whitbread Ale Yeast

Steep the Oats, and the cracked grains for 1/2 hr in cold water.  
Heat mixture and remove grains as boil is reached. Throw in malts and  
make your wort. NOTE: We were using a 5 gallon brewkettle and had to  
tend it for 15 minutes; the hot break is VERY assertive and hangs out  
for quit a long time. Boil Bullions for 45 minutes, Willamette for  
5-7 minutes. Have fun. Starting SG: 1.052 Finishing: 1.019

Comments: I would cut back on the finishing hops, or boil them  
longer; the aroma was too assertive, although it is mellowing a bit  
now (after 2 weeks in the bottle). I would also change the proportion  
of malts to 4 lbs. LIGHT and 3 lbs. dark; there's enough color and  
lighter malt will yield more alcohol. Also, probably only 1 package  
of good yeast is needed for this mixture, I just got paranoid over my  
last stuck fermentation.

I was very sparing on the oatmeal due to their oily character; if you  
put in much more, you'll lose the head entirely.

Subject: Ads on the digest.

I rather enjoyed Jack's ad for his video, and thought it downright decent of him to offer it to digest readers at a low price. I do not object to beer related advertising on the digest so long as it is obviously an ad and not an ad hidden as information.

How many of you would read Zymurgy and skip all of the advertising? I didn't think so. I, too, like the high concentration of good material here, and wouldn't want things to get out of hand, but they haven't in the past, and I don't think we need to address a non-problem.

When a person is in business for himself / herself, they need to take advantage of all opportunities to sell. I see no harm in Jack's mentioning of his new product here. Now, if he sold patio furniture, and advertised it here, I'd object, because it wasn't directly beer or brewing related.

Again, let's not make a giant blowoff over a few bubbles in the airlock.

>Just looking at the place makes me think it may be older than the US  
version.

The Anchor Brewery was founded in 1896 in SF. Don't know where they got  
the  
name. Fritz didn't get involved till '65.

There is also a brewery in Kuala Lumpur, Malaysia that produces a beer  
called  
Anker. Pronunciation and meaning are the same as our version, and the  
logo  
is somewhat similar, but the similarity stops there. Like most beers in  
that  
part of the world, Anker is a pale yellow fizzy thirst quencher. It  
tasted  
like it was made with rice, which is a common practice throughout SE  
Asia.

Subject: SA holiday brew

I heard from the local Sam Adams salesman that SA is working on a cranberry lambic (!), which would unlikely be a real lambic. My guess is that we'll see it around Thanksgiving. No word on a winter warmer, but that'll probably happen too.

I didn't notice the label change with SA Boston/Stock Ale, but it does seem that they've cut way down on the hops, so now it's only \*really\* hoppy. Anyone else notice it?

From: Greg Roody - dtn 237-7122 <roody@necsc.enet.dec.com>  
Subject: The votes are in, & we have a new Unit of Measure.... the SmU

Well, the results are in and unanimous. Out of the thousands who responded (well, ok, it was only three or four, but they all said the same thing) nobody wanted to see advertising in the HBD.

As a side note, we did establish a new unit for homebrew ratings: the Schmidling Unit (SmU). This unit will vary inversely to the Quality; as the quality goes down, the Schmidling goes up.

But be careful, this is a powerful unit; a slight chill haze would be measured in pico-Schmidlings, oxidation would be milli-Schmidlings, and full fledged infections (lacto, coloform, salmonella, etc) would be full Schmidling defects;  
9 SmU's will blind you and 10 SmU's will kill you.

So, there you have it. Happy Schmidling.

Date: Tue, 8 Oct 91 13:01 PDT  
From: Bob\_Konigsberg@3mail.3com.com  
Subject: Brown Ale

I'd like some advice on a Brown Ale a friend and I have been making. What I'm specifically looking for is what would provide the "nutty" character (a la Samuel Smith's Nut Brown Ale). This is an extract brew based on the following recipe for 10 gallons

6# light liquid extract  
6# dark liquid extract  
2# Medium Crystal Malt  
8oz Black Patent Malt  
12 AAUs per 5 gallons (24) Cascade boiling hops  
2 oz Kent Goldings finishing hops  
4 oz French Oak Chips

The French Oak chips seem to have been a stumbling block so far, in that boiling them (as the original recipe said to) produced an unpleasant aftertaste. We've done 4 batches so far, and the two in which the oak chips were boiled were flawed. One batch we forgot to add them, and one batch we added them late with the finishing hops so that the chips did not get boiled. The latter two were pretty good, but none of the batches have the nutty character of Samuel Smiths.

To answer someone's question on food grade plastic: I called the Rubbermaid company's 800 number and found that all of their food grade containers are tested with acid foods (organic acids), alkalies, strong oxidizers (inorganic acid, chlorine?), and are measured for weight loss (which would indicate seepage into the food), deformity, discoloration etc. I'm waiting on further information, so I will post it if I get anything else.

From: STROUD%GAIA@leia.polaroid.com  
Subject: Papazian coming to Boston

Here is an item that New England homebrewers in the Boston area may be interested in:

To help celebrate the opening of their new store, Barleymalt & Vine has arranged for Charlie Papazian, the guru of homebrew, to come to town on Saturday, October 26th for a booksigning with a homebrew tasting and beer dinner to follow.

To quote from BM & V's press release:

'Papazian will appear at the newest branch of Barleymalt & Vine on Route 9 in Framingham, MA where he will be from 10 to 2. At 2:30 Papazian will travel to Barleymalt & Vine's store in West Roxbury where he will stay until 6pm. Later that evening Dave Ruggiero (BM & V's owner) will host a dinner and beer tasting in Papazian's honor at the Boston Fencing Club in Watertown. A large selection of locally brewed commercial beer as well as some choice imports will be served with a buffet dinner whose dishes have been prepared with beer. Later that evening Papazian will provide his insights into 6 homebrewed beers prepared especially for the occasion by local brewers. A signed copy of the new edition of Papazian's 'Complete Joy of Homebrewing' may be reserved by contacting Barleymalt & Vine. Tickets to the dinner may be obtained at one of the Barleymalt & Vine locations or by calling (508) 820-3392. Seating is limited so order early!'

I talked to Dave today and here are some more details:

Charlie will be signing copies of his new book at the two stores and just talking it up with other homebrewers if you'd like to tip a few with him and ask him some questions.

The dinner will start at 7 pm and is being catered by Prince St. Caterers. Paul Correnty (cider maker, professional chef, and Wort Processor) will be assisting in the menu planning. Cost for the dinner is \$30 (\$37 if you'd like dinner and a signed copy of the book, that's \$3 off the regular price of the book).

Pre-registration for the dinner is required and seating is limited. If you're interested, call NOW!

From: Martin A. Lodahl <hpfcmr.fc.hp.com!hplabs!pbmoss!malodah>  
Subject: Fave Recipe, Adverts

My favorite recipe? Why, the one that's in the fermentor now, of course! It's a really great Scottish ale, with some of the malt smoked over a peat fire, and a new type of water treatment that'll get rid of the astringency this time for sure, and ...

But here's my second favorite:

\_Trappiste\_

Ingredients - 7 lbs domestic 2-row pale malted barley  
4 lbs Munich malt  
8 oz wheat malt  
1.5 oz chocolate malt  
1 lb dark brown sugar (in boil)  
Bittering hops: 1 oz Chinook (10.8% AA)  
Finish hops: 0.5 oz Tettnanger (4.7%),  
0.5 oz Hallertauer (2.8%),  
0.5 oz Kent Goldings (5.2%)  
Priming: 1 cup light dry malt extract

Process - Mash water: 14 qts @ 135F  
Mash-in: 3 min @ 131F, pH 5.3  
Protein rest: 30 min @ 131-28F  
Conversion: 2 hrs @ 150-141F  
Mash-out: 5 min @ 168F  
Sparge: 5.5 gallons @ 168-165F, pH 5.7  
Boil: 120 minutes, adding bittering hops @ 60 min  
and finish hops at end

OG: 1.078 TG: 1.013

As students of Dave Miller will recognize, this recipe doesn't differ from his in any important detail. The most critical parts are the hops and the yeast. The only substantive change I'd make to the hopping is to dry-hop rather than finish-hop, using the same quantities of the same varieties. The yeast was cultured from a bottle of Chimay Rouge. After three weeks of fascinating fermentation, a strong beer was produced that was intriguingly complex and true to type. After a few months in the bottle it acquired a strong banana-ester component in the nose that priming with corn sugar rather than DME might have ameliorated. It was fermented in a 25L carboy, then racked to a 5 gallon carboy for 5 days of clarification, then bottled. Good stuff, IMHO.

=====

My \$0.02 on the subject of advertising in HBD: Overall, it's been a rare sight, and until Jack's video ad, had always been a tasteful offering of something of unquestionable immediate interest to the HBD community. The only examples I can immediately recall were Mike Sharp's lambic cultures and culturing equipment, Kinney Baughman's almost reluctant admission that there is a company named BrewCo selling brewing equipment, a couple of folks offering yeast cultures, and, of course, a few beer festivals and contests. I'd hate to see us throw away a useful aspect of the forum in reaction to the crassness of a single posting. I support Greg Roody's suggestion of a (voluntary) length limit for commercial messages, but feel that

the polling should be done off-line, and the results forwarded to  
Our Benefactor and Moderator, the ever-elusive Rob Gardner, as a  
sampling of group sentiment. Just One Man's Opinion ...

From: Ifor Williams <ifor@computer-science.manchester.ac.uk>  
Subject: Oxidising Wort

I've recently read Dave Millers Complete Handbook of Home Brewing and was left with the impression that I'm not careful enough with the wort! For example, Miller recommends that the boiled wort should be cooled with an immersion chiller before being poured into the hopback so as to minimise oxidation. Similarly, he recommends taking care during sparging to avoid oxidation.

This leads to my question - if the wort oxidises so easily, does it not oxidise during a long open boil? If not, why not? If so, is the oxidation not much more significant that can be expected during the other brewing stages?

What am I missing?

Ifor.

Date: Mon, 7 Oct 1991 22:58:02 -0400 (EDT)  
From: D\_KRUS@UNHH.UNH.EDU (Daniel L. Krus)  
Subject: Yeast and Spec. Grav's.

There's been a few questions lately about yeast and characteristics associated with them. Here is a retype of some information I received from Wyeast relative to their yeast. This information was obtained a while ago and supposedly this was to be updated and expanded. If anyone has the latest update I would appreciate a copy of it from you since Wyeast wasn't too tickled that I contacted them directly. Sorry if there are any typos.

#### YEAST CHARACTERISTICS

Some yeast strains are more active and vigorous than others. Lager strains in particular do not show as much activity on the surface as many of the Ale strains. We provide an adequate quantity of yeast to complete fermentation with varying amounts of lag time depending on strain, freshness, handling, and temperature. If you find it too slow, make a starter as recommended on the package. In any event, a closed fermenter with an airlock is recommended.

#### TEMPERATURE

The slow onset of visible signs of fermentation can be improved by starting fermentation at 75 deg. F (24 deg. C) until activity is evident, then moving to your desired fermentation temperature. A few degrees does make a significant difference without adversely affecting flavor.

The normal temperature for Ale yeast range from 60-75 deg. F (16-24 deg. C). A few strains ferment well down to 55 deg. F (13 deg. C). 68 deg. F (20 deg. C) is a good average. Lager strains normally ferment from 32-75 deg. F (0-24 deg. C). 50-55 deg. F (10-12 deg. C) is customary for primary fermentation. A slow steady reduction to 32 deg. F (0 deg. C) during secondary fermentation typically works well.

The fermentation rate is directly related to temperature. The lower the temperature, the slower fermentation commences. Fluctuations in temperature such as cooling and warming from night to day can adversely affect yeast performance.

#### ATTENUATION

Apparent attenuation of yeast normally ranges from 67-77%. The attenuation is determined by the composition of the wort or juice and the yeast strain used. Each yeast strain ferments different sugars to varying degrees,

resulting in higher or lower final gravities. This will affect the residual sweetness and body.

#### FLOCCULATION

All brewing yeast flocculate. The degree and type of flocculation varies for different yeast. Some strains clump into very lary flocculate. Some floc very little into a more granular consistency. Most yeast strains clump and flocculate to a moderate degree.

#### pH RANGES

Typical pH range for yeast fermentations begins at about 5.1 and optimally 4.8. During the course of fermentation the pH reduces to typically 3.9-4.1 and as low as 3.1 in some wines.

#### ALCOHOL TOLERANCES

The alcohol tolerance for most brewing yeast is as least to 8%. Barley wines to 12% can be produced by most Ale strains. Pitching rates need to be increased proportionally to higher gravities. Alternately, Champagne and Wine yeast can be used for high gravities sometimes reaching alcohols to 18%.

#### YEAST PROFILES

Ales (*Saccharomyces cerevisiae*)

1007. Our original Ale Yeast of German origin. Ferments dry and crisp leaving a complex yet mild flavor. Produces an extremely rocky head and ferments well down to 55 deg. F (12 deg. C). Flocculation is high and apparent attenuation is 73-77%. Optimum fermentation temperature: 62 deg. F (17 deg. C).

1028. British #2 (London Ale previously British Ale). Rich minerally profile, bold woody slight diacetyl production. Medium flocculation. Apparent attenuation 73-77%. Optimum fermentation temperature: 68 deg. F (20 deg. C).

1056. American Ale Yeast. Ferments dry, finishes soft, smooth and clean, and is very well balanced. Flocculation is low to medium. Apparent attenuation 73-77%. Optimum fermentation temperature: 68 deg. F (20 deg. C).

1084. First considered just British, but now more specifically Irish. Slight residual diacetyl is great for stouts. It is clean smooth, soft and full bodied. Medium flocculation and apparent attenuation of 71-75%. Optimum fermentation temperature: 68 deg. F (20 deg. C).

1098. British Ale Yeast from Whitbread. Ferments dry and crisp, slightly tart and well balanced. Ferments well down to 55 deg. F (12 deg. C). Medium flocculation, apparent attenuation 73-75%. Optimum fermentation temperature: 70 deg. F (21 deg. C).

1338. European yeast from Wissenschaftliche in Munich. A full bodied complex strain finishes very malty. Produces a dense rocky head during

fermentation. High flocculation, apparent attenuation 67-71%. Optimum fermentation temperature: 70 deg. F (21 deg. C).

#### Lager (*Saccharomyces uvarum*)

2007. Our original Lager Yeast Strain. Specific for pilsner style beers. Known as many things, we call it Pilsen. Ferments dry, crisp, clean and light. Medium flocculation. Apparent attenuation from 71-75%. Optimum fermentation temperature: 52 deg. F (11 deg. C).

2035. American Lager Yeast. Unlike American pilsner styles. It is bold, complex and woody. Produces slight diacetyl. Medium flocculation, apparent attenuation 73-77%. Optimum fermentation temperature: 50 deg. F (10 deg. C).

2042. Danish Yeast Strain. Rich, yet crisp and dry. Soft, light profile which accentuates hop characteristics. Flocculation is low, apparent attenuation is 73-77%. Optimum fermentation temperature: 48 deg. F (9 deg. C).

2124. Bohemian Lager Yeast. The traditional sazz yeast from Czechoslovakia. Ferments clean and malty, rich residual maltiness in high gravity pilsners, medium flocculation, apperent attenuation 69-73%. Optimum fermentation temperature: 48 deg. F (9 deg. C).

2206. Bavarian Yeast Strain used by many German breweries. Rich flavor, full bodied, malty and clean. Medium flocculation, apparent attenuation 73-77%. Optimum fermentation temperature: 48 deg. F (9 deg. C).

2308. Munich Yeast from Wissenschaftliche in Munich #308. One of the first pure yeast available to American homebrewers. Sometimes unstable, but smooth soft well rounded and full bodied. Medium flocculation, apparent attenuation 73-77%. Optimum fermentation temperature: 50 deg. F (10 deg. C).

#### *Saccharomyces delbrueckii*, *S. cerevisac*

3056. Bavarian Weissen. A 50/50 blend of *S. cerevisiae* and *Delbrueckii* to produce a south German style wheat beer with cloying sweetness when the beer is fresh. Medium flocculation, apparent attenuation 73-77%. Optimum fermentation temperature: 56 deg. F (13 deg. C).

#### Wine Yeast

3021. Prise de mousse, Institute Pasteur champagne yeast race bayanus. Crisp and dry, ideal for sparkling and still red, white and fruit wines. Also can be used for Barley wines. Optimum fermentation temperature: 58 deg. F (14 deg. C).

3028. French wine yeast ideally suited for red and white wines which mature rapidly. Enhances the fruity characteristics of most wines. Optimum fermentation temperature: 72 deg. F (22 deg. C).

#### Malo-lactic Bacteria

##### *Leuconostoc oenos*

4007. Malo-lactic culture blend isolated from western Oregon wineries.

Includes strains Ey2d and Erla. Excellent for high acid wines and low pH.

Softens wines by converting harsh malic acid to milder lactic acid.  
Can be added to juice any time after the onset of yeast fermentation when sulfur dioxide is less than 15 ppm.

---

There have also been some questions about Spec. Grav's. and conversion to 60 deg. F (15.6 deg. C). The following is the information that came with my hydrometer.

#### TEMPERATURE CONVERSION

This hydrometer gives an accurate reading when the temperature of the liquid is 60 deg. F (15.6 deg. C). The following tables show how to correct for temperature difference.

| Temperature |        |       | Spec. Grav. |
|-------------|--------|-------|-------------|
| deg. F      | deg. C |       | Correction  |
| 50          | 10.0   | - 0.5 |             |
| 60          | 15.6   | 0     |             |
| 70          | 21.1   | + 1   |             |
| 77          | 25.0   | + 2   |             |
| 84          | 28.9   | + 3   |             |
| 95          | 35.0   | + 5   |             |
|             | 105    | 40.6  | + 7         |

#### Example:

Specific Gravity is: 1.100 at 84 deg. F.  
Correction figure is: + 3 to correct to 60 deg. F.  
-----  
Corrected Spec. Grav. is: 1.103

---

I plot Correction vs. Temperature and keep this plot in the back of my brewing note book for quick and handy visual reference. This data does not yield a linear relationship thus a graph is quicker to work with than some polynomial equation.

I hope some of this information helps.

Dan

From: hersh@expo.lcs.mit.edu  
Subject: Boston Ale

The Boston Ale is brewed in 2 places.  
A lot of the draft Ale, particularly for local consumption is brewed here  
in  
Boston in the Jamaica Plain brewery using what used to be Bill Newman's  
Albany  
Amber brewing setup. I am told that the bottling line there is fully  
functional  
and that from time to time they do bottle some of the Boston Ale brewed  
there.

However most of the Boston Ale found in the bottles is brewed at the F.  
X.  
Matt's brewing company in Utica, N.Y. under contract. Also some of the  
keg beer  
found outside the Boston market is brewed there as well.

The Lager product, both bottle and draft is produced by the Pittsburgh  
Brewing  
Co. of Pittsburgh. Pa. under contract.

This information is correvt as of sometime earlier this summer when I was  
at  
the brewery, though these arrangements are fluid (get the pun :-), and of  
course may have changed.

From: Richard.Stueven@Corp.Sun.COM (Richard Stueven)  
Subject: Relevant (?) Advertising

I thought I was going to be able to stay out of this, but...

I was disturbed to hear from a fellow HBD/r.c.b subscriber yesterday that he was reluctant to post an announcement of an upcoming homebrew competition because of the recent flap about advertising on the net.

HBD has been (and r.c.b has the potential to be) a great resource for the dissemination of brewing news. My definition of "brewing news" includes (but is not limited to) information about clubs, tastings, competitions, and yes, even products.

Having said that, it seems that there are limits to what net.users consider to be "good taste". These limits appear to be biased toward the subdued end of the spectrum, and in my opinion, that's a good thing. (Id est, keep the hype and UPPERCASE and exclamation marks to a minimum!!!!!!!!!!!!)

Would anyone have a problem with a posting like this:

October 12 Calistoga CA  
8th Annual Calistoga Beer and Sausage Fest.  
This year features chili and creole rice dishes.  
707-942-6333

I wouldn't.

Would anyone have a problem with a posting like this:

My "Brew It At Home" videotape is finally finished. If you're interested, contact me at xxx@yyy.zzz for more information.  
Special deal: I'll sell it to HBD/r.c.b readers at cost.

I wouldn't.

And even if I did have a problem with it, I'd start the discussion via email. We don't need to intimidate people and discourage them from posting items that are valuable to the brewing community. If we do, there won't be any point to having these forums, because there won't be anyone left to post.

thx  
gak

From: MIKE LIGAS <LIGAS@SSCvax.CIS.McMaster.CA>  
Subject: S. delbrueckii growth rate

>> A question for HBD-land: Wyeast wheat-beer is (unfortunately) a mix of  
>> S. Delbrukii a basic beer yeast. Do you think repitching like this  
would  
>> select for eventual domination by one or the other strain?

>I don't know of a way to guarantee which would dominate (if one ever  
does).  
>However, if your goal is a pure culture of S. Delbrukii you can 'plate  
out'  
>the Wyeast culture. You will note that there are two different size  
>colonies. I \_believe\_ (someone who remembers help me out) the S.  
cerevisiae  
>is larger in size than the S. Delbukii. So, you then take a culturing  
>loop and grab up a bunch of these smaller colonies & grow them in ~5ml  
of  
>starter solution. Then you perform the whole process again (plating,  
etc)  
>until you don't seem to have any more S. cerevisiae. Of course it  
>may just be easier to find someone who have already done this. Drop me  
>a line in a week or two & I can tell you for sure if its the large or  
>small colonies you want.

The larger colonies would be S. delbrueckii. If you're interested I wrote  
a  
fairly extensive article on purifying S. delbrueckii from the Wyeast  
mixed  
culture. The article appeared in HD686, July 24, 1991, "Isolating S.  
delbrueckii". It is possible that the S. delbrueckii strain would  
eventually  
dominate the culture judging by its rapid growth rate on plates, although  
I've  
never done a growth rate determination of this strain in liquid culture.  
The  
yeast population of this strain appears to grow rapidly \*but\* ferments  
slowly  
ie. rate of attenuation. Doubling time and fermentation rates can vary  
quite  
drastically from strain to strain. A nice example of this can be found in  
the  
Zymurgy "Yeast and Beer" special issue, Vol.12, No.4, 1989, pp. 49-54.

Date: Thu, 17 Oct 1991 09:14 EDT  
From: MIKE LIGAS <LIGAS@SSCvax.CIS.McMaster.CA>  
Subject: My Favourite Recipe: Sweetport Porter

Sweetport Porter

Ingredients:

3.3 lbs. (1.5 kg) Munton & Fison dark malt extract syrup  
2.2 lbs. (1.0 kg) dark dried malt extract  
1.1 lbs. (500 g) light dried malt extract  
8.5 oz. (250 g) malto-dextrin powder  
1.1 lbs. (500 g) crystal malt (40 L)  
4.25 oz. (125 g) chocolate malt  
4.25 oz. (125 g) black patent malt  
1 cup light clover honey  
1 cup brown sugar  
1/3 cup blackstrap molasses  
1 oz. (28.5 g) Clusters hop pellets (45 minutes)  
1 oz. (28.5 g) Cascade hop pellets (45 minutes)  
1/2 oz. (14.25 g) Cascade hop pellets (5 minutes)  
1 tsp. gypsum  
1/4 tsp. Irish moss (15 minutes)  
3/4 cup dextrose (to prime)  
1/2 quart (500 ml) Irish ale yeast culture (WYeast #1084)

Procedure:

Crush grains and steep for 30 minutes in water at 158F (70C). Strain into boiling vessel and sparge with 158F (70C) water. Add malt extracts, dextrin, honey, brown sugar, molasses and gypsum and bring to a boil. Add boiling hops, Irish moss and finishing hops as indicated. (Total boil = 50 minutes) Cool to at least 68 F (20C) before pitching yeast. Prime with dextrose as usual.

Comments:

Although I tend towards all grain brewing it seems I always come back to this one as my Porter. The rich body and residual sweetness of this beer is something which I have found hard to replicate in an all grain recipe. This beer finished 2nd at the Canadian Amateur Brewers Association national competition in 1989 and a variation of this recipe finished 3rd in 1990 (if it ain't broke don't fix it). The yeast strain is critical as well as the molasses to get the most out of this beer. I can hear the anchor dropping.

Specifics:

O.G. = 1.066 (68 F) F.G. = 1.025 (68 F)  
Primary Ferment: 5 days Secondary Ferment: 3 weeks  
  
\* This recipe makes 6 US gallons (5 Imp. gallons) \*

Subject: Wyeast 1007

Hi. I wanted to alert HBD readers to a possible problem with packets of Wyeast 1007 (German Ale) code dated August 14, 1991. I recently bought some and 'popped' according to instructions. After two days, no puffing of the package was evident but I pitched to a starter anyway, hoping for the best. Since I was a little concerned, I took the package into work and looked at a sample under the microscope. I was surprised to see a huge number of bacteria in the culture. The package contents were also incredibly sour. I am quite confident this wasn't due to contamination on my part, since only one hour passed from opening the packet to looking under the microscope (the doubling time of bacteria is usually on the order of 20' and MANY doublings would have been necessary to produce the number of bacteria I saw). I also streaked the culture out on YEPD plates (rich media), and sure enough got singles of both yeast and bacteria. Needless to say, I didn't want to use the starter I had pitched, but I kept it and examined it after a couple of days. Very little fermentation activity was evident, but there were also few or no bacteria present in the culture. So, I figure, either there is a lag time for bacterial growth relative to yeast and they will show up in a few days, or the bacteria cant grow in my starter solution (which is made with hopped malt extract, providing one possible explanation). Anyway, this packet was clearly infected and my concern is that others of that code date might have the same problem. I know that Wyeast has an excellent rep, and this sort of thing is an anomaly, but be careful out there.

Subject: Cat's Meow/HBD FTP site

Boy, It's good to have the HBD back on-line again. I was going through  
withdrawals this past week. Here is a posting that was destined for  
reading  
over a week ago:

\*\*\*\*\*  
\*\*\*

For those of you who have tried to access the FTP server at 131.151.23.  
29, I  
am sorry for it being so slow during ascii file transfers. There is a  
bug  
in software and I don't have the time to run it down right now. If you  
set "type binary" prior to transfers, it will run about seven times  
faster.  
So as a work-around, please set "type binary" immediately after login.

I have also moved my Homebrew digests into the HBD sub-directory. This  
directory contains all of the homebrew digests (except for 153 and 718),  
in .ZIP format. Download the index to find out the contents of the .ZIP  
files.

Mark Stevens and I are compiling recipes for a new Volume of "The Cat's  
Meow". If you have any recipe corrections/submissions that are destined  
for "The Cat's Meow, Vol. 2", please put them in the UPLOADS sub-  
directory.  
Please put suggestions here as well. But please, no requests like "Send  
me a copy when ...". These will be ignored/deleted. We will announce to  
the Digest when the book is ready.

Subject: anybody want a carboy?

Hey now- I hope I'm not getting myself into trouble with this, but here's the deal: my roommate has a friend who works for a water company and has approximately 60 used glass carboys. I snagged 2 so far- they're a little beat up on the outside but the insides are okay. They are all 5 gallons. He MIGHT want to sell them for like 7 to 10 bucks each, plus shipping (from central NJ) depending on how much interest there is. If you are at all interested, please send me email and include the word carboy in the subject line. I'm not getting anything out of this, I'm just passing the word along, so if you feel the need to flame send it to /dev/null or to a more anal newsgroup ;-) ....

later!

From: pyle@intellistor.com (Norm Pyle)  
Subject: Wyeast info and SG measuring

1st:

Thanks to Dan Krus for providing the great info from Wyeast. It's real handy

to have put together like that.

2nd, Dan says:

>I plot Correction vs. Temperature and keep this plot in the back of my  
>brewing note book for quick and handy visual reference. This data does  
not

>yield a linear relationship thus a graph is quicker to work with than  
some

>polynomial equation.

Plotting this is a good idea for a quick reference. I just do a quick  
and

dirty interpolation (read guesstimate) for other temperatures. Do you  
really

think anyone does a calculation of some polynomial equation? Let's  
face

it, we're talking a change of .001 for several degrees F of temperature  
change. Does anyone care if their gravity (specific) is off by .001??? I  
think the gravity of the earth changes that much.

Cheers!

Norm

P.S. Anybody know an easy way to siphon my Christmas Ale off of a dozen  
or so

mashed up apricots without aerating the hell out of it?

From: lg562@koshland.pnl.gov  
Subject: apricots in beer

A while back I asked about using apricots in a beer recipe. Hearing of no direct experience with this fruit, I put on my experimentalist hat and here's what resulted.

1 lb German pilsner malt (steeped at 150 F for 1 hour)  
4.5 lb light dry malt extract  
1/4 tsp irish moss  
1/2 tsp salt  
1.0 oz Chinook hops (12.2% alpha) added at the 30 min mark  
0.5 oz Mt. Hood hops (5.3% alpha) added in the last 2 minutes  
2.5 lb frozen, pitted, halved apricots  
1 packet ale yeast  
3/4 cup corn sugar for bottling

Original gravity about 1.050, final gravity 1.015.

The apricots were added at the end of the boil. The wort was then sparged into the primary fermentor, say about 10 minutes after the apricots were added. The wort was cooled over night and the yeast was pitched in the morning. After a week, the beer was racked to the secondary. Here it rested for one month (either I'm busy or patient; I wish I could say the latter) before bottling.

How did it turn out? It was a fine light ale. Nice golden amber color with a good hop bite. About half way through a mug, I start noticing the taste of cloves. But I didn't notice any apricot taste. I think it would be worth trying it again only letting the apricots sit in the primary fermentor. At least that's what I'd try next.

I did notice a slight bacterial/wild yeast infection in the beer -- the small white stuff around the neck of the bottle. Since it didn't cause any harm to the beer or my health, I guess I've created a lambic. Hey, why would the air in my basement be any worse than the air in Belgium?

Date: Thu, 17 Oct 91 14:37 CDT  
From: jws3@engr.uark.edu (JW Smith)  
Subject: Another set of first-batch questions.

First post, and all that. I'm new to homebrewing, and in a fit of silliness, I decided to try the recipe for spruce beer which is in Papazian's book (the second one, not the fancy one). Yeah, dumb choice for a first try, but it's done.

here's the ingredients:

1 can Edme SFX dark malt extract  
1 3/4 lbs. Laaglander Dark dried M.E.  
2 oz. Hallertauer hops pellets  
-brought above to boil and held 30 min.  
1/6 oz. spruce extract (got it free from the supplies lady)  
-added during last 3 minutes of boil

Sparged above through a screen strainer into a carboy of bottled spring water (I paid for it, why waste it?) which I'd shook around a bit to aerate. Ended up with about 4" of space in the carboy. Pitched yeast at 79 F, 9/21. Got activity after about 10 hours; at 35 hours my blowoff hose plugged with hops bits, and foam hit the ceiling while about 2-3 quarts of beeroid went into my carpet. Any suggestions on how to avoid that particular problem? My apartment has stunk ever since.

Anyway, the kraeusen fell in on 9/24, and I put on the airlock. Since then, the bubbles have ranged randomly from 1 per 2 minutes to 1 per 10 minutes, with no dependence on anything that I can see. It's still cloudy, though a lot of white stuff (yeast, I guess) has settled out. I acquired a hydrometer on 10/3, and it tested 1019 at 80 F (the thing said "accurate at 70 F", but I cooled the stuff to 70 F and there was no difference). 10/5 it was 1018, 10/6 it was 1016. If anything, fermentation seems to be speeding up.

UPDATE (I originally sent this Oct 9): Bubbles are down to about 1 per 10 minutes and constant, but the beer is still very cloudy. SG is 1016.

Questions: How long am I gonna have to wait for this stuff? Will sitting much longer in the primary ruin the beer? I don't have another carboy. Has anyone tried this recipe and knows how it's supposed to come out? It's so weird tasting, I don't get any information out of tasting it.

The yeast was Cooper's, from Australia. Is it normally slow after the initial active fermentation?

Does anyone have any recipes for decent, economy ale? I'd like

to brew stuff that's substantially cheaper than storebought horsewater,  
being  
a poor student type. I'll get into the real stuff when I get a real job.  
:)

Any other suggestions for a novice brewer, especially concerning  
troubleshooting, when to bottle, and taste testing?

Reply via email, please, if these subjects are flogged to death on the  
digest.

thanks,

From: Jacob Galley <gal2@midway.uchicago.edu>  
Subject: Sir Kenelm Digby, Kt. -- Egg whites in the boil?  
Subject: Sir Kenelm Digby, Kt. -- Egg whites in mead?  
Message-Id: <CMM.0.90.2.687309459.gal2@ellis.uchicago.edu>

I have finally found a copy of The Closet of the Eminently Learned Sir Kenelme Digbie Kt. Opened: Whereby is Discovered Several Ways for Making of Metheglin, Sider, Cherry-Wine, &c. Together with Excellent Directions for Cookery, as also for Preserving, Conserving, Candyng, &c., Published by his Son's Consent. Originally printed in 1669, the copy on my lap is a reprint (London: Philip Lee Warner, 1910).

I am looking forward to trying one of the many mead recipes, but there are some peculiarities in Sir Digby's language that I'd like to straighten out first. I quote an example (without permission, of course) from page 32:

**STRONG MEAD**

Take one Measure of honey, and dissolve it in four of water, beating it long up and down with clean Woodden ladels. The next day boil it gently, scumming it all the while till no more scum riseth; and if you will clarifie the Liquor with a few beaten whites of Eggs, it will be the clearer. The rule of it's being boiled enough is, when it yieldeth no more scum, and beareth an Egge, so that the breadth of a groat is out of the water. Then pour it out of the Kettle into wooden vessels, and let it remain ther till it be almost cold. Then Tun it into a vessel, where Sack hath been.

This recipe raises a few questions:

Has anyone out there ever heard of putting egg whites in the boil? I don't see how that could have any positive effect, though I'm no expert on eggs or on mead. (In another recipe, Sir Digby requires that the egg be "freshly laid.")

What on earth does the phrase "beareth an Egge" mean? Most of his mead and metheglin recipes bear eggs near the end of the boil. Is this an especially mucky portion of the scum? Is it the remains of the egg whites?

What does the thickness of the "Egge" have to do with anything, if you've been scumming off the top all the while? (My Webster's says that a groat is an old coin worth four pennies.)

I hope somebody reading this can help me out!

Here is the address to complain to:

From: Jeff Frane <70670.2067@compuserve.com>  
Subject: Welcome Back!

Glad to know that everything has gotten straightened out with the Homebrew Digest. #742 was a welcome visitor in my mailbox this morning.

In 741, Martin Lodahl: I've been planning a Belgian abbey-style double or triple. Wuffo you put in that brown sugar? I know Jackson has mentioned that some of these beers have "candy sugar" added in the kettle. I'm not clear what the British or Belgians consider candy sugar; could be something like rock sugar. Anyway, local beer importer Jim Kennedy visited the brewery at Chimay and is certain there was NO sugar added. Hmm. WYeast, by the way, will be offering a abbey-style yeast within the next month or so. You might have better results and avoid the banana-esters; it's possible the bottle yeast wasn't all that clean. ??

To Ifor Williams: I've been told that some British breweries \* deliberately\* oxidize the wort in the kettle in order to darken it; this in lieu of adding more caramel malt. Since you seem to be in the right place to ask, why not knock up a few quality brewers and ask them. You might also ask them how we get torrified barley or wheat. Hmmm? I'm not at all sure what Miller has in mind; aerating the wort on its way to the fermenter should be a Plus, since the yeast need the oxygen. Maybe it depends on whether you're trying to brewing Budweiser or not. Sometimes I think Miller's too close to A-B.

To Darryl: We'll have to wrassle about recommending Dave Miller's book. I think it's absolutely the wrong book for a beginning brewer; only an experienced brewer is likely to notice all the places Miller's wrong. And his decision to offer an American light lager as the first beer for a new brewer is simply absurd. Not to mention the illustration on how to start a siphon! Aaaagh! Get your mouth off that, Dave!

John Reed: Look around for Fred Eckhardt's book on beerstyles. Malt liquors are generally standard American commercial beers with a lot of extra fermentables, usually in the form of corn syrup added to the boil. Hopping rates are generally below threshold. They're technically lagers, although they're not lagered for

any appreciable length of time. Our local club once held a blind tasting of malt liquors, including Schlitz Red and Blue Bulls, Old English 500 (?00). (Actually, Fred Eckhardt held the tasting; the club members who unwitting victims.) The only beer deemed potable was a ringer: Kaliber, a non-alcoholic brew from Guinness.

To Bob Konigsberg: It's probably a bad idea to boil the oak; it's not even clear to me why they're in there. You'll have better luck reaching that nutty taste by adding a small amount of home-toasted malt. Try 4-8 ounces of pale malt that's been toasted in the oven at 300^ for about 1/2 to 1 hour. Spread it on a cookie sheet and periodically give it a stir. Then crack it and put it in a cheesecloth bag along with your crystal malt. Make an infusion in 150^ water for 45 min.-1 hour and use this liquid in your wort. I would also suggest cutting WAY back on the black malt, particularly if you're using American rather than British. Better yet, leave it out and substitute 2-3 oz. of chocolate malt.

From: KCDESCH@ucs.indiana.edu  
Subject: Sanitizing plastic

Recently I have been using a seven gallon plastic fermenter for the primary fermentation stage. I use a seven gallon bucket so that my net yield to the secondary glass carb is 5.0 gallons. Thus the carboy is basically full and the exposure to oxygen is kept low. I use plastic instead of glass because 6.0 gal.carboys tend to be too expensive.

Anyway, the plastic fermenter was quite aromatic after its first use. I sanitized it with a bleach solution but the smell didn't go away. I continue touse the plastic but it bothers me that I can't get rid of the smell. So:

Does anyone know a good way to sanitize plastic fermenters?  
Is bleach a bad idea?  
Do I need to worry in the first place?

I sure would appreciate anyone's view on the subject.

Subject: oxidizing wort

Oh, what a relief- the HBD is back!! (Now I know what my smoker friends must go through! ;-)

Sometime last week, before we were interrupted, Ifor Williams <ifor@computer-science.manchester.ac.uk> posed a question that caught my interest:

>This leads to my question - if the wort oxidises so easily, does it >not oxidise during a long open boil? If not, why not? If so, is the >oxidation not much more significant that can be expected during the >other brewing stages?

>What am I missing?

Hmmm... Yeah, what? Certainly, hot wort is exposed to oxygen during a long, open boil. We're told that these are all the criteria (hot wort + O2) that cause oxidation, with all its consequences. (Can't remember what they are, but I remember being told to avoid it.) So what gives? Is this another (God help us) "momily"?

Chuck  
(I have nothing original to contribute, but I didn't want the subject to be dropped.)

Subject: Unofficial overview of The New CJofHB

Hi everybody,

This is a reposting of my earlier submission that I think got lost.

Today I received The New CJofHB and thought I'd give a relatively comprehensive summary of additions/deletions/modifications relative the the 1st version. This might help you to make a decision as to whether to buy the book or not.

- 
- Old: No index New: index
  - Old: 331 pages w/o index New: 393 pages w/o index.
  - Old: \$8.95 New: 9.95
  - Old: cheap paper New: same cheap paper

- 
- smaller margins (more words/page)
  - BEER, HISTORY, AMERICA AND HOMEBREW
    - A long, long time ago
  - gramatical changes
  - ESPECIALLY FOR THE BEGINNER
    - Getting Your Homebrewery Together
  - Equipment
    - stype changes
  - Ingredients
    - stype changes
    - addition of information of using malt to prime
  - BETTERBREW - INTERMEDIATE BREWING
    - Color
  - whole section added. discusses Lovibond and SRM w/ color guideline chart.
    - Compendium of Ingredients
  - Specialty Malts
    - Vienna is now included w/ Dextrine and Munich w/ a short description.
    - Hops
  - added section on, "How Bitter is Bitter?" containing a section detailing the crude calculation of a HBU.
  - added section on hop oil.
  - hop varieties reference chart greatly expanded w/ many new hop varieties added.
  - Yeast
    - section on "Where Can Good Brewing Yeasts be Found and How Are They Packaged" is rewritten.
  - Miscellaneous Ingredients Often Used By Homebrewers
  - section on vegetables added.
  - section on coffee added.
  - Some World Classic Styles of Beer
  - References to "English Ale" are reworded to reference "British Ale"
  - whole section has been vastly rewritten now including more data w/ added section on Scottish Ale

- Other Top-Fermented Styles of Beer
- section vastly rewritten with more data included. a greater number of styles described.
- German and Continental Lagers
- section vastly rewritten with more data included. a greater number of styles described.
- American Lagers
- section vastly rewritten with more data included. a greater number of styles described.
- added: "Beer Styles Table" which shows data relative to a great variety of beers.
- "Guidelines For Brewing 5 Gallons of Traditional Beers" table greatly expanded.
- Worts Illustrated
- Homebrew Recipes
  - section on notes, Substitutions and Adjuncts expanded.
  - "Gardylloo Bitter" recipe deleted (pg 154, old).
  - "Palace Bitter" recipe added.
  - "The Sun Has Left Us On Time" Stream Beer recipe has been reworked and rewritten.
  - "November's Lady Light Lager" recipe deleted (pg 160, old).
  - "Quiddity Dutch Lager" recipe deleted (pg 162, old)
  - "Oktoberbest Golden Malt Lager" recipe deleted (pg 165, old).
  - "Whoop Moffitt Vienna Lager" recipe added.
  - "Crabalocker German Pils" recipe added.
  - "Lovebite Weizenbier" recipe added.
  - "Osmisis Amoebas German Alt" recipe added.
  - "Tumultuous Porter" re-renamed back to "Goat Scrotum Ale"
  - "Borborygmous Bock" recipe reworked and renamed to "Doctor Bock"
  - "Danger Knows No Favorites Bock" recipe reworked and renamed to "Danger Knows No Favorites Dunkel"
  - "Limp Richard's Schwarzbier" recipe added.
  - "Armenian Imperial Stout" recipe added.
  - "New Moon Black Smoke Ale" recipe added.
  - "Cherries in the Snow" recipe reworked and rewritten.
  - "Who's in the Garden Grand Cru" recipe added.
  - "Daisy Mae Holiday Lager" recipe reworked and rewritten as "Daisy Mae Dortmund Lager".
  - "What the Helles Munchner" recipe added.
  - "Uckleduckfay Oatmeal Stout" recipe added.
  - ^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^ = [Great Title!]
  - "Limnian Wheat Dopplebock" recipe added.
  - "Colonel Coffin Barley Wine Ale" recipe added.
- ADVANCED HOMEBREWING FOR THE PRACTICAL HOMEBREWER
- Adjuncts Commonly Used and Available To Homebrewers
- section on "Quinoa, Tef, Buckwheat, Dinkel, Amaranth" added.
- Advanced Homebrewing and Hops
- highly welcomed section on calculating IBUs w/ table of "Hop Utilization Chart Based on Density of Boiled Wort and Boiling Time" added.
- All-Grain Recipes
- "Amaizeing Ale" renamed to "Amaizeing Pale Ale"
- "Hesitation Red Pilsener" renamed to "Hesitation Red Maerzen"
- "Propentious Stout" reworked and renamed to "Propentious Irish Stout"
- "Dream Lager" reworked and renamed to "Dream Export Lager"
- "Spider's Tongue German Weiss-Rauchbier" recipe added.
- APPENDIX 1 - Glossary
  - some words added
- APPENDIX 2 - Kegging
  - short section on Quick Draft Beer added
- APPENDIX 5 - Making Honey Mead
  - section greatly expanded which includes much more information.

- "Antipodal Mead" recipe added.
- "Chief Niwot's Mead" recipe added.
- APPENDIX 6 - "Sour Mash/Extract Beers and Belgian Lambic" added, 7 pages.

Includes recipes: "Vicarious Gueuze Lambic" and "Loysenian Cherry Kriek"

- APPENDIX 8 - Troubleshooting
  - section on Bacterial Infections, Solving the Problem written.
  - new picture of Charlie listening to his beer.
- APPENDIX 13 - Conversions and Measurements
  - mildly expanded.
- APPENDIX 14 - Bibliography of Resources
  - greatly expanded.

>While making up a batch of India Pale Ale last night, I  
>discovered that the summer humidity had turned my DME into  
>something better suited to building a house out of rather than  
>brewing beer from. After several hours with a hammer and lots  
>of hot water, I finally managed to get it all dissolved.

I apologise for the late addition to this thread, but I've been behind in my HBD's. During a home renovation, my DME ended up rock hard and musty smelling from being stored in the basement. A few hammer blows shattered it nicely, so I placed the resulting chunks into my wort pot, added warm water and covered it. Twenty-four hours later I was happy to find the chunks had almost entirely dissolved, with the remaining pieces disappearing in the boil. There was no musty odor or taste in the resulting beer. While I wouldn't recommend this as standard brewing procedure, I wouldn't toss less-than-ideal DME either. Interestingly, the second batch I did this with sat in the pot for two days before use, and showed signs of fermenting on it's own before I turned it into wort and boiled.

From: Mike Zulauf <zulauf@orbit.Colorado.EDU>  
Subject: another Christmas recipe

Welcome Back HBD!

Since everyone was posting their favorite recipes before the break, I thought I might contribute one of mine. This is also in keeping with the recent requests for holiday brews. Unfortunately, it is probably too late to brew this one if you want to have it in peak form for Christmas.

#### Zulu's X-mas Lager

3.3 lb. can Munton & Fison Light Hopped Malt Syrup  
2 3/4 lb. (approx) light dry malt extract  
2 1/2 lb. light clover honey  
1 lb. crystal malt  
2 tsp. gypsum  
2 oz. Cascade hops (4.5% alpha) - 60 min  
1 oz. Cascade hops - 8 min  
1/2 oz. Cascade hops - 5 min  
1/2 oz. Cascade hops - 2 min  
2 tsp. dried ground ginger - 10 min  
2 tsp. dried ground nutmeg - 10 min  
3 tsp. dried ground cinnamon - 10 min  
grated orange peel from 4 oranges - 10 min  
1/4 tsp. Irish Moss- 10 min

3/4 cup corn sugar for priming

M. eV. German Lager liquid culture in a 1 qt. starter  
Original Gravity : 1.071  
Final Gravity : 1.018

Primary Fermentation: 50 degrees F.  
approx 12 days

Secondary Fermentation: 40 degrees F.  
approx 30 days

Lagering: 30 degrees F.  
approx 30 days

This recipe makes a golden, rather than dark, Christmas beer. With the proportions of hops and spices used, you get a complex mix of aromas, with none of them being too dominant. Other than being a lager and using various temperatures, this is a very easy brew to make. If anyone else tries it out, I'd be curious to hear the results.

Good Luck!  
- Mike

Subject: first aid tip, repitching note, recipe

I finally had my first brewing related injury, and thought I'd share the experience. I was removing my boiling priming syrup from the stove, sloshed some onto the back of my hand, dropped the whole pot and spilled more on my stomach. It's the first time I've been scalded.

Some notes on scalding -- this method of burning yourself can cover \* lots\* of surface area very quickly. Most kitchen burns are small, from things like accidentally touching a pot. You just burn your fingertips or hand. Scalds can get big. I only spilled about a pint of liquid, and I burned about a 3" x 6" area on the back of my hand, and a 5" x 7" area on my stomach. At that, I was lucky, since most of the hot liquid landed on the floor, not on me. I don't even want to imagine what I could have done with 3 gallons of boiling wort.

First aid notes: If you spill on your clothing, get the clothing out of contact with your skin as quickly as possible. Second, apply ice, as much and as fast as possible. I had ice packs on both burns within seconds of the injury. As a result, neither burn blistered. It's been five days now, and both areas are deep, dark red, but neither blistered. I kept the ice packs on for over 12 hours, straight.

For some time I've been repitching the yeast slurry from my secondary fermentor for new batches. I generally got fair results, with active fermentation in about 24 hours. This most recent batch, the beer was only in the secondary for two weeks when I bottled the beer and repitched the slurry. Usually, due to laziness I leave the beer in the secondary for 4-6 weeks. The freshness of the slurry makes a big difference. This time I had 3" of krauesen in 6 hours! So, you repitchers, sooner is better.

Finally a recipe that came out great:

7 lbs. amber liquid extract (Alexanders, I think)  
2 lbs. crystal malt, cracked  
1 lb. chocolate malt cracked  
2 oz. Hallertauer hops  
2 oz. Saaz hops  
4 oz. fresh ginger, grated  
2 TBSP. ground cinnamon  
Wyeast American Ale (Sierra Nevada ?) yeast, 1 pint starter

Steep crystal and chocolate malt in hot, but not boiling, water for about 1/2 hour. Strain out grains, sparge with hot water. Add extract, stir until dissolved. Bring to a boil and add all the Hallertauer hops, the ginger and the cinnamon. Boil 1 hour. Chill the wort, transfer to primary, and add Saaz hops. Pitch the yeast. When the fermentation slows, transfer to secondary fermentor. Prime with 3/4 cup corn sugar and bottle when fermentation appears complete.

Notes: Really nice balance of flavors. The dry-hopped Saaz blended with the ginger and cinnamon aroma really well, and the ginger flavor is perfect. The cinnamon didn't contribute much flavor, and seems to have led to a muddier beer than I usually get. Probably would have been better to use stick cinnamon instead of ground... The color is much lighter than I would have expected.

Subject: Bass India Pale Ale

Hey guys, any ideas?:

I have been trying to fashion a recipe to give a brew similar to Bass Ale. I am a malt extract/specialty grain brewer and do no real mashing. So far I have come up with brews that are more like Dock Street Amber or New Amsterdam Ale (both more malty than Bass). Fred Eckhardt has two descriptions of Bass India Pale Ale in his book "Essentials of Beer Style", an 1896 version and a more recent version (1975, I think). He says that Bullion, Fuggles, and Goldings are mandated and that the Brits are not above using adjuncts in their beer. Members of my homebrew club (Outlaws of Homebrew, Staten I., NY) have suggested that I use half malt extract and half brown sugar in the wort to achieve that Bass look and feel. I haven't used any adjuncts in my beer so far and don't have a feel for how they would work out. Any ideas? Recipes?

From: Mike Sharp <msharp@cs.ulowell.edu>  
Subject: Digby, Mead, the new CJoHB, Sour Mash lambics, s. delbruckii

Drew Lawson asks:

> How long does it take for mead to clarify? Most of what I  
and then he wonders:  
> I just want to know whether I was too impatient or just have a cloudy  
batch.

Yup, you were too impatient. It can take more than a few months for a  
mead  
to clear. How long exactly? Well, it all depends on the mead so there  
isn't a norm. When making mead its best to just forget about it after  
you  
rack it into the secondary. In a few months time (like 3 or 4) go dig it  
out of the back of the closet and see what its doing. If its not clear  
then  
forget about it for a while longer.

Mike Ligas says:

> The larger colonies would be S. delbrueckii. If you're interested I  
wrote a  
> fairly extensive article on purifying S. delbrueckii from the Wyeast  
mixed  
> culture. The article appeared in HD686, July 24, 1991, "Isolating S.  
> delbrueckii".  
Thanks Mike, you've saved me time analyzing the two yeasts. I've already  
isolated the two strains, I was just about to try and figure out which  
was which.

Jacob Galley asks:

> I have finally found a copy of The Closet of the Eminently Learned  
> Sir Kenelme Digbie Kt. Opened: [whot a long title!]  
This is a \*wonderfull\* resource for mead/metheglin/mellomel recepies.  
Its more than a few orders of magnititude better than anything currently  
in print on mead making. Of course you do need to figure out what  
Digby is talking about first...

> Has anyone out there ever heard of putting egg whites in the boil? I  
> don't see how that could have any positive effect, though I'm no  
> expert on eggs or on mead.  
hmm, I remember reading something about this. I could be completely  
wrong, but I believe the egg white had something to do with helping to  
clarify the mead.

> What on earth does the phrase "beareth an Egge" mean?  
What Digby is doing is using an egg to measure the sugar (honey) content  
of you wort. Then you have enough honey (I use 10lb/5gal) an egg will  
float on the top of your wort.

When he refers to 'summing off the top', he means you want to remove  
the majority of the wax that will form a scum on top of your wort.

> Jacob Galley, merely an undergraduate in The College  
and probably a new SCA member? It seems that only SCA members have kept  
Digby's works alive -- via the xerox printing house.

and, from a summary of the new CJoHB:

> - APPENDIX 6 - "Sour Mash/Extract Beers and Belgian Lambic" added, 7  
pages.

> Includes recipes: "Vicarious Gueuze Lambic" and "Loysenian Cherry Kriek"  
hmm, I guess I can pack up my lambic mailing list now. The brewing gods have spoken & it only takes 7 pages to cover making lambics. I can just hear J-X Guinard going into his 'abuse of the term lambic' speach right now.

Anyway, I just wanted to point out something here. Sour Mashing does not by any stretch of the imagination yield a lambic. Yah, you get an acidic beer, but its a differnt kind of acidity (the taste is significantly different) further, you still don't have the yeasts that add the distinctive flavors of a lambic. These yeast, BTW, are not even related to *S. cerevisiae* and you won't be seeing them in a Wyeast package. Finally, since I don't want to appear to be bashing too heavily on Charlie, I will be going out and getting one of these now CJoHB. I may even make one of these sour mashed pseudo lambics myself so I can demonstrate my point about sour mashing v.s. bacterial infection (the 'real' technique is to contaminate your beer with *P. cerevisiae* on purpose).

and on scalding yourself: for those of you with BruHeats, watch out for the little spiggot. I had the unpleasant experience of watching it drop out of the bucket ~2min. from the end of my boil (at about 1:00AM too!) I have no idea why it did this. All I can think of is that I hit the nut with my spoon, but even that doesn't make sense. Oh well, I'll be moving up a homemade stainless setup soon.

Date: Fri, 18 Oct 91 7:59:59 EDT  
From: cbema!wbt@att.att.com  
Subject: Chrishmash (hic!) Ale

Two weeks ago my brewing partners and I tried to make Phil Fleming's Christmas Ale from the recipe posted here. I got a lot of requests for the recipe, so I'll reproduce it here:

Ingredients for 5 gallons

3 1/2 pounds Munton and Fison Stout Kit  
3 1/2 pounds Munton and Fison amber dry malt extract  
3pounds Munton and Fison amber dry malt extract ] ?? Typo ??  
1/2 ounce Hallertauer hops (60 minutes)  
1/2 ounce Hallertauer hops (5 minutes)  
3/4 pound honey  
53-inch cinnamon sticks  
2teaspoons allspice  
1teaspoon cloves  
6ounces ginger root  
6rinds from medium size oranges (scrape the white insides of the rind away)  
Wyeast No. 1007 German ale liquid yeast  
7ounces corn sugar for priming

\*O.G.: 1.069  
\*T.G.: 1.030  
\*Primary fermentation: 14 days @ 61 degrees F.  
\*Age when judged: six months

#### BREWER'S SPECIFICS

Simmer spices and honey (45 minutes). Boil malt and hops (50 minutes). Add finishing hops and boil (5 minutes). Cool, strain and pitch yeast. [Note: It's not made clear, but the honey/spice mix is added to the wort just before cooling, they're not boiled together.]

- - - -

Many will recall the debate over whether that second addition (3 pounds) of DME is actually needed or is a typo. When we brewed two weeks ago, we assumed the latter and left it out; this produced an O.G. of 1.049. Someone else wrote to the digest at that time that they'd just brewed this recipe and had got an O.G. of 1.050.

On the weak justification that "it's not fair to judge the recipe without making it right," (but in fact because we just wanted more beer) we decided to try again with the extra 3 lbs. Actually, we only used 6 lbs total of the amber DME because I was too lazy to open a third (3-lb) bag of extract for that last half pound. Inexplicably, though, we arrived at an O.G. of 1.088 (estimated; our hydrometer scale stops at 1.080).

Sense any not make this me to does. In our first brew we had 3.3 + 3.5 + .75 lbs or about 7.5 pounds of fermentables; OG 1.049 means we were getting about 6.5 s.g. points per pound. It doesn't make sense that adding an additional 2.5 lbs would add nearly 40 more s.g. points.

My belief is that there was something wrong with our gravity measurement. We certainly rechecked it many times, and we took the reading after the cooled wort was racked into a carboy and agitated (so it should be well mixed, and if not, the denser liquid should have sunk to the bottom of the carboy; our gravity sample came from the top). There were certainly a lot of unsedimented particles in the wort, but I can't rationalize how they could increase the gravity that much (and they were present when we brewed our first batch to o.g. 1.049, as well).

At this point, I'm accusing my brewing partner of having dense water. 8- )  
I stand by my earlier recommendation that the second, 3-lb entry is needed.

And if nothing else, at least we can offer our Christmas brew in both Regular and High-Test!

>criteria (hot wort + O<sub>2</sub>) that cause oxidation, with all its  
>consequences. (Can't remember what they are, but I remember  
>being told to avoid it.) So what gives?

OK, to further muddy the waters, we know that boiling water  
"drives out" all the dissolved O<sub>2</sub>, so we need to be increasingly  
vigilant about aerating when using pre-boiled water.

So, does a long, open boil continually add and then "drive out"  
O<sub>2</sub>? Or does something else happen instead?

What about the "caramelization" that happens to boiled wort? Is  
that all due to heat or at least partially due to the presence of  
O<sub>2</sub>?

From: Marc Rouleau <mer6g@fuggles.acc.Virginia.EDU>  
Subject: Re: Father Barleywine's yeast reuse trick -- first attempt

I've been using the same yeast (Wyeast German Ale) from one original packet for the past fourteen batches. At first I would just save some slurry in a bottle and use it to pitch the next batch. Starting last spring when Father Barleywine posted his articles about pitching directly onto the yeast cake and not worrying so much about sanitation, I have pitched repeatedly (8 times) by dumping new wort onto the yeast cake in the same 7 gallon carboy.

I siphon the beer off the cake and bottle it. I leave the carboy and the yeast cake in the fermentation fridge at 55 degrees. The next time I brew, I just drain the clear cool filtered wort directly into the carboy.

I use a half-teaspoon of Irish moss in the last 15 minutes of the boil to encourage a good break, and I filter the cool wort through a fine-mesh nylon straining bag to eliminate trub. The yeast cake has gotten kinda big (about 2 inches deep), but there's still enough headroom for a fairly vigorous fermentation.

Last spring I also stopped using bleach. I don't sanitize anything. Ordinary kitchen cleanliness standards (get the big chunks off!) have been sufficient for me. I don't keep my beer around for more than a few months though -- I don't know if it would keep for a year or more.

I've been assuming that the lowest temperature at which a yeast strain can operate is the best one to use. Most beer-spoiling bacteria and wild yeast aren't happy at 55 degrees, right? I wonder how Wyeast defines "optimum". Perhaps it's the highest temperature at which yeast can operate without producing undesirable byproducts?

Should I ferment at 62 or 55?

From: Timothy Mavor <tmavor@pandora.cms.udel.edu>  
Subject: Recipes

My jitteriness has now subsided, thanks to HBD being back on line!

Concerning recipes that are posted here.....

I certainly encourage people to post recipes, as I am always willing to experiment with a different style or the addition of certain spices and whatnot, but I noticed that many do not include what size the batch is making. Is it 5 gallons, or 6, or 10? This may seem unimportant to some, since they may realize by inspection of the recipe and the amount of malt, etc. and the SG that it is X gallons. But us beginners (only 11 batches made to date) need most everything explained out in black and white, and a noting of the batch size would certainly help me out. I don't want this to sound like a flame, it's just that when I'm making homebrew, I don't want to worry! ;^)

From: "Spencer W. Thomas" <Spencer.W.Thomas@med.umich.edu>  
Subject: Raspberry mead

I had the most wonderful raspberry mead last night at the Ann Arbor Brewer's Guild meeting. It reminded me of those wonderful eau-de-vies you can get in France, but without the high alcohol bite. The raspberry flavor was ethereal and fresh. I asked the brewer how he did it. This, roughly, is his recipe (I apologize in advance for any errors and omissions):

As the raspberries become ripe, pick them and freeze them on trays (he implied he picked them several times a day to get peak ripeness). Once frozen, they can be scraped off the trays into a large plastic container (and kept frozen). Once you have enough raspberries (10lbs in this case), dump them into your fermenter and sanitize with sulfite for 24 hrs. (I assume this means that you add the sulfite, cover and let sit for 24 hours. Not having used sulfite as a sanitizing agent, I'm not sure.)

Boil up the honey and water (I think he used 17 lbs in that batch, for 5 gallons of mead), cool, pour over the raspberries, and pitch (not sure of the yeast). Age at least 6 months. He started this batch in June, and it was (quite) drinkable last night. It should continue to get better at least until Christmas.

Next berry season, I may have to try this.

From: "Spencer W. Thomas" <Spencer.W.Thomas@med.umich.edu>  
Subject: old terminology

Here's my guess:

Egg whites are used as a clarifying medium. They help precipitate proteins that will cause cloudiness.

A groat is a grain (usually of oats).

I believe that "beareth an Egg" means that you should put a whole egg into the wort (is it still wort if it's mead?) and see if it floats. At least the thickness of a groat (oat grain) should be sticking out above the surface (about 1/16 inch?). This would correspond to a particular specific gravity. The density (specific gravity) of an egg changes as it ages, thus the requirement for a freshly laid egg.

You may already know this, and it doesn't help, anyway, but "Sack" typically means sherry.

-----

Date: Fri, 18 Oct 1991 10:23 EDT  
From: Dave Rose <CHOLM@HUBIO2.HARVARD.EDU>  
Subject: Egges and such...

Recently, in regard to an old (mead?) recipe, someone queried:

>Has anyone out there ever heard of putting egg whites in the boil? I  
>don't see how that could have any positive effect, though I'm no  
>expert on eggs or on mead. (In another recipe, Sir Digby requires that  
>the egg be "freshly laid.")

>

>What on earth does the phrase "beareth an Egge" mean? Most of his mead  
>and metheglin recipes bear eggs near the end of the boil. Is this an  
>especially mucky portion of the scum? Is it the remains of the egg  
whites?

>What does the thickness of the "Egge" have to do with anything, if  
>you've been scumming off the top all the while? (My Webster's says  
>that a groat is an old coin worth four pennies.)

I don't know the answers for sure but I'm willing to take a couple  
of guesses:

I think I have read of egg whites, or purified albumin which is  
pretty much the same thing, being used as a clarifying agent by some  
commercial breweries. Basically, albumins are pretty big pretty inert  
proteins that coagulate when you boil them. That's why boiled eggs turn  
white, the protein has coagulated and come out of solution. When you  
boil

your wort, proteins in the wort will denature, but will not necessarily  
coagulate (clump together), since they are present in pretty low  
concentration, and are therefore not very likely to glom onto one  
another.

By throwing in a lot of albumin you increase the amount of protein, and  
when

the albumin coagulates all the wort proteins coagulate along with it.

The (relatively) big blobs of coagulated protein will settle out,  
clearing the wort. Eggs also contain some proteases which break down  
albumin

over time into smaller polypeptides. That's why the white of a fresh egg  
will be very viscous, but an older one will be more watery. Since larger  
proteins coagulate better, you want your albumins as in tact as possible.

I

think that explains Sir Digby's preference for fresh laid eggs.

As for "Beareth an Egge" I would bet that an egge is an egg (not  
too consistent in their spelling, these colonial types), and that it  
means

that the S.G. of the wort is high enough that an egg will be "borne", i.  
e.

will float. I don't know the density of an egg, but it is greater than  
water (I seem to remember from the few times I have boiled eggs that they  
sat on the bottom of the pan), and as you boil the solution will become  
more dense due to the evaporation of water, and at some point an egg  
added

to the boil will float. In short, behold the egg: the first hydrometer!

From: Fritz Keinert <keinert@iastate.edu>  
Subject: Re: Eggs in Mead

In HD 743, Jacob Galley asks about some weird instructions in an old recipe for mead:

> ...  
> ... The rule of it's being boiled enough is, when it yieldeth  
> no more scum, and beareth an Egge, so that the breadth of a groat is  
> out of the water.  
> ...  
> What on earth does the phrase "beareth an Egge" mean? Most of his mead  
> and metheglin recipes bear eggs near the end of the boil.

This is just a wild guess, but it sounds to me like he is using an egg as a primitive hydrometer, to measure starting gravity. If the egg sticks out a certain distance (whatever a "groat" is), the gravity is right.

From: eisen@kopf.HQ.Ileaf.COM (Carl West)  
Subject: beareth an egge..., oxidising boiling wort

Digby is using the egg as a hydrometer,

The rule of it's being boiled enough is, when it yieldeth no more scum, and beareth (holds up, floats) an (whole) Egge, so that the breadth of a goath (an area the size of a goath) is out of the water.

if the liquor were not boiled enough the egge would float lower and expose less area above the water.

The trick now is finding out how big a goath was in 1669. And finding a fresh-laid egge. Or finding someone who has already done these things \*and\* taken a hydrometer reading.

It seems to me that though the wort is open to the air and it is hot, you'll find that the atmosphere just at the surface of the wort is relatively low in O2 and relatively high in H2O (probaply a minor consideration). More importantly note also that the surface-area:volume ratio is low, especially compared to when you pour the stuff. For example, consider a pot filled with burning gasoline, the size of the flame is largely dependent on the amount of gasoline exposed to the air, now consider pouring the burning gasoline into another container (DON'T \*DO\* IT!), the flames will reach far above your unfortunate hand because you have increased the surface area \*tremendously\*. Yes, you are getting some oxidation of your wort during the boil, but not much. Perhaps we should be maintaining a blanket of inert gas on top of our kettles :-)

Carl West

When I stop learning, bury me.

From: BREIN@dsfvax.jpl.nasa.gov  
Subject: Bearing eggs...

Jacob Galley writes:

>What on earth does the phrase "beareth an Egge" mean? Most of his mead  
>and metheglin recipes bear eggs near the end of the boil. Is this an  
>especially mucky portion of the scum? Is it the remains of the egg  
whites?

>What does the thickness of the "Egge" have to do with anything, if  
>you've been scumming off the top all the while? (My Webster's says  
>that a groat is an old coin worth four pennies.)

>I hope somebody reading this can help me out!

Dear Jacob:

In my opinion 'beareth an Egge, so that the breadth of a groat is  
out of the water' means will a \*whole\* egg float in the liquor so that it  
protrudes to the diameter of a groat coin. Your knight was not making  
himself  
clear.

As hydrometers were not available to Sir Kenelme Digbie a floating egg  
would  
have provided an approximate reading. Are there any numismatic  
hydrologists who  
would care to convert to a hydrometer reading a floating egg protruding  
to the  
diameter of a groat coin?

As for the egg being freshly laid, this was probably to avoid using a  
rotten  
egg.

Subject: Advertising & HBD

>I was disturbed to hear from a fellow HBD/r.c.b subscriber yesterday  
>that he was reluctant to post an announcement of an upcoming homebrew  
>competition because of the recent flap about advertising on the net.

No one should ever be reluctant to make an announcement of a Homebrew competition here on the HBD. Part of the HBDS purpose has always been to provide a forum for such an announcement. I would not call passing along info & details of competitions an "advertisement", but an "announcement" as the nature of the information is pretty different.

When it comes to club events, tastings, announcements and events I think things are pretty clear. The grey area approaches when it comes to products. Sure it is nice to know about products, but I don't think anyone wants the HBD to become the e-mail equivalent of the home shopping channel. While concise announcements of the availability of new products with pointers on where to get more info (e-mail, snail mail or phone) for those interested are perhaps acceptable, full fledged ads such as that we have recently seen here definitely step beyond the implicit boundaries of good taste we have seen here in the past.

I would propose that any future announcements of commercial products be limited to a brief (1 or 2 line) description of the product and inclusion of a followup address for more info.

I would suggest that for competitions, tastings, club meetings and other events such information as necessary to inform the HBD members of the event be provided within the boundaries of conciseness and good taste.

Well there my \$0.02

- Jay (I've posted many a competition & event announcement here with no problem in the past) Hersh

From: dcb@sunsrvr2.cci.com (Douglas Brainard)  
Subject: Eggs and Mead

Jacob Galley asks two questions about the use of eggs in making mead.

The practice of adding egg whites to a mead was apparently an attempt to clarify the mead. I'll admit that I have not tried this particular variation yet, and can't say if the eggs work in the same manner as would more modern additives.

As to the matter of bearing an egg, think of it as a primitive hydrometer - which is exactly what it is. At the proper specific gravity, the egg should float in the mead, with a part of the egg exposed - about equal in width to a groat coin. I have never seen a reference to an egg used this way for a beer or ale - I suspect that the gravity is not sufficiently high enough to bear an egg at all. I'm planning to do an article on eggs in brewing for a newsletter I put out (next issue in January). I'll post the article here as well.

Subject: RE: New Brewer suggested reading (J.\_ Time:8:24 AMDate:10/18/  
91  
JF> To Darryl: We'll have to wrassle about recommending  
JF> Dave Miller's book. I think it's absolutely the wrong  
JF> book for a beginning brewer...

I read Miller, then Papazian prior to my first batch (Miller had just  
been  
released, and I found it in a "regular" bookstore before I found a local  
brew  
shop and Papazian). While not very encouraging to the fledgling extract  
brewer, I think Miller gave me a much better sense of the role of  
sanitation

and the actual brewing process (starch conversion, fermentation,  
"breaks", etc)  
that has stuck with me. He comes to his subject with a very serious  
attitude.

I must say that I was a bit relieved when I found Charlie and his "Relax"  
attitude. He is far more "readable" and certainly makes homebrewing  
sound more

attractive to the novice. However, I think some folks come away from his  
book

a bit too relaxed. Brewing good consistent beer is not a casual thing.  
It

requires a lot of scrubbing and attention to the small details. If that  
attitude can be instilled in novices from the start, more of them will go  
on to

become advanced brewers. To folks who are serious about getting started I  
always suggest reading both of these books and brewing a batch with an  
established brewer, first. I include a caveat that none of our  
homebrewing

Gurus are 100% correct and that experience is the best teacher (a nod to  
Mr.

Richman). To those who just want to "try" it for the sake of saying that  
they

have brewed their own beer, I say "Go see Steve Norris at the Home Brew  
Co.

He'll set you up with a kit and guide you through a batch."

From: cckweiss@pollux.ucdavis.edu  
Subject: oxidation vs. oxygenation

>This leads to my question - if the wort oxidises so easily, does it  
>not oxidise during a long open boil? If not, why not? If so, is the  
>oxidation not much more significant that can be expected during the  
>other brewing stages?

>What am I missing?

Boiling tends to drive off all dissolved gases, including oxygen. I think  
this  
is due to the vapor pressure in the boil being greater than ambient air  
pressure. Colder liquids hold more dissolved gases -- that's why warm  
beers fizz more than cold beers.

The oxidation issue is also a function of temperature. At high  
temperature  
the stuff in the wort that is subject to oxidation is highly reactive,  
and  
combines with oxygen easily to form nasty tasting compounds. When cold,  
the stuff is not as reactive. If you don't believe that temperature can  
affect  
the rate of oxidation, just fill your room with crumpled newspapers and  
raise the temperature to around 450 degrees F... ;-)

What you want for optimal yeast growth is a large amount of available  
dissolved oxygen in the wort, not a large amount of oxygen that has been  
used up in chemical reactions with components of the wort. That's why you  
chill the wort first (reducing reactivity and increasing capacity to hold  
dissolved O<sub>2</sub>) and then aerate.

>that cause oxidation, with all its consequences. (Can't remember what  
>they  
>are, but I remember being told to avoid it.) So what gives? Is this  
>another (God help us) "momily"?

Well, \*my\* mom told me that boiling drives the oxygen out of wort.  
So even though there is oxygen in the air surrounding the wort,  
gasses are being expelled from the boiling liquid, not dissolved  
into it. Consequently, oxidation doesn't occur.

From: Chuck Coronella <CORONELLRJDS@CHE.UTAH.EDU>  
Subject: My favorite porter

You know, I was thinking about my favorite recipe, and I think I've got it.  
But I should add that it's been my favorite for a relatively short time (just had my first bottle about a week ago.) It seems like my favorite recipe changes frequently, almost as often as I brew. ;-)

Well, as CP says, enough shuck and jive, on with the recipe.

#### Rainy Day Porter

##### Ingredients:

2 lb Alexander extract syrup (pale)  
4 lb Yellow Dog extract syrup (amber)  
1 1/4 lb Brown Sugar

|                         |  |                    |
|-------------------------|--|--------------------|
| 1/2 lb. Black Patent    |  |                    |
| 1/4 lb. Roasted Barley  |  | Steeped at ~ 65 oC |
| 1/2 lb. Crystal (60 oL) |  | for ~ 40 minutes   |
| 1/2 lb. Crystal (40 oL) |  | before boil        |
| 1/4 lb. Chocolate Malt  |  |                    |

22 AAU (2 oz Nugget); 60 minutes boil  
3 oz Fresh Grated Ginger; 10 minutes boil  
1 oz Cascade; Steeped after boil for ~ 10 minutes

Ale yeast (see below)  
3/4 cup corn Sugar (priming)

OG: 1.057  
FG: 1.016

Details: 2 gallon, 60 minute boil. After waiting for the steep, I used my newly constructed wort chiller to cool the 2 gallons down to around 35 oC. Racked off trub, added water to 5.3 gallons. Pitched yeast. Bottled after 3 weeks.

I used two types of yeast pitched simultaneously for this brew. One was 5 g. (rehydrated) Doric Ale yeast, and the other was a "large" sample taken from a previous (cherry ale) brew a few weeks earlier, originally Whitbred Ale yeast. [As a side note, it is interesting to note that this cherry ale is a prominent former favorite brew. ;-] Fermentation started pretty quickly, if I remember right, about 6 - 12 hours.

This recipe started with one of CP's recipes from TCJoHB, what-the-hell-was-it-called. Obviously, this is a very heavy ale, almost like a stout. I'd liken the flavor to Sierra Nevada's porter, but heavier, a little sweeter,

and with (delicious) ginger. After about 3 weeks in the bottle, it was, uh, WOW!!! Delicious!! What a combination of flavors! I'd say that this is the exactly correct amount of ginger for such a dark, heavy ale (for my taste). I've had (lighter) ales with too much ginger, but this was just right.

Cheers,  
Chuck

From: Bob Jones <BJONES@NOVA.llnl.gov>  
Subject: Cleaning buckets & safety

>Karl Desch asks the question  
>Does anyone know a good way to sanitize plastic fermenters?

I would suggest filing the bucket with gasoline and light it! If you are going to invest your personal time in brewing you should invest a little money in a glass carboy. I know some of you will say you have been fermenting for years in a plastic bucket and all your beers are GREAT. I would ask you how many awards have you won with your beers? That's not to say you aren't brewing good beer if you aren't winning contests, I am saying that competitions are a good way of getting unbiased comments on your brewing efforts. Plastic buckets are good for first brews, but the critters will eventually take up residence in the plastic and their effects will dominate your best efforts. These effects are most noticeable in lighter flavored beers. So if you always brew Imperial Stouts these effects can be masked depending on your luck and the phase of the moon.

In regard to Ken Weiss's comment on brewing safety I would add that I see a lot of brewers with jury rigged stands for supporting 15 gal kegs used for kettles. Think about Ken's experience magnified 1000 times. California brewers should also think about the possibility of experiencing an earthquake while brewing! I don't think the safety aspects of brewing are emphasized enough!

Subject: Re: Sir Digby's mead

Jacob Galley (gal2@midway.uchicago.edu) quotes from Sir Digby on the making of mead:

> and if you will clarifie the Liquor with a few beaten whites  
> of Eggs, it will be the clearer. The rule of it's being boiled  
> enough is, when it yieldeth no more scum, and beareth an Egge,  
> so that the breadth of a goate is out of the water.

Just a guess here, but it seems to me that the two egg procedures involved here are separate. First, the use of beaten egg whites to help clarify the boil. I would guess that "floaters" in the boil would stick to the egg froth, making them easier to remove, hence a clearer Liquor. The second procedure sounds like it involves a whole egg, in the shell, and that the idea is to provide a gravity measurement. When the Liquor "beareth an Egge, so that the breadth of a goate is out of the water", you've boiled down to the correct specific gravity. Any biologist/historians out there who could find the density of an egg and the thickness of a goate and figure out what that gravity would be?

From: tighe@inmet.camb.inmet.com (Michael Tighe)  
Subject: Kenhelme Digbie's "Eggs"

The egg was used as a primitive hydrometer (hygrometer?) - i.e. a way to tell what the specific gravity of the liquid is.... Most of Digby's recipies use the floating egg as a way of determining when enough of the water has been boiled off. You can achieve the same result by adding more honey (obviously).

I believe Digbie boiled for longer times and used egg-whites to clarify his mead - remember that he is probably using "raw honey", which still has bits of wax and bee-parts floating in it. Most of the "scum which riseth" is probably pollen and wax. If you don't skim it it leaves a cloudier drink and often leaves a dull taste/covering on the tongue.

Try the "weak-honey-drink" (p 147?) which has 9 parts water to one part honey and uses ginger root and the peel of a (lemon/lime?). Its my favorite.

Subject: Where There's Smoke....

Hey All,

Last night I was involved in a tasting that was really great, so I thought I'd share the experience.

We had a good group assembled. There was one professional brewer, two excellent homebrewers (both national award winners), a reporter from the Oakland Tribune, one from the NY Times, and two from the Celebrator Beer News.

The theme was smoked beer. We had assembled all of the commercially produced smoked beers known to the group. They came from the Rogue Brewing Co., the Alaska Brewing Co., the Vermont Pub & Brewery, the Otter Creek Brewing Co., and the sole import, Rauchbier from Bamberg Germany. In addition, we had two smoked homebrews. There were four porters, an ale, a bock, and a lager.

My overall impressions were that all of these beers were good (with the possible exception of the Rauchbier). The smokey flavor adds a richness and complexity not present in other types of beer. Its bite complements the sweetness of the malt well. Some of the beers had no noticeable hop component, but if malt, hops and smoke were all present, the balance and interplay between the three flavors was intriguing.

The Rogue was generally favored over the others. It had a woody flavor that the others lacked. The homebrewed bock had the elements of a high octane beer that fit well with smokiness. The Otter Creek didn't compare too favorably, but in all fairness it had been Fed-Ex'd in earlier that day and needed time to rest. Most agreed that the Rauchbier was overdone, and tasted like carbonated liquid smoke. All of the American beers were much more refined, which I found surprising given our penchant for excess.

Most of these beers are pretty hard to get, but if you do get the chance, check 'em out.

Cheers,  
CR

From: pyle@intellistor.com (Norm Pyle)  
Subject: Apricot, Spruce, Oxygen

To Michael Bass:

I've just brewed an apricot-ginger ale for my Christmas brew. This recipe calls for leaving the apricots in the brew during primary fermentation, as you suggest. That's the point I'm at now, so I'll have to let you know later how it turns out. BTW, I used a couple of pounds of canned apricots (with no preservatives) and smashed them with a potato masher. I also added them after the boil as you did.

To James Smith:

I'd bottle the stuff. If the gravity is still 1.016 after a week then it's done. I don't have any info on Cooper's yeast. As far as avoiding a plugged blowoff hose, it sounds like you filtered the wort on its way into the primary. That's all I do and I haven't had a problem. I ferment in a seven gallon carboy, though, so there is a lot more head space (I've never gotten any blowout). As far as economy homebrew, the upfront cost of all-grain brewing is higher, but each batch is much cheaper. I'd brew several extract batches first. There a loads of recipes in Papazian's book, Miller's book, and even Reese's book. Good Luck!

To Chuck Coronella:

It's my understanding that it is desirable to aerate the wort, not the beer. This because the yeast needs oxygen in the reproduction stage. After that, the yeast drives off oxygen as it ferments the sugars. I don't know the details of oxidized beer, but it ain't good. I try to aerate while I pour the wort into the primary, then siphon quietly any time after that. Flames and real information are invited on this one. 8\*)

Date: Fri, 18 Oct 91 15:52:41 PDT  
From: chad@mpl.UCS.D.EDU (Chad Epifanio)  
Subject: Christmas ale & general observations

Hello. Good to see the HBD again.

Someone asked for Christmas beer recipes a while back. Here is a funky beer I made:

10 lb Klages pale malt ] mashed at 158F for 1.5 hrs  
0.5 lb amber crystal malt]  
2 oz Cascade(4.9%) 10 HBU  
3 lbs plums, depitted & sliced  
7 oranges; flesh sliced, and peels diced(didn't remove pith)  
2 lemons; flesh sliced, and peels diced(didn't remove pith)  
1 T gnd nutmeg  
3 t whole cloves  
5 2"-sticks cinammon  
0.5 cp fresh grated ginger root  
William's English Brewery Ale yeast(from 12oz starter)  
NOTE: forgot Irish Moss

There was too much particulate(orange pits, plum halves, etc) to get an original SG, so I didn't even bother with a FG.

Boiled hops for 1 hr. Added fruit and spices during final 10min of boil. Cooled to 80F in half-hour and pitched. Racked after 5 days, and noted rocky head from fruit pulp. Added 2T dissolved gelatin after 12 days. Bottled after 15 days.

It tastes a bit tart, but the hops is a good balance for the sweetness. Its quite clear, considering all the shit that went in it. A pale yellow color. I have a cold, so I can't describe the smell, but they tell me it smells like fruit(shocker). Probably not enough spice character, namely the cloves and cinammon. All in all, quite drinkable, but the taste does stay with you for awhile.

In the last four batches, I've added 2T gelatin about 3 days before bottling. I'm pleased with the results. For the first time, I get beers that you can see through.

I calculate that on most of my all-grain brews, I calculate I'm only getting around 1.025/lb of Klages. I just finished 2 identical batches of brown ale. On the first one, I accidentally boiled the mash for awhile(forgot the stove was on). This one started 1 point Balling lower and ended 0.5 Balling higher than the other batch.

I wanted to keg this double batch, because I was trying to avoid the 4 hour bottling session we had last night. HBD went down before I got any reply about my kegging question. So here it is again: Anyboy used commercial beer kegs successfully? ASAIRIZ, I have instructions for removing the ball-tap assemblys. Is it easy, or even recommended? I have a commission to do a super bowl party, and I'd rather not go through bottling 15 gal of beer. And please don't tell me to go buy a keg system, as that won't happen in the near future, unless the beer fairy leaves one under my pillow.

From: <HAPANOWI% CERAMICS.BITNET@CUNYVM.CUNY.EDU>  
Subject: Slow fermentation. I'm relaxed and pondering.

On 9/14/91 I brewed up a batch of Pale Ale. The original SG was 1.045. After about a week I transferred the batch into a secondary fermenter. The transfer was made because the fermentation had slowed. The SG at this time was around 1.035. I thought it was quite high. The airlock would bubble occasionally, but the time interval between bubbles was long. Another note; At the brew time the temperature was around 60F, then a sudden heat wave gave temperatures in the upper 70's for about four days during the initial fermentation.

I thought the fermentation was stuck, so I took the advice from a brew shop owner and added champagne yeast. Fermentation continued but the rate never really picked up. I measured the SG today, 10/18, the measure result was 1.030. Can anyone give me some advice. I tasted the beer about two weeks ago, since I added oak chips it had a wood flavor, I can only describe it as fit for fire-breathing dragons. There was also sweetness to it. Today the beer tasted sweet, but the wood seemed to mellow out, it is not bad, there are no "off" flavors. The wood chips were added the time of transfer to the secondary fermenter, they were removed about one week later. What do you think? Sit on my hands for a few more weeks? Can I help the fermentation at all? How would I do this? The airlock still bubbles but the time interval is quite long, >15 min.

From: Brian Capouch <brianc@zeta.saintjoe.EDU>  
Subject: Egg Whites and Boiling

In HBD #743 (and thanks be to Gardner we're back on the air. . ) Jacob Galley writes:

Has anyone out there ever heard of putting egg whites in the boil?

I've never heard of doing it with brews, but back when I was spending the time I now spend brewing as a cook (Yup, me too. . .) egg whites occurred pretty often as a stock clarifier. You might check McGee's excellent "On Food and Cooking" (first volume)--I'd be surprised if it weren't discussed in there. I can remember the startlingly clear soups I produced when I used an egg-white method (which I don't recall very well) to clarify.

> What on earth does the phrase "beareth an Egge" mean?

Well, how about, "floats an egg," which is what I'm sure he means. The evaporation of water and concomitant rise in the SG of the liquid, I presume, would allow one to gauge the progress of the boil by dropping a fresh egg into the liquid, in case the hydrometer lacked a hundred years or so of being invented :-)

> What does the thickness of the "Egge" have to do with anything, if  
> you've been scumming off the top all the while? (My Webster's says  
> that a groat is an old coin worth four pennies.)

Groats are cracked grains, "larger than grits" according to my dictionary. I would guess this means that just the slightest amount of eggshell presents itself above the liquid level.

-----

Date: 20 Oct 91 12:55:00 EDT  
From: Henry (H.W.) Troup <HWT@BNR.CA>  
Subject: Digby and 'beareth an egg'

Digby uses (used?) eggs as hydrometers. 'Beareth an egg ... the breadth of a groat' means that a fresh laid egg floats so that a circle the size of a groat coin is above the liquid. A groat was worth four pennies (Webster's Ninth) and my faulty memory says that it was about the size of quarter, so we're talking pretty stiff mead here.

A friend of mine in the SCA wrote a paper "The eggs of the very eminently learned Sir Kenelm Digbie, refloated". He speculated that the eggs were equivalent to modern bantam eggs. Somewhere I may have a copy, don't hold your breath.

Hope it's useful...

From: Martin A. Lodahl <hpfcmr.fc.hp.com!hplabs!pbmoss!malodah>  
Subject: A Quick Note

I must confess, HBD's unplanned hiatus was well-timed, for me. Between mushrooming work commitments, editorial deadlines, and a beer-fest that seems to be firmly resisting my efforts to organize it, I just haven't had the time to be my usual blatherskite self.

But Jeff Frane said a couple of things in HBD 743 that I can't let pass without commentary:

>In 741, Martin Lodahl: I've been planning a Belgian abbey-style double or  
>triple. Wuffo you put in that brown sugar?

I was trying for an effect, and it worked. The idea was to introduce just a hint of the flavor that in its extreme form is called "cidery". If just above threshold, it's perceived as a pleasing complexity. I did the same thing for the same reason in the batch of Scotch "wee heavy" that I bottled yesterday, and don't find it pleasing in that batch. Next time I use that recipe, I'll omit the sugar, add some flaked barley, and peat-smoke the crystal malt more intensely.

> ... WYeast, by the way, will be offering  
>a abbey-style yeast within the next month or so.

And, if it's like their other products, it will certainly be excellent ...

> ... You might have better results  
>and avoid the banana-esters; it's possible the bottle yeast wasn't all that  
>clean. ??

As I said in my initial posting, this batch went through a hot fermentation. Others I've spoken with who've fermented hot with Chimay yeast have had the same results. It appears to be a "nature of the beast" question.

Which reminds me: does anyone know with a degree of certainty if Chimay bottles with their regular fermenting yeast (ala Sierra Nevada), or if, like Worthington and like Orval, they maintain a separate culture for the purpose? I've heard the question answered both ways, and would really like to know.

>: I've been told that some British breweries \*deliberately\*  
>oxidize the wort in the kettle in order to darken it; this in lieu of adding  
>more caramel malt ...

Odd as it may sound, this makes sense to me, especially for brew that is not to be bottled. If an entire batch is to be kegged and consumed within 3 or 4 weeks of brewing, oxidation is less of an issue. Ditto infection, as a discouraging number of California pubbrewers seem intent on proving.

>To Darryl: We'll have to wrassle about recommending Dave Miller's book. I think

>it's absolutely the wrong book for a beginning brewer; only an  
experienced  
>brewer is likely to notice all the places Miller's wrong.

This puzzles me greatly. Could you point out a few of these places,  
Jeff? And what book would you recommend in its place? By the way,  
I'm with Darryl. I'd recommend Miller without hesitation.

> Not to mention the illustration on how to start a siphon! Aaaagh! Get  
> your mouth off that, Dave!

I wonder about this. I've never tried any other way, and the only  
three batches I've ever had with any symptom of infection at all  
have all been directly traceable to the yeast used (dry, in all  
cases). I personally am not inclined to view it as a problem.

Well, playtime's over. Back to work ...

Subject: Civil War Beer recipes: found

Hello, fellow history lovers.

Back on September 12, I posted a request for any information on the kinds of beers produced in the United States during the Civil War era. I want to brew up a batch to give to my brothers, avid reenactors. Thanks to Jay Hersh, Mile Schrempp, John Otten (especially) for tips and information.

Here is what I found: Ales, stouts and porters were popular in the 1830's due to the "British heritage". Most ale was brewed at home before this, but the commercial breweries became popular with the growth of the cities. Most ale breweries were established between 1830 and the mid-1850's. Lager beer was introduced in 1840, and was immediately popular with the German immigrants, who found the Ale style too thick and bitter. Lager didn't really become popular with the mass market until the early 1850's, but by 1860 had more of the market share than the ales. For example, there were dozens of ale breweries in Milwaukee in 1850. By 1867, one was left, and that was sold, (and closed down) in 1880.

So in 1860-1865, both ale (porters and stouts) and lagers were being brewed and enjoyed. As for the war itself, due to the shortage of manpower both to collect ice and to brew, ale regained a brief popularity. Even though troops were officially dry, enterprising brewers still managed to supply the troops. The NEW YORK HERALD of August 23, 1862 complains bitterly of the wealthy suppliers who "sip champagne" while "supplying ale and porter" to the troops. Rum was also extremely popular (that British heritage, I suppose). Beer brewed at home was popular again, due to the shortages of the war.

Thanks to the National Park Service, I was able to get a hold of a reprint of an 1863 "Confederate Receipt Book: A Compilation of Over One Hundred Receipts Adapted to the Times" copyright 1990 by Jefferson Davis Freeman. Reprinted here, (without permission) are several recipes used by resourceful confederates to lessen the hardships of a wartime blockade. The word "receipt" means "recipe".

#### TABLE BEER

To eight quarts of boiling water put a pound of treacle [molasses], a quarter of an ounce of ginger and two bay leaves, let this boil for a quarter of an hour, then cook, and work it with yeast as other beer.

#### ANOTHER RECEIPT

Eight quarts water, one quart molasses, one pint yeast, one tablespoon cream of tartar, mixed and bottled in twenty-four hours; or, to two pounds of coarse brown sugar add two gallons of water, and nearly two ounces hops. Let the whole boil three quarters of an hour, and then work as usual. It should stand a week or ten days before being drawn, and will improve daily afterward for a moderate time.

#### SPRUCE BEER

Take three gallons of water, blood warmth, three half pints of molasses, a tablespoon of essence of spruce, and the like quantity of ginger, mix well together with a gill of yeast, let it stand over night, and bottle in the morning. It will be in a good condition to drink in twenty-four hours.

#### GINGER BEER

One pint of molasses and two spoonfuls of ginger put into a pail, to be half filled with boiling water; when well stirred together, fill the pail with cold water, leaving room for one pint of yeast, which must not be put in until lukewarm. Place it on a warm hearth for the night, and bottle in the morning.

I plan to try at least some of these, and assuming I survive, I'll let you know how they turn out. There is a whole mess of other recipes and tips here too, like Catsup and charcol tooth powder and toothache cures. If anyone is interested drop me a line and I'll let you know how I got my copy. Also, in my readings, I came upon quite a few other old recipes, such as Persimmon Beer (which looks like an alcoholic fruit drink), Corn Stalk Beer (yes, made from green corn stalks) and the beer recipe from a virginian gentleman named Geo. Washington. If I get enough mail requests (more than 5), I'll post those too. (Karl L., are you interested?)

Intersting facts I learned:

B. Franklin is credited with bringing a recipe for spruce beer back from France. There is also a recipe in the journal of a british governor that was written in 1760. Spruce beer was quite popular in the seventeenth and eighteenth centuries.

Eberhard Ahheuser was a soap manufacturer before inheriting a brewery. You may draw your own conclusions from this.

From: George.Fix@utammat ( gjfix@utammat.uta.edu )  
Subject: Hot Wort Oxidation

Ifor Williams asked (HBD #741) why Dave Miller would recommend against rough treatment of hot wort when there is already so much oxidation in the boil.

I feel that Dave's recommendation is sound for the following reasons (which may or may not be his).First, the oxidation reactions in the boil are primarily with hop constituents. These reactions are poorly understood (at least by me),and some may even be beneficial.Rough treatment of the wort,on the other hand,tends to oxidize malt constituents generally called reductones.They are also oxidized in the boil(which results in an increase in wort color),but to a lesser extent than e.g. when hot wort is splashed during transfer.

Oxidized reductones will interact with alcohols in beer (among other things) producing a variety of aldehydes.These tend to have an astringent "grain bitter" flavors which are sometimes accompanied with a hard metallic finish. Ironically, reductones which are passed on to the finished beer in their reduced state tend to act as flavor protectors.They ultimately will become oxidized by headspace air (no beer has an infinite shelf life),but if the beer is kept cool during storage this will take a long time.Oxidation reaction rates increase exponentially with temperature.

It is impossible to prevent some reductones from oxidizing either in the boil or elsewhere.But experience has shown that beer flavors tend to be more stable if the oxidation is held to a minimum when the wort is above say 40C (105F). Our yeast need O2 at the start of the fermentation.However,this is best suppliedafter the wort is chilled and just before the yeast are added.

The above are qualitative trends only.To determine their quantitative relevance for own brewing systems,weneed only examine the contributions from malt to the flavors of our beers.If they are smooth and rounded,and if these characteristics tend to be stable,then forget the above.If on the other hand, some of the flavor tones cited above are sometimes evident,then one might wish to take another look at the brewing procedures used.

I tried to spell out the reaction systems in detail in my book on brewing science.I hope this brief summary is useful.

>JF> To Darryl: We'll have to wrassle about recommending  
>JF> Dave Miller's book. I think it's absolutely the wrong  
>JF> book for a beginning brewer...

>I think Miller gave me a much better sense of the role of  
>sanitation and the actual brewing process (starch conversion,  
>fermentation, "breaks", etc) that has stuck with me. He comes  
to his subject with a very serious attitude.

Let me add another \$.02 worth. I read Papazian first and came  
away thinking it was cute but didn't really help me learn how to  
brew. I then read Miller and came away thinking it actually told  
me every step I needed to know in order to brew. I could  
actually write down my own variation of the procedure and feel  
confident I hadn't missed anything (and in retrospect, that was  
true). So, for people like me who would otherwise be nervous  
and worry, Miller is *\*much\** better.

Recipes are a whole 'nother issue. I liked Papazian for recipes  
until I tried one that was a dud. He is certainly more fun to  
read through, especially when you have more experience and  
knowledge to avoid much of the bad recommendations.

BTW, I just recently switched from sucking to start the siphon.  
But my old theory was to drink lots of homebrew before starting,  
so that the homebrew yeast population was greater than any  
bacteria in my mouth :-). May not have been scientifically  
valid, but made siphoning more fun.

Marc> Last spring I also stopped using bleach. I don't sanitize anything.  
Marc> Ordinary kitchen cleanliness standards (get the big chunks off!) have  
Marc> been sufficient for me. I don't keep my beer around for more than a  
Marc> few months though -- I don't know if it would keep for a year or more.

This is fantastic -- it's great to hear all the old myths deflated!

On the sanitation issue itself -- not the idea of iconoclasm -- it makes sense that if the wort is boiled, it's clean; the yeast-cake carboy must be too, and if you keg in a just-emptied keg, it too is clean (besides, at this point the alcohol should help prevent infections).

Only one place I can see problems cropping up: the siphon hose from the cooled wort to the keg. Unless perhaps you use a counter-flow rather than immersion chiller. Any comments, Marc?

I'm not necessarily advocating everyone throwing away their bleach -- just intrigued at how much aggravation can be eliminated by taking advantage of existing conditions and already-known-clean equipment.

From: KCDESCH@ucs.indiana.edu  
Subject: Collecting Yeast

All this talk about repitching yeast from previous batches has motivated me to give it a try. I realize that sanitation is a great concern. But how does one remove the yeast from the secondary and store it before repitching so that no nasties get involved? I use british ale yeast for pale ales but I don't enjoy spending five bucks a pop. If anyone can give me some advice before the 25th of October I would sure appreciate it.

the way, I think I've come to a decision about the use of a plastic fermenter. The general response to my question in the last digest about getting rid of the smell in my plastic primary fermenter was "good luck!" So I think I'll just have to sell some blood plasma and purchase a six gallon glass carboy. Plastic is too risky.

Thanks for the advice and please send more about repitching yeast.

Subject: Homebrew Digest #744 (October 21, 1991)

> So, what is cara pils? Is it a malt that also goes by some other name?  
What  
> does it add to the brew?

The other name for "cara pils" is dextrin malt. This malt is similar to crystal malt in that during processing the starchy endosperm becomes crystalized. The crystal, however, is almost colorless due to being kilned at a significantly lower temperature than crystal malt. Dextrin malt is suppose to add unfermentable dextrans, but very little color to the beer. The dextrans are suppose to add body, i.e., mouth-feel to the finished beer.

I say "suppose to" in the previous two statements because they have been the subject of significant previous discussions in this forum. Specifically, it has been argued that if the dextrin malt is mashed, then a large portion of the dextrans are converted to simple sugars and so are fermented out and don't add much residual body to the beer. The other discussion has revolved around whether proteins or dextrans are primarily responsible for adding mouth-feel to beer. With that said, I use dextrin malt in some of my lighter beers and feel that it does indeed add some residual body to the finished product (and I do mash it with all of the other grains)

>Subject: Request for info...

> 1) Saaz hops - Where are they grown? Distinguishing characteristics.  
>Alpha content. Classic beers it is found in. That sort of info.

Ahh, those Saaz hops!!! Saaz hops come primarily from a small hop-growing region near the town of Zatec in Czechoslovakia. Zatec is about 40 miles northwest of Prague. I believe that they are now grown in other places in Europe, but this is their place of origin and the majority of them still come from this region.

Saaz hops are often described as having a "spicey" character. I'm not sure I totally agree, but they do impart a wonderful hoppy aroma and flavor to the

beers they are added to. I don't have any information with me, but I believe that Saaz hops are fairly low alpha acid hops in the 3.5-4.0 percent range. They are used primarily in classic Pilsner style beers and I believe are the only hops used by the Pilsner Urquell brewery which produces the beer that defines the Pilsner style.

From: Chris Shenton <chris@endgame.gsfc.nasa.gov>  
Subject: OG of an ``Egge''

I don't suppose it would be too much trouble to plop an egg (shell on) into the wort and take a hydrometer reading when the width of a groat (about 1/16th inch?) is above the surface.

But couldn't you do the same off-line by just dissolving sugar in water which has an egge in it, continuing to add sugar until the egge was at the appropriate displacement? Then just measure the SG of this solution.

By the way, I assume the egge is raw when plopped into the wort, but becomes \*hard\* boiled after a while. This shouldn't change it's SG, should it?

From: microsoft!larryba@cs.washington.edu  
Subject: Re: Chrishmas (HBD#744)

Bill Thacker:

The recipe for christmas ale calling for 10lb of extract malt would certainly get you an OG > .070. If you look at Miller (TCHOHB). The SG/lb/gal for malt extracts (and honey) is ~.040, for dry extract it is .044. Simple math will tell you what your OG \*will\* be:

```
3.5lb * .040    - syrup
3.5lb * .044    - dry extract
.75lb * .040    - honey
-----
.324 / 5.0    - final volume
-----
1.065        - OG
```

If you throw another 3lb of dry extract into the boil the calucated OG would be (Golly, guess what!) 1.088!!!

Cheers!

Larry Barello

P.S. I believe in "Brewing as a Science" for those things easily calculated and measured, "Brewing as an Art" for the rest.

Subject: recipes

Date: 21-Oct-91 Time: 04:06 PM Msg: EXT02116

Hi folks,

I have a few recipes for cooking with beer. They were in the paper last week. If anyone wants them, e-mail me. If I get more than a few, I'll post to the digest.

I bottled an xmas porter last week. It was far thinner than I anticipated, Could this have been due to insufficiently cracked grains? There was also a bit of white scum around the top edges of the beer. How can I tell if this was bacteria or wild yeast? The beer tasted ok, although due to the orange peel and spices, it was a bit sharp. I anticipating this mellowing by xmas.

Recipe: (5 gallons)  
6.6 lbs light malt extract  
crystal malt (about two double handfuls)  
chocolate malt (about one double handful)  
cluster hops  
chinook hops  
calcium carbonate  
irish moss  
M&F ale yeast  
6 cinnamon sticks  
10 cloves  
about 1 inch grated fresh ginger  
peel of 3 oranges (grated, no pith)

I crushed the grains, steeped them for barley tea, and took them out when the boil started. Put the malt in and the cinnamon, cloves and cluster hops. I grated the rinds and ginger in as the boil commenced (getting the last of the orange rind in only about 5 min. before the end). I put in the chinook hops 1/2 at 15 min and the rest at 25 min. Put cold water in a carboy, strained my wort in, sloshed a lot, and let cool overnight. Pitched a starter the next morning, and the fermenting seemed to run its course in about 2 days. Wow! We did have 95+ temps those days.... I also had a massive boilover (mom always calls at the worst times...). It sat in primary for 2 weeks, then sat in secondary for 2-3. We bottled last week, and it tasted ok for flat, warm beer. No noticeable spice, the fruit gave it a small bit of acid tang. Of course, we'll be tasting

it every 2-3 weeks between now and xmas just to see how it develops. Next batch  
I plan to try to use my hydrometer. This was a kit from BarleyMalt and Vine and  
I added the spice and fruit. They make nice kits. 617-327-0089.

Subject: Repitching Yeast

Karl Desch asked about repitching yeast.

What I do is collect some of the yeast sediment in a sanitized bottle (I usually try to get 1/4 to 1/2 a bottle), cap it, and put it in the refrigerator. I have successfully stored and reused yeast for up to 1 month this way. I don't really know what the limit would be, 1 month is just my upper limit for being relaxed about it.

I use the BrewCap system, so the collection is a very simple task.

Subject: Homebrew Digest #745 (October 22, 1991)

>Saaz hops are fairly low alpha acid hops in the 3.5-4.0 percent range.

Without having any information with me at work, I made this incorrect statement in a digest reply yesterday. When I got home, I looked up the alpha

acid content of Saaz hops and found that it was a little higher than I thought.

One reference listed Saaz as being in the 4-6% alpha acid range and a second

reference listed them as being about 5% alpha acid.

> coffee, cooling it down and placing it in the primary with 2  
> gallons of fresh water before pouring the semi-cool wort in. What  
> do you think?

I think it's a great idea but too much. Coffee, like spices and spruce,  
will quickly dominate the taste of your beer. I "dry-beaned" a 5 gallon  
batch of stout with a bit less than 1/5 cup Peruvian dark roast coffee  
beans.

The coffee taste was definitely noticeable; if I had doubled the amount  
and/or  
ground the beans beforehand it would probably have tasted like coffee  
beer.

I'd start with a smaller amount of coffee and, if you like the effect,  
increase it in later batches. Let us know how it turns out.

Subject: siphon and brewpot

Date: 22-Oct-91 Time: 10:39 AM Msg: EXT02122

Hi,  
When starting a siphon one of the two books I have (Miller or Papazian) said if you have to suck on the hose to start a siphon, suck on some high proof alcohol before doing it (and swish it well around your mouth). I got pretty looped bottling my first batch (NOT the plan, I tried not to swallow much at all, but I'm a small person), and this time tried starting with water in the siphon tube. Fill the tube with water, stick the source end in, keep the middle pinched, let water go into a bucket, pinch, put now beery end into target and let go. Works nicely. The Fall issue of Zymurgy suggested (at least from carboys into stuff) one of those 2-plug rubber carboy caps. Stick your hose through the bigger one, blow hard through the smaller one until pressure forces beer out your tube. You can stop blowing when your siphon is going. Honestly, I'd probably pass out on that one, but it might be easier than it sounds.

I had occasion to pick up my nearly full ceramic-coated boiling pot, and heard those ominous "crackle" sounds from the handles. Well, guess what my next big investment is gonna be? Can those handles be welded back on if they come off? Has anyone had a pot fail like this and written to the company that makes them? After all, if they make them that big, they should expect someone to fill them up and then have to move them....

Date: Tue, 22 Oct 91 08:45:48 PDT  
From: Richard.Stueven@Corp.Sun.COM (Richard Stueven)  
Subject: gak & gerry's First All-Grain Batch!

Gerry and I finally took the plunge and brewed our first all-grain batch last Saturday. The recipe ("Redcoat's Revenge Porter", although we'll probably come up with a different name by Bottling Day) came from the Sept/Oct 1991 issue of "The New Brewer" magazine. If this stuff is even remotely drinkable, we're \*never\* using extracts again! Here's the approximate recipe...I don't have my exact notes in front of me (I need to get this stuff on-line!):

7.5# pale malted barley  
1# 10L crystal malt  
0.5# chocolate malt  
2 oz black patent malt  
1.5 oz Cluster hops (60 min)  
1.0 oz Cascade hops (10 min)  
1.2 oz Cascade hops (finish) (recipe called for Talisman, but I  
couldn't find any)  
Wyeast British

Added all grains to cold water, raised to 150F and maintained 150-155F for 90 minutes, stirring constantly.  
Sparged with ~4.5 gallons of 170F water to total volume of 6 gallons.  
Added Cluster hops, boiled 50 minutes.  
Added first Cascade hops, boiled 10 minutes.  
Added second Cascade hops  
Chilled to ~80F, racked & pitched.  
OG 1048. Volume ~5 gallons.

We saved more than \$15, compared to what we usually spend on an extract batch! The procedure was much easier than we thought - I can brew an extract batch by myself in 4 hours (including cleanup), but this batch took the two of us only 5.5 hours.

Our biggest concerns were that we wouldn't be able to control the temperature accurately enough (kettle covers two burners on electric stove), and that we wouldn't be able to get enough water hot enough to sparge. Somehow we did it, and all that's left is the waiting.

Any comments/suggestions on our procedures?

have fun

If so, I missed it. I've been wondering about the same thing recently.  
The  
inspiration was a pint of Appleton Brown Ale at The Swans in Victoria, B.  
C.  
It reminded me of a rich coffee dessert of some sort. Got me so excited,  
I  
came home and tried my first batch of brown ale. It's in the bottle 3  
days.  
Just thinking about it makes me so crazy I ...

Sorry about that, I'm back. Well the point is, I seriously considered  
tossing  
in some coffee grounds, but since it was my first crack at this style, I  
decided to keep it simple. But as I gaze longingly at my empty carboy,  
remembering that brown, creamy head, the dark, warm, malty aroma ...

Oh Wow, that was great. Anyhow, forget the private email. If somebody  
has  
tried coffee in some form or another, let's hear about it.

Subject: repitching

Karl Desch asks:

>how does one remove the yeast from the secondary and store it before  
repitching  
>so that no nasties get involved? I use british ale yeast for pale ales  
but I  
>don't enjoy spending five bucks a pop. If anyone can give me some  
advice before the 25th of October I >would sure appreciate it.

I use the simplest possible method -- I don't store the yeast at all. I  
set  
a batch of beer to boiling on the stove, and watch it long enough to be  
confident it won't boil over. Then I go down to the basement and bottle a  
batch from one of my secondary fermentors, leaving the yeast sediment  
behind in the carboy. About the time I get done bottling, the beer on the  
stove is ready to chill. I chill it, put it in my primary fermentor, and  
dump in the yeast slurry from the secondary that I just bottled.

Last time I did this the yeast in the secondary was fresher than usual,  
due  
to an accelerated holiday brewing schedule. I had vigorous fermentation  
in  
six hours, using Wyeast American ale yeast.

Subject: RE>HBD #745 (Coffee & Beer)

Reply to: RE>HBD #745 (Coffee & Beer)  
Rather than using Drip coffee and cooling (as Marc Light suggests) I'd try a cold water method. My local coffee retailer sells a system which makes "Turkish Extract". The process involves soaking 1lb of fine (espresso) grind coffee in 2 quarts of cold water for 24 hours. This is then filtered and the remaining liquid is used like instant coffee (1/4 cup extract to 1 cup hot water). The resulting coffee has none of the acid harshness which is usually found (especially in very dark roasts). Many cream & sugar folks can drink this stuff straight.

My point is that if you prepare coffee this way for use in brewing you avoid extra acid (as well as the oils extracted under the hot water method) in your wort. Sorry to say that I have not made any tests along this line (I'm not drinking all that much coffee these days). Also you could add this extract after fermentation to adjust for taste. Just boil up a little of the extract and Dry Hop with it, sort of...

Just a thought. Oh yes, the gizmo to make this costs about \$15 at Peets in San Francisco. You could as easily use a large pot and a Melita (sp?) filter.

First, a comment. Chris, make sure your housemate knows how to weld  
stainless!

Chris' question actually goes along with a question I have. I'm about to  
help construct a 15gal mash-tun using an old keg. (fwiw, this is  
not my system. mine is already designed) When I was at the last  
AHA conference there was a workshop on making a 15gal keg system.  
In this workshop it was said that the false bottom of the mash  
tun could be rested on the \_\_\_\_\_. The question is, what do I  
fill in the blank with? does it rest on the bottom most weld  
or on the lowest reenforcing bead in the side of the keg?

[minor commercialism warning]  
Dan Hall & I are now the proud co-owners of a sheet of 18gauge perforated  
stainless thats about 3'x8' with 1/8" offset holes. Its somewhere around  
30% open. If anyone needs some drop Dan or I some mail. Obviously this  
is \*much\* more than either of us needs.  
[hope that was both tastefull and brief enough :-) ]

Says Chris Shenton :

(The heretic) Marc Rouleau <mer6g@fuggles.acc.Virginia.EDU> writes:

Marc> Last spring I also stopped using bleach...

This is fantastic -- it's great to hear all the old myths deflated!

Well, I would hardly call one example of success a deflation...

On the sanitation issue itself -- not the idea of iconoclasm -- it makes sense that if the wort is boiled, it's clean; the yeast-cake carboy must be too, and if you keg in a just-emptied keg, it too is clean (besides, at this point the alcohol should help prevent infections).

There's not enough alcohol in beer to really stop infection; if there were, there'd be no such thing as infected beer. I agree that the carboys will be somewhat clean, but realize that while the carboy is open it's exposed to every mote of dust that drops in. Note also that much household dust consists of discarded human skin cells. Yes, the yeast population is sufficient to overwhelm most bacterial infections, but it is still true that some beer does become infected.

I'm happy that some people don't work on sanitation. I don't really care what you do, if you're happy with your beer. I live in a relatively small apartment with two dogs, two cats, and two lovebirds. I keep the windows open most of the time. I have no doubt that the biota in the atmosphere of my kitchen is of an amazing variety. I sanitize diligently.

I'm not necessarily advocating everyone throwing away their bleach -- just intrigued at how much aggravation can be eliminated by taking advantage of existing conditions and already-known-clean equipment.

I really don't see where the aggravation comes from. I mean, it's not really much work to slosh around some chlorine solution in a glass jug.

From: Bob Jones <BJONES@NOVA.llnl.gov>  
Subject: Re: Homebrew Digest #745 (October 22, 1991)

I am starting to feel the obligation to comment on the on-going recommendation supporting both the repitching of yeast and the subsequent comments about even eliminating sanitation practices. Racking onto yeast from a previous batch will definitely produce beer. Large scale brewers will reuse yeast for many generations. We as homebrewers don't have the tools to examine yeast and wash it, if needed, like the large scale brewers do. I will guarantee you that you can not find yeast an any quantity that does not have some form of bacteria present. I have looked through a microscope at yeast in large brewery's labs side by side microbiologists and always you will see bacteria. The quantity of said bacteria is what matters. As homebrewers we can actually have an advantage in this area since we can strive to control our brewing environment better than the large scale brewers. All of this control can be wasted if one continually repitchs yeast. A few generations, OK. But watch out after two or more especially if your fermentation temps are above 70 deg, So do it! Just be aware that the critters can dominate the fermentation. Also off-tastes from large quantities of dead yeasts and fermentation byproducts (trube) can occur , especially at higher fermentation temperatures. I would suggest to always repitch onto a bigger style beer to reduce the chances of off-flavors. Like, repitch your light ale onto an amber ale. Then repitch your amber ale onto a porter onto a stout onto a barley wine. You get the picture!

As for the comment on "everything started clean, so it must still be clean if I repitch. I don't even need to clean anything", HOGWASH. Brewing is and always will be 80% cleaning and 20% brewing. If you want first class brews, clean, clean, clean! At least until we get a good strain of Killer yeast. Has anyone heard anything about the progress on this experimental yeast strain?

Subject: Re: Father Barleywine's yeast reuse trick

Chris S. sez:

>On the sanitation issue itself -- not the idea of iconoclasm -- it makes  
>sense that if the wort is boiled, it's clean; the yeast-cake carboy must  
be  
>too, and if you keg in a just-emptied keg, it too is clean (besides, at  
>this point the alcohol should help prevent infections)

What makes you think the yeast sediment is clean? This is a great place  
for  
bacterial growth. Dead & decaying yeast also provide food for bacteria.  
Why do  
you think commercial breweries spend time washing their yeast??

I recall reading through a collection of research papers on Brewing Yeast  
I  
found in RPI's library. Munton & Fison had a paper that was about certain  
strains of yeast that help to pull bacteria out of the beer. These yeast  
had  
the characteristic that they were attractive to the bacteria, basically  
rather  
than having to move about the yeast solution themselves to feed, the  
bacteria  
would hitch a ride. When the yeast flocculated the bacteria went with  
them.  
This had the desirable result of reducing bacterial concentration in the  
finished product, at the expense of increasing it in the yeast sediment.  
All  
yeasts do this to some extent, M&F was actually seeking strains with a  
strong behavior to help in the reduction of bacteria in the finished  
beer,  
and thus reduce the risk of beer spoilage. This behavior is why big  
brewers  
who re-use their yeast employ acid washes to try to reduce the presence  
of  
mutated yeasts and bacteria.

On the consideration of kegs and keggings equipment it is also foolish to  
assume  
a just emptied keg is clean wrt bacteria. Nonsense. Why do you think most  
restaurants clean their tap lines regularly?? They do this because  
bacteria can  
and does grow in tap lines, and also kegs.

While I don't see anything amiss to re-pitching onto the yeast sediment  
(cake  
as others have called it) for a moderate number of times, as this  
essentially  
approximates the same behavior of collecting and re-using yeast sediment  
from  
one batch to the next I would advocate moderate usage of this technique  
and  
periodic changing of the yeast. To say that this must work since it was  
done  
for hundreds of years ignores the fact that quality control, and the  
causal

relationship of the effects of yeast metabolism and bacteria upon  
spoilage  
(the universally hailed work of one Louis Pasteur) mean nothing.  
Obviously  
spoilage WAS a problem or there would have been neither a call for, nor  
support  
for Pasteur's work.

So I say to those who would begin to employ these techniques and cast off  
the lessons of the last 100 years of microbiology that they take a step  
backwards in casting the quality of their beers to the whims of nature  
and  
bacteria. Yes perhaps you've had no problems to date, but that does not  
guarantee future results, rather it increases the chance of exposure to  
the  
same pitfalls of bacterial damage to ones beer that brewers for centuries  
before Pasteur were subject to. The techniques to reduce the risk of  
bacterial  
contamination are hardly complex nor excessively costly, yet the  
reduction of  
risk of spoilage by bacterial contamination justifies their use as surely  
today  
as 130 years ago when Pasteur discovered these causal relationships.

I step down from my soapbox now.

JaH

**Subject: Hop Tea**

Someone recently mentioned a recipe for Hop Tea - I think it involved malt and hops. Does anyone have details on this, or indeed any other recipes (other than beer) using hops?

Regards,

Colin Carruthers. cc@ee.ed.ac.uk. Tel +44 31 668 1550.

Subject: Cranberry Ale

Hello:

This is my first posting to the board so if this is ancient material, you have my apologies. Secondly let me say in advance that I've learned a lot so far and would appreciate any responses.

1. Working all day makes it difficult, but not impossible, to brew during the week. I have, on a few occasions, however had to let the wort sit covered over night before the boil. I am assuming that nothing nasty that could harm the ale could survive the boil... Am I missing the boat here?

2. Last fall I made a Wheat/Cranberry ale, loosely based on the recipe used by Sam Adams:

5# wheat  
6# 2 row  
3.3# BME Weise beer kit  
6 12 oz. bags of whole cranberries (crushed)  
7 AAU's Tett. Hops  
41 oz Pure Vermont Maple Syrup  
DME Ale yeast

Primed with 1 cup maple syrup

I wanted to make this again this year but could use a little advice in altering the recipe. First the ale was very very hazy. Is this a function of the wheat or perhaps pectin in the berries? Secondly the ales were very volcanic when opened. Is this a due to the wheat as well, or perhaps too much maple syrup... By the way S. Adams was much better.

Thanks in advance.

Subject: adding egg white: to clarify

Hi.

i tried to use egg white (albumin) to clarify my brew three or four batches ago, when (for some forgotten reason) the secondary fermentation was too cloudy

i took 2 cups of wort from the fermenter and boiled it, adding egg white as if

making egg drop soup, with a lot of stirring. After cooling rapidly, i tossed the

whole soup (without a taste test :- ) into the secondary. After two days, the

beer was clear!! i haven't tried it again, as i haven't needed to.

This method was suggested by a Bulgarian friend who says that this is fairly common in his country in home wine making, which it seems, is a fairly

common practise in Sofia. Their apt. complex has a basement converted into a

cooperative wine crushing setup... !!

From: bgros@sensitivity.berkeley.edu (Bryan Gros)  
Subject: adding egg white: to clarify

Here's my latest batch. my third, and first partial mash.

Alcatraz Wheat Beer

1 lb Barley malt  
2 lb Wheat malt  
3 lb dried wheat extract  
1 lb dried malt extract  
2.5 oz Mt. Hood hps  
Wyeast Wheat beer yeast

OG: 57 FG: 12

I mashed the three pounds of malt a la Miller, and had no problems. I boiled for one hour, adding 1.5 oz hops at the start, 0.5 oz at 30 min, and 0.5 oz at 5 min. Strained into a bucket of ice, but still had to wait several hours for it to cool (shoulda used the bathtub).

I made a starter for the yeast a couple days before (liquid yeast, another first). added it and the wort to the carboy and waited. The krausen didn't seem as big as previous batches with Red Star.

I primed half the batch(5 gal) with 1/3 cup corn sugar and the other half with 1/2 cup clover honey. After two weeks, the beer was great. the beer primed with honey, however, was way too carbonated. All you can taste is bubbles.

In direct taste tests, this beer has more body than WheatHook, and is slightly sweeter. Compared to EKV, the beer is similar, but EKV Wiezen is slightly sweeter.

If anyone wants to add this to Cat's Meow vol II, feel free. Thank you to all who helped me, especially Martin Lodahl.

Subject: Mead at brewpubs

Last Friday, I had a very pleasant surprise. My group decided to have an off-site meeting at the Wyncoop brewpub in Denver. While they were scrambling around trying to find a table for the lot of us, I took a look at the list of seasonals that were currently available. Lo and behold, they had an alfalfa mead! I had to have some, of course. Although not quite the style I like (I prefer still meads), it was still quite good.

So, my question is, how many times have you (that's the collective you, kind of like the royal We) seen mead at a brewpub? Was it a regular feature?

-----

during the last 20 mins. I like the idea of making coffee and just adding it more than either boiling beans or "dry coffeering". I haven't brewed this yet either, but suspect I'll try a hybrid of the two. I really like the idea of a little vanilla.  
BTW - I don't remember who sent this recipe in.

-----  
Here is a recipe that I have used several times now with excellent results.

It's an extract with adjuncts brew but I don't let that bother me. The Sierra Nevada yeast culture is not terribly attenuative and the last batch was a bit sweeter than I'd prefer. Next time I'll use Wyeast's Irish Stout Yeast that Florian and others have recommended.

This is based fairly on and is still very close to "Baer's Stout" from Dave Baer of Sun.COM. I call it "Speedball Stout".

4oz Flaked Barley  
4oz Medium Crystal malt

6# Dark Australian malt extract  
1/2# Dark Australian dry

4oz black patent malt  
4oz molasses

2oz cascade (bittering) at 4.7 AAU  
0.6oz northern brewers (aromatic) ? AAU  
1/3lb Coffee, whole bean (I use Peet's Costa Rican, a fairly dark roast)

We've been using a Sierra Nevada yeast culture for the last few batches and it's been a very nice brew. Prestarted Wyeast British Ale yeast has worked well also.

OG: 49 - 51  
FG: 17 - 20

Fermentation temp: 55 degF though I've done it much hotter.

Steep 50 minutes at 153 degF: flaked barley and crystal malt

Boil 90 minutes.  
Add black patent and molasses at 45 min.  
Bittering in thirds each 30 min.

Fill a hops bag with the coffee and aromatic hops and add to the hot wort just before chilling. If you don't have a wort chiller you'd better wait until pitching. Remove the bag after about 24 hours or when the fermentation is going strong, whichever is longer. Rack to secondary once initial fermentation has died down, about 5 to 6 days. The last couple of times I've left the bag of coffee beans and hops until racking without over doing the coffee flavor. This cuts down on the potential for contamination.

Subject: Oops: raspberry mead and pectin

Re the message I sent a couple days ago about raspberry mead, I just remembered another step. He added something (an enzyme of some sort) to the raspberries to degrade the pectin. This is why they had to sit around for 24 hours before pouring the honey "wort" over them. This would probably also solve the problem doug@bitstream.com reports with his cranberry beer. Does anyone know what this substance might be?

Subject: Re: Chrishmash (hic!) Ale, corrected recipe

>3pounds Munton and Fison amber dry malt extract ] ?? Typo ??

I checked with Phil Fleming, this is the correct recipe:

Ingredients for 5 gallons

3.3 pounds Munton and Fison Stout Kit

3.3 pounds Munton and Fison amber malt extract syrup

3pounds Munton and Fison light dry malt extract

1/2 ounce Hallertauer hops (60 minutes)

1/2 ounce Hallertauer hops (5 minutes)

3/4 pound honey

53-inch cinnamon sticks

2teaspoons allspice

1teaspoon cloves

6ounces ginger root

6rinds from medium size oranges (scrape the white insides of the  
rind away)

Wyeast No. 1007 German ale liquid yeast

7ounces corn sugar for priming

\*O.G.: 1.069

\*T.G.: 1.030

\*Primary fermentation: 14 days @ 61 degrees F.

\*Age when judged: six months

#### BREWER'S SPECIFICS

Simmer spices and honey (45 minutes). Boil malt and hops (50 minutes).

Add finishing hops and boil (5 minutes). Cool, strain and pitch yeast.

[Note: It's not made clear, but the honey/spice mix is added to the wort  
just before cooling, they're not boiled together.]

From: csswingley@ucdavis.edu  
Subject: Yeast at bottling

A quick question relating to adding yeast before bottling. Three and a half weeks ago I brewed an all-grain porter based on some of the past winners in Zymergy. Now three and a half weeks later (or three weeks in the secondary fermentor at 70-75 degrees F) it is still bubbling. This doesn't really concern me as I've had beer sit that long before. But what I've also had happen with long times in the secondary fermentor is the beer once primed and bottled, doesn't get carbonated. It's a real drag having two cases of pale ale that have no carbonation, let me tell you.

To my question: Miller advises against adding yeast with the priming sugar because that would increase the amount of yeast at the bottom of the bottle which could lyse. He says that even if you let your beer clarify quite a bit in the fermentor there will still be enough yeast in the beer to carbonate it upon adding more sugar. Is he right? And has anyone else experienced this no-carbonation phenomenon? The only explanation I can come up with to explain why my pale ale remains uncarbonated to this day is that I killed the yeast somehow--or that it all settled out before bottling.

Anyhow, in the next couple weeks I'm sure my all-grain porter (which took 8 hours to brew) will stop bubbling. Let me know what you all think about adding yeast before bottling.

Thanks in advance.

From: John D. Sullivan.wbst311@xerox.com  
Subject: DIGEST SUBMISSION

Reply to David Ballard (beer ball kegging)- my dad has been using 5 gallon beer balls for some time now, and has had very good luck. The tap uses a CO2 cartridge similar to a pellet gun (good or bad idea? The beer tastes excellent.) You have to replace it once, when the keg is half full.

Reply to Dave Resch (saaz hops) - As with all hops there are variables . I have some whole compressed saaz hops packaged right from Czeckoslavakia (sp?) with an alpha of 3.2. By the way, they are heavenly finishing hops.

Reply to Pat Patterson (Papazian's Rocky Raccoon Crystal Honey Lager) - I agree this is an excellent, easy to make beer. I tried honey in an amber beer, and would recommend sticking with lights. My next Honey Lager I will prime with 1/2 cup honey, should be good.

> cooled wort to the keg. Unless perhaps you use a counter-flow rather  
than  
> immersion chiller. Any comments, Marc?

I assume you meant "cooled wort to the CARBOY"?

I immersion-chill in the boiler (usually emptying all the icecube trays in the freezer into the boiler as well!) and then strain the 70 degree wort into a big plastic bucket (recently washed with dish soap) with a plastic spigot near the bottom.

I strain by fitting a fine-mesh nylon straining bag into one of those handled stainless steel colanders. The straining end of the colander has two inch-long metal loops protruding from the edge. I rest the strainer atop the bucket on the handle and the two protruding spurs. Then I ladle the cool wort into the strainer. Trub quickly slows the process to a trickle. If I'm in a hurry I can complete the process in five minutes by squeezing the straining bag and emptying the trub once or twice, but that results in a less clear wort.

Then I just drain the wort into the carboy, which already has a pile of happy yeast at the bottom waiting to make beer!

Or do you mean "BEER to the keg"? I just run warm tap water through the siphon hose for a minute or two before and after each time I use it.

Regarding my abandonment of commonly accepted sanitary practices and my ongoing experiment in carrying repitching \*way\* too far :-), I'm no microbiologist, but I am a beer drinker. My beer pleases me and my friends (and sometimes even my wife :-), and that's all I'm after.

I'm sure there's all sorts of bacteria in that carboy and that there are subtle things going on in those unwashed bottles too (I run used bottles through the dishwasher and reuse them as-is during the next bottling session), but I've had no mold in the carboy or gushing bottles or anything obviously wrong with any of my batches.

I homebrew for the fun of it. Aspects of it as it is commonly practiced are unpleasant to me. I don't like worrying about stuff I can't see, and I especially don't enjoy getting bleach water all over my skin. Rinsing 50+ bottles or baking them or whatever everyone else does turns an already noxious task into a grueling ordeal.

I also don't like paying \$4 a pop for yeast -- I don't use extracts for exactly the same reason -- \$25 a batch is way too much to pay when I can brew from grain for \$8. Besides, of all brewing tasks, mashing is definitely the most fun for me. Turning dry grain into sweet wort is magic!

I'm not suggesting that any of you do anything different. I'm just sharing my personal experience. Take what you like and leave the rest.

From: GC Woods <gcw@garage.att.com>  
Subject: NJ homebrew laws

>From: Bob Hettmansperger <Bob\_Hettmansperger@klondike.bellcore.com>  
>A) I understand that brewpubs are currently illegal in New Jersey (as is  
>homebrewing apparently). Is there any effort currently underway to make  
>them  
>legal? Anyone know who to write to? Anyone have any information on  
>micros?  
>I know that there is one in Vernon, but that's all I know about. Are  
>micro  
>licences hard to come by?

There is presently a bill (A-114) currently before the NJ legislature to  
make homebrewing legal and to remove the permit (\$3) for making wine.  
This saga however has been going on since 1986 and every previous bill  
was never voted on, so it dies and must be reintroduced during the next  
meeting of the NJ Legislature (every 2 years).

The current bill (like the old ones) is sponsored by Art Albohn (NJ  
State Assembly representative - if anyone is in his region please vote  
for him!) who is a friend of my brewclub president (Ed Busch MASH). One  
of  
the problems is the head of the ABC (Alcoholic Beverage Control) has  
been replaced and the new person amended the bill adding permit  
requirements (must be a democrat). Ed has testified many times now and  
the bill has also now picked up support from the Libertarian party  
because it "enhances personal freedom", but they do not agree with the  
permits. Anyway the bill passed the state senate (36-0) , so now goes  
back to the assembly for another vote. The problem is that another vote  
is not scheduled in the assembly, but hopefully they will vote on it  
before it is left to die again.

My person opinion is that they are out of their minds if they think I am  
going to pay for a permit in the Peoples Republic of NJ!!

Now for the big laugh - the current law defines wine as "any fermented  
vegetable". So if they consider grapes to be a vegetable why not barley  
and hops. The only problem is that none of us want to be the test case,  
so our brewclub keeps a low profile.

I do not know why there is only the one micro in NJ. Should have asked  
when I was there for a tour. By the way the micro is now called Clements  
and they now make good beer (unlike vernon valley) - in fact the blond  
dopplebock was excellent. The micro uses antique equipment imported from  
Germany, in fact the beer is still fermented in open oak barrels.

When if ever Homebrewing becomes legal in NJ, then the next plan of  
attack will be for brewpubs. Micros and brewpubs are much harder to get  
through state legislatures because the big mega breweris will lobby to  
prevent this from happening. It is hard for the little guy to fight this  
kind of vote buying!

From: microsoft!larryba@cs.washington.edu  
Subject: Headless Christmas Ale

A month ago I brewed a Christmas ale based upon the recipe passing around this digest last summer. I converted the extract into an all grain (sorta a porter with honey + spices, lightly hopped)

Anyway it is GREAT. The only problem is that it has a nice creamy head that collapses pretty fast. Even though it is pretty well carbonated it takes vigorous pouring to get a head to rise. Why?

My guess is that the problem is the oils from the Orange Zest and possibly the cinamon/cloves/allspice.

Anyone else notice this with their spiced beers?

From: eisen@kopf.HQ.Ileaf.COM (Carl West)  
Subject: pot handles, groats&egges, cranberry clouds, sanitation

Pot handles

Sorry Lee, if the handles come off they \*can\* be welded back on, but it won't be an enameled pot anymore, the enamel will spall off because of the heat from the welding. Oh well, save up for that \$stainless \$steel.

Groats &c.

Length is generally the measure of the greatest dimension of an object, breadth is the measure of the next largest dimension, thickness is generally the measure of the least dimension. Digby says specifically, "the breadth of a groat". Do not confuse breadth for thickness. The medievalist cooks I know are also known for their research and in their estimation, according to paintings where they have found egges rendered next to objects of known size, the medieval egge is about the size of our medium hen's egg. To make a strong mead, boil it until a medium egg floats with a 28mm circular area exposed. Seems like a VERY high gravity to me. I wonder if groats were still 28mm in 1669?

Cranberry Clouds

If the berries were in the boil, that would be the root of the haze problem. The volcanism? doesn't sound like overpriming. Maybe premature bottling? otherwise benign infection?

Sanitation

Well, I've tried the less anal route to sanitation and it isn't working for me. Anybody want some Relief Owl Beer? I think my problem is that my town's water is untreated local well water, no chlorine. From here on in I'm boiling it all.

Carl West

I'm still learning, don't bury me yet.

From: chad@mpl.UCS.D.EDU (Chad Epifanio)  
Subject: Bucket 'o flame

Concerning Bob Jones' remark about carboys:

I've never truly flamed before, but Mr. Jones is just plain wrong. How can you make that absolute comment about carboys over plastic? I personally started with both 6.5 gal and 5 gal fermenters in a two stage setup. I personally thought these things were a pain in the ass. They take so long to fill and rinse, and if you get a stain, kiss goodbye to several hours and say hello to a pain in the back.

>I would ask you how many awards have you won with your beers?

To be honest, I'm 0 for 0. I entered none, since I brewed all my previous batches hours from any club or competition. Upon moving to San Diego, I met a man by the name of Bob Writner who convinced me of the merits of plastic primarys. Yes, he has won a few medals. They filled up an entire wall. The ones that wouldn't fit on the wall, he put in boxes in the basement. He is also consulting brewmeister to Temecula Brewing Company. I would drag him in here to defend plastic, but he is away on a research experiment. Like all of us, he has a real job on the side :>

Plastic is so much easier to use. They are lighter, and you can haul them around easily by the handle. After the boil, just dump the wort through a strainer, reserving some of the cold break matter in the kettle. It airates fine as it splashes into the bucket. To sanitize, just fill with a bleach solution and rinse with the garden hose. If you want to save some yeast, just stick your hand down there and grab a cup. I even converted my priming bucket so it can be used as a fermenter in those emergencies when I have to make more than 10 gal at a time.

I would recommend a beginner use a glass carboy, just for the sheer enjoyment and amazement of watching the process. Also, the beginner can clearly see the yeast sediment and activity stop. The bad part about plastic is that you can't see any of this going on.

Relax. Use what you feel most comfortable with. I like the plastic, and save the glass for the lagging.

Date: Wed, 23 Oct 91 14:20:20 PDT  
From: Martin A. Lodahl <hpfcmr.fc.hp.com!hplabs!pbmoss!malodah>  
Subject: Yeast Repitching's Risks

I was interested to see Bob Jones and Jay Hersh address so well the risk of bacterial infection in repitched yeast, and I'd like to toss in my goat's worth. Reading the standard references and discussing the question with brewing microbiologists has convinced me that even if a brewer is able to keep the bacteria under control, there is a limit to how many times a culture can be repitched, if large pitching rates are used. The reason is respiratory-deficient (petite) mutants. This is apparently a heritable mutation: daughter cells budding from a respiratory-deficient mutant seem themselves to be respiratory-deficient. In fact, the name (given by Pasteur) arises from his observation that certain single-cell cultures on a streak plate were smaller than others, due to their inability to exploit an aerobic environment. It spontaneously occurs at a more-or-less constant rate (which I've forgotten) in non-mutant cells, so as you can see, the long-term trend under anaerobic conditions is toward the mutants becoming an increasing fraction of the population. The result is slowed and stuck fermentations, incomplete attenuation, and increased production of diacetyl and other usually-avoided products. Commercial practice seems to be to periodically regenerate the culture by growing several successive generations under aerobic conditions, allowing the non-mutants to use their substantial reproductive advantage under aerobic conditions to "regain the upper hand" in the culture. We just buy another packet of Wyeast ...

Yes, continually examining our process and testing "heresies" is a very good thing, but I think it's a mistake for us to automatically reject what the "pros" do, because we don't much care for their beer. I assure you, it doesn't taste that way by accident (malicious intent?). For them, it's critical that every batch be saleable, so they've developed very elegant means of assuring such a result. Our question then becomes one of whether a specific technique is appropriate to the specific results we desire, rather than whether it's a conceptual breakthrough or a colossal blunder. I'll step down off the soapbox, now ...

Date: 23 Oct 91 19:38:18 EDT  
From: Jeff Frane <70670.2067@compuserve.com>  
Subject: Notes on Recent Digests

I've been out of town, and came back to a nice big stack of Homebrew Digests.  
(Although I can't seem to find one numbered 744; anyone got a spare?) As others commented, the time it was missing was not unlike an unmasked-for withdrawal from a happy addiction.

On the question of beginner brewers and books, etc. and more specifically, on Dave Miller: I don't have a copy of Miller's book in front of me, and it's been several years since I sat down with it. My specific objections which leap immediately to mind have to do with his advice for new brewers and a general distrust of his--to my mind--entirely too facile recipes. In spite of Martin Lodahl's apparent success with starting a siphon with his mouth, I think it's a very poor idea. Much prefer Lee Katman's suggestion of pre-filling the siphon; myself, I use a turkey baster to suck on the hose for most siphons and the pre-filling method to start the flow through the wort chiller. Miller also offers as his beginning recipe an American light lager (with rice syrup? as I remember, or anyway rice), which strikes me as patently ridiculous. I have always tried to get brewers started on a very straightforward and flavorful ale, not only because it's easy but because it's fairly opaque to error.

I will say that I thought some of his more technical information was very well presented. JaH recommends Byron Burch's book. I haven't looked at that in quite a long time but remember not being particularly impressed, in spite of Byron's expertise. I included a list of brewing texts in my beginning brewing class and at that time, several years ago, wrote this: Although Byron knows a lot about homebrewing, the book isn't very well organized; Bryon has trouble knowing what a brewer needs to know and when he or she needs to know it. He does touch on all the important parts, though, and the book has the virtue of being very inexpensive.

I recommend Papazian's book to new brewers, mostly because of the organization: a very simple beer, followed by more information and a more complex brew, and finally, all-grain brewing. It seems most logical to me, and the simplest, in spite of a few problems.

One of those problems, which didn't get corrected in the latest edition, is the blowoff tube. ^^James Smith^^ ran into this problem, I think, in his spruce beer. "My blowoff hose plugged with hop bits, and foam hit the ceiling.. ." I know of one fellow who blew his carboy all over the kitchen when the hop bits plugged the blowoff hose. The illustration in the new edition still shows a small diameter hose pushed into a drilled rubber plug. James, is this what you used? If so, throw it out and get a 1" o.d. hose about 4' long. As far as I can tell, this is impossible to plug and will not cause explosions from vigorous fermentation.

Eric Allen asks about Bass Ale: I think your friends are on the right trail, but too far past the fork in the road. 50% brown sugar is **\*\*WAY\*\*** too much. Martin Lodahl seems to have a handle on using sugar to achieve a cidery effect, but I don't think that's what's called for in Bass. My feeling from reading British brewing texts is that they only use enough to substitute for the more expensive malt while remaining undetectable in the finished beer. I definitely wouldn't wander above 5-10% and would add plenty of crystal malt and a touch of roast malt (chocolate) to help disguise the sugar.

Martin Lodahl: I tried adding turbinado sugar to a Scotch ale, myself, and wasn't pleased with the result. In fact, I've yet to have a convincing homebrewed Scotch ale, and suspect the wily northerners use a very aromatic malt I haven't been able to track down. Your idea of using peat-smoked crystal malt is an interesting one; I'd love to taste your beer.

Thomas Manteufel posted some early recipes including one that was mostly molasses. I had the (?)fortune of tasting a similar beer that Fred Eckhardt brewed from a George Washington recipe. I would imagine that vulcanized rubber has a similar flavor. It was about five years old at the time, and Fred said it had improved considerably over the years.

Thanks to George Fix for the usual amazingly informed words on wort oxidation. At times, it embarrasses me to open my mouth around him (figuratively, of course) because I'm sure I'll say something stupid. But George, how come there are no spaces after your sentences?

There's a good deal of talk about repitching yeast. In a praiseworthy comment on the importance of good sanitation, Bob Jones suggests that homebrewers lack the

capacity to wash yeast. In mid-September I posted some notes from WYeast's Dave Logsdon on how to wash and store recaptured yeast; I hope everyone has gotten that because its very simplicity makes it extremely useful.

Dave Resch mentions previous discussions about the use of Cara-pils or dextrine malt and the conversion of the contained dextrans to simple sugars. My understanding is that this is the whole point of dextrine malt--that mashing did NOT affect this conversion. My experience has been that dextrine malts make a significant difference in beers, heightening the malt flavor and increasing mouthfeel considerably. Could we hear something authoritative, perhaps from George Fix? Hint, hint.

Rick Hapanowicz asked about his fermentation problem. It's difficult to say what happened, without more information about yeast, but I would imagine that the initial problem had to do with either underpitching or a lack of oxygen in the wort at the time of pitching. I don't think simple repitching would help, nor that adding oxygen at this stage would be a good idea. My own suggestion would be to brew another batch of beer, aerate the hell out of it, pitch with a vigorous yeast starter, and then blend the two when fermentation in batch #2 was at high krausen. Worth a try, anyway.

I follow with interest the discussions of coffee/beer. Liz has been after me to make a coffee beer for awhile now, and we've been exploring the wonders of fine coffee and espresso together. Mostly, Liz does the drinking, since I'm a tea man (but a cafe mocha, hmmm) but I'm fascinated by the process of making good coffee and the differences in styles between the East and West. I shall root around in the documentation I've found and see what they say about cold- and hot-water extraction. Interesting that Rad Equipment's retailer offers a cold-water "Turkish Extract"--since the Turkish method is to \*boil\* the coffee grounds \*with the sugar\*! What do the coffee oils do to head retention in the beer? ??

No, you were doing fine. I just bought Saaz "whole hop plugs" from Great Fermentations of Marin, and they were labelled as 3.1 % alpha acid. BTW, the degree of compression obtained in these plugs is unbelievable! From a package about the size of a pack of cigarettes (ugh!) I ended up with a heaping colander full of whole hop blossoms! The aroma was very good, but I won't taste the results for several weeks yet. (Czech Pilsner).

Cheers,  
Mark Sandrock

Date: Wed, 23 Oct 91 22:37:35 -0700  
From: John S. Watson - FSC <watson@pioneer.arc.nasa.gov>  
Subject: Report on Number 23

This a report on my second use of "maltose" (a cheap rice malt available from most Oriental Markets). In the previous attempt ("Number 17", see HBD #541 or The Cat's Meow: p 36) there were a few problems. It was also my first attempt at culturing yeast (from a Sierra Nevada Pale Ale), and for various reasons, it didn't work very well. The other problem was I used to much maltose, about 40%, which made the result a little to light.

This time I decided to use about 20% maltose, which IMHO, is just about right. I've also since perfected yeast culturing.

The result is a nice thirst quenching, summer ale, which, with my favorite pizza, is heaven\*2.

\* \* \*

Ingredients for 5 gallons:

4.0 pounds plain light malt extract syrup  
1.1 (750 grams) Maltose

0.66 oz Chinook Hops, flower, ( boil: 1/2 for 60 minutes, 1/2 for 30 minutes)  
0.33 oz Cascade Hops, flower, ( finish: last 2 minutes of boil)  
0.50 oz Cascade Hops, pellets, ( dry hopped: when transfered to secondary )  
Ale Yeast, cultured from Sierra Nevada Pale Ale,  
Corn sugar (3/4 cup) at bottling

Aug. 4, 1991 ... Culturing.

Started SNPA yeast culture (from 2 bottles) and about 4 tablespoons of plain light malt extract syrup and a couple hop pellets.

Aug. 11, 1991 ... Boil.

Boiled major ingredients, ala "Complete Joy of Home Brewing", in 2 gallons of water. Then combined with 3 gallons of ice cold tap water (which was boiled the previous night, and cooled in the freezer) in a 7 gallon carboy.  
Initial gravity:  
1.036 at 74 degrees F

Since the temperature was cool enough, I pitched the yeast immediately.

Aug. 18, 1991 ... Secondary.

Vigorous fermentation over the week.  
Placed 0.5 oz of Cascade pellets at bottom of secondary, before I siphon in the beer.

Sept. 8, 1991 ... Bottling.

Final gravity:  
1.006 @ 69 degrees F.  
Taste: Excellent!

Yield = 49 12oz bottles  
= 588 oz

Percentage Yield =  $588/640 \times 100\%$   
= 91.2%

**Subject: Bad Burst**  
Full-Name: Curt Freeman

Now that I whetted your appetites with that empty message the other day, here's my problem...

I went to burst the inner lump of my Wyeast package, and the seal at one end of the outer package opened instead. Just a very small leak, but of course it renders the package useless for the initial "puffing". The inner package didn't seem to burst, and since I don't have yeast leaking all over my 'frig, I'd say it is intact. So, at the risk of loosing an extended "best-way-to-burst-liquid-yeast-packages" debate, how should I start these yeast beasts?

From: ml4051@mwvm.mitre.org (John DeCarlo)  
Subject: Re: Brewing Practices

OK, I couldn't resist getting on my own personal hobby horse and ranting and raving once again :-). Just consider yourselves lucky not to have to experience this in person :-).

Beer is a product of heredity and environment. Heredity refers to the ingredients and their quality. Environment to the brewing process and where/how it takes place.

For new brewers, you can tell them a lot of very useful information about the heredity of a beer, but the environment is often a big unknown.

For this very reason, \*I\* (IMHO) consider it extremely important to emphasize sanitation to the new brewer. While you cannot control the microflora and microfauna, the ambient temperature (and fluctuation therein) the quality of the air and water, etc., you can be fairly confident in telling people that if they do a rigorous job of sanitizing everything, follow a good brewing procedure, and use good ingredients, they will end up with good beer.

Now, I can say that I know my environment pretty well. I can often tell from listening and looking at my beer what is happening. I detected a stuck fermentation without the use of a hydrometer (used it for confirmation) because of just noticing that something felt wrong about the fermentation. Is this useful to anyone of you? Probably not. Would I be able to explain it to a new brewer in a useful manner? No.

In conclusion, there are things I do nowadays that I wouldn't recommend to anyone else. All I can say to justify it is that my beers are improving as far as club competitions and my limited palate can attest to. This is how I view all the other similar brewing stories being told--mildly interesting should I want to perform my own tests, but probably a product of a specific brewing environment as well as increased attention to non-obvious signs from the beer.

**Subject: Fermenting vessels**

After listening (sic) to the discussions about plastic vs glass, I had a thought (A thought? We'll have none of that now!). I believe in the sanitary aspects of glass, and would like the conveniences (I have never used plastic) attributed to plastic. So...why not a large battery jar (is that the right name? It's been a long time since chemistry class). It is essentially the same thing as a plastic bin, but in glass. It would be very heavy, and probably expensive, and would be interesting to handle, but it has the best of both options.

Then there is the matter of a lid...

Cheers...Gary

Subject: Starting a Siphon

In regards to starting a siphon. I saw it on the HBD before: just use a sanitized funnel and then remove it as the flow starts--then put the hose into your carboy.

In regards to the use of a dishwasher for bottling. Whomever suggested that should get a medal. It saves a lot of time and is great if you happen to spill any beer. I highly recommend it (if you have a dishwasher)

From: orgasm!davevi@uunet.UU.NET (David Van Iderstine)  
Subject: Making Hard Cider

I'm making my first real batch of Apple Jack (that is, purifying it & then adding yeast, as opposed to just letting it sit as it comes) and I'd like to get some advice on a few points--well okay, many points.

First, what are the opinions regarding the different sterilization options? There's boiling, steeping, and sulfites. I went the potassium metabisulfite route for this batch, at about 60 ppm.

Assuming sulfite sterilization, how long should the cider sit before pitching the yeast? And what about yeast choice? Adjuncts? Yeast nutrients?

Then how often should it be racked, and is it necessary to perform any further sterilizations, or maybe additives for clarification? Finally, how long should I wait to bottle the stuff, and should I prime it, a la wort, for a carbonated product? WHEW!

Thanks in advance. Now deserve it!

Thanks, Marc. Good advice for life, really.

As far as beer goes, I've got a question to pose to the net. Has anyone ever had a batch turn darker \*during fermentation\*??? I brewed an Apricot-Ginger Ale a fortnight ago, putting the apricots in the wort after the boil, while the wort was still quite hot. These were canned apricots, in a heavy syrup (I didn't use the syrup) and, as far as I could tell, there were no preservatives in it. The brew is an amber ale with lots of crystal (3 cups) added. After carboying it, it appeared to me to be a nice deep amber, with a slight red tint to it. I racked it after three days, getting the fruit off of it. The colour looked normal to me then. A few days later, it appears to be much darker, on the order of a brown ale. Have I had too many homebrews? Has anyone seen anything like this?

I plan to bottle in the next few days, but not before a taste-test.

Norm

Subject: Re: Homebrew Digest #747 (October 24, 1991)

>In reply to Chad Epifanio's question : I would ask you how many  
>awards have you won with your beers?

The answer to this question is about 35, (I didn't think anyone would ever ask) but then again who's counting. I've been brewing for 13 yrs. Not that I think I need to justify myself to you, but there are a lot of beginning brewers who read HBD and I think they should get the most generally excepted advice from experience brewers. Your experiences with brewing in plastic may work for you and your friend, making beer you and your friend enjoy, however it won't stand as "State of the Art Brewing Technique". Most of brewing technique is tradition based on hundreds of years of trial and error. It's good to experiment with new ideas and techniques, just be careful to state them as such. Your signature trailer said it so well.

"There are no bad brews. However, some are better than others."

Date: Thu, 24 Oct 91 14:21:37 EDT  
From: tix!roman@uunet.UU.NET (Daniel Roman)  
Subject: NJ state laws

Bob Hettmansperger asks about NJ law and brewing:

Well Bob, here is what I know, the current New Jersey law allows residents to make 200 gallons of WINE a year for personal consumption with a \$3 permit. Because beer making is not specifically mentioned, it's considered forbidden according to State Division of Alcoholic Beverage Control Director Catherine Costa. Nobody has ever been arrested however. Their view is that they have other priorities.

I am not sure of the current status of new laws, but there were two bills floating around a few months ago which would change the status. One would have allowed up to 100 gallons of beer or wine a year without a permit and 200 with a permit. That seems to have been dropped and replaced with one that requires a permit for up to 200 gallons of beer or wine. I don't plan to get a permit either way. I think it makes more sense to be in line with the federal regs but then I'm not a politician. For what it's going to cost NJ to issue and track these stupid permits it'll probably cost them 100 times the cost of the \$3 permit. I'm going to save the NJ taxpayers some money and (continue) to ignore it. I'm not sure of the current status, but it might have been passed by now. Assemblyman Albert Albohn from Morris County is the sponsor. I don't think he is a homebrewer.

I don't have any info on brewpubs but if they allow breweries, micros, and bars that sell beer I don't understand why no brewpubs, but like I said I'm not a politician (or a lawyer).

From: tomm@pet.med.ge.com (Thomas Manteufel 5-4257)  
Subject: More old receipts

Hello again, fellow history lovers.

As promised, here are some more old homebrewing recipes. I received quite a few requests for them. More readers than we realize are interested in living history. Some things to remember: Spelling rules were followed rather haphazardly, as were punctuation. I have entered these recipes as closely to the sources I got them from as I could. Bear is Beer, Pompion is Pumpkin. Most of the recipes use unknown or uncertain units, and are probably more of historical rather than practical interest. Some of the terms I don't understand, such as "seen to break" in the Green Corn Stalk recipe. Anyone have any ideas? Could it have something to do with the capillary tubes the wine makers use to measure alcohol? Small or Strong refers to a beer's strength. Small beer was not seeped in the grains for as long, and was meant to be drunk as soon as it fermented. Think of it as (gag) light beer. Strong beer required aging before it could be drunk. It had a higher alcoholic content. Most of these recipes are from the book "Brewed in America" by Stanley Baron. The Persimmon Beer is from the "Old Timey Receipts from Appomattox: The Heart of Virginia" by the National Park Women (of Appomattox). Enjoy:

Receipt to make Bear

Major Thomas Fenner, early 1700's

One ounce of Sentry Suckery or Sulindine one handful Red Sage or Large 1/4 Pound Shells of Iron Brused fine take 10 quarts of Water Steep it away to Seven and a quart of Molases Wheat Brand Baked Hard. one quart of Malt one handful Sweeat Balm Take it as Soone as it is worked.

Translated into modern English, the recipe is most likely:

Recipe to make Beer

One ounce of the dried leaves of the senna tree, chicory, or celandine. One handful of red sage or crushed 1/4 pound shells of iron [which may be the hop-like fruit from an ironwood, *Ostrya Virginica*, also known as the hophornbeam. The ironwood is known as hophornbeam because the fruit it produces look so much like hop bracts, unlike the fruit of the American Hornbeam, which don't.]  
10 quarts of water, boiled down to seven.  
A quart of molasses.  
A cake of hard baked wheat bran.  
A quart of malt.  
One handful of barm. [brewers yeast cake from a previous batch]  
Drink it as soon as it is fermented.

Col. George Washington's Small Beer (1737)

To Make Small Beer

Take a large Siffer [Sifter] full of Bran Hops to your Taste. - Boil these 3 hours then strain out 30 Gall[ons] into a cooler put in 3 Gall[ons]

Molasses while the Beer is Scalding hot or rather draw the Melasses into the cooler & St[r]ain the Beer on it while boiling Hot. let this stand till it is little more than Blood warm then put in a quart of Yea[s]t if the Weather is very Cold cover it over with a Blank[et] & let it Work in the Cooler 24 hours then put it into the Cask - leave the bung open till it is almost don[e] Working - Bottle it that day Week it was Brewed.

#### Pumpkin Ale

An anonymous recipe for pumpkin ale appeared in the papers of the American Philosophical Society in February, 1771. The author notes that he obtained this recipe from someone who claimed this tasted like malt ale, with only a slight "twang". After two years in the bottle, this twang had mellowed to an acceptable level.

#### Receipt for Pompion Ale

Let the Pompion be beaten in a Trough and pressed as Apples. The expressed Juice is to be boiled in a Copper a considerable Time and carefully skimmed that there may be no Remains of the fibrous Part of the Pulp. After that Intention is answered let the Liquor be hopped cooled fermented &c. as Malt Beer.

#### Directions for Brewing Malt Liquors

>From the letters of Joseph Clarke, general treasurer of the Rhode Island colony, sometime around 1775.

You are first to have ready the following Implements, a mash Vat, to put your malt in; a Vessel under this to receive the Wort in; a Copper to boil in; a Rudder to stir your malt with, and Vessels to cool your Liquor in;

First then fill your Copper with water, take then 6 Bushels of Malt and put into your mash Vat, leaving about a Peck to sprinkle over the Liquor when in, Let your water simmer, and be in the next degree of boiling but not boil; lay it on upon the Malt well ground, and when you have laid on such a quantity as you can draw off a Barrel of Wort, stir the malt well together with your Rudder; and then sprinkle the remaining Peck of Malt over all covering it up with Cloths to keep the heat in; for three hours; only when it have stood an hour and half draw off a pail full or two; and lay it on again to clear your tap hole.

This done the next Business is to boil a Copper of Water, to scald your other Vessels with; always taking care to have a Copper of Liquor hot to lay on, upon the malt when you draw off the first Wort, and this will be for small Beer.

The three hours now expired; let go (as the Term is) which is let the first wort run off, putting into the Vessel which receives it a pound of Hops; when all drawn off lay on the hot Liquor for your small Beer, clean out your Copper and put the wort, Hops and all into the Copper and boil it for two hours; strain it then off thro: a Sieve into your Vessels to cool it; and put your small Beer into Copper and the same hops that come out of the first Beer and boil it an hour.

When both are almost cool add Yeast to them; to set it to work, breaking the head in every time it rises; till it works itself clear and tun in; Bung it up with Clay and keep it in your Cellar, in three months you may bottle the strong Beer, the other in a weeks time will be fit to drink.

#### Green Corn Stalk Beer

Published in the Virginia Gazette on Feb. 14, 1775. A family recipe by Landon Carter.

The stalks, green as they were, as soon as pulled up, were carried to a convenient trough, then chopped and pounded so much, that, by boiling, all the juice could be extracted out of them; which juice every planter almost knows is of saccharine a quality almost as any thing can be, and that any thing of a luxuriant corn stalk is very full of it, ... After this pounding, the stalks and all were put into a large copper, there lowered down it its sweetness with water, to an equality with common observations in malt wort, and then boiled, till the liquor in a glass is seen to break, as the breweres term it; after that it is strained, and boiled again with hops. The beer I drank had been made above twenty days, and bottled off about four days.

#### General Amherst's Spruce Beer

>From the journal of General Jeffrey Amherst, governor-general of British North America

Take 7 Pounds of good spruce & boil it well till the bark peels off, then take the spruce out & put three Gallons of Molasses to the Liquor & and boil it again, scum it well as it boils, then take it out the kettle & put it into a cooler, boil the remained of the water sufficient for a Barrel of thirty Gallons, if the kettle is not large enough to boil it together, when milkwarm in the Cooler put a pint of Yest into it and mix well. Then put it into a Barrel and let it work for two or three days, keep filling it up as it works out. When done working, bung it up with a Tent Peg in the Barrel to give it vent every now and then. It may be used in up to two or three days after. If wanted to be bottled it should stand a fortnight in the Cask. It will keep a great while.

#### Benjamin Franklin's Spruce Beer

Translated from the french while he was stationed in France.

#### A Way of making Beer with essence of Spruce

For a Cask containing 80 bottles, take one pot of Essence and 13 Pounds of Molases. - or the same amount of unrefined Loaf Sugar; mix them well together in 20 pints of hot Water: Stir together until they make a Foam, then pour it into the Cask you will then fill with Water: add a Pint of good Yeast, stir it well together and let it stand 2 or 3 Days to ferment, after which close the Cask, and after a few days it will be ready to be put into Bottles, that must be tightly corked. Leave them 10 or 12 Days in a cool Cellar, after which the Beer will be good to drink.

Persimmon Beer

An old family recipe that used ingredients available in Virginia in the 1860s. It's not actually beer because there is no hop nor malt in it, but corn. Of course, the North American brewers get away with calling their product beer, and it's got a lot of corn in it, so ...

Wash 1 gallon ripe persimmons. Mash well and add 1/2 cup cornmeal. Add 5 gallons water and 2 cups sugar. Let set until fruit rises to top (3 to 4 days). Strain, bottle and seal. (Clear, light colored, fizzy. Fill bottles 2/3 ..... Explosive!)

Subject: Re: Pectin and Fruit Beer

Mr. Thomas was wondering about an enzyme to degrade pectin. There is such an enzyme, and not surprisingly, it is called pectic enzyme. In my experience, it ABSOLUTELY WORKS VERY WELL. My first two cranberry beers were very cloudy, the last one using pectic enzyme (at 4 grams, or 4 tablespoons per 4 gallons) was crystal clear. I add it to the primary about a day after 24 hours after pitching. This also prevents, IMHO, the thick foam that often clogs the blowoff tube. I just dump it in dry and relax. I didn't have any trouble finding this stuff, even in Montgomery County, MD.

Which reminds me, I have to start this year's batch up for Thanksgiving while I listen to Arlow's Alice's Restaurant.

MORE ON THE OXIDATION MOMILY

As a debunker of MOMILIES, I decided to conduct my own experiment regarding assertions that the billowing foam in my video "BREW IT AT HOME", would cause oxidation leading to "cidery" or "cardboardy" tastes.

The experiment goes like this:

I brewed a batch of extract beer following all the does and don'ts derived from the discussion on oxidation. No splashing or foam and minimum of head space. I even tilted the bottles until the filler head was covered to preclude turbulence at that point.

I left about a quart of beer in the priming vessel and did just the opposite to this. I abused it in every way I could think of. I sloshed it around for several minutes. I poured it into a quart bottle through a funnel and then decanted it back and forth into another bottle about a dozen times. I then poured this into three 12 oz bottles, with a funnel, leaving about 3 inches of head space.

The bottles were numbered T1, T2 and T3. They are to be opened and tasted at 30 day intervals, beginning 30 days after bottling and compared with the control samples.

We tasted T1 today and neither my wife nor I could detect the slightest difference. Be back in 30 days.

Subject: Yet more on hot wort oxidation

Pardon me if I am resurrecting an old issue, but it seems that there may be more implications of avoidance of hot wort sloshing. Presumably, sparging systems which make use of a series of cascading buckets may also be a problem. What is the verdict ? BTW, I find that I have to heat my sparge water to near boiling before it will raise the temperature of the actual grain bed high enough to kill enzyme activity. Am I missing something ?

Subject: Barleywine & Miller

In HBD 747, Martin A. Lodahl <hpfcmr.fc.hp.com!hplabs!pbmoss!malodah> writes on Yeast Repitching's Risks:

> if a brewer is able to keep the bacteria under control, there is a  
> limit to how many times a culture can be repitched...

Well, I have begun using a mixture between Father B and Dave Miller's recommendations in order to keep sanitary and to reduce costs.

First, I use Miller's method for premixing and canning 3 gallons of "sterile" wort. Miller misused the word. Its really sanitary wort that wont allow stuff to grow, due to acidity and hops. Lots of stuff isn't killed by canning at atmospheric pressure, but the stuff that remains can't do anything. I find this method easy, just a couple of hours. And I have lots of quart jars filled with ready to use wort.

I culture yeast in my primary fermenter, a 5 gal carboy. So, I pitch the yeast and a jar or two of wort and attach a fermentation lock. This way, I avoid any contamination problems that might happen when re-pitching from small jugs into the fermenter later.

After the kraeueueaeueeesen (did I spell it right?) has fallen, I carefully pour off the "used" wort, leaving a nice trub on the bottom of the fermenter, and then send my cooled wort in on top. Thanks, FB! Less chance of contamination, and no need to mess with gallon jugs, smaller corks, or the mess of 12-ounce bottles in the fridge that some folks use.

I intend to culture from my homebrew, using only the first generation of beer made from the original lab grade yeast. This is Miller's recommendation. This way, I avoid both mutations (somewhat) and contaminations (somewhat) while reducing cash outlay (somewhat). To date, my Wyeast brewing has required very different yeast strains.

From: Dr. Tanner Andrews <tanner@ki4pv.compu.com>  
Subject: Re-Using Yeast

If you wish to avoid the worry about number of generations of yeast re-use, you can cut the number with a simple change of procedure.

After you have racked the beer out of secondary, perform any appropriate sanitation rituals around the neck of the carboy and pour the yeast slurry (there is always a little beer that you can't rack out) into a clean jar. Cap; keeps for at least a few months in the fridge.

Make a starter using a spoon-full of this a day before you brew. You'll get several spoons full from the jar full of yeast, and all of these ferments will be second generation instead of higher. The spoon-full of yeast in a starter gives me good, vigorous starts.

I tend to agree with this, especially since we've gotten some "advice" now and then (particularly within the past couple months) from folks who don't brew much, haven't even tasted other homebrews, etc. I remember some of the swill I made early on, before I started interacting with other brewers and getting help to figure out what was wrong with my brews.

Could we get this one straight? Oxidation leads to the cardboardy taste. Cidery is something entirely different, and I'm thankful to report I've not tasted any cider which is like cardboard (nor any cardboard which is like cider, although of late I'm strictly limiting my cardboard intake).

From: Jim White <JWHITE@maine.maine.edu>  
Subject: Plastic vs Glass - Haven't we forgot something?

I happen to have a unique 6 gal. Stainless Steel container that was, once upon a time, used on a dairy farm. It's about the size of a large brewpot, and features a heavy grad of SS, a strong 'pail style' handle. It's, maybe, 16" wide at the bottom, narrowing to a 6" wide opening at the top. For a cover I sanitize a piece of thin poly and attach it over the top with a large elastic.

I observe the following advantages..

- Moving it , esp. when full, doesn't risk death or dismemberment from falling upon (or under) foot long, razor sharp shards of glass.
- It's easy to clean.
- It doesn't scratch like plastic.
- Doesn't soften, crack, or break when hot wort is poured into it.

Doesn't anyone else use a SS fermentation vessel?

Jim White

From: gkushmer@jade2.tufts.edu (Greg Kushmerek)  
Subject: Homebrew Digest #748 (October 25, 1991)

A little while back, after I'd washed some homebrewing equipment, my cat knocked something on the floor and the dog chewed it up.

That "thing" was the tiny piece of plastic I used to connect my rubber stopper to all my tubing. Of course, since it was so inconsequential, I've been ages in getting to replace it.

Then again, it's necessary and I haven't been able to homebrew.

Last night, I was at the Modern Brewer in Cambridge - good place BTW - and they kindly GAVE me the piece of plastic. But, they don't have the art of cutting it up quite up to par (which they admitted before giving it to me). So the piece has scratches on the ends.

They said just to sandpaper it down and melt it with a flame to smooth it out.

Any opinions on this? Otherwise I'll give it a go.

ENTER MY DAD: He's a plumber. Turns out, he's got that size of tubing in copper. So my question is - would the copper affect the wort? This thing would be up top, but the blowoff would definitely make contact with it.

He also has tons of soft copper (it's \$7 a roll for him) and I was thinking of making an immersion chiller. Since this would be from scratch, any recommendations about what would be easiest for me?

Thanks

Subject: Re- NJ State Laws

Subject: Re: NJ State Laws

tix!roman@uunet.UU.NET (Daniel Roman) writes:

>I don't have any info on brewpubs but if they allow breweries, micros,  
>and bars that sell beer I don't understand why no brewpubs, but like I  
>said I'm not a politician (or a lawyer).

I think the whole issue regards the normal "three-tiered" alcoholic  
beverage  
distribution. It goes something like this:

The "big-guys" sell to wholesalers who sell to retailers who sell to  
consumers  
Micros sell to retailers who sell to consumers  
Brewpubs sell to consumers  
Homebrewers can't sell

As far as I know, NJ does not currently allow brewpubs (i.e. a brewery  
that  
can sell directly to consumers), but will allow micros. Whether or not  
you  
could open a micro, and then "sell" your beer exclusively to a bar that  
you  
happen to also own, I don't know. I'd guess there's probably a clause in  
the laws somewhere to prohibit this.

Cheers,

Bob Hettmansperger

Subject: Strange color change

>As far as beer goes, I've got a question to pose to the net. Has anyone  
ever  
>had a batch turn darker \*during fermentation\*???

I have had a beer turn darker \*in the bottle\*! It was an all-grain wheat  
beer  
that started out a nice light yellow, but after aging about a month and a  
half  
at 45 degrees, it had turned a dark orange. It didn't even really look  
like  
beer anymore. It wasn't cloudy--if anything it was clearer than when I  
bottled  
it. Also, the head was still white. There wasn't any noticeable change  
in  
carbonation and the flavor didn't change in any strange way, but I  
assumed that  
it had picked up an infection somewhere along the way. Does anybody have  
any  
ideas?

Subject: RE>HBD #748 (Color change,

Reply to: RE>HBD #748 (Color change, O2 Testing, Starters, & CA State\_ To Norm Pyle and his question about darkening beer: I have noticed a similar effect in brews which have lots of "stuff" in suspension (yeast, trub, etc.). While frementation is active the stuff is pretty uniform and gives the beer a yellow/amber (albeit cloudy) appearance. Once the stuff begins to settle and the beer "clears" it takes on a much more red/brown color. Darker but clearer. I have a weizenbock in secondary at the moment which has a very distinct line between these two states. The lower third is still quite cloudy and yellowish while the upper portion is much darker looking. The line sinks a little each day.

To Jack Schmidling and his Oxidation test: You really ought to allow an independent palate to taste the two brews side by side, blind. Not that I doubt your ability to detect flaws. I just think that you get better feedback from someone who has no attachment to the beer. Still it will be interesting to hear how the remaining two bottles turn out. Are they stored at room temp or under refrigeration? What style of beer is this?

As far as Josh Grosse's starters go: What a great idea! Never thought of using the carboy to make the starter and thereby save a few steps. Nice going!

California State Homebrew Competition: We (The San Andreas Malts) need judges for the State Comp on November 10th in San Francisco. Interested parties should contact Alec Moss at (415) 359-4783 ASAP. Apologies to any clubs which were overlooked this year (we seem to have lost a few addresses to the "bit bucket").

Date: Fri, 25 Oct 91 10:30 MST  
From: DAVID KLEIN <PAKLEIN@ccit.arizona.edu>  
Subject: Best batch...

Well....I tried submitting this earlier, but the digest go bye bye...so I will try again, I hope it does not cause the digest to go up in smoke again (what--me parinoid?)

I not meet the conditions of the original posting (>10 brews (I'm only at 9)) but feel that this beer is distintive enough to be mentioned.

"Black Dwarf Imperial Oatmeal Stout"  
3.3 lb liquid Northwestern amber  
3.3 lb liquid Northwestern dark  
3 lb pale 2 row  
1 lb wheat malt  
2 lb dark crystal (90)  
3 cups roasted barley  
<1 cup chocolate  
1.75 cup black patent  
2 lb flaked barley  
1.5 lb steel cut oats  
1 stick brewers liq.  
5 oz malto dextrin  
1.5 C molassis  
1.5 oz old leaf northern brewers leaf hops  
.5 oz mt hood pellets  
2 oz 3.0 alpha hallertau  
1.25 l starter--Wyeast Irish Ale  
Champaigne yeast (was not needed though)

Mashed all grain like substances for 1 hour at 130-140 F IN 2.5 gal water.  
added 1.5 gal boiling water to bring to 160, keep there for 1.5 hour. The high temp was used to get a high final gravity. Sparge: 5 gallons fresh 170 F water.

Bring to boil, add northern brewers (tot 60 min). Added mt. hood 15 min to end and irish moss. Cool, place in fermenters. hallertau dryhopped in secondary, champaigne yeast added then too, but not needed.

O.G. 1.090  
F.G. 1.032  
primary 4 days  
secondary 7 days

A heavy thick brew. The flavor lasts for upwards of a minuite. (hops and dark grains followed by full malt/grain flavor, finishing with molassis. Bit alcoholic tasting when warm. I might recomend more water or dump an extract. (BTW this was about a 6 gallon batch).

Dave

Subject: Question on Traditional Receipts

>From what I have read it wasn't until the early part of the 19th Century (around 1830 or so) that it became to be understood that there was some organism or chemical responsible for fermentation, and not until the later part of that century (~1860s) that Pasteur documented that the single celled organisms we call Yeast were actually responsible.

So in light of this how is it that Ben Franklin, George Washington, et. al. have recipes that refer to adding a pint of Yeast?? Was this a name for the sediment (which of course contained the organism we now refer to as Yeast, and perhaps the origin of it's name) which brewers collected from one brew and tossed into the next (brewer's had long known the sediment had some connection with the cause of fermentation, but the mechanism was unknown till Pasteur's discovery despite the earlier innovation by Van Leeowehuk (sp?) of the microscope)??

Subject: Brewing Environments

From: ml4051@mwvm.mitre.org (John DeCarlo)

>Beer is a product of heredity and environment. Heredity refers  
>to the ingredients and their quality. Environment to the brewing  
>process and where/how it takes place.

>For new brewers, you can tell them a lot of very useful  
>information about the heredity of a beer, but the environment is  
>often a big unknown.

>For this very reason, \*I\* (IMHO) consider it extremely important  
>to emphasize sanitation to the new brewer.

Well said. I've had some experiences which testify to the importance  
and uncertainty of unknown brewing environments.

I've been brewing regularly for 5-6 years, and in that time have  
lived in 6 different homes. With each move, the quality of my beer  
would temporarily suffer. It just wasn't up to the standards that  
I had achieved in my previous residence. As a result, I would re-  
examine my techniques, usually taking the shotgun approach of sterilizing  
everything and doing it all "by the book". After getting all anal  
and making good beer again, I've typically been able to relax my  
cleanliness standards in certain areas. But in each location, the  
particular standards that were relaxed has been different from the  
last.

This has made it very clear to me that different environments call  
for different techniques, and that it's difficult (if not impossible)  
to predict exactly which steps are crucial in a particular environment.  
Given that, I too would consider it extremely important to emphasize  
sanitation to the new brewer.

From: hersh@expo.lcs.mit.edu  
Subject: Jack & Oxidation

Jack could you please describe for us what you perceive are the characteristics of oxidized beer?? I'm not convinced you know what it is.

I ask this in all seriousness because many people have "blind spots" in their sensory perception, while others just don't know what to look for in the flavor.

As an example many people who drink light damaged beer come to consider it a component of the flavor they desire. Since most if not all green and clear bottled beers get light damaged (this can happen as fast as 45 minutes in sunlight or artificial light like fluorescents seen in beer coolers worldwide) and the damage is so prevalent that it is difficult to get non-light damaged beers.

Other examples of the "I don't like this beer without the off flavor" phenomenon is a taste test rumored to have occurred with import german beers. Fresh import beer was served against old import beer. The old beer was reputed to have been quite stale and oxidized. The results of this test supposedly indicated that consumers selected the stale beer as being what they considered the "normal" flavor for the beer and the fresher beers were described as too bitter. The plausible reasoning behind the results was that the stale beer was what consumers were used to.

I have been hosting Doctored Beer Sessions with Steve Stroud for about 2 years now, and for over a year before that. We line up reference samples against beer intentionally tainted for flavor defects. Our findings have been that for various flavor defects people's ability to taste specific defects varies, often quite widely with some not being able to taste certain defects at all, and others being highly sensitive. We have taken notes, adjusted doctoring levels, and in general tinkered with the quantities of doctoring substances, but still we find that some people have sensory "blindness" to certain flavor components.

The ability to perceive oxidation is dependent upon the recipe, oxidation is much harder to detect in darker and/or stronger beers where other strong flavors mask it. Development of oxidized flavors is affected by storage conditions as well. Higher temperatures speed up the process by which the flavor degrades.

I would state that your experiment, while it may prove successful in demonstrating oxidation, may also demonstrate nothing for at least the above reasons. Should your single experiment not show demonstrable oxidation I would not deem it conclusive. I would point to the bottling technique used by commercial brewers as more conclusive proof that oxidation is a consideration. The manner in which commercial brewers bottled leaving little head space, filling bottles under CO2 counterpressure to reduce foaming of the beer and exposure to air all indicate that these brewers, who have a large commercial stake in maintaining the freshness of their product, consider oxidation a potential problem.

> often tell from listening and looking at my beer what is  
> happening. I detected a stuck fermentation without the use of a  
> hydrometer (used it for confirmation) because of just noticing  
> that something felt wrong about the fermentation. Is this useful  
> to anyone of you? Probably not. Would I be able to explain it  
> to a new brewer in a useful manner? No.

This is a general phenomenon that homebrewers pick up as they gain experience. It's a matter of using your 5 senses (6? ;- ) during the course of brewing as well as making use of the scientific instruments like the thermometer and hydrometer. After all, brewers have had to make a relatively complex set of steps occur to produce beer, and have been able to do so for far longer than those tools (well, maybe not the "egge" hydrometer, but certainly longer than the standard goat) have been around.

I find that by observing my brewing in my environment (which I'll have to do again, since my environment has just made a radical shift northward), I can predict a good mash temperature (steam begins to come off of the mash at about 150-155F), a good sparge temperature (that boiling noise begins around 170F), and I can tell by the mash texture when conversion is near finished (the grittiness fades away and the wort has a silky feel on the tongue, ignoring husk bits).

I find it fascinating to rediscover these clues, which might allow me to brew "modern" beer without modern instruments. But it is important to be able to note what it is that clues you in to each step, and I think that putting that in words is important. So, John, the next time you notice something funny about your ferment and discover that it's stuck, try to put into words what it is that caught your attention.

From: Jeff Frane <70670.2067@compuserve.com>  
Subject: All Kinda Stuff

And a most gracious thank you to Dave Murphy, who took the time to send me a divided copy of HBD #744, which had apparently been stuck in CompuServe's mail and never delivered.

On WYeast: I note several people have had problems, either with packages exploding or some form of contamination. I would imagine that packaging is a problem in both cases. I know that the WYeast staff work very hard at ensuring clean yeast, but considering how many packages are shipped out every week, it doesn't amaze me that once in a while the foil seal is defective. The contamination might well have come from a pinhole leak; certainly the exploding package (which used to be more common) was the result of a failed seal. Anyone who goes to all the trouble of plating out their failed package really should take the time to drop Dave Logsdon a note--he's most respectful of homebrewers and very quality conscious. If the package does swell completely within 12 hours, as Bill writes, the best thing to do--outside of adding it to a starter--is to pop the thing in the refrigerator until it's going to be used.

Marc Roleau asks if optimum temperature is "the highest temperature at which yeast can operate without producing undesirable byproducts?" Without getting on the phone to check with Dave, I would say that this is indeed accurate. In general, the warmer the temperature the more vigorous the ferment, and the more vigorous the ferment the better--as long as no unpleasant side effects result.

Curt Freeman asks about a burst WYeast package and what to do about the contents of the inner package. Unfortunately, I think you'll find that the inner package is the growth media (basically wort), and that the yeast culture is in the outer--now contaminated--portion of the pouch. Not much can be done at all.

In respect to the discussion about reusing yeast, I would reference again my notes on washing yeast. According to Dave, storage of the washed yeast will be considerably better for them than storage under beer--the explanations were in the notes.

Thanks to Stephen Hansen for including the coffee recipes. This will make Liz happy. I believe I'll take a shot at the Speedball Stout, tampering a bit with the hops. The information about adding the coffee is a little confusing. If I read it correctly: If one has a wort chiller, the coffee and finishing hops are added only to end of the boil. If one does \*not\* have a wort chiller, the finishing goods are added to the fermenter for 24 hours. Is this right? And what's the comment on contamination relevant to?

On the question of cold-extraction of coffee, I offer the following, from Corby Kummer's "Untroubled Brewing" in the June 1990 Atlantic. Kummer, by the way, is as anal-retentive about coffee as I am about beer, so I like his stuff. "The third form in which infusion survives is coffee made with cold water. This method becomes fashionable every few years and then retreats into deserved obscurity. Ground coffee steeps in cold water for ten to twenty-four hours and is then filtered through a funnel-like

device. The resulting extract, which is stirred into hot water, is mild and characterless, because cold water does not extract the lighter aromatics or acids in coffee--or the oils, or much of anything."

I've also noticed a couple of unanswered questions about cider in recent Digests. Isn't there a Cider Digest? Seems to me that they are (or were) being stored in the CompuServe Beer Forum library, but that they originated somewhere on this network. Robin? Got an answer?

#### EASY MASH

Now that the orders for "BREW IT AT HOME" are pouring in by the billions and billions, I have begun research leading to the sequel.

I want to develop an all grain process that reduces the cost and effort to the minimum while producing an acceptable beer.

As I have the same aversion to plastic as I do to aluminum and to keep within the budget of most hobbieists, I decided to base the system around the old enameled 8 gal kettle that grandma used for canning.

The same kettle is used for mashing, sparging and again after dumping the spent grains, for the boil. It is never lifted full so the problem of handles falling off is not an issue.

A few simple mods are required to make it fit the process. A small brass spigot is fitted to the bottom with a short piece of pipe extending several inches toward the center on the inside.

A small piece of window screen is rolled several times around the pipe and secured with a hose clamp or twisted copper wire. The screen roll extends several inches past the end of the pipe and the last inch is bent over itself to prevent anything from entering the spigot that has not passed through several layers of screen.

The original setup also had the traditional false bottom, fashioned from a SS plate with a zillion holes laboriously punched into it. It has SS screws on the bottom acting as feet to hold it up off the bottom. I abandoned the false bottom on the third batch and found that the screen was all that is needed for a super simple sparge operation. It also serves to keep the hops out of the wort chiller after the boil.

I won't go into the details of the mash because I don't want to get into a flame fest (yet) about times and temps but obviously the mashing is done by direct heat and judicious stirring and temperature monitoring. A partial decoction is simple as pie because all you need to is tap a few quarts and bring it to a boil on another burner. It's fun and gives you something to do while watching the buns rise.

When the mash is complete, shut it off and let it sit while heating water on another burner. If you have control over the hot water heater, you can get it almost hot enough out of the tap. I prefer to bring it to a boil anyway and just keep adding to the kettle as the clear wort comes out.

I found that laying a dinner plate on top of the grain and pouring the sparge water into the center of the plate distributes it evenly around the grain with minimal disturbance.

I sparge until the gravity falls below 1.010 out of the spiggot. With 8 lbs of 6 row, I get about 7 gals at 1.035. I then dump the spent grain on the compost pile and rinse out the kettle and screen.

The seven gallons of wort will fit easily into the kettle for the boil. A minimal one hour boil will evaporate about a gallon so you can play with the volumes in various ways. You can increase the gravity by more boiling or boil less and have more beer.

After the boil, it is tapped into the primary after cooling, either overnight or with a wort chiller after sitting about 15 minutes. I am currently running tests to see if the chiller is worth the trouble.

The last batch was with the chiller and seems to be clearing faster but if it eventually clears either way, then it probably is not worth the trouble.

The kettle seems to be universally available for about \$35 and the rest of the stuff can be had for less than \$5 making it a pretty inexpensive system.

I happen to have a small foundry furnace that I use to boil on and have not actually tried boiling on the kitchen stove but I gather from others that two burners will eventually bring 5 gals to a boil. My furnace will bring 7 gals to wild boil in about 20 minutes and provides a true "fire-brew". It is made out of a few fire bricks, a small blower and some pipe fittings. I am toying with including a "hot to" segment on the furnace in the video.

More to come, comments welcome.....

From: gjfix@utamat.uta.edu (George J Fix)  
Subject: EASYMASH  
FROM: George Fix(gjfix@utamat.uta.edu)  
SUBJECT: Dextrins

Jeff Frane: Thanks for the kind remarks. In my opinion, there is no such thing as a stupid question as far as brewing is concerned. It would be difficult to count the number of times that queries, drawn from practical brewing experience, which on the surface appear to be "uninformed", in fact turn out to touch on issues that one and all have overlooked. What makes brewing so exciting is that everything is not known. While this might be frustrating to some, just think how boring things would be if it were otherwise!

DEXTRINS: The one good thing "dry beers" have done is to increase awareness and discussion on the role dextrins play in beer flavors. Dextrins appear tasteless when dissolved in water solutions. They do however carry calories (30-40% of the total in most beers) as well as adding to the perceived viscosity of beer. This is, as I understand it, the primary motivation in "dry beer" formulations. The dextrins are greatly reduced in order to lower the calories and produce a less satiating beer without affecting normal flavors. In reality, flavors are affected in nontrivial ways, and producers of these beers are now using the "no aftertaste" line (as opposed to "less filling") to promote them. This is of course the problem many have with this beer style. While one does not want the flavors of our beers to cling for hours, it would be nice, on the other hand, for their half-life to be measurable in units larger than nanoseconds!

I feel the relevance of dextrins derives in large part from their role as flavor carriers. In particular, their interaction with malt based proteins is apparently responsible for defining much of the malt character of beer. That different barley varieties (and hence malt types) vary dramatically in their protein content is well established, and this one reason why different malts produce different beer flavors. However, for these effects to be fully realized, sufficient dextrins must be present to "carry" the flavors. I first became aware of this in an experimental brew using Irek pilsner malt in an extended low temperature mash (63C-145F) designed to minimize the dextrin content of the wort. I have a very high regard for the Irek malt, and I particularly value its quintessential continental flavloring. Much to my surprise the latter was greatly subdued in the experimental brew. In fact, when I first tasted the beer I actually thought I had screwed up and used the wrong malt.

For the above reasons I feel that dextrin malts can be used to advantage in a wide range of beer styles, not only as body builders but also as flavor enhancers. My own personal favorites are the light crystal malt made by Irek as well as the one distributed by Great Western Malting. The

latter is produced under license for G.W. in the U.K.

A serious practical issue is whether the dextrin malts should be mashed. The obvious concern is that the dextrans from the specialty malts would be broken down into fermentables and thus nullifying the desired effects of these malts. I personally prefer to mash all my grains for a variety of reasons. However, I generally hold the crystal malts out of the first part of the mash. In particular, I usually mash in at 52 -55C( 125-130F ) with all of the specialty malts and some of the base malt held out. This rest is held for 30 mins. during which time additional water is heated to a boil in a separate kettle. At the end of this rest the additional water is added incrementally to the mash. This plus a small amount of external heat is all that is needed to achieve a steady increase in temperature. I usually go up to 68-69C( 154-155F ). I have found that gently stirring in the remaining malt at this point will serve as a "brake" on the temperature rise, and allow the mash to lock in on the desired temperature without overshoots and related hassle. This rest is held from 30 to 60 mins. depending on the type of beer being brewed. While some dextrans are being degraded in this rest, many do survive. I have found that the effects of the crystal malts can be discerned in comparative brews even with charges as low as 5%.

I do not want this post to read like a anti-dry beer diatribe. These beers do have a function , and they likely will be around for some time. I have actually worked out a dry brew formulation, and brew it on occasion. In particular, my wife makes a supercharged version of Kung Pao chicken using peppers that would make jalapenos seem mild as marshmallows. Of all the beers I brew, the crazy dry beer is the one that comes out best with this dish , and I brew it explicitly for this purpose. I am amazed how the Kung Pao can pull flavors out of this beer which are invisible when the beer is tasted alone without the food.

From: chad@mpl.UCS.D.EDU (Chad Epifanio)  
Subject: Random comments

Somebody had no head on a Christmas Ale:

I've experienced similar problems with three of my spiced ales. The only ingredient they had in common was ground cinnamon. I used cinnamon stick in my last batch, and the beer had a pleasant head. This is just an observation in my beers.

Dave Iderstine asked about Apple Jack:

You might post a message on the Cider Digest for more info.

Subscribe: [cider-request@expo.lcs.mit.edu](mailto:cider-request@expo.lcs.mit.edu)

Submit: [cider@expo.lcs.mit.edu](mailto:cider@expo.lcs.mit.edu)

My litterature recommends sufiting, then adding yeast after 24 hrs. I used wine yeast in three of my ciders, and they all came out very dry. There seems to be a running discussion on the Cider Digest as to how exactly to achive sweet cider. Traditional cider is made in the fall, and bottled in the spring, acording to what I've read. Some suggest to carbonate it slightly to inhibit the production of vinegar. I would suggest treating the cider more like a wine than a beer. My lattest attempt evolved into a Cyser, so I'm treating it like a mead. By the way, I am under the impression that "Apple Jack" was an old method to condense the cider; i.e. the finished cider is allowed to freeze, a hole is punched in the ice cover, and the underlying contents siphoned into a waiting carboy. This process is repeated until the liquid no longer freezes. A primitive distillation perhaps.

Reply to Bob Jones:

Perhaps a communication error on my part. I was not asking you how many award you have won, merly adding your quote for reference. From your comments, it is apparent that you are knowledgeable, and your advice is appreciated. Not wishing to beat this thread any longer, I just wish to clarify my previous comments. You implied that plastic will not make award winning beers. Granted, in the breakdown of awards listed in some Zymurgy competition results, there are more awards won with glass than with plastic, but there are some with plastic. Perhaps beginners, and I may still have one foot in this catagory :), should learn the techniques with glass first. With good sanitation, why not go to plastic if so inclined? I would consider the technique, more than the equipment, as the dominant factor in creating an award winning brew. Just my opinion...

To Jack Schmidling:

Excellent idea!

Jeff, yup! Our buddy Jay Hersh <hersh@expo.lcs.mit.edu> moderates the  
Hard Cider Digest, which is up to No. 52, I believe. And yup again, we  
archive them in .ARC form in the CompuServe Wine/Beer Forum library.  
Since most of the posts are short, I generally hold them until I have  
five or 10 and then upload them as a single consolidated file. Look for  
filenames in the form HCDnnn.ARC, where nnn is the number of the latest  
digest in the batch. Or, of course, you can have it sent to you  
directly.

Jay is a regular participant here, and he may well have already responded  
to you with the details.

From: Tom Dimock <RGG@CORNELLC.cit.cornell.edu>  
Subject: welding stainless

The learning curve for stainless isn't bad IF you have the right equipment, which very few people have. The right equipment is a TIG or MIG welder, which are high frequency arc welders which keep the arc submerged in a flow of inert gas (usually argon), use a tungsten electrode (Tungsten Inert Gas -> TIG). The filler rod is fed into the arc by hand or by wire feed. There are persistent stories that people who use this equipment have health problems, but I don't know too much about that. Trying to weld stainless with an oxyacetylene torch will just get you very frustrated. Find a pro welder to do it for you or sign up for the advanced welding course in your local night school and learn to use their TIG welder.

Yes, I have done it, and yes, I own a TIG welder. Unfortunately I don't have the argon tank or flow meter for it, so I still get my stainless work done by the guy who sold me the welder. He accepts (actually prefers) payment in his favorite beer - Genesee Cream Ale....

Subject: Taps ?????

Hello -- I just bought a 5 gallon cornelius keg and since I already has a small kenmore fridge and co2 tank I have a few questions.

1) the fridge I have has a small freezer compartment internal to the fridge and I was wondering if I can remove this? It looks like it provides the cooling for the rest of the fridge. does anyone have a setup like this?

2) also what kind of tap should I get? i have heard mention of some that aerate the beer. Does anyone make a tap that would mount on top of the fridge so I could set my beer mug under the tap?

3) also what steps should I follow to keg my first ale?

Thanks

From: eisen@kopf.HQ.Ileaf.COM (Carl West)  
Subject: brazing \$tainless \$teel

I have done a little bit of brazing \$tainless, what has given me greatest success was using borax as a flux. Heat the metal and the brazing rod to a dull red, dip in, or sprinkle on, a liberal amount of borax (available in the laundry aisle of the supermarket) melt the borax into place, heat the metal to orange-red and flow the brass into the joint, it's very much like lead soldering, just hotter.

Welding SS requires either special rods for oxy-acetylene or a MIG or TIG welder.

From: night@mapme7.map.tek.com  
Subject: Miller's book

Hello one and all,

In the past few digests I have noticed several people slaying David Miller's book TCHOHB. Specifically, that it was no good for beginners. It was stated several times that he recommends a beginner to brew a light lager as their first brew.

HOGWASH! You might pull out you book and refresh your memory...

Let me quote:

Dave Miller, TCHOHB page 9. Before the first recipe:

"If you are not sure what style of beer you want to brew, I would urge you to choose one of the other recipes in this chapter. They are British ales with much heartier flavor than American lager, and for this reason are easier to brew successfully. The strong flavor and aroma mask many small defects that would be apparent in a light lager. In addition, the higher fermentation temperatures are usually easier to manage. Finally, you can be looser about making substitutions in these recipes."

Now, that doesn't sound like he's pushing light lagers on beginners to me...

Ahhh, and now in his other book:

Dave Miller, Home Brewing for Americans, page 31.

"I recommend trying something other than light lager for your first brew."  
"

So, I would prefer that if people are going to do book comparisons... they should at least get the facts straight and KNOW WHAT THEY ARE TALKING ABOUT... before instilling false statements about a good author into beginner's heads.

Enough said...

Cheers!

From: pyle@intellistor.com (Norm Pyle)  
Subject: Darker during fermentation???

Thanks to all who replied to this question. For those who care, it appeared that my Apricot-Ginger Ale (Xmas brew) turned darker during fermentation. I think RW explained it best: that it probably only appeared darker because suspended yeast, etc. had fallen out (this stuff causes it to appear lighter earlier in the life cycle). Curiosity got the best of me and I siphoned off a glass-full; it was a beautiful amber-red color, not brown as I thought. To summarize, I think I was fooled by yeast in suspension, a dark room, and a couple too many HB's.

I bottled it and tasted it; the ginger is the prevailing flavor. The apricot taste is very subtle, but this is why I brewed it now for Christmas. The hope is that the ginger will mellow over time (as I've noticed finishing hops seem to do) and this will be as good a brew as I tasted at Bo's Xmas of '89. I'll probably taste-test once a week until then so I'll report back on it.

Thanks again.

From: rcd@raven.eklektix.com (Dick Dunn)

>Suggestion: DON'T say "applejack" unless you really mean it! You'll  
save  
yourself a lot of grief and harangues on liquor laws and the dangers of  
home distillation. Applejack is a distilled spirit--in effect, it's  
distilled cider.

Wrong! It's distilled FERMENTED cider.

>Could we get this one straight? Oxidation leads to the cardboardy  
taste.  
Cidery is something entirely different.....

It is really wonderful to have all such confusion made "straight" by a  
simple declaration. Unfortunately, there seem to be a large number of  
brewers who disagree with you. I don't happen to be one because I have  
tasted neither in beer and am simply trying to learn something.

As a self-proclaimed authority on the subject, I wonder how much  
cardboard  
you have tasted that gives you such strong credentials on the subject.  
Presumably all cardboard does not taste the same so perhaps you would  
like to  
suggest an industry standard so that we can all read from the same  
script.

Are we talking about, corrugated or the stuff on the back of note pads?  
What  
if it is coated? Is it recommended to eat a piece of bread between  
tasting?  
Is a little salt helpful? Then of course, we will have to deal with the  
problem that some folks might like "cardboardy" beer and want to know if  
it  
would be better to mash cardboard instead of just splashing around to  
get  
that real cardboard gusto.

Sorry, it's hard to quit that one.

From: Rad Equipment <Rad\_Equipment@rad-ma1.ucsf.EDU>

>To Jack Schmidling and his Oxidation test: You really ought to allow  
an  
independent palate to taste the two brews side by side, blind. Not that  
I  
doubt your ability to detect flaws. I just think that you get better  
feedback  
from someone who has no attachment to the beer.

Any volunteers? I use Bud as the low limit and Baderbrau as the upper. Anything in between is acceptable, if not necessarily desirable. I am not very sophisticated but I can not drink bad beer, even if I made it. As I certainly have made bad beer on occasion, I know what lies beyond the lower limit. I have, however never made beer that tastes like cider or cardboard.

>Still it will be interesting to hear how the remaining two bottles turn out.

Indeed.

>Are they stored at room temp or under refrigeration?

Room temp.

>What style of beer is this?

Nothing exotic. A can of John Bull amber and 10 cups amber dry. Red Star yeast and hallertau hops. I can't grade it on any official scale but it tastes about typical of the extract beer I have been making for 20 years. I would put it in the middle of my Bud to Baderbrau scale.

From: hersh@expo.lcs.mit.edu

>Jack could you please describe for us what you perceive are the characteristics of oxidized beer?? I'm not convinced you know what it is.

You are asking the wrong person. I have been "oxidizing" my beer for years and it was not until people told me that it should taste "cidery or cardboardy" that I started getting sensitive about it.

>I ask this in all seriousness because many people have "blind spots" in their sensory perception, while others just don't know what to look for in the flavor.

This is true but unless something is inherently distasteful, the rest is totally subjective.

>As an example many people who drink light damaged beer come to consider it a component of the flavor they desire. Since most if not all green and clear bottled beers get light damaged (this can happen as fast as 45 minutes in sunlight or artificial light like fluorescents....

This thought occurred to me the other day as I was looking at a carboy fermenting in front of a window. I wonder how many people carefully put their beer in brown bottles but forget about the fermenter.

>The results of this test supposedly indicated that consumers selected the stale beer as being what they considered the "normal" flavor for the beer and the fresher beers were described as too bitter...

When you consider the wierd stuff people intentionally put in home brew, the fact that the vast majority of Americans prefer Bud, along with the subjective nature of taste, one can't help but wonder about the meaning of "normal" flavor.

The reason people win awards for their beer is not because it "tastes better" but because it fits into a set of previously agreed to rigid standards of what "normal" beer should "taste" like. Can a million Frenchmen be wrong? They don't even like beer. Can tens of millions of Americans be wrong? They love Bud and given a comparison, most of them will still prefer it to "normal" beer.

> Our findings have been that for various flavor defects people's ability to taste specific defects varies, often quite widely with some not being able to taste certain defects at all, and tohers being highly sensitive.

The same can be said for any skill. I do not, but one could take the position that it sure seems stupid to spend so much effort and training to learn how to not like something.

>I would state that your experiment, while it may prove successful in demonstrating oxidation, may also demonstrate nothing for at least the above reasons. Should your single experiment not show demonstrable oxidation I would not deem it conclusive.

I never said it would be conslusive. I am not even defending the splashing and foam in the video. I have changed my process and discuss it later in the video. What I am trying to do is verify the allegations made about the procedure with a simple experiment. If the intentionally rough treatment nor my past twenty years experience produce something that I find objectionalble, then I will be less concerned about minor infractions of the "proper" procedure.

From: cjh@diaspar.HQ.Ileaf.COM (Chip Hitchcock)  
Subject: ref recent glass v. plastic discussion

You suggest -"going to plastic with good sanitation"-. The rap on plastic is that it CANNOT be sanitized for more than a few use cycles; after a while it //will// scratch, and bacteria in the scratches are extremely hard to kill. The plastic will also adsorb bleach and release it into the wort, giving room for some unpleasant flavors which can be perceived at extremely low levels---that's a Hobson's choice for you!  
This

suggests that anyone who uses a plastic fermenter should do only a small number of batches before throwing it away (or downgrading it to a bottle-soaking tub) and getting a new one.

Note that the figures for the 1989 Nationals showed that the incidence of top (1st-3rd place) beers brewed in plastic was HALF their incidence at entry; this brings up the question of what those results would have been if they were subdivided by the age/#-of-uses of the plastic and the type of beer (heavier beers being more likely to mask the off-flavors of traces of infection or chlorine).

> within 12 hours, as Bill writes, the best thing to do--outside of  
> adding it to a starter--is to pop the thing in the refrigerator  
> until it's going to be used.

The yeast issue of ZYMURGY (what an oxymoronic-sounding line!) warns, as have a few people on this list, that sudden temperature changes of >15-20 F can stun yeast so badly it never recovers---it may not be technically dead but it's not going to work very well. Based on other figures in this issue, a starter is important for getting the best out of liquid yeast; at typical yeast population densities, there's only room in the liquid provided for ~10% of the number of cells you'd like in a 5-gallon batch. Moving up to a 2-cup starter, and perhaps leaving it at 65-70F instead of ~80F if you can't be ready to brew soon, should be a win.

Subject: Xmas ale recipe

Thanks everyone, for their great brewing ideas and recipes.

I had a party and everyone(50) liked this brew ( 1 month aging.)  
It has a medium head, a pleasant hint of spices(not strong but very  
noticeable)  
and smooth taste.

Recipe makes 4 gallons.  
4 1/4 lb Australian light extract malt (liquid)  
1/2 lb crystal malt  
1/4 lb choc. malt  
1/8 lb flaked barley  
1/2 cup brown sugar  
2 1/2 oz Northern brewer hops  
1/2 cinnamon stick  
1 whole clove  
1 oz cascade (finishing)  
Ale yeast.

All the grain into the boil,(I added the malts before  
the water started to boil).  
After it started to boil, add Northern brewer and spices.  
After ~45 minutes, turn off burner, add the cascade.  
After 20 minutes, filter into carboy.  
clarify and bottle in a week.

I know that this isn't very precise instructions, but I don't  
own a hydrometer yet.

To Jack Schmidling:

Great idea on your mashing technique. I am looking into  
getting way from extracts.

Does anybody have a good mead lager recipe? I have only  
seen mead ale recipes. Is there anything I should watch out for  
with mead? I plan to do it in the basement this winter.

From: night@mapme7.map.tek.com  
Subject: Grapes in beer..

Recently someone asked about using grapes in beer. Well, the other day I happened upon a brew recipe that called for grapes!... I haven't tried it... but it does sound interesting...

by M.R.Reese in Better Beer and How To Brew It.:

Champagne Beer

6 cups (3 pounds) light dried malt extract  
4 cups (32 ounces) white grape juice  
10 grams (1/3 oz.) pelletized Hallertaur hops  
1 package lager beer yeast  
1 1/4 cups corn sugar for priming

for 5 U.S. Gallons

Ferment at 55-65F

Boil hops with malt 25 minutes. Add white grape juice along with water to make up 5 gallons. Ferment down to terminal gravity of 1.004 or below.

This recipe doesn't have much grape juice... but a little may do the trick.  
I would bet that it will be somewhat like champagne because of both the grapes and the high priming sugar content.

Good luck... and Cheers!

Subject: Wyeast Bavarian - No Head Starter

Subject: WYeast Bavarian Wheat--No Head Starter

I'm new to the digest, so I hope this makes it without any complication.  
..

I bought a package of WYeast's Bavarian Wheat yeast Sunday, intending to brew on Tuesday, so I broke it immediately. \*6 hours\* later the package threatened to burst, and I was out of extract, so I improvised a "mini-mash" starter and pitched the yeast. Apart from a 30-45 minute lag between boil and room temperature, my sanitation was up to my usual standards.

Now, 24 hours later, my starter glugs away happily--but there is \*no\* head or visible krausen. The sediment in the mini-mash extract is goin' round and round, and the starter is definitely \*active\*, but at a distance you couldn't tell it from any other cloudy golden beverage. It smells okay, a little fruity and complex but no off smells, just strong ale yeast smells. Anyone seen this before? Any ideas? Thanks.

From: Jeff Frane <70670.2067@compuserve.com>  
Subject: Naked Ambition

To Jack Schmidling: The problem with enamel cookpots isn't just the handles falling off--which I'd never heard of before discovering this crowd--but the fact that enamel is crap, and quickly cracks through to the metal--which rusts. The main problem with using the kitchen stove for brewing is damage to the stove. Pots which overhang the burners or lap between two burners, reflect heat downward onto the enamel surface of the stove--which seems to be very hard on the enamel. (This is NOT a momily, this has been observed by these very eyes!) This tends to p\_\_\_ off the other stove users in the house. I have also been warned off electric stove elements burning out during this process. You find plenty of documentation elsewhere about the desirability of boils longer than one hour, and I needn't go into them here. I think you should also do a little reading about wort chillers; you seem to be under the misapprehension that it has to do with "clearing", by which I presume you're referring to some form of cold break. While this has its place, the real reason is to reduce the wort temperature from boiling to pitching temperature so the yeast can start their work quickly.

If I may say so, I feel that your desire to make brewing beer easy and inexpensive is commendable, but it seems at times that you are more interested in hastily debunking traditional brewing practices than in achieving this goal. (Take note of someone like George Fix, who is applying real scientific methodology to homebrewing.) Quick and easy isn't always the answer; sometimes all you get is instant coffee.

And please note Dick Dunn's comment in re: oxidation and cardboard (not cider) and the excellent commentary from Rad Equipment and JaH.

To Darrylnowinseattle: I noted your reference to the Roaster in the CIS beer forum; didn't you find it a little pricey? O'course, coming from LA... Have you yet made it to Big Time or the Trolleyman? Liz and I were planning on spending last Monday in Seattle, visiting coffee roasters and Liberty Malt but instead spent the whole day and \$400 getting the car fixed in Monroe. Feh! Have you

tried Thomas Kemper Oktoberfest? Is it still on the shelves? (If you've had it on tap, I don't want to know.) Just thought you'd like to know: Portland's pubs are better!

On the question of darkening beer: It's possible that the darkening is a result of extreme oxidation. I had an enlightening conversation with Fred Eckhardt today (he came by to get issue no. 2 of his sake newsletter laid out), in which he explained that chinese shao xing wine and sherry were both darkened deliberately through oxidation (the distinctive sherry flavor is another result). Certainly oxidation is responsible for a brown discoloration in white wines. Somehow, though, it doesn't seem likely that this would happen in the short beer ferment. ???

From: Brian Capouch <brianc@zeta.saintjoe.EDU>  
Subject: Blanche de les Nieges

This weekend my brewing partner brought down some beers he purchased at Sam's (on North Avenue near the Kennedy, for those who ain't found it yet) in Chicago.

One of the beers was called "Blanche de les Nieges" (or something somewhat close to that). It was brewed in Belgium, and came in an enameled 330 ml bottle.

My question: I swear I can taste coriander in this beer. My friend thinks the subtle, aromatic flavor comes instead from hop oils or dryhopping. Visits to Jackson's guides didn't turn up anything.

Does anybody out in HBD-land know anything about this beer? Have any of you brewed with coriander? I happen to have a pretty substantial amount of it, since I like to have a lot of cilantro, and it goes wildly to seed.

This is very similar to one I tried when attempting to replicate  
Wadworths  
6X with the help of Dave Line's "Brew Beers Like Those You Know"(?). It  
was  
very good: dark, rich and strong with a brownish head.

The sugar will make a difference, demarara imparts a lighter taste and  
colour to dark brown. I used light brown sugar and it was still  
noticeable.  
If you use molasses I suspect the colour and taste will remain but the  
beer  
will be weaker, which may be what you want.

I used Fuggles for the copper and Goldings for late; no dry hops. I also  
used too much of them, nearly 3 oz each. But I think the quantities given  
above may be too little, I'd go for 1.5 or even 2 oz each. I take it it's  
a  
4 gallon batch?

Has anyone tried this potion?  
I'm considering replacing the 1 pound of dark brown sugar with 2 ounces  
of molasses - comments?  
-Ron Ezetta-

Just that it will add the obvious bitterness that molasses has  
(blackstrap much more than light), and that molasses is 1/2 as sweet  
as raw sugar.

From: Bob\_Konigsberg@3mail.3com.com  
Subject: Stovetop burning

In reference to Jeff Frane's comment about messing up the stove top, I finally figured this one out. I have made several batches, only to find that the stove top got burned and yucky. I first assumed this was from some minor boil-over that I failed to notice. It turns out that many stoves, unless scrubbed daily, have a thin film of grease or oil on the enamel surface, and the reflected heat from the bottom of the boiler is baking and then burning that grease/oil onto the enamel surface where it is almost impossible to remove. The solution: Scrub the surface of the stove very clean \*before\* the wort boil (preferably with a nylon scrub pad so as not to scratch the enamel), and there will be no more burned on mess on the enamel afterwards.

The Roaster is not cheap, that's for certain, but compared to Father's  
Office, perhaps the best place to drink micros in LA, where a pint  
regularly  
costs \$4 (!), it's still a bargain. Naturally, Big Time and Red Hook are  
less expensive. TK's Oktoberfest was the first NW beer that passed my  
lips when I arrived: it was available in the supermarket I walked up to  
after I got off the bike. Lovely stuff, but I would condemn it with Sam  
Adams Oktoberfest as being of the NA Micro variant of styles with too  
much hops. And with regard to Portland's drinking establishments v.  
Seattle's, I'd ask you not to put me into that position! Both sides  
would likely take an outsider like myself (from the unwashed south)  
and string me up.

I would disagree with this dismissal of plastic, although I would tend to agree with your reasons. I use nothing but plastic right now: a 32 gal. plastic food grade trash can for primary and polycarbonate carboys for secondaries. But I don't use bleach for sanitizing: I use boiling water. This allows me to sanitize with heat instead of chemicals, and the heat works even if there is not direct contact between the water and the undesirables. It is true that the inside of my primary is stained and rough, and has been so for a couple years now, but I have had no difficulties.

> Note that the figures for the 1989 Nationals showed that the

I would suggest that there are other potential interpretations: there is a strong aversion from plastic among the more experienced brewers--I would point you out as an example--and the experienced brewers, through their experiences, would tend to produce better beers. In any event, I would not try to draw any strong conclusions from these crude stats.

From: STROUD%GAIA@leia.polaroid.com  
Subject: Wit Biers

Brian Capouch asks about Blanche des Neiges.

It is brewed by the Huyghe Brewery in Ghent, Belgium, the people who also produce the stunningly strong triple-style ale known as Delerium Tremens (aka Mateen here in the states).

Your nose isn't fooling you Brian, there's coriander in that beer, as well as a strong orange aroma.

Both coriander and orange (curacao) are traditional flavorings in Belgian wit (white) beers. The premier Belgian wit is Hoegaarden, made from 45% wheat, 5% oat (both unmalted) and 50% malted barley. There are lots of imitators, including Dantergemse, Steendonk, Brugs Tarwebier, and others. All of them have similar spicing profiles. They're great hot weather biers.

As a note of interest, the new Celis Brewery currently under construction in Austin, Texas, will produce a wit beer in the Hoegaarden style. Those of you in that area should look for it around Christmas.

From: Peter Glen Berger <pblp+@andrew.cmu.edu>  
Subject: Help. Stuck Fermentation

My ginger beer was fermenting for about a week very nicely. As of yesterday, it seemed to have stopped. The SG had dropped from (about) 1.070 to 1.020. I am using Whitbread Ale Yeast. Taking a risk, I roused the yeast this morning; I don't know if that had any effect yet.

It actually doesn't taste terrible at this point, just a little too sweet. I am worried that if I try to bottle it, however, no carbonation (or too much!) will occur. So, do I:

- 1) Roust some more, splash the wort around, etc.
- 2) Pitch some champagne yeast.
- 3) Some other option that I haven't thought of yet.

Please respond quickly!

Thanks,

Subject: More on Ceramic Pots

In HOMEBREW Digest #750, Jeff Frane made some interesting statements concerning ceramic-on-steel kettles:

> The problem with enamel cookpots isn't just the handles  
> falling off ... but the fact [?] that enamel is crap, and quickly  
> cracks through to the metal--which rusts.

Odd. This has not been my experience at all. Yes, if an enameled steel kettle is banged around enough it will crack, and yes, if cracked it will rust. But I have one kettle I've used more than 2 years as a mashtun and boiler that is still uncracked (except on the outside, where the handle came off), and another I've used much longer than that (a fifty-cent yard sale special) that's both cracked and rusted, a fact which seems to have only a cosmetic effect, as I have no reason to believe it has ever added anything to the beer. Personally, I'd love to have a 40-qt, restaurant-grade stainless steel stockpot (with lid), but unless the Cookware Fairy leaves one in my kitchen, I'm not likely to have one soon. In the interim, I've had great results from the enameled kettles. I'd feel more than just a bit hesitant, though, to use them with one of those Mega-Burners that turns the bottoms of kettles cherry-red. I doubt that either the enamel or the comparatively thin steel could stand much of that treatment. The thinness of the steel also would preclude my ever even considering drilling any sort of hole in the kettle.

Then:

>The main problem with using the kitchen stove for brewing is damage to the  
>stove. Pots which overhang the burners or lap between two burners,  
>reflect heat downward onto the enamel surface of the stove--which seems  
>to be very hard on the enamel. (This is NOT a momily, this has been  
> observed by these very eyes!)

This may vary on a stove-to-stove basis. My stove has been in nearly-continuous use for some 80 years, and after being replaced as a cookstove after WW II by one of them new-fangled stoves with a pilot light, was relegated to the wash-house where it was always used with multi-burner coppers, until I bought it to use as a cookstove again. Its enamel is in great shape, except where the handle of the copper used to hit the side of the oven.

I agree completely about the advantage of the wort chiller.

Concerning Jack Schmidling:

>If I may say so, I feel that your desire to make brewing beer easy and  
>inexpensive is commendable, but it seems at times that you are more  
>interested in hastily debunking traditional brewing practices than in  
>achieving this goal.

>(Take note of someone like George Fix, who is applying real scientific  
>methodology to homebrewing.) Quick and easy isn't always the answer;  
>sometimes all you get is instant coffee.

>

>And please note Dick Dunn's comment in re: oxidation and cardboard (not  
>cider) and the excellent commentary from Rad Equipment and JaH.

I couldn't have said it better.

Then:

>On the question of darkening beer: It's possible that the darkening is  
>a result of extreme oxidation ... Certainly oxidation is responsible  
>for a brown discoloration in white wines. Somehow, though, it doesn't  
>seem likely that this would happen in the short beer ferment. ???

No ferment required. I was amazed at how much paler my pale ale was  
when I began chilling in the kettle, rather than pouring hot wort  
through a strainer into the fermentor. The chapter on browning  
reactions in George Fix's outstanding book, "Principles of Brewing  
Science" explains why.

>One of the beers was called "Blanche de les Nieges" (or something  
>somewhat close to that). It was brewed in Belgium, and came in an  
>enameled 330 ml bottle.

>My question: I swear I can taste coriander in this beer. My friend  
>thinks the subtle, aromatic flavor comes instead from hop oils or  
>dryhopping. Visits to Jackson's guides didn't turn up anything.

Never heard of Blanche de les Nieges, but Belgian beers aren't known  
for their hop character. There are some Belgian brews made with  
coriander,  
however. For commercial versions check out Dentergems or Hougarden (sp?)  
,  
they are both excellent examples of Belgian White Ales. The coriander  
adds a unique "flowery" component to both the aroma and flavor.

I brewed my own attempt at a Belgian White some years back. The  
recipe isn't handy, but I used lots of unmalted wheat with a pale  
malt mash, some stale hops, a Chimay yeast, and added coriander  
(about 1tbs) to the fermenter a few days before bottling. At bottling  
time I decided that the coriander wasn't pronounced enough, so I added  
1/4 tsp. to half the bottles. As you might expect, coriander was the  
dominant flavor in that half. The result didn't quite match a Belgian  
White, but the beer was really enjoyable nonetheless.

Anyone else out there experimented with coriander beers???

began brewing. Recently, I started reading Miller's TCHOHB. I'm about  
3/4 finished with the book and have found only a few things with which  
I disagree (I don't have them at hand - maybe when I'm done reading, I'll  
post my concerns). I feel that either Papazian's TCJOHB or Miller's  
TCHOHB

are fine books for beginners, but if I had to offer a book to a beginner,  
I would choose Papazian. There's a lot more information not specifically  
about brewing that I found interesting, the writing is more  
conversational,  
and the whole attitude about brewing less intimidating. I think that if  
I

would have read Miller first, I may have been intimidated into delaying  
my first batch till I found an expert to help me. Granted, even after  
Papazian, I was a bit nervous on my first batch, but I did it without any  
private coaching and it turned out quite well. I suggest reading  
Papazian  
first, followed immediately by Miller (brew a year before reading Fix).

scale  
>but it tastes about typical of the extract beer I have been making for  
20  
>years. I would put it in the middle of my Bud to Baderbrau scale.

Red Star produces \*LOTS\* of esters. Primarily banana esters to be exact.  
If you have been using Red Star all along, you may have been converging  
up many of the defects (like oxidation) that we suggest you may have in  
your beers.

Jay writes:

>>Jack could you please describe for us what you perceive are the  
>>characteristics of oxidized beer?? I'm not convinced you know what it  
is.

Jack replies:

>You are asking the wrong person. I have been "oxidizing" my beer for  
years  
>and it was not until people told me that it should taste "cidery or  
>cardboardy" that I started getting sensitive about it.

One more time: cidery "flavors" come from too much cane or corn sugar  
while  
cardboardy (or sherry-like I'd like to add) come from oxidation. While  
on

the subject, I tasted homebrewed "beer" two weeks ago while in Ontario and it was a textbook case of cidery beer. My guess was that the brewer used 3/4 cane sugar to 1/4 malt extract (residual sweetness). If I hadn't been told it was beer, I wouldn't have known.

Jay:

>>I ask this in all seriousness because many people have "blind >>spots" in their sensory perception, while others just don't know what to >>look for in the flavor.

I'd like to add that our tongues only identify four distinct flavors. The rest of flavor perception is done with the nose. You don't have to taste cardboard to know the "cardboardy taste." Wet some corrugated cardboard and smell it. This goes back to answer Jack's ravings about cardboard flavor which (for obvious reasons) I chose to omit from my reply.

Jack:

>The reason people win awards for their beer is not because it "tastes better" >but because it fits into a set of previously agreed to rigid standards of >what "normal" beer should "taste" like.  
^^^^^

No, within a set of predefined characteristics of a particular \*style\*.

Jack:

>Can tens of millions of Americans be wrong?

Yes.

Jack:

>They love Bud and given a comparison, most of them will still prefer it to >"normal" beer.

A-B Bud is vile. Bottom line. Labatt's Bud is less vile. Most American men drink beer because it is cheap, gives you a buzz and because if they drank wine coolers they would be ridiculed. Men in Wisconsin, the beer "center" of the U.S., used to drink whiskey till the government raised the taxes on hard liquor. They turned to beer, and only then did so many beer companies grow there. (My reference is an article in a 1988 or 89 Zymurgy on the history of beer.) Advertising companies decide which beer is the one you should drink. Given an honest choice, most "beer drinkers" would probably rather drink soda pop, but society has forced them to learn to like a bitter liquid that, I'm sure you'll all agree, takes some time to get used to. If you're learning to like something you don't like, you can learn to accept additional annoyances, like those in Bud. My grandfather used to smoke. He used to buy the finest tobacco and the finest rolling papers. During WWII, a Russian soldier asked him for a cigarette. The Russian soldier hated the cigarette and asked how my grandfather could smoke such an awful thing. You see, Russian soldiers were not issued cigarette papers... they used to roll in newspaper. Without the smell of burning printer's ink, the Russian soldier hated the cigarette.

\*\*\*\*\*

Jacob Galley asks where to get a deal on carboys in Chicago.

Try Sparkling Spring (look in the Yellow Pages under water... well, under the "water" category). I just bought six glass carboys full of distilled water, paid the \$6 deposit and never looked back.

Subject: Recipe: Wee Heavy/Old Ale

I'm glad to see recipes being posted to HBD on a pretty regular basis now. Here's one I'm very pleased with:

Holiday "Wee Heavy" (really an Old Ale)

Ingredients for a 5-gallon batch:

10 lb 2-row pale malted barley  
2 lb 80Lovibond crystal malt, smoked  
8 oz wheat malt  
1 oz chocolate malt  
1 lb brown sugar (in boil)  
Bittering hops: 1 oz Northern Brewer (7.4 AAU)  
Dry hops: 1/2 oz Willamette, 1/2 oz Hallertauer,  
1/4 oz Cascade  
3/4 cup light dry malt extract (priming)  
Wyeast 1098 "English" (Whitbread) ale yeast

Process:

Mash water: 18 qts @ 140F, pH 5.3  
Mash-in: 5 minutes @ 130F  
Protein rest: none  
Conversion: 60 minutes, 158-150F  
Mash-out: 168F, 5 minutes  
Sparge: 5 gallons @ 168F, pH 5.7  
Boil: 90 minutes, w/ bittering hops @ 30 minutes

SG: 1.070 TG: 1.020

Specifics: It's confession time. This was intended to be a Scottish "Wee Heavy", but works much better as an Old Ale. I just haven't quite captured that uniquely malty characteristic of Scotch ales, but I'm still trying. I really began this batch about a week before brewing day by boiling my brewing water. I have about 750ppm of hardness in my well water (this changes dramatically, I've discovered), and much of it, apparently calcium carbonate, precipitates out when boiled. A couple of days later I started the yeast culture growing. Then I tried smoking the crystal malt over a peat fire, which really wasn't terribly successful in imparting peaty flavors to the malt. Next time I'll get the peat really soggy; perhaps that will work better.

The mash was punctuated only by the handle coming off my kettle (I'm sure you're all tired of hearing about that, but if one person escapes a scalding because they heard of such a thing happening ...) and by conversion long, long before the 60 minutes I'd expected. I let it "go the distance" anyway, while I thought of ways to work around the missing handle. The sparge proved too much for my kettle to deal with, and I ended up with an extra 10 bottles of 1.034 wort that will come in handy as yeast starter. The rest of the brew session and the fermentation was routine. I dry-hopped 3 days after pitching, and bottled 4 weeks later.

How is it? Well, I brewed it for Thanksgiving, but I doubt any will survive that long. It's rich, vinous, with complex port-like ethers and not a hint of astringency (a common hard-water problem) or off-flavors. Next time I brew it, though, I'll delete the wheat malt (plenty of head, for the style, without it) and the brown sugar (the vinousness is too much for a Scotch ale), substitute 2 lbs dextrine

malt or flaked barley (still mulling this over) for an equal weight of pale malt, and smoke the cystal more heavily. Possibly cut back a little on the priming extract, as well. I can always find flaws with my beers, but on the whole, I'm delighted with this one!

of  
> >home distillation. Applejack is a distilled spirit--in effect, it's  
> >distilled cider.  
>  
> Wrong! It's distilled FERMENTED cider.

Umm saying it's distilled cider is acceptable. Typically the British  
refer to  
the fermented product as cider, and the unfermetned stuff as simply  
juice.  
Here in the States the terminology differs (to the dismay of many Brits)  
. .  
Juice is filtered apple juice, cider is unfiltered apple juice, and Hard  
Cider  
is the fermented product.

I'm sure EVERYONE knew what Dick meant, since the process of distillation  
typically requires that the precursor already have some alcohol in it,  
and that  
this alcohol is distilled to a higher concentration.  
So let's not pick nits...

> >Could we get this one straight? Oxidation leads to the cardboardy  
taste.  
> >Cidery is something entirely different.....  
>  
> It is really wounderful to have all such confusion made "straight" by a

Ah but FORTUNATELY a largenumber of Judges agree with this. Those that  
don't  
got the question WRONG on the judge certification test!

> You are asking the wrong person. I have been "oxidizing" my beer for  
years  
> and it was not untill people told me that it should taste "cidery or

to  
> >look for in the flavor.  
>  
> This is true but unless something is inherently distasteful, the rest  
is  
> totally subjective.

As I said, some just don't know what to look for in the flavor. Apparently it is not totally subjective. Judges are able to detect and agree upon flavor defects present in beer. Typically the more experienced the judges the more more capable they are of accurately isolating flavor components present. This has nothing to do with subjectivity (people's personal preferences for styles and/or flavors) and everything to do with perceptual abilities. Fortunately it is quite possible to "train one's palatte" by exposing to beers doctored with specific substances served side by side with undoctored "reference" samples of the same beer. As I mentioned I have had great success in training individuals to recognize flavor components which they either did not previously detect, or detected but could not associate a "label" (the proper name for the flavor component) to. This encompasses 2 types of training, first palatte sensitization, and second cognitive abilities. The first is teaching people how to detect a substance in the milleiu of flavors, the second is teaching them to associate the proper name with that sensation.

> When you consider the wierd stuff people intentionally put in home brew, the  
> fact that the vast majority of Americans prefer Bud, along with the  
> subjective nature of taste, one can't help but wonder about the meaning of  
of  
> "normal" flavor.

Seems you misunderstood, though I though I was clear here, the "normal" flavor referred to was for a SPECIFIC STYLE of beer from a SPECIFIC MANUFACTURER, so normal has nothing to do with "weird stuff" homebrewers use, or the vast majority who prefer Bud, it has to do with what people who normally drink that style of that brand expect the flavor to taste like.

> The reason people win awards for their beer is not because it "tastes better"  
> but because it fits into a set of previously agreed to rigid standards of  
of  
> what "normal" beer should "taste" like.

Not quite. The reason people win awards for their beer is because the beer they have brewed is free of flavor defects and it's flavor best typifies the flavor defined for the specific category in which the beer is entered. There is no such thing as "normal" beer, rather there 2 major criteria, absence of flaavor defects, and appropriateness for style.

>Can a million Frenchmen be wrong? They don't even like beer.

Not quite true. While wine does outsell beer in France there are several French breweries, and the Biere de Garde style which is uniquely French. Belgian beers

are also quite popular in France.

> Can tens of millions of Americans be wrong? They  
> love Bud and given a comparison, most of them will still prefer it to  
> "normal" beer.

As before you have totally ignored the context in which the term "normal"  
was  
used and applied you own.

> The same can be said for any skill. I do not, but one could take the  
> position that it sure seems stupid to spend so much effort and training  
to  
> learn how to not like something.

The training is not to learn how to not like something, rather to learn  
how to  
identify it. For some flavor compounds their presence in some styles is  
defined  
as improper, while for other styles it is deemed desirable. The presence  
of  
phenolics which the clove-like aromas and flavors of many wheat beers are  
attributed to is such an example. While no one can say that a particular  
beer  
is good or bad in general since this is subjective, it is possible to say  
that  
a particular beer is appropriate/inappropriate for style, where the  
definition  
of that style is typically based upon either a single "classic" beer that  
defines the style (say Steam beer for example), or a range of common  
characteristics of beers brewed to that style (Stout or Oktoberfest are  
examples here).

In general while it is conceivable that for certain objectionable flavor  
components which just about everyone would agree are undesirable there is  
someone who considers this flavor tasty, or at least not objectionable,  
then  
it's presence in a beer regarding the description of that beer as good/  
bad  
would be subjective. However, if the profile of a style excludes that  
flavor  
component as being part of the style's flavor profile, then the presence  
of that  
component is always inappropriate for style, and is not a subjective  
matter.

I hope this more clearly explains the difference. This is one of things  
that I  
often have to get across to new judges who I am paired with, just because  
you  
like the beer doesn't mean it is appropriate for style in the context of  
judging.

> I never said it would be conclusive. I am not even defending the

treatment nor  
> my past twenty years experience produce something that I find  
objectionable,  
> then I will be less concerned about minor infractions of the "proper"  
> procedure.

Well perhaps I am mistaken, but this seems to be a little retreat of what I perceived your earlier position to have been. It appeared to me that you were dismissing the problem of oxidation offhand as just another "momily" when in fact I think it is a legitimate concern to both commercial brewers and homebrewers, and is in fact quite a well understood chemical phenomena.

If you have never experienced it in your years of brewing then as I suggested perhaps you have a blind spot wrt perception of it, perhaps your palette is not trained to detect it, or you consider it a desirable flavor component, perhaps despite your brewing technique (which if I understand correctly from your past descriptions introduces air into the beer upon bottling) fast consumption of the beer or favorable storage conditions (cool or cold temperatures) minimized the development of off flavors.

There are a host of factors which can mitigate the problematic effects of oxidizing the beer upon bottling. That doesn't mean I would recommend to new brewers using a technique which is known to introduce air into the beer during bottling. Since it takes little or no effort to reduce the introduction of air into the beer at bottling time, and the effects of oxidation upon beer are pretty well understood by brewing chemists, to me it is just common sense to take those steps that reduce introduction of air into the beer at bottling time.

I see no point in playing Russian Roulette with my brewing (to which I devote both time and \$\$) and prefer to take REASONABLE steps to insure the quality of it's outcome. Also I see no great conspiracy in trusting the knowledge of hundreds of years of brewers and scientists. It's not like someone is profiteering off my bottling without the addition of excess air at bottling time.

There is no grand conspiracy I see to cause me to distrust well founded research and conclusions on the effects of oxygen upon fermented beer. While I agree that there are perhaps certain "momilies" espoused as truth in the realm of brewing which are worth investigation, the negative effects of oxygen on beer is not what I would have considered to be the next great brewing debate of the century, rather I consider it a pointless revisitation of a well understood chemical process, and hope we can close this issue and move on to other more fruitful discussions.

Subject: Welding stainless

I recently took a welding class from a local High School. It was a quick intro to many kinds of welding on many different metals, so be wary of my advice.

We did a bit of stainless welding. While TIG may be better, stainless can be welded with an arc welder and special stainless steel rods. I'm no pro, but the stainless welds I did with the arc welder looked pretty good. I did warp the crap out of the sheet though. It'll be a while before I try it on my stainless car.

I'm not sure if you need DC, or you can get away with a cheap AC buzz box.

From: Jeff Frane <70670.2067@compuserve.com>  
Subject: I DO KNOW!

Having apparently been the one to set Mark Nightingale off, in my criticism of Dave Miller's text, I have in fact gone back to check my memory. As a veteran of ten years' book reviewing, I know how important it is to read carefully. As Mark points out, the caveat is included suggesting people might brew an ale instead. On the other hand, having spent a single paragraph on that, Miller proceeds to demonstrate over the next ten pages how to brew an "American Light" with rice syrup and dried lager yeast (he says the liquid yeast is too much bother for beginners). The process includes the need to get the beer down to 50°F (max. 60°F), which I submit is a whole lot more difficult for the beginning brewer than opening a package of Brewer's Choice yeast. I dunno, maybe it's a regional thing. Miller seems to think that beginning brewers will be most familiar with Bud-style beers. My own experience teaching beginning brewing has been that--in this area, anyway--new brewers are familiar with microbreweries and imported beers and are interested in brewing something like BridgePort or Widmer or ... Miller is, I believe, from the St. Louis area and his experiences are no doubt different.

To Art Hebert: I have a refrigerator like yours and simply ignore the freezer unit (it's pretty small). I don't know a thing about refrigeration but it looks to me as though the freezer was integral to the system; won't catch me messing with something like that. My tap(s) are mounted on the front door. There is a drip pan underneath, mounted with sheet metal screws, that easily holds the weight of a beer glass--even a full one. The only aerators I know of are sparklers that are used with some beer pumps--not for CO2 driven systems.

To Jack Schmidling: We are getting a little testy, aren't we? Saying that "it's distilled cider" is "Wrong! It's distilled FERMENTED cider" is not only picky, it's borderline innacurate. We have, after all, two forms of cider: sweet and hard. They are both cider. Hence, "Applejack is distilled cider" is accurate. Not perfectly concise, maybe, but certainly not "Wrong!".

Perhaps you could amplify the statement you make to Dick Dunn that a large

number of homebrewers disagree with his distinction between cardboard  
flavor and  
cidery flavors. I've not heard much confusion on this previously. I  
repeat my  
previous offer: Come to Portland next May and taste beers at the Oregon  
State  
Fair. Out of the 150-200 beers, I guarantee there will be some that are  
badly  
oxidized; once having tasted such beer, I also guarantee you will not  
question  
the use of the term "cardboard."

I'd also like to hear some amplification of your comment to Rad Equipment  
that  
differences in sensory perception are "totally subjective." You are too  
hastily  
dismissing an important point about tasting beer, that some people have  
blind  
spots--or are hypersensitive--to certain flavors. My soon-to-be-wife,  
Liz, seems  
to have one for the above-mentioned cardboard; I've met others who were  
acutely  
sensitive to diacetyl, still others who didn't seem to notice it. The  
point is,  
Jack, not whether people \*like\* those flavors or not, but whether they  
can even  
detect them.

Coming from someone who says he's never tasted anyone else's homebrew,  
your  
judgments about why people win awards for their beer sound strange.

To Ken Weiss: I'd assume that anything with Blanche in the name was a  
white beer  
(witbier), a revived beerstyle. I'd also say you were right: coriander is  
a  
likely ingredient. A Eugene brewer named Chris Studach brewed a fantastic  
white  
beer last year; I shall ask him for permission to reproduce his recipe.

From: "Daniel Butler-Ehle" <DWBUTLER@MTUS5>  
Subject: Bottles of skunks and cans of worms

I have heard many arguments about what color glass bottles should be in order to avoid light-struck beer. It is my understanding, however, that hardly anything (including beer) reacts with visible light; it is the ultraviolet light that reacts with stuff in the beer (often said to be the hops, but the jury is still debating) to cause that skunky, light-struck taste (as exhibited overpoweringly by every imported Pilsner Urquell I've ever had).

The large output of UV is the primary distinction between light from such sources as fluorescent lights and the Sun and light from weaker UV producers like incandescent light. This is evidenced in the phenomena Jay Hersh reported to us a few days ago: (HBD #749)

"most if not all green and clear bottled beers get light damaged (this can happen as fast as 45 minutes in sunlight or artificial [sic] light like flourescents [sic] seen in beer coolers worldwide) and the damage is so prevelant [sic] that it is difficult to get non-light damaged beers."

However, my current belief (subject to change without notice) is that the color of the bottle has nothing to do with it.

A few years ago, a big scare arose about sunglasses. The scare resulted from the theory that because the color or shading of the lenses affects only visible light that when we wear sunglasses and our irises open in response to the decreased visible light, we must therefore be subjecting our retinae to unnaturally large amounts of UV.

Well the truth to the issue never received much attention. Sunglasses, especially glass ones, naturally reflect most UV. Even the cheapest glass sunglasses block a greater percentage of UV than of visible light, and thus wearing them is better than not wearing them.

What's this got to do with beer? What's true for glass lenses is true for glass bottles. The color of the bottle affects only the visible light. (That's why it has color in the first place.) Glass, regardless of color, stops most UV. Therefore, beer in brown bottles should be no more or less susceptible to light damage than beer in green or even clear bottles.

Any comments? I ain't no physicist, so I'd like to hear from someone who knows. We got any opticians out there?

Subject: Naked Ambition

[Read: Naked Aggression]

Naked Aggression that is, Against the Mush Brained Masses that people like you are frightening away from our hobby.

>To Jack Schmidling: The problem with enamel cookpots isn't just the handles falling off--which I'd never heard of before discovering this crowd--but the fact that enamel is crap, and quickly cracks through to the metal--which rusts.

Perfect example of NAAMB. You leave the nervous, tentative beginner with two choices: spend \$150 for a SS pot or drink Bud.

For what my numb-tongue opinion is worth, when I dis-interred my enammel pot after ten years of storage, it did indeed have some rust spots. In fact, some so serious that I check for leaks before boiling. Needless to say, I will get a new one but I as have boiled hundreds of gallons of maple syrup, hundreds of fish boils and now that it is rusty about a dozen batches of beer, I can't help but chuckle at your comments.

>The main problem with using the kitchen stove for brewing is damage to the stove. Pots which overhang the burners or lap between two burners, reflect heat downward onto the enamel surface of the stove--which seems to be very hard on the enamel.

Right! Now the guy who is hesitant about getting into beer making, must consider a \$200 brew stove.

>I think you should also do a little reading about wort chillers; you seem to be under the misapprehension that it has to do with "clearing", by which I presume you're referring to some form of cold break.

Perhaps you should do a little reading of the HBD. I concluded after reading a number of articles posted by people who seemed to know what they were talking about, that chilling forces various things that tend to stay in suspension without it, to sink during secondary fermentation and promotes better clearing.

If this is incorrect, I will not promote its use, as I have already concluded that worrying about contamination during the cooling period is, if not a momily, at least not worth worrying the beginner with.

>You find plenty of documentation elsewhere about the desirability of boils longer than one hour, and I needn't go into them here.

I said a "minimal one hour boil". You know, like nominal. I also said I started with 7 gals and boiled down to 5 at one gal per hour. That's at least two.

>If I may say so, I feel that your desire to make brewing beer easy and inexpensive is commendable, but it seems at times that you are more interested in hastily debunking traditional brewing practices than in achieving this goal.

It's all part of the learning process. How can I simplify a process without questioning the accepted methodologies?

>(Take note of someone like George Fix, who is applying real scientific methodology to homebrewing.)

As someone once said: Mr Schmidling, you're no George Fix!

>Quick and easy isn't always the answer; sometimes all you get is instant coffee.

You seem to forget that lot's of people like or at least drink instant coffee. I suspect many homebrewers would have been happy to end up with instant coffee instead of beer that they had to throw away or never even made because of NAAMB.

>And please note Dick Dunn's comment in re: oxidation and cardboard (not  
cider) and the excellent commentary from Rad Equipment and JaH.

And just what do I do with the "excellent commentaries" that claim that  
oxidation produces cidery beer?

.....

Kudos to Mark Montgomery for info on 10 gal SS kettle. I phoned in my  
order  
and hopefully my next batch will be rust free.

Subject: RE: Welding Stainless  
Full-Name: Christopher A. Nissen

Although Tom Dimock comments in HD750 that you need a MIG welder to weld stainless, he is presenting the picture that one cannot do it at home without a MIG. In fact, it can be done using a couple of propane torches, a little silver solder, and the proper flux (designed for silver solder). I recently used such an arrangement to install a spigot in the bottom of my 15.5 gallon ss kettle (a.k.a. half-barrel that never made it back to the Bush factory). I also supplemented the rivits I use to hold the stainless rod handles on the kettle with a small application of silver solder. I have carried this kettle around the basement with 10 gallons of boiling water and never doubted the strength of the handles.

Likewise, the spigot on the bottom of the kettle has never failed me in any way. Granted, a MIG welder is what the "pros" use, and it IS required for applications where the stainless is thick or has an extremely large load bearing requirement, but for the small homebrewer, I have found that silver solder works fine.

One comment is that you need to get the stainless RED hot with the silver solder approach, and this is best accomplished using two propane torches; on both sides of the material (ask a friend to help).

From: 2121dtam%ucsbuxa@hub.ucsb.edu (Marc Tamsky)  
Subject: Homebrew laws & Best fermentation volume

First Question:

I know there are laws in California governing the amounts that an individual can produce. (i.e. Head of household 200 gal or individuals 100 per year.)

What are the age requirements to homebrew? Is it legal to ferment your own alcoholic beverages under the legal drinking age in your state?

Second Question:

When fermenting in a 5 gal. glass carboy whats the best volume to ferment with?

I want to leave enough room for the head. I fear that the yeast will stop working because of the high alcohol concentration if I have a low-volume ferment.

I know this isn't a FAQ but, is this dumb?  
Are the alcohol concentrations in a primary ferment not even close to the max working concentrations for yeast?

BTW I used the ale yeast that came with a Mountmellick Export Ale kit. I fermented with about 3.5gal and added the rest when racking to the secondary.  
After 1.5 weeks in secondary, I primed with 1 cup corn sugar and bottled. 3 weeks later the batch still has a sugary taste but carbonation is ok.

Any ideas?

Subject: Grolsch-type bottles

In Digest No. 751, Don Karon asks:

>Has anyone experienced any problems using resealable bottles  
>like the ones Grolsch comes in? Before I go out and drink  
>40 Grolsch's I wanted to make sure this was indeed a clever  
>idea.

Sure! Just make sure that the rubber gaskets haven't dried out or cracked.  
Inexpensive replacements are widely available from homebrew-supply shops.

I use a lot of Fischer Bitter d'Alsace bottles, which are "flip-top" containers like Grolsch but boast three (3) significant advantages:

- \* The bottles are heavy brown glass.
- \* They hold 22 ounces, enough for me to split the brews with my wife along our usual 20:2 ratio. :-)
- \* I find the beer marginally more pleasurable to dispose of responsibly than Grolsch. Avoid the Fischer AMBER d'Alsace, though; it's an unpleasant potion indeed.

Say, Don, I see by your "handle" that you're a CompuServe member. Have you dropped by the Wine (and Beer) Forum? Check us out at GO BEER.

I find them easy to bottle in, easy to open, and easy to reseal  
when only drinking half a bottle of beer. Wish I had more, but  
am not willing to drink Grolsch to get them. Also wish the brown  
glass bottles were more prevalent.

The only caveat is that the rubber gaskets get worn and dried out  
with age, so you need to keep a replacement supply on hand.  
Also, be sure to sanitize those gaskets along with the rest of  
the bottle.

I think that Marc has hit the nail on the head: "I don't keep my beer around for more than a few months though..." I am quite confident that if you finish your beer in a few months, you can be sloppy in your sanitation techniques. I use the "fill the siphon hose with hot water" method, but have been salivating over the Cole-Palmer catalog in anticipation of purchasing a peristaltic pump (hose pump).

Since there are a lot of beginners reading this forum, I think that recommending sloppy sanitation is an invitation to brew lactic acid. Results like that may turn off a lot of potential brewers. It's not that hard to use bleach solution and rinse well (I've taken to rinsing with hot tapwater and then cheap beer, but that's another story) and the benefits have been documented numerous times.

From: Scott Knowles <NECHO%NCSUMVS.BITNET@ncsumv.cc.ncsu.edu>  
Subject: Who has brewed a hot-pepper beer?

Hiya,

Does anyone have experience brewing spicy beer? The idea is not as odd as it might seem; I'm familiar with one commercial brand called "Cajun Beer" that is quite peppery and very tasty. To get a feel for how good the combination can be, trying sipping one of your own light/medium ales while nibbling on a chili or jalopeno....

The heat and flavor of peppers varies greatly. I'm familiar enough with a halfdozen varieties to use them judiciously in cooking, but I just can't predict how they might behave in a brew. Experimentation is obviously in order, but I welcome the advice of peppermeisters.

To save bandwidth, please reply directly to me, and I'll post a summary of response to BEER-L.

From: R\_GELINAS@UNHH.UNH.EDU (Russ Gelinias)  
Subject: jack, grolsch

I'd like to throw in a comment about Jack S. and his video, and then maybe we can go on to more interesting stuff. It seems to me, that we (and he) are missing an important distinction. There is a vast difference between how you brew your \*own\* beer and how you tell others to brew \*their\* beer. As the beer judges on the list have pointed out, people perceive flavors (or defects) differently. You may actually \*like\* the taste of oxidized beer, or may not even be able to notice it, while it may make a beer undrinkable to me. So \*you\* can go right ahead and not worry about introducing O2 into your brew, while \*I\* should take precautions against it. The problem, Jack, is that you are making a how-to video, for general consumption, so to speak, of a wide range of people, with all the inherent differences in their tasting perceptions. Cardboard flavor from oxidation is a well documented fact, even if you have never tasted it. I'm not sure I have, but I don't want to, so I take the precautions against it. If you're not just out to make a quick buck, and you really want to help people make good beer, then your \*demonstrated\* technique should impart a minimum of off flavors. Brew your own beer any way you like.

`Nuff of that. Grolsch bottles are great, for whoever asked. You might need to replace the rubber gasket from time to time. Fischer bottles are good too, and they're bigger, although some have said they are too thin and tend to break. I've never had any problems with them.

I've been drinking my latest, a stout, and I get a headache from it. I was going to ask some questions about it, but I just realized that this is the first batch in a new 7-gallon carboy, and it did not blow-off! All my other batches were in 5-gallons c's and blew off crud. This is the only batch that has ever given me headaches. Cause and effect? Momily? Or a case where an individual is susceptible to something (fusel alcohol-induced headaches) and should use techniques to avoid it, while others who are not susceptible may not have to worry about it? You decide.....

Longwindedly yours,

I have 45 of them at this time and I absolutely love them. They currently contain my Christmas beer and I use them to bottle stouts in as well. For me, 16 oz. is a better size serving of my homebrew than 12 oz. and the fact that I don't have to cap them makes bottling easier. I have used them 4 or 5 times without replacing the gaskets. None of them show signs of wearing out yet. I got most of mine by drinking Grolsch but a couple of friends contributed 6 or so. You could do well by going to a bar where Grolsch is served in the swing top bottles and ask them to save you some. A friend of mine went to a local Irish pub and got a dozen on his first trip this way. Free. The only thing wrong with my Grolsch bottles is that there aren't 45 \*more\* of them! I seem to recall someone mentioning in this forum that there was a place in Canada (I think) that sold new Grolsch-style bottles that were brown instead of green. Would someone post the address/phone number of this place, if it exists, along with pricing information?

Subject: Rotting Garbage?!?

We brewed a batch of Dave Line's Newcastle Brown recipe on Sunday. When I got home from work yesterday afternoon, our apartment was filled with the smell of rotting garbage! A bit of olfactory detective work determined that the odor was coming not from the trash can, but from the bubbling airlock. Near the fermenter, the smell was strong enough to make your eyes water.

Not that I'm worried, see, but what might that smell be? I suspect it's DMS-related, because there's a big "sulfur dioxide" component. Any ideas?

For the last year or two I have been using swing-top bottles exclusively for my beer. You may need to replace the gaskets, but your homebrew supply shop should have replacement gaskets. Knowing when to replace them is easy, if the rubber is hardening and cracking, dump them.

They make bottling easier because they are larger and quicker to cap.

From: cjh@vallance.HQ.Ileaf.COM (Chip Hitchcock)  
Subject: re skunks/worms

Your argument that most light-based reactions are driven by UV rather than visible light //may// be accurate; I never spent enough time on photochemistry (when I was a practicing chemist) to have an overall grasp of the field. Certainly sunburn (the light reaction people are most likely to be familiar with) is driven by UV.

HOWEVER, skunkiness in beer has been specifically pinned down to a photolysis of hop extracts at ~525nm; this is well within visible light (~450--750nm). The rap on green glass is that it blocks light at >~550nm,

so it's useless to prevent this reaction.

Note that this doesn't totally invalidate your sun&fluorescent-vs-incandescent argument. Incandescent give off ~93% of their energy as heat, and what little comes out as light is mostly the adjacent (longer visible) wavelengths; the standard filter or coating to make incandescent light imitate sunlight is a metallic blue, and the converters for shooting

outdoors with indoor film are correspondingly orange. Fluorescent lights probably don't give off /much/ UV (cheap glass doesn't pass UV very well)

but they do spread further up the range of visible light. So sunlight and fluorescents will harm beer in green glass faster than incandescent light will---but I wouldn't assume incandescent is /safe/.

From: microsoft!larryba@cs.washington.edu  
Subject: Re: SS Fabrication

I asked a buddy of mine how hard it was to weld SS (and more to the point, could he do it with his TIG welder). He said the way to go is to silver solder. It can be done with a regular blow torch, is food safe and most important, it is very easy to do and control. The cost of the silver solder is nominal compared to the cost of a wire feed TIG welder... or hiring someone who owns one.

Anyone know of any reason why this wouldn't be a good idea? The only thing I can think of is long term galvanic corrosion at the silver/SS interface.

Date:Wed, 30 Oct 91 11:31:10 EST  
From: William Boyle (CCL-L) <wboyle@PICA.ARMY.MIL>  
Subject: off flavor

I have a slight problem, two of my last three batches have turned out with a, as my brew partner calls it, "bandaid" flavor, I think it's a bitter flavor but not a hop bitterness. The recipe was:

1 can of yellow dog  
1/2 lb of crystal malt  
1 lb of amber dme  
.75 oz of cascade hops AA=5.7, 1 hour boil  
Wyeast London yeast #1028

We fermented in my basement which is about 67 to 69 degrees F during the summer (this was last May). The beer was in the primary for three days, at that point it had a strong off smell, two weeks in the secondary and then we bottled. I thought it may have been infected but last week I had a bottle and the flavor and mellowed but was still there. There were no gushers, it may have been under carbonated if anything. I thought the flavor may be due to the low hop rate, so I made some hop tea and added some to a bottle it seemed to help a little.

The next batch was made on 10-23 with the recipe as follows:  
1 can of American Eagle unhopped  
1 lb of amber dme  
1.25 oz cascade hops AA=5.7, 1 hour boil  
Wyeast American #1056

It was in the primary for 5 days and during racking we smelled the same thing as the other batch. The temperature was around 69-70 degrees F.

Does anybody have any idea were this smell/taste can be coming from and/or how I can fix this. Any advise or comments will be greatly appreciated.

Date: Wed, 30 Oct 91 11:25:46 -0500  
From: ted@evi.com (Ted Stefanik)  
Subject: Applejack

My references define applejack differently than the last few to mention it.

Therefore, let me set the record straight.

I'll pick up with Jay Hersh's definitions (USA usage) and complete them:

Juice: Filtered apple juice  
Cider: Unfiltered apple juice (sometimes called soft cider)  
Hard Cider: Fermented cider  
Apple Wine: Fermented cider or juice with lots of additional sugar added.  
Apple Brandy: Distilled hard cider or apple wine. This is heat distillation.  
Applejack: Hard cider which has been fortified through fractional crystalization (freezing out the water).

Applejack and Apple Brandy are supposedly two very different things. Apple Brandy contains only the volatile components of the fermentation product, while Applejack contains the entire result concentrated. Supposedly it can give you a hangover much easier.

To quote from Chad Epifanio (who got it right):  
By the way, I am under the impression that "Apple Jack" was an old method to condense the cider; i.e. the finished cider is allowed to freeze, a hole is punched in the ice cover, and the underlying contents siphoned into a waiting carboy. This process is repeated until the liquid no longer freezes. A primitive distillation perhaps.

By the way, the US government views any sort of purification of alcohol in the same light, so it is just as illegal to make Applejack as to make Apple Brandy.

From: night@mapme7.map.tek.com  
Subject: Miller's Book

Jeff Frane writes:

>Miller seems to think that beginning brewers will be most familiar with  
>Bud-style beers. My own experience teaching beginning brewing has been  
that--in  
>this area, anyway--new brewers are familiar with microbreweries and  
imported  
>beers and are interested in brewing something like BridgePort or Widmer  
or ...  
>Miller is, I believe, from the St. Louis area and his experiences are no  
doubt  
>different.

I cannot agree with you more. It seems that Miller's approach is that  
home-  
brewers WANT to brew beer like BUD. It is also apparent that he enjoys  
light lagers himself, and thus puts more effort into the lager sections  
in  
his books.

However, just because he likes light lagers doesn't mean he can't  
give excellent advice on brewing. On the other hand, I'm not saying  
Miller's  
books are better than any others either. My point was that several  
people  
stated blatantly wrong information about Miller's book. I felt that  
everyone  
who is interested should have the right to know that those things simply  
were not true.

Okay, another subject:

Has anyone tried canning wort in jars so to sterilize and preserve it for  
future use in making yeast cultures? How did it work? Does the extreme  
temperatures and pressures of canning effect the taste enough that a  
starter  
would off flavor you next batch?

And... one more subject...

I would agree that Red Star Ale yeast gives a definite estery flavor to a  
batch of beer. However, I now use the Red Star yeast and brew at 58F.  
This  
seems to almost completely eliminate the esters produced by the yeast.  
So,  
with this information... I can brew styles that benefit from esters at a  
warmer temperature... and other styles with no esters at lower  
temperatures.

Has anyone else experienced this? How about with other brands of yeast?  
Is there any published information on yeast's different fermentation  
characteristics at different temperatures?

Cheers!

Mark Nightingale    night@tekig7.map.tek.com

> 1 ounce Fuggles (boil 30 minutes)  
> 1/2 ounce Fuggles (steeped 15 minutes)  
> ale yeast

> Has anyone tried this potion?

> I'm considering replacing the 1 pound of dark brown sugar with 2  
ounces

> of molasses - comments?

>  
This is very similar to one I tried when attempting to replicate  
Wadworths

6X with the help of Dave Line's "Brew Beers Like Those You Know"(?). It  
was

very good: dark, rich and strong with a brownish head.

The sugar will make a difference, demarara imparts a lighter taste and  
colour to dark brown. I used light brown sugar and it was still  
noticeable.

If you use molasses I suspect the colour and taste will remain but the  
beer

will be weaker, which may be what you want.

I used Fuggles for the copper and Goldings for late; no dry hops. I also  
used too much of them, nearly 3 oz each. But I think the quantities given  
above may be too little, I'd go for 1.5 or even 2 oz each. I take it it's  
a

4 gallon batch?

Subject: Re: Where to get a deal on carboys in Chicago?

References: <9110290800.AA06181@hpfcmi.fc.hp.com>

<digest.Ud3FMke00Ukc80hV06@andrew.cmu.edu>

Here Here to another first time post....

I recently called around to find glass carboys and was able to find  
several smaller drinking water supply companies that were willing to  
sell a few of theirs for 8 to 10 dollars. My recommendation to anyone  
interested in glass carboys is to go through the local yellow pages and  
call the companies that sell drinking water.... i.e. look under WATER  
or WATER DISTRIBUTERS. I found out that the bigger companies such as  
Polar use the plastic containers so start off by calling the smaller,  
less known ones.

Subject: Re: Grolsch-oid bottles

When I was in NY I used \*only\* Grolsch bottles, and have never had a problem. The only possible problem that may arise is that the rubber washers wear out, but you can easily get replacement rubber washers at most homebrew stores - and they are reasonably priced.

They were relatively easy to come by in NY because of the recycling movement. When I moved to CA, I returned all the Grolsch bottles at 5 cents a piece, since I assumed that they would be as easy to get here. Imagine my dismay when I was told that recycling these bottles were considered \*illegal\* in CA (in violation of some recycling guidelines), and therefore impossible to obtain! I wish I'd hung on to my cases of Grolsch! I honestly believe that this has put a damper on my brewing.

>Has anyone experienced any problems using resealable bottles  
>like the ones Grolsch comes in? Before I go out and drink  
>40 Grolsch's I wanted to make sure this was indeed a clever  
>idea.

I've had mixed results from Grolsch swing-tops. I used about 10 for my  
last  
batch, and so far have had one under-carbonated and one completely flat.  
I did  
\*not\* have new gaskets for them; I used what came on the bottle, though  
they  
appeared to be in good shape.

I've purchased some new gaskets from my local supplier and will try again  
with  
the current batch. I think that the new rubber will make a big  
difference.

Regards,

Perry Donham

Subject: Lack of carbonation?

I'm fairly new to homebrewing. I have brewed and sampled three batches of fairly simple ales from extract. The first was really good, and had good carbonation, a good head, etc. The next two batches were quite tasty, but lacked the carbonation and head of the first batch. All have been primed with 3/4 CUP of corn sugar in five gallons.

What factors could cause this less-than-impressive carbonation? Thanks!

Subject: coriander beer

My roommate and I brewed a coriander beer a couple of months ago. Initially, it was undrinkable due to an intense bitterness in the aftertaste. Being hopelessly optimistic, we decide to wait before fertilizing our garden. After a month in the bottle, the bitterness went away but the coriander was no where to be seen. I tried a bottle during the seventh game of the series and WOW, coriander. The beer has a spicey, gingery finish with the tiniest hint of sourness. Its gotten quite good.

I don't have the recipe but it is an extract of Alexanders pale malt. We colored the beer by soaking crystal malt and roast barley in a quart of hot water each, mixing the liquids to get a reddish color. Now that the beer has cleared, it is a beautiful deep red.

We spiced the beer at bottling time with an extract made from Vodka and about 1/2 tsp of coarsly crushed coriander seeds. I let the coriander sit in the Vodka for about a week.

Looking back on it, I would heat the extract before adding it to the beer in an attempt to drive of the alcohol. I wonder if this is where the bitterness came from...

Subject: Bitter and better...

I'd like to second Caitrin Lynch's request for a Hook Norton Best Bitter recipe, and would add a request for a recipe for their stronger brew Old Hooky. I learned (not hard!) to love both of these beers while a guest at the Butcher's Arms Inn in Woolhope, England. A charming place in a 15th century building where the ceiling beams in the pub were just about at the level of my nose! I guess people weren't six foot two back then!

To Jack: The reason I'm trying to learn to recognize subtle flaws in beer is not "to learn to dislike them". What I'm aiming at is to be able to be able to identify the flaws in a very good beer, so that next time I can come a little closer to making a GREAT beer. I have no idea whether I'll succeed, but I figure I have a much better chance at a great beer if know why my current batch isn't great than if I just keep changing random factors, hoping someday I'll get it right. Probably an artifact of a scientifically oriented upbringing combined with a strong perfectionist streak, but that's why I do it. My fathers favorite aphorism (he had lots) was:

Good, better best,  
Never let it rest,  
Till your good is better,  
And your better's best.

Knowing the difference is an essential part of the process (for me at least).

Yes and no. What you're overlooking is that the color comes from ingredients in the glass; blue from cobalt, for instance, and that the effect we see in the visible spectrum may only be the tip of the iceberg. How does cobalt affect the UV spectrum? I don't know, but it's reasonable to guess that clear, brown, and green glass have different reflection/absorption/transmission characteristics in other spectra besides visible light.

> Glass, regardless of color, stops most UV.

So why do I have to buy a special UV filter for my camera, which has a glass lens? (I'm not being a smart-ass, either; maybe you're right, in which case I'm being ripped off.) Also, why does the dashboard of my car become slowly faded and cracked from (I'm told) UV exposure, despite having the windshield above it?

Who needs those creeps, just ask an engineer! 8-) Take your favorite beer, and transfer three bottles worth into one each blue, green, and brown glass bottles. Place in bright sun for 45 minutes (with caps on) then taste. They'll all be flat, of course, but the skunk odor should be distinct enough that it won't matter, right?

From: bgros@sensitivity.berkeley.edu (Bryan Gros)  
Subject: Honey Basil Ale

I was in a local brewpub (Bison Brewing) recently and they were serving a Honey Basil Ale. It was very good, medium bodied, with just a lingering hint of Basil after swallowing. I was considering trying to reproduce this beer and am soliciting suggestions from more experienced folks.

My first recipe might look something like:

6 lbs pale malt  
1 lb wheat malt  
8 HBU Cascade  
1 cup honey  
ale yeast  
1/8 cup chopped fresh basil, added to fermenter

Any suggestions for :

how much honey? when should it be added to the boil?  
what kind of hops? how much? beer shouldn't be very bitter.  
how much basil? when to add it? to the boil? the fermenter?  
what kind of yeast? sierra nevada i guess.

thanks for the help.

Subject: Re: Grolsch bottles

Don Karon asks about Grolsch bottles.

I have never used them, but have read (in this forum) that they work very well if you replace the gaskets before the first re-use and every so often (2, 3 or 4) re-uses. The gaskets are available from many homebrewer's supply shops, but if you can't find them, I know that Lil' Olde Winemaking Shoppe (708-557-2523) and Winemaker's (in Elmhurst, IL) have them. I would also recommend storing them in the dark (see my previous post) or using Altenmunster bottles (brown bale-top bottles) instead. There's an ad in virtually every Zymurgy for a place that sells empty bale-top bottles -- you might try that instead.

From: hartman@varian.varian.com (John Hartman)  
Subject: Various Topics

Maris Otter malt:

A few weeks ago I made queries about torrefied wheat and a type of barley malt called Maris Otter. Thank you to those who responded via email and in the digest. I purchased some Maris Otter malts from Liberty Malt Co. in Seattle. It's a nice store by the way. I brewed two batches of strong ale with this grain. I'm only a judge in the sense that I know what I like and with that in mind I say that Maris Otter malt does brew a fine beer. I seems to have more body and a richer (spicy?) flavor. Using this grain I was able to produce my most athentic English ale to date. Perhaps I'll brew the exact same recipe with and without this malt to get a better idea of its qualities. If you're interested in trying it out, you can contact Liberty Malt at 206-622-1880. Unfortunately it's rather pricy at \$1.55/lb...

Torrefied Wheat:

It's still not clear to me whether torrefied wheat is made by popping it, scorching it, or both. I guess I'll have to plan a road trip to the Young's brewery in London. On the other hand perhaps one of our London readers could take the tour and ascertain the facts. I could think of worse duty;-)

Plastic vs. Glass:

I use a 20 plastic primary. I'm troubled by the AHA statistics and often wonder what if any off flavors might be attributable to my use of plastic. I think the statistics \*may\* be misleading. Have not glass carboys been around longer? Perhaps the more experienced brewers therefore use glass. Also plastic is cheaper. Thus new brewers start with plastic, then switch to glass later in order to eliminate the risk of off flavors, especially when competing. Those who can afford glass probably have a bigger equipment budget. I suggest that the stronger correlation is between years of experience/budget and winning of awards.

Good source of grain:

A few months ago someone was looking for a good source of grain. I buy mine at:  
Brewmaster  
2315 Verna Court  
San Leandro, CA 94577.  
800-288-8922 or 510-351-8920

They have a huge selection of supplies (no torrefied wheat:-)) for both beer and wine making. For bulk orders of 20 lbs. or more domestic two-row pale ale malt is \$.65/lb. For British two-row pale ale malt is \$.64/lb. Add \$.04/lb. for crushing.

Cheers,  
John hartman@varian.com

From: andy@wups.wustl.edu (Andy Leith)  
Subject: Light and Bitter

Daniel Butler-Ehle writes that most UV is reflected by glass and that the colour only effects visible light. The first part of this statement is partially true, the second part is wrong. UV from sunlight that can penetrate the atmosphere is in the 0.3 to 0.4 micron wavelength range. Depending on the type of glass some portions of the specrum are indeed not transmitted, however some wavelengths within this range are transmitted with a transmisivity of up to 90% and it is these that cause the damage. Photochemical changes are specific to particular wavelengths, and if the wavelength in question is transmitted through the bottle the reaction will occur regardless of how much of the rest of the spectrum is reflected or absorbed. Green bottles permit a significantly higher amount of UV light through than brown bottles. A look through the CRC handbook of Physics and Chemistry section on Corning and Wratten filters should convince you of this. Incidentally the handbook lists the wavelengths in the Corning section as being in nanometres and I think this is a typo and should read microns.

Nick is looking to duplicate an English bitter, I suggest you get hold of a copy of Dave Line's Brewing Beers Like Those You Buy, which has many good ideas (remember that the recipes are given in Imperial units), despite the fact that Bitter is quintessentially a draught product you CAN make reasonable facsimiles in a bottle, although it is easier to use a keg.

I'm afraid not. Fluorescent lights and the Sun produce considerably more GREEN light than incandescent lights. It is true that they also produce more UV, but it is green light (see below) that we are concerned about when it comes to skunky (or catty - no skunks in the UK, you see) beer.

>UV producers like incandescent light. This is evidenced in the

Here's a part of a post from Darryl Richman in HBD 609, in which he corrected me when I made a similar mistake:

>Light struck is defect noticable by a skunky or catty aroma. This is  
>brought on by a transformation in one of the hop constituents under the  
>influence of green light. This compound is converted into a mercaptan,  
>one of a class of extremely aromatic compounds. (Natural gas is  
>odorized with a mercaptan, at about 5 ppb.)

I contend that clear and green bottles transmit green light, whereas brown bottles absorb most of it. However, if you keep your beer in the dark until you drink it, you can use any color you have handy. (Just for the record, I cover my carboys with opaque plastic bags to prevent the production of mercaptan.)

From: strasser@raj3.tn.cornell.edu (Tom Strasser)  
Subject: Skunks and Grren Bottles Revisited

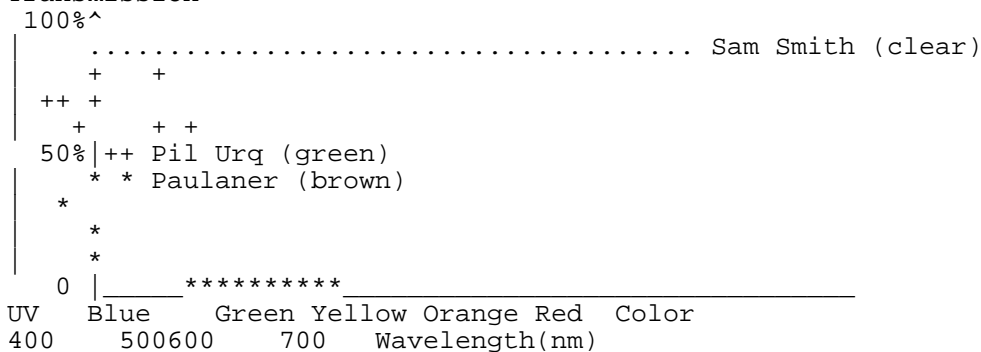

```
] From: "Daniel Butler-Ehle" <DWBUTLER@MTUS5>
]
] I have heard many arguments about what color glass bottles should
] be in order to avoid light-struck beer. It is my understanding,
] however, that hardly anything (including beer) reacts with
] visible light; it is the ultraviolet light that reacts with stuff
] in the beer (often said to be the hops, but the jury is still
] debating) to cause that skunky, light-struck taste (as exhibited
] overpoweringly by every imported Pilsner Urquell I've ever had).
```

I just finished writing an article for our club newsletter on lightstruck beer and the abilities of different bottles to protect beer from light. I thought I'd share only a portion of this with the digest due to space; anyone wishing a copy of the full article can mail me directly.

First of all I would like to refer everyone back to digest 729 and a submission from Steve Stroud. This article focused my thoughts on how different bottles protected beer, and I thank Steve for bringing this article to my attention.

The experiment I undertook was to test seven different bottles in a spectrophotometer to determine the transmission of each bottle at different wavelengths in the visible spectrum (from 400 to 700 nm). The bottles test were a clear Samuel Smiths; green Pilsner Urquell, Molson, and Grolsch; and brown Budweiser, Paulaner short neck, and the New Paulaner long neck. It turned out that the green and brown bottles all showed the same peaks and valleys in the transmission spectrum, with the transmission level shifted slightly depending on the thickness of the bottle. These results lead me to believe either these imported beers are bottled in the US, or the bottle compositions for a given color bottle are very similar everywhere. In either case the results I've found would seem to apply to most if not all beer bottles in the US. I've tried to give you an ascii plot below to give you an idea how the transmission varies for different color bottles:

Transmission

To evaluate how these allow lightstruck beer, I got some technical information posted in the digest:

```
) HBD729
) From: STROUD%GAIA@sdi.polaroid.com
)
```

) I recently came across an article entitled "Photochemistry of Beer", published in The Spectrum, Vol. 4, Issue 2, Summer 1991. The author is Denis De Keukeleire, State University of Gent, Gent, Belgium.

) From the article...  
) The thiol is formed by direct UV-radiation, but also by visible light or sunlight. Since the iso-alpha-acids do not absorb in the visible region, the reaction is very probably sensitized by riboflavin (Vitamin B2). Colored substances, such as polyphenols, may also affect the light-induced decomposition of the iso-alpha-acids (5). Indeed, it is well-known that dark-colored beer is more susceptible to the development of the lightstruck flavor than light-colored beer (6).

) Only ultraviolet light has enough energy to break the iso-alpha bonds necessary to lightstrike beer, but a color substance as discussed above can absorb high energy visible light (say <400nm) and transfer this energy to break the iso-alpha bond. Although this method is not efficient, the threshold for the mercaptan caused by lightstruck beer is less than 1 part per billion! The above article said light less than 500 nm is efficient enough to be considered in this process. I think there may be some reaction at wavelengths slightly higher, but these would be at a reduced efficiency in causing the lightstruck flaw. In my analysis I consider the portion of light from 400 to 500 nm which is transmitted by each bottle. So I integrated the transmission curves over the 400 to 500 nm region for comparison. This result could be weighted to favor lower wavelengths which would be more efficient; however, common light sources (except direct sunlight and fluorescent light) have a decreasing intensity as the light approaches 400nm. Due to the lack of exact weighing, and competing effects involved, I chose a linear integration for comparison.

The results were that the green Pilsner Urquell bottle blocked 1.5 times more light over this region, while the brown Paulaner bottle blocked 68 times more light.

I conclude that brown bottles are significantly more effective at preventing lightstruck beer, but since the threshold for detection is so low, keeping all beer bottles in the dark as much as possible is the answer, NOT just keeping your beer in brown bottles.

Daniel's questions from yesterday's digest:

] The large output of UV is the primary distinction between light from such sources as fluorescent lights and the Sun and light from weaker UV producers like incandescent light.

] ...  
) What's this got to do with beer? What's true for glass lenses is true for glass bottles. The color of the bottle affects only the visible light. (That's why it has color in the first place.)  
) Glass, regardless of color, stops most UV. Therefore, beer in brown bottles should be no more or less susceptible to light damage than beer in green or even clear bottles.

Two things to note here, first of all, that 400-500nm light can transfer energy and cause lightstruck beer as noted above. The second thing is that it can be seen above that the trend for transmission into the UV is that the brown bottles will transmit far less UV light than the others. This was true for all 3 different brown bottles I tested, so although the color of the bottle is only directly indicative of transmission in the visible spectrum, it can be seen above that in practice it also is indicative of the relative ultraviolet behavior of different colored bottles. (Yes, the green and clear bottles are certainly

not ultraviolet transparent, but it can be seen in the above plot that they will transmit more UV light than the brown bottles will, unfortunately I couldn't measure the UV behavior to prove this).

] Any comments? I ain't no physicist, so I'd like to hear from  
] someone who knows. We got any opticians out there?  
Well you got my 2 cents worth. While I was writing this, this  
month's "Ithaca Brew News" just came off the press with a more  
complete elaboration on lightstruck beer (as well as a much better  
transmission plot). So the IBU's out there can anxiously await the  
arrival of their copy soon. The rest of you can look for the IBN  
at your local newsstand ;-). (or perhaps I could mail you the text  
at your request).

Auf ein neues,

From: Brent Ball <staf1282%slcsl.bitnet@utcs.utoronto.ca>  
Subject: reply Grolsch Bottles

Don, I thought that I would respond to your inquiry about reuseable containers such as Grolsch bottles. I have been using them for over two years without any problems. As a matter of fact, my local homebrew supplies store here in Kingston sells new rubber seals for these bottles at about 12 cents each. He also sells empty Gr. bottles (hey, no fun that way eh?) for about 75 cents each. Only once so far have I had any carbonation problems (ie. it varied from bottle to bottle drastically and wasn't a fault in the beer) so I replaced all of the seals and haven't had a problem since. As a matter of fact, Grolsch bottles are very structurally strong. Last spring I made a batch of Australian Ale and over-carbonated it more than just slightly. Nary did a bottle break. The only problem was upon opening the beer because it blew the wire closure/porcelain cap clean off the bottles!!!! This was replaced without trouble. But the batch did cause me severe finger bruises and pinches during the opening process. In my opinion Don, drink away and have fun acquiring a new set of bottles!!!!!!  
!!

**Subject: reply Grolsch Bottles**

I have followed the discussion regarding plastic with more than just a passing interest as I am still very much a beginner (having brewed only about a half year now) and use a plastic primary. While I understand the logic behind a preferences for glass, how is it that the plastic bottling buckets everyone seems to recommend do not create the same difficulties as a plastic fermenter? Is the time of contact too short?

Regarding off flavors, all the talk of late has caused more than a little concern with my own efforts (not all of which I have been crazy about). Since each brewing effort has thus far been different from the last (too many new styles to try to bother repeating something old), and since my technique remains basically the same, I wonder if I am not producing "tainted" brew unknowingly. I have noticed references in the past regarding, I believe it was called, doctored beer. Can someone direct me to where I might get information on intentionally creating the most common off-flavors (short of purposely ruining my next half dozen batches, or so) so as to familiarize myself with that which I should be trying to avoid? I suspect the very thing that prevents me from touting my efforts as total successes is some off-flavor that I unwittingly introducing.

Thanks  
Frank

From: microsoft!larryba@cs.washington.edu  
Subject: Re: Oxidized beer flavor

Jack: to get a clear idea of what oxidized beer tastes like, purchase some bland bottled beer (rhinlander is popular out here, Old Milwaukee should do fine), open it up, dump a little beer out, get some air in, re-cap, shake well and store somewhere warm (>100f) for a week. later, cool to normal serving temperatures and serve. It should be pretty awful. Hopefully your test beer will never get that bad.

To get a similar example of light struck, get another bottle and simply set it out in the sunlight for a week or two. Don't use Miller (in clear bottles) - that has been doctored to be resistant to light struck.

I believe that the above recipes were used for the last Brew Brothers Doctored Beer Defects tasting.

I would guess the reason why actively fermenting beer in a carboy is not so strongly affected by light is that the noxious compound is blown out by the fermentation gasses.

Good luck.

Boiling hops alters the Alpha acid groups to Isoalpha acids (isomerization). These Isoalpha acids are unstable in the presence of light - a reaction occurs with sulfurous proteins resulting in 3-methyl-2-butene-1-thiol, a mercaptan which is perceptable at the PPB level. The frequency of the light that causes this reaction is 520 nanometers, which is blue-green. UV light is in the 300 nm range. Brown bottles typically block ~80% of the 520nm range, most green glass blocks ~70% at ~450nm but only blocks ~30% at 520nm. I have heard that the tinting of the green in beer bottles can alter the transmission, so your milage may vary.

**Subject: Worms and beer...**

This reminds me of a story my wife tells about her late maternal grandfather.

The old gent was from Ireland (worked on the construction of Shannon airport, for example), and was reportedly quite a character. When I began brewing, and being the fanatic that I am (I like it that way, thanks), I sanitized to a fare-thee-well. Upon noticing that, my wife explained how her granddad raised fishing worms in wooden barrels in the summer. In the winter, he would rinse (yes, just rinse) a barrel out, and brew his beer in it. This conjures up all kinds of interesting thoughts. Must have led to some interesting names too...Annelid Ale?

Which leads to the old joke about a preacher who put two shot glasses on the pulpit - one with water, and one with an alcoholic beverage. He dropped a worm in the water, and it swam furiously. He then dropped it in the other, and it curled up dead. He then asked for the moral of the story. From the back of the room came a slurred reply - "if you drink alcohol, you'll never have worms."

And lastly, since I am rambling...why is it that many (most?) postings I have seen, here and on Usenet, that refer to that quintessential Irish dry stout, show it misspelled? Usually with one "n", sometimes with one "s". I mean, if you drink enough of them to affect your spelling, you are looking at enough of them to transcribe the name right, no?

Happy Halloween.

Cheers...Gary

Subject: food grade plastics

I tried to send this message on Tuesday (10/29) but it never seemed to show up.  
I'm sending it again. Sorry if it shows up twice.

- ----- Begin Included Message -----

Ok I got an idea/question. There's been alot of chatter out there about using and not using plastic fermenters in the brewing process. Well, I use a 7 gallon plastic fermenter for the primary fermentation stage. My old one was getting discolored and scratched so I recently purchased a new one. I just brewed my first batch with it and have noticed (or at least think I've noticed) that a particular flavor that used to "characterize" my beer (not one that I particularly liked) has gone away. So now I'm thinkn' "sheesh am I going to need a new plastic primary every dozen batches or so?" Then I do the math = big \$ (at least by my standards). So here's the idea/question. If I could line my primary with a disposable liner then I'd have a "new" plastic primary each time I brewed. A trash bag would do the trick, but of course it was designed to carry gross junk and to be dropped from hot air balloons onto suburban roof tops and not to carry tasty fermenting fluid. Does this matter (I assume it does)? I know they make plastic bags to hold food (i.e them ziplock bags for instance). Are these made of food grade plastic? What is a food grade plastic anyway?

Subject: Re: Homebrew Digest #752 (October 31, 1991)

We just put together an order for the next few batches and thought we'd try making a barley wine. We found a recipe in miller's book that sounds good, but has a peculiar bit of instructions. I can't remember exactly, but he seemed to want you to have the secondary fermentor CLOSED 1 gallon jugs. He doesn't mean that does he? There's still an air lock, right?

If any one has words of wisdom concerning Miller's recipe, or personal experience with barley wine, and whether it really is any different than bringing any other beer, we'd appreciate the advice.

thanks,

From: HEISCH@ZEN.RADIOLOGY.ARIZONA.EDU (Bob Murphy)  
Subject: Coriander Ale Recipe

Brian Capouch <brianc@zeta.saintjoe.EDU> asks about brewing with coriander.  
Good question, Brian. I have been meaning to send in 'my favorite beer recipe' for some time now, and it just happens to be a coriander beer. I've made it 3 times (out of 40 some batches over the last 3 years) now and each has turned out better than the last.

#### Bob's Coriander Ale

1 lb light crystal malt, steep for 60 min. at 160 F. then sparge  
add 6 lbs. light unhopped malt extract,  
1 oz Cascade hops 5.5 alpha - 60 min  
1 oz whole Coriander Seed - 30 min  
1 oz whole Coriander Seed - 10 min  
1 tsp Irish Moss - 10 min  
Pitched Chico Ale yeast from a previous batch  
Original Gravity 1.040  
Final Gravity 1.012

I strain off the hops & coriander seed when transferring to the primary. I use a 2 stage glass carboy fermentation with blowoff tube for the first 2 days. Leave in the primary for 5 days, and in the secondary for around 10 days.

Each batch has been a bit different, but good. The coriander isn't real strong, but is noticeable. Some people have a hard time identifying it. For some reason they all seem to lack much head, maybe the oils in the coriander? Lack of head is not a problem any of my other beers have. Overall a nice slightly spicy light beer. Probably good for lawn mowing if I had a lawn. Good right away but seems to get better after 3 to 4 weeks in the bottle. The flavors blend together a bit more with age.

From: darrylri@microsoft.com  
Subject: Bottle color

(Dare I say it?) I consider the bottle color to be, if not a momily, at least irrelevant. I come to this conclusion as the result of one experiment, and what I hope is common sense. The experiment is one I've carried out numerous times in anticipation of a Dr. Beer session I've done for the past 3 years for folks taking the Falcons' BJCP preparatory. You can take a beer in any bottle, green, brown or clear, and expose it to the sun for as little as 15 minutes and be amazed at the strength of the reaction. I use Budweiser for the experiment, in long neck bar bottles (heavy, dark brown), even though Bud has almost no hops. From this, I conclude that bottle color is irrelevant for commercial beers: if they are poorly treated, it doesn't matter what color the bottle is. For homebrewers' purposes, I once again conclude that bottle color matters little, since we have long been warned about the danger to beer from light, and hopefully, we store our beer out of the light. In this case, of course, bottle color can have no effect either.

> can produce. (i.e. Head of household 200 gal or individuals 100 per year.)  
> What are the age requirements to homebrew? Is it legal to ferment your own  
> alcoholic beverages under the legal drinking age in your state?

Many states defer entirely to the federal laws, which have the volume limits you mention. The federal laws also state that a brewer must be over 21. It is not unheard of that minors might get away with brewing their own as long as they remain discreet about it, although the Falcons had to discourage a young fellow who was obviously underage once, from attending the meetings.

> Second Question:  
> When fermenting in a 5 gal. glass carboy whats the best volume to ferment with?

> ferment.  
> I know this isn't a FAQ but, is this dumb?  
> Are the alcohol concentrations in a primary ferment not even close to  
> the max working concentrations for yeast?

There's nothing dumb about this at all. In fact Miller and AB both practice this technique, which is usually referred to as high-gravity brewing. You can calculate your effective gravity by taking your measured gravity, at 4 gallons say, and multiplying by 4/5 to get the effective gravity at 5 gallons. (It's close enough to a linear relationship at the gravities we work to use it as if it were correct.) If you are trying to formulate your recipe ahead of time, you can take your predicted OG at 5 gallons and multiply it by 5/4 to see what effect the concentration at 4 gallons has. You can do this with predicted final gravities as well.

The average ale yeast (if there is such a thing), in good condition, ought to have no difficulties with beers up to 8% alcohol by volume. This translates, again on average, to an OG in the 1.080s. This is not to say that a beer fermented at that concentration and then watered to match a lower effective gravity will taste the same as a beer that started out that way: in the higher densities, yeast will tend to produce more esters and aldehydes, and leave a greater sweetness behind.

From: STROUD%GAIA@leia.polaroid.com  
Subject: Skunks, worms, and lightstruck beer

Daniel Butler-Ehle writes in HBD # 751:

"I have heard many arguments about what color glass bottles should be in order to avoid light-struck beer. It is my understanding, however, that hardly anything (including beer) reacts with visible light; it is the ultraviolet light that reacts with stuff in the beer (often said to be the hops, but the jury is still debating) to cause that skunky, light-struck taste (as exhibited overpoweringly by every imported Pilsner Urquell I've ever had)."

The jury is NOT still debating whether or not hops are implicated in skunky beer aromas, they came in with their verdict a long, long time ago. Hops were found to be guilty as charged.

I am not sure where you got the idea that visible light is essentially inert. There are many, many reactions that occur with visible light. Plant growth is the predominant one on this planet. The skunking of beer is another example.

While it is true that UV light can cause the light-struck reaction to occur in beer, visible light does also. That fact has been very well documented in the scientific literature. In a bottle of beer, in fact, visible light is probably the major source of skunking, since as you pointed out, beer bottles may filter out most UV radiation.

The mechanism is believed to involve energy transfer from riboflavin (and perhaps polyphenols), both of which are present in beer and absorb in the visible region of the spectrum, to the iso-alpha-acids derived from hops which then undergo a free radical fragmentation. The produced radical then combines with a thiol radical delivered from sulfur containing proteins to form 3-methyl-2-butene-1-thiol, which has been unambiguously identified as the offending skunk odor in beer.

Brown bottles, do in fact, filter out far more light in the 400-500 nm region than green bottles do and hence are better for protecting beer. However, skunky beer can be found in either color of bottle if exposed to enough light radiation.

I reprinted an excellent article in HBD about a month ago, which dealt with the photochemistry of beer and the causes of the lightstruck odor. It was from The Spectrum, Vol. 4, # 2 and was written by Denis de Keukeleire, a well-repected photochemist at the University of Ghent, Belgium. He is considered to be an expert in the field of hop photochemistry. I don't have

the HBD# at hand that it was printed in (I don't save them), but maybe someone else here can speak up with the info. If not, I'll repost the article in HBD.

Chip Hitchcock writes in HBD #752:

"HOWEVER, skunkiness in beer has been specifically pinned down to a photolysis of hop extracts at ~525nm; this is well within visible light (~450-~750nm)."

Pardon me, but that "magical" 525 nm number is pure BS. I've seen it repeated so many times that it appears to have become a classic momily. Rather than keep repeating it ad naseum, I would ask you to justify it with a reference. I suspect that you will have difficulty.

Also, Chip writes:

"The rap on green glass is that it blocks light at >~550nm, so it's useless to prevent this reaction."

This is simply not true. The rap on green glass is that it transmits part of the visible light BELOW 500 nm, while brown glass is almost opaque in the high-energy part of the visible spectrum. This is why brown glass is better than green. Again, I will refer you to the article that I reprinted a month ago in HBD.

Better living through photochemistry,  
Steve Stroud

From: Tom Dimock <RGG@CORNELLC.cit.cornell.edu>  
Subject: Welding & soldering stainless

I'm glad to be corrected on my mis-information re: fastening stainless. I learned my welding from someone who tends to only talk about what he feels is the "best" way to do something, and I failed to check the effect of that attitude on what I was saying. Mea Culpa.

If you're going to silver solder, you might want to try to find a MAP or an air-acetylene torch, either of which put out a LOT more heat than your standard propane torch, which will make the process much faster and less frustrating. The MAP torches should be available at the same store as a propane torch - don't know how the prices compare. Air acetylene (aka Prest-o-lite) is my favorite, I bought mine at a going out of business sale of a plumber for next to nothing. It is also a GREAT tool for peeling peppers when you're make Chilles Rellanos (sp) :-). Whatever heat source you use, best of luck and happy brewing!

From: pyle@intellistor.com (Norm Pyle)  
Subject: Jack Schmidling, mostly

All the anti-Schmid-etism around here is starting to wear thin. I don't necessarily agree with \_all\_ that Jack says (read he says a LOT), but I do agree with some of his motives. If he manages to get another homebrewer hooked on brewing, who would have otherwise skipped it, I think that's good. Like he said, lots of people drink instant coffee, and lots of them like it. If they can make homebrew that beats Bud (we always seem to pick on Bud) and they like it, let 'em make it. If it doesn't stand up to \_your\_ (you know who you are) high standards, what's the big deal? Also, if a new brewer wants to improve his beer, he'll have every opportunity to do it. I know we don't want to promulgate (neat word) "bad" practices in homebrewing to keep from botching batches, but if there are some steps in the gray area, maybe it should be mentioned and left at that.

BTW, I'm no fan of commercial advertising. Maybe we should start a [rec.crafts.brewing.new\\_products?](#) 8^]

On to beer: I primed my Christmas brew with honey (typical clover honey from the local supermart). I used 1/2 cup boiled in a couple of cups of water for a 5 gallon batch. Is this going to do it? Have others done this?

From: Dave Rose <CHOLM@HUBIO2.HARVARD.EDU>  
Subject: Siphons

I have followed the debate lately about siphoning technique, and so far have held my tongue. But the suggestion in HBD #752 that the use of a peristaltic pump might be a good solution was just too much. For about \$2 you can get a rubber carboy top that has two holes, one for your racking tube and one to blow in. These work great and you never have to worry about the issue again. Of course, this only works if you use a glass fermenter, and that is an entirely different can of worms which I don't want to keep open any longer than necessary. If you use a plastic fermentor, you can always use the water method; I've never tried it, but it's got to make more sense than blowing all kinds of dough on a pump. Of course you've got to sanitize the tube, the water, your thumbs, etc.

Is anyone else incredibly tired of the word 'momily?'

Dave Rose  
CHOLM@HUBIO2.HARVARD.EDU

Oh, also: I have never used a blowoff tube and I have never gotten headaches from my beer. Just an observation. Maybe you should dissolve one aspirin in each glass of stout.....

Subject: Canning Wort

Mark Nightingale asks:

> Has anyone tried canning wort in jars so to sterilize and preserve it  
for  
> future use in making yeast cultures? How did it work? Does the extreme  
> temperatures and pressures of canning effect the taste enough that a  
starter  
> would off flavor you next batch?

Yep, I do this all the time. I use the canned wort for both yeast  
starters and for priming.

As for any off flavors, none that I can notice (of course, from some of  
the discussions here I might not be able to tell the difference between  
vinegar and beer).

It really makes priming very simple. I usually pressure can 4 - 1 quart  
jars of wort at a time. At bottling all you have to do is wipe the  
outside of the jar with a little sterliant and pour.

I also use it some for starters, but since I culture my own yeast, I  
usually just pressure cook some starter along with the slants.

If anyone wants more detailed info, I will be glad to elaborate.

Bill

> would off flavor you next batch?

Yes, I've tried this and it works just fine. I cooked up some  
pale extract with some yeast energizer + hops (a small amount of  
whatever I had lying around) and canned into quart mason jars.  
(I have a pressure canner)  
I then took some yeast sludge from my last batch that had been stored  
in the fridge, and pitched into the canned starter. I had a nice  
starter within about 6 hours. I did try the result before I pitched  
into my wort, and it was unremarkable to say the least, so I wasn't  
concerned about off flavors.

Subject: Canning Wort success

In HBD 752, Mark Nightingale asked if anyone has used Miller's sterile wort canning methodology, and if the boiling destroyed the wort flavor.

I've used this method VERY successfully. I use my primary fermenter as my culturing fermenter, then pour off the wort after the kreuesen has fallen. I pitch cool wort on top of the trub, and get great results. This way, the wort used in culturing is not used in pitching, so there are no tastable effects from wort recipe differences. Thanks to Father Barleywine and Dave Miller, both.

From: larryba@microsoft.com  
Subject: Liberty Malt Grain Prices

The price of grain at Liberty Malt (Seattle, WA) has stopped me from purchasing there. However, the quality of beers made with proper malt for the style - i.e. english malt for english beers, german malts for german beers - is driving me closer to purchasing there. That is my US 2row versions of beers just don't compare to versions made by other brew brothers using proper malts.

If the \$1.55/lb scares you off, note that a 50lb purchase drops the price to \$1.10/lb. A 250lb grain card (I assume you don't want all that grain at once) drops the price to \$1/lb. Although their prices still don't come close to brew-club prices (\$.50/lb), given that a typical batch o beer takes 8lb of grain it is still dirt cheap.

Anyone up here in Seattle want to split a 250lb grain card? I would front for 75 lb worth...

> alcoholic beverages under the legal drinking age in your state?

Yes, and you can even drink it. Private individuals can serve it as well, so long as no money changes hands. That's how the ABC officer who talked to our club explained it; what someone might get hassled for is another matter.

> When fermenting in a 5 gal. glass carboy what's the best volume to ferment with?

>

> I want to leave enough room for the head. I fear that the yeast will stop

> working because of the high alcohol concentration if I have a low-volume

> ferment.

Most any yeast can handle 8% by weight. The gallon or so you need to remove to avoid blowing foam from a five gallon carboy would only increase the gravity by 25%. With the 3.5 gallons used in this batch, the gravity should be about 43% higher. If you have anything but a barleywine or doppelbock in the fermenter, and a reasonable yeast for the style, I wouldn't worry about it.

It's messy, but letting the primary blow foam will accomplish the same thing, without having to top off later. Use an adequate sized blow-off tube, and don't leave hops floating in the primary to plug it (dry hopping works best in the secondary or keg anyway).

> After 1.5 weeks in secondary, I primed with 1 cup corn sugar and bottled.

> 3 weeks later the batch still has a sugary taste but carbonation is ok.

>

> Any ideas?

A cup is too much for a five gallon batch; this should result in a very fizzy brew, which wouldn't be appropriate for the style. After 3 weeks, it should be done carbonating, but if the carbonation is ok, my guess is it isn't. If the beer isn't as fizzy as Budmillob, let it sit at room temperature for another two weeks or so, then try it again. The sweetness should be gone, leaving lots of little tiny bubbles in its wake.

Subject: canning wort in jars (Homebrew Digest #752)

In Homebrew Digest #752 (October 31, 1991), Mark Nightingale  
(night@tekig7.map.tek.com) writes:

>Has anyone tried canning wort in jars so to sterilize and preserve it  
for  
>future use in making yeast cultures? How did it work? Does the extreme  
>temperatures and pressures of canning affect the taste enough that a  
starter  
>would off flavor your next batch?

I've done it; it worked just fine for me. I used the canning method  
described in Miller's book. The first time I used quart for starter, I  
poured off the "beer" and only used the slurry at the bottom for  
pitching. If you have concerns about tainting the flavor of your  
batch, perhaps one might consider using only the slurry.

Others have suggested that canned starter might be a perfect use for  
old extract - which might not make really good beer. In that case I'd  
definitely pour off the "beer". Otherwise, if the starter "beer" and  
the target wort are compatible, I now just dump the whole thing in.  
For compatibility sake, the canned wort I make is pale, so I can use it  
with all styles.

> to make your eyes water.  
> ....  
> Not that I'm worried, see, but what might that smell be? I suspect  
> it's DMS-related, because there's a big "sulfur dioxide" component.

Hmmmm .... sounds like you have a contaminated batch. It's difficult to  
say for  
sure without knowing a few other factors:

1. Did you boil the entire batch?
2. Did the boiled wort cool quickly?
3. What kind of yeast are you using and at what temperature?
4. Are sulfites used anywhere in the recipe?

Chances are it's your yeast that is causing the phenomenon. Sulfur  
containing  
compounds like methionine and cysteine (two essential amino acids),  
sulfates,  
sulfites and even free inorganic sulfur are all metabolized by yeast to  
produce  
a vast array of molecules which can leave your beer smelling and/or  
tasting like  
cabbage, onion and rotten garbage amongst other things. The most common  
of these  
metabolites is H<sub>2</sub>S (Hydrogen sulfide) which smells like rotten eggs and  
is  
detectable at 5-10 ppb depending on your personal degree of sensitivity.  
Yeasts bearing mutations in gene products involved in sulfur metabolism  
can  
produce overbearing amounts of H<sub>2</sub>S. Furthermore, your source of yeast  
could  
have been contaminated with any of the bacterial strains which produce  
H<sub>2</sub>S.

SO<sub>2</sub> (Sulfur dioxide) is probably not involved, at least directly. DMS  
(Dimethyl  
sulfide) is more noticeable in the flavour of the beer tasting much like  
corn  
and/or onion. Yeast can produce DMS during fermentation but DMS problems  
are  
usually a result of an insufficient boil and/or slow wort cooling. DMSO  
(Dimethylsulfoxide) and SMM (S-methylmethionine) are two common DMS  
precursors  
in wort. Their levels in malted barley and malt extract are a result of  
the  
germination process during malting and are therefore out of your hands. A  
good  
boil however will drive off any DMS (formed during malting and storage

from the precursors and during the boil from the breakdown of SMM). A quick chilling of the hot wort also reduces DMS by reducing the time spent in the temperature ranges required to produce DMS from SMM and SMM from methionine (anyone out there know these temperatures?).

The good news is that all may not be lost. Most H<sub>2</sub>S and some DMS are driven off or "scrubbed" by CO<sub>2</sub> release during fermentation. I'd wait until bottling time to decide whether or not to dispose of the batch unceremoniously. If I was in your shoes, I'd do the following with my next batch:

- i) sanitize everything anally.
- ii) boil the wort vigorously for at least 1 hour.
- iii) cool the wort quickly.
- iv) change your yeast.

For a more complete picture of sulfur compounds in beer I'd highly recommend the book "Principles of Brewing Science" by George Fix.

Subject: coriander beer

> Looking back on it, I would heat the extract before adding it to the  
> beer in an attempt to drive off the alcohol. I wonder if this is  
> where the bitterness came from...

The essential oil(s) in coriander seeds are quite volatile. I suspect that if you heat the extract up enough to drive off the alcohol from the vodka, you'll cause much of the coriander oils to evaporate. You'd end up with only the water-soluble coriander fractions remaining in the extract; most of the fragrance would be gone.

I'd suggest using a smaller amount of vodka, and crushing the coriander seeds before steeping them. This may allow you to liberate most of the coriander oils, without adding too much alcohol to the brew.

You could also try adding a few drops of commercially-extracted coriander oil to the mix before bottling... I believe that it's possible to purchase food-grade essential oils from a number of herb companies (Penn Herb in Philadelphia comes to mind).

From: doug@metabolism.bitstream.com  
Subject: Cranberry ale, again.

Hello Again: Made a verision of the cranberry ale I posted here a few weeks ago.... thanks for the tip on pectic enzyme anyway... I modified the recipe a bit and added considerably less maple syrup (because we really didn't enjoy the maple taste last year) and now I'm sort of stuck with a beautiful red, clear ale that is still in secondary but is EXTREMELY bitter. I was considering two approaches to fix this problem 1) make a small batch of sweet (light colored) wort combine the two and repitch or 2) bottle as is and hope this powerful bitterness subsides a bit... Any help would be appreciated.

concluded  
> that worrying about contamination during the cooling period is, if not  
a  
> momily, at least not worth worrying the beginner with.

It is semi correct. A counterflow wort chiller helps create a better  
cold  
break which precipitates in the primary fermenter (I've only seen  
"secondary  
fermentation" mentioned relating to Fruit Lambics where fruit is added to  
a Lambic and the secondary fermentation is of the fruit). An immersion  
chiller, the kind I use, has the added benefit of precipitating the cold  
break in the kettle which allows you to get the sweet wort off the trub  
sooner and reduces trub in the primary. Both types of chillers have the  
benefit of allowing you to pitch sooner and thus giving wild yeasts and  
bacteria less time to infect the beer. This gives your cultured yeast  
a competitive advantage. The one glimmer of truth I found in this part  
of your post is that I too wouldn't worry a beginner with a wort chiller,  
but instead would warn him/her that they should cover their kettle while  
the sweet wort is cooling to minimize the chance of contamination. I  
think that after five batches, however, they could start thinking about  
a wort chiller, because after five batches, you're hooked and might as  
well begin collecting equipment.

While on the subject, I'd like to add a couple more reasons that I feel  
the  
immersion chiller is better than the counterflow type:

1. cleaning is easier on an immersion chiller and you can see how clean  
the surface that contacts the sweet wort is,
2. sanitation is easier - all you have to do is dunk it in the boiling  
wort before turning on the cooling water (you may also be able to  
sanitize  
a counterflow similarly, but intuitively, I suspect that by the time  
the hot wort is at the exit end of the chiller, even with the cooling  
water off, it has dropped below 180F which does little to sanitize the  
tubing, and

3. I, personally, would not want to start a siphon (with my mouth (besides the sanitation risk) or by other means (turkey baster, etc.)) on a 170+ F liquid!

>>If I may say so, I feel that your desire to make brewing beer easy and >>inexpensive is commendable, but it seems at times that you are more >>interested in hastily debunking traditional brewing practices than in >>achieving this goal.

>  
> It's all part of the learning process. How can I simplify a process without > questioning the accepted methodologies?

I, personally, think that Mr. Schmidling is more interested in gaining notoriety, validating his self-proclaimed expertise in homebrewing and making money, than making brewing beer easy and inexpensive. I'm almost convinced that Mr. Schmidling knew very little about brewing before joining this forum. Twenty years of brewing vinegar does not an expert make.

>>And please note Dick Dunn's comment in re: oxidation and cardboard (not >>cider) and the excellent commentary from Rad Equipment and JaH.

>  
> And just what do I do with the "excellent commentaries" that claim that > oxidation produces cidery beer?

I don't recall anyone but you, Mr. Schmidling, associating oxidation with cidery beer.

Those of you who know me and have read my comments in this Digest, know that only on one other occasion have I been so rough. I feel that Mr. Schmidling has caused the tone of this forum to change. I'm now spending more time contradicting him than asking or answering questions. Please stop with the ad campaign for your videos and stating your opinions as if they were facts! If this Digest was only experts and no beginners were reading it, I would just ignore you. However, there are beginners here and I'm not going to let you fill their heads with incorrect information.

On second thought, maybe this exchange of \*is\* a useful way to debunk common homebrewing fallacies. Keep those fallacies coming Jack, we're ready for you.

From: Doug Latornell <latornel@unixg.ubc.ca>  
Subject: Grolsch-like Bottles in Canada

In #752 someone asked about the alleged availability of brown Grolsch-like bottles in Canada. Both of the homebrew shops that I frequent sell them:  
Wine-Art, 3429 West Broadway, Vancouver, BC, 604-731-4739  
Pacific Coast Vintners and Brewers, 3419 Kinsway, Vancouver, BC  
604-433-8918

If memory serves, the price at Pacific is ~C\$16/dozen (C\$1 ~ US\$0.89) and the price at Wine-Art was marginally higher. I don't know what either of these outfit's policies are on mail orders and shipping to the US.

I hesitate to mention it, given the ongoing glass/plastic controversy, but both of these places also sell 0.5 and 1.0 litre PET plastic bottles with reusable, screw on lids (the lids are good for about 4 uses, like the Grolsch rubber seals). I've been using some of these PET bottles (along with some Grolsch-like bottles and some regular crown cap ones) for almost a year now with no evidence (to my palate and those of my friends) of off flavours. No problems with holding carbonation either. If anything, the PET bottles are more reliable than the crown capped ones.

> with a, as my brew partner calls it, "bandaid" flavor, I think it's a  
> bitter flavor but not a hop bitterness.

"Band-aidlike" or "medicinal" off-flavours are the result of phenolics.  
Given  
the recipes you provided we can rule out oversparging and boiling of  
grains.  
Other possible causes are:

- 1) brewers yeast contaminated with wild yeast and/or bacteria.
- 2) water supply contaminated with wild yeast or bacteria.
- 3) highly chlorinated tap water used for brewing.
- 4) non-food grade plastic used as fermentor or tubing, etc.
- 5) microbial contamination from unsanitized brewing equipment.

Are any of these applicable in your case?

Subject: Re: best fermentation volume

Marc Tamsky asks:

>Second Question:

>

>When fermenting in a 5 gal. glass carboy whats the best volume to ferment with?

>

>I want to leave enough room for the head.

I don't... purposely. What that procedure is called is the "blowoff method" of fermentation. It's merits have been argued in the HBD, but I believe it makes the end product taste better, so I continue to use it. Papazian says that the krauesen contains fusel oils (I've seen fusel alcohols elsewhere) which some say contribute to hangovers. The most graphic proof I have for using the blowoff method is to challenge anyone to drink a glass of blowoff. YUK! Just sniffing it is enough to guarantee my continued support of this procedure.

I fill the carboy to within 1 inch of the bottom of the stopper and use an oversized (3/4 inch) plastic tube in a drilled-out stopper, running down to a gallon jug 1/4 filled with water. Use an oversized tube to prevent clogging and carboy geysers. Some even use a 1.5 inch tube and no stopper:

Dave Wiley writes:

>Some other members of the club and I have switched to 1.5 inch diameter

volume

>ferment.

>

>I know this isn't a FAQ but, is this dumb?

>Are the alcohol concentrations in a primary ferment not even close to  
>the max working concentrations for yeast?

I don't think they are even close. I've used more than 1.8 lbs of extract per gallon in some batches and had no problems with Wyeast (your mileage may vary, but I don't think you need to worry).

>BTW I used the ale yeast that came with a Mountmellick Export Ale kit.

>I fermented with about 3.5gal and added the rest when racking to the secondary.

>After 1.5 weeks in secondary, I primed with 1 cup corn sugar and bottled.

>3 weeks later the batch still has a sugary taste but carbonation is ok.

I haven't tried Mountmellick, but some extracts do have more unfermentable sugars than others and the sweetness may be due to that. There are two things I did notice in your last paragraph that I'd like to comment on:

1. When topping up the secondary (at which time the yeast has certainly completed its respiratory phase and can no longer use dissolved oxygen) you should pre-boil and cool your water, being careful not to aerate your topping-up water. The boiling will both kill nasties and drive off dissolved oxygen which would subsequently oxidize your beer. You may have done this, but I figured it was worth a mention for anyone who may be contemplating a similar procedure.

2. You hadn't mentioned how much was "the rest" so I assumed your batch size was 5 gallons after topping-up. If so, since this is an ale, 1 cup of corn sugar may be a little much, but this is nit-pick based upon the "normal" carbonation level of what is appropriate for the ale \*style\*.

> I'd like to throw in a comment about Jack S. and his video, and then...  
The problem, Jack, is that you are making a how-to video, for general consumption, so to speak, of a wide range of people, with all the inherent differences in their tasting perceptions. ....If you're not just out to make a quick buck, and you really want to help people make good beer, then your \*demonstrated\* technique should impart a minimum of off flavors.

I agree wholeheartedly. Just two points. First of all, I am not a stubborn Kraut, just a Kraut. All the errors that have been called to my attention have been fixed, acknowledged or banded around and the oxidation discussion, at this point, is academic.

Secondly, the fact that it is being discussed and "promoted" on this forum gives the false impression that people such as us represent my target audience. When I began production, I did not know that HBD, rec. brewing, Zymurgy or even brew clubs existed. I used to see the owner of the local brew shop standing outside his shop watching cars go by, every time I passed and I just assumed the hobby was as unpopular as it ever.

Aside from the valuable info I have received from the above sources, I have no delusions of selling videos to most of these people for anything other than cult entertainment.

My target was and still is all those people out there that do not even know that one can make drinkable beer at home. Let's face it, most of them like Bud. How can the subtleties discussed in these fora possibly be of interest to those people? The "Easy Beer" process described in "BREW IT AT HOME" makes beer that any beginner can be proud of. My philosophy is to get them hooked and they will find and use these other sources in due time.

From: scott@gordian.com (Scott Murphy)

>My roommate and I brewed a coriander beer a couple of months ago. Initially, it was undrinkable due to an intense bitterness in the

aftertase.

My wife was thumbing through a seed catalog last night and ran across a blurb touting coriander as a cure for flatulence. Don't give up your research, you may be on to something.

From: Tom Dimock <RGG@CORNELLC.cit.cornell.edu>

> Good, better best,  
> Never let it rest,  
> Till your good is better,  
> And your better's best.

>Knowing the difference is an essential part of the process (for me at least).

Hanging in my living room is my motto:

NOTHING GREAT IS LIGHTLY WON

I might add, in line with my above comments, that great things are usually won in small steps and "BREW IT AT HOME" is simply one small step for beginners but a giant leap for brewkind. :)

From: wbt@cbema.att.com

>> Glass, regardless of color, stops most UV.

>So why do I have to buy a special UV filter for my camera, which has a glass lens? (I'm not being a smart-ass, either; maybe you're right, in which case I'm being ripped off.)

It is entirely possible that you are being ripped off but more importantly, does it work? The other possibility is the fact that you missed the word "most". Simple glass absorbs over 95% of the incident UV. Ever try to tan inside, through a window? A clear glass filter can be honestly sold as a UV filter because it will indeed, attenuate UV by 95% but if it goes through several lenses later, one must really wonder.

Every wonder why "sun lamps" are so expensive? There's no magic in the light source, the cost comes from the fact that the envelop must be made out of quartz to minimize the losses.

> Also, why does the dashboard of my car become slowly faded and cracked from (I'm told) UV exposure, despite having the windshield above it?

I would be more suspicious of the intense heat but there still is that 5%, you know.

3429 West Broadway,  
Vancouver, B.C.

phone (604) 731-4739

The bottles are exactly the same as Grolsch bottles, but they have a plastic stopper (using the same washer) instead of the ceramic one.

Last I checked, they were *very* expensive (\$1.36 Canadian *each*).

I lucked out and found someone who was quitting their brewing hobby, and sold me over nine dozen mixed Grolsch (green and brown) and Kulmbacher (similar cap system, 500ml brown bottle) bottles, plus a few more with the same capping system but unidentifiable origin (12 oz. bottles), plus carboy, etc, etc, all for \$40... I laughed all the way home...

It pays to keep your eyes in the newspaper classified section... I've seen lots of others selling used brewing equipment.

Hope this helps...

Ross

Subject: Homebrewer's Gran Prix Results

On Sunday October 20th, the second approximately annual Homebrewer's Gran Prix was held at the Malibu Gran Prix track in Houston, Texas. The first GP was during the AHA conference in Oakland last year. This year's event was an official part of the Dixie Cup.

I was defending my title as "America's fastest homebrewer". Since they do things bigger in Texas, the title was elevated to "the world's fastest homebrewer".

I didn't record the official times, but they will be printed in the next Brewsletter Urquell. I do remember the general results:

Chuck Cox world's fastest homebrewer (54.11 seconds)  
Steve Stroud Meffa's/Polaroid's fastest homebrewer  
Darryl Goss world's fastest professional brewer  
Chris Todd Texas' fastest homebrewer  
Sarah White world's fastest female homebrewer  
Dave Messersmith world's fastest homebrewer over 6' tall

If you want a title, show up at the next Homebrewer's Gran Prix.

From: Mark Stevens <stevens@stsci.edu>  
Subject: India pale ale recipe

This is my contribution to the 'best recipe' discussion. It's an India Pale Ale that I've made twice. Both times it turned out fine. Nicely hoppy.

Striped Cat I.P.A.

6 pounds pale dry extract  
1 pound amber dry extract  
1 pound crystal malt  
3/4 pound toasted pale malt  
1/4 pound pale malt  
1 ounce Bullion hops (8.2 alpha)  
1/2 ounce Brewers Gold hops (7.5 alpha)  
1 ounce Cascade hops (4.2 alpha)  
2 tsp. gypsum  
1/4 tsp. Irish moss  
1 pack Wyeast #1098  
1/2 cup corn sugar for priming  
handful steamed oak chips

Procedure is that described by Papazian...steep grains, boil 1 hour (boil Brewers Gold and Bullion). Remove from heat and add the cascades. Primary ferment: 4 days, secondary ferment 10 days. Prime and bottle.

Subject: Carbonation in General

Another thought off the top of my head. (Oh no!)

We all condemn high levels of carbonation, because the "gassiness" of such beer will tend to make it difficult to appreciate the other tastes in the beer.

However, we all also know that in many parts of Germany, they take at least 7 minutes to pour a beer, to get rid of that gassy taste (I believe).

So, is there some theory that says that overcarbonating your beer, then pouring it to get lots of foam and drive off the carbonation, can be somehow better than not overcarbonating in the first place? Is it particular to the lager style? Or is it just tradition to brew this way, forcing the pouring method? Or is it something else, such as being useful during the extended lagering stage or somesuch?

In any case, I think I will try the long, foamy pouring method for beers that taste overcarbonated.

>>or individuals 100 per year.) What are the age requirements to  
>>homebrew? Is it legal to ferment your own alcoholic beverages  
>>under the legal drinking age in your state?

>Many states defer entirely to the federal laws, which have the  
>volume limits you mention. The federal laws also state that a  
>brewer must be over 21. It is not unheard of that minors might  
>get away with brewing their own as long as they remain discreet  
>about it, although the Falcons had to discourage a young fellow  
>who was obviously underage once, from attending the meetings.

My copy of the federal bill that was made into law states that  
only adults are exempt from the brewing taxes and such. Here is  
a small quote to hopefully expand on Darryl's answer:

"(e) BEER FOR PERSONAL OR FAMILY USE.-- Subject to  
regulations prescribed by the Secretary any adult may,  
^^^^^

without payment of tax, produce beer for personal or family  
use and not for sale. The aggregate amount of beer exempt  
from tax under this subsection with respect to any  
household shall not exceed--

"(1) 200 gallons per calendar year if there are 2  
or more adults in such household, or  
"(2) 100 gallons per calendar year if there is  
only 1 adult in such household.

For purposes of this subsection, the term 'adult' means an individual  
who has attained 18 years of age or the minimum age, if any, estab-  
lished by law applicable in the locality in which the household is  
situated for individuals to whom beer may be sold, whichever is  
greater."

I suspect that with the recent drive to make the drinking age 21  
in all states, that just going with the 21 age limit is safe. I  
did want to emphasize that there is no "100 gallons per  
individual". There is only a limit based on a household.

From: SEAN J CARON - BLDG 66-200 - X5-1170 <CARONS@TBOSCH.dnet.ge.com>  
Subject: Well water brewing

Good morning, ladies and gents!

I have been getting the HBD for about two months now, and in that time there have been discussions on just about every ingredient and process used in brewing with one very notable exception - water.

In HBD 751, Martin Lodahl writes:

> I really began this batch about a week  
> before brewing day by boiling my brewing water. I have about 750ppm  
> of hardness in my well water (this changes dramatically, I've  
> discovered), and much of it, apparently calcium carbonate,  
> precipitates out when boiled.

I too have very hard well water, as well as a high degree of dissolved oxygen which gives the water a pleasant but short lived effervescence ( i live just outside of Saratoga, NY, famous for its horse racing and bubbly mineral water). In addition to calcium carbonate, i have a large amount of dissolved iron and other minerals ( not bacteria, thankfully!). For everyday use i have a water-softener which strips most of this stuff out and replaces it with salt.

In the past, (on the advise of my local brewing supply store owner) i have simply bypassed the softner when i started cleaning, and by the time i needed water to brew, i was drawing nice hard water directly from the well. This method has produced some good to exceptional (IMHO :-)) brews (>15 extract/adjunct batches, but no lagers).

In the spirit of

"Good, better best,  
Never let it rest,  
Till your good is better,  
And your better's best." (Tom Dimock's father, HDB 752)

I'd like to have a little more control over exactly what is going into my pride and joy. Should I be boiling all my brewing water ahead of time? Will that remove most of the suspended minerals? (as well as all that nice dissolved oxygen?) What's the best way to do this (boil and then rack the water off anything that comes out of suspension?) I assume i would then have to treat the water to bring it back up to the correct hardness.

Let's hear from some of you other well-water brewers! What do you do?

Sean J. Caron

I tried this on the advice of a local supplier; I've never gotten a cap  
that could hold in the air pressure needed to push the wort over the  
crook  
of a racking tube (people who have heard me sing can attest to my lung  
power, however misdirected). It's possible these caps only work (for  
siphon  
starting) with the (relatively squat) 5-gallon carboy; I have only 6's  
and  
3's---the 3's in particular seem to have slightly smaller lips than the  
caps are built for, and I've had to make some plastic washers to persuade  
cap and carboy to make enough of a seal to make gas come out of the  
fermentation lock instead of around the edges of the cap.

Dave> to sanitize the tube, the water, your thumbs, etc.

... Your mouth, lungs, lips, etc...

Seems to me blowing air from your lungs and mouth into the carboy isn't  
much better than getting your mouth over the racking tube. I'd think  
you'd  
introduce all kinds of ugliness into the wort.

Perhaps I should try an experiment with two wort-agar plates:

1. Sucking-siphon-simulation: `kiss' or lick the agar
2. Pressure-start-simulation: breath heavily on the agar  
(awfully erotic, isn't it? :-)

Let sit a couple days and watch the critters grow!

Others have mentioned the technique I use: fill the siphon with water,  
hold  
the two ends up, cover the outlet hole, immerse the pickup side in the  
wort, lower the outlet side below the wort level and release the outlet  
hole. You have to empty the first-runings (water) out of the hose, of  
course. Easy, relatively clean (easier to bleach your finger than your  
mouth).

From: Mark Sandrock <sandrock@aries.scs.uiuc.edu>  
Subject: Preventing oxidation and skunkiness

Miller mentions that the use of DME to prime beer will minimize the amount of oxygen still present in the bottled beer, as it will be utilized by the yeast. He also states that this does not take place in glucose (corn sugar) primed beer, due to the Crabtree effect. There are potential disadvantages to DME priming, however, in particular Miller mentions (additional) esters in the final product, if the second fermentation is at warm temperatures.

As for skunkiness, I've always read that fermenting beer should be kept in the dark. It's easy to keep a brown plastic garbage bag over the carboy, and you can still pull it up for a quick peek as needed. It may be that any mercaptans formed are expelled in the ferment, but when dealing with ppb levels as here, why take chances with it?

Cheers,  
Mark Sandrock

Subject: Wort Chillers, headaches

Jack Sez:

> Perhaps you should do a little reading of the HBD. I concluded after  
reading  
> a number of articles posted by people who seemed to know what they were  
> talking about, that chilling forces various things that tend to stay in  
> suspension without it, to sink during secondary fermentation and  
promotes  
> better clearing.  
>  
> If this is incorrect, I will not promote its use, as I have already  
concluded  
> that worrying about contamination during the cooling period is, if not  
a  
> momily, at least not worth worrying the beginner with.

Well Jack, there are 2 types of wort chillers. Counter-flow wort chillers  
acheive a very fast cold-break. This has 2 effects, one that various  
precipitates form and will drop out of solution as a result of a quick  
change  
from hot to cold, and two that the beer is ready to pitch more quickly  
allowing  
the yeast a better jump on the bacteria.

The immersion chiller acheives objective number 2 well, but is less  
effective  
at creating the cold-break effect (though not completely ineffective)  
since it  
takes a longer period of time for the wort to chill with an immersion  
cooler.  
In counterflow chillers all the wort that passes through the chiller  
acheives  
the same instantaneous drop in temperature. In the immersion chiller the  
whole  
wort cools at the same time and the same rate (slow, but substantially  
faster  
than with no chiller).

My impression is that most people use immersion chillers since they are  
easier  
to clean and less expensive. I am also under the impression that the  
benefit  
that a majority of people would cite as being the most important in a  
wort  
chiller is the accelerated cooling of the wort to allow for quick  
pitching of  
the yeast.

Jack again:

> And just what do I do with the "excellent commentaries" that claim that  
> oxidation produces cidery beer?

Who are these from?? I don't recall seeing any like this.

Again I point you to George Fix's book (Principles of Brewing Science) and to the Zymurgy Troubleshooters issue.

Russ G sez:

>I've been drinking my latest, a stout, and I get a headache from it. I was going to ask some questions about it, but I just realized that this is the first batch in a new 7-gallon carboy, and it did not blow-off! All my other batches were in 5-gallons c's and blew off crud. This is the only batch that has ever given me headaches. Cause and effect?

Well Russ, I switched to carbouys & blowoff tubes a few years back and while not all my pre-blow-ff beers were headache beers, I never get headaches from homebrew now. So call it a momily, but this brewer's opinion is that the use of blow-off tubes has reduced whatever headache causing compounds previously arose in my beers.

Tom D sez:

>To Jack: The reason I'm trying to learn to recognize subtle flaws in beer is not "to learn to dislike them". What I'm aiming at is to be able to be able to identify the flaws in a very good beer, so that next time I can come a little closer to making a GREAT beer. I have no idea whether I'll succeed, but I figure I have a much better chance at a great beer if know why my current batch isn't great than if I just keep changing random factors, hoping someday I'll get it right. Probably an artifact of a scientifically oriented upbringing combined with a strong perfectionist streak, but that's why I do it.

Perfectly phrased Tom!

From: Jay Hersh <hersh@expo.lcs.mit.edu>  
Subject: bottle color, Jack who??

Geez Darryl,  
I always use Molson's for doing the light struck beers at our DR. Beer sessions.  
One year I tried using Labatts in the Brown Bottles, left it in the window for a week, nothing!  
So since then I always use the Molson's in the green bottle.  
The Golden is the best, and I always pop open a sealed case in the walk in cooler when the store clerk isn't looking so I know I'm getting bottles that haven't yet been light damaged.

I'm sure the hoppiness of the beer being used has some effect, hoppier beers probbaly skunk better than less hoppy beers.

Of course even when I use brown bottles for my homebrew I always store it in cases in the dark. Just because brown bottles screen more of the damaging lighth wavelengths, they still don't screen all of them , so it's only a matter of time until the beer gets light damaged, unless you keep it out of the light.

Norm Pyle sez:

>All the anti-Schmid-etism around here is starting to wear thin. I don't >necessarily agree with all that Jack says (read he says a LOT), but I do >agree with some of his motives. If he manages to get another homebrewer >hooked on brewing, who would have otherwise skipped it, I think that's good.

The road to hell is paved with good intentions.

This is an issue I dealt with years ago working for Dan Hennessy at his store.  
I advocated giving new brewers lower expectations that they would make OK beer early on and could then learn to make great beer. The reason behind doing this was because many new brewers can quickly become turned off to brewing by making bad batches early on. Even if it was small easily correctable mistakes new brewers are very susceptible to early discouragement. That is why it is important to get them off to a good start. Overemphasis on sanitation is IMHO a good thing in that while it may dissuade some newcomers, it results in better results for those not discouraged, and therefore less of a dropout rate among

new brewers. So my personal feeling based on a lot of years of getting new people into brewing is that it is very counterproductive to not encourage "good brewing practices" even if they are a little anal retentive. As the new brewers gain more experience they learn to modify procedures to suit their needs, but all the ones I've known were very wary of bad results early on and having those first few batches come out good was important to keeping them with the hobby.

My personal opinion of Jack's position is that while he seems interested in spreading the word about homebrewing (very commendable) he seems to be propagating a too rosy scenario to newcomers that IMHO will lead to new brewers who run into early dissapointments due to too high expectations, and subsequently let the hobby drop and the equipment collect dust in the closet. His dismissal of the very same practices that helped myself and many other brewers grow to become experienced brewers with an ability to make good beers and a willingness to teach others to do the same just doesn't sit well with me, nor many others I know.

I don't think anyone is well served by the creation of large numbers of poorly informed newcomers. The "momily" I always tell new brewers is "It is as easy to make bad beer as it is to make good beer," this seems to server well to temper people's expectations and keep them involved in brewing as a long term goal, and not a "tried-it-once-didn't-like-it" phenomena.

```

Several years ago (while we were still in college, in fact), my (ex-) wife attempted a batch of ginger beer. She bottled it using a bunch of Grolsch bottles that we had accumulated. Well, needless to say, this didn't work too well. No exploding bottles, fortunately, but lots of self-emptying ones. I took a couple outside to try to open them without severely damaging ourselves or the apartment. On each of them, I just \*barely\* touched the wire holding the stopper on, and the stoppers were out of here. We never did find them. And the ginger beer went almost as far.

She never tried to make ginger beer again. :-)

(\_I\_, on the other hand, have my second batch of homebrew fermenting away in my closet, and my first batch in bottles [and part of that already consumed].)

> plastic primary each time I brewed. A trash bag would do the trick, [. . .]

Several things to beware of:

- it is unlikely that the bags are sanitized
- the garbage bags that I've smelled (oh no, my secret vice is now public) have a lot of out-gassing. I know that the plastic used in such food-grade containers such as cheap canteens take a while to lose their smell, so this is likely affect your beer aroma (phenolics?)

So, this is really an idea that is a false economy. You can buy a new plastic carboy from a water for about \$6 and amortize that cost over a dozen batches for an amazing pennies per day...

From: GARY MASON 01-Nov-1991 1558 <mason@habs11.ENET.DEC.COM>  
Subject: Dave Line's saccharin

I never have seen an answer to this...or even a discussion, that I can remember. Line specifies one saccharin tablet (characterized as the one that has the "sweetness" of one tsp of sugar) per gallon in many of his recipes. What does that mean? The residual sweet taste, with no intentional addition of fermentables? If so, what can one substitute for the same result? If one uses sugar, it will ferment, and presumably lose it's "sweetness". Again, I assume that what he wants is the sweetness in the finished product only.

While I'm here...I have seen several tables relating various malts, etc. through the amount of sugar they represent. Am I correct in assuming that it is this relationship (rough as it is) that one is to use to convert grain recipes to extract recipes? For example (I have no data in front of me) , I would assume that the ratio of dry extract to syrup in such a table would be 1.1:1 (or .91), given that most recipes specify 3.3# of syrup or 3# of dry extract.

I think I am getting serious again. Nothing like a trip to Real Ale country to get you going strong again.

Cheers...Gary

Subject: Colored bottles

IN HBD # 753, Darryl R. sez:

"I consider the bottle color to be, if not a momily, at least irrelevant. I come to this conclusion as the result of one experiment, and what I hope is common sense....You can take a beer in any bottle, green, brown or clear, and expose it to the sun for as little as 15 minutes and be amazed at the strength of the reaction. I use Budweiser for the experiment, in long neck bar bottles (heavy, dark brown), even though Bud has almost no hops. From this, I conclude that bottle color is irrelevant for commercial beers: if they are poorly treated, it doesn't matter what color the bottle is."

Sorry, Darryl, but I think that your experiment is basically flawed. I think that it would be akin to taking two pieces of wood, soaking one of them in water for a day, then burning them both up with a flamethrower. The conclusion? Water doesn't affect the ability of a stick to burn!

The problem is that by putting the bottles in the sun, you are putting them in an extreme environment, one which most bottles will never see. The sun is a high intensity light source (summertime in LA?) and puts out large amounts of UV and blue light. None of the colored bottles are totally opaque and as you have discovered, they all skunk quickly.

A better experiment would be to put the bottles under fluorescent light and incandescent light at varying distances and for varying times, trying to simulate what a bottle of beer might go through on a retailers shelf. Under those conditions I'd put my money on the brown bottles being much more resistant to skunking.

I think that if we are talking about moderately mistreating beer (as in letting it sit under a store's lights for some time), the color of the bottle DOES matter. Ever wonder why the skunky beers that you get off store shelves are generally in green bottles? When was the last time you had a skunky Heinekin? When was the last time you had a skunky SN pale ale?

Steve

Subject: Deep Sigh

To Jack Schmidling:

Jack, if you don't want comments don't ask for them.

For the record, I have taught introductory homebrewing to somewhere between 100 and 150 people and all-grain brewing to 50-60. As far as I can tell, most of these people are still brewing and some of them are participating in this digest. So much for your theory that I'm frightening people away from "our hobby."

It is true I'm not interested in teaching people how to make "instant coffee."  
I've offered people plenty of money-saving suggestions, but my emphasis is on making high-quality beer. None of my students have ever qualified as "mush brained."

To Tamar:

I love barleywines and see nothing wrong with Dave Miller's recipe, except that I would not use sugar at all. On the other hand, I don't see any need to do the primary fermentation any different than the usual carboy. I filled my cooler-mash tun with grain (seven kinds of malt) to get a four gallon batch. After primary fermentation in a carboy, I racked to gallon jugs (yes, with fermentation locks) where it matured for six months. The beer was great (although Dave Miller thought it was too dark) and still is, four years later. I've had excellent barleywines that were partial mash-extract beers but I wanted an all-grain beer--and besides, it's cheaper. It did take a lot of work, and I had to wait a long time to drink it, which is why I can't understand making only two gallons as Miller suggests.

Two things: I didn't sparge at all, but used only the liquid in the mash. I boiled for 2 hours to reduce it to four gallons. I initially pitched a pure champagne yeast, as Miller and others have suggested. It pooped out after two days. Fortunately, I had some ale fermenting alongside and ran a couple of pints of that into the barleywine wort. It took off like a maniac and fermented the beer from 1.094 to 1.025 (at racking). The only real flaw in the beer are some banana esters which I'm convinced came from the champagne yeast. Of the

microbrewers I know who brew barleywines, NONE use anything but their regular ale yeast.

The British barleywines I've tasted were virtually still and too syrupy for my taste. A too-young Thomas Hardy (about 1 year old) tasted like cough medicine. After four years, it's better. My barleywine was ready to drink a few weeks after bottling, although it's even better now. (I have no idea why it should have matured so quickly, but BridgePort's Old Knucklehead was likewise (perhaps the lack of sugar in each recipe?) Unlike Miller, I would suggest aging the beer in bulk, then bottling. I know that wines age better in higher volumes, and have also heard that Thomas Hardy in pints ages better than that bottled in nips.

To Darryl: You know, I think you're right. That's why I always love that Mexican beer in the black-painted bottle. <Aagh! Just kidding!> Seriously, it's clear that not everyone \*has\* gotten the message about light-struck beer. Otherwise, why would it keep cropping up at beer judgments? If you're going to drink your beer in a closet, it doesn't matter what kind of bottle it's in, but I still think it's courting trouble to use Sam Smith bottles as some homebrewers use. Everytime I sit in the courtyard at Produce Row, sipping a pint of Sierra Nevada I try to set it in someone's shadow. I'm the nervous type.

Pat Patterson asks:

>Has anyone tried using honey instead of (corn) sugar at bottling time?  
>If so, what amount of standard off-the-shelf clover honey is equivalent  
>to the usual 3/4 cup of sugar?

and Norm Pyle writes:

>I primed my Christmas brew with honey (typical clover honey  
>from the local supermart). I used 1/2 cup boiled in a couple of cups of  
>water for a 5 gallon batch. Is this going to do it?

My own experience is this--honey is made of sucrose (very easy for yeast to break down) and is concentrated. I bottled a batch last year using slightly less than 3/4 cups and had a gusher on my hands--no explosions, but a good long wait for all that cream colored foam to turn into black stout! Err on the side of too little rather than too much, and LET US KNOW if you do it right! I've heard this question asked in a lot of places and have yet to hear a real answer, just a bunch of hypotheses (um, like this one : ) ).

Bob Murphy writes:

>The coriander isn't real  
>strong, but is noticable. Some people have a hard time identifying it.  
>For some reason they all seem to lack much head, maybe the oils in the  
>coriander?

Certainly the oils in the coriander, I think. I've had the same problem, and I used 2 oz. coriander for 15 min after the boil--not very long, but long enough. Try brewing coffee with some fresh ground coriander in it--the naturally oily coffee gets some good sized mini-pools of oil when you throw in the coriander.

>the suggesstion in HBD #752 that the use of  
>a peristaltic pump might be a good solution was just too much.

Here, here! I've done the Absolut-mouthwash-suck away siphon technique for three years, and nary an infection yet! Faugh on chemistry-set brewing! Thank you, Dave Rose.

From: hopduvel!john@linac.fnal.gov (The Hop Devil)  
Subject: canning wort

Check the special issue of Zymurgy about yeast. There are several good articles on culturing, the one I wrote on sterile transfer involves a simple modification to canning jars to insure sterile transfer, and using a syringe to move the yeast from purchased pure culture pak to various culture vessels. I even do that in a glove box, but its probably not a requirement on a small scale with just a few 'generations' used before a fresh culture is introduced.

I have brewed in a variety of environments, and sanitation is something that can be almost ignored in some cases, and is a real requirement in others. IMHO its better to start off a little overzealous in sanitizing than make a bad batch of beer. This does not mean I soak everything is 50k PPM of CL04, I admit I was heavy handed with the clorox when I first started brewing, but I only use about 50 ppm at the max anymore. (CL04 test strips are a restaurant supply houses - cheap)

From: Brent Ball <staf1282%slcsl.bitnet@utcs.utoronto.ca>  
Subject: glass & plastic & light

I am new to this forum and maybe someone has asked this already, but here goes!

I've been hearing a lot about the glass vs. plastic fermenters debate. I have

gone through several food grade plastic primaries over the years and now that I

think about it, I see a direct correlation to the fact that my best beers were

brewed in the NEW pails. My logbook confirms this suspicion. So I tend to agree

with the person who says change your plastic fermenters after 10 batches or so

(at this point, this number is quite arbitrary and I would appreciate further

comment on what is "the right number") Now I would like to add a twist to the

conversation; after about 5 days or so I transfer my brew from the plastic

primary pail to a glass carboy secondary to finish up. This is a clear glass

vessel and it sits in the corner of my sunlit kitchen (no direct sunlight though). Am I doing light damage to my beer in the process of making it?

Should my glass secondary be relocated to my dark (and bit damp) basement or could

I simply loosely cover the carboy by placing over it a big(D size) photographic

paper "light resistant" bag (this should attenuate all UV)? I guess if I used

exclusively stainless vessels this point would be moot but unfortunately my

pocketbook isn't that deep right now. By the way, I too use an enameled boiler

and it still has its handles and enamel coating in tact. It is 7 years old now

and even sees use from my wife during jam season. Finally, I would like to

apologise for my terrible typing in my last submission. It should have been

proofread but I was in a rush to complete it.

Regards,  
Brent Ball

Subject: STUFF

To: Homebrew Digest  
Fm: Jack Schmidling

Re: Martin L.

> In the interim, I've had great results from the enameled kettles. I'd  
feel  
more than just a bit hesitant, though, to use them with one of those  
Mega-Burners that turns the bottoms of kettles cherry-red.

I am sure you value my opinion dearly but for what it is worth, mine  
sits on  
top of a 2500 deg, forced air melting furnace and brings 7 gals to a  
boil in  
about 15 min. I suspect talk of cherry-red bottoms on a kettle full of  
water  
is a bit of a rhetorical flourish. But even so, you can't possibly hurt  
a  
steel kettle on anything even that hot. I originally tested it on a 5  
gal  
aluminum kettle but I felt very uncomfortable doing it and was just  
asking  
for trouble.

>The thinness of the steel also would preclude my ever even considering  
drilling any sort of hole in the kettle.

I can't speak for new ones but I put a small spiggot and fittings on my  
15  
year old one and don't know how I ever brewed without one. You will  
never  
have to worry about the handles coming off again.

Fortunately, if UPS comes through, tomorrow's batch will be boiled in my  
new  
SS pot thanks to whoever pointed me to Rapids. I will still mash in the  
enamel one on the kitchen stove because there may be some advantage in  
having  
the boiler ready while sparging. That however, still leaves me with  
rusty  
beer.

>Red Star produces \*LOTS\* of esters. Primarily banana esters to be  
exact.

If you have been using Red Star all along, you may have been converging  
up many of the defects (like oxidation) that we suggest you may have in  
your beers.

Thank you. I have already been warned and EDME is going into tomorrow's  
batch.

From: Jay Hersh <herhsh@expo.lcs.mit.edu>

>The presence of phenolics which the clove-like.....

BINGO!

The second most recent batch (just about drinking age now) has precisely that taste and aroma. Aside from that anomaly, it is possibly the best tasting beer I have ever made. It also happens to be my first all (commercial) grain batch and drinking it has become almost a mystical experience.

Where did those bloody cloves come from? I used 6 row barley but the same guy who told me that oxidation causes a cidery taste sold me the "barley". He couldn't possibly have sold me wheat malt, could he?

From: Jeff Frane <70670.2067@compuserve.com>

> My tap(s) are mounted on the front door. There is a drip pan underneath, mounted with sheet metal screws, that easily holds the weight of a beer glass--even a full one. The only aerators I know of are sparklers that are used with some beer pumps--not for CO2 driven systems.

I hate to be so bold, but it appears that even you could learn something by watching "BREW IT AT HOME". In the cozy privacy of Ken Pavechevich's little conference room at the Baderbrau brewery, he demonstrates his version of the "Pilsner pour".

He pushes the handle back, the glass fills up with foam and sets it down to settle out before doing it again. Then he pulls the handle forward and fills three glasses of beer in the traditional "American" way which we all enjoy while watching his silly foam settle down in the first glass. He claims that it is a special tap only available in Europe.

>I repeat my previous offer: Come to Portland next May and taste beers at the Oregon State Fair. Out of the 150-200 beers, I guarantee there will be some that are badly oxidized; once having tasted such beer, I also guarantee you will not question the use of the term "cardboard."

Thanks for the offer but I just got the name and phone number of the local brew club and I will pursue the idea here. Sounds like good family fun.

From: microsoft!larryba@cs.washington.edu

<Jack: to get a clear idea of what oxidized beer tastes like, purchase some bland bottled beer (rhinlander is popular out here, Old Milwaukee should do fine), open it up, dump a little beer out, get some air in, re-cap, shake well and store somewhere warm (>100f) for a week. later, cool to normal

serving temperatures and serve. It should be pretty awful. Hopefully your test beer will never get that bad.

I am not sure why you say that if you read the details of my experiment. The rigor with which I attempted to oxidize the sample makes your process look like doctoral thesis from Masterbrew U.

>To get a similar example of light struck, get another bottle and simply set it out in the sunlight for a week or two. Don't use Miller (in clear bottles) - that has been doctored to be resistant to light struck.

Damn! I have been collecting Miller bottles cause I like to look at my beer.

From: pyle@intellistor.com (Norm Pyle)

>All the anti-Schmid-etism around here is starting to wear thin.....

Sure is, thanks. However, think of all the extra publicity my video gets responding to all the whiners. Silly, people...

>BTW, I'm no fan of commercial advertising. Maybe we should start a [rec.crafts.brewing.new\\_products?](#) 8^]

The one thing it would certainly prove is the idiocy of all the bitching about my one little plug. My guess is that it would sit dormant for about six months until "BREW IT AT HOME, THE SEQUEL" is released.

Date: Sun, 3 Nov 1991 11:01 EDT  
From: Frank Tutzauer <COMFRANK@ubvmsb.cc.buffalo.edu>  
Subject: An IBU ? 4 U

I'm trying to calculate IBUs given certain hop schedules, or, conversely, what quantity of hops to add at what times in order to reach a target IBU.

I've been using the equations in Charlie II, and they're pretty straightforward. The problem is that to calculate percent alpha acid utilization, Charlie refers you to a table that lists the %AAU for various

specific gravities and boil times. If I match my s.g.'s and boil times to the chart, I sometimes end up with hop weights like 1.2 oz. Since my scale is not

too precise, I would like my hop additions to be in ounce or half-ounce units.

I don't want to round off because that can result in IBU swings of about 10

points, more than I'm willing to tolerate. Using some experimentation along

with some linear interpolation of the tabled entries, I can get numbers like I

want. The problems with this approach are: a) it takes several trial and

error attempts; b) it sometimes requires double linear interpolation (the table is a two-dimensional table, so if I want, say 50 minutes at an s.g. of

1.050, I have to interpolate between 45 and 50 minutes and between s.g.'s of

1.040 and 1.070, or vice versa--it's not clear which interpolation should be

performed first); c) it seems there has to be an easier way.

Surely, %AAU can be written as a continuous function of two variables (time and s.g.). I understand why Charlie provided a table--most homebrewers

are probably not the tech weens that many of the HBD people are, so a table is

easier for the person who's afraid of equations. Still, I would like to see

the equations. So, I guess my IBU ? 4 U is this: What is the formula for

expressing %AAU in terms of boil time and s.g. This question is not answered

in any of the half-dozen or so books I've got. It sounds like something that

would be in Fix, but I'm not yet competent enough to have purchased it. Can

anyone help me out?

IBU and you be me...

From: Eric Rose <rose@aecom.yu.edu>  
Subject: Dry Malt

On a recent trip to my local homebrew shop, I purchased the ingredients called for in the "Wheat Amber" (?right name?) recipe in the Cat's Meow. It called for 3 pounds of "dry malt extract." I asked the shopkeeper for this and he brought three bags of a beige powder out of his fridge, which did indeed say "dry malt" on them. My question is, how do I use the stuff? (I naively thought the "dry" in dry malt meant "not sweet" or something, and that it would be liquid like other malt extracts).

Do I just put it into the wort with the can of bitter extract called for in the recipe? Any other technique needed? Please advise, many thanks,

Jack Schmidling comments:

>>I use Bud as the low limit and Baderbrau as the upper. Anything in >> between is acceptable, if not necessarily desirable. I am not very >> sophisticated but I can not drink bad beer, even if I made it. As I >>certainly have made bad beer on occasion, I know what lies beyond the >>lower limit. I have, however never made beer that tastes like cider or >>cardboard.

Jack, as far as "you" are concerned your beer has never tasted like cider or cardboard. These are flavors (along with many others found in beer) which different people have different sensitivities to. This is why I suggest you have an independent palate, preferably one that has experience with homebrew, taste your experimental brew against your control batch. Many people like some of the flavors/aromas which occur as "flaws" in brewing. This is especially true of fruity esters which show up in many ales.

As far as cardboard is concerned, it isn't so much the taste as the aroma which exhibits a character which comes closest to that of "wet cardboard". This is not to say that it "is" the smell of wet cardboard, but that, when many people perceive it in beer, it "reminds" them of the smell of wet cardboard. It is a device to describe an off aroma in the brew, as are many other terms which brewers use to verbalize what their senses tell them about beer.

If you are happy with your beer as it is, then keep on brewing as you are. However your position that things like oxidation and off flavors/aromas don't exist or occur, simply because you have not experienced them, is poor science. Perhaps your environment allows you to brew with a casual attitude towards certain accepted practices and still succeed. I have no idea since I don't know you or your beer. When you begin to get feedback from other brewers you

may get confirmation of your abilities, or you may find that there are  
some  
things in your beer which you are not aware of. Enter a competition  
where your  
beer will be judged anonymously and then review the judges' comments with  
an  
open mind. Get a second opinion, Jack.

From: "Russ W. San Fran/CA" <72300.61@compuserve.com>  
Subject: Canned Guinness Draft!?!

(Again, apologies if this shows up twice. I suspect my connection to the Digest via Internet is gone for the moment. RW...)

THIS IS NOT A COMMERCIAL ENDORSEMENT

I had the good fortune to be invited to attend a very special beer happening (am I dating myself with that term?) recently by Tom Dahldorf of the California Celebrator. The event was Guinness' unveiling of their new product, Pub Draught Guinness. Now, I can hear the lot of you saying to yourselves "Yeah, yeah, another 'draft beer in a can', big deal". But this one is different. For the most part this product actually does what it is supposed to do!

Anyone who has had Guinness Stout on draught and from a bottle knows there is a vast difference between the two brews. The brewery makes no secret of the fact that the recipes are different not only between the kegged version and the bottled, but also between different bottled markets. Now the folks at Guinness have developed a system which dispenses their stout from a can in such a way as to rival a pub tap. They have been working on this for some 20 years and the final method was preceded by over 100 failed attempts.

The problem has always been the fact that draught Guinness is (or should be) dispensed with a mixture of Nitrogen and CO2 gasses rather than the conventional CO2 alone. The nitrogen is used because it makes very fine bubbles while it is not absorbed into the brew as the CO2 is, thus it does not "over-carbonate" the beer. Also a special faucet is preferred which, in combination with the gasses, creates that wonderful creamy brown head which lasts to the bottom of the glass. The new can combines the original kegged stout recipe with technology which creates the draught effect to a tee.

Dr. Alan Forage, creator of the technology, was on hand to explain the mechanics of the new can. This is the way the system works: The 16.9 ounce can (containing 14.9 ounces of beer) is fitted with a small plastic device (Guinness calls it a "smoothifier") which sits in the bottom of the can. This device has a pocket or cavity which is open to the atmosphere via a pin hole in its top. The can is evacuated of oxygen and filled with beer. Prior to sealing the can, a dose of liquid nitrogen is added to the beer. The can is closed and as the liquid nitrogen warms a pressure is created. The pressure

forces about 1% of the beer and nitrogen into the plastic cavity. When the can is opened, the pressure is released and the small amount of beer in the cavity is forced back through the pinhole quite violently. The agitation created by this "geyser" mixes the nitrogen with the beer in such a way as to reproduce the tap handle character. Open up the first empty can you have in order to see what the "smoothifier" looks like.

Prior to serving, the beer must be chilled. Guinness suggests a two hour stint in a refrigerator, with a target serving temperature of 45-50 degrees (if opened while warm, the beer gushes with excess force). This is the one area where flavor will be variable since most American refrigerators hold their temperatures closer to 35-40 degrees. We all know the colder the beer the less the flavors are perceptible. Education will be the key here. The entire contents should be emptied into a 16 ounce glass. The head which forms is exactly like that of the draught version. And yes, it does last to the bottom of the glass.

How does it taste? In my opinion, this is virtually the same as what you get at a well maintained pub. The texture is right on. The flavor is wonderful. I suspect there may be some slight differences as a result of the volume of the package (14.9 ounces vs. 15.5 gallons) but I didn't notice any. According to Declan Maguire, group marketing director of Guinness Import Company here in the U.S., extensive taste comparisons were made throughout Ireland and England during the development of the product. This includes side-by-side blind tastings with the original version.

The cans come in packages of 4. The suggested price is \$5.99. The stout is 4% alcohol by volume. Guinness is releasing the new product in the San Francisco, Chicago, and Baltimore/Washington D.C. areas to begin with. Locally, Safeway stores are carrying it at \$3.00/2 cans. The cans can be recycled just like other aluminum ones. I suspect the insert is made from the same plastic which is used to coat the inside of the can and will burn off during the recycling process.

Congratulations to Guinness on the success of this new package.

Subject: Grolsch, what again O'Connor?

SOrry to add one more comment--but since I'm not going to tell you to replace the gasket like everyone else, I thought I throw in my \$.25 (inflation, you know).

Anyway, my friend Dwight, who shall remain nameless, doesn't like them because he thinks the neck causes the beer to pour funny. Causes too much bubbling or something. I dunno. I don't mind them because of ease of bottling. I've got about 125 or so, and I got 'em from bottle return centers.

One suggestions tho', if you plan to enter any of your beers in contests, make sure you bottle some homebrew in 12 ounce or 16 ounce regular bottles. Many AHA contests will not take Grolsch type bottles. I usually put 6-10 bottles/batch in regular bottles.

Keep on Brewin'

[stuff deleted]

I have been mashing, boiling, fermenting and barreling in plastic for ten years now and only ever had one batch go bad - after sterilising with boiling water instead of chlorine based cleanser!!! So take care Darryl.

Yes it does scratch, yes they probably harbour bugs, but they CAN be killed,  
and a proprietary chlorine cleanser such as Chempro SDP does not impart any  
taint to the beer, (though I'd expect bleach to - I'd never use it).

I speak from experience, not theory.

Subject: Mt. Hood hops

In Homebrew Digest #754, David Odden (dodden@magnus.acs.ohio-state.edu) writes that he's hooked on Mt. Hood hops but that his supplier is not carrying them any longer.

Dave: Switch suppliers.

I just place an order on Friday with Alternative Garden Supply in Illinois. They have this year's harvest of Mt. Hood hops in stock. (I'm also hooked on Mt. Hood.) They also just had an ad in the latest special Zymurgy issue for Northwestern extracts, \$4.95 for 3.3 pounds....this is a great deal....about \$2 less than I can do locally. You can contact them at (800)444-2837.

Cheers!

Subject: Hangovers

- --> Warning! This post is based on "old wives tales" backed up by experience! On the other hand, it does seem to work for me.... <--

Hangovers seem to have at least three components: dehydration, Vitamin B imbalance, and toxins (fusel oil, for example). The first two you can deal with by washing down a fairly large dose of Vitamin-B complex with lot of water before retiring. When bladder pressure gets you up, drink more water. The toxins you can only deal with by not ingesting them to begin with, which means not brewing them into the beer if possible. As to what by-products contribute to hangover, and how much, I'd guess that that is highly specific to the individual? Anybody know any facts in this area??

(BTW - someone asked whether fusel is an oil or an alcohol. My dictionary defines Fusel Oil as "a mixture of amyl alcohols obtained as a by-product in the fermentation of grains.)

From: akullber@BBN.COM

Subject: wort chilling

I've only brewed 3 batches, but I've found the following method chills the wort immediately.

The night before brewing, I boil 4 gals. of water. I let it cool over night to room temperature in a sanitized pail. In the morning, I transfer it to my 5 gal. sanitized carboy. I then store it in my chest freezer for about 7 hrs. It gets a slight amount of ice on the surface. It is at about 35 degrees F.

The boiling wort cools to about 70 instantaneously when added into the cold water.

Anybody see anything wrong with this method (besides the obvious "don't forget and let the carboy freeze & crack")?

Alan

Subject: The siphoning controversy...

Chip Hitchcock writes:

>Dave Rose <CHOLM@HUBIO2.HARVARD.EDU> writes:  
>>\$2 you can get a rubber carboy top that has two holes, one for your  
>>racking tube and one to blow in.

>I tried this on the advice of a local supplier; I've never gotten a  
>cap that could hold in the air pressure needed to push the wort over the  
>crook of a racking tube (people who have heard me sing can attest to my  
lung  
>power, however misdirected). It's possible these caps only work (for  
>siphon starting) with the (relatively squat) 5-gallon carboy; I have  
only 6's  
>and 3's---

I have used mine for 5's and 7's, and I've never had a problem. True,  
if you just blow into the think it leaks a lot. I just squeeze it tight  
around the neck of the carboy when I blow, and it works fine. I will say  
that  
some friends to who I recommended this device have never gotten it to  
work, and  
I am at a loss to explain why, since I have never gone over to watch  
their  
technique. However, in my hands, it has never failed.

Chris Shenton chimes in:

>Seems to me blowing air from your lungs and mouth into the carboy  
>isn't much better than getting your mouth over the racking tube. I'd  
think  
>you'd introduce all kinds of ugliness into the wort.

This is a reasonable expectation, but it turns out to be wrong. I work  
in a yeast lab, and we routinely inoculate cultures by blowing yeast out  
pipettes into culture tubes; by blowing some bubbles in the culture, the  
yeast  
get mixed up. This absolutely does not lead to contamination, or I would  
never finish my thesis (granted I STILL might never finish, but that is  
another  
issue). I have actually done the experiment you suggest, but with a  
slight  
modification. There are three tubes:

1. Spit in the tube.
2. Blow bubbles through a sterile pipette.
3. Blow into the tube, or cough or whatever.

Tubes 1+3 will become contaminated, but tube 2 will be clean. Saliva  
certainly does contain micro-organisms, so tube 1 is no mystery. But,  
apparently, breath is sterile. In tube 3, your breath is directing  
airborne  
beasties from the air into the tube. In short, breathing into the carboy  
is  
not a problem, as long as you don't drool into it or something.

From: STROUD%GAIA@leia.polaroid.com  
Subject: Lightstruck beer: The myth of green light and 525 nm

It's amazing how many responses have been generated by Daniel Butler-Ehle's posting in HBD 751 concerning the skunking of beer. It's certainly a good subject to "air out". Tom Strasser's posting in HBD 753 was excellent and visibly demonstrated the vast difference in light absorptivity between green and brown bottles.

I must question some recent statements in HBD concerning the relationship between green light and the lightstruck aroma of beer:

Algis R Korzonas writes in HBD #753:

>Fluorescent lights and the Sun produce considerably  
>more GREEN light than incandescent lights. It is true that they  
>also produce more UV, but it is green light (see below) that we  
>are concerned about when it comes to skunky (or catty - no skunks  
>in the UK, you see) beer.

Here's a part of a post from Darryl Richman in HBD 609:

>Light struck is defect noticeable by a skunky or catty aroma. This is  
>brought on by a transformation in one of the hop constituents under the  
>influence of green light.

Chip Hitchcock in HBD 752 said:

>"HOWEVER, skunkiness in beer has been specifically pinned down to a  
>photolysis of hop extracts at ~525nm; this is well within visible light  
>(~450--~750nm)."

And from John, the Hop Devil in HBD #753:

>Boiling hops alters the Alpha acid groups to Isoalpha acids  
>(isomerization). These Isoalpha acids are unstable in the presence  
>of light - a reaction occurs with sulfurous proteins resulting in  
>3-methyl-2-butene-1-thiol, a mercaptan which is perceptible at the  
>PPB level. The frequency of the light that causes this reaction is 520  
>nanometers, which is blue-green.

\*\*\*\*\*

First, a little information for anyone out there who is unfamiliar with the electromagnetic radiation: Visible light is generally recognized as light whose wavelength falls between 400 and 700 nanometers (nm). Light with shorter wavelengths (<400 nm) is called ultraviolet light and light with longer wavelengths (>700 nm) is called infrared light. Photographic chemists consider the visible spectrum to be roughly divided into red light (600-700 nm), green light (500-600 nm), and blue light (400-500 nm). There are gradations within

this range of course, so that light at ~500 nm would look blue-green, etc.  
From this range of wavelengths we get the red/orange/yellow/green/blue/indigo/violet spectrum of the rainbow.

I am challenging the assertion of postings in this forum that green light (and the "magical" 520 or 525 nm wavelength) is somehow responsible for the skunking of beer.

>From every scientific article that I have ever read, it is the high-energy part of the visible spectrum (i.e. blue light), roughly from 400 - 500 nm, that causes most of the damage to beer (ultraviolet light does as well, but that is a different subject for a different time).

I would refer you to my posting in HBD #729 (the excerpt from the article by Denis De Keukeleire and references therein). There is also an interesting article entitled "Photochemistry and Beer" in The Journal of Chemical Education, Vol. 59, # 1, 1982, p. 25 in which the absorption spectra of brown and green bottles are shown. According to this article, "It is now well known that the light sensitivity of beer extends from the UV to about 500 nm." There are numerous other useful references in this article.

Even George Fix's "Principles of Brewing Science", refers to the damaging wavelengths of light being 400-500 nm.

I am very curious as to the origin of the numerous references to green light and especially to the 520-525 nm wavelengths of light being detrimental to beer. To the four people listed above and to anyone else who has made similar claims, I would ask for references to substantiate your allegations.

From: ssi!mtd@uunet.UU.NET (Mike Daly)  
Subject: Richter Scale Ale

This last weekend we had a beer tasting party. We tasted about 20 different kinds (everyone brings a 6-pack, gets to take some home). I have a question about one particular bottle:

Among the prized awarded was "worst of show (a beer suitable for slug bait in the garden)" to this year's Richter Scale Ale (from somewhere in CA). Now I had a bottle of this stuff about 2 years ago and I remember it (vaguely) as being pretty good. This year's batch tasted like dish soap. Well, on first sip, first it tasted like hops, then it tasted like dish soap, then it tasted like very thin beer, then you finished the swallow and looked around the room to hear everyone else say "soap?".

We didn't have a second bottle to compare with.

Now if light struck -> skunk (we had several of those in the tasting) and oxidation -> cardboard. What gives soap?

Mike

From: Jacob Galley <gal2@midway.uchicago.edu>  
Subject: Wy dyd my Wyeast wyther?

(Hats off to whoever used this pun about a month ago.)

This is my first encounter with Wyeast, it hasn't gone well!  
My Wyeast has not started to show signs of fermentation yet, after  
about 55 hours as of this morning. Here's the specifics:

I popped the inner package on Thursday morning, anticipating a Friday  
night pitch. By 1 am on Saturday morning, the fresh wort was about luke  
warm, so I pitched. But, by this time, the package was filled with  
lots of gas -- like, I was half expecting it to splatter all over the  
room when I opened it up. (It didn't.) So I dribbled the yeast into my  
carboy.

One thing in the instructions that I didn't do was aerate the wort  
after pitching. It didn't seem all that important. When there was no  
trace of fermentation by last night, I decided to rack it into my  
other carboy, since about three inches of spoogy sediment had already  
accumulated. I also thought that racking would aerate it a little.

This morning: no action. Any advice? My wort is still okay, right? I  
can go out and get some more yeast and pitch again, right?

From: tomm@pet.med.ge.com (Thomas Manteufel 5-4257)  
Subject: a scary halloween (well, almost) story

With all the postings recently about what is really important and what is just assumed, please allow me to relate my own recent experience. I started

a batch of ale three weeks ago. I use dry yeast because with two small kids, my life is too chaotic to even assume I can use a starter when I want to. My normal yeast, Whitbred Ale, was out of stock at the homebrew store. In a fit of desperation (and stupidity), I bought Red Star Ale yeast. That was my first mistake. I let the wort cool overnight in a covered pot (possible mistake number two; no wort chiller), and pitched the rehydrated Red Star. Twenty four hours later, no sign of life. The Red Star was dead. I got a cupfull of live yeast from a friend's starter, and pitched that evening. Almost two whole days had passed before I got active yeast into my wort. Sounds like a recipe for infection? You bet. Three weeks later, after fermentation had slowed, stopped, and restarted. I tasted some of the brew (2 or so Ozs.). It tasted terrible. With a tear in my eye (some of it from the smell), I dumped it down the laundry tub. This was Friday evening. All day Saturday I had a sour stomach, and woke up at midnight Sunday morning with severe stomach cramps. My wife took me to the emergency room, where I spent a fun-filled four hours getting tests. Final diagnosis: possible food poisoning. I'm much better now, thanks.

So, class, what have we learned? Not all yeast is created equal. It is just remotely possible that Red Star just isn't as good a yeast as Whitbred. Whether dehydrated Whitbred is as good as liquid is left as an exercise to the reader. Creating a starter would have let me see that the Red Star was dead, and given me more time to find live yeast. I take reasonable sanitary precautions, and I still wound up with five gallons of poison because the yeast didn't take off right away. The carboy had been filled with bleach water, and all the surfaces that touched the wort were clean. A wort chiller would have helped. Sanitation is vital unless you can with a straight face tell me that you are assured that your yeast will take off immediatly. Let's not take unnecessary chances with five gallons of bacteria food.

From: Jeff Frane <70670.2067@compuserve.com>  
Subject: Serious Business

To Jack Schmidling:

Jack, if you don't want comments don't ask for them.

In reference to your theory that I'm frightening people away from "our hobby":  
For the record, I have taught introductory homebrewing to somewhere between 100 and 150 people and all-grain brewing to 50-60. As far as I can tell, most of these people are still brewing and some of them are participating in this digest. As Fred Eckhardt is fond of saying, "Rats! Another great theory destroyed by the facts."

It is true I'm not interested in teaching people how to make "instant coffee."  
I've offered people plenty of money-saving suggestions, but my emphasis is on making high-quality beer. None of my students have ever qualified as "mush brained."

To Tamar:

I love barleywines and see nothing wrong with Dave Miller's recipe, except that I would not use sugar at all. On the other hand, I don't see any need to do the primary fermentation any different than the usual carboy. I filled my cooler-mash tun with grain (seven kinds of malt) to get a four gallon batch. After primary fermentation in a carboy, I racked to gallon jugs (yes, with fermentation locks) where it matured for six months. The beer was great (although Dave Miller thought it was too dark) and still is, four years later. I've had excellent barleywines that were partial mash-extract beers but I wanted an all-grain beer--and besides, it's cheaper. It did take a lot of work, and I had to wait a long time to drink it, which is why I can't understand making only two gallons as Miller suggests.

Two things: I didn't sparge at all, but used only the liquid in the mash. I boiled for 2 hours to reduce it to four gallons. I initially pitched a pure champagne yeast, as Miller and others have suggested. It pooped out after two days. Fortunately, I had some ale fermenting alongside and ran a couple of pints of that into the barleywine wort. It took off like a maniac and fermented the beer from 1.094 to 1.025 (at racking). The only real flaw in the beer are some banana esters which I'm convinced came from the champagne yeast. Of the

microbrewers I know who brew barleywines, NONE use anything but their regular ale yeast.

The British barleywines I've tasted were virtually still and too syrupy for my taste. A too-young Thomas Hardy (about 1 year old) tasted like cough medicine. After four years, it's better. My barleywine was ready to drink a few weeks after bottling, although it's even better now. (I have no idea why it should have matured so quickly, but BridgePort's Old Knucklehead was likewise (perhaps the lack of sugar in each recipe?) Unlike Miller, I would suggest aging the beer in bulk, then bottling. I know that wines age better in higher volumes, and have also heard that Thomas Hardy in pints ages better than that bottled in nips.

To Darryl: You know, I think you're right. That's why I always love that Mexican beer in the black-painted bottle. <Aagh! Just kidding!> Seriously, it's clear that not everyone \*has\* gotten the message about light-struck beer. Otherwise, why would it keep cropping up at beer judgments? If you're going to drink your beer in a closet, it doesn't matter what kind of bottle it's in, but I still think it's courting trouble to use Sam Smith bottles as some homebrewers use. Everytime I sit in the courtyard at Produce Row, sipping a pint of Sierra Nevada I try to set it in someone's shadow. I'm the nervous type.

In Digest #754, Jay Hersh makes some excellent points about new brewers and expectations. I think--given the disagreements about "momilies" and instant coffee and ghod knows what--it might be valuable to decide what it is about homebrewing that makes it valuable. The response I got to my instant coffee remark, from a couple of people, was that some people \*liked\* instant coffee and ... Well, I couldn't agree more. Some people do like instant coffee and some people don't really care what kind of beer they're drinking.

I've been operating under the assumption that people brew beer at home (at least in the U.S.) because they want to make something better than that available in the stores, or something as good but less expensive. I know that beer has gotten pretty expensive in places like the U.K., but in the U.S. if you \*want\* to drink Old Heidelberg (pretty much the beer equivalent of instant coffee), by ghod, go to the store and buy some. It's certainly going to cost less than the equivalent

beer brewed at home, and if things like sanitation and clean yeast are too much trouble, hey, pick up a sixer.

If someone does want to brew at home and wants to do it quick and easy, fine.

Absolutely. I say encourage this person to pick up some kits, or do a very simple extract/grain brew and, by ghod, they'll be brewing at home. If they're willing to take a little care and a little time, they can make very good beer.

In fact, I've tasted some extraordinarily good beers that were made just this

way, with a very small investment in money. But with a very large investment in care.

I do not believe you can make really good beer, consistently, with slapdash methods. Simple methods, yes, but not by deciding that everything that takes a little effort is too much work. And, really, what's the point? My father used to drive me wild with this aphorism, but I'm not a kid anymore and it makes a lot of sense: "Anything worth doing is worth doing right." And that includes brewing beer (and he *\*loves\** my beer).

David Odden asks about Mt. Hoods: Tell your supplier to get it together! These hops were developed here in Oregon a few years ago as a replacement for the German Hallertau, which was coming into scarce and unreliable supply. The end result was a hop that, from both the brewer's and grower's perspective, was superior to the original. Any reliable mail order place should have them available, but you could contact FresHops (somehow ran the address here recently) or call F. H. Steinbart (503-232-8793). I *\*know\** they have them; I just called. (And, yes, it's a delicious hop.)

Date: Mon, 4 Nov 91 17:46:02 EST  
From: rich@bedford.progress.COM (Rich Lenihan)  
Subject: Sour Beer, Carbonation, Wheat Stout and more!

Just a few items:

1. doug@bitstream.com asked about what to do with a sour batch of Cranberry Ale. Depending on the amount of sourness involved (and cranberries are *very* sour) you bottle as is and hope that age will mellow the brew (don't count on it) or you can sweeten it with lactose before bottling. I don't know if this will improve the overall flavor of the ale (it might just make a sweet'n'sour ale, suitable for serving with polynesian-type take-out food). My own choice (and one I've used in the past) would be to keep some "normal" beer around and custom-blend at serving.
2. John DeCarlo mentions pouring beer to relieve some of the carbonation. When I was in college, I once attended a marketing presentation given by an A-B sales rep (hey, the beer was free!). The point of this demo. (besides shilling A-B products) was to illustrate how pouring a beer affected the taste. In side-by-side tastings, we compared Bud poured straight down the middle with Bud poured gently down the side (Ed McMahon used to demonstrate this same procedure on TV but I always figured he'd say *anything* for a buck). Anyway, the straight-down-the-middle Bud was much better than the gently-down-the-side (whether this raised it to the level of drinkable, is subject for discussion). The sales rep suggested that this was because the release of carbonation "activated" the flavor of the hops and malt. I don't know, maybe it was because without that extra carbonation our taste buds (ahem) weren't numbed beyond sensation. When I pour, I always try to release some of the carbonation but not so much as to let it go flat before I finish drinking it (more of a problem with my homebrew than with commercial products).
3. While reading the new edition of TCJoHB I noticed in the foreword (or introduction) that CP mentions drinking a wheat stout (I don't recall the exact name) while he was writing the intro. The idea of making a wheat stout intrigued me, so I immediately flipped to the now-famous index and lo and behold - no recipe for this brew :- ( Do you think maybe he's holding it out for TCJoHB, 3rd ed.? If anyone has the recipe for this (or any other) Wheat Stout, I would be most interested.
4. I recently tasted Xingu Black Beer from Brazil. For those of you who haven't tasted it, it's very black, slightly bitter, and a strong taste of...I don't know what. The only beverage that I could closely compare it to would be Moxie Cola. I suspect that the similarity is due to the use of some root or root extract. Does anyone know what this might be? Not that I wish to duplicate it; just curious.
5. Thanks to all who answered my question re: Fix's "Principles of Brewing Science" and whether someone (me) who had no prior knowledge of chemistry would be wasting his time on it. The general consensus was that the book is not light reading but it's not impenetrable either and definitely worth the effort. I haven't bought it yet, but I will.
6. Good beer is no accident.

That's all for now

Subject: wort chiller

Hi. I got a mailer from "Bradcoop Direct Mail Service" today and they want to send me homebrew retailer coupons six times a year if I give them \$3.50. Anyway, to get me started they sent me a few coupons, one of which was for free shipping on the immersion wort chiller from The Home Brewery (321-BREW). I've been eyeing this chiller since it seems kind of inexpensive (\$29.95) so this opportunity seems good. So, has anyone purchased this chiller or know anything about it? They don't give any stats but say it can chill 5 gallons in about 15 minutes and it's copper with brass fittings on the end. I want to start full mash brewing in 5 gallon batches soon, so I need a chiller that will work for that. Thanks for any help!

From: srussell@snoopy.msc.cornell.edu (Stephen Russell)  
Subject: Congrats to our winners

Peoples,

I just got the Special 1991 Zymurgy today, you know, the one containing the 1st Place Winners from this year's competition. Congrats are in order for all the winners, but I figured I'd give special mention here to those winners who also subscribe to the Homebrew Digest (that I know of):

Mike Zulauf.....Specialty Beer  
Andy Leith.....English and Scottish Bitter  
Mike Fertsch.....Wheat

Sorry if there's anyone I missed (I'd be surprised if I knew all 1200 or so subscribers).

Might as well follow up on this with a recipe, just for kicks and so you all don't think that all I do is schmooze :-)

Desert Storm American Steam Beer

-----  
(by Tom Strasser and Steve Russell; guess when this was brewed)

4# Pale Ale malt  
5# Klages lager malt  
1# crystal malt (40 or 60 deg Lovibond)  
1/2 tsp Irish moss  
1.5 oz Northern Brewer (alpha 8.0), boil 60 min (49 IBU)  
1.5 oz Hallertauer (alpha 4.1), boil 1 min (4 IBU)  
MeV High Temp Lager liquid yeast

Mash: 25 min at 52C, 90 min @ 66C, 10 min @ 75C

Judges said it was perhaps a tad thin compared to Anchor but otherwise OK and it took 2nd out of 30 amber beers at the Hudson Valley competition last March. With MeV 'kaput', I recommend using a sturdy lager yeast or even an ale yeast for this one.

Brews to ya,

STEVE

Well folks, I've got one of those humbling infection problems which really takes a homebrewer down a peg. I throw this out to the HBD community, not expecting that someone will reply with the genus and species of the critter (and why not tell me where it's coming from while you're at it?)

but instead looking for a little guidance for hunting the beast. :-). Some experiences with background infections that kick in only after bottling would be of help.

In anticipation of some replies: yes, I plan to throw away every piece of equipment that isn't stainless steel or glass. I might even leave my current rental home (mostly because I want to get some equity; I'm not quite that obsessed with brewing).

**The problem:**

Background microbial infection. Small white colonies, typically right underneath the beer surface in the bottle. Turns up between 4 and 5 weeks after bottling. Usually causes malt and hop flavors to essentially disappear. In one particular batch, a fungus-like stench was noted in the bottle's yeast sediment. Before the infection, beer flavor and appearance are outstanding.

This problem has not been noticed in Cornelius-kegged beers. The keg was sanitized with Iodophor rinsed with boiled water, rather than bleach. Kegs are purged with CO<sub>2</sub>, whereas bottles are not. Note however that the relative size of the keg could cause a difference in the life cycle of the critters. Also, I can't see inside the keg to see evidence of infection or lack of same.

**Theories:**

Although some plastic equipment is reused, airborne infection is more suspect; the brewery is in the Pacific Northwest and black molds are in evidence on the casement windows at the end of every spring. However, many brewers of my acquaintance in this area have never seen this kind of infection before.

**Terms:**

Boil-sterilized: Boiled for 15 minutes @ 212F.

Bleach-sanitized: Exposed to 1 Tbsp/ 1 Ga Clorox solution for 15 minutes. Air-dried for 5-15 minutes.

Baked: Baked at 350 F for 90 minutes.

**Common Equipment:**

Plastic Funnel, slightly scratched, several brews.

Plastic Tubing, several brews.

Plastic Siphon Cane, several brews.

Plastic Wine Thief, several brews, somewhat darkened by wort/beer.

#### Common Conditions:

Fall/Winter/Spring weather in Portland Oregon (60-100% humidity, mold grows on inside surfaces by windows, etc.).

#### Process (common to all problem batches):

##### Prepare Starter

Boil 30 minutes. Baked starter bottle for 90 minutes at 350F. Pour boiling wort into bottle fresh from the oven (HOT). Cap with boiled bottle cap immediately. When packet is pitched into starter, starter looks good (no evident fermentation or other decomposition).

Sealed starters have been observed for several months without evidence of the infection.

##### Start Yeast

Bleach-sanitized Wyeast packet (almost all ale strains) pitched into starter bottle.

##### Brew

90 minute boil. 30 minute cool (brewpot in ice). Transfer via boil-sterilized saucepan into bleach-sanitized fermenter. Boil-sterilized strainer and bleach-sanitized funnel.

##### Rack off Break

Rack off break into second bleach-sanitized carboy with sanitized siphon cane/plastic tubing started by sanitized wine thief with boiled water. Pitch yeast from starter with funnel.

##### Primary Fermentation

1 week duration at 68-70 F. Fermentation looks good.

Bleach-sanitized carboy. Bleach-sanitized blowoff tube to sanitizing solution in gallon jug for 2 days, then bleach-sanitized fermentation lock.

##### Secondary Fermentation

2 to 3 week duration at 65 F.

Bleach-Sanitized Carboy. Bleach-Sanitized siphon hose and cane, started by beer or boiled water with bleach-sanitized plastic wine thief.

Sometimes dry hop with steamed hop bag; sometimes not.

Fermentation looks good.

##### Bottle

Bottles are cleaned with dishwasher detergent and hot water. Rinsed well with hot water and baked at 350F for 90 minutes. Siphon Cane and plastic tubing are bleach-sanitized. Bottling Wand is bleach-sanitized. Priming sugar (dextrose) is boiled 15 minutes. Bottle Caps are boiled for 15 minutes.

2 to 3 weeks after bottling (bottles at room temperature)

Beer is carbonated and tastes excellent.

4 to 5 weeks after bottling

(bottles either at room temperature or refrigerated for a couple of weeks)

"Mold" ... (small colonies; 1/4 size of a pinhead around neck of bottle. Once the yeast cake in the bottles smelled like athlete's foot). At best, the quality of the beer is diminished, at worst it gets poured down the sink.

Subject: BLOWOUT

To: Homebrew Digest  
Fm: Jack Schmidling

TO BLOW OR NOT TO BLOW (OUT)

I have been entranced with the idea of "blow out" primary fermentation and had to give it a whirl. The following are my observations on the procedure.

1. The batch size is critical. The carboy must be "full" in order to blow out all the foam but not so full that a lot of wort is lost.

This may seem like a simple problem when making up an extract batch wherein brewing water can be added to top it off or make up the full wort. Even then, I would guess that, what works in winter would be an explosion in warm weather.

However, when brewing all-grain, the end amount is far less predictable. I usually sparge out about 7 gallons to allow for evaporation and end up with a nominal 5 gallons. Well, this time I ended up with an extra gallon, most of which I eventually was able to add, as the blow out, blew out but it was a pain in the butt.

2. It is now under a conventional fermentation lock and I am having nightmares about cleaning that dried crud out of the top of the carboy after another week or so of this.

3. It appears that I lost about 2 quarts of wort. In my normal skimming routine, I doubt that the foam converts into more than a half a cup.

4. There still is a substantial amount of foam that could not be blown out because of the level and I guess that it is more than what I miss in the skimming process.

5. On the plus side, it was a mystical experience watching the foam "trains" traveling through the tube. The color of the wort (a creamy brown) during primary was also a surprise.

I won't make a recommendation but I will suggest my next experiment. The

best part of the procedure is being able to see the fermentation but the most interesting part (the foam) is all jammed up in the top and trying to get out.

So, I got a piece of glass a few inches larger than my primary fermenter and I am just going to set it on top and see what happens. The fermenter is the standard 8 gallon plastic job and allows a wide variation in batch size. The lids that come with these things leak anyway and the ferm lock is nothing but a passifier.

I used to panic because the fermentation always seemed to stop after a few days because the lock quit bubbling but when I look inside it is fermenting furiously but not quite enough to keep up with the leaks.

BTW, I like skimming. It makes me feel like I am contributing something to the process.

Now for the momily buster.....

How come Baderbrau pumps the chilled wort into a fermenter and 30 days later drains it off to be filtered and bottled? They do not seem to be concerned about the foam falling back in. This is the beer that Jackson proclaimed the best American Pilsner.

From: Mike Sharp <msharp@cs.ulowell.edu>  
Subject: AHA Video

Chris Shenton asks:

> Doesn't the AHA have a video on homebrewing for beginners, starring all  
your  
> favorite (-) stars, like Papazian, et al?  
Interesting question Chris. I just got out my latest Zymurgy and:

Yes, The AHA does have a video. I've seen it in the local supply shop.  
I'm sure it goes wonderfully with Charlie's new edition of The Complete  
Joy of Homebrewing. Imagine that, an intro video & and intro book!  
But wait, there's more -- I believe they also have a (free?) flyer on how  
to  
brew your first batch. Then there are all the other books/materials..  
.

The writeup on the video reads:

"Homebrew Video -- Brew with the masters! There is nothing like hands-  
on  
training for learning an art, and in this three-part 76-minute home study  
course acclaimed homebrewer Charlie Papazian, author the TCJOHB and  
publisher of Zymurgy magazine, demonstrates the complete process of  
brewing for you. Is there a clearer, more comprehensive way of learning  
to brew? We don't think so!  
Charlie shows the required equipment, ingredients and techniques for  
brewing,  
then several other homebrewers tell you their brewing secrets. Finally,  
two brewmasters share their tips with you, one of whom takes you  
behind-the-scenes at his brewpub in Toronto."  
[hmm, I wonder who checks their copy...]

The AHA can be reached at (303)447-0816

FWIW, Jack pointed out that commerialism is OK on Internet so I thought  
I'd just add my \$0.02. Perhaps we should post information about this  
video on a regular basis. After all, it would be for the enlightenment  
of the new brewers -- we should do everything possible to get new  
brewers started. Maybe I'll even buy a few copies of the video and  
rent it out...

(-: :-) (-: :-) (-: :-) (-: :-) (-: :-) (-: :-) (-: :-) (-: :-)

Subject: Re: Canned Guinness Drafft!?!

"Russ W. San Fran/CA" <72300.61@compuserve.com> expounded on the delights of discovering Draught Guinness in a can.

I will second Russ' opinion on this subject. We have been lucky enough to have had draught Guinness for a couple of years now. I was surprised that it hadn't made it to the States when I was there from Jan '90 thru Sept '91 (officially of course - more than one 4 pack came back with me every time I returned from a trip home!). Until recently it was the only commercial brew that was worth keeping at home, but upon my return to England I have discovered that they are using the same, or similar technique with Bodingtons Bitter, from Manchester I think. Anyway, now my fridge is always well stocked and I don't have to go to the pub for real beer. Hopefully some of the other real brewers in England will start to produce real beer in cans. Many others have started to but without the thingy that makes the difference. Since I have been back I have discovered Brakspears, Pedigree, Bodingtons and 6X in cans and Old Hooky in a bottle, all of which are a vast improvement on what I have been forced to drink for the last two years, but none of which measure up to a pint of the real thing from a barrel!

The new 'Good Pub Guide' came out this week, and brought along with it a controversy about the price of a pint in various parts of the country. For example it is possible to buy a pint (20oz) in Manchester for the same price as a half pint (10oz) in London. The average price of a pint in London is now about L1.80 (\$3.00) and the rest of the country comes out to about L1.20 (\$2.20).

Subject: First two batches great - thanks!

Well, Mike (tanenbla@division.cs.columbia.edu) and I have now brewed two batches, both of which worked wonderfully, and we wanted to thank everybody on the digest for all the info we have picked up over the last few months of reading - it certainly made things easier. We had no real surprises thanks to HBD - every time something came up, we remembered reading something here about it, and that helped us relax ... The first batch we did was a Bitter, which came out much better than either of us thought was even vaguely possible (several people, who kept telling us that every homebrew they had ever tasted was terrible, tasted this one and decided that maybe it *was* possible to brew good beer at home). We used one can of Coopers Ale (hopped) with a bag of NW amber and some extra bittering hops, and it came out wonderfully bitter, but clean, and even clear! The second batch is an IPA - a very nice pale ale taste, just a touch cidery, with a bit of a chill haze. We are now doing two batches, both the same Anchor recipe from the Cat's Meow, but one with lager yeast at cool temps, and one with ale yeast (all recipes so far done with Whitbread). We are curious to see what the taste difference will be. One problem we did run into, which maybe somebody could comment on, especially for other beginners, is bottling! For the first batch, we just had a tube, and we tried to stop the flow by pinching the hose, or raising the end, both of which seemed to guarantee lots of beer on the floor. We used a makeshift valve taken from a Dinkel Acker mini-keg for the second batch, and bought a bottler for \$3 for all subsequent batches. What does everybody else do? Again, thanks alot everybody - looking forward to posting more as we brew more!

Again, I  
>assume that what he wants is the sweetness in the finished product only.

I seem to remember a discussion a while back on substitutes for the  
saccharin  
called for in some of Dave Line's recipes. While I have never used it, I  
believe that some had suggested using lactose as a substitute. Lactose  
(milk  
sugar) is unfermentable by brewer's yeast and so leaves a residual  
sweetness in  
the finished product. Lactose is often called for in "milk stouts" which  
have  
a characteristic residual sweetness. Sorry, but I don't remember any of  
the  
details regarding the quantity to substitute... maybe someone else knows  
or  
remembers.

> simulate what a bottle of beer might go through on a retailers shelf.  
Under  
> those conditions I'd put my money on the brown bottles being much more  
> resistant to skunking.

I cannot disagree with you to the extent that brown bottles are likely to stave off the reaction longer than green. Perhaps you have better retailers in the east, but my experience is that I often get skunked beer, regardless of bottle color, when I can't find one that has been kept in the dark. Certainly 15 minutes of sunlight (btw, these were in February or March, but it appears that LA sun in February is stronger than it ever gets in Seattle ;-)) is a big dose relative to fluorescent bulbs, but how big? 1000 times? That's merely 24 days under artificial light. Anyway, I will stick by my rule of thumb here, and I will refuse to prejudice myself by the bottle color in a contest (which was the true point of my posting). Skunky beer is beer that has been handled poorly, and it seems easy enough to do so regardless of bottle color.

> I think that if we are talking about moderately mistreating beer (as in letting  
> it sit under a store's lights for some time), the color of the bottle DOES  
> matter. Ever wonder why the skunky beers that you get off store shelves are  
> generally in green bottles? When was the last time you had a skunky Heinekin?  
> When was the last time you had a skunky SN pale ale?

Well, I don't generally buy SN Pale Ale in a bottle when it was one of the easiest beers to enjoy fresh from the tap in LA; perhaps that'll change up here. But the bottles I consistently saw were pretty new. With regard to imported beers, however, I have had the great disappointment of getting skunky Warsteiner as well as Heineken. And I've already had the displeasure of a skunky Bridgeport that I bought late one night from the super I can easily walk to. Bridgeport comes in brown bottles, and is unfortunately, undated.

> Tom Strasser's posting in HBD 753 was excellent and

> visibly demonstrated the vast difference in light absorptivity between  
green  
> and brown bottles.

It was interesting to see what the different transmittance properties  
of the glass were, but based on my tasting experience, it is clear  
that either I was going to the wrong retailers in LA or that it just  
doesn't take very much small-wavelength light to produce the effect.

> Here's a part of a post from Darryl Richman in HBD 609:  
> >Light struck is defect noticeable by a skunky or catty aroma. This is

>  
> I am challenging the assertion of postings in this forum that green  
> light (and the "magical" 520 or 525 nm wavelength) is somehow  
> responsible for the skunking of beer.

I've had this pointed out to me since I posted, and I went back and  
checked through my materials. You are absolutely right, I was unable  
to locate a reference, and now I wonder where I read or heard about  
this specific wavelength. (It might be Beer and Brewing #9, since  
one of my dogs had his way with it, or it might not, but that is  
the only place I could have read it and not verified it.) Every  
reference I have does indicate that there is a broad range of  
the spectrum that can cause the transformation.

> uses sugar, it will ferment, and presumably lose it's "sweetness".  
Again, I  
> assume that what he wants is the sweetness in the finished product  
only.

I hope you'll allow me to speculate on Dave Line's experiences, without  
construing them as being the truth. His mashing technique, while bold  
for  
the early seventies, was a bit crude. I think that he probably  
got a very good return on his grain, converting as thoroughly as possible  
all of the starches into simple sugars. (As I recall, he advised putting  
the mash in a picnic cooler overnight.) He also recommends dried yeast,  
which he then goes on to repitch.

Thus, he has selected what some of us have determined to be the  
most attenuating circumstances to brew under. His resulting  
beers therefore, were pretty dry. Since he knew that many  
famous styles were not dry, he looked around for ways  
to gain this sweetness, which he could not obtain in the normal way  
of high mash temperatures and low attenuating yeast.

Thus he began to experiment with sweeteners that could not be  
fermented and hit upon saccharine. I suspect that in small  
quantities, saccharine would not be very obtrusive, perhaps  
lending some "interesting" flavor that might not be identified.

All of this is, of course, the merest speculation.  
I must also admit to not owning "Brewing Beers Like Those  
You Buy", and am referencing instead "The Big Book of Brewing".  
I keep this book at hand because Line is an interesting source of  
insight to British beermaking technique, since he clearly spoke  
with a number of brewers. He also has much to teach about using sugar  
in beer (gasp!).

From: kerl@cmack.b11.ingr.com (Dan Kerl)  
Subject: RE: Dave Line's saccharin

If I remember what I read in Dave's book, "Brewing Beers Like Those You Buy", the reason that saccharin was used in his recipes was because that the dry yeasts available to him at the time were overly attenuative. He explained that to get a similar level of sweetness to a commercial brew (where they didn't have to put up with the same yeast compromises), he needed a non-fermentable source of sweetness.

I suspect that with the improved yeast cultures available to us today, such compromises as this are unnecessary. It would be interesting to try to modify Dave's recipes to eliminate the saccharin adjunct by using a more appropriate yeast culture.

I'm interested in his recipe for Ruddle's County Bitter. Has anyone tried it?

Subject: New canned "Draught" Guinness

> From: "Russ W. San Fran/CA" <72300.61@compuserve.com>  
> Subject: Canned Guinness Draft!?!

... < Now the folks at Guinness have developed a system which dispenses  
their  
stout from a can in such a way as to rival a pub tap. > ...

I can verify this man speaks the truth! The new draught system has  
transformed canned Guinness into something virtually indistinguishable  
from  
the best obtainable in pubs anywhere outside Ireland. In the UK the  
system  
is also used in a new (delicious!) Guinness Bitter and in Boddingtons. I  
expect it to revolutionise beers where a thick, tight, creamy head is  
part  
of the drinking experience.

I would, however, warn against making it too cold or too warm. If too  
warm  
it froths all over the place; if too cold the system only produces a  
small,  
disappointing head and flattens the flavour of the beer. Frankly I think  
two hours in the fridge is too long. (Maybe mine is colder than theirs).  
Serve it cool, not cold.

Subject: Re:Bandaid (tm) beer

B^2 asks:

> I have a slight problem, two of my last three batches have turned out  
>with a, as my brew partner calls it, "bandaid" flavor, I think it's a  
>bitter flavor but not a hop bitterness.

Bill wisely included the recipes \*and\* fermentation temperatures, but  
my possible source for the "Bandaid (tm)" flavor/smell is, alas,  
unrelated  
to these two pieces of information. The off flavor/smell is due to  
phenolics.  
According to the Zymurgy troubleshooting issue, Troubleshooting chart, it  
can be caused by:

Chlorinated (tap) water, wild yeast, bacteria, oversparging of mash,  
boiling  
grains, cleaning compound residue, plastic hoses and gaskets, and  
defective  
bottlecap linings.

I omitted a few causes listed in the Troubleshooting Chart from the  
troubleshooting issue (Vol 10, #4, Special issue 1987) because I disagree  
with them (so there!) and have included a few which I think are less  
likely  
to cause the particular flavor with which you are concerned (bottlecap  
linings, oversparging and boiling grains, specifically) but this is just  
intuition. I have not personally had this problem, so I'm afraid my  
suggestions are based upon reading, combined with intuition, but for what  
it's worth, I think that the most likely sources are:

1. chlorinated sanitizing solution residue (solution: rinse better) and
2. chlorinated water (solution: boil all the water you are using in the  
beer).

Subject: Homebrew Popularity & Cloviness

A general comment, not part of any previous debate...

Jack sez:

>I used to see the owner of the local  
brew shop standing outside his shop watching cars go by, every time I  
passed  
and I just assumed the hobby was as unpopular as it ever.

Poor guy. Don't know what he's doing wrong. My friend Jeff owns the  
Modern  
Brewer here in Cambridge, Ma. He's been open a little over a year and  
he's  
doing really good business right now, even with the bad economy. My  
observation  
is that the growth in interest in micro-brewed beers and homebrewing is  
very  
strong. Of course these are my observations here in Beantown (and a few  
other  
areas I've traveled to, your mileage may vary..)

> My target was and still is all those people out there that do not even  
know  
that one can make drinkable beer at home. Let's face it, most of them  
like  
Bud.

My personal experience is that few people go from Bud to homebrew.  
Typically  
they "discover" microbrews or imports and their tastes change before they  
make  
the leap to brewing themselves. Again your mileage may vary.. (hey let's  
introduce a new acronym for this... YMMV)

> From: Jay Hersh <hersh@expo.lcs.mit.edu>  
>

>  
> The second most recent batch (just about drinking age now) has  
precisely that  
> taste and aroma. Aside from that anomaly, it is possibly the best  
tasting  
> beer I have ever made. It also happens to be my first all (commercial)  
grain  
> batch and drinking it has become almost a mystical experience.  
>  
> Where did those bloody cloves come from? I used 6 row barley but the  
same  
> guy who told me that oxidation causes a cidery taste sold me the  
"barley".  
> He couldn't possibly have sold me wheat malt, could he?

Jack I'm not sure what to make of this reply, I think you may have

misunderstood. The cloviness comes from the YEAST not the wheat malt...

'  
Red Star Ale, which you said you used to use until recently if I read  
this right,  
(which I stopped using long ago after a friend got the banana beer that  
tasted  
more like bananas than bananas do..) is reputed to produce clove flavors  
under  
certain fermentation conditions (I don't know what these are supposed to  
be).

Subject: Bag It

From: Brent Ball <staf1282%slcsl.bitnet@utcs.utoronto.ca>

>after about 5 days or so I transfer my brew from the plastic  
>primary pail to a glass carboy secondary to finish up. This is a clear  
glass  
>vessel and it sits in the corner of my sunlit kitchen (no direct  
sunlight  
>though). Am I doing light damage to my beer in the process of making it?  
Should  
>my glass secondary be relocated to my dark (and bit damp) basement or  
could  
>I simply loosely cover the carboy by placing over it a big(D size)  
photographic  
>paper "light resistant" bag (this should attenuate all UV)?

What to do if you don't have a convenient dark storage place for your  
fermenting beer?

Take a standard brown grocery bag and cut a hole in the center of the  
bottom.  
Make this hole slightly larger than the neck of your carboy. Invert the  
bag  
and place it over your five gallon carboy, it's a perfect fit.

I'm sure if you put the carboy in direct sunlight in Southern California  
(;-)  
you could still damage the beer, but under "normal" circumstances you  
should  
be OK. If you want added protection, use two bags.

Cheers,  
CR

From: larryba@microsoft.com  
Subject: Hey, Jackie baby - chill out.

Not everyone on the HBD is your nemesis. Either you are pulling peoples cords just to see what kind of boing they make or you are being a bit too defensive.

Anyway, my recipe for oxidized doctored beer was a attempt in helping you understand the oxidized flavor/aroma in beer so you would be better equiped to detect it in your homebrew beer. I don't necessarily think that you will detect oxidation in your "mishandled" beer. Why? Because it is my belief that if you have active yeast in your beer, oxidation may not be an issue. Beer that is primed and bottled has live yeast in it. Live yeast is very reductive (?) and chews up the oxygen + reduces the oxidized components. I have heard that damaged beer can be revived by adding fresh wort, yeast and letting it re-ferment. I think that is what happens for many home brews: they are harsh at first (green?) and then as they age they mellow out. I think it is the yeast doing it's magic. Comment, Dave Rose, George Fix?

Anyway, I lager in the refer (ales and lagers) until the beer is fairly clear. I then keg and artificially carbonate. There is little or no yeast activity at this point. If I am not careful about O2 infiltration I get a distinct "stale" taste/smell to my beers (sample of 2 out of 17 so far). I have never had that happen with bottled homebrew or kegs I primed. Typically, my beers are very drinkable/clean as soon as I carbonate them. Aging helps, but not nearly as much as it helped my old, sloppy, bottled extract beers of long ago.

The point is that you may well be right that oxidation is not an issue for homebrews if the air infiltration is not grotesque and there is a secondary ferment in the bottle. It probably depends upon the gestalt of your brewing setup. What works for you might not work in all cases. Knowing the defects and what the underlying causes are can help you determine what is important for your setup (or videos!)

As for skunk beer in Miller bottles: I trust you were kidding me... The beer has been doctored, not the glass!

From: Joel (J.N.) Avery <JAVERY@BNR.CA>  
Subject: priming with honey

I posted an article in the last week of September about priming with honey when someone else was asking. Anyways, for a 5 US gallon batch, I use about 3 or 3.5 oz of liquid honey, but I tend to prefer a lighter carbonated beer when compared to my homebrewing buddies. You are better off brewing a flatter beer the first time, and then adjusting the amount of honey you use.

Make sure you boil the honey with some water to kill off any live cultures that might exist in the honey. It also makes the priming "sugar" mix better with the beer. I just pour the boiled honey and water into my priming pail shortly after starting my siphon from the carboy. Never had a problem.

From: Loren Carter <lcarter@claven.idbsu.edu>  
Subject: doctored beer

A while back someone(I think it was Chris Shenton) asked about doctoring beer in order to train judges etc.

Our club has done this several times in the past with good results.

In addition to skunky(light struck) and oxidized beers mentioned in HBD we have used the following:

Metalic taste   FeSO4  
sweet taste     sugar  
acidic        lactic acid or vinegar  
alcoholic vodka  
medicine taste listerine  
phenolic   phenol  
butterscotch   diacetyl(use butter or butterscotch flavoring)  
ester flavor   bannana oil

In place of the listerine and the phenol last time we used oil of cloves. This seemed to work as well or better than the listerine and phenol and is easier to get than the phenol for most people.

Hope this helps.

>> Seems to me blowing air from your lungs and mouth into the carboy  
>> isn't much better than getting your mouth over the racking tube. I'd  
think  
>> you'd introduce all kinds of ugliness into the wort.

> This is a reasonable expectation, but it turns out to be wrong. I work  
> in a yeast lab, and we routinely inoculate cultures by blowing yeast  
out  
> pipettes into culture tubes; by blowing some bubbles in the culture,  
the yeast  
> get mixed up. This absolutely does not lead to contamination ....

I'd be quite surprised Dave if you use unplugged sterile pipettes to  
dispense  
your yeast. The fibrous plug found in the top of culturing pipettes is  
tightly  
packed and adsorbant enough to stop potential microbial contamination  
carried  
by microscopic particles dispelled with each humid breath.

> apparently, breath is sterile.

If you've ever done animal cell culture or bacterial culture using media  
much  
richer than liquid malt or malt/agar you'd know, from painful experience,  
that  
breath is not sterile.

> In short, breathing into the carboy is not a problem, as long as you  
don't  
> drool into it or something.

I'd tend to agree with this without any contradiction to my above  
comments. The  
media conditions must be hospitable to potential contaminants and acidic  
hopped  
wort may not be well received by the types of microbes in your breath.  
Furthermore, no homebrewer's wort is "sterile" but this poses no problem  
if  
enough healthy yeast are pitched to outgrow other life forms. I'm still  
extra  
careful anyways. It helps me RDWHAHB. ;-]

> As to what by-products contribute to hangover, and how much, I'd guess  
> that that is highly specific to the individual? Anybody know any facts  
> in this area??

>From my simple understanding of the phenomenon, the main culprit is  
dehydration  
with some credit going to vasodilation in the skull. Both alcohol and  
fusels  
along with some amines are the cause. The liver, that wonderful  
detoxification  
centre, requires the B-complex to provide cofactors for various detox  
pathways.  
The high demand for B-vitamins results more in a shortage than an  
imbalance.  
I've had better luck taking time-released B-complex prior to indulgence  
rather  
than after but either way will help. As mentioned above, plenty of water  
is  
still the best treatment since it rehydrates the spinal fluids and helps  
to  
flush ones system of toxins. Taking a teaspoon of fructose rich honey  
along with  
water also provides the liver with a good energy source.

However, there's always the breakfast of champions....coffee and tylenol.

Correct me if I'm wrong, but are you sure that seeds were specified in the recipe? Coriander seeds have a very different flavor from the leaves, which are yet again different from the root. Three completely different spices from one incredibly groovy plant. I can't remember the recipe that was given, but the leaf flavor is the most common one in most forms of cooking (aka chinese parsley). Off the top of my head, I would think I'd prefer the leaf flavor (common in Mexican and Indian cooking) in beer to the seeds. But then, maybe I'm completely off base.

From: BAUGHMANKR@CONRAD.APPSTATE.EDU  
Subject: Counterflow chillers

Greetings friends and neighbors:

I've been quiet enough lately. Guess I should put my two cents in on the chiller discussion. I'm not trying to be testy. Just want to make sure things remain balanced.

And please, let's don't ever say "m\_m\_y" again. It's a stupid word and besides, my Mom wouldn't even think of making beer!

>While on the subject, I'd like to add a couple more reasons that I feel the  
>immersion chiller is better than the counterflow type:

>1. cleaning is easier on an immersion chiller and you can see how clean  
>the surface that contacts the sweet wort is,  
>

>2. sanitation is easier - all you have to do is dunk it in the boiling  
>wort before turning on the cooling water (you may also be able to  
sanitize  
>a counterflow similarly, but intuitively, I suspect that by the time  
>the hot wort is at the exit end of the chiller, even with the cooling  
>water off, it has dropped below 180F which does little to sanitize the  
>tubing, and

Actually I find sanitation and cleaning of the counterflow chiller to be just as easy and effective as sanitizing the immersion type. Drain the chiller body of cooling water after a round of brewing and siphon boiling hot water through the empty chiller until the boiling hot water exits the bottom. Store it dry.

Before the next brewing session, I generally siphon some of my just-prepared, ever-present solution of 1 Tbsp. clorox to 1 gallon of water sterilant solution through the copper and let it sit for 20-30 minutes. That's not enough to corrode the copper, BTW. Then just to make EXTRA sure that everything's sterile, I start my chilling session with the chiller dry, so that immediately after the short clorox soak, the copper comes into contact with boiling hot wort. If boiling hot wort is good enough to sterilize the outside of immersion chillers, it's good enough to sterilize the inside of counterflow chillers, too, unless I'm missing something. :-)

>3. I, personally, would not want to start a siphon (with my mouth  
(besides  
>the sanitation risk) or by other means (turkey baster, etc.)) on a 170+  
F  
>liquid!

Me neither. That's why I (a) either let the clorox water that's inside the chiller start the siphon or (b) insert a small 2" piece of 3/8" tubing into the end of the siphon hose and suck on it. When the wort approaches the mouth, pinch the hose shut, remove the tubing, and direct the flow to the fermenter.

I do like the fact that the counterflow chiller chills the wort very quickly. One drop of wort goes from 212 degrees to 70 degrees in about 6 seconds and then comes into immediate contact with the yeast. Not much time for a bacterial infection there.

Whichever chiller you decide to use -- and in the end it is a matter of personal choice -- I do agree that it's the time-saving features of the chiller that I enjoy the most. But I happily accept the associated reduced risk of contamination and better cold-break.

While on the subject of time-saving, again, I might as well make the point that the counterflow chiller saves more time especially if you make a habit of siphoning into the fermenter anyway. With the counterflow, you can start siphoning into the fermenter immediately. With the immersion, you have to wait 20 or 30 minutes for the wort to chill before you can begin the siphon.

A nit-picking point, I admit. But, hey, at least I'm not arguing about whether oxidation is a real phenomenon. The first 3 or 4 batches of beer that I kegged were deep-sixed because I couldn't tell whether it was beer or some sort of weird sherry.

As for initiating homebrewers into our hobby, I emphasize the following:

Use good ingredients, good recipes, and good clean equipment. Make up a 4 or 5 gallon batch of sterilant and soak everything that touches the cooled beer in it for 20 or 30 minutes. Keep racking to a minimum. When it's time to rack, treat your beer like your lover. Be gentle with her. Don't abuse her. Don't slap her around or dump her into bed, er, I mean, the carboy. Ease her into it. Talk nice to her. Let her know you care.

See! That wasn't difficult was it? Homebrewing is easy.

Hey, Darryl, you radical! You've gone from "Eunuchs" to Microsoft and MSDOS!!! My how the mighty have fallen! Is there any hope left for us all? Where is the truth? What is realty?

Cheers ya'll,

Subject: Skunks sighted at 520 nanometers!, AHA competitions, metabolism of ethanol

Re: AHA competitions

Someone commented that swing-top bottles were unacceptable at AHA sanctioned competitions, and recommended 12 or 16 oz. bottles. I would like to suggest that for competitions, please use nice clean unscratched 12 oz. standard longnecks. It is ok to use 10 to 14 oz. brown or green bottles (please do spectrophotometer readings to test for light blockage between 423-587 nanometers ;- ) but it is much better to use the standard bottles, it makes life easier for everyone. I have directed an AHA state competition and a judged a coupla AHA nationals and its makes life easier if the bottles are all uniform. I talked to Dave Welker (AHA national director) about this and he had to disqualify some good brews because they were out of spec re: the bottles, and I know it really bothered him. Read Zymurgy Vol. 14, no. 1 (spring 1991) article on shipping beer to competitions ("Fragile - This Side Up" pg. 27 - Russ Wigglesworth). If you send your prettiest bottles it helps!

RE: Hangovers

Alcohol gets converted (by alcohol dehydrogenase) to acetaldehyde, which is sickening, it builds up because alcohol is converted to acetaldehyde faster than acetaldehyde is broken down. The acetaldehyde probably causes the majority of problems (along with fusel oils) it causes direct cell damage and is a free radical. L-Cystine scavenges the free radicals off of the acetaldehyde and in single blind experiments (unpublished observations) it seems to alleviate the 'edge' of a hangover when given with lots of water and b vitamin complex prior to processing the majority of the alcohol consumed. Interested parties ;) are refered to Molecular and Cellular Mechanisms of Alcohol and Anesthetics Annals of the NYAS, 1991.

Stroud wants to know about the specific 520nm light damage done to beer, Boy, did I have to dig around to find where I got that from! I would welcome references to something newer (it may have been posted recently but mail has been sporadic), but I got my info partly from Michael Tierney, a Ph.D. chemist and homebrewer, who wrote an article about the chemical reaction in Zymurgy vol 12, no 3 1989. The information may be dated, and I would like to be current! If I can get enough info to interlibrary loan new articles please let me mail me. You mentioned 400-500nm, gee I was only out of range by 20 nanometers!

excuse spelling errors, I've been evaluating Sierra Nevada Bigfoot.

In HBD #755, des@swindon.swindon.ingr.com (Desmond Mottram) writes:

>Plastic pressure barrels with cheap CO2 injectors and cylinders are very  
>common here in the UK. Can't you get them in the States? Ask your home  
brew

>supplier if they are made or imported. If you get no joy, I suggest you  
>import them yourself and make a small killing!

The Saffron Superkeg, a 6+ US gallon plastic keg with an (optional?) cap for CO2 cylinders and a pressure relief valve, is distributed in the US by Crosby & Baker. Your homebrew store should be able to order it from them.

It happens that I kegged my first batch in one last night, so I can't give any practical results yet. However, be warned, as I was, that such kegs are designed for British "real ale" levels of carbonation, i.e., very low. The Superkeg is designed for at most 15 psi, which is the nominal level at which the relief valve opens. Since I'm drinking my last batch (a porter) by keeping the bottles at room temperature, and letting the beer sit a few minutes after opening to allow it go flat (it tastes best to me like that), I don't expect a problem. "Your mileage may vary."

(Note: I am not affiliated with Crosby & Baker.)

From: loc@bostech.com

Subject: Wyeast #1007 Info

A couple of months back there were a couple of postings regarding bacteria found in a Wyeast package of German Ale yeast #1007. Being that I use this particular yeast a lot and have had no problems with it I had my homebrew shop check into the report and see if they could find anything out from the manufacturer.

They finally got a chance to call Wyeast regarding the reports about an infected batch of #1007. According to Wyeast they have not had any reports of an infected batch of yeast. They do inspect each batch, but for obvious reasons not each package. They do take these reports seriously and are looking into the matter.

So, if and when I get any more info I will post it.

Still not worrying,  
Roger L.

Date: Wed, 6 Nov 1991 10:18:02 -0500 (EST)  
From: R\_GELINAS@UNHH.UNH.EDU (Russ Gelinias)  
Subject: infection

First, R. Al M. talked about some "ring-around-the-bottle". Most likely it's bacteria, not mold. I had the same thing once and had it checked at my wife's bio lab, and it was bacteria, 'though they couldn't say what kind without more (ie. \$\$\$) tests. All new plastic cured it.

Thomas M. got "possible food poisoning" from his infected wort. Yes, it's possible, but more likely you just picked up a flu bug. There's a bug out now (I'm just over it, knock on wood), that mimics food poisoning pretty well, with stomach pains that are \*unbelievable\*. In the past I got what I thought was food poisoning after eating at a restaurant, went to the emergency room, and found 5 other people with the same symptoms, who hadn't eaten at the restaurant. The culprit? Flu. The hospital folk said "stomach distress" cases are much more likely to be the flu than food poisoning. So it could have been FP, but my experience says it's not likely, for whatever that's worth.

lactose?

I used it in a cream stout, to provide a bit of residual sweetness rather  
than a dry, Guinness (sp? :-) taste. Worked very well. Uh, I think I used  
a  
half pound in a 5 gallon batch.

Sierra Nevada  
> I try to set it in someone's shadow. I'm the nervous type.

Well, that \*is\* pretty nervous ;-). I guess I've not made myself clear,  
and I'm sorry about that. From the point of view of the brewer, it makes  
sense to protect their beer as well as is necessary with their methods.  
For homebrewers, this may not require the use of dark brown bottles,  
since  
they (often) know better. For a commercial brewer bottle color may not  
matter at all since ignorant retailers (by far the majority) can hurt  
them regardless.

But, from the point of view of the taster/judge, bottle color makes no  
difference, since a clear bottle may contain perfectly fine beer, and the  
darkest brown bottle may contain skunk juice. I take as my starting  
point that commercial beer will be skunky if I don't know how it was  
treated, and that homebrew will not (since there is a "real" person  
behind it who would do their best not to hurt it). I also wanted to  
make the point, since I've heard about judges who automatically assume  
that  
beer in a green bottle is of lower quality than brown (and more than  
once),  
that that is an outrageous and unwarranted assumption.

>of someone who has. Has anybody out there used or heard of using  
lactose?

Let me try to ferment two worts with one pitch, as it were. I've tried  
to duplicate Xingu, but reduce some of the roast barley bite. I think  
I've succeeded, though I haven't done a side by side comparison. I  
believe that Xingu is what's known in the UK as a milk stout, as I  
believe that lactose is used to add body and to very slightly sweeten  
the flavor.

Here's "Josh's Better Xingu." Again, it's close to Xingu, but I think  
its better:

To make 5 gallons:

6.6 lbs M&F Dark Extract  
1 lb Crystal Malt  
1/2 lb Chocolate Malt  
1/4 lb Black Patent Malt  
1/4 lb Roast Barley  
1/2 lb Lactose  
2 oz Northern Brewer (Boiling only. No finishing hops.)  
Gypsum  
3/4 cup Dextrose (priming)  
Wyeast 1028

Crack and steep specialty grains at 150 F for about an hour in 1/2 gal  
water. Sparge with 1.5 gallons of 165 F water. Add the extract and  
Gypsum. When boiling, add the hops. Boil for one hour, add the  
lactose to the boil for the last 15 minutes.

Primary 3-7 days  
Secondary 7-14 days

Jack, most of us who use "blow-off" methodologies do so using a 5 gallon carboy as the primary fermentation vessel. The benefits are closed fermentation and removal of crap with reduced risk of infection.

>BTW, I like skimming. It makes me feel like I am contributing something to

>the process.

You'd mentioned earlier (in rec.crafts.brewing) that you've been losing two out of ten batches to contamination. It may be possible that your open fermentation and/or skim technique may be contributing to this.

I used to use a 7.5 gallon plastic tub, and skim, and had similar problems, no matter how careful I was with sanitation. I switched to a closed fermentation technique some years ago and haven't had an infection since. I truly believe this was due to airborne stuff in my house, as the same procedures and ingredients would produce great beer one time and weed killer the next, due to infection.

Check out Papazian's book. The first section, supposedly for beginners, will show you the carboy/blowoff methodology and has a great discussion on using plastic primary fermenters at its end.

Subject: my \$.02 on light damage

Hey now- I just wanted to add my \$.02 on light damage and skunkiness since I had a recent problem concerning just that. I decided (after some prompting) to enter my first batch, a pale ale, in the NYCHG competition in NYC on 11/2. I was pretty psyched 'cause the stuff came out really good and has been improving with age. The age at judging time was about 5 weeks after bottling.

Anyway, I check out the judges sheets after the contest and their only real complaint was skunkiness. Now, I had a bottle of the stuff on the night of 11/1 and it was anything but skunky. I cracked open a left-over bottle at the competition and sure enough it smelled/tasted like Pepe le Peu's bathwater! All I can figure out is this- when I dropped my three bottles off at Greg Zaccardi's (who did a great job organizing by the way), we were standing around bs-ing for like 10 or 15 minutes and the bottled were in the sun. The were brown Whitbred bottles, really thick.

I guess this doesn't add much to the conversation other than more proof that exposure of even just 10 or 15 minutes is enough to do some extensive damage...

From: Richard.Stueven@Corp.Sun.COM (Richard Stueven)  
Subject: Garlic Beer

Due to numerous requests (four, to be exact) here's the "recipe" for  
gak & laurel's Garlic Beer:

We didn't keep any notes on the garlic beer, so here's my best  
recollection:

6# plain light extract syrup (hopped? who knows...)  
2oz Cascade leaf (60 min)  
2oz Cascade leaf (10 min)  
one Big Thing of garlic (maybe half the size of your fist)  
Whitbread dry ale yeast

The procedure is the same as for any simple extract beer. Chop up the  
garlic and throw it into the boil for the full 60 minutes. If you  
don't want quite so much garlic flavor, strain the garlic bits out  
before racking (we didn't).

have fun

Subject: Re: Wy dyd my Wyeast wyther?

>One thing in the instructions that I didn't do was aerate the wort  
>after pitching. It didn't seem all that important.

Yow! It's Very Important! You can get good results without aerating  
(although you didn't this time), but if you want your yeast to really  
take off, aeration makes all the difference. Here's what I do:

- Rack into carboy (or bucket or whatever)
- Seal it up
- Shake it and roll it and slosh it for two or three minutes
- Open it up and pitch the yeast
- Reseal with airlock
- Relax

>When there was no  
>trace of fermentation by last night, I decided to rack it into my  
>other carboy, since about three inches of spoogy sediment had already  
>accumulated. I also thought that racking would aerate it a little.

A little, but probably not much. Try shaking the hell out of it. This  
should stir up the sediment and aerate it at the same time. If that  
doesn't help, jeez I don't know...maybe your yeast died somewhere  
between the packet and the beer.

>My wort is still okay, right?

Probably...

>I can go out and get some more yeast and pitch again, right?

Absolutely. It sounds like that's probably the best bet. You might  
want to throw some dry yeast in right away instead of waiting for  
another Wyeast packet to inflate... (asbestos on)

good luck

From: pierce@chips.com (John Pierce)  
Subject: UV light

As several people here have made some generalizations about UV light and glass, I thought I'd throw my 2 bits in.

UV filters for cameras DO work. Ordinary glass only blocks SHORT wave UV, not the near visible LONG wave that photographic film is sensitive to. Try this... With a decent 35mm SLR, and color film (especially slide) shoot some distant scenic pictures of say mountains on a reasonably clear day. Shoot a few more with a standard (SKY) UV filter. Shoot some more with a HAZE filter. The pictures shot with a naked lens will show a definite blue haze in the air that the two UV filters will reduce significantly. Try shooting said distant scene through a piece of medium gray colored plastic. Now shoot it through a pair of decent sunglasses. (I've never tried this last, actually, let me know how it comes out ;-).

Now, I am not a photo-chemist, so I don't know what wavelengths beer is photo-sensitive too. But I'll bet the answer is more complex than you might think....

From: gjfix@utamam.uta.edu (George J Fix)

>From: George Fix (gjfix@utamam.uta.edu)  
Subject: SS Fermenters

I share Jim White's (HBD 749) enthusiasm for stainless steel fermenters. Moreover, the comments he made about their practicality seem to be right on target.

I switched to stainless half kegs (volume=1/4 bbl.=1/2 keg=7.75gals.) from glass carboys of the same volume in 1988. They were obtained from a draft beer outlet for a "deposit" of \$20. One word of caution about such kegs. When you get them they will be sealed with a small beer residual inside. The latter will be totally oxidized. Thus when you break into the keg be prepared for a highly unpleasant aroma. When I first did this my wife had just come into the room, and she almost passed out. I wasn't doing all that well either! Given the raunchy nature of the smell, one might get the impression that the keg was totally contaminated. Nothing of the sort, it is oxidation pure and simple. A good hot water rinse will remove the offending materials. After that they can be cleaned and sanitized by standard methods, and then are ready for use.

My interest in half kegs stemmed from the following:

1.Geometry- In the late 1940's deClerck studied fermenter shapes and concluded (for a long list of reasons) that it is desirable that the surface area of the fermenting wort be sufficiently large compared to its depth. For cylindrical fermenters he recommended that the diameter be at least 1.5 times its height. The half kegs have a diameter of 15" and a height of 8", so they are well into deClerck's desirable range. An extra bonus is that they will fit into most refrigerators. In addition, the outlet on these kegs is 2", so either airlocks or blowout tubes are easy to attach.

2.Kegging- Much has been written in Zymurgy and elsewhere about the value of closed systems of transfer, where beer is pushed from one vessel to another by CO2 pressure. This can be done with half kegs particularly if Cornelius or Firestone soda pop kegs are used for beer storage. Two points are important. The first part of the flow out of the fermenter will come from the top of the yeast sediment. It will consist of dead yeast and trub. Bacteria, if present, will usually be buried in the trub. This should be discarded until a clear flow is evident. This will usually result in a loss of a pint (two at max) of beer. It is also important to purge the receiving tank with CO2 before transfer, and then vent it to drive out air. In addition, it is desirable to allow a slight

CO2 bleed from the receiving tank during transfer. This will purge all residual air from both the tank and the beer as well. This means that storage will take place under strict anaerobic conditions.

There is alas a downside to stainless. First, stainless generally means "less stain" and not "no stain". Chlorine is very aggressive to metal if left in contact for a sufficient length of time. Sterilizing with boiling water having a high iron content can have the same effect. Calcium Oxalate deposits from hard water have always been a concern about stainless fermenters. These deposits can lead to intractable hazes and other instabilities. Debois Chemical makes a product called Pro Kleen (54% phosphoric acid, 10% isopropyl alcohol, 4.5% sulfonic acid) which is capable of dealing with these problems, but only if this is done when they first appear. They quickly can become intractable if left unattended.

An alternative sanitizer that is finding widespread acceptance for stainless is iodophor (1.75% iodine, 18.75% phosphoric acid). This agent is neutral to stainless steel, and in fact can be stored in SS vessels for extended periods. The FDA rates iodophors as a "no rinse required" sanitizer, and their standards are high in such matters. (Some poor little mouse probably had to consume a liter of residuals per day for years to check this!) However, it is important to realize that the FDA is in the food safety not the food flavor business. Thus rinsing is probably a good idea. I sterilize with iodophor immediately after the equipment is used and cleaned. The iodophor residual is left on it. Rinsing is done just before reuse. Sterile beer absorbs this agent much more than water, and hence is preferred for rinsing.

It is to be emphasized that stainless equipment will last a lifetime if it receives proper care. Thus, used can be just as good as new, and this also applies to auxiliary items like CO2 tanks. Such systems quite "user friendly", and need not cost more than alternatives. One just has to look in the right places.

Date: 06 Nov 91 13:57:52 EST  
From: Jeff Frane <70670.2067@compuserve.com>  
Subject: On 756

I don't know if I've been posting late or what, but my submissions to the Digest seem to be slipping by a day or so. I reposted, with changes, something I'd sent before, which is why my contribution to 756 may have sounded somewhat familiar.  
Hmmm. Perhaps if I e-mail this out early...

To Mike Daly: What gives soap? Perhaps . . . soap?

To Jacob Galley: I know it's days later and probably of no use to you, but you could just as easily have left your beer alone for another day or so to see if activity picked up. You don't mention temperature, but if it was pretty cool (and an ale yeast) you might stir things up by raising the temperature to 65-70 or so. Aeration, however, IS VERY IMPORTANT!! Aerate it more than you think necessary, lots more, when you pitch. And if at all possible, you should use a starter. Your lag time was long, but not unusual for WYeast yeast without a starter and without proper aeration.

To Al Marshall: I dunno, Al, I don't live that far from you and I've never had a problem with the moldy gook, although maybe you should scrub around the window frames once in awhile, 'cause lots of people are allergic to the stuff. Anyway, once possibility for your problem (I know your technique is good 'cause you had a good teacher), is that somehow the bottles are not perfectly sealed when capped. It sounds as though they are getting mold spores \*after\* closure. Anyway, try someone else's capper (borrow mine, for example) and see if this fixes the problem.

To Jack Schmidling: I, for one, am not faintly convinced that blow-off tubes are necessary, although I use one and, like you, love to watch the foam crawl down the tube. I use this technique because it allows me to fill a 5-gallon carboy and ferment without blowing fermentation locks around the room. I've also used two carboys with the wort split between them. None of the microbreweries in the Northwest use anything like a blowoff, nor do they skim. Most use closed cylindrical fermenters. The blow-off is a rough equivalent of the old Burton Union system in which the blow-off would have fed yeast from one fermenter into

the next. British ale breweries skim their big fat crop of yeast and garp off the top, because that's how they harvest yeast and because they've been doing it that way for a very long time (at least a month). I've never tasted a beer with flaws traceable to a failure to blow-off or skim.

To Mal Card: It is possible to have extremely long mashes, depending on your pH.

H L Hind's brewing text relates a fascinating experiment done by German brewing scientists in the 30s, replicating the water of Vienna, Pilsen, Munich and

Dortmund, with identical grists. The mash times varied from 15 to 75 minutes,

and the color and aroma of the mash varied as widely. I agree with CP.

With the

addition of gypsum to my water, my ale mash is usually done in 45 minutes. On

the other hand, I disagree with CP about boil; based on all my reading about hop

utilization, I strongly recommend 90 min for most beers, even longer for stouts,

etc.

To Jeff McGown: Go out and buy a bottling cane, the one with the little spring

valve on the end!!!! You will save on beer and on cleaning, far in excess of the

nominal cost.

Subject: light-struck beer -- a data point

I am sad to report that I have a data point to offer in the ongoing debate about light-struck beer and glass color. I have before me a glass of Orval Trappist Ale, with the date 1990/2 printed on the label. I don't know if that's a bottling date or an expiration date, but I hardly think it matters, being 21 months ago in any case. It came in a brown bottle.

It is definitely light-struck. I know that Orval has an unusual taste, because I've tasted it and other trappists, lambics, and bieres de garde, but this isn't what it's supposed to taste like. It's definitely contaminated by eau de polecat.

The store I bought it from keeps the beer on display on a shelf in a lighted room, at normal room temperature, so I assume that the off flavor is due to the lighting (fluorescent) or to the storage conditions. Given the established relationship between light exposure and the skunky flavor, (we do agree on \*that\*, don't we?) I'd venture a guess that brown glass does not provide an absolute protection from the adverse effects of light on beer, and that long exposure to light will cause off flavors even when beer is in brown bottles.

Subject: Filters/water/bottles

I was talking to the rep from the company that makes "Brita" water filters, which are the gravity fed two container ones you put in your fridge. I recently made beer with one, and had filtered 25 litres in a few hours. They recommend no more than 6 litres per day.

A few of her comments:

The reason the that they reccomend no more that six litres has to do with the ion exchange resin beads they use to filter heavy metals. There is a limited diffusin rate in the resin, so that it is only the ions near the surface of the beads that are active, and when these are depleted, it takes a while for them ot be refreshed by diffusion from the inside of the beads. If you filter more water than the six litres per day, the heavy metal removal efficiency goes down. She said that there are only two ways to remove heavy metals. Ion exchange, and sodium exchange, and that the people who sell carbon filters claiming to filter heavy metals are wrong. Carbon based filters won't remove the metals!

She said they will soon release a under the counter, replacable cartridge BRITA filter for tap water. I t will provide a full capacity stream of filtered water.

I'll report on the filtered water beer when it is finished.

Regarding the bottle color issue: In Ontario, beer comes in light tight cardboard cases, and then it usually goes into a dark fridge? Also I brew my beer in a dark basement with an old shirt on the carboy. After bottling it, it is in a dark room, or dark fridge???

So what is the issue here?

A lot of people are flaming Mr Schmidling. However when you try so hard to show him how smart you are, you are telling all he needs to know for his little commercial enterprise. YOu are in effect providing him with a lot of free consulting service???

From: florianb@chip.cna.tek.com  
Subject: poisoned beer

Yesterday, Thomas Manteufel gave a terrifying account of getting sick from beer that had been fermented with questionable yeast. I'd like to comment on this.

First, having picked up a packet of Red Star yeast and pitched it into the wort which had set overnight introduces several possibilities. I just can't believe Red Star is the source of the problem. I have used just about every kind of yeast available to me here in Oregon, including Red Star (both ale and lager). I have used Red Star in about 40 batches over the years. Apart from cosmetic differences (due perhaps to wild yeast content), Red Star has always been a good performer for me in terms of speed, attenuation, and overall quality. It *\*NEVER\** fails to ferment out very quickly. Furthermore, I can't believe that Red Star could contain anything which would make you sick, or that it could ferment out to produce anything which can make you sick. I mean, I have never seen any evidence from my brewing to support anything like that. That the Red Star failed to ferment tells me that there was something else in the wort which was killing the yeast, and nearly you.

Second, that the wort was sitting overnight is suspicious. Did the wort sit in a metal boiling pot?

Third, could your kids have poured something into your wort? I have kids too (1.5 and 5.5 years) and have to watch them like hawks to prevent them from "helping me" with brewing. Just last night, my son dropped a rubber toy into some bread my wife was making and we didn't discover it until the loaf was done!

Fourth, are you using only plastic or glass for fermentation vessels?

Fifth, what were your starting ingredients? Did you use malt extract from a metal can?

Finally, I *\*highly\** suspect that somewhere in your process is a metal container that "got you". If not, then this is a mystery for someone else to solve. But in the final analysis, I just don't believe Red Star has anything to do with it.

wherein  
> brewing water can be added to top it off or make up the full wort. Even  
> then, I would guess that, what works in winter would be an explosion in  
warm  
> weather.

Why do you speculate this, what effect would the season have on how blow-off works?? I don't see the connection. Please explain, I have never noticed any seasonal difference, but my abode maintains reasonably close summer and winter room temps.

As for why big brewers don't use blowoff. I have often wondered this myself. I have noticed that some micr-brewns seem to produce headaches where others don't, but I can't claim any correlation between brewing technique and presence/absence of headaches in micro-brewns.

The correlation was clearly there in MY homebrews.

Purely guessing I would guess that this may be an effect of brewing to scale. From what I can observe it does not appear that the amount of "blowoff material" (ie what commercial brewers would blow off if they did) has a linear relation in the large open top ferments that I have seen. By this I mean that the amount of this material is smaller as a percentage of total batch size for them than it is for homebrewers.

Other factors that may have bearing are temperature control. Any homebrewers out there that do blow-off in a temperature controlled brewing environment?? Any guesses??

I'd also speculate some dependence on yeast strain, as I never do blowoff with lagers, and would also guess that it's usefulness (to those that favor it) may vary with strain.

As for blow0ff being a "m-word" I don't recall seeing anyone religiously espousing it's usefulness, or lack thereof. As I stated earlier I found there

to be a difference in the results of my brewing process when I use the  
blow-off  
method. I recommend it to people, but I wouldn't say I do so with the  
religious  
fervor most associate with the "m-word"

From: kjohnson@argon.berkeley.edu (Ken Johnson)  
Subject: Yeast poppers (the flying carboy cap)

I just pitched a starter of Wyeast German Ale yesterday, and this morning I found the carboy cap laying next to the carboy and massive mounds of yeast and foam all over the floor. I assume that the yeast took off really quickly, clogged up the cap, blew it off, and spewed.

So here's the question: What form of blowby allows the passage of yeasties and foam without clogging and becoming airborne? I was using the 3/8" tube on the cap.

Covered in yeast,

kj

Yes. It is residual sweetness that is the reason for the saccharin  
tablets.

Some recipes call for lactose, which is a non-fermentable sugar. I  
have never used either, rather I use a less-attenative yeast, such as  
Wyeast Irish Ale. Does someone know how much lactose to substitute for  
a saccharin tablet (i.e. substitute for one teaspoon of sucrose)?

Subject: Re: poisoned beer

> Florian's account of possible problem's and sources of the toxins

Hi, Florian. I see you can appreciate my kid problems. Mine are 8mths and 3yrs. The wort sat in a teflon coated pot overnight. The kids couldn't touch it - it was locked in the basement in a covered pot. I use a glass carboy, it was filled with bleach solution before use and was well rinsed with hot (~130 F) water before filling. Malt was from a 60# bucket, scooped into ziploc bags and frozen until dumped into boiling water for the half hour boil. I used a plastic spoon to stir, and plastic tubing to siphon from the brew kettle into the carboy (got to watch that oxidation after all) when the wort was cool. No metal, everything was washed and clean but not sanitized like the carboy was. I talked to Erik H. and now I sumise maybe a mold from somewhere got into the wort. (I agree, let's not start flaming Red Star for being the source of infection. All I know is that it didn't take.) Anyhow, I have severe allergies to molds and this could just as well have been an allergic reaction. By the by, I didn't eat or drink anything that other people in the family didn't also have, and no one else got sick.

The fact is, something got into my batch and made me sick. It may have been a harmless (for normal people) mold, but it did get in. I, for one, am going to tighten up a little on sanitation procedures.

Subject: Wort Chillers, headaches

>Well Jack, there are 2 types of wort chillers.

Apparently, I invented a third. If you take an emersion chiller and put it in a bucket of water with a garden hose filling the bucket and the run-off, running off, one could experiment with it both ways.

> Counter-flow wort chillers acheive a very fast cold-break. This has 2 effects, one that various precipitates form and will drop out of solution as a result of a quick change from hot to cold,

It is to be understood that it will drop out in the primary or a settling tank.

>In counterflow chillers all the wort that passes through the chiller acheives the same instantaneous drop in temperature. In the immersion chiller the whole wort cools at the same time and the same rate (slow, but substantially faster than with no chiller).

I received a flyer in the mail from The Home Brewery claiming that their emersion chiller will chill 5 gallons to pitching temp in 15 min. It looks like about 7 turns of 1/4 copper tubing. This seems utterly preposterous.  
Can someone save me the trouble of proving it.

From: parker@mprgate.mpr.ca (Ross Parker)

>I smell an acronym here - How about 'OWT' (Old Wive's Tale) in place of the much overused and somewhat idiotic sounding Schmidily... this is in keeping with age old TLA (Three Letter Acronym) tradition.

If you are so obsessed with beating me down by making my words "nonwords", I suggest you at least improve on them.. Did you every "say" OWT? There are five syllables in it compared to three in momily. Try a little harder.

>(mind you... 'schmidily' has a nice ring to it also... :-)

Yah .... and only two syllables.

From: Mike Sharp <msharp@cs.ulowell.edu>

>Yes, The AHA does have a video.....  
>The AHA can be reached at (303)447-0816

JSP can be reached at (312) 685 1878 or arf@ddswl.msc.com for more info.

"Brew It Yourself" is a far more interesting video and at half the price to netters.

(Non-commercial disclaimer)  
"BREW IT YOURSELF" is also available at most libraries.

>FWIW, Jack pointed out that commercialism is OK on Internet so I thought I'd just add my \$0.02. Perhaps we should post information about this video on a regular basis. After all, it would be for the enlightenment of the new brewers -- we should do everything possible to get new brewers started. Maybe I'll even buy a few copies of the video and rent it out...

Great idea but let's make sure we promote the most useful and informative video. Knowing that you have not seen both, we need to be a little skeptical of your recommendation.

Subject: Re: cloves

Jack writes:  
>Where did those bloody cloves come from?

More than likely, they came from your yeast. As you have already mentioned, you use Red Star, which although has been known to produce banana esters, may possibly (at certain temperatures) produce 4-vinyl guaiacol, which has a clove-like, phenolic flavor. There are two strains of yeast that are known to produce clove flavors: *S. delbrueckii* (the Bavarian wheat beer yeast) and *S. diastaticus* (a superattenuating wild yeast). A commercial yeast that I know produces a clove character (which, I personally, don't like and which took almost 8 months to go away in a batch I recently made with this yeast) is Munton & Fison's Muntona yeast fermented at 68 F.

Two years ago, I switched to Wyeast and now I will only use dry yeast if I'm trying to duplicate a recipe exactly. I recommend this switch to everyone. I think you'll be as pleasantly suprised as I was.

> The writeup on the video reads: .....

That sounded familiar. Papazian did that video as a home study course for TVOntario (hence the Toronto locations for interviews), and it's been aired countless times this past year. I've watched it several times and would highly recommend it to any beginning homebrewer.

If a picture is worth a thousand words, a video is worth at least a few pictures, especially when it comes to things like demonstrating how to start a siphon (BTW, Charlie uses the tube filled with water technique). However it's hard to use a video for reference in the middle of brewing, so I think you still need his book for the real details.

In the video he demonstrates making a kit beer including sanitizing, boiling, fermenting, and bottling, and then makes another extract beer with specialty grains.

The interviews with brewmasters, brewing clubs and individual homebrewers add to the video. It becomes obvious that homebrewers have "opinions", and they don't always line up with each other. Sorta like a camera whirring while HBD members sound forth.

The only unrealistic part of the video is where Charlie is babbling on about water quality or something, and all of a sudden he rushes over to the stove. The unrealistic part is that he manages to rescue the wort BEFORE it boils over :-).

From: Brian Capouch <brianc@zeta.saintjoe.EDU>  
Subject: Request for Testers

I am a graduate student working on a project involving electronic journals.

My project, stated briefly, involves designing software that will allow electronic journals to be hierarchically structured, then interactively browsed. The software is to be public domain, and the design calls for it to support a wide variety of potential platforms. The current, alpha-version software runs on vanilla ASCII terminals, as well as X windows.

Since I am a longtime HBD subscriber, I'm going to use it as one of my "practice" journals.

I'm looking for a few (hmmm, perhaps the first dozen) people who'd be willing to test this software, knowing that it's in alpha form only, and provide feedback to me about the workability and design of the system.

I have partitioned a few recent digests into the following categories: Technique and Technology; Ingredients; Recipes; Breweries and Pubs; Meads, etc.; and Miscellaneous. Each digest will be burst and sorted by topic. The software will allow browsing by topic or title, or serially, as is done most likely by most of you as it is.

Respondents can help me greatly by using the keyword "homebrew" in the Subject: line of any messages--I'm cross-posting this to three other lists, and need to keep track of which group my respondents belong to.

Thanks in advance to all who are willing to help.

-----

Date: Wed, 6 Nov 91 23:03:05 PST  
From: Dave Suurballe <suurb@dumbcat.sf.ca.us>  
Subject: 520 nm

Volume 8, Number 2 of New Brewer (March-April 1991) mentions the magic number on page 10 in an article by Owens-Brockway entitled "The Right Glass":

"The degeneration problem occurs most frequently in warehouses or retail outlets where fluorescent lighting is the norm. While all light with the wavelength of 520 millimicrons has the potential to cause beer skunkiness, it is the ultra-violet (UV) portion of the light spectrum below 400 millimicrons that is the most harmful to beer in the shortest period of time. (See graph.) In fact, it can affect beer flavor in as little as 24 hours."

The graph, which I obviously cannot reproduce, shows that amber glass transmits about 5% of the light below 400 nm (UV), green glass about 80%, and clear glass about 90%. Between 400 and 520 nm (green), amber glass climbs from 5% to 30%, green drops from 80% to 50% (at 450 nm, which is blue-green) and then climbs back to 80%, and clear glass stays around 90%.

If these facts are correct, the correct technical choice for bottle color cannot be controversial.

Suurballe

Subject: The past week

HOGWASH! You might pull out your book and refresh your memory...  
So, I would prefer that if people are going to do book comparisons...  
they should at least get the facts straight and KNOW WHAT THEY ARE TALKING ABOUT... before instilling false statements about a good author into..

..  
Could we get this one straight? Oxidation leads to the cardboard taste.

Cidery is something entirely different.....  
It is really wonderful to have all such confusion made "straight" by a simple declaration. Unfortunately, there seem to be a large number of brewers who disagree with you....

As a self-proclaimed authority on the subject, I wonder how much cardboard you have tasted that gives you such strong credentials on the subject.

...  
If the intentionally rough treatment nor my past twenty years experience produce something that I find objectionable, then I will be less concerned

about minor infractions of the "proper" procedure....  
I think you should also do a little reading about wort chillers; you seem to be under the misapprehension that it has to do with "clearing".... Perhaps you should do a little reading of the HBD.... but it seems at times that you are more interested in hastily debunking traditional brewing practices...

As before you have totally ignored the context in which the term "normal" was used and applied you own....  
Naked Aggression that is, Against the Mush Brained Masses that people like

you are frightening away from our hobby...  
Perfect example of NAAMBM. You leave the nervous, tentative beginner with two choices: spend \$150 for a SS pot or drink Bud....

Right! Now the guy who is hesitant about getting into beer making, must consider a \$200 brew stove....  
Since there are a lot of beginners reading this forum, I think that recommending sloppy sanitation is an invitation to brew lactic acid...

.  
Pardon me, but that "magical" 525 nm number is pure BS. Rather than keep repeating it ad nauseum, I would ask you to justify it with a reference.

I suspect that you will have difficulty....  
I, personally, think that Mr. Schmidling is more interested in gaining notoriety, validating his self-proclaimed expertise in homebrewing and making money, than making brewing beer easy and inexpensive. I'm almost

convinced that Mr. Schmidling knew very little about brewing before joining this forum. Twenty years of brewing vinegar does not an expert make..

..  
Please stop with the ad campaign for your videos and stating your opinions

as if they were facts! If this Digest was only experts and no  
beginners  
were reading it, I would just ignore you. However, there are beginners  
here  
and I'm not going to let you fill their heads with incorrect  
information....

Tough Crowd.

From: STROUD%GAIA@leia.polaroid.com  
Subject: lemon in weizen biers

There have been some postings over the last few months commenting that wiezen biers in Germany are rarely served with lemon any longer.

I thought that an excerpt from a Michael Jackson article might be of interest  
(from What's Brewing, Oct. 1991):

"When I first encountered South German wheat beers in the early to mid 1960s, they were regarded as an old-fashioned, rustic style, favoured by old ladies with large hats. The beer was at that time customarily garnished with a slice of lemon.

"People have told me the lemon was to mask the taste of the uneven products made at that time by unscientific country brewers; I do not believe that. Some of the wilder wheat beers might taste odd to the uninitiated, but not to people who grew up with them.

"I have also heard it said that the lemon reduced the foam to manageable proportions, but why would anyone want to flatten a naturally sparkling drink?

"I believe the lemon accentuated the tart, refreshing character of the beer, and I am sorry that it is so rarely seen in Germany today.

"Apparently the green movement is worried that the rind may carry pesticides; a new generation of purists dislike the lemon; and it does not go so well with the heavily sedimented style currently favoured."

From: Jay Hersh <hersh@expo.lcs.mit.edu>  
Subject: Bottle Color & Judge Prejudice

Our buddy Darryl sez:

>But, from the point of view of the taster/judge, bottle color makes no  
>difference, since a clear bottle may contain perfectly fine beer, and  
the  
>darkest brown bottle may contain skunk juice. I take as my starting  
>point that commercial beer will be skunky if I don't know how it was  
>treated, and that homebrew will not (since there is a "real" person  
>behind it who would do their best not to hurt it). I also wanted to  
>make the point, since I've heard about judges who automatically assume  
that  
>beer in a green bottle is of lower quality than brown (and more than  
once),  
>that that is an outrageous and unwarranted assumption.

This one reason why I am STRONGLY against beers being distributed in  
bottles to  
the tables at competitions, as opposed to having stewards serve them in  
pitchers. Since no scoring is done based on "bottle observation" (at  
least  
there is no place on the score sheets for it as far as points goes) I see  
no  
need to do this. Additionally I think that having one steward pour the  
beer  
clear into the pitcher allows all the judges at the table to get the same  
beer,  
rather than having various levels of clarity because a beer got poured  
from the  
bottle into several glasses and inevitably got some yeast sediment kicked  
back  
in (Maybe I'm just spastic but I have a tough time pouring a beer to  
several  
glasses without kicking some yeast into it).

The only drawback to this is having stewards & pitchers. This hasn't been  
a  
problem either at NE Regionals, or the 1st round Nationals here in NE.  
Perhaps at small local competitions, and at the AHA finals, but you'd  
think at  
the AHA final they could come up with some stewards and a few pitchers..  
.

So I say just say NO to bottles when judging!! We actually leaned on our  
steward and brought our own pitchers to the table at last years AHA  
Finals, and  
this seemed to work pretty well..

From: Jay Hersh <hersh@expo.lcs.mit.edu>  
Subject: Cold Condition, Honey Priming

larryba@microsoft.com sez:

>Anyway, I lager in the refer (ales and lagers) until the beer is fairly clear. I then keg and artificially carbonate. There is little or no yeast activity at this point.

Hey I do this too, only I refer to it as Cold Conditioning. I got going on doing this shortly after I got my kegging system. It was Norm Hardy's descriptions of what he saw in Germany that made me think to do this. I have found that while helpful for lagers (ie this amounts to the lager aging period most lager brewers use after ferment) it also has a splendid effect on my Ales!!

A 2 week cold condition at around 35F really knocks the yeast out of suspension. I also find it causes any chill hazes to precipitate and settle, and leaves me with a clear, bright beer which side by side taste tests (with bottles off the same batch that were not cold conditioned) have shown has a cleaner flavor. I attribute this to the precipitation of the haze and suspended yeasts which I think were had flavor components, proteins and perhaps tannins, which while not show stoppers wrt the flavor, are still better off removed from the beer.

So if you have a spare fridge and the time and inclination to try Cold Conditioning (then you can brag like Miller Inc. does....) I'd recommend it. It does nice things to the flavor profile!

Thanks Norm!!

Oh yeah, I haven't had any oxidation problems with this technique as larry indicated he sometimes does. guess YMMV!!

Joel Avery sez:

>Make sure you boil the honey with some water to kill off any live cultures that might exist in the honey.

I thought that due to it's extremely high osmotic pressure that bacteria wouldn't grow in honey. I don't know about molds or wild yeasts, and this may only effect growth in the honey and not on it's surface. Anyone with any solid info out there??

Subject: priming with honey

My understanding is that due to the extremely high concentration of sugar, the osmotic pressure in the honey environment is such that few organisms can survive. Therefore, boiling honey is not necessary. It should be dissolved in warm (boiled then cooled) water. Boiling drives off most of the aromatic compounds that make honey interesting in the first place.

I don't really see the point of priming with honey. I seriously doubt that the relatively small amount of honey will make any detectable difference in the taste.

Subject: Orval

I'm trying to culture the yeast (and other denizens) from the dregs of a couple of bottles of Orval Trappiste Ale. I'll report on my results.

The head formed by pouring a bottle of Orval gently into a glass is really amazing. The foam is unbelievably dense and creamy; it's quite similar to the Guinness-on-tap foam. It stands up in little shapes like the foam in industrially-polluted streams. Wow. I wonder how they do it? It's crystal-clear, with no detectable chill haze. I'm going to try a batch with a pound or so of wheat flakes and see if I can come close.

The beer has a delectable hint of "Belgian sourness"; not as strong as Satan, but stronger by far than Duvel. Chimay has none of this, which is why I want to ferment with Orval yeast in the first place. (I hope it's the same culture in the bottle.)

From: Dave Rose <CHOLM@HUBIO2.HARVARD.EDU>  
Subject: Siphoning: the last word (?)

In HBD 757 (I think) Mike Ligas writes:

>I'd be quite surprised Dave if you use unplugged sterile pipettes to  
>dispense your yeast. The fibrous plug found in the top of culturing  
pipettes  
>is tightly packed and adsorbant enough to stop potential microbial  
>contamination carried by microscopic particles dispelled with each  
>humid breath.

Though I am reluctant to continue what is essentially a very boring  
thread, I do not use plugged pipettes. They are just open, sterile,  
glass  
pipettes.

>If you've ever done animal cell culture or bacterial culture using  
>media much richer than liquid malt or malt/agar you'd know, from painful  
>experience, that breath is not sterile.

It is true that I havent done cell culture work in some time, but  
I don't think the result would be any different. Cell culture work is  
tough  
because the generation times of the cells are so long that fast growing  
organisms can easily take over the culture; I don't think it has much to  
do with the culture media. The media we use in the lab is a good deal  
richer than liquid malt. It's yeast extract, peptone, and glucose as a  
carbon source. Granted I have not performed the experiment with fetal  
calf  
serum or some other cell culture medium, but I doubt I would get a  
different  
result.

Anyway, we both agree (I think) on the important aspect of this issue:  
That in wort the technique is safe. Whether that's because breath is  
sterile  
or because what critters it contains are present in very low titer or  
can't  
grow in wort isn't really the issue.

I'm also happy to note that the 'm' word is taking it's knocks out  
there. But I am also concerned that "your mileage may vary" is rapidly  
taking it's place as annoying phraseology of the moment....

Subject: Re: Wy dyd my Wyeast wyther?

In Homebrew Digest #757 (November 07, 1991) Richard Stueven (Richard.Stueven@Corp.Sun.COM) responds to a query in Homebrew Digest #756 by Jacob Galley <gal2@midway.uchicago.edu>:  
J>>Subject: Re: Wy dyd my Wyeast wyther?

J>>This is my first encounter with Wyeast, it hasn't gone well!  
J>>My Wyeast has not started to show signs of fermentation yet, after  
J>>about 55 hours as of this morning. [...]

J>>One thing in the instructions that I didn't do was aerate the wort  
J>>after pitching. It didn't seem all that important.

R>Yow! It's Very Important! You can get good results without aerating  
R>(although you didn't this time), but if you want your yeast to really  
R>take off, aeration makes all the difference. [...]

I thought "someone else" would address the question, which I think was missed by Richard. That is, liquid yeast, even when properly activated, does not supply sufficient quantities of active yeast for a vigorous start to fermentation of a 5 gallon batch. Certainly, aeration is important, but I think this is secondary to creating a "sufficient" quantity of active starter.

J>> [... from #756] But, by this time, the package was filled with  
J>>lots of gas -- like, I was half expecting it to splatter all over the  
J>>room when I opened it up. (It didn't.) So I dribbled the yeast into my  
J>>carboy.

Creating a "sufficient" quantity of active starter has been recommended by other contributors in HBD; in Miller's book, and it might even be on the Wyeast package. Otherwise, you'll experience long lag times. Jacob, I'll bet by now your fermentation has taken off.

Here's what I do for building the starter solution:

About five days before I intend to brew, I pop the inner "bubble" inside the Wyeast package, and set it aside on the counter in my kitchen. A couple of days later when the packet is swollen, I sanitize a 12 oz beer bottle and fermentation lock and beer-bottle-size stopper. I open my jar of "canned starter wort" (a la Miller) and measure about 3/4 of a beer bottle (NOT with the sanitized one!) into a covered saucepan. I bring this wort to a boil and simmer for 20 minutes. I do this because I can my starter wort in quart jars and keep the opened jars refrigerated. Some people rehydrate dried malt extract instead of using "canned starter"; I'm told that works just fine, too.

The covered saucepan goes into the freezer to cool down to ~80-90 degrees F. I flame the mouth of the sanitized beer bottle (with a propane torch, but only briefly!) and pour the cooled wort into the bottle. The swollen liquid yeast packet is swabbed with alcohol, and the scissors run through the flame of the propane torch. I shake the packet and then snip off one of the upper corners. The contents are carefully poured into the sanitized beer bottle, and the fermentation lock placed on the bottle. The bottle is then agitated (to aerate) and set aside.

In a day or so when active fermentation is observed, I sanitize a 22 oz

beer bottle; boil/cool another ~3/4 of a 12 oz beer bottle's worth of starter; flame the mouth of the 22 oz beer bottle and pour the cooled wort into the 22 oz bottle and agitate to aerate. The 12 oz bottle of already-fermenting starter is poured into the 22 oz beer bottle, and the fermentation lock placed on the larger bottle. A day or so later, I've got a pint of vigorous starter, suitable for pitching.

Some people recommend making even greater quantities, like a quart (another day to double from a pint) or even a half-gallon (doubled again). I once did a half-gallon starter, and the fermentation took off like a shot! Even with a low starting gravity 5 gallon batch in a 6.5 gallon carboy, I had significant blowoff through the blowoff tube! For all practical purposes, fermentation was complete within 24 hours!

Subject: Re: MS-DOS, Dry vs Wet yeasts

Kinney Baughman writes:

Hey, Darryl, you radical! You've gone from "Eunuchs" to Microsoft and MSDOS!!! My how the mighty have fallen! Is there any hope left for us all? Where is the truth? What is realty?

Gosh, a good old fashion unix bigot! While all you guys toodle around on the Packards and Edsle's of OS's, Microsoft is cleaning up making fords! Can 10 million Windows users all be wrong? ;=)

Tee, hee. Couldn't resist.

Regarding dry vs wet yeasts. I notice that in the Zymurgy yeast issue one manufacture of dry yeast got pretty darn high marks for yeast quality - even better than \*most\* of the wet yeasts tested (not many). That was Whitbread Ale and Lager yeast. I have been using the ale exclusively for the last year with good results. Certainly there has not been any defects that could be obviously traced to the yeast variety. Even recycling the yeast several times produced excellent results. Now that is cheap yeast!

My latest lager was jumped started with a packet of Whitbread Lager. I was pretty nervous since I have always used "Official Wet Lager Yeast" in the past. However, it appears to have turned out Ok. It looks, tastes and smells like a lager.

It is my opinion that unless one is a Very Refined Super Duper Brewer that the whitbread yeast can take one pretty far down the road to perfect beer. It is cheap, it is Vigorus, it is clean and as Father Barleywine noted the Ale will ferment in lager temps producing lager like beers.

My guess is that having a large amount of viable yeast prevents a whole rash of other problems that get introduced when underpitching wet yeast. Yeah, I know a starter is the right thing to do, but sometimes it just doesn't work out correctly and one still gets the 48-72 hour lag period. In my experience that never happens with a packet of whitbread.

Cheers!

> by 20 nanometers!

Just to clarify this a bit, it is really sub-500 nm light which  
is of concern here. The 400 nm limit was somewhat artificially placed  
on this issue by the measurement range of my equipment. Note that the  
lower the wavelength is from 500 nm, the more efficient it will be in  
lightstriking beer, with the most efficient damage taking place in the  
UV. As I've stated this damage may occur up to 520 nm, but is unlikely  
to take place very efficiently here.

Another reason the 400-500 nm range was singled out by me was  
that it is the light which is most likely to effect even the most careful  
homebrewer (or retailer) because incandescent lights have significant  
intensity at these wavelengths (not to mention the more harmful  
flourescent, sunlight sources). Therefore, if you have the choice, I  
recommend you keep your beer in brown bottles, especially for  
competitions where you don't know for sure how they'll be stored. And  
yes, I do have green bottles which I use on occasion :-).

that  
> beer in a green bottle is of lower quality than brown (and more than  
once),

> that that is an outrageous and unwarranted assumption.

I wholeheartedly agree that bottle color should not prejudice a judge on the merits of a beer in competition. I definitely do my best not to think about such things when judging, and to concentrate on what I'm tasting. I do think that as far as the normal homebrewer is concerned, this statement is clouding the issue of bottle color. What I tried to show in my previous submission was that brown bottles are definitely more resistant to the lightstruck flaw than green or clear bottles. This had not been previously proven, at least to me. In addition, however, I stated that brown bottles are not the answer to the problem, as Dave's submission indicated:

>

> From: dab@pyuxe.cc.bellcore.com (dave ballard)

>

> Hey now- I just wanted to add my \$.02 on light damage and skunkiness

>

> Anyway, I check out the judges sheets after the contest and their only

over

> bottle at the competition and sure enough it smelled/tasted like Pepe  
le

> Peu's bathwater! All I can figure out is this- when I dropped my  
> three bottles off at Greg Zaccardi's (who did a great job organizing  
> by the way), we were standing around bs-ing for like 10 or 15 minutes  
and

> the bottled were in the sun. The were brown Whitbred bottles, really  
thick.

What is important to keep track of here is that Dave's entries would have definitely been worse if he had used green or clear bottles, and that is true regardless of whether you believe the <500 nm or the 520 nm camps (I've already put my word in on that one). I just felt it was very important to stress this as the most important point of this lightstruck discussion from a practical standpoint, and I didn't want it to get lost in all this other discussion.

(with

> > some minor modification) into my code base. (He gets a mention in my  
> > manual's bibliography.)

So Darryl (or whoever), while we're on the subject, what do you think of  
Rager's

vs. Burch's kettle hop utilization numbers? From personal results, I'm  
in

Burch's corner on this one. For those unfamiliar, these two  
sources vary considerably in the 25 to 45 minute boiling time regime.

While these numbers are approximations which will vary from batch to  
batch, we the homebrewers have to start with a number somewhere, and then  
adjust our results accordingly.

From: florianb@chip.cna.tek.com  
Subject: hangovers

Yesterday, MIKE LIGAS <LIGAS@SSCvax.CIS.McMaster.CA> said, in part,

>From my simple understanding of the phenomenon, the main culprit is  
dehydration  
>with some credit going to vasodilation in the skull. Both alcohol and  
fusels  
>along with some amines are the cause. The liver, that wonderful  
detoxification

Comments well-taken. The trouble I have with this theory is that it  
doesn't explain the correlation to types or brands of beer. Below is  
a list of beers that give me a headache:

Nearly all brands of US beer.  
Some German beers consumed in Germany.  
Any and all bottled or fresh microbrewed beer.

Below is a list of beers that have never given me a headache regardless  
of quantity consumed:

My home-brewed beer.  
A certain beer brewed commercially right here in Oregon  
and costing very little per 1/2 case.  
Most German beers consumed in Germany.

To me this continues to be the greatest mystery about beer and home  
brewing in particular. Someday, I hope someone will explain this to me.

From: "MR. FANTASY" <HOPKINSCH@urvax.urich.edu>  
Subject: Hello from a beginner

Hello! I just wanted to drop a quick Email to give my greetings and thank you all for some wonderful reading. I have only been reading this digest for about 5 days and have found my interest peaked. I have never tried to brew before but the idea is appealing (which is why I read this...).

I have seen those beginning kits that is basically a big bag that one fills with water (I assume) and lets it ferment for awhile. I think they may require a bit more care than that but I not sure. Nonetheless, is this an easy place to start? Do they work? I think those sorts of kits start around \$30 and, as I'm a college student, I don't want to be dropping \$30 on something that won't work (hey, who would?).

Any help appreciated.

Subject: STUFF

To: Homebrew Digest  
Fm: Jack Schmidling

From: Jay Hersh <herh@expo.lcs.mit.edu>  
Subject: Homebrew Popularity & Cloviness

> My observation is that the growth in interest in micro-brewed beers  
and  
homebrewing is very strong. Of course these are my observations here in  
Beantown (and a few other areas I've traveled to, your mileage may vary.  
..)

I don't doubt your observation but considering that there is one (maybe  
two)  
microbreweries in the entire Chicago Met area, it is obvious we are  
behind  
the times here.

>Jack I'm not sure what to make of this reply, I think you may have  
misunderstood. The cloviness comes from the YEAST not the wheat malt..  
..

Well, I do not have the original but I could have sworn that the clove  
was  
connected to wheat. I have made mistake before....

>Red Star Ale, which you said you used to use until recently if I read  
this  
right

'  
(which I stopped using long ago after a friend got the banana beer that  
tasted more like bananas than bananas do..) is reputed to produce clove  
flavors under certain fermentation conditions (I don't know what these  
are  
supposed to be).

Neither do I, those are not my words you are quoting.

From: larryba@microsoft.com

> I don't necessarily think that you will detect oxidation in your  
"mishandled" beer. Why?

>Because it is my belief that if you have  
active yeast in your beer, oxidation may not be an issue. Beer that  
is primed and bottled has live yeast in it. Live yeast is very  
reductive (?) and chews up the oxygen + reduces the oxidized  
components. I have heard that damaged beer can be revived by adding  
fresh wort, yeast and letting it re-ferment. I think that is what  
happens for many home brews: they are harsh at first (green?) and  
then as they age they mellow out. I think it is the yeast doing it's  
magic. Comment, Dave Rose, George Fix?

This is great. You start out by boinking me for being a boor then  
proceede to  
layout an excellent hypothesis which supports my momily that started the  
whole discussion. To wit, a little splashing, foam or air in the  
headspace  
is not necessarily going to wreck home brew.

>The point is that you may well be right that oxidation is not an  
issue for homebrews if the air infiltration is not grotesque and  
there is a secondary ferment in the bottle.

Do I hear an echo?

> It probably depends upon the gestalt of your brewing setup.

Not sure how to transmit gestalt on a video tape but I think we finally  
have  
a resolution to the issue.

From: joshua.grosse@amail.amdahl.com

>Jack Schmidling (arf@ddsw1.mcs.com) writes:

> TO BLOW OR NOT TO BLOW (OUT)

>

>I have been entranced with the idea of "blow out" primary fermentation  
and

>had to give it a whirl. The following are my observations on the  
>procedure.....(discoveries/observations using plastic tub deleted)...

<Jack, most of us who use "blow-off" methodologies do so using a 5  
gallon carboy as the primary fermentation vessel. The benefits are  
closed fermentation and removal of crap with reduced risk of infection.

Not sure of your point. I used one also in the experiment which you  
deleted  
and seem to have misread.

>You'd mentioned earlier (in rec.crafts.brewing) that you've been losing  
two out of ten batches to contamination. It may be possible that your  
open fermentation and/or skim technique may be contributing to this.

Certainly possible, but you guys just got me sold on changing yeast. I  
take

great pains when skimming to maintain near sterile conditions so I  
highly  
suspect an external influence and yeast fits the bill, for the present.

>I used to use a 7.5 gallon plastic tub, and skim, and had similar  
problems, no matter how careful I was with sanitation. I switched to  
a closed fermentation technique some years ago and haven't had an  
infection since.

It is poor science to change more than one variable at a time and I am  
working on yeast now. When/if I get a bad batch with the new yeast, I  
will  
take the next step.

I don't even want to think of the possibility of THIS batch going bad.  
New

yeast, blow out in glass fermenter.

Date: Thu, 7 Nov 91 21:03:41 -0700  
From: dinsdale@chtm.eece.unm.edu (Don McDaniel)  
Subject: chillproofing technique question

I've gotten to the point where I'm happy with the flavor of my brews and I'm working on appearance; more specifically chillproofing. I've had consistent chill haze in most of my beers. I plan to use Irish moss in the boil for the next ale this weekend. Question:

Irish moss is traditional in the brewing of ales. What of its use in lagers?

Another question: I've got a Dortmunder export in the secondary right now. It's been there for about ten days and it's still very cloudy. Should it refuse to clear, I am considering using gelatin finings. My concern is that gelatin is known to precipitate yeast. Should I anticipate any problem with having enough yeast to bottle condition after gelatin fining?

As a final aside, Miller says that oxidation during sparging can contribute to chill haze and recommends finding a sparging method that minimizes splashing. I myself use a two-quart pitcher to transfer sparge water into my lauter tun. This does involve considerable splashing. Any comments on the relative contribution of sparge splashing to chill haze? What about ideas for splash-free sparging in a 5-gallon food bucket lauter tun? I tend to think that splashing at this point isn't too critical because 1) the water and wort are at 168F or less and hence not as reactive as boiling wort, and 2) any O<sub>2</sub> dissolved into the wort at this point that hasn't reacted may be driven off during the subsequent boil.

Any Ideas are appreciated.

Subject: blonde double bock

Hey now- I finally ventured across the river from Piscataway to New Brunswick to check out a place called The Old Bay. They have amazing New Orleans style food as well as Clements and Stoudts on tap. We chatted with the bartender and managed to get samples of a pilsner and ale from Stoudts and a red ale from Clements (the best of the three). He then brought over a glass and announced it was something new from Clements- a blonde double bock. It was a beautiful gold color with a really nice head, and lots of chill haze. It tasted great! Real nice hop/malt balance, leaning towards malt with a definite alcohol twang (it's about 9% by volume). For those of you around central NJ, you gotta give it a try.

Does anyone have any thoughts on how to make a blonde double bock? I would assume there's a ton pf pale malt to start with, due to the color and haze. I would definitely like to give it a try.

Oh yeah, the line of the night had to be when the bartender asks: "You guys aren't by any chance homebrewers, are you?" That got quite a chuckle...

later!

Subject: hook norton best bitter

I found a copy of Roger Protz's "The Real Ale Drinker's Almanac" in a Chicago bookstore. It's definitely a nice-to-have if you enjoy bitters and pale ales and want to brew them. Here's what he says about Hook Norton Best Bitter.

Original Gravity: 1036  
Alcohol by Volume: 3.3%

Ingredients: Maris Otter pale malt 94%  
              flaked maize 6%  
              caramel for coloring  
              Fuggles, Goldings, and Challenger whole hops

Tasting notes:

Nose--pronounced hop resin aroma with grain and fruit developing  
Palate--Light dry balance of grain and hop with delicate finish and  
          some citric fruit notes  
Comments--A distinctive pale bitter with some light fruit complexity.

Subject: **Canning Wort**

Some people e-mailed me requesting more info on my canning procedure, so I figured I'd post it to the digest. Sorry I've taken so long to do this.

The main thing I use the canning for is making priming solutions. I also sometimes use it to make pre-prepared starters.

To make a priming solution I added whatever amount (I usually use around 1 cup) of dry malt extract to 1 qt canning jars and then fill the jars with hot water. Put the lids on the jars and shake to mix up the extract. The extract doesn't need to be completely dissolved, the canning will take care of things.

Put the jars and some water in the pressure cooker, close it up, and start heating. If you have the type with a weight that controls pressure, leave it off until steam has been to escaping for about 10 minutes.

Put on the weight and monitor the pressure. When it hits 15 lbs, start your timer. Depending on your stove, you may have to cut back on the heat to keep the pressure from rising.

After 15 minutes, turn off the stove and let the cooker cool. When it is cool, take the jars out and put them somewhere to cool further. Try to avoid drafty places!

To prime with this stuff, just wipe the top of the jar with some sterilant, open the jar, and pour!

That's about it, it really can't be much easier. I realize that pressure canning is a bit overboard, from what I understand you really don't need to cook at 15 lbs for 15 minutes to kill the things that might get into your beer (they die much easier). BUT I don't think this a real hassle and I relax better knowing that there ain't nothing going to live in there.

Subject: BEERREC.RFT

Date: 08-Nov-91 Time: 10:07 AM Msg: EXT02204

Hi folks,  
here are the recipes for food made with beer that I promised about 2 weeks ago. Sorry it took so long, I had to take a trip to Kansas City. This was in a Gannett Westchester Co. NY newspaper. By the way, I had Boulevard Beer (a pale ale I think) in KC. It was nice with lots of hops (at least I think so; my palate is not yet truly educated.)

A cold beer in a frosty mug is the perfect drink for a hot summer's day. But beer does not only have to be a quick thirst-quencher, it can (and should) be savored for its aroma, and because of its aroma, it can also successfully be used in cooking. Beer dishes such as the meatball and the vegetable recipe that follows taste particularly good in chillier weather. A warming bowl of spinach and beer soup with Cheddar cheese and a bit of sausage, accompanied by a thick slice of fresh whole grain bread, makes a meal. If you have the time, you could serve the garlic/zucchini fritters with the soup. They make excellent hors d'oeuvres or snacks as well. It is one of my prize recipes. Serve them freshly made when they are hot and crispy.

Just as in cooking with wine: the better the beer, the better the dish. I have indicated some of the brands appropriate for a particular recipe. Each brand will impart its own unique flavor. Try some of the beers from the micro-breweries now springing up all over the country.

Mother's meatballs with beer

Preparation time: about 10 minutes  
Cooking time: about 20 minutes

1 thick slice bread, crusts removed  
2 tablespoons milk or water  
1 pound lean ground beef, or meatloaf mixture of beef/veal/pork  
1 egg  
2 tablespoons minced onion  
1 teaspoon salt, or less  
Freshly ground black pepper  
1/4 teaspoon freshly grated nutmeg  
Butter or margarine for frying  
2 cups Heineken or similar beer, at room temperature

Soak the bread in the milk or water and squeeze dry. Stir or knead into the meat together with the egg, onion and spices. Form into four balls. Heat the butter or margarine, and brown the meatballs on all sides. Pour in 1 cup of the beer. Bring to a boil, turn down the heat and cover the pan. Simmer for about 15 minutes. Check to see that it does not cook dry and add more beer when needed. Serve as is, or thicken the sauce with cornstarch, if desired.

Cabbage saute with beer

Preparation time: about 10 minutes  
Cooking time: 10 minutes

3 tablespoons butter, margarine or oil  
4 cups shredded or finely cut green cabbage  
3 large carrots, peeled and coarsely grated  
1 tablespoon flour  
Salt and sugar to taste  
4 ounces Bass ale or similar beer

Heat the butter, margarine, or oil and saute the cabbage and carrots for five minutes in the butter, stirring frequently. Sprinkle with flour, salt and a little sugar. Mix and stir in the beer. Cover and cook for 5 minutes over low heat.

Peter's beer soup with spinach, cheese and sausage

Preparation time: about 15-20 minutes

Cooking time: 15 minutes

1/2 pound breakfast sausage, not Italian sausage  
1-2 tablespoons vegetable oil  
1 pound fresh spinach, washed and coarsely chopped  
4 scallions, finely chopped  
1/4 cup flour  
2 cups skim milk  
1 cup or more full-bodied beer, such as Heineken, Grolsch, Molson  
8 ounces of grated Cheddar cheese  
Salt and freshly ground pepper to taste

Cut the sausage into small slices or pieces and brown in a pan, large enough to hold the soup. Drain and set sausage aside. Heat the oil. Add the scallions and cook for 3 minutes, then add the chopped spinach. Cook and stir until the spinach is wilted. Add the sausage. Sprinkle the mixture with the flour. Slowly add--while stirring--the skim milk. If you need to hold the soup, prepare it up to this point. When ready to serve add the beer. Bring to a boil. Add the cheese. Cook until melted. Taste and season with salt and pepper. Serve immediately.

Garlic zucchini fritters made with a beer batter

Preparation time: 5 minutes, standing time about 20-30 minutes

Cooking time: 3-5 minutes

1 cup self-rising flour  
6-7 ounces of beer such as Budweiser  
2 or 3 small zucchini, approximately 3/4 cup when cut as directed  
1 large, or 2 smaller, cloves of garlic, minced  
2 heaping tablespoons minced fresh chives OR finely minced scallions with green parts  
1/4 teaspoon salt  
Freshly ground pepper  
Vegetable oil for frying

Cut the zucchini into 6 strips lengthwise and cut them across into thin slivers. Combine the flour and beer into a smooth thick paste. Add the zucchini, chives or scallions, garlic, salt, lots of freshly ground pepper and combine. It will seem barely enough to cover the zucchini pieces. Let it stand to rise for about 20-30 minutes. After it stands, if the batter is too thick add a little more beer, if too thin add a little more flour. Heat some oil in a saucepan or deep fryer (or better yet a wok) to about 340 F. Scoop out a tablespoon of batter and push it off the spoon with the aid of another spoon and let

it carefully drop into the hot oil. Turn to fry golden on both sides. Remove and drain on paper towels. Continue until all batter is used. Keep them hot in an oven set at 300 F. if necessary. They can also briefly be reheated in the microwave. They are best served immediately.

Jack, I promise you that anyone you haven't alienated by your repeated  
plugging of your products has now been alienated by this. Your ignorance  
of many elements of the brewing process has already made itself evident  
in  
your postings, yet now you claim that your video is more interesting than  
that  
put together by Charlie Papazian?

I've never met either of you, but I've read both your work. From his  
editorials in Zymurgy to his book to second-hand accounts of his antics,  
it's obvious that Papazian is one heck of an interesting person. I  
suppose  
"interesting" applies to your writing as well, though I'd be more  
inclined  
to use "bizarre."

I have just one question. In your video, do you include a plug for the  
AHA?

Subject: orval,cloves,good beer,K

How's that for a descriptive subject line?

Someone mentioned having an Orval dated 1990/2, and it was skunky. I've had 2 Orvals dated 1990/2, and both were bad (phenolic, medicinal), but not skunky. They did have that tremendous thick foamy head, though.

Re. cloves: I pick up clove flavor in *\*all\** German beer. The one beer I made with Wyeast German Ale (#1007?) had that same clove taste. I can't drink real wheat beer because of the cloves. Anyone else as sensitive to it as me?

To the gloater: Goudenband? Had one last night. Fuller's ESB? Got 3 of 'em left in my cellar. SS Stout? Had a SS Imperial Stout a couple of days ago. And there's still more in my collection from Yankee Spirits, but it's almost time to go back.....

Re. hangovers: I've also heard that restoring potassium helps cure a hangover. Bananas seem to help, as does tomato juice (hair-of-dog vodka is optional).

From: Dave Rose <CHOLM@HUBIO2.HARVARD.EDU>  
Subject: The last word on syphons (?)

In HBD 757 (I think) Mike Ligas writes:

>I'd be quite surprised Dave if you use unplugged sterile pipettes to  
>dispense your yeast. The fibrous plug found in the top of culturing  
pipettes  
>is tightly packed and adsorbant enough to stop potential microbial  
>contamination carried by microscopic particles dispelled with each  
>humid breath.

Though I am reluctant to continue what is essentially a very boring  
thread, I do not use plugged pipettes. They are just open, sterile,  
glass  
pipettes.

>If you've ever done animal cell culture or bacterial culture using  
>media much richer than liquid malt or malt/agar you'd know, from painful  
>experience, that breath is not sterile.

It is true that I havent done cell culture work in some time, but  
I don't think the result would be any different. Cell culture work is  
tough  
because the generation times of the cells are so long that fast growing  
organisms can easily take over the culture; I don't think it has much to  
do with the culture media. The media we use in the lab is a good deal  
richer than liquid malt. It's yeast extract, peptone, and glucose as a  
carbon source. Granted I have not performed the experiment with fetal  
calf  
serum or some other cell culture medium, but I doubt I would get a  
different  
result.

Anyway, we both agree (I think) on the important aspect of this issue:  
That in wort the technique is safe. Whether that's because breath is  
sterile  
or because what critters it contains are present in very low titer or  
can't  
grow in wort isn't really the issue.

I'm also happy to note that the 'm' word is taking it's knocks out  
there. But I am also concerned that "your mileage may vary" is rapidly  
taking it's place as annoying phraseology of the moment....

From: pyle@intellistor.com (Norm Pyle)  
Subject: Honey Priming, Rats

To Mike McNally:

You wrote that you don't see the point in priming with honey, because the small amount will make no taste difference. I agree; this is the same principle that says people can prime with corn sugar, even though they wouldn't normally use it in their brew. The reason I primed my last batch with honey is this: I had cleaned and sterilized all of my bottles before I realized I had no corn sugar, no dry malt, nothing. It was table sugar or honey or wait until I could get to the HB store. The honey, to my tongue, had no taste effect; it just gave me carbonation, as I desired.

To Curt Freeman:

Touche... Now, does anyone have any real information on blowoff? Maybe Zymurgy or one of the oft-quoted HB Bibles gives something more than "...it's really a personal preference...". I used a blowoff tube for my first few batches. Then I got a 7 gal. carboy and commenced to just putting the f-lock on top at the start of fermentation. With 5 gal. batches, so far, there's never been enough krausen to reach the f-lock, and I can't taste a difference (rats \*ss or otherwise). BTW, I'm not a big stout man (I'm sort of medium sized :0), but your recipe is intriguing...

Gregory> resembling one of the good Munich weizens. I'd like to try  
Gregory> brewing one but if it's going to turn out like some of the  
Gregory> American varieties I've tried, (eg. Anchor, Sam Adams, Grant's)  
Gregory> then I'd rather not bother.

I now do all-grain, but did a \*real\* simple weizen a month back which got raves from a friend who lived in Munich for 3 years, from my homebrew club, and was quite favorably received by one who is a certified judge.

I'll try to reproduce the recipe from memory as best I can. First, I consulted Eckard (not him, his book -- \*great\* resource) to see what hopping levels are appropriate for Bavarian style Weizens -- they are pretty low -- and then cranked IBU's to ounces for Hallertauer and Tettnanger at three boil times. I can't remember them, so you'll have to do this yourself, or write me direct and I'll scrounge up the actual amounts I used.

Weizen-1 (for 11 gallons)

13.2# American Classic wheat beer extract syrup (60% wheat, 40% barley)  
?? oz Hallertauer leaf (~ 5% alpha) 60 minutes  
?? oz Tettnanger leaf (~ 5% alpha) 30 minutes  
?? oz Hallertauer leaf (~ 5% alpha) 15 minutes  
750 ml Wyeast wheat beer culture  
12 gal Water

Boil the whole batch for 60 minutes, adding hops as specified.  
Force cool.

Save 1 gallon for priming in fridge.  
Split yeast between two carboys, then siphon beer in.  
It fermented about 10 days at 60-70F  
Primed with 1/2 gallon of the saved wort in each of 2 kegs, siphoned the beer in and let sit for 3 weeks at ~60F.

Sorry, I didn't take OG or FG readings.

Not as good as the beer from Schneiderweisskeller (Munich), but it had the right clove aroma, a very slight tartness, and good body. Perhaps a bit dark for style, but that's hard to avoid using extract.

I kegged a clone of it last night which had 50% more malt and hops; I used Father Barleywine's yeast cake trick. Ummmm... getting thirsty thinking about it.

From: Bob Jones <BJONES@NOVA.llnl.gov>  
Subject: Glass Fermenters

After my strong recommendations regarding the use of glass fermenters I would like to relate an interesting story about one of the brewers in our club. Seems this brewer kept bringing obviously infected beers to our meetings and asking "what I am doing wrong?". We would all ask the usual questions, The fermenter was always high on the list of potential sources for contamination. He was using a glass carboy. After months of this quizzing I suggested maybe he should take up sewing :-- / Well one day he walks in with the solution to the mystery. While he was cleaning his carboy he couldn't remove a particular stain. After getting his glasses (brewers over forty will relate to this) he discovered the stain was not really a stain but a bubble on the inside of the carboy. There was this green blob living very happily in that bubble. He bought a new carboy and yep his infection problems went away. He now brews award winning beers consistently. So, check those new and used carboy closely! Stainless definitely has an advantage in this respect. I'll relate another story about plastic fermenters at another time.

>was cool.

After boiling and cooling, you WANT to aerate the wort thoroughly. It's  
the  
only time you really want to introduce lots of oxygen into the wort, so  
the  
yeast can utilize it during the respiration phase. Low oxygen levels tend  
to cause slower starts, longer fermentations, and a higher probability of  
stuck fermentations. (If your parenthetical note was a bit of humor,  
please  
ignore my response... I've been out of touch for a couple of weeks, and  
can't tell who's for real around here anymore)

>the characteristics offered by the seed but they wouldn't be  
>excited about what the leaf would offer. My hunch is that  
>previous discussions about coriander in beer did indeed mean to  
>say seed and not leaf....

In fact, we did use the seed and not the leaf, and the flavour bears no resemblance to the mexican/chinese flavour. I must admit, I am intrigued now and would like to brew a lager with the leaf in the boil. The coriander beer is wonderful, though, even with the much maligned Red Star yeast.

Subject: OXIDATION

To: Homebrew Digest  
Fm: Jack Schmidling

MORE ON THE OXIDATION MOMILY

This evening I had the opportunity to check my taste buds against some experts at a meeting of the Chicago Beer Society. Before I present their opinion of my oxidation experiment, a little background.....

As a debunker of MOMILIES, I decided to conduct my own experiment regarding assertion that the billowing foam in my video "BREW IT AT HOME", would cause oxidation leading to "cidery" or "cardboardy" tastes.

The experiment goes like this:

I brewed a batch of extract beer following all the does and don'ts derived from the discussion on oxidation. No splashing, foam and minimum head space. I even tilted the bottles until the filler head was covered to preclude turbulence at that point.

I left about a quart of beer in the priming vessel and did just the opposite to this. I abused it in every way I could think of. I sloshed it around for several minutes. I poured it into a quart bottle through a funnel and then decanted it back and forth into another bottle about a dozen times. I then poured this into three 12 oz bottles, with a funnel, leaving about 3 inches of head space.

The bottles were numbered T1, T2 and T3. They are to be opened and tasted at 30 day intervals and compared with the control samples.

We tasted T1 today [10/14] and neither my wife nor I could detect the slightest difference.

.....

Tonite 11/7, I poured samples for three certified judges and several lurkers, of a control bottle and T2. They had no idea what was done to T2, only that it was the same batch and given special treatment. No clue as to good or bad treatment.

The concensus of the judges was that T2 is "cleaner and smoother" than the control.

I rest my case on that one.  
.....

It was a fun time and we met a lot of fine people and sampled a lot of beer.

Marilyn liked everyone she tasted better than the last one. I naturally liked mine best. In spite of this, I let her drive home.

What really made the evening was meeting at least three readers of HBD and usenet. It reconfirmed my faith in the fact that in spite of all the big mouths (me included) there are a lot of neat people out there who just yawn and enjoy it.

I left a copy of "BREW IT AT HOME" with one of the judges to look at and post a review.

So hopefully, we can hear some comments on a video that someone has actually viewed.

Subject: Remove some members

Greetings!

Thank you for adding the alias "homebrew@cirrus.com" if you could now send me a list of your members that are within our domain and remove them I would appreciate it. Since some people may have used UUCP style addresses

here are some examples:

```
user@cirrus.com
user%cirrus@oliveb.ATC.Olivetti.Com
user%cirrusl@oliveb.ATC.Olivetti.Com
...!cirrus!user
...!cirrusl!user
```

or any other peculiar address users can whip up. Thanks and I'll keep my eye our for you message so I can get them switched over quickly.

Regards,

~mitch

From: BAUGHMANKR@CONRAD.APPSTATE.EDU  
Subject: It's Flame Time!!

Flame on!!

OK. I've had it!

Both behind the scenes and on the scene, there have been plenty of complaints about how the signal to noise ratio has been increasing on the HBD these days. The cause? (I hate to even say it..) Big Jack's refusal to respect the norms concerning commercial advertising on the Internet.

As a business person who loves the HBD and wants to see it return to the HBD of old, allow me to make a few points. And then, frankly, I'm ready for this crap to come to an end. Direct all flames/comments to me personally. Let's not waste this bandwidth any more. I'm sorry about this post but "I'm mad as hell and can't take it anymore."

Jack, I know you think you're cute and quick and witty the way you keep sliding in comments about your maybe-good-maybe-bad video. But you're stretching the bounds of decency now, Pal, and I'm asking you wake up and smell the coffee. Wrap that doubled-barrelled immersion/counterflow chiller you "invented" around your neck and chill out! Your surreptitious references to your enterprise is out of place and in bad taste. You're only fooling yourself. We know all about your cursed video by now. My God, man, you won't let us forget about it!

I appreciate the fact that after making a dozen batches of beer, you feel the need to enlighten the world about how easy homebrewing beer is. Great! Fine! Why you think a dozen batches of beer qualifies you as saviour of the world is beyond me. But from the tone of your posts, lack of ego is a disease from which you do not suffer. You've made your freaking video now. You've pummeled us over the head about it. We all have enough information before us, behind us, and on top of us to make up our minds about it. Or do you think because the money isn't pouring in from all us netters that we're all just too stupid to know a good thing when we hear about it? Or maybe the comment you made about how some of us are "silly people" reflect your deep down opinion of us.

Speaking as a business person, now let me bust a few of your bubbles. Welcome to the homebrewing business world. This is the world where if you're in it to make money, you're suffering from oxidation of the brain! If all you have is one video to sell you'll be belly up in a year if not before. If you're going to sell anything at all, you have to advertise in a COMMERCIAL forum. I suggest Zymurgy. 4 ads a year will set you back about \$1000. That's a lot of VHS tape, Jack! And your product is competing against products produced by people who have been brewing beer for over 15 years. Gee! I wonder whose opinion I'd be better off following?

I'm begging, I'm pleading, I'm on my knees to you to cease and desist. We've had a good thing going here in the Digest for as long as I've been a subscriber. I've learned more here about making beer than anywhere. I participate as a homebrewer. I go out of my way NOT to mention my products and my business. (Can you name my business? I doubt it.) A question was asked about one of my products a couple of weeks ago. Did you see me answer it in these electronic pages? No. I handled it the way I always handle them. Quietly. Behind the

scenes. And since you don't seem to be able to take a hint, let me tell you outright. THE WAY IT'S SUPPOSED TO BE HANDLED!! The crass, Madison 5th Avenue type commercialism you've seen fit to bombard us with makes me want to puke. And in the process, you've caused the quality of the Digest to go downhill.

Having said all this, let me point out that we really are more than happy to have you in the Digest. Don't get me wrong. The purpose here is to discuss homebrewing related issues. If in the natural course of discussion, someone wants to talk about the relative merits of all the videos available, fine, then jump in and TRY to make objective comments about the products under discussion. But you're totally out of line to initiate the discussion yourself. And you're simply out of touch to refuse to let it run its course.

So from one Digest subscriber/businessperson to another, get a grip. You've already achieved pariah-level notoriety. You're not doing yourself, your business, nor the Digest any good.

Flame off!

Sorry to take up bandwidth, you guys. But like a bad case of jock-itch, I've been hoping that Schmidlyitis would die the death it deserved. Consider this a bottle of castor oil down the throat of the demon.

Now back to our regular scheduled programming.

Regretfully,

Kinney Baughman | Beer used to be, now flaming is,  
baughmankr@conrad.appstate.edu | my business and I'm hard at work.

>blow-off makes your beer marginally less tasty.

>Anyway, I bring this up to the net to see if anyone can find a  
>thorough study that either supports or refutes my belief.

Hi John:

I'll bet you knew I'd bite on this one. John and I have discussed  
some of this before in Fidonet's Zymurgy forum. Below is an edited  
version of some of those discussions.

But before I begin:

>Because blowing off or skimming foam doesn't make a rat's \*ss bit of  
>difference, IMHO. (that ought to start a nice little flame war...)  
>Cheers!  
>Norm

Sure. Now that flaming is my business, here I go... :-)

- - - - -

I admit the blow-off method is a much disputed technique. My opinion  
comes from my own personal experience. I definitely think my beers  
have improved from this system. The point I usually make along these  
lines is to taste the brown scum that forms on the kraeusen head.  
Since never in my wildest dreams would I intentionally add anything so  
bitter to my beer on purpose, I've found comfort in letting the blow-  
off method remove it for me.

John has made the point to me before that fermentation is a chemical,  
not just a mechanical process and that perhaps some of those bitter  
constituents get processed in the course of fermentation. That's a  
good point and I am in no position to say one way or the other.

Still, looking at the literature, I find that skimming is at least  
advised in most of the brewing textbooks. A look at my copy of  
Malting and Brewing Science, Page 652: (Discussion on the progress  
of primary fermentation...) The head gradually collapses, leaving a  
dark-coloured, bitter-tasting scum which should be separated from the  
beer by skimming or suction. Some breweries arrange for this scum to  
stick to the roof of the fermenter and then be removed by special  
chutes at the side of the vessel. Another suggestion is that plastic  
balls floating in the fermenter will retain the scum while the  
fermenter is drained. (Interesting suggestion, huh?)"

The Practical Brewer also says that the beer should be skimmed,  
though more to collect the yeast than to remove bitter substances:

"As the fermentation proceeds, a head forms.... The yeast flocculates, rises to the top and is pre-skimmed during the next 24 hours leaving a layer of around 3-5 cm thickness behind. One method of skimming or yeast collection is the use of a built-in funnel arrangement at the liquid level into which the yeast flows and is then transported through pipes to the yeast room. Another method is the use of a mechanically operated board travelling over the liquid level pushing the yeast towards a collection point. (I have seen systems like this in a couple of the breweries I've toured in Belgium.-krb) Such systems often make use of vacuum pumps to collect the yeast."

I guess I'd argue at this point that even if they skim to collect the yeast, they're taking the bitter scum along with it as they do.

An important point here is to do those things that you deem important to improving your beer, given your own personal experiences. My early homebrews (pre-blow-off) suffered from a bitter astringency that I found objectionable. The first beer I tried using the blow-off method didn't have it and I've never gone back.

I do have a tendency to get on my soap-box about the blow-off method, though, so my apologies to all. But I was falsely accused of blowing carboys a couple of years ago by none other than Zymurgy, the same guys who said it's OK to blow-off using siphon hose. In my Less Than Humble Opinion, that one section in The Complete Joy of Homebrewing (an otherwise excellent book, I should add) has done more to cloud this issue than anything else. But such is life...

To wit,

>From Ken Johnson:

>Subject: Yeast poppers (the flying carboy cap)

>I just pitched a starter of Wyeast German Ale yesterday, and this morning I  
>found the carboy cap laying next to the carboy and massive mounds of yeast  
>and foam all over the floor. I assume that the yeast took off really quickly,  
>clogged up the cap, blew it off, and spewed.

>So here's the question: What form of blowby allows the passage of yeasties  
>and foam without clogging and becoming airborne? I was using the 3/8" tube  
>on the cap.

This is why Michael Lewis, of UC Davis, who first came up with the idea of the blow-off for homebrewers, advised stuffing 1" ID hose into the neck of a carboy. Nothing will clog those suckers. I'm extremely surprised that Charlie, knowing full well that his advice has caused hundreds of homebrewers to suffer the popped cork syndrome, refuses to amend that portion of his book.

So spread the word. Don't blow-off through siphon hose. Regardless of what the "The Book" says.

From: eisen@kopf.HQ.Ileaf.COM (Carl West)  
Subject: **Beasties in honey**

My understanding is that micro-beasties dont \*grow\* in honey but they do \*survive\*, just waiting for the day when someone dilutes it with water and makes life liveable again.

The very simplest way to make a mead is to mix a bunch o' honey and water together and let it go, no cooking, no quality control, no guarantees. The wild yeasts in the honey will do the job. I don't recommend it.

Carl West

High fives to Jeanne Sova ASQNC-TAB-IS 5320 <jsova@APG-9.APG.ARMY.MIL> for the posting "The past week". It was an idea that had crossed my mind but I simply didn't have the guts. Someone else recently mentioned that the mood of HD had changed recently and has been less-than-friendly at times. I agree.

It really doesn't matter how it all got started. Everyone involved is guilty of fanning the flames. I enjoy reading HD. It can be informative and fun. Unfortunately the recent rash of direct insults, insinuating subject headers, string pulling and general impoliteness has left me considering cancelling my subscription. It's probably best to send hostile letters directly to the person one wishes to make miserable. The sense of personal vindication should be the same and it'll clean up HD a little. Anyways, I doubt that many readers are impressed or amused at how cunning and sarcastic other people can be. I only speak from my own little soapbox but it is quite possible that I'd get solid backing on this issue if I'd call for it.

I've taken the time to go through a few back issues and it's clear that EVERY subscriber responds well to an alternate viewpoint provided it is stated diplomatically. Let's all chill out, chill a few beers and slip in a smiley every now and then :-)

> running off, one could experiment with it both ways.

The homebrew world has actually heard of that one before, using an ice-water slurry or cold running water as you mentioned. It works much like a counterflow system but isn't as efficient as counterflow in achieving a rapid local drop in temperature. Counterflow is the way to go if one is concerned about efficiency.

I know many brewers would attest that the method described by Jack or the immersion chiller method are both easier to setup. I chose counterflow after seeing a 'make-it-yourself' article in Zymurgy (I don't have the reference with me) and I have had no headaches or problems with it. In the final analysis they all work well and the important point is that chilling your wort by any method available will help you make better beer. Go with the flow %-]

Hmmmmmm .... we could be slowly developing the ultimate drinkers diet here on HD. Time released B-vitamins, honey, Gatorade, bananas and water, water, water.  
The problem is we're not leaving enough room for the beer! ;-)

Actually, I have heard that dehydration does lead to ion channel abnormalities but dammit Dave, I'm a molecular biologist, not a physiologist/neurologist. I'll check into it with a friend of mine who should know the answer. BTW, it's myelin :-]

It is true that bacteria and molds will not GROW in honey, since  
the cells are unable to absorb any moisture. However, they do  
not automatically die. They just lay dormant and wake up with  
a killer case of cotton mouth, and set off to drink your beer.

Just for the record, Baderbrau gives me a headache. So does Samuel  
Adams,  
for that matter. Miller Lite (my unobtrusive, "what, you don't carry  
Sierra  
Nevada?!?," lawnmower, wedding, bowling beer), does not. Nor do any of  
the  
Sierra Nevada, Sam Smith's, or Belgian brewery products. Two Budweisers  
in  
one night and the next morning I have a "looking for a gun to shoot  
myself"  
headache! One of these days I'll do the experiment right, including  
duplicating meals the days of the drinking, and then having the beers  
analyzed, to see what component the headache beers have in common.

I'd like to point out that in his last two posts, Jack seems to have  
taken  
a considerably humbler tone. Thanks, Jack.

Subject: Re: Blowoff

Subject: Comradery  
From: George Fix

To Jeanne Sova:

I was deeply moved by your post in HBD#758. I feel, however, there is another interpretation of "affaire de Schmidling". Imagine yourself in a room with a bunch of people just learning to drive. Imagine someone speaking to this group about the advantages of driving down one way streets the wrong way at a high rate of speed. I suspect you might have something to say. Your comments might even become a bit pointed if the speaker defensively insists that he has been using this procedure all his life without harm.

I cannot tell you the number of times beginning home brewers have told me at meetings about how much help people like Al, Jay, Jeff, Larry, Mike, etc. have given them. All of these people have played a very constructive role as mentors in the best sense of that term. There is a home brewing community, and while it is quite diverse, a "tough crowd" it is not. Be assured that the comradery among those men and women who love and brew beer is as strong as ever. I sincerely hope that this aspect is visible to you.

From: "Rad Equipment" <rad\_equipment@rad-mac1.ucsf.EDU>  
Subject: Perception

Subject: Perception Time:8:09 AM Date:10/30/91  
Jack Schmidling comments:

>>I use Bud as the low limit and Baderbrau as the upper. Anything in >>  
between  
is acceptable, if not necessarily desirable. I am not very >>  
sophisticated but  
I can not drink bad beer, even if I made it. As I >>certainly have made  
bad  
beer on occasion, I know what lies beyond the >>lower limit. I have,  
however  
never made beer that tastes like cider or >>cardboard.

Jack, as far as "you" are concerned your beer has never tasted like cider  
or  
cardboard. These are flavors (along with many others found in beer)  
which  
different people have different sensitivities to. This is why I suggest  
you  
have an independent palate, preferably one that has experience with  
homebrew,  
taste your experimental brew against your control batch. Many people  
like some  
of the flavors/aromas which occur as "flaws" in brewing. This is  
especially  
true of fruity esters which show up in many ales.

As far as cardboard is concerned, it isn't so much the taste as the aroma  
which  
exhibits a character which comes closest to that of "wet cardboard". This  
is  
not to say that it "is" the smell of wet cardboard, but that, when many  
people  
perceive it in beer, it "reminds" them of the smell of wet cardboard. It  
is a  
device to describe an off aroma in the brew, as are many other terms  
which  
brewers use to verbalize what their senses tell them about beer.

If you are happy with your beer as it is, then keep on brewing as you  
are.  
However your position that things like oxidation and off flavors/aromas  
don't  
exist or occur, simply because you have not experienced them, is poor  
science.  
Perhaps your environment allows you to brew with a casual attitude  
towards  
certain accepted practices and still succeed. I have no idea since I  
don't  
know you or your beer. When you begin to get feedback from other brewers  
you  
may get confirmation of your abilities, or you may find that there are  
some  
things in your beer which you are not aware of. Enter a competition  
where your  
beer will be judged anonymously and then review the judges' comments with  
an

open mind. Get a second opinion, Jack.

Subject: Beer Styles

!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!  
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!

I am passing along the following comments from Micah Millspaw. He reads copies of HBD I pass on to him via floppy disk, but has no access to the net. Any and all comments will be passed on to him. Me and my mail box will merely act as a conduit .

!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!  
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!

I am very disturbed by the many references to making ALES with BOTTOM fermenting yeasts and vice versa. Anyone out there know your definitions of beer style? While it is possible to cold ferment with a top fermenting(ale) yeast, the resulting beverage is not a lager beer(maybe an alt though). The reference to a dark brown beer that was bottom fermented as an "obvious ale" is way off base. The color of a beer is the result of the grains used to make it, not the yeasts.

Want to redefine your ale-lager values? Buy a bottle of EKV28 (Germany) and a bottle of DUVEL(Belgium). Try these beers side by side. The EKV28 is very dark, thick and malty, it is also a lager beer. The DUVEL is so pale that it is almost clear, and it is an ale.

Before making any more beer ignorant statements try reading some descriptive beer styles books, they are widely available.

Subject: Draught Guinness in a can!?

Subject: Draught Guinness in a can!?!Time:11:22 AM Date:10/30/91  
THIS IS NOT A COMMERCIAL ENDORSEMENT

I had the good fortune to be invited to attend a very special beer happening (am I dating myself with that term?) recently by Tom Dahldorf of the California Celebrator. The event was Guinness' unveiling of their new product, Pub Draught Guinness. Now, I can hear the lot of you saying to yourselves "Yeah, yeah, another 'draft beer in a can', big deal". But this one is different. For the most part this product actually does what it is supposed to do!

Anyone who has had Guinness Stout on draught and from a bottle knows there is a vast difference between the two brews. The brewery makes no secret of the fact that the recipes are different not only between the kegged version and the bottled, but also between different bottled markets. Now the folks at Guinness have developed a system which dispenses their stout from a can in such a way as to rival a pub tap. They have been working on this for some 20 years and the final method was preceded by over 100 failed attempts.

The problem has always been the fact that draught Guinness is (or should be) dispensed with a mixture of Nitrogen and CO2 gasses rather than the conventional CO2 alone. The nitrogen is used because it makes very fine bubbles while it is not absorbed into the brew as the CO2 is, thus it does not "over-carbonate" the beer. Also a special faucet is preferred which, in combination with the gasses, creates that wonderful creamy brown head which lasts to the bottom of the glass. The new can combines the original kegged stout recipe with technology which creates the draught effect to a tee.

Dr. Alan Forage, creator of the technology, was on hand to explain the mechanics of the new can. This is the way the system works: The 16.9 ounce can (containing 14.9 ounces of beer) is fitted with a small plastic device (Guinness calls it a "smoothifier") which sits in the bottom of the can. This device has a pocket or cavity which is open to the atmosphere via a pin hole in its top. The can is evacuated of oxygen and filled with beer. Prior to sealing the can, a dose of liquid nitrogen is added to the beer. The can is closed and as the liquid nitrogen warms a pressure is created. The pressure forces about 1% of the beer and nitrogen into the plastic cavity. When the

can is opened, the pressure is released and the small amount of beer in the cavity is forced back through the pinhole quite violently. The agitation created by this "geyser" mixes the nitrogen with the beer in such a way as to reproduce the tap handle character. Open up the first empty can you have in order to see what the "smoothifier" looks like.

Prior to serving, the beer must be chilled. Guinness suggests a two hour stint in a refrigerator, with a target serving temperature of 45-50 degrees (if opened while warm, the beer gushes with excess force). This is the one area where flavor will be variable since most American refrigerators hold their temperatures closer to 35-40 degrees. We all know the colder the beer the less the flavors are perceptible. Education will be the key here. The entire contents should be emptied into a 16 ounce glass. The head which forms is exactly like that of the draught version. And yes, it does last to the bottom of the glass.

How does it taste? In my opinion, this is virtually the same as what you get at a well maintained pub. The texture is right on. The flavor is wonderful. I suspect there may be some slight differences as a result of the volume of the package (14.9 ounces vs. 15.5 gallons) but I didn't notice any. According to Declan Maguire, group marketing director of Guinness Import Company here in the U.S., extensive taste comparisons were made throughout Ireland and England during the development of the product. This includes side-by-side blind tastings with the original version.

The cans come in packages of 4. The suggested price is \$5.99. The stout is 4% alcohol by volume. Guinness is releasing the new product in the San Francisco, Chicago, and Baltimore/Washington D.C. areas to begin with. Locally, Safeway stores are carrying it at \$3.00/2 cans. The cans can be recycled just like other aluminum ones. I suspect the insert is made from the same plastic which is used to coat the inside of the can and will burn off during the recycling process.

Congratulations to Guinness on the success of this new package.

>components. I have heard that damaged beer can be revived by adding  
>fresh wort, yeast and letting it re-ferment.

I made this same mistake once myself and was corrected by several kind souls on the Digest. My mistake was to state that, since the beer was yet to be fermented, aerating hot wort was OK. Several posters corrected me by saying that, since the wort was hot, the oxidation reactions took place much faster and that the wort should be cooled to below 80F before aerating. When I began doing this (mind you this was more than 3 years ago), I finally brewed my first light-colored beer. All my previous beers were very brown even though I used the same ingredients! My palate was not as developed as it is now, but I faintly recall a sherry-like flavor in all those early beers. I guess I just thought it belonged in my beer and didn't question it.

I don't know if it's true that the yeast "reduces the oxidized components." I had never heard this, but would agree with you that oxidation after fermentation is much more serious than oxidation before fermentation. I would be interested to know if that reduction really does take place.

I'll bet you meant 2' (have you seen "This is Spinal Tap?"). Either  
that or you're a much better siphoner than I. ;^)

>  
>With the  
>counterflow, you can start siphoning into the fermenter immediately.  
>With the immersion, you have to wait 20 or 30 minutes for the wort to  
>chill before you can begin the siphon.

Good point! I hadn't thought of that. All in all, it's 6 of 1,  
half a dozen of the other. The bottom line is: wort chillers  
improve your homebrew. I'm convinced of it.

Subject: Re: cloves

>There are two strains of yeast that are known to produce clove flavors:  
S.  
delbrueckii (the Bavarian wheat beer yeast) and S. diastaticus (a  
superattenuating wild yeast).

Thanks for the comments. However, one of the things I find most  
confusing in  
this discussion about yeast is use of the term "strain". In any science  
that  
I am aware of (we are talking botany with yeast), the word strain is  
used to  
identify a predictable and known variation of a species.

For example, bread yeast and ale yeast are variations (different  
strains) of  
Saccharomyces cerevisiae, a single species.

You have identified two different species. It's like the difference between a rose bush and an apple tree (same genus, different species) as compared to a red rose and a pink one (same species, different strains).

This may seem like trivia but I suggest that it is far more relevant to understanding beer characteristics than whether one says "blow-out" or "blow off". In one case, it offends science; in the other, just shop talk.

SUBJ:Yeast in beer bottles

Larry (Re- HBD #757):

You are right. Bottle conditioned beers are usually not as quick to stale as those which do not contain yeast. Kiren has a new product called Fine Draft where a small amount of fresh yeast has been added at fill in beer that has already been carbonated. They report that the shelf life is triple what they normally achieve. As you might expect, the procedure can backfire if defective or old yeast is used. They also found that high levels of air uptake during fill can totally negate the advantage of the yeast. A summary of their experience can be found in MBAA Tech. Qr., Vol.28, No.2, 1991. Maybe there is something here for those of us producing "sediment free" homebrew to think about.

Father Barleywine's "yeast cake" procedure was apparantly used by some small commercial breweries around the turn of the century. Charley Liebermann, a brewer from the old school, discusses the pros and cons of this and related procedures in a highly readable article titled "Yeast Management". It appeared in Brewers Digest a few years ago.

Subject: Margarita's Moul't Scotch Ale

Here are my brewing notes from a recipe that seems to be turning out very nicely.

Batch #53

Made 10/19/91, bottled 11/2/91, 4 gallons.

Comments: Margarita's Moul't Scotch Ale. An all grain (well, it has a pound of DME in it) Scotch Ale, designed by Joel Bauman and brewed by him, me and Dan Hall. Half way through the process, I discovered that Margarita, my pet Mexican Redleg Tarantula, had moulted. Hence the name. Eight lbs. English 2 row pale malt, 1 1/2 lbs. English crystal (40 L.), 1 oz. chocolate malt, 1/2 lb. dark brown sugar, 1 lb. M&F light dried malt extract, 1 1/2 oz. Kent Goldings (4.7 Alpha), 1/2 oz. Styrian Goldings, 14 gm. Whitbread dry ale yeast.

Added 1 tsp. gypsum (Nashua water is very soft) to 2 1/2 gal water, brought to 165F, added to the grains and doughed in at 152F.

Mashed for 75 minutes (152 to 148F).

Mashed out with 3 quarts boiling water, giving a temp. of 160F (was shooting for 165).

Drew off a quart and recirculated. Repeated nine more times.

Sparged with five gallons water and 1 tsp. gypsum at 168F. Gravity was only 1.055 so decided to include 1 lb. light M&F DME. Started the boil.

At boiling, added the DME and 1/2 lb. dark brown sugar.

At 15 minutes into the boil, added 1 1/2 oz. Kent Goldings (Alpha 4.7).

At 62 minutes, gravity was 1.070 and volume was low, so added a gal. of boiling water.

At 73 minutes, added 1/2 oz. Styrian Goldings (unknown Alpha).

At 90 minutes, started wort chilling .

After 53 minutes of chilling, racked to carboy, aerated by gently sloshing the fermenter.

Rehydrated Whitbread ale yeast in sterile water for a few minutes, pitched, sloshed carboy again, installed airlock. Estimated OG 1.070. Four gallons. Krausen formed overnight, fell in another day and a half.

After 14 days, bottled with 1/2 cup corn sugar. Final gravity 1.019. Looks nice, malty smell and taste, noticeably alcoholic, a little harsh.

It's been in the bottle a little over a week now and is starting to smooth out. I wish I had made more of this. I like the Scotch Ale style, especially now that cool weather is coming. Anyone have a SA recipe they would like to share? Anyone have a source of real Scottish grains?

BTW, we used Dan's 200,000 BTU Blowtorch-from-hell Cajun Cooker. This thing is really intimidating!! At the lowest setting it boiled the full wort in something like seven minutes! Don't get one of these unless you're doing industrial level brewing! We also discovered that boiling wort on the back porch attracts yellow jackets. They swarmed around the brewpot and kept drowning themselves in our beer glasses whenever we set one down.

Bill

From: GC Woods <gcw@garage.att.com>  
Subject: Zip City and NJ Homebrewing

For the NYC area HBD folks, the "Zip City Brewpub" will be opening November 21. The address is 3 West 18th Street (NYC) and phone # is 212-366-6333. Our homebrew club president was recently at the pub judging for a local competition and said they are making excellent lagers.

But the big news is HOMEBREWING IS NOW LEGAL IN THE PEOPLES REPUBLIC OF NEW JERSEY. Yes the homebrewing bill finally passed last Thursday. The limits are the same as federal law, but there is yearly permit required just like wine (\$3/yr). To give you an idea how much effort is spent enforcing the permits - there were less than 200 wine permits issued last year and I'm sure that in the Peoples Rep. of NJ that \$600 is more than enough money to justify a full time person to log them. If anyone is truly interested in getting a permit you'll have to wait because the state assembly hasn't wasted enough time in meetings to decide how they want to set up the permit system!

There is also some judge in Cape May, who owns the Queen Victoria Bed & Breakfast (this place is beautiful) and wants to take on the noble cause of making brewpubs legal in NJ. I hope he can do it because we are down to just 2 brewers in NJ - Anheuser-Busch in Newark and Clements in Vernon.

> Burch's corner on this one. For those unfamiliar, these two  
> sources vary considerably in the 25 to 45 minute boiling time regime.  
> While these numbers are approximations which will vary from batch to  
> batch, we the homebrewers have to start with a number somewhere, and  
then  
> adjust our results accordingly.

I think that Burch's published numbers are very generalized; I think  
that  
Rager's density adjustment is a fudge factor; and I think that no  
formula  
could hope to cover the myriad of different variables that occur in hop  
utilization for any broad sweep of homebrewers. In particular, while it  
is  
very interesting to know exactly how the curve flows, I would also wonder  
aloud how often and how much hops are being added in this time period.

In talking to Dr. Fix, he has pointed out that variables such as wort pH,  
kettle geometry, and boiling temperature and pressure can have a  
tremendous  
effect on hop utilization. So, a tall kettle with a small surface area  
in  
relation to its volume is probably more efficient. Folks at sea level  
might  
use less hops than those at the top of the Rockies.

If you have used the Brewer's Worksheet spreadsheet I uploaded a while  
back  
(it's in the archive at mthvax and sumex-aim, and is a Macintosh-Excel  
spreadsheet, but Art Steinmetz produced a converted copy for PC 1-2-3),  
you  
would note that hop utilization for pellets and for flowers are factors  
that  
the user must enter. Even then, the whole IBU calculation is of first  
order  
value only. Perhaps that ought to be 0th order, since I would only guess  
that this yeilds in the right 5 IBUs or so, with careful tasting against  
controls for a particular brewery. Beware of too many decimal places!

I can only say that the Brewer's Worksheet uses a very simple formula,  
essentially the same as Rager's (some might argue that Rager's article  
wasn't as clear as it might have been), minus the gravity adjustment, and  
I  
was able to "tune" it for my brewery so I could predict bitterness in  
relation to commercial examples, using a full wort boil. I suspect that  
it  
could be tuned to reach approximate values for most other breweries as  
well,  
at least to the extent that it is useful for predictive efforts.

Date: Mon Nov 11 09:01:38 PDT 1991  
From: darrylri@microsoft.com  
Subject: re: Canning Wort

Bill Pemberton gives us his pressure canning procedure for saving wort for starters. I just wanted to note that I use a boiling water bath canning (the closed jars are boiled for 15 minutes in an open pot and then allowed to cool), and have never had a problem, even with some of the jars lasting 6 months. Because my procedures tend to leave 1/2-1 gallon in the kettle after transferring (15 gallon batch size), along with hops and break material, I filter this out and generally cut it half with water to get low gravity starters, and then can in quarts and pints.

Also, I think someone else (sorry!) discussed their starter methodology, which involved taking Wyeast into a 12 oz. container and then a 22 oz. size before pitching for 5 gallons. This is really more effort than is required, since the yeast can generally build up through 4 or 5 doublings pretty quickly. So I would advise putting the Wyeast packet into a quart starter and then using that to pitch directly into a 5 gallon batch. I use about 1/2 gallon for my 15 gallon batches and get very good results.

>>detoxification ...

>Comments well-taken. The trouble I have with this theory is that it  
>doesn't explain the correlation to types or brands of beer. Below is  
>a list of beers that give me a headache:

Florian also provided a list of beers which do not give him headaches  
which  
included, thank Gambrinus, homebrew. ;-] I've also noticed this  
phenomenon  
but I haven't documented the beers as well as Florian. The best I can say  
is  
that, for me, the culprits seem to be beers brewed with corn or corn  
sugar as  
adjuncts. Yes, that means I'm not a big fan of many Mexican beers and I  
use  
corn sugar only sparingly in my homebrew. Chalk this one up as another  
reason  
to brew beer at home! :-D

From: arf@ddsw1.mcs.com (Jack Schmidling)

>>Jack I'm not sure what to make of this reply, I think you may have  
>>misunderstood. The cloviness comes from the YEAST not the wheat malt.  
...'

>Well, I do not have the original but I could have sworn that the clove  
was  
>connected to wheat. I have made mistake before....

No mistake. The "Troubleshooters" Special Edition of Zymurgy does state  
that  
clove flavours can come from using wheat malt. The intense clove flavour  
in  
Weizen is however the product of fermenting with S. delbrueckii.

From: Jeff McGowan <MCGOWAN@esb.com>  
Subject: Bottling cane, and cidery flavor.

To Jeff Frane : thanks for the suggestion of buying a bottling cane - we actually did it already and used it last weekend to bottle an ale. The difference in energy expended and hair pulled out was amazing - I would \*definitely\* recommend one to any beginner!

The India Pale Ale we bottled two weeks ago, which had a slight cidery taste last week, had none at all this weekend! From what I have read here, I assume this is not terribly unusual, right? It seems that it \*is\* worthwhile to let the beer age for at least a little while in the bottles (if you can). Probably a silly question - how do commercial breweries which produce naturally carbonated beers which are not bottle conditioned get the carbonation in the bottle? Do they do part of the fermentation in a sealed container to carbonate the beer before bottling, then bottle under pressure after filtering?

Just curious.

From: martin@daw\_302.hf.intel.com (martin wilde)  
**Subject: Fast Attenuation**

I was reading that Widmer Beers are fermented at 68 degrees for 4 days and then lagered at 41 degrees for 3 days before kegging.

What type of yeast attenuates this quickly? Is it because they inject oxygen into their fermenter to get the yeast to take off quickly and thus ferment fast?

From: polstra!norm@uunet.UU.NET (Norm Hardy)  
Subject: **Bottle color**

The first (annual?) Novembeer fest took place last weekend; sponsered by the Brews Brothers of Seattle. Several certified judges from the NW, including Canada, did a good job.

The judges doing the pilsener category really slammed the entries with green bottles. One judge wrote "green bottles are the kiss of death" on one such entry. I think the bottle color affected their perception of the beer.

Perhaps Darryl R can give some insights from his table (bitters). My duties were to aid in the data entry for the scores.

Oh, the top two beers (of 83 entries) went to Rob Nelson, Brews Brother, and the steward in charge of sorting the beers upon arrival. Maybe he tweaked the computer's scores (just kidding, the judges knew what they liked).

>I checked Schuster/Jackson last night, and he says Portland and Seattle  
are  
>beer meccas in the US. Help me out -- what are your favorite haunts?  
>  
>Thanks...

I can give you my completely unbiased opinion.. :-)

First off, anything in the McMenemy's empire is good starting place.  
The Brothers Beer have something like 26 pubs/brewpubs in Oregon of  
which all but about 4 are in the Portland Metro area. The food is  
standard hamburger fare and the beer is good to excellent and if your  
drinking the house brews, fresh.

Mission Theatre & PubFree Movies with the brews.  
1624 NW Glisan

Blue Moon TavernDown on Yuppie row.  
432 NW 21st.

The Cornelius Roadhouse and Brewery In an 1859 farmhouse  
Sunset Highway and Cornelius Pass Rd.  
(Take Hiway 26 west from Portland about 20 min.)

Edgefield Manor Not completely open yet.  
East of Portland in the Gresham area.  
Former Poor Farm/Old Folks home.

Next is my favorite place for a Saturday evening. An eclectic variety of  
music, no cover, no smoking, killer pizza and good fresh beer.

Bridgeport Brewpub  
1313 NW Marshall  
NW Marshall between 13th and 14th

And last the small pub connected to Portland Brewing Co. (so small that  
the stage for the weekend music is located on a balcony above everything.  
)

Portland Brewing Co./Brewpub  
1339 NW Flanders

There are lots more, but these are from my personal experience. I'm sure  
you'll hear from some of the other Portland people.

Date: Mon, 11 Nov 91 20:10:17 CST  
From: Jacob Galley <gal2@midway.uchicago.edu>  
Subject: Sir Kenelm Digby, Kt. -- and ?Quinine Beer?

Hi all. First, thanks for all the help with my little questions. My Wyeast got going the very minute I sent my last panicky note. (All it took was a little of that Preventitive Murphy's Law.) I got a good deal on a carboy: \$5 a pop at Bonne Sante in Hyde Park. They don't have them very often though. Call ahead.

Now, another recipe from The Closet of Sir Kenelme Digbie, Kt. Opened (London: H. Brome, 1669) since the last one seemed quite popular. This is from page 94. (Reproduced without permission, naturally.)

A RECEIPT FOR METHEGLIN OF MY LADY WINDEBANKE

Take four Gallons of water; add to it, these Herbs and Spices following. Pellitory of the Wall, Sage, Thyme, of each a quarter of a handful, as much Clove gilly-flowers, with half as much Borage and Bugloss flowers, a little Hyssop, Five or six Eringo-roots, three or four Parsley-roots: one Fennel-root, the pith taken out, a few Red-nettle-roots, and a little Harts-tongue. Boil these Roots and Herbs half an hour; Then take out the Roots and Herbs, and put in the Spices grosly beaten in a Canvass-bag, viz. Cloves, Mace, of each half an Ounce, and as much Cinnamon, of Nutmeg an Ounce, with two Ounces of Ginger, and a Gallon of Honey: boil all these together half an hour longer, but do not skim it at all: let it boil in, and set it a cooling after you have taken it off the fire. When it is cold, put six spoonfuls of barm to it, and let it work twelve hours at least; then Tun it, and put a little Limon-peel into it: and then you may bottle it, if you please.

This one definitely sounds like Fun. Are there any opinions about why one shouldn't skim this one? I don't see any source of yeast in here. No clarifiers or eggdrometers either. If I can actually find all those Roots and Herbs, I'll let you folks know how it turns out.

I have one other question (which I could probably do some research on instead but I think there might be some interest in this here, maybe):

Has anybody out there heard of or seen, tasted or made beer with quinine as an added flavoring? I really like drinking tonic water straight, so this idea intrigues me. Maybe I'm weird, so what?

Here is the address to complain to:

Subject: Skunks caused by rough transportation?

I was talking to a friend who spent two years in Germany this weekend past and he said that skunkiness in beer was not only caused by light, but by the rigors of transportation. He went on to say that the Germans import few beers because they are damaged in transport.

Though I do not know for sure, I can well imagine that rough handling, or even a lot of gentle handling, can cause a problem with beer. Can one of our resident experts comment on this?

Subject: Re: Welding Stainless - A Warning

Hi gang,

Just a bit of self-introduction: I'm Chris' house-mate-with-welding-gear, and in an indirect manner, responsible for this thread. I also brew, but admittedly I've been too lazy to read the digest (that will change RSN, just sent in the request :-), so Chris has been bouncing relevant things at me as they come down the pipe.

> CADMIUM CONTAINING [filler alloys]  
> ARE NOT RECOMMENDED FOR ANY FOOD PREPARATION MATERIALS

If I could add to that... Cadmium, being the health hazard that it is, presents a danger to the welder (brazer?) as well. A snoot full of the vapors can, I believe, be lethal. Ventilation and appropriate safety gear would be a must. Every experienced welder I've talked to has told me to stay away from the stuff all together. So far, I've been following their advice. (Not too difficult to do, when you look at the price of sil-brazing fillers :-)

> ...

> PS. I have a 1978 copy of the Metals Handbook. It's possible that the  
> filler rod designations may have changed, but the basic warning is  
still  
> valid.

I believe that the designations are still the same, at least according to the references I have available (a late 80's Metals Handbook in the library here, and my friendly neighborhood welding supply shop.

The warning about cadmium is definitely a good one, and bringing it up is hardly beating a dead horse. I'd hate to see what sort of horror stories the press could come up with about people getting cadmium poisoning as a result of drinking, or making, homebrewed beer and/or brewing equipment.

Date: Tue, 12 Nov 91 12:59:19 CDT  
From: agerhardt@ttsi.lonestar.org (Alan Gerhardt)  
Subject: Stainless Steel Fermenters

The comments in a previous HBD about stainless steel fermenters made from kegs are interesting. In my area, you can get them for a forfeited deposit (\$12). I have used one for a boiler by cutting the top out, etc.

I  
but would be interested in how anyone has modified a typical AB keg into a fermenter.

Most AB kegs I have seen have the single tap fitting in the top, which handles both CO2 in and beer out. The fitting can of course be cut out to leave a hole big enough to get your arm in for cleaning, etc., but a hole that big would be difficult to rig any kind of fermentation lock onto.

If you have a relative in the welding business, you could obviously weld something up, but most of us don't have that luxury.

Would anyone who has worked out these kinds of problems please post their solutions?

Cheers,  
Alan Gerhardt

Date: Tue, 12 Nov 91 22:35:06 PST  
From: Dave Suurballe <suurb@dumbcat.sf.ca.us>  
Subject: Sunstruck Flavor

The latest Journal of the American Society of Brewing Chemists (Vol. 49 No. 4, Fall 1991) has an article entitled "Sunstruck Flavor in Beer" written by four people from Kirin Brewery.

Predictably, it confirms previous experiments with bottle color:

"The formation of 3-methyl-2-butene-1-thiol increased proportionally to the ability of the bottle to transmit light between 350 and 500 nm."

After this, they experimented with different beers in the same color bottle and noticed something very interesting:

"In dark lager beer, 3-methyl-2-butene-1-thiol was not detected. The quantity of 3-methyl-2-butene-1-thiol formed in lager beer brewed without adjuncts was less than that formed in lager beer brewed with adjuncts. Thus, beer brands contribute more to the formation of 3-methyl-2-butene-1-thiol than green bottles do."

This inspired them to identify the constituents of beer that cause skunkiness in the presence of light, so they concocted various solutions of various beer constituents and tested them. Their conclusion:

"From these results, we propose that the main route of formation could be such that when beer is exposed to sunlight, isohumulones decompose to the 3-methyl-2-butenyl radical, and sulfur-containing amino acids and protein decompose to the SH radical in riboflavin-photosensitized reactions. Both radicals then combine to form 3-methyl-2-butene-1-thiol."

"The riboflavin content in beer appears to be one of the important factors resulting in differences in beer brands in formation of 3-methyl-2-butene-1-thiol. And if riboflavin could be removed from beer, a beer free from sunstruck flavor might be obtained."

Less interesting is their discovery that you can make the sunstruck flavor go away after it is developed by storing the beer for four weeks at 50 degrees centigrade. They didn't say how it tasted after that treatment.

Suurballe

Date: Wed, 13 Nov 91 08:03:16 PDT  
From: Mark James Easter <eastern@ccmail.orst.edu>  
Subject: Homebrew Digest Submission

Greetings! Some friends of mine and I started batches of Cherry Fever Stout and Propensity Pilsener Lager (ala Papazian) last night and we wondered over bottles of stout about a couple of issues.

1. What are the potential impacts of pitching yeast while the wort is still warm? We pitched at ~85-90 degrees F.
2. While sparging the lager, some of the hops made it past the screen and into the carboy. Will this have impacts beyond added "hoppiness"?
3. How much should a homebrewer shake/roll the carboy around to mix in the yeast after pitching? I've heard arguments from two camps, one that says we shouldn't add any more oxygen than we have to and another that says the benefits of thoroughly distributing the yeast outweigh any problems from added oxygen.

I'd appreciate any comments you all might have...ciao.

From: Jean Hunter <MS3Y@CORNELL.A.cit.cornell.edu>  
Subject: Germs and Spores in Honey (HBD 758)

What? Not boil honey? Do you know where that stuff comes from? Ordinary honey is nearly invulnerable to bacterial, yeast and mold infection due to its low water activity (essentially the same as high osmotic pressure), as has been pointed out already on the Digest. OTOH, honey is made outdoors by insects who come in contact with any and every bacterial cell, mold spore etc. that is in the natural environment. Raw honey is full of pollen, dust, plant and insect fragments and the like. Even refined honey which has been pasteurized and filtered still may contain heat-resistant bacterial spores. These spores are the reason why no honey in any form should ever be given to infants under 6 mo. old - Clostridium botulinum spores in the honey have established themselves in the digestive systems of infants, leading to "infant botulism" and at least a dozen deaths since the phenomenon was identified. The lesson here for brewers is that in the case of honey, shelf stability does not imply cleanliness. Oh, and if you're determined to use honey for priming, give it a nice long boil, at least 10 minutes, in as concentrated a form as you can. A quickie one-minute simmer won't do the job, because the most reliable way to reactivate dormant clostridial spores is a heat shock. We use it right here in the lab and it works great to establish a thriving population. Now certainly Clostridia won't thrive in the acidic environment of finished beer, but you might as well be on the safe side.

At this point you might expect a strong recommendation for corn sugar, but upon reflection, I don't know what nasties might be lurking in it, either.

Bottom line, a little obsession( with sanitation) can prevent depression (grieving over a lost batch).

To the homebrewer with poisoned beer, did you sanitize your bottlecaps?

Cheers, Jean.

Clever aphorisms and fancy signature bars are so much noise.

b. sending@hpf (47431)

> Is there an easy process to determine the alpha acid content of  
homegrown  
> hops? If there isn't an easy process, what's the difficult process?

It depends on what you call easy. It's essentially impossible for the  
homebrewer to get at the kind of sophisticated lab equipment that's  
required for an AA test.

Oregon State University will conduct a hops analysis for a fee; I think  
it's about \$40. It requires ~1 oz. of hops.

Interested parties should contact the office of Al Haunold.

From: Brian Capouch <brianc@zeta.saintjoe.EDU>  
Subject: Re: Coriander, leaf or seed?

There is no doubt in my mind that all brewing uses of *Coriandrum Sativum* (the plant that yields both the leaves known in the southwest as cilantro and the seeds known as coriander) would involve the \*seeds\* and not the leaves.

The difference in both flavor and aroma between the two is highly remarkable: one would never know they came from the same plant.

My brewing partner and I were discussing this the other day when one of us observed that indigenous cuisines in which coriander leaves are used also seem to make heavy use of chile peppers: Mexican, Chinese, Indian, and Thai are the first to come to mind. Even though this is only tangentially related to homebrewing, can any of you homebrewers (who, we've found out, often turn out to be cooks as well) think of a cuisine which uses one but not the other? A half-dozen people I've asked so far have been unable to come up with one. . . .

> happens for many home brews: they are harsh at first (green?) and  
> then as they age they mellow out. I think it is the yeast doing it's  
> magic. Comment, Dave Rose, George Fix?

Note that Miller points out that yeast will NOT consume O<sub>2</sub> in the  
presence  
of a high ratio of glucose to other fermentables. This is the situation  
brought about when using corn sugar to prime a batch, for example. This  
is  
also an argument *\*against\** those beginners recipes which call for the use  
of large amounts of corn sugar in place of malt extract. This phenomenon  
is  
known as the Crabtree Effect. (No idea where that name originated!)  
Bottom line: glucose (corn sugar) priming does NOT cure aerated beer.  
Use DME (or equivalent) to prime if O<sub>2</sub> is an issue in the fermented wort.

Cheers,

From: IO10676@maine.maine.edu  
Subject: Yeasts, and ordering advice

First, a question: I have a couple of recipes I'd like to duplicate that involved extract-based kits, usually with other grains, hops, etc. added. However, some of them used the yeasts that came with the kits. Since these dry yeasts are of questionable viability, I'd prefer to use a yeast I can trust, but I want to remain as close to the original recipe as possible.

So, my question is, is there any way to find out what yeast strains these kits supply? Other than culturing them all, which I don't have the equipment for. What I'm ideally looking for is a reference that says something like, "Mountmellick Stout uses the same strain as Wyeast #xxx, Ironmaster Brown Ale uses Wyeast #yyy," and so forth. I know I probably won't get something that nice, but hey.

Second: I recently joined a local food cooperative that carries brewing supplies at nice, low, just barely above wholesale prices. Definitely a Good Thing. However, the person who used to order this stuff has left them, and I got roped into doing the job. So, here's my proposal to the HBD:

Given a budget of, say, \$350, what should a brew supplier order from their wholesaler? Obviously malt, hops, yeast, and accessories, but more specifically . . . Anyway, I'll be drawing up the order sometime next week. Please email me your suggestions; after I make the final list, I'll probably post it to the digest.

Thanks!

Subject: Re: Ads on HBD

Hi, before I too join the Jack/Commercialism thread, I thought it would be good to actually post a few things about homebrewing so...

I need some help. I need a bio-tech. type person in eastern MA/southern NH to run some tests for me. More specifically, I'd like someone to determine the 'purity' of a number of cultures I have. These are not common everyday cultures, and cannot be easily replaced. In fact, they're not even Saccaromyces cultures. To the best of my knowledge they are fairly uncontaminated, but I would like that verified. Further, if I'm wrong, I'll need some isolation work done. Finally, I'd like to have a few master tubes placed in an ultra-low temp freezer. I am willing to pay/barter for these services -- the reason I'm asking here is that a fellow HBDer might not rake me over the coals as much. Anyone interested should send me e-mail for details.

(how about that, HBDS first Help-Wanted)

and something to add to the general discussion:

How does one place a false bottom inside a 15gal keg? I've been trying to figure this one out for a while. I've come up with a number of good techniques, but all of them involve welding inside the keg. I know that someone at the last AHA conference gave a talk on building a 15gal keg-brewery, but I can't remember upon what the false bottom reseted. Does it fit snugly into that lower reenforcing band with some feet for hold up the middle? Does it sit on the bottom weld in the very bottom of the keg?

and finally,  
Al Korz writes  
> Jack quotes Mike--  
> >>FWIW, Jack pointed out that commericalism is OK on Internet so I thought  
> >>I'd just add my \$0.02.  
> I don't think it's OK here.  
> >Perhaps we should post information about this video on a regular basis.  
> Perhaps not, Mike.  
> I'd like to point out that Kinney Baughman is Mr. BrewCap, BrewHeat, > and BrewChiller and has always (to the best of my recollection) been > very non-commercial in his discussions of these products.

Yes, I've dealt with Kinney before, although he might not remember it. I've had nothing but good experiences in dealing with him.

Anyway, on to my main point, are you trying to tell me that you missed that \*entire\*line\* of smilies in my original message? Were you reading the original through a sarcasim filter? Actually, I agree with you about 98%. Generally commercialism on HBD should be avoided, but I do believe it should be ok to use it as a forum for selling surplus or old equipment and the like NOT as a replacement for Zymurgy ads. A while back it was suggested that such announcements be limited to something in the neighborhood of 5 lines. I like that idea.

-Mike

Subject: Re: Draught Guinness in a Can

Draught Guinness in a can is not all that new. They were coming out with it a few years ago while I was still living in England (they used the theme from Hawaii 5-0 to promote it. That was a kick).

Every time I go back, my ex-girlfriend's dad stocks the fridge with them. I just have to drink it out of courtesy, and he just feels obligated to finish off what I can't :-].

But seriously, it tastes pretty good and is worth a couple bucks to try just once. Now that it's coming to the U.S., I'm hoping to do the same.

From: Tom Dimock <RGG@CORNELL.CIT.CORNELL.EDU>  
Subject: Chillers redux

Some comments and a question or two on chillers.

I have been very interested in the relative merits of immersion and counter-flow chillers, and thought it might be useful to summarize some of that information as background to a few questions.

Speed of chilling: It sounds like either type can chill a five gallon batch in 15 to 20 minutes, the important distinction being that with an immersion chiller this is a parallel process (each little bit of wort takes the same time to cool) whereas the counterflow chiller is a serial process (each little bit of wort cools in a matter of seconds, but they have to wait their turn). Also, with a counterflow chiller, the wort is protected from oxidation and contamination during the entire time it is being chilled (assuming the chiller is properly sanitized). Here I would definitely give the advantage to counterflow.

Cold break: If I understand correctly, this is a function of how fast the drop in temperature happens. Advantage counterflow.

Ease of sanitizing: The immersion cooler can be put in the boiler for the last part of the boil. The counter-flow must be either pre-sanitized, or you can run some of the boil through before turning on the chilled water (I don't think I'd trust this, myself). Some folks have indicated a certain nervousness about how you make sure that the inside of a copper pipe is really clean - it's really hard to see in there! Advantage here goes to the immersion chiller.

Cost: Depends a lot on your construction techniques and skill at scrounging. A counterflow chiller is more work to put together, and involves more fittings, but it uses less copper tubing. Immersion chillers are both more available and cheaper from commercial sources. Probable advantage: immersion.

Efficiency of water use: Dead heat. Both can recirculate water if you live in a place where that's a problem.

Separation of wort from trub/cold break: Here is where I have a question or two. The immersion chiller has no problem here - you can whirlpool the cooled wort and then siphon off carefully, leaving most of the trub and cold break behind. With the counterflow chiller, the trub can be left behind, but the cold break would seem to end up in the primary. So how do you counter-flowers out there deal with the (very good) cold break? Do you just ferment on top of it, or do you use an intermediate vessel where you can whirlpool and aerate and then rack to your primary?

beer.  
> Marilyn liked everyone she tasted better than the last one. I  
naturally  
>^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^  
> liked mine best. In spite of this, I let her drive home.

Wow! Who is this Marilyn and what does it take to get her to one of our tastings! This truly was a Bacchanalia in every sense of the word, huh? (Yes, I know what you meant..."every one" and not "everyone", but couldn't resist the humour possible).

Seriously, though, about your post, I think it's great that you actually tried this oxidation experiment. I, too, have never noticed the awful effects of oxidation when I know I screwed up somewhere and splashed a lot. However, I'd also have to ask about your experiments concerning the storage conditions. As we all know, certian reactions (well most reactions) exhibit a temperature dependant rate. Depending on at what temperature these beers were stored, you may not notice any effects. Further, there are actually two problems with splashing, as I understand it. First, there is oxidation. Again, as I understand it, this is really only a concern while the wort is really hot. Oxidation is a chemical reaction. Then, there is aerobic activity, which is caused when yeast get exposed to oxygen while fermenting. This is a biochemical reaction. How would one structure experiments in order to isolate one effect from the other? I don't know for sure about that, but I think it would have been interesting if you'd actually abused 9 bottles, stored 3 batches of 3 at various temperatures, and opened one from each batch of 3 over time. You can't flame someone for noticing oxygen effects if they're storing their beer at 85F and you have yours in a cold room.

SECOND TOPIC : Gloaters...

I'd like to take an opportunity to thank all who suggested things to do, beers to drink, etc... in my somewhat recent request for information of Belgium and Germany. Also, I guess, I'd like to gloat!

We spent 5 days in Belgium followed by about 10 days in Germany. German beer is very good, for what it is, but is far less "interesting" than the stuff in Belgium...ergo...reccommendation. Go to Germany first, then Belgium. The beer highlight in Belgium had to be the Kulminator. For you gloaters paying \$5 for Duvel at Weinkeller, I had a 1985 Stille Nacht for less, and a 1980 Chimay Blue for \$7. This place is absolutley fabulous for variety. Also excellent were Liefmans Goudenband and Rodenbach Grand Cru. Of course there were several others including Orval, several frambois'es, krieks, gueze's, etc...

Apparently there is a bit of controversy over a recent decision to start filtering Duvel...in any case, the stuff I bought here had yeast in it, the stuff over there did not. One thing you notice for sure is that something horrible often happens to this beer in transit when they import it, because it all tasted better over there (and it wasn't just atmosphere).

Germany was fun too. We visited both Hofbrauhaus and Andechs. The four in our group thought the Hofbrauhaus was a lot of fun, but both the beer and atmosphere at Andechs were better. We also had the opportunity to have real Budvar Budweiser on tap, which was quite good. Someone here made mention of these brewery hotels in this forum. We stayed one day at Hirsch hotel/brewery in Ottobeuren. Some of the beer here was not good; however, both the light and dark spezial made up for this. Also, if anyone is going over there, or if the person who's keeping the database of pubs/ etc... wants to know about it, we picked up a whole little booklet about brewery hotels all over germany while we were there. I wish I could actually list the beers we tried, but they are far too numerous to even remember. The best part of German beer, or better stated, the part we enjoyed the most was getting fresh Weizen and Dunkel Weizen, as that is what is most difficult to come by in this part of the states. One more note...although this is a beer forum, if you're driving through the wine regions and enjoy wine at all, don't miss a chance to taste some wonderful wine and experience great atmosphere all for a reasonable price.

Overall, we were able to bring back 27 assorted bottles of beer of varying sizes and styles, much of which was bought at Maroun Markt - the largest beer market in the world. It's like going out and buying a case of Bud here to go there and buy a case of Weizen.

FINAL TOPIC : Porters...

Another side advantage of the recent trip was that when I came home, two batches of homebrew that were bottled before we left seemed to age gracefully. We had made a weizenbock and a porter. The latter had me worried upon initial tasting because I used a pound of black patent as someone else did in the Winners Circle. The initial tasting of this beer indicated that there was far too much black patent. Now, though, either my taste buds are accustomed or this beer aged very nicely. So what I'm asking is how much dark grain do the rest of you porter lovers use and what do you feel is the optimal "time in bottle"?

From: Rob Malouf <V103PDUZ@ubvmsb.cc.buffalo.edu>  
Subject: Blow off, blow out, blow by, blow up

>An important point here is to do those things that you deem important  
>to improving your beer, given your own personal experiences. My early  
>homebrews (pre-blow-off) suffered from a bitter astringency that I  
>found objectionable. The first beer I tried using the blow-off method  
>didn't have it and I've never gone back.

It is finally time to retire my old plastic fermenter, and I am trying to  
decide whether to start using the blow-off method. My first brews also  
suffered from a bitter astringency (to say it was "objectionable" is an  
understatement). As my skill as a brewer increased, the harshness faded.  
Now

that I have switched to all-grain brewing, there is no hint of that old  
harshness left (so all the other flaws come through clearly!). I wonder  
if the  
blow off method is like a long aging period for ales. A month or so in  
the  
basement greatly improved those old harsh ales, but now my brew is  
drinkable as  
soon as it's carbonated. Perhaps the blow-off method allows the beginner  
to  
get away with not-so-great brewing technique. Has anyone ever stopped  
using  
the blow-off method once they became "expert" brewers? Then again, maybe  
all  
those early brews permanently desensitized my tongue, and I just don't  
notice  
the astringency anymore.

From: pyle@intellistor.com (Norm Pyle)  
Subject: Ales, Lagers, Beer

To Micah Millspaw:

I think most people in this forum know the difference between a lager yeast and an ale yeast (and therefore the difference between a lager and an ale). It is easy to stereotype, though, since most lagers running around (the US anyway) are lighter recipes, and most ales (who are greatly outnumbered) tend to be darker and more full-bodied. The point is well-taken but has it really been that prevalent on the hbd?

To All:

With all of the microbreweries popping up around, does anyone know of a job opening? I'm thinking of maybe an apprentice taster position... 80)

Keep on Brewin'

From: sean@evi.com (Sean Conway)  
Subject: Trouble shooting bad beer...

I thought it would be useful to list some common problems of bad beer and what MOST LIKELY could be the reasons for why they turned bad. None of these quotes are my own but come directly from Charlie Papazians' first edition of the "The Complete Joy of Home brewing" (my bible).

BTW: Bravo to "BAUGHMANKR"!!!

\*\*\*\*\*  
\*\*\*\*\*

All excerpts from TCJOHB by Papazian are in quotes (just protecting myself. I dont want to become another Joe Biden or the Joaquim ? from BU)...

#### CIDERY FLAVORS

"The number one reason why homebrewers may brew a cidery flavor beer is that an excessive amount of corn sugar and especially cane (or beet) sugar is used."

#### SOUR FLAVORS

"Bacterial infection often enhanced by warm brewery temperatures and sluggish fermentations are to blame for sour beer."

#### MOLDY BEER

"Moldy beer is the result of inadequate cleaning of equipment and undue exposure to microorganisms. Mold also is more likely to develop with inapprpocate lagering (aging) at temperatures above 60 degrees F (16 C)."

#### CLOUDY BEER

"The problem is, again, another kind of bacterial infection. It isn't the fault of the malt nor the sugars, and unless you are using very old or contaminated yeast, it isn't the yeast's fault either."

#### FLAT BEER

"I don't know of a reason unless you've left an excessive amount of sterilant in your bottles or you are storing your beer at excessively cool temperatures."

My \$ 0.02 cents worth - you forgot to add priming sugar... OR its the morning after the frat party and you are drinking the leftover beer out of the keg.

#### OVERCARBONATED BEER

"The simple explanation is that you've added too much priming sugar."

#### STRANGE AFTERTASTES

"If you've got 'em, either leave those baby diapers out of the brew  
of keep the risk of bacterial infections to a minimum."

A FAMOUS DADILY - he who brews with diapers may get bad beer. Anyone  
want to try experiments

APPARENT PREMATURELY STUCK FERMENTATION

"More often than not you're worrying... Aeration of the wort and  
choice  
of yeasts will make some difference, but usually minimal. Roll with  
the punch and bottle when fermentation has stopped or is negligible."

\*\*\*\*\*  
\*\*\*\*\*

Hope some people of there find this summary usefull!

Somehow this got garbaged in #760, I'm trying again :-/

Russ suggested:

>...that brewer's yeast and garlic will keep  
>away bugs, like mosquitos and black flies, and fleas too so give some to  
your  
>dog/cat.

OK for dogs, but apparently it can be a very effective way to kill a cat.  
I have this from a veterinarian who has watched too many cats die in the  
arms of their owners after they had been `treated' at home with garlic.  
Apparently it does bad things to their blood (exactly what, I don't  
remember).

I know it doesn't have anything to do with beer, but I couldn't let it  
pass.  
(we've got four cats at home and they're all very special to me)

From: Bob Jones <BJONES@NOVA.llnl.gov>  
Subject: Cardboard Nose

Thought I'd pass on a recent experience with cardboard nose beers. I helped judge last week at the Calif. All State Homebrew Competition. This comp. is always well run and great fun. Lots of brew discussions, food, music and of course BEER. Great job again this year! The San Andreas Malts won the coveted homebrew club of the year award this year. They deserve it. When I got there I noticed they were using glasses for the judging samples instead of plastic cups. I was relieved to see Steve Norris busy rinsing that cardboard smell out of the glasses with a hot water rinse. Since Steve don't enter competitions anymore, they make him do the dishes. Anyway the first few beers we judged had a distinct cardboard (sometimes almond like) nose. I knew it couldn't be the glasses I saw them being rinsed and they smelled clean prior to pouring. I ran into this same thing at the Calif. State Fair comp. 2 years ago. If your sensitive to this smell, its like judging next to someone who is smoking. I got a plastic cup and we poured the next beer into a rinsed glass and the plastic cup, and the smell was only in the "rinsed" glass. I don't understand what is going on here but it ain't good for beer competitions. I stayed with the plastic cup for the rest of the judging, rinsing after each beer. Maybe the smells get released when the beer hits the glass do to the alcohol or ph or something. I think all competitions should switch to clear plastic cups to prevent this problem. What the hell their cheap.

I have been advised by constructive critics that responding to the likes of you may satisfy my ego but serves no useful purpose.

Instead of responding to your hateful rubbish in public I will let this one pass as a test of your sincerity.

From: "Rad Equipment" <rad\_equipment@rad-ma1.ucsf.EDU>

>Jack, as far as "you" are concerned your beer has never tasted like cider or cardboard. These are flavors (along with many others found in beer) which different people have different sensitivities to. This is why I suggest you have an independent palate, preferably one that has experience with homebrew, taste your experimental brew against your control batch.

I did just that and posted the results yesterday. But more to the point, another beer that I have been calling clove-like, they declared, "banana". It was instant and unanimous. I was dumbfounded. I have sniffed and tasted it a hundred times since and still call it clove without the slighted hint of banana. Marylin, BTW now agrees with them.

Subject: Sir Kenelm Digby, Kt. -- and ?Quinine Beer?  
Message-Id: <CMM.0.90.2.689911817.gal2@ellis.uchicago.edu>

Hi all. First, thanks for all the help with my little questions. My Wyeast got going the very minute I sent my last panicky note. (All it took was a little of that Preventitive Murphy's Law.) I got a good deal on a carboy: \$5 a pop at Bonne Sante in Hyde Park. They don't have them very often though. Call ahead.

Now, another recipe from The Closet of Sir Kenelme Digbie, Kt. Opened (London: H. Brome, 1669) since the last one seemed quite popular. This is from page 94. (Reproduced without permission, naturally.)

A RECEIPT FOR METHEGLIN OF MY LADY WINDEBANKE

Take four Gallons of water; add to it, these Herbs and Spices following. Pellitory of the Wall, Sage, Thyme, of each a quarter of a handfull, as much Clove gilly-flowers, with half as much Borage and Bugloss flowers, a little Hyssop, Five or six Eringo-roots, three or four Parsley-roots: one Fennel-root, the pith taken out, a few Red-nettle-roots, and a little Harts-tongue. Boil these Roots and Herbs half an hour; Then take out the Roots and Herbs, and put in the Spices grosly beaten in a Canvass-bag, viz. Cloves, Mace, of each half an Ounce, and as much Cinnamon, of Nutmeg an Ounce, with two Ounces of Ginger, and a Gallon of Honey: boil all these together half an hour longer, but do not skim it at all: let it boil in, and set it a cooling after you have taken it off the fire. When it is cold, put six spoonfuls of barm to it, and let it work twelve hours at least; then Tun it, and put a little Limon-peel into it: and then you may bottle it, if you please.

This one definitely sounds like Fun. Are there any opinions about why one shouldn't skim this one? I don't see any source of yeast in here. No clarifiers or eggdrometers either. If I can actually find all those Roots and Herbs, I'll let you folks know how it turns out.

I have one other question (which I could probably do some research on instead but I think there might be some interest in this here, maybe):

Has anybody out there heard of or seen, tasted or made beer with quinine as an added flavoring? I really like drinking tonic water straight, so this idea intrigues me. Maybe I'm weird, so what?

Here is the address to complain to:

Subject: London Inns

Warning: this isn't exactly homebrewing, but it's related...

Does anyone have a copy of the CAMRA guide to Inns? I'm not sure of the exact title, but I've seen it mentioned in the Good Beer Guide. I'm looking for recommendations for a place to stay in London with an excellent pub on premises.

Traveler's Tip: you can drink later in a pub if you are a 'resident' of the attached inn.

So this message isn't a total waste of bandwidth, let me recommend the following inn:

Traquair Arms, Innerleithen, Scotland. The name says it all. Bear Ale on draft, and Traquair House Ale in bottles (try a mixture). Decent restaurant. The castle is just outside of town. If you visit the brewery, say 'hi' to Ian.

stories  
> the press could come up with about people getting cadmium poisoning as  
a  
> result of drinking, or making, homebrewed beer and/or brewing  
equipment.

I recall reading a story some years back about a family who received  
cadmium poisoning by using refrigerator shelves as barbecue grills!!  
Apparently the metallic coating on the shelves contained cadmium, which  
was absorbed into the food as it cooked. Don't remember any other  
details,  
but ever since I've avoided placing raw food, such as fruits or veggies,  
directly on the refrigerator shelf just in case.

Can anyone comment about this? It's a bit off the subject, but surely  
worth any enlightenment possible due to the seriousness of the effects.  
All I can say is that whoever decided to use cadmium in a product such  
as refrigerator shelving has to be criminally stupid, imo. Not that the  
person who decided to use them for grilling was being real smart either.

I don't know if cadmium is still used this way, but I surely hope not!!

I'd think that with your stated goal of helping bring newcomers into the  
homebrewing hobby you would naturally want to tell them how to get in  
touch  
with the AHA. It is, after all, the largest homebrewing association in  
America, if not the world, not to mention a tremendous source of useful  
information. Even if you don't care to join the organization yourself,  
it  
would seem sensible to at least inform your viewers of its existence.

OK, if it is impossible for homegrowers to determine the AA content of  
your  
hops, how do you figure out how much of your hops to use? Many recipes  
call  
for x amount of bittering units. Do you just guess?

From: jmill@anubis.network.com (Jeff J. Miller)  
Subject: licorice root, multiple bottle filler

Re: Pauls suggestions for licorice root:

I have used both licorice root and stick in brewing porters - very fine!  
When using the licorice root be sure to bruise it (beat the hell out of  
it with a hammer) to be sure the veins will be exposed to the beer. I  
believe I used 3-4" in a 5 gallon batch.

Question about multiple head bottle fillers:

Anybody got the scoop on a multi head filler? I've seen adds for some  
but I always tended to stay away from them because I thought they would  
cost too much. Then again, I always thought I would make my own but  
thats  
another story.

> From: Jeff McGowan <MCGOWAN@esb.com>  
> ..... how do commercial breweries which produce naturally carbonated  
beers  
> which are not bottle conditioned get the carbonation in the bottle? Do  
they  
> do part of the fermentation in a sealed container to carbonate the beer  
> before bottling, then bottle under pressure after filtering?

This brings up an interesting point. Just what is meant by "naturally  
carbonated" in the commercial sense. I know of one case where a beer is  
touted  
as naturally carbonated simply because it is not mixed with deoxygenated  
and  
highly carbonated water on its way to the bottling line (a process  
employed by  
the big breweries). The fermented beer is cold-filtered and placed in  
cold  
storage where it is allowed to carbonate slowly under constant CO2  
pressure. It  
is then bottled under pressure. This avoids having to filter carbonated  
beer  
under pressure which would create obvious problems.

The Okanagan Spring Brewery in Vernon, British Columbia, Canada, bottles  
just  
like the average homebrewer .... yeast and all!!! Doesn't seem to stop  
the  
customers. I guess quality beer sells itself. ;-)

From: Frank Tutzauer <COMFRANK@ubvmsb.cc.buffalo.edu>  
Subject: The Color of Beer

Help me with the colors of my beers. I know SRM is a measure of color-- I've even read about it. But for the life of me I can't remember where, and I can't locate anything in any of my books, digests, or Zymurgys. (Of course, that doesn't mean it's not there--I just can find it by using the indices, tables of contents, and relatively detailed perusal.) So question number 1: What's SRM, how is it measured, etc.?

Second: I'm trying to produce a beer about the color of Anchor Steam. The recipe I'm using only has light dried malt extract, a little bit of pale malt, and 2 cups of crystal malt, so it's primarily the crystal that's responsible for the color. I only have available to me 60 Lovibond crystal and 120 lovibond. Last time, I used all 60L and it was too light. I have since learned (from the most recent Zymurgy) that the color I'm shooting for is 11-13 SRM (whatever the hell that means; see question number 1). So, question number 2 is: Assuming I only want to use 2 cups of crystal, how do I get 11-13 SRM? Do I use all 120L or some combination of 60 and 120? What combination would that be?

thanks,  
- --frank

p.s. If you'd have told me that by batch #7 I would be worrying about esoteric things like the exact color of my beer, I'd have told you you were nuts. But, hey, I guess the learning curve's steep.

> water-softener which strips most of this stuff out and replaces it with  
salt.

I also have very hard well water. I do have a sediment filter  
for iron and other sediments which does an excellent job.  
I don't use any additives to the water to change the hardness.  
Also, I only boil about half the water. I fill the primary right out  
of the tap and have had no problems with bacteria in the beer.  
It works for me. If it ain't broke...

On an non-brew related note:

As far as the dissolved oxygen is concerned, I had a similiar  
effect, that turned out be be a hole in the diaphragm of my pump  
tank. The tank is supposed to be pressurized @ ~30psi. I discovered  
the hole when one of my neighbors noticed my pump cycling on and  
off alot and recommended checking the pressure in the tank.  
I pumped the tank up which caused my water to have short lived  
effervescence. A couple of well/pump companies told me this is  
typical of a bad tank. I had the tank replaced and the effervescence  
went away and the pump cycled correctly.

Do you neighbors have a similiar effervescence in their water?

Neil Mager

From: kla!kirkish@Sun.COM (Steve Kirkish)  
Subject: Up Yoors Coors (A bumper sticker, not a flame)

On my way into work the other morning I passed a big 'ol pick-up truck with the following bumper sticker on the back end:

```
-----  
| UP YOORS COORS! |  
|   Boycott Coors   Non-Pasteurized Beer |  
-----
```

I couldn't tell who sponsored the message (maybe "Friends of Louis Pasteur?") and I wondered why this guy preferred his beer roasted on an open fire or nuked or whatever is done to heat-pasteurize beer. I can just picture this guy making his own homebrew..."Hey, honey, how long am I supposed to leave the beer in the oven???"

Which actually raises some questions:

1. Why would a beer be pasteurized? As a yeast-icide method? Won't heat affect the flavor of the beer? Is this why Coors "cold-filters"?
2. At what point in the process would a brewer pasteurize his beer?

This is particularly sad/humorous since Pilsner Urquell (arguably the  
"Ur-pilsner") is bottled in green glass. One might argue that brown  
bottles are out of style for pilsner!

Had a nice glass of Urquell at the Ann Arbor Brewer's Guild last  
night. The person who brought it had bought a whole, unopened case  
from a new shipment (so it was presumably as fresh as it would get).  
There was no hint of skunk at all.

From: Frank Tutzauer <COMFRANK@ubvmsb.cc.buffalo.edu>  
Subject: corriander and chile peppers

Brian, noting the connection between cooking and homebrewing, asks about cuisines that use chiles, but not corriander, or vice versa:

Yeah, you're right. A lot of homebrewers cook. I got started cooking first, and picked up homebrewing second. I'm pretty expert on Chinese, and ok on Indian and Thai. I can't comment on Mexican. You're correct, the three Asian cuisines use both chiles and cilantro (corriander). I think it's just an accident of geography. Also, keep in mind that Chinese is a very varied cuisine, and although cilantro is pretty widespread, chiles are used in any significant quantities only in Szechuan and Hunan cuisine, but very little or not at all in Cantonese, Fukienese, Tawainese, Shanghai, and Mandarin cuisines, although these latter types do make use of cilantro. In Indian and Thai, both chiles and cilantro are everywhere. The seeds, roots, and leaves are all used in Indian and Thai. In Chinese, it's primarily the leaves.

Now, here's a cuisine (another one I'm fairly expert at) that uses chiles, but not cilantro: Cajun and Creole. Both Cajun and Creole use a lot of chile, primarily cayenne and tabasco peppers, but virtually no cilantro. Cilantro just isn't cultivated in Louisiana.

I would also be tempted to say that real Southern Barbecue is a cuisine (yes, I would define it as a cuisine) that uses chiles, but not cilantro, but the importance of chiles in BBQ is arguable, so maybe this shouldn't count as an example.

Ok, enough non-homebrewing talk. I'm taking it to email.

YES, YES, YES, Glass carboys are an evil thing!

> - It's easy to clean.  
> - It doesn't scratch like plastic.  
> - Doesn't soften, crack, or break when hot wort is poured into it.  
>  
> Doesn't anyone else use a SS fermentation vessel?

I've been fermenting in SS for about a year now and absolutely love it. I use the standard 3 and 5 gallon cornelius soda kegs. These have all the aforementioned advantages in addition to;

- 1) Convenience in racking, as George Fix followed up on.
- 2) You can force carbonate your beer in them.
- 3) The beer is ready to serve from the keg when conditioning is complete.
- 4) They are endlessly durable.
- 5) They don't explode or produce beer volcanos.

In HBD 758 George Fix adds;

> My interest in half kegs stemmed from the following:  
>  
> 1.Geometry- In the late 1940's deClerck studied fermenter shapes and  
> ...  
>  
> 2.Kegging- Much has been written in Zymurgy and elsewhere about the  
> value  
> of closed systems of transfer, where beer is pushed from one vessel to  
> another  
> by CO2 pressure. This can be done with half kegs ...

Your use of 1/4 bbl beer kegs has peeked my interest. As is obvious I think highly of stainless steel and the use of standard beer kegs as fermenters is something I would like to pursue, at least in theory if not in practice. Questions:

- 1) What type of beer kegs are you using; Sanke, Golden Gate, Dual Probe?
- 2) How do you handle the racking of beer? Do you use a simple racking tube, or some kind of closed transfer system based on the kegs original design?

> ... particularly if Cornelius or Firestone soda pop kegs are used for beer storage. ... The first part of the flow out of the fermenter will come from the top of the yeast sediment. ... This should be discarded until a clear flow is evident.

Another method which I've described before (as well as others) is to shorten the liquid dip tube. I have mine shortened 1 inch. This is a fairly good average. Sometimes it leaves a little beer behind, but zero sediment is picked up. Other times I have to discard the first cup when trub and/or yeast levels are high.

I've just ordered an extra dip tube and I'm planning on cutting it at 1/2 inch. This I will use when racking beers from a secondary fermentation/settling tank to it's final serving keg.

One thing I have noticed when the level of trub/yeast is higher than bottom of the dip tube is; not only is the first cup of beer transferred laden with sediment, but the last cup is as well. Thus I recommend the use of a dip tube which is above the level of sediment when possible.

George continues:

> There is alas a downside to stainless. First, stainless generally means "less stain" and not "no stain". Chlorine is very aggressive to metal if left in contact for a sufficient length of time. Sterilizing with boiling water having a high iron content can have the same effect. ...

This I did not know about. I frequently use boiling water to sterilize my kegs. I consider the use of boiling water to be another advantage to the use of stainless steel. I did not know that this could be harmful to them. I'll have to pull out a flashlight and examine the insides of my kegs for rust spots.

> An alternative sanitizer that is finding widespread acceptance for stainless is iodophor (1.75% iodine, 18.75% phosphoric acid). ...

What about "B-Brite"? Although I can't remember what chemicals are used in it, the label does have them listed. Do you know of any downside to using this product?

When I want to give my kegs a good cleaning I disassemble the connectors and lid parts, fill the keg with a B-Brite solution and then place all of the parts inside. This I let sit for about 15 to 20 minutes, while bringing two gallons of water to a boil. After rinsing off the B-Brite and reassembling the keg I then proceed with the boiling water treatment. This is what I typically do in preparing a primary fermenter.

And there is another downside to stainless steel; you don't get to watch the furry of the primary ferment as the yeast goes to town. Purely an aesthetics issue though.

From: krweiss@ucdavis.edu  
Subject: YAY!, Wyeast Irish ale bottle attenuation

First, I'd like to sound a loud cheer! HBD 761 was the first one in weeks that contained almost nothing that I had to page through without reading. Ahh, sweet normalcy. I still find it hard to believe that the writings from George Fix and some of the other stuff that's been posted here lately were from the same digest. Hell, it's hard to believe they originated from members of the same species.

I'd like to get some opinions from people with experience with Wyeast Irish Ale (stout) yeast. I made a total of four batches in a row with this yeast -- high gravity, highly hopped beers. I was aiming for a very full bodied beer, with the residual sweetness cut by a high hopping rate. From a flavor aspect, I got what I was after. However, all four batches refused to carbonate to any significant degree, even after I went to a full cup of corn sugar for priming. As soon as I switched yeast to the American Ale (Sierra Nevada?), I was able to drop back to my usual 1/2 cup of priming sugar.

Has anyone else found that the Irish Ale yeast is a very sluggish performer in the bottle?

Oh yeah, to Jeanne Sova, Red Tail Ale is great. It's in the general Sierra Nevada family, but if my addled memory serves, it has more body, and the balance is shifted towards malt and away from hops. It's still a highly hopped beer, just less so than SNPA. I dunno about shelf life. Skunks??? Who brews with skunks?? Don't they clog the blow-off tube? :-)

From: gjfix@utam.uta.edu (George J Fix)  
Subject: leigh-williams liquid bittering hops

Subject: SS Fermenters (G.J. Fix)

I have had a number of e-mail messages asking for more details concerning how half kegs (sometimes called pony kegs) can be used as fermenters. The following are some additional remarks.

All major commercial brewers use the kegs for draft beer. Each has a slightly different shape, but all are essentially the same. In particular, all use the same disconnect, and this can be obtained at a draft beer outlet along with the keg. The kegs used by Millers have rubber insulation around their outside which is an extra bonus.

To break into the keg for the first time one does the following:

1. Attach the disconnect to the keg outlet at the top. Move the rod on the disconnect to the open position and let the foul stuff escape. You may want to attach a hose to the beer port on the disconnect before doing this.
2. Remove the disconnect. Then use a screw driver to remove the SS ring in the outlet. This may take some practice, but you will quickly learn how to do this in minutes. There is a tool for this, but it is expensive (\$75-\$80), and is not needed.
3. Once the ring is removed, the SS tube in the outlet can be lifted out. This leaves an empty keg with a 2" diameter hole in its top.

For fermentation, an appropriate rubber stopper can be added to the mouth of the outlet, and this can be used to mount an airlock or blowout tube. Welding or other modifications of the keg is not needed. The stopper should be replaced with the SS tube near the end of the fermentation.

For transfer one does the following:

1. Seal the tank by adding the SS ring. You will need some pliers for this.  
As above, with a little practice you will be able to do this in minutes.
2. Attach the disconnect to the fermenter.
3. Attach a hose from a CO2 supply to the gas port on the disconnect.  
Attach another hose to the beer port.
4. Turn on the CO2 supply and then move the rod on the disconnect to the open position. When a clear flow is obtained, it should be stopped and the beer line hose attached to a disconnect on the receiving tank. (Cornelius or Firestone kegs are ideal for the latter.) Move the rod on the disconnect back to the open position, and the receiving tank will start to fill.

Other thoughts:

1. The CO2 supply should have a regulator attached. Only 10-12 psi is needed to induce the transfer.

2. Don't forget to purge the receiving tank with CO2 before transfer.

3. There will be some yeast carry over to storage, but this is desirable.

They will keep the beer "alive" during storage. There should also be ample yeast left in the fermenter for collection and repitching if that is desired.

4. Don't forget to vent all CO2 out of the keg before you attempt to reopen it.

Iodophors can be obtained from Diversity Chemical. Call 313-281-0930 to get the name of a local distributor. Tell the latter you are doing small scale pilot brewing for possible commercial application at some point in the future, and would to test their product. They will then sell it to you a gallon at a time which is practical for us, as opposed to a drum which is not.

P.S. John> Soapy flavors generally come from fatty acids produced during fermentation. Normally they will be reduced to well below their flavor threshold by the end of the fermentation. If detectable, and soapy is an excellent descriptor for these constituents, then this is a good sign of disfunctional yeast or yeast approaching this state.

Subject: Digby's Metheglin

There is a source of yeast in the recipe, the barm.  
It's the krausen from some other batch.

I wonder if this is related to describing someone as `barmy',  
meaning maybe `froth-head' or maybe affected by beer? Brits?

From: Bob Jones <BJONES@NOVA.llnl.gov>  
Subject: Fruit Beer

I've noticed a lot of discussion about fruit beers and meads. There are many ways to use fruit in beer but only a few are very efficient.

My experience with the use of fruit in beer comes from doing recipe formulation for the commercial beer industry. Effectiveness and cost are important factors when you have to sell your product.

The type of yeast to use is not as critical in fruit beers as in other styles. This is because the fruit flavours and aromas tend to mask most primary yeast characteristics. The main thing to consider is the attenuative nature of the yeast that you choose. Leaving some residual sugars can enhance the effect of most fruits. Both lager and ale

yeasts work well. I recommend against wine yeasts as they tend to ferment out to well, making a too dry beer.

Next, to the subject of fruits. Your selection of fruit to use in beers is very crucial as some types much easier to use than others. Most berries and stone fruits are easy to work with. The seed fruits such as apples, pears, oranges and the like are pulpy and difficult to prepare, I do not recommend them for beginning fruit beer brewers.

When selecting a fruit flavour keep in mind what is in season and what is available in concentrate form. Concentrates are much easier to use than whole fresh or frozen fruit. Fruit concentrates can be purchased at winemaking supply shops in a variety of flavours. Concentrates work best when added directly to the fermenter. Whole fruits should be crushed or liquified. These may be added as is to the fermenter or they can be pasteurized if you feel that it is necessary to your mental well being. The majority of wild microflora found on fruit do not compete well in the fermentation environment. Always wash the fruit thoroughly before using. It is safest to add the fruit 2-3 days into the ferment to insure your yeast has the upper hand.

Fruit may be pasteurized by placing it in a pan and heating to 160F you must stir constantly sticking or jelling. Hold at 160F for ten minutes then cover and cool by immersion. When cool add to fermenter.

Haze in the beer from the fruit can be reduced by racking to a third vessel (or the second back to a cleaned first), use of anti-pectic enzyme (brand name PECTINOL available from home wine making shops), and if you using a kegging set up, sub-micron filtration or all of the above.

As to a base beer any thing you want can be made to work, and will taste great (maybe?). If your goal is to make a beer whose primary feature is a fruit flavour/bouquet the base beer needs to be nonassertive. (cherry stouts are great but they are still mostly stouts, OK) Use of crystal and dextrin malts in the base beer will help retain some body. The fruits tend to thin out a beer and the unfermentables can balance it out. Hopping levels should be kept low so as not to mask the fruit.

If it is possible to find fruit essences in the flavour your using these will greatly enhance the bouquet and flavour profile of your beer.

The essence should be added at the time of bottling or kegging. If you plan to filter your beer and the essence afterwards as it is possible to filter it out.

I hope this information is of use to some of you, if you more specific

questions post them or email to Bob Jones, I'll get them. And we can discuss making fruit and spiced meads if anyone is interested.

Well, I can answer some of my own questions:

The CAMRA book is called 'Beer, Bed & Breakfast'.

Based on recommendations in this book and a couple of others, I made reservations at Ye Olde Windmill Inn, in Clapham (SW4), just SW of central London. The lodging is in the former home of the founder of Young's brewery. The pub is tied to Youngs (surprise), and near the brewery. It is supposed to be haunted. It is reasonably priced. I'll let you know how it turns out.

Subject: Chillers, Papazian Trouble Shooting.

Tom Dimcock sez:

>Also, with a counterflow chiller, the wort is protected from  
>oxidation and contamination during the entire time it is being  
>chilled (assuming the chiller is properly sanitized).  
>Here I would definitely give the advantage to counterflow.

Nice summary Tom. I would object to your use of the term oxidation here. To my (perhaps incorrect) understanding, oxidation is a process whereby oxygen is introduced into the beer during and/or after fermentation. Aeration, ie mixing in of oxygen (ie air) is more appropriate here. Of course the thing you want to avoid (don't think you made this clear) is the aeration of the HOT WORT.

In this respect I don't think there is a substantial difference between the two, as in the counterflow a substantial volume of beer stands hot waiting for it's turn, while in the immersion the entire volume reduces temperature evenly. Here I defer to Mr. Fix, who if I recall correctly warns against the aeration of the Hot Wort, so as long as care is taken to leave the pot (whether it be hot wort being siphoned, or immersion chilled) covered and unagitated, this danger is not extreme. Of course once chilled, aeration is desirable.

Perhaps I am just picking nits here, and this is indeed what you meant, but I thought this was important and merited clarification.

Sean posted a bunch of Charlie P Quotes from the first edition, and with all due respect to Charlie and Sean, I'd say that much of that is useless and/or out-of-date. A much more useful source of troubleshooting info is the Zymurgy Special Troubleshooting Issue. Perhaps some of this made it to the NEW edition of Papazian.

The comment on cloudy beer, was certainly inadequate. Non-flocculating yeast, Chill Haze, there are many reasons for cloudy beer, infection being perhaps the least common of them. Flat beer, unhealthy yeast will often ferment OK in the primary, but give out after bottling, also as Sean pointed out insufficient priming. Overcarbonated beer, here is one where bacterial infection can be a

culprit, but that isn't mentioned. Etc... the point was TCJOHB was a good  
book  
but I'm sure the New one adds a bit to places where the original was too  
short  
(or too flip) to be of use.

From: gkushmer@Jade.Tufts.EDU  
Subject: Old Carboy, new problems (Part II)

I took the wise advice offered to me from some digest readers and soaked a sixty-year old bluish-tinted carboy in a strong chlorine-bleach solution.

After a few days of this, the carboy now has more of a greenish tinge to it. That, and the dirt on the inside has entirely dissolved and went away with the water when I poured it out.

New Problem: There must have been a ferric pebble on the bottom because a close examination spotted a rust spot. I've tried scrubbing with a brush and am now soaking it in a strong ammonia solution.

Any other advice on what to do? If the spot does not go away, would it affect wort? I was thinking of maybe using it for a very long mead since I wouldn't be investing much and it would get some use.

Then again, I could use it as my grandfather did - throw in some water and food coloring and let it sit in the sun on the steps for aesthetics (Maybe not).

Thanks.

From: Jay Hersh <hersh@expo.lcs.mit.edu>  
Subject: Plastic Cups

Bob Jones mentioned his experience vis-a-vis glass vs. plastic.  
What kind of plastic was used Bob??  
I have found in putting together competitions that there are 2 kinds.  
The hard plastic glasses are fairly odor free, where softer plastic often  
have  
odors. If you used the soft plastic glasses, the odors from these could  
have  
masked any odors you were detecting when using glass.

Glass is usually odor neutral. If you picked up odors when using the  
glass  
glasses, my guess is those odors were there, and not an artifact. Was any  
kind of  
detergent used on the glass?? My experience judging has led me to always  
prefer  
glass to plastic. I would say that if you noticed the odor in the glass,  
but  
not the plastic, that it was actually there. It would not be unthinkable  
that  
all the beers you were sampling had a common defect. Did you continue to  
try  
additional samples glass vs plastic, to see if the aromas persisted?? I  
would  
hesitate to advocate using plastic glasses over glass based on a sample  
size of  
one.

As I said my experience is that while some plastics are odor free, many  
are not.  
Glass almost always is though, and I have found myself in competitions  
with  
beer after beer (though not every single beer) in a category exhibiting  
off  
aromas or flavors. I have found oxidation to be a failry common one, so  
perhaps  
by switching to plastic you simply masked out a component of off aroma  
that  
you had previosuly never detected. In your previous judging experience  
did you  
use plastic or glass??

**Subject: Plastic Cups**  
Subject: SS fermenters-yet again (George Fix)

More e-mail, and alas this time they contain requests that I explain my explanations. Shucks, I am determined to make the post on fermenters comprehensible if it is the last thing I do.

I have fallen into a bad habit of using the term "disconnect" in a loose and imprecise way. In particular, I tend to use this term for any devise, which when added to a tank will permit inflow or outflow. Most of the human race, on the other hand, uses the term "beer tap" when such devices are used on draft kegs. Thus, if you replace "disconnect" everywhere in my last post with "beer tap" it might make more sense. At least  
I hope so.

The tool for breaking into or sealing draft kegs with Hoff-Stevens fittings can be obtained from the following:

Draft Systems  
19791 Bahama St.  
Northridge, California 91324-3397  
818-882-8012

As I mentioned in the post this tool is not really needed.

From: READMORE@readmore.com

Hi all,

I'm having a problem which I hope someone can help me with.

I've been trying to brew a guinness stout and the results have been a little off. My problem is I can't seem to impart the "sweet" taste Guinness has. I've been using an all-grain recipe. Various recipes I've seen add sacharine to prior to racking. I just can't see doing that. Does anyone have any suggestions as to how I can get this flavor. Either by using a different yeast (currently using Whitebread) such as WYeast Irish Stout or by adding extra grains. Currently 7lbs 2 row 2 lbs patent.

Any suggestions, ideas or comments?

Thanks in advance.

I believe that this beer is contract brewed for Old Chicago by the  
Boulder  
Brewery in Boulder. After their near demise, the Boulder Brewery seems  
to  
have found a second life as a contract brewery in addition to producing  
their  
own products. They brew the beers for the Becketts restaurants  
(Colorado),  
the bottled version of the Walnut Brewery's Buffalo Gold (and possibly  
kegs of  
the same), and the Wrigley Red that you mentioned. Personally, I prefer  
most  
if not all of their contract beers to their own products.

I just go ahead and ferment on top of it. After a day of all-grain  
brewing I'm  
really not ready to wait another hour or so to end up going through a  
racking  
procedure (more time and more cleaning). My beers still taste great,  
IMNSHO.  
I've also read that too efficient removal of cold break prior to  
fermentation  
can result in onion-like flavours in beer. I really should try it though  
just  
for the experience but since I've never had problems with my beers I've  
always  
viewed removal of cold break as being one step too anal retentive. My  
homebrew  
acquaintances will probably be in shock when they hear that one. :)

indices,  
> tables of contents, and relatively detailed perusal.) So question  
number 1:  
> What's SRM, how is it measured, etc.?

I'm quoting from "The Essentials of Beer Style" by Fred Eckhardt:

\*\*\*\*\*  
\*\*\*\*\*  
\* COLOR DEFINITIONS \*

```

* *
* Color 1-10 scale: SRM * *
* *
* 0 water 0 *
*1-1.5 light straw1-2.5 *
*1.5-2 pale straw 2.5-3.5 *
*2-3.5 dark straw 3.5-5.5 *
* 3.5-4.5 light amber5.5-10 *
* 4.5-5.5 pale amber 10-18 *
* 5.5-6.5 dark amber or copper 18-26 *
* 6.5-8.5 very dark amber "dark" 26-40 *
* 8.5-10 "black" 40 & up *
* *
* *SRM = Standard Research Method degree, roughly equivalent to the
old *
* lovibond degree, and is used by the ASBC, (American Society of
Brewing *
* Chemists). In this system color is noted as degree SRM. The
Europeans *
* use a unit called "EBC (European Brewery Congress) degree". This is
*
* variable, but sometimes: *
* 1 degree EBC = 2.65 degree SRM, less 1.2. *
* 1 degree SRM = 0.375 EBC degree, plus 0.46.*
*****
*****

```

The 1-10 scale is the one used in the book. The SRM numbers are the ones you are interested in. As far as using SRM or lovibond ratings of grain to formulate a recipe, remember that one pound of grain with a rating of 20 will yield one gallon of wort with an SRM of 20. This is always an approximation because mashing and sparging efficiencies vary from brewer to brewer. Anchor Steam beer has an SRM of 5. (Don't ya just love all these "roughlies" and "approximatelies" ;-)

```

> From: kla!kirkish@Sun.COM (Steve Kirkish)

with
> the following bumper sticker on the back end:
>
> _____
> | UP YOORS COORS! |
> |   Boycott Coors   Non-Pasteurized Beer |
> |-----|

```

Hmmm .... shouldn't that say "Non-Flavoured Beer".

```

> Which actually raises some questions:
>1. Why would a beer be pasteurized? As a yeast-icide method? Won't
> heat affect the flavor of the beer? Is this why Coors "cold-
filters"?
>2. At what point in the process would a brewer pasteurize his beer?

```

Pasteurization knocks out yeast and a good portion of any bacteria in the beer. Result: storage stability. Yes, heat affects the flavour, for the worse. Cold filtering at 0.4 micron or less does remove microbes. They also cold filter to

remove potential chill haze components for appearance sake. I'm not sure at what point in production a large brewery like Coors would pasteurize their beer but homebrewers who are interested in trying it (god knows why) can do it after bottling. The caveat is that the beer must be filtered since the heat would cause the yeast to lyse and the result would be an intense yeasty flavour in the beer. Furthermore, the carbonated and filtered beer must be bottled using a counter-pressure bottle filler in order to minimize oxygen contact with the finished beer. The heat of pasteurization would accelerate oxidation reactions and the beer would taste "cooked" so oxygen is a real problem in pasteurization. Seems like alot of trouble to produce a beer the likes of which most homebrewers are deliberately attempting to avoid.

> "sufficient" quantity of active starter.

Due more to procedural error than to design, I had the opportunity to do a side-by-side experiment this weekend. (In English, "I screwed up and forgot to make a starter for the second batch.")

Batch #25A is a Bass Ale clone from "The Cat's Meow". I made up a starter two days in advance, and shook the hell out of the carboy before pitching.

Batch #25B is identical in ingredients and procedure to Batch #25A, except I didn't make a starter.

Fermentation in #25A was going great guns in about 12 hours, and had slowed considerably after 36 hours.

Fermentation in #25B didn't really get started for almost 36 hours.

A side note: I made the wort for the starters on a Sunday, the day my supplier is closed. I didn't have any extract, so I did a "full mash" of exactly one quart of beer.

Wrigley Red is brewed by the Walnut Brewery in Boulder as a contract  
brew.

There is also a chain of pubs called "Beckett's" that, like Old Chicago,  
are owned by Concept Restaurants. Beckett's serves "handcrafted beers"  
that  
are contract brewed by the Walnut also.

Date: Mon, 18 Nov 91 13:12:06 CST  
From: milton@ccu.UManitoba.CA  
Subject: poor brewing method?

In a discussion on oxidised beer it was mentioned that a 'sherry like' flavour may be present and could be a problem caused by oxidization. I frequently have this sort of flavour, also a carmalized flavour. My beers are usually a light straw colour. Is it possible that my technique is poor and is causing this 'sherry like' or carmalized flavour.

I use a 30 litre plastic pail for the primary and 23 litre glass carboy for secondary. At one point the plastic secondaries I got with the beer kit started to smell - nothing I could do would get rid of the smell so I began to use the glass carboy - no more strange smells of skunky beer. I siphon the beer carefully from the primary to secondary once the krausen (sp?) has disappeared and let fermentation go to completion in the secondary. After this, I siphon back into the sterilised primary and bottle from there. This last step has helped me make much clearer beer - less sediment in the bottle.

For making the wort I put 5-10 litres of cold water into the primary. Then I boil 8 litres of water with sugar (if required) and malt extract for

20 to 30 minutes. After boiling I pour it into the cold water and add enough water to bring the total volume up to 23 litres. This step usually generates lots of foam; I thought this was beneficial since it would add oxygen needed for the yeast into the wort - I'm not so sure now.

Normally the temperature of the wort at this point is about 35 C which is far too hot so I wait until the next morning before adding the yeast.

Is there something wrong with the above method? What can I do to improve it?

Thanks for any help

I don't believe that there's any smell that can "stick" to glass that doesn't "stick" to plastic. Cost is not the reason for NOT using plastic cups, in my opinion. Unless the cups are going to be recycled (which still uses more energy than washing glassware) they're going to go into a landfill or be burned. The only time I use plastic cups is for outdoor parties, and then I use some thick plastic cups that I reuse. Maybe the problem at the competition was a smell in the water?

From: "rpierce.US" <rpierce@US.oracle.com>  
Subject: BEERBEERBEERBEERBEER

Howdy all-

How's that brew coming??

Just a couple questions for other Bay Area homebrewers. First, My partner and I just tasted our most recent batch, and were very pleased with

the results, so we are trying to find out if there are any contests/festivals

coming up where we could share the product. Any info would be greatly appreciated since we're pretty new to brewing in S.F. Secondly, we are contemplating dry hopping one of our upcoming batches. Anyone out there have any hints on how to best do this??

On a different note, my brother was in town this weekend, and we went on the Anchor Steam Brewery tour friday afternoon. Boy'o'boy was that fun.

It happens every week day at 1 pm and is free. They take about 30 people per

tour and reservations are required. It usually draws a pretty good crowd so if

you are considering it, call a couple weeks in advance. The actual tour is

killer-a complete trip through the brewery. This part takes about an hour and

then they let us loose in the tasting room. They offer all their beers on tap-

free of charge-and usually have a couple special bottled batches they break out. On tap, they serve their Wheat beer, the regular Steam, Liberty

Ale(one of my favorites), the Porter and a Barley wine that's about 7% and is known as Foghorn Lager. They were also pouring a Spruce Beer that they

brewed only 3000 cases of for a 10th Anniversary Festival in Denver this past

summer-that's only available in Denver and San Francisco-lucky us. It had

a very pine like smell and flavor and I really liked it-though some of the

feabler tasters hated it-but who cares what they think. They also told us that

their Christmas beer is coming out after Thanksgiving, and that they will be

offering that to tour guests as soon as it hits the retail market around December 1st. That's it for now, but there's always more on the way.

KEEP ON BREWING THE GOOD BEER-----Russ Pierce

P.S. If anyone would like more info regarding the Anchor Tour, feel free to

contact me and I'll try to help you out-and I might even take a day off and join you on the tour.

From: winter@cirrus.com (Keith Winter)  
Subject: chillers

>> ...after five batches, however, they could start thinking  
>> about a wort chiller...  
>And maybe not. After 80 batches, I'm still just thinking about  
>the chiller. I'm actually just dropping the pot in the pool and  
>letting the heat dissipate harmlessly into 20,000 gallons of  
>(seasonally cold) water.  
>  
I've using this method, for about two years now. The pool is an  
effective  
heat-sink (comparrded to two or three gallons of wort, 22,500 gallons is  
effectively infinite). During the winter, the water in the pool is  
around  
45F degrees so it will cool the wort in about 30 minutes. I strain this  
into  
three gallons of chilled, pre-boiled water in a sanitized primary and get  
a  
real nice cold-break. After sitting for a couple of hours in the  
refridgerator  
(at 40F degrees or so), it whirl it and siphon into the primary, leaning  
all  
that nasty trub behind, and then pitch the yeast starter. Of course,  
this  
doesn't work quite as well in the summer when we maintain the pool around  
80F degrees but it still brings it down quickly and when added to the  
pre-chilled water yields a good cold-break.

So far, I have not had a reason to spend the money on a chiller. Using  
the  
pool also saves water (an important consideration in drought-ridden Ca.)  
over  
running a chiller and dumping the water down the drain (I like the idea  
of  
running the output of the chiller into the pool, however...).

From: Bob Jones <BJONES@NOVA.llnl.gov>  
Subject: Mash Tun False Bottoms

>In HD 762 Mike Sharp asks :  
>How does one place a false bottom inside a 15gal keg?

I have used two different methods. One is with SS screen sandwiched between two SS rings cut from a large diameter SS pipe. One of these SS rings is placed inside the other, with the SS screen between. The sandwich is held together with SS screws and nuts. I then made a copper L shaped pipe with a compression fitting that connects to the fitting that passes through the keg wall and on to the output valve. One end of this pipe rests on the bottom of the keg after passing through the SS screen. It is held in place in the screen with two washers soldered on each side of the screen to the pipe. Whew! We need some drawing tools here. This screen method works great, however it is complex to make (unless you have a machinist friend who likes beer). I have used another method that I think is easier to make and works just as well. You make a ring out of copper tubing that has a T in it. The output of the T connects to more tubing that connect to a compression fitting that connects to the same fitting that passes through the keg wall. This circular ring that rests on the bottom of the keg has lots of saw kerfs in the bottom of it. I mean one every 1/4 inch. The compression fittings allow you to remove either fixture for cleaning. Obviously the hole in the top of the keg is a little larger than the fixture. Mine are about 10-12 inches in diameter. I have been using the SS screen method for years for both kettle and mash tun. I recently went to the tubing method when I gas fired my mash tun for step mashing. I was afraid the mash liquid would not be properly mixed if below a screen, hence the new tubing design. Both work very good in a mash tun situation. I never liked the idea of using a picnic cooler for mashing. The thought of leaching weird chemicals out of the plastic don't settle with me. I know the manufacture says that these liners are safe, I just don't want to take the chance. Besides the SS keg will last forever, and is cheap (the cost of a deposit). I hope no one from AB is listening. Good luck.

Subject: re dry vs wet yeasts

wrt the ratings of various yeasts, it should be noted that in the ZYMURGY yeast ratings only one yeast scored as high as 8 out of 10; that was M&F dry ale yeast.

note, however, that Wyeast sells a great many varieties marked for different beer styles; has anyone ever determined which dry yeasts are best for which styles, or does the need for hardiness override style-related variations?

From: Arthur Delano <ajd@itl.itd.umich.edu>  
Subject: A couple questions and an answer

Is there a simple mathematical formula which helps in converting whole-grain recipes to extract? Can I have a copy? (I'd rather brew whole grain, but I can't afford to buy any more brewing equipment and still have money for ingredients (:->)).

I've got some clear plastic siphon hoses -- the standard 3/8" diameter - - and a couple of them have clouded up. I've found that their soaking in bleach (in roughly the strength Papazian recommends) clouds them. Are they still good for siphoning? I've switched to new, clear hoses for siphoning, but still use the cloudy ones as blow-off tubes. Is this wise? A brief soaking (under 15 minutes) will not cloud the tubes, but I don't feel that they're sanitized sufficiently that way.

Frank Tutzauer <COMFRANK@ubvmsb.cc.buffalo.edu> asks about how to duplicate the color of Anchor Steam Beer. This summer we used Papazian's second American Steam recipe in the chart on pp. 146-147 (older edition). It came out very well, probably a bit darker than Anchor, but that's just a guess, as we did not compare them side-by-side.

**Subject: A couple questions and an answer**

I'm an extract brewer and have had some experience using the Wyeast liquid cultures. I wanted to culture the dregs from a Chimay bottle but it doesn't look like I've had any luck. It's been about 4 days with no activity. I used a Grand Reserve bottle dated 10/90. Was this bottle too old to culture? I had boiled about 3/4 cup DME with about 3-4 cups of water for 1/2 hour and poured it into a wine jug fitted with an airlock. I then cooled the jug to room temperature, flamed the lip of the beer bottle, and poured the dregs into the jug. Was there too much volume of wort in the jug? Should I have started the dregs in a smaller volume of wort and then after some activity, pitch that into a quart or so of wort? What's the recommended procedure? Would anyone have an extract-based recipe for a Trappist Ale? How many lbs. of extract should be used? etc.

Subject: Science Indeed!

My sister found this somewhere in her medical studies. She gave it to me, and as I found it somewhat enlightening, I decided to pass it on to the digest.

#### Solution of The Secret of Alcoholic Fermentation

"Beer yeast, when dispersed in water, breaks down into an infinite number of small spheres. If these spheres are transferred to an aqueous solution of sugar they develop into small animals. They are endowed with a sort of suction trunk with which they gulp up the sugar from the solution. Digestion is immediately and clearly recognizable because of the discharge of excretements. These animals evacuate ethyl alcohol from their bowels and carbon dioxide from their urinary organs. Thus one can observe how a specifically lighter fluid is exuded from the anus and rises vertically whereas a stream of carbon dioxide is ejected at very short intervals from their enormously large genitals."

From: Jeff Frane <70670.2067@compuserve.com>  
Subject: Portland Beer & etc

See what happens? You go away for a few days to get married and come back to a mailbox stuffed with Homebrew Digests. Pretty nice. (And thanks to Martin Lodahl for sending me #760, which got stuck in the CompuServe craw.) With luck this will actually show up in the Digest; previous messages have been long-delayed or disappeared altogether.

Comments on 762:

Russ Gelinas suggests fermenting in a brewpot, and why not? When I first met Dave Logsdon he had developed a terrific system using a converted commercial coffee maker. He found it, unused, in a military storage sale or some such. The unit was originally fitted with two urns, which were removed and replaced with a single tub. The whole thing had to be plumbed properly so that it could be controlled with steam and/or cold water. Dave mashed in it, sparged out to another container, then back into the unit for boiling. Cold water was pumped through the jacket to cool the wort and a thermostat controlled fermentation so that everything could be done right in the coffee maker. Worked great.

Your problem is not doubt different and I would consider the drawback to be getting a good fit on the lid while allowing release of CO2. To me it would make more sense to pick up a used Cornelius keg and fit it with a fermentation lock. Or maybe two old kegs each half-filled.

Frank Tutzauer, the homesick Cajun: Yeah, and peripherally, it's interesting to note that chile peppers (and the widely-used peanut) are indigenous to the Western Hemisphere. They sure caught on in southeast Asia, though.

Steve Kirkish: Beers are pasteurized to kill any potential trouble-causing microorganisms. Yes, it's generally conceded that pasteurization has a strong affect on the beer's flavor--negative affect, of course. My understanding is that most kegged beers are not pasteurized, since the distributor has more control over their climate (they are kept cold from the time they leave the brewery until you drink 'em), but bottled beers are pasteurized with long, slow heat. When I toured the Anchor Brewery about six years ago, they said they used

a "flash-pasteurization" process, with very high heat used very quickly. They claimed taste tests had proven no negative effects on the beer.

Coors uses some form of micro-pore filtration designed to filter out little animacules; virtually all microbreweries use some form of filtration which is nowhere near as fine. Any form of filtration is going to strip other desirable characteristics from beer along with the yeast.

On where to drink in Portland: I sent Chris this information by e-mail, but thought some more information might be welcome.

BridgePort Brewery, 1313 NW Marshall, my favorite place to drink really fine ales, including several served as cask-conditioned; very jolly place, big with lots of tables and standing room. Gets VERY crowded in the evenings. (Don't think it's open on Mondays). Excellent pizza.

Portland Brewery, 1339 NW Flanders, longish walking distance from BridgePort. Very good ales, including the cleanest versions of Grant's Scottish Ale and Grant's Imperial Stout. Tiny. (Just next door is Bogart's, which has a large selection of beers)

Produce Row, 204 SE Oak, huge selection of bottled and draught beers, fun place, great (in two senses) sandwiches.

B. Moloch, 901 SW Salmon, site of the "other" Widmer Brewery and the Heathman Bakery & Pub, which makes excellent bread and pizzas (of the designer variety--the lamb sausage, feta and spinach is truly mind-blowing). Goodish selection of fresh local brew. VERY CROWDED just after work, as it is downtown and a major trendy spot. Don't let the trendiness scare you off.

Dublin Pub, 6821 SW Beaverton-Hillsdale Hwy. Not really in Portland, but nearby and they do have more than 100 beers on draught. Pricey and the beers aren't always at their freshest. But still . . .

There are brewpubs/taverns all over the place owned by the McMenamin Brothers. I'm not a big fan of their beer, but . . . Among the best is Blue Moon, 432 NW 21st, which is a hip neighborhood (try Casa U Betcha, just down the street, or Delphina's (Italian)). Or you could try the Baghdad, 34th & SE Hawthorne, wherein you can drink beer and watch recent movies . . . for a buck.

That oughta do ya. The big Widmer Brewery has tours on Saturday afternoons, from noon-2 pm. Give them a call (281-BIER) for details.

They also do tours at Blitz-Weinhard, a lovely old regional brewery, although I believe some of the tourguides are remarkably iggerant.

If you're mobile while here, you should travel up the Columbia Gorge to Hood River and visit the brewery and White Cap Pub (Full Sail ales). Or go farther the other way, to the coast, and visit the BayFront Brewpub in Newport (fantastic ales) or even the McMenamin brewpub in Lincoln City. At any rate, have fun!

Also might check out the Burlingame Grocery, which has the largest selection of bottled beers in town. Basically, if it's available in Oregon they'll have it. For better prices on more standard beers (Oregon micros, that is) the North Hollywood Fred Meyer and the Jantzen Beach Safeway have excellent selections and lower prices.

Subject: tastes of proto-homebrewers

Jack raises one issue which I haven't seen addressed yet:

> My target was and still is all those people out there that do not even know  
> that one can make drinkable beer at home. Let's face it, most of them like  
> Bud. How can the subtleties discussed in these fora possibly be of interest  
> to those people?

I think you don't understand how hard it is to make something that close to  
flavorless, consistently over many batches, starting with natural  
products

(yeast, whole grains)---and they do this in many different parts of the  
country (try comparing St. Louis with Nashua NH, ~40 miles NNW of Boston)  
!

Leaving aside the opinion of this digest about the results, the  
manufacturing process is outstanding; if US automobile makers were  
anywhere  
near so consistent they would have no worries about competition from  
imports.

Telling BudMiLob fans they can easily brew something they like is like  
telling someone in front of a 100-piece orchestra equipped randomly with  
parts from all the Mahler symphonies that he can make minimalist music  
with  
just a few gestures. Taking your economic viewpoint, I would expect the  
results to be a short burst of sales followed by such rotten word of  
mouth  
that the seller would go out of business.

From: sbsgrad%sdph.span@Sdsc.Edu  
Subject: Dark of the Moon Cream Stout

From: Steve Slade <sslade@ucsd.edu>  
Date sent: 18-NOV-1991 14:58:22 PT

My fiancée and I brewed this stout five weeks ago. I waited until now to post the recipe so we could let several people taste the final product, and all like it and want more. We got this recipe from the Great Fermentations 1991 brewing supplies catalog. For five gallons:

5 lbs dry dark malt extract  
1.5 lbs crystal malt 20L  
2 lbs crystal malt 40L  
12 oz chocolate malt  
4 oz roasted barley  
6 oz dextrin powder  
1/2 tsp calcium carbonate  
First bittering hops:  
    1/2 oz eroica (20 BU)  
    1/4 oz chinook (12 BU)  
Second bittering hops:  
    3/4 oz Nugget (12 BU) (subst. N. Brewer (? BU))  
Aromatic hops:  
    1 oz cascade (5 BU)  
    1 oz eroica (4 BU)  
Wyeast #1098 British Ale yeast  
1 cup DME for priming  
SG = 1.053  
FG = 1.020

The catalog describes this as having "overtones of caramel, with a touch of creaminess which adds richness to the character."

Brewing details and last minute changes:

Made a yeast starter 3 days before pitching. Used 2 tbls DME and 1 cup water. Next time use 2 cups water. All grains were cracked and steeped for 30 minutes at about 160 F along with the calcium carbonate. The steeping water was added to about 2.5 gallons pre-boiled water and the grains were crudely sparged over the boiling kettle using a collander, which brought the total boil to about 5 gallons. Dry malt and dextrin were added and brought to a boil. First bittering hops were added when the boil began. Second bittering hops added after 30 minutes, and boiled for another 30 minutes.

Chilled with an immersion chiller (this took about 20 minutes to cool about 4 gallons of wort). BTW an immersion chiller must be stirred often to achieve efficient cooling. Racked to a carboy, filled to 5 gallons and let sit overnight to allow the trub to settle out. (Most had settled after 4 hours or so). The next morning I racked it to a plastic primary, pitched the yeast starter, and added the dry hops.

And now for the changes. I had originally planned for a single stage

fermentation, with bottling a week after pitching. However, there was no time to bottle after a week, so I racked to a secondary glass carboy to get the beer out of the primary, which does not seal very well. The dry hopping should have been done in the secondary, but at the time I had no plans for using one. I suspect the hops did not spend much time in contact with the beer in the primary, as they got pushed up by the krausen and stuck to the walls.

When I bottled 2 weeks after brewing, I tried what might be called "wet hopping." On the suggestion of sometime brew partner Mike Fetzter, I made a hop tea by steeping 1 oz N. Brewer in 2 cups water after the water had just stopped boiling. This was kept covered for about 10 minutes. I bottled half the batch, then added the hop tea and bottled the second half. The bottles aged in my closed for two weeks before tasting.

This turned out to be a very nice dry stout. It is dark and thick, with a brown head that lasts to the end and sticks to the side of the glass. The "no tea" beer is not terribly aromatic, and has a noticeable bitter aftertaste. The "hop tea" beer is more aromatic, and has a smoother finish, with what I think is a better blend of flavors. My fiancée likes the "hop tea" beer better as well, but a friend who only likes dark beers likes the "no tea" beer better. Perhaps this would be a good way to introduce friends to darker beers, while preserving half the batch for the true stout lovers. I should add that Mike tried this same hop tea idea with an IPA and a sweet stout. You could barely taste the difference with the IPA, and not at all with the sweet stout. I think you have to use high alpha acid hops in the tea to make a taste difference.

Anyway, thought I would add this recipe for those who compile them, as it did turn out quite well and we plan on brewing it again. Anyone else out there ever experiment with using a hop tea at bottling time?

From: Darren Evans-Young <DARREN@UA1VM.UA.EDU>  
Subject: Green glass / Counterflow chillers

RE: Green glass

Here is an excerpt from an article titled The Beer Enthusiast by Fred Eckhardt from All About Beer magazine (June/July 1990):

Right from the start, Brewmaster Fred was determined to clear up some of this Fred's foggy ideas about beer and green glass and skunky flavor esters. It seems that light damage has more to do with how the glass is made than with its color. If the glass maker adds chromium oxide to the process to defend against light of less than 520 angstrom wavelength, then the possibility of light damage is severely restricted. To prove his point, we tasted some of his green bottled Pils. We started with a six month old sample that had not only been exposed to daylight all that time, but had been on an automatic shaker as well. The brewery had been doing experiments to determine the shelf-life expectancy of it's products. We compared the 6-month old shaken light exposed green bottled sample to that of a current bottling. There was no skunky flavor in either. The beer was clean, but there were differences between them, especially the color: the shaken sample was slightly darker than the fresh sample. "But wait," Fred said, "there's more." He opened another 6-month old sample which had been stored carefully in its light protected case. This beer tasted very similar to the other two. Finally, he offered me a fourth bottle, an eight month old CLEAR GLASS bottled Pils, in a Miller's bottle which had also been left in room light (including fluorescent light) and it, too, showed very little difference in flavor. I wouldn't call such old beer great, but it certainly didn't show the damage I have detected in so many store worn bottles I have spent so much money on. I asked Fred if it was common practice for brewer's bottles to be thus protected. "That's the problem," he said, "I have to check on the bottle manufacturer all the time." Most bottle makers make no such effort, unless the brewery insists on it at all times. "So most beer in green and clear glass bottles is still going to be skunky," I said. "Not Frankenmuth Beer!" There you have it ---- a German brewmaster speaks out.

RE: Counterflow chillers

I don't buy all this talk about not being able to see if your counter-flow chiller is clean or not. I've never had an infection using mine. Here's what I do. I assemble the tubing/siphon pickup/etc then connect to my kitchen faucet and run hot tap water through it for at least 5 minutes (140 dF). Then I siphon bleach solution through it and let sit for 10-15 minutes. After that, I then run hot tap water through again for about 2 minutes. I leave filled with tap water to get my siphon started. After I'm done chilling, I run hot tap water through for 5 minutes to clean. Occasionally (once per 10 batches), I run boiling water through just to be anal. By the way, I siphon into a sanitized plastic fermenter and let sit for about 2 hours to settle any cold/hot break, then from there into my carboy. I have VERY little trub by the time my beer reaches the carboy. Works great! Admittedly, setting up the chiller is small pain, but a BIG glass of homebrew helps calm me down. If you clean the chiller before and after with hot water, I don't see a problem. There's my 2 cents. Just trying to be a MOMILY BUSTER! ...sorry, I just couldn't let another issue go by without that word. :-)

Darren

Subject: Re: Help with using liquid yeast.

- -----

I need some advice. I have decided to use liquid yeast (for the 1st time) for my next homebrew. I picked up some Wyeast #1028 at my local homebrew store and popped the inner bubble. In about 4 days the package had swelled to the point that it looked like it would burst so I figured it was time to make a starter. I put about 1/2 pound of liquid extract into about a quart of water (probably way too much extract) and boiled it for about 15 minutes then let it cool. I sanitized 2 beer bottles, torching the tops etc, filled them about 3/4 full of the cooled wort, and pitched the yeast about equally between the two bottles. It has been about a week and not much has happened. There seems to be a tiny amount of CO2 percolating from the fermentation locks but barely. If I lightly shake the bottle it percolates for a couple of seconds and then stops. The date code on the package is April and the package says that the yeast has a shelf life of about 6 months. It had always been refrigerated until its use. Is it old or did I do something wrong? Can I use this stuff or should I just chuck it? Thanks for any help.

From: KARL DESCH <KCDDESCH@ucs.indiana.edu>  
Subject: I've Cut the Keg!

A couple weeks ago I asked about how I should go about cutting the top off a 15 gallon keg. Thank you for your suggestions. After determining that the keg was aluminum and not SS, I new that it would be easy to cut myself. A new hacksaw blade was all I needed to saw off the top.

Before

I had time to make handles for this pot I used it to brew an all-grain brown ale. Luckily I had a friend to help me pour the wort into the hop back.

That thing wieghs a ton! A few questions came to mind after brewing with this keg conversion.

1. This keg appears to be all aluminum. If memory serves me correctly Papazian suggests to avoid using aluminum as a boiling pot. What about SS makes it better than aluminum?

2. Because I could barely move this pot when it was full of 5.5 gallons of boil -ing wort I initially siphoned the wort into the hop back. The silicon siphon soon became flacid in the heat so that siphoning was impossible. Did I release any nasties into my brew from this process?

I would appreciate any discussion on these questions

Thanks again,

Karl Desch

>How does one place a false bottom inside a 15gal keg? I've been trying to figure this one out for a while.

Try this..... From "EASY MASH".....

A few simple mods are required to make it fit the process. A small brass spigot is fitted to the bottom with a short piece of pipe extending several inches toward the center on the inside.

A small piece of window screen is rolled several times around the pipe and secured with a hose clamp or twisted copper wire. The screen roll extends several inches past the end of the pipe and the last inch is bent over itself to prevent anything from entering the spigot that has not passed through several layers of screen.

The original setup also had the traditional false bottom, fashioned from a SS plate with a zillion holes laboriously punched into it. It has SS screws on the bottom acting as feet to hold it up off the bottom. I abandoned the false bottom on the third batch and found that the screen was all that is needed for a super simple sparge operation. It also serves to keep the hops out of the wort chiller after the boil.  
.....

I have now produced 5 batches with this system and I think it is safe to say that the false bottom is gross overkill for the homebrewer.

From: R\_GELINAS@UNHH.UNH.EDU (Russ Gelinias)  
Subject: primary in SS

> Is there any reason for not doing a primary ferment in a 10 gallon stainless brewpot? Cook, cool, and pitch right into the pot.

Great minds really do travel the same roads.

I just brewed my first batch in my new 10 gal SS kettle and reluctantly fermented it in the old plastic fermenter, really itching to try just what you suggested but decided to save that for the next experiment. Such a shame to put that lovely kettle on the shelf and ferment in plastic.

There were several reasons why I decided not to do it but the major one was not to introduce too many variables in my experiments to brew the perfect "EASY MASH" beer. The other experiment failed but it was related.

I tried a plate glass cover on the primary instead of the usual leaky plastic one but it fit so poorly when the fermenter was full that I put the regular cover on.

The other reason I didn't do it was because the thought of leaving the wort in the kettle never occurred to me but the more I think about it, the better I like it. I was thinking in terms of temporary storage of the chilled wort while cleaning out the kettle and this involves too much trouble.

I personally do not think the leaking of the top is much of an issue. Mine (Polar) fits well enough that it would be pretty much a one way leak, (CO2 out).

I suspect the real problem is in fermenting on the trub from boiling but I will leave that to the experts' opinion. Hopefully, we will have some answers before my next batch.

My inclination is to only leave it in a few days or until the main fermentation is over and then rack (drain) into a glass carboy.

OOPS... One other problem occurred to me. The wort would not be aerated using your system.

>  
>1) Convenience in racking, as George Fix followed up on.  
>2) You can force carbonate your beer in them.  
>3) The beer is ready to serve from the keg when conditioning is  
complete.  
>4) They are endlessly durable.  
>5) They don't explode or produce beer volcanos.

The idea of fermenting in soda kegs intrigues me, but I cannot figure out  
how you fit a air lock or blow out tube to the large opening in a soda  
keg?

Also I would think there could be over an inch of trub in the keg - do  
you  
have problems with the dip tube clogging?

If 1/4 kegs are used - how is the keg cleaned? Glass carboys are enough  
of a pain, but at least you can see what junk still stuck inside.

From: R\_GELINAS@UNHH.UNH.EDU (Russ Gelinias)  
Subject: Catamount xmas ale

Catamount has a Christmas Ale out. It's very good, but it tastes suspiciously like Frank Jones ESB. Catamount contract-brews for Frank Jones. The xmas ale has no description of ingredients, which is odd because the 3 regular Catamount brews have a rather in-depth list of ingredients. In any event, the brew is reddish, with a nice mix of hops and malt, leaning more towards the malt than FJ ESB (which is very hoppy, like Sierra Nevada Pale Ale). And it costs about \$1.50 less a six than the FJ ESB. But it's not the spicy "winter warmer" I had expected. Have to wait for Harpoon's version, I guess. Is Anchor's xmas ale spiced?

Quick question: How quickly can beer be force-carbonated in a keg, hours or days?

And a warning: If you're thinking of pasteurizing a carbonated bottled beverage (for whatever reason), think again. It *can* be done, but it is dangerous. The bottles can explode, violently. Be careful.

Russ

From: "RICHARD HAPANOWICZ" <HAPANOWICZ@bigvax.alfred.edu>  
Subject: Old ingredients

I recently came across some EDME DMS malt extract at a low price. The catch is that it had been sitting around for a long time. How long can one store canned malt extract without side effects? Does the time differ for hop vs. unhopped cans? I brewed a batch up using this malt extract and edme yeast. The yeast activity was good, a layer of foam rose and one day later the bubbling stopped. The final SG was 1.010. The batch consisted of 3.5# of DMS and 1# of amber dry malt, grains and hops.

>>There is alas a downside to stainless. First, stainless generally means  
"less  
>>stain" and not "no stain". Chlorine is very aggressive to metal if left  
in  
>>contact for a sufficient length of time. Sterilizing with boiling water  
having  
>>a high iron content can have the same effect. ...

I'm not sure I follow this. Iron-bearing water does not, to my  
knowledge,  
corrode stainless steel. What does the corrosion product look like?

What I suspect you're seeing is iron from the water being deposited on  
the  
surface of the stainless steel and corroding, giving a rust stain. I  
would  
think that could be removed with a bit of scrubbing, but if not, an acid  
pickle should do the job. (Hey, if brewers can call sugar-water "wort"  
metallurgists can call an acid bath a "pickle" 8-)

While nitric, sulfuric, and hydrochloric acids are normally used for  
industrial pickling of stainless steels, I doubt anything that severe is  
necessary in this instance. I'd suggest, believe it or not, toilet bowl  
cleaner, aka phosphoric acid. Stainless is not affected by this, and  
it's  
great for removing rust stains. Obviously you'll want to clean and rinse  
very carefully afterwards, and wear chem-resistant gloves; I'd also try  
to  
find a brand of cleaner that minimizes other additions, especially  
perfumes and dyes.

Chlorine cleaning agents should definitely be avoided, especially in  
pressure kegs. Chlorine can lead to stress corrosion cracking of  
stainless steels, in addition to less catastrophic forms of attack.

Another job for toilet bowl cleaner. Again, rinse very thoroughly when  
you're done, and use detergent. Let it dry thoroughly before adding your  
sanitizing agent.

From: larryba@microsoft.com  
Subject: Serendipitous Sanitization Experiment

Just an interesting side note. 6 weeks ago I made a pilsner style beer. I diverted a quart-o-wort out of the chiller and stored it in the fridge. Last night I wanted to prepare some starter jars for brewing this weekend. I took the wort out, opened it up (to dilute and boil) and what should I find but fermented wort!

It was mildly carbonated and had some very peculiar flavors (wild yeast no doubt). But it didn't smell rank or taste obviously infected.

The interesting thing is that I would have expected little to no biological activity: the wort was boiling hot going into the chiller. The chiller had been sanitized by draining 3 gal on 195f water through it (leftover boiling water from sanitizing a keg) and the mason jar just came out of the dishwasher.

So, at least for my (kitchen) brewery, I need to be aware of wild yeast potentially everywhere. I guess the importance of a strong clean starter yeast to overwhelm those rouge bugs can't be stressed too much. Perhaps my Red Star Bread yeast was escaping? Anyone try this stuff in a lager?

It would be an interesting experiment for you folks out there in Net land: Divert a sample of your latest batch before pitching yeast. Let it sit for a month and see what you got. It could be a good test of your overall sanitation efforts - how long can it sit before becoming obviously biological! Also the experiment might be a good indicator of the source of off flavors in your beers.

Cheers!

From: Bob Jones <BJONES@NOVA.llnl.gov>  
Subject: Cardboard,Bay Area Brewoff Competition

To Jay Hersh -

My experience with cardboard nose smell in glass glasses is not isolated to one experience. Several years ago at the Calif. State Fair this problem really caused havoc because the stewards were pouring the beers for the judges. I kept smelling this cardboard/almond nose in the first three beers judged. I finally asked the steward not to pour the beer before we smelled the glasses. The smell was in the glasses! The entire competition was stopped while the glasses were re-rinsed. The problem I noticed most recently was very similar. The glasses were stored in cardboard boxes then rinsed before the competition with hot water only. Another problem is the transport of the glasses from the back room to the judges. They are very often carried in a six pack carrier with the entry. The glasses are sometimes placed upside down in the carrier, where they can pick up this cardboard nose. Does anyone know of a good source for SS storage boxes for glasses? Please direct info. to Russ Wigglesworth. The cardboard nose appeared in the glass glasses on two samples, when each was poured into both glass and hard plastic glasses. Maybe we should flame each glass or I know just pass the bottle around and each judge take a hit :-). I prefer glass glasses to plastic glasses IF the associated smell problem can be absolutely eliminated everytime. The problem as I see it, is the variability of the cleaning(we are all human) of the glass glasses. I am putting together the Bay Area Brewoff this year and we will be using hard plastic glasses for judging. As for the recycling or environmental issue raised by Al Korz I say the homebrewer pays an entry fee to have his/her beer judged in the most unbiased professional manor we can give. So the environment looses out on this one.

I will be posting info for the Bay Area Brewoff soon. Briefly, it will be in January 25, 1992 at Lyons Brewery Depot, Dublin, Ca. Categories are : Porter, Dry Stout, Amber Lager (Steam style), Pale Ale(3 styles), Barley Wine, Mead and a Christmas Beer (just for the fun of it). This last category was largely due to the interest I see here in HBD. Happy brewing and good luck!

Bob Jones

From: "Rad Equipment" <rad\_equipment@rad-mac1.ucsf.EDU>  
Subject: Glass & Cardboard

Subject: Glass & Cardboard Time:8:42 AM Date:11/19/91  
Since I am one of the organizers of the event (California State Comp) which Bob Jones refers to in his observations of detecting almond/cardboard in glass but not in plastic (HBD #762), perhaps I can answer some of Jay Hersh's questions of HBD #763.

The glasses were washed with generic (cheap) automatic dishwashing detergent, after their previous use and then rinsed with hot water just prior to their use in the competition mentioned. The problem here is that the glasses are stored in their original cardboard boxes. The cardboard does seem to remain with the glasses, even after the rinse. Alternate storage containers have been considered in the past however nothing has been adopted which is both economical and superior to the cardboard. We have some 40 dozen of these glasses which we use for 2 major competitions and for several minor club competitions during the year. That translates to 14 boxes of 3 dozen glasses each.

The general consensus among the Malts is that we'd like to continue to use the glasses since we share Jay's belief that it is generally a better medium for judging beers. We also want to address the lingering cardboard problem. Many of you are involved with large competitions, how do you store your glassware? We have considered purchasing a mobile dishwasher to take to the various locations at which we hold the major competitions, but this isn't practical. Obviously we need to replace the storage containers or the glassware.

Now, this is not to say that the all the aromas which Bob noticed were the fault of the glasses. In fact we had very few such comments this year. We have made a better effort to wipe out the cardboard since we are more aware of it. Perhaps Jay is correct that the fault was really there and that the plastic was masking real problems. The plastic glasses, if they were from the bar we had set up for the day, were the hard, wide mouth, 7 ounce(?), type. But, it is possible that the glassware was at fault, and to eliminate that chance I'd like to correct the storage problem.

What are your suggestions? Hmmm, I think I'll bundle these three messages and post them to the new Judges' list.

RW...

Subject: Question on Traditional Recipts

Hello,

This topic has past, but I think this query got lost as I don't recall ever seeing it posted, or any answers put forth, so I submit it again.

>From what I have read it wasn't until the early part of the 19th Century (around 1830 or so) that it became to be understood that there was some organism or chemical responsible for fermentation, and not until the later part of that century (~1860s) that Pasteur documented that the single celled organisms we call Yeast were actually responsible.

So in light of this how is it that Ben Franklin, George Washington, et. al. have recipes that refer to adding a pint of Yeast?? Was this a name for the sediment (which of course contained the organism we now refer to as Yeast, and perhaps the origin of it's name) which brewers collected from one brew and tossed into the next (brewer's had long known the sediment had some connection with the cause of fermentation, but the mechanism was unknown till Pasteur's discovery despite the earlier innovation by Van Leeowehuk (sp?) of the microscope)??

> you can't possibly hurt a steel kettle on anything even that hot

I don't know what you used to determine you temperature but it would not be possible to boil water or wort in a controlled manner at 2500 degrees F. The problem is (and its just a small problem) that carbon steel melts at 2500 degrees F. Stainless steel and aluminum have much lower melting temps. I suggest that you try using a tantalum kettle it won't melt till 5100 degrees F. And just so you know water boils at 212 and is a gas after that.

>The tool for breaking into or sealing draft kegs with Hoff-Stevens fittings....

I ignored this discussion until I came to "Hoff-Stevens".

I have several aluminum 1/4 barrels from my other life that were modified for home kegging as I have previously described. I refuse to use aluminum in this enlightened age but all attempts at finding SS 1/4 bbls in Chicago have hit a stone wall. They simply are not available.

I just bought a Cornelius and like it a lot but I much prefer the larger capacity of the 1/4 bbl and I have a lot of H-S hardware and fittings I would like to put back into use.

Here is a great business opportunity for some enterprising brewer. "Buy" for the deposit barrels from your friendly distributor and smuggle them to Chicago. Any takers? I have one customer in mind.

From: Bob Jones <BJONES@NOVA.llnl.gov>  
Subject: Mash Tun False Bottoms

>I was afraid the mash liquid would not be properly mixed if below a screen, hence the new tubing design.

This is a very serious problem with a false bottom. The stuff under the bottom is boiling and if your not very careful, will burn or at least carmelize.

On the other hand, if properly controlled, it simulates all the good aspects of decoction mashing without all the mess. Unfortunately, it can not be controlled very easily.

The screen wrapped pipe which I described yesterday, eliminates this problem just as your tubing does.

I would love to hear from someone who tries my system. The effort and skill required to build what you have described, is enough to scare away most tentative beginners. It is a very clever idea though and I have visions of the ship in the bottle problem.

Date: 19 Nov 91 17:01:22 MST (Tue)  
From: rcd@raven.eklektix.com (Dick Dunn)  
Subject: pasteurization (commercial), Coors

MIKE LIGAS <LIGAS@SSCvax.CIS.McMaster.CA> comments on pasteurization:

> ...I'm not sure at what  
> point in production a large brewery like Coors would pasteurize their  
beer but  
> homebrewers who are interested in trying it (god knows why) can do it  
after  
> bottling...

Used to be there were two ways of pasteurizing in a commercial brewery:

"tunnel" - after bottling, bottles go through a heated tunnel.  
This is obviously hard on the beer, since you have to heat the  
bottle long enough to get the entire contents up to temp. You  
can neither heat nor cool too quickly or you'll break the bottle.

"flash" - beer is passed through a heated section of tubing on its  
way into the bottle. Heating/cooling happens much faster. As I  
understood the process, it was a little trickier--and obviously  
the bottling line has to be clean.

Used to be that almost all large-scale commercial brewers pasteurized  
their  
beer, and most used the tunnel method. I don't know how much it's  
changed  
with the ultra-fine filtering that's now practical, but I think it would  
be  
interesting if anyone knows.

As for the bumper sticker:

```
> >
> > |-----|
> > | UP YOORS COORS! |
> > |   Boycott Coors   Non-Pasteurized Beer |
> > |-----|
```

Coors was one brewer which did not pasteurize even "back then". This is  
\*one\* reason they kept such tight control on distribution/sales of their  
beer...regardless of whether you like their beer, at least they  
understood  
that it was a perishable food. They tried to ensure that it didn't  
travel  
too far and stayed cold. (Obviously, with beer as light as Coors, \*any\*  
off-taste is a serious problem.)

OK, now, the rest of this is just for information. I take no position on  
the politics; I don't want to talk about the politics here because the  
topic is beer...but if you want to make sense of the bumper sticker and  
the  
matter of pasteurization, here goes: There are various Coors businesses  
held by various members of the Coors family. As a rule they have been  
active in politics and quite conservative. There is a long-standing feud  
between the brewery management and organized labor--e.g., labor accuses  
management of union-busting or discriminatory practices; management  
accuses  
labor of featherbedding. After one particularly bitter dispute some  
years  
ago, a campaign began on the labor side (not to say that the unions

approved it \_per\_se\_) to convince people that Coors was somehow unhealthy or potentially dangerous because, unlike most other beers, it wasn't pasteurized. It was not because of any particular incident related to unpasteurized beer; it was just a means of manipulating public opinion. I don't think it had much effect, and in fact I'm surprised to see such a sticker still around these days (with more beers not being pasteurized).

FWIW.

From: arf@ddswl.mcs.com (Jack Schmidling)  
Subject: ORGANIC

To: Homebrew Digest  
Fm: Jack Schmidling

Subject: ORGANIC MALT

Good news for the health food nuts.

My research into nitrosamines in beer has ended by finding a source of malt that not only contains the absolute minimum levels of nitrosamines but is also available in an organically grown version.

BACKGROUND:

Nitrosamines (a dangerous carcinogen) are produced in malt by the chemical reaction between combustion by-products and precursors generated by germination.

Nitrosamines can be reduced in two ways. The first and most expensive is to use indirect kilning where in the grain is heated through heat exchangers to avoid contact with flame products.

The second method is "sulphuring" wherein elemental sulphur is sprayed on the grain before and during kilning. I have no idea what the chemistry is but it reduces the nitrosamine production significantly... by "coincidence", just enough to get directly kilned malt just under the 10 PPB FDA limit.

The most effective process is to do both procedures. This typically results in undetectable levels (less than 1PPB) of nitrosamines.

The major producer of malt in this country is Bries and its affiliates and from what little I could extract in telephone conversations with the president, all their malt, except crystal malt is direct/sulphur.

Nitrosamine production is maximal in malt that is kilned with high moisture content such as crystal malt. That is why it must be indirectly kilned and sulphured just to meet the FDA max.

Minnesota Malting, makes malt using any of all of the above in addition to supplying organically grown grain, if desired. What they call "organic malt" is indirect without sulphur because their customer doesn't want any chemicals added but it is still organically grown.

They will sell 25 lbs bags, ship UPS and the price is .55 per lb plus shipping.

I just received a bag of two row today and for what it is worth, the 25 lb bag weighs 32 lbs. It seems to meet all the criteria for good malt according to Noonan. I will give it a try in a couple of days.

Just specify 2 row or 6 row, indirect. You will have to check on the price of the organically grown. I am not sure if it is the same.

Subject: Boots bitter kits

Howdy,

One of my co-workers just returned from England and brought me two cans of Boots Bitter concentrated wort. I've never heard any reviews, comments, flames, praises, etc. on this brand, so I was wondering if anyone has tried it. It sez on the can it uses 'hop extract'. Should I add some hops to the boil??? The instructions also say to use 2lbs sugar, I think I'm gonna use a couple #'s of honey instead. Good Idea or Bad Medicine?? It also comes with a little foil pouch of dry 'genuine Brewers yeast'. Any ideas? should I just trash it and use wyeast, or can this be used w/ a starter?

Any responses would be greatly appreciated.

BTW, has anyone developed any recipe databases for DOS? I saw some mentions of hypercard stacks for this purpose but nada on IBMs. Let me know if there is any interest.

This reminds me. I know the Wyeast package recommends using a  
1.020 SG starter (less than half a typical wort SG). Is there in  
fact a likelihood that Kevin killed his yeast (or shocked or  
whatever) by using much more extract than called for?

Subject: Green glass and thanks

Looks like I confused some people (oops): I mentioned that the carboy had a greenish tinge only as a passing reference. There probably was a layer of film from some food coloring that dissolved and left the carboy's normal color - clear with a greenish tinge. The thing is old and so I'm not worried about the color.

Thanks everyone for the advice on chemical agents to get rid of the rust spot. I'll get that soon.

Subject: sanitizing with bleach

Arthur Delano writes in HBD#764  
> A brief soaking (under 15 minutes) will not cloud the tubes, but I  
don't feel that  
> they're sanitized sufficiently that way.

Actually, 15 minutes is much longer than you need, assuming there are  
no scratches or other places for the nasties to hide. I have been  
told, by someone who should know, that a very weak bleach solution  
(10-20ppm, about a "capful" in 5 gallons) will kill almost all the  
bacteria in 10 seconds. A nice advantage of using such a dilute  
concentration is that you don't have to rinse afterwards (especially  
nice, if you suspect the cleanliness of your water source).

Subject: Re: Chimay yeast

To Kenneth Munno:

I tried the same trick, but with Chimay Red. I used two bottles also dated 10/90. The starter consisted of 1/2 cup of DME and 2 cups water. It took about a week at 70F for any activity to appear. The Abbey Ale that I brewed with this yeast is probably one of the finest beers I've made to date. It is an all-grain recipe which I'll post if anybody is interested.

To all HBD:

Is it normal to take this long when culturing yeast from a bottle of commercial beer? I believe that the yeast used by Chimay actually consists of five different strains (kinds?). If I re-pitched this yeast several times wouldn't one of the more dominant strains take over?

Waiting for Enlightenment,  
Jeff

From: Peter Glen Berger <pblp+@andrew.cmu.edu>  
Subject: Bitchez Brew Stout

This came out fantastic. I highly recommend brewing it.

6 lbs. dark dry malt (M&F)  
2 lbs. amber dry malt (M&F)  
.75 lb. roasted barley  
.5 lb. black patent  
1 lb. crystal malt  
2 CUPS (not lbs) Quaker Oats  
2 oz. fresh Bullions hops (boil)  
.6 oz. fresh Willamette hops (finish)  
Whitbread Ale Yeast

Add hops in last 5-6 minutes of the boil. All specialty grains should be cracked, first. Soak the specialty grains & Quaker Oats in cold water for 15 minutes, bring to a boil, remove grains with strainer as wort comes to a boil. This has an awful hot-break, and needs to be nursed for about 5 minutes before you can leave it safely. I went light on the Oatmeal because the oils in it tend to be detrimental towards head retention.

Comments: This beer improves substantially after about 2 weeks in the bottle, as hop aroma subsides and the large amount of roasted barley assumes it's place in the forefront. It's my favorite beer to date, but if I were going to brew it again I might cut back on the roasted barley by about .25 lb, and lessen the boiling hops (either to 1 oz. of Bullions, or 1.5 of some lower alpha hop). Whitbread ale yeast was used because of the low attenuation rate: this stout is NOT sweet, but has lots and lots of body.

From: arf@ddswl.mcs.com (Jack Schmidling)  
Subject: STUFF

To: Homebrew Digest  
Fm: Jack Schmidling

From: Bob Jones <BJONES@NOVA.llnl.gov>

J. Schmidling:  
>> mine sits on top of a 2500 deg , forced air melting furnace and  
brings  
7 gals to boil in about 15 min. you can't possibly hurt a steel kettle  
on  
anything even that hot

> I don't know what you used to determine you temperature but it would  
not  
be possible to boil water or wort in a controlled manner at 2500 degrees  
F.  
The problem is (and its just a small problem) that carbon steel melts  
at  
2500 degrees F. Stainless steel and aluminum have much lower melting  
temps.  
I suggest that you try using a tantalum kettle it won't melt till 5100  
degrees F. And just so you know water boils at 212 and is a gas after  
that.

I will try to be gentle responding to this utter rubbish. I don't want  
to be  
accused of being confrontational.

1. I measure the flame temperature with a thermocouple pyrometer. This  
instrument is to a foundry what a hydrometer is to a brewery.
2. SS contains chromium which has a melting temperature around 3500 F.  
This  
puts the melting point of the alloy significantly above that of carbon  
steel.
3. Aluminum melts around 1200 F. To lump aluminum with SS is  
misleading at  
minimum.
4. Precisely because water boils at 212 F and turns into an expanding,  
cooling gas, one can heat it in kettles without worrying about the  
kettles  
melting. This is true, even if the flame temp is far above the melting  
point  
of the kettle.

Aside from an oxy-acetyline torch, with its intensley hot and  
concentrated  
flame, you can not melt a steel kettle in an ordinary flame,  
particularly if  
full of water. A empty steel kettle will sit on my furnace all day and  
never melt. It will get red hot and eventually oxidize and fall apart  
but it  
will never melt. An aluminum kettle would melt into a puddle in a  
couple of

minutes if empty, but boil water all day.

While I am counter-flaming, I would like to point out that most reasonable people would find the following sort of comments far more offensive than anything I have ever said.

>Occasionally (once per 10 batches), I run boiling water through just to be anal.

Just what does such gutter talk have to do with beer making? And why is it necessary and accepted without anyone else objecting?

From: KARL DESCH <KCDESCH@ucs.indiana.edu>

>1. This keg appears to be all aluminum. If memory serves me correctly Papazian suggests to avoid using aluminum as a boiling pot. What about SS makes it better than aluminum?

It has a much stronger tendency to leave your brain cells intact. Oops, forgot to turn off flame.

Although there is a great deal of debate about the cause and effect of aluminum found in the brains of Alzheimer victims, the implication is far too frightening to even consider using an aluminum kettle for long term boiling.

Do yourself a favor and take it to a recycling center and consider the sawing an aerobic exercise.

From: Peter Glen Berger <pblp+@andrew.cmu.edu>  
Subject: Gingered Ale

Brewed, aged 1 month, and sampled. Pure heaven.

"Old-Time Jaspers Gingered Ale"

A five gallon recipe

9 lbs. Pale dry malt extract (M&F)  
.75 lbs. crystal malt, cracked  
3 lbs. light clover honey  
1 oz. Hallertau hops (boil)  
1/2 oz. Hallertau hops (finish)  
6 oz. fresh ginger, peeled and grated  
grated peels of 4 oranges  
1.5 tsp. cinnamon  
.5 tsp. nutmeg  
1.5 tsp. Irish moss  
Whitbread Ale yeast

SG: 1.071 FG: 1.019

First, a word about the hops: Yes, Hallertau is a lager hop. However, the ginger and orange peel both go a long way towards both bittering and flavoring the beer. Using a more assertive ale hop would a) add too much bitterness and b) overpower the other flavors that I want to come through. Besides, Hallertau has that spicy touch that makes this perfect for a holiday brew.

This brew is just barely sweet, at the threshold of perception. A strong, heavy body follows, the ginger and orange blending together and taking you through from the midrink to the aftertaste. The finish is incredibly long, both the high alcohol content and the ginger-orange aftertaste lingering for a full 8 or 9 seconds after swallowing.

Using a more attenuative yeast would make this drier and more alcoholic, but I like the balance given by the Whitbread. Primary fermentation took about 6 days, 6 days in secondary, aged 1 month at tasting. This beer is copper colored; I'm thinking of making a version with a little lactose instead of the crystal malt to try to retain the sweetness while having a paler color. Irish moss is a necessity with this brew.

Bob,

>Another problem is  
>the transport of the glasses from the back room to the judges. They are  
>very often carried in a six pack carrier with the entry. The glasses are  
>sometimes placed upside down in the carrier, where they can pick up this  
>cardboard nose.

Sounds like another good argument in favor of using pitchers (one of my favorite judge related crusades :-)...

Competitions I have worked the beers were served at pitchers, and the glasses collected and rinsed separately. Once they were removed from the boxes and cleaned the never touched cardboard during the judging. Sounds like some procedural changes there might help a lot. Also we often just rinse our own from water in pitchers right at the table, saves the stewards some work.

>So the environment looses out on this one.

Umm, I'll fight you on this one. At least you can use HDPE 1 or 2 glasses and collect them and give them over to recycling...

Russ sez:

>The glasses were washed with generic (cheap) automatic dishwashing detergent,  
>after their previous use and then rinsed with hot water just prior to their use  
>in the competition mentioned.

AAAck. I never use soap on my beer glasses. I use B-brite. There are other cleaning agents that many/most bars use. Soap is much more difficult to rinse clean without leaving a film. The cleaners bars use (sorry don't know any brand names) are chosen because they do rinse clean. B-Brite also does, which is why I use it on my glassware. Perhaps this is a little anal, but I have found soap doesn't rinse nearly as well. I'd suggest changing your cleaning agent. Soap also may not clean away the cardboard aroma.

From: Bob Jones <BJONES@NOVA.llnl.gov>  
Subject: Stress Testing Beer

To Larryba on stress testing your beers.

This is not a new idea. Many micros test their brewery operations in this manor. They take samples from several different points in the brewery, cap the bottles and let them sit at room temp. By observing the turbidity of the sample, one can correlate cleanliness. I think 4 days plus indicates adequate cleanliness. George Fix has related some procedures for the practical homebrewer in a paper he presented a few years ago at an AHA conference. He also discusses other easy steps to allow one to test their brewing operation with minimal high tech tools. Interested parties can contact the AHA for conference transcripts. I like the one comment George made once. "If you want to give your beers the ultimate stress test, just ship them via UPS anywhere !". Low level bacterial contamination has been the death of several microbrewers and a continuing problem for others. These low levels of contamination really starts showing up when the brewers start bottling their beers. The average liquor/grocery store is as good a tester as UPS.

On a more humorous note, I recently toured the AB facility in Fairfield, Ca. The tour didn't go through the brew house. They said they were "remodeling". I have always contended that the American brewing industry is determined to convince the average American beer drinker that the more beer tastes like water the better it is. This way they can just bottle water and like magic they have mega profit. Well I think they have succeeded. I speculate that they really DIDN'T have a brew house at AB. They are just bottling carbonated water. You can do your own testing to verify this hypothesis. Just blind taste their beer next to a cold glass of carbonated water. I rest my case.

Boots bitter kits, like all bitter kits in the UK, already have hop  
extract  
added. You only need add more if it's not bitter enough for you. Mostly  
we  
don't bother. The yeast is usually OK but you may prefer to use one you  
know. I'd say give it a try as it is. It'll give you a perfectly  
reasonable  
British bitter for little effort. If you tinker with it you won't know  
whether it's the kit or your changes that make it the way it is.

Boots kits are not the best available. Ask your friend to track down a  
homebrew retailer next time he's here and drool over the range available.  
I maintain the best is John Thompson, but that's just MHO.

Like, cool, man...call it "utter rubbish" and then say you'll try to be gentle. How stupid do you think we are? Wrong; guess again.

> 2. SS contains chromium which has a melting temperature around 3500 F. This  
> puts the melting point of the alloy significantly above that of carbon steel.

The melting point of an alloy is related to the melting points of its constituents in complex ways. If you don't believe this (and you've never encountered the rare substance called "solder") go look up the word "eutectic."

If you think you can predict the melting point of an alloy based on a minor constituent, please tell me what you're smoking (and where I can buy some).

> 4. Precisely because water boils at 212 F and turns into an expanding, cooling gas, one can heat it in kettles without worrying about the kettles melting. This is true, even if the flame temp is far above the melting point of the kettle.

This is true only within limits. You shouldn't have to worry about melting the bottom of a kettle unless you've got a bodacious flame, but you \*CAN\* damage a kettle without much effort on a good home gas stove. The controlling factor is the rate of heat transmission through the bottom of the kettle.

Well, as long as I'm at it...

> While I am counter-flaming, I would like to point out that most reasonable people would find the following sort of comments far more offensive than anything I have ever said.

What do you find objectionable? Unlike your tendency to disbelieve anything you haven't proven within your own quite limited abilities, I find a certain tendency to possibly-excessive cleaning to be not only normal, but reasonable. Perhaps you don't understand the full context of "anal"? It refers to "anal-retentive"--not in the least "gutter talk" but rather a phrase from psychology turned to pop-psych. I don't care whether it's in your vocabulary, but if it isn't, go educate yourself instead of sniping. Your marginal literacy is not our problem.

[Aluminum vs SS]

> It has a much stronger tendency to leave your brain cells intact. Oops,  
> forgot to turn off flame.  
>  
> Although there is a great deal of debate about the cause and effect of  
> aluminum found in the brains of Alzheimer victims, the implication is  
> far too  
> frightening to even consider using an aluminum kettle for long term  
boiling.

Only if you're scientifically illiterate. Start by repeating ten times,  
"Correlation does not imply causality." There is no implication such as  
that with which you attempt to scare us.

If you'd keep up with more recent work, you'd probably have read that  
although the correlation between Alzheimer's and aluminum in the brain is  
sound science, causality (from Al to Alzheimer's) doesn't hold up. Stated  
simply, we don't know why the excess Al ends up in the brain, but it's  
not  
the causative factor for Alzheimer's.

From: dab@pyuxe.cc.bellcore.com (dave ballard)  
Subject: quick tip of the day

Hey now- Just a quick tip for you carboy users: You know how it takes like a week to pour all of the water out of a full carboy due to all the glugging? Take a racking tube and stick it all the way to the bottom. When you start to pour, move the end to the newly formed air space. The air that's needed to push the water out will be sucked in through the tube and avoids all glugging. You'll get a nice smooth stream that empties the carboy on seconds! Pretty cool, huh?

If you've already thought of this, I apologize. I'm kinda slow sometimes.

For a demonstration of this technique, check out my video: "Carboy Cleaning At Home"... :- ) :- ) :- ) (can you believe I said that?)

later!

Sorry, Jay, but I couldn't let this go by without comment.  
\*Soap\* leaves a film. \*Detergent\* does not. People who clean  
items that come into contact with beer use detergents, since soap  
leaves a film and will cause off-flavors and destroy the head of  
the beer. Bars use detergents (at least the ones I used to work  
at did) for this reason.

From: Tom Dimock <RGG@CORNELLC.cit.cornell.edu>  
Subject: Chillers and Winners

The response to my question as to whether users of counter-flow chillers ferment on top of the cold break or not was about half and half. Some just leave it there, others let the wort settle for some period of time (some chill it all the way down to near freezing and then bring it back up to pitching temperature) and then rack it off. No strong opinions as to which is best. John Lenz (a fellow Ithaca Brewers Union member) mentioned that he uses a flow-thru chiller that is not technically a counter-flow chiller - he puts the coil of copper into a bucket of cold water. This allows him to use heat to sanitize the copper coil.

Major congratulations to HBD denizens and IBU members Steve Russell and Tom Strasser, whose festbier took 2nd place in the recent AHA club-only competition. Way to go, guys! I was fortunate enough to have tasted this beer, and it was indeed great stuff!

From: dbeedle@rs6000.cmp.ilstu.edu (Dave Beedle)  
Subject: Oatmeal Stout...thick stuff!

Good day all! I brewed up my first oatmeal stout this past week end using 18oz of Quaker Old Fasioned (rolled) oats. The stuff was pretty thick in the brew pot and pretty messy to deal with but I was really suprised when I trasfered to a secondary. About the last three inchs of brew in the fermenter was too thick to siphon! I ended up with about a gallon of trub/yeast/stout going down the drain. This is my first oatmeal stout so I ask, Is this normal? I didn't get a very good cold break and the trub didn't really pack down like it usually does. Would a better break help keep from putting so much (hopefully) good brew down the drain? I'm just hoping some of that body carries through to the finished product!

Actually, a pyrometer is to a foundry what a thermometer is to a brewery;  
a way to measure temperature.

> 2. SS contains chromium which has a melting temperature around 3500 F.  
This  
> puts the melting point of the alloy significantly above that of carbon  
steel.

Ah, but carbon steel contains carbon, which melts at 6700 F! Seriously,  
this reasoning has no relationship to actual melting phenomena. Stainless  
steel, in fact, melts at a temperature \*lower\* than pure iron or  
chromium.

(For a household example, consider the melting point of salt, that of  
ice; and then what happens when you put salt on ice.)

A typical "household" stainless steel melts in the range 2500-2600 F; a  
1050 medium carbon steel begins melting at around 2600 F, and low carbon  
steels will hold out a bit above that. There's really not much  
difference, in other words; maybe 100 degrees in favor of the carbon  
steel.

What you both need to keep in mind is a little bit of heat transfer. Your  
flame may be hot enough to barely melt steel, but as heat transfer  
isn't perfect, you'll find that the temperature of the pot's surface is  
several hundred degrees lower than the flame temperature. In Jack's  
case,  
I'd guess that his pot, depending on how thick-walled it is, never  
exceeds 1000F at any point, and probably averages about 500F in the  
center of the sidewall.

What's this got to do with brewing? Well, "Know your equipment and know  
yourself, and in a thousand brews you will never worry." - Sun Tzu  
Papazian

From: tix!roman@uunet.UU.NET (Daniel Roman)  
Subject: Quick comments

Jack:

1) "Anal" is a psychological term when used in this context and any text book on Freudian pschology will have this word you have a phobia about plastered all over the pages. It is a very accurate slang description I think, about the way some people (including me) approach certain aspects of homebrewing.

2) Alzheimer's disease is hereditary and you could eat aluminum cans all you

want or avoid aluminum it won't matter, if you have the gene, you get the disease. CP suggests avoiding aluminum cookware because it has a tendency to oxidize and could contribute flavors to the beer. Aluminum doesn't really oxidize easily unless exposed to chemicals such as chorine, but it certainly oxidizes MUCH easier than stainless. If you are on a tight budget or don't know if you want plunge into homebrewing completely as a beginner, using an aluminum pot for awhile and later shelling out the big bucks for a stainless steel one is not all that terrible. You'll still be able to make good, drinkable beer.

> necessary and accepted without anyone else objecting?

I'm hoping you were only joking Jack, but the reason why nobody finds the  
term  
"anal" more offensive than anything you have ever said and the reason why  
it is  
not "gutter talk" and is in fact related to beer making is because it is  
a  
legitimate term for people who are overly fastidious. Here's the  
definition from  
the Webster's New World Dictionary:

anal - designating or of such traits in the adult as orderliness,  
stinginess,  
obstinancy, etc., regarded as unconscious psychic residues of that  
stage.

Time to catch up on your Freud! :)

From: andy@wups.wustl.edu (Andy Leith)  
Subject: Spice beer question, Chimay yeast reply, Belgian beer , Gushing

Hello,

I recently (4 weeks ago) made a batch of the Xmas ale that has been posted on here several times. At present the taste of the ginger is overpowering, will this mellow with time? There is also a soapy taste at present, I have never had this problem before, and am wondering if it will go away with time, and if this is common with spice beers. I added 1/2 teaspoon of vanilla extract to the secondary to help meld the flavours, but so far it doesn't seem to have worked.

With regards to the postings on culturing Chimay yeast, I have tried this on several occasions with Chimay red and have had good results every time although the time it takes for activity to start has varied from 2 days to 2 weeks.

My wife recently returned from a trip to Holland and brought back several (9) different varieties of Belgian and Dutch beer. One of these was Gulden Draak by Bios, which I expected to be fairly sour as are their other beers, but which turned out to be a fabulous fruity barley wine type beer with strong blackcurrant overtones, which I highly recommend to anybody who likes strong ales (although I've never seen it available in the midwest).

A quick reminder that the St. Louis Brews annual christmas competition is coming up (entry deadline is early December) for anyone interested. We will also be giving the beer judge certification exam (Dec 14th).

I recently read an article in the European Brewery Convention monograph VI (Helsinki 1980). In which a correlation was found between barley malt contaminated with Fusarium moulds and gushing. I was suprised that the contaminated malt would cause gushing considering that the worts were boiled for 60 minutes. I have always assumed that gushing was the result of infections obtained during the brewing process, but it appears that poor quality grain can cause this problem regardless of the care that you take with your brewing procedure. (The cure for this problem is to add formaldehyde to the steeping water used to make the malt, which doesn't sound like much of a cure!)

From: Tom Barstow <barstow@apollo.hp.com>  
Subject: How to reduce the noise level

I've hesitated to write this since it, too, adds to the noise in the HBD but I can't take it any longer.

I started reading the Digest about a year and a half ago, back in the days when politeness and civility reigned and flaming was associated only with brewing. In the last few months the S/N ratio has deteriorated badly due to the number and intensity of arguments and personal attacks that have appeared here.

Frankly, I don't blame JS for the deterioration -- I fault those people who have overreacted to him, replying not just to him but also to the Digest. Just think how much less noise would have been in the Digest had his commercials been shrugged off! Suppose he advertised weekly -- the S/N ratio would *still* have been better than what it has been. Let's ignore the junk postings just as we do those that come through the U.S. Mail.

And as for the I've-got-to-reply-because-others-will-be-misled justification -- fine, correct the misinformation but, for God's sake, take some lessons from Miss Manners before you start typing. Pass on the information you have to the Digest and post your personal comments separately to the submitter WITHOUT INCLUDING THE HBD IN YOUR EXPLOSION.

Let's get back to where reading the Digest was a great way to start the day.

Tom

>>competition mentioned.

>AAAck. I never use soap on my beer glasses. I use B-brite. There are  
other  
>cleaning agents that many/most bars use. Soap is much more difficult to  
>rinse  
clean without leaving a film. The cleaners bars use (sorry don't know >  
any  
brand names) are chosen because they do rinse clean. B-Brite also does, >  
which  
is why I use it on my glassware.

I believe Miller (CHoHB) discusses the difference between hand  
dishwashing  
detergent and automatic detergent. The hand stuff is certainly a no-no  
(Tom  
Ayres taught me this many years ago while I was washing up one night at  
his  
place). The automatic stuff acts more like B-Brite in that it uses  
oxygen or  
some such to do its cleaning and often has some chlorine in it to assist.  
As  
long as you don't use ones like Cascade which have some additive which  
coats  
the glass to prevent spotting the glassware should rinse out clean. I  
have  
never experienced the head loss associated with hand detergents when  
using the  
automatic stuff. A double rinse doesn't hurt either.

As far as the cardboard is concerned, I am still researching alternate  
containers (the boxes I have now are so old that they aren't much good  
anyway).

So far all suggestions have been for commercial dishwashing racks which  
won't  
really work as they are open to the air. Plastic boxes seem to offer the  
best  
future, but I'm concerned about trading one smell for another.

Subject: shocking yeast with too much malt?

I suppose you COULD hurt the yeast with too much malt -- in large enough concentrations it should be a preservative (a la sugar). No way would you do it in any reasonable setting, though. When I have used Wyeast I pitched directly from the package into 5 gallons of wort, OG 1055, with hops, crystal malt, and other junk. I ferment cold (by ale standards) at 58 -- not the ideal for the yeast, but very good for the taste. Fermentation started a little slowly, but went fine. Very nice beers. By the way, this was with both German and Irish yeasts (I do not recall the numbers, but both were definitely ALE yeasts).

Geoff Sherwood

From: sherwood@adobe.com  
Subject: arf

Look, people. Jack has toned things down quite a bit. He made one ill-advised posting (his promo piece) and got a lot of crap over it. I was not overly fond of it myself, but I vastly preferred it to all of the bitching that followed. If you don't like something, IGNORE IT. Or if you have to get it off your chest, use email. Don't clutter up the digest, because nobody really gives a damn if you are pissed over Jack's (or anyone else's, for that matter) postings.

Yes, I realize I am doing the same thing, but I am at least pleading for some sanity here. Jay Hersh's diatribe over Jack's mentioning his videos in passing prompted me to break my own rule here. The diatribe was boring and petty.

To Jack: trying to show that others are more obnoxious than you are doesn't help your case. Darren's comment about being anal was hardly vulgar. He was obviously using it in a clinical sense (as in anal retentive) meaning that he didn't think it made any difference whether he ran the boiling water through it, but he did it anyway. You do post a lot of interesting information, like the nitrosomine info today, and I hope you continue. Your correction on melting kettles was apt and well presented.

From: melkor!rick@uunet.UU.NET (Rick Larson)  
Subject: Re: Boots bitter kits

Ah, what memories.

My first homebrew was made using Boots extracts. My Mom when to England with a friend and came back with two kits. I remember making a 2 gallon batch in my college dorm kitchen. Beer was not allowed campus so went the RA asked my girlfriend (now wife ;- ) what are we making, he was suprised. I used plastic milk jugs, open fermentation, and bottled the ``beer'' in plastic quart pop bottles. I don't remember if the beer was good or not (this was 1979!), but my roommate fell into a lake that was a few miles away and I kept on brewing. Looking back I am suprised it was any good due to the lack of sanitation but boy what fun!

I think Boots is a drug store and sells it's own brand of wort.

I would not use any corn sugar let alone 2 pounds. You didn't say how big the wort is (I thought the little cans were about 2.2 pounds maybe less) but I would use both cans, 2 pounds of light dried malt extract, an ounce of Kent Golding hops bittering, 1/2 ounce aromatic, and 1 packet of Whitbread Ale Yeast. Add enough boiled and cooled water to get OG ~ 1.035. I would doubt the extra expense of Wyeast would improve the final product. This beer is to have fun with. When it is ready have your co-worker over for the bitter and one of your better brews. Maybe [s]he will start brewing also.

From: GERMANI%NSLVAX@Venus.YCC.Yale.Edu  
Subject: Pasteurization (or lack thereof), and how much bleach?

Greetings,

Here's one more data point on pasteurization. Several beer factories have products labeled "cold filtered". I know, at least for Miller, that this means that they don't pasteurize the beer but the use these ultra-fine ceramic filters. This means that beyond the filters the lines must be kept sanitary.

From what I can tell Miller actually has ceramic coated lines and a "clean room" around the filler. It doesn't sound worth it to me (there is so little flavor in industrial beer anyway), but it seems to be a good marketing ploy.

I'd rather just forget about industrial beer and wait for my Holiday Ale (ginger and coriander seed this year). While waiting, in fact, I think that I'll have a fresh brown ale or some of my latest cider. Isn't this one of the most rewarding hobbies imaginable!

On to another subject. Spencer W. Thomas says that "someone who should know" told him that 10 seconds of dilute (1 capful in 5 gal) bleach sol'n will kill all. Now, Miller (the book) says 10 min. with something like 2-4 oz of bleach in 5 gal. is necessary. Of course, some people advocate not using any sanitizing stuff. Not to open up this whole can of worms again, but does anyone really know what is needed in order to insure adequate sanitization? (I know, this is probably not a well defined question).

Keep on fermenting,

Joe

P. S. js, look up anal retentive personality in a psychology textbook-- it's not really that offensive.

From: mcnally@Pa.dec.com  
Subject: rust on a carboy

Get some Zud cleanser, or go to a "rock shop" (a store catering to rock hunting hobbyists) and get some oxalic acid. Mix some (not too much) with hot water and pour it in the carboy. The rust will vanish.

An alternative is to cook up a bunch of spinach and pour it in with the cooking water. There's a miniscule chance this will work, because spinach contains oxalic acid.

Now, I can't speak for what will happen to you if you don't sufficiently rinse the stuff away. In fact, it might render the carboy permanently toxic.

By the way: I'll bet the blueness is a natural discoloration of the glass from exposure to solar radiation. Certain types of glass thusly discolor. In fact, in Boston it's a great distinction to have a blue glass window on a house, because it indicates the house's authentic antiquity: a shipment of glass from the continent in the 18th century was apparently left exposed to sunlight for a long time, and turned blue.

(One might ask why window glass doesn't all turn blue. I don't know. Maybe this is all a myth.)

From: Bob Jones <BJONES@NOVA.llnl.gov>  
Subject: Bay Area Brewoff

Dear Fellow Homebrewer:

You are invited to participate in the 1992 Bay Area Brew-off homebrew competition. This years competition is hosted by The Draught Board homebrew club. The competition will be held at Lyons Brewery Depot in Dublin, Ca. on Jan 25, 1992. Entries will be received the week of Jan. 10-17 at Lyons Brewery. Entry deadline is Jan. 17, 1992. Mail or deliver your entries to Lyons Brewery Depot, 7294 San Ramon Road, Dublin, Ca. 94568. Entries consist of 2 - 12 oz. bottles. Entry fee is \$5.00 per entry. One entry per category. Label each entry with category and sub category if needed, your name, address, phone number and club affiliation.

The catagories for this years competition will be as follows:

Dry Stout  
Porter  
Pale Ale - Sub Cat. are Classic Pale Ale, India Pale Ale, American Pale Ale  
Amber Lager - Steam style  
Barley Wine  
Mead - Sub Cat. are Traditional, Melomel, Cyser, Metheglin (all still and sparkling)  
Holiday Beer - Spiced, herbed or other special beer brewed for the Christmas holidays.

This is always a fun get together for homebrewers. I look forward to seeing you all there.

If you want additional details on the catagory definitions or have general questions about the competition call Bob Jones (510)743-9519 or email to BJONES@NOVA.LLNL.GOV

See you at the competition,

Bob Jones

From: larryba@microsoft.com  
Subject: Detergent is not Soap

in HBD 765 Jay Hersh claimed (indirectly) that dishwashing detergent is soap. I do not believe he is correct. Detergent is detergent, not soap. Most dishwashing detergent (hand or machine) is detergent + sodium carbonate. In fact, machine stuff is primarily sodium carbonate. Washing Soda (sodium carbonate) is actually a very good agent for cleaning glasses. It rinses off easily and cuts most dirt items. It also makes for very easy label removal from bottles.

The biggest problem with some automatic dishwashing detergent is that they sometimes have a "rinse" agent in them. That stuff is suppose to be death to beer heads. So avoid brands that claim to be "spotless".

Soap (like hand washing soap or liquid ivory) is a different matter. They are sodium or potasium salts of fatty acids (e.g. fat) and are indeed very hard to rinse completely off of glass.

I have used Electrosol with excellent results for bottles and glasses. You can even call up their consumer hot line and get a complete skinny on what is in the stuff. Washing soda (blue box at your supermarket) is dirt cheap. I used to use that for my kegs & carboy, but now just use a squirt of Dawn liquid detergent.

Another note. Because of the high temperatures and overkill in amounts of detergent used, glasses will eventually etch. That is bad since the etching seems to "hold" some of the detergent (that awful dishwasher smell). Two things can be done: lower the hot water temp (mine is set to 115f) and cut the amount of detergent used. You might have to pre-wash the dried on spagetti, but your glasses will live far longer and the beer taste so much better...

- Larry Barello

Subject: Boiling Vessals / Conservation of electrons.

Jack S. may be correct about boiling water over a very hot source. I used to win bets on camping trips by placing a styrafoam cup full of water over a hot bed of coals and showing that, so long as it had water in it, it would not burn or melt. In fact, I boiled soup in paper cups once and won more bets.

About conservation of bytes. This digest has gotten very long. I love all the reading, but many people pay for every kilobyte and reading unnecessary material may be unfair to them. May I make the following suggestions:

1. Use as little copied material as possible when referring to another post.
2. Keep signature lines and tag material to a minimum. Unless the "From:" line is wrong, there is no need to relist your email address. Unless you are inviting letters of phone calls, mail addresses and phone numbers aren't really necessary, either. I like cute sayings, too, but I don't really like paying for them.

No offense intended. This is just offered in the spirit of making the maximum use of expensive space.

Subject: Steel vs. Aluminum

In HBD 765, KARL DESCH <KCDDESCH@ucs.indiana.edu> says:  
> >1. This keg appears to be all aluminum. If memory serves me  
correctly  
Papazian suggests to avoid using aluminum as a boiling pot. What about  
SS  
makes it better than aluminum?  
And arf@ddswl.mcs.com (Jack Schmidling) replies:  
> Although there is a great deal of debate about the cause and effect of  
aluminum found in the brains of Alzheimer victims, the implication is  
far too  
frightening to even consider using an aluminum kettle for long term  
boiling.

I've got a much more pragmatic, less controversial answer.  
The average K-Mart-quality steel pot is more sturdy than the average K-  
Mart-  
quality aluminum pot. I have no knowledge about high-end aluminum  
cookware  
(i.e. Calophon), but although it seems sturdy, it costs \$80 and up for a  
twenty quart pot. We have a sixteen quart aluminum stock pot we use for  
general cooking, and a twenty quart steel stock pot for brewing, and the  
aluminum is certainly showing its age.

Hope this provides some help.

From: semantic!bob@uunet.UU.NET (Robert A. Gorman)  
Subject: Fermenting In Soda Kegs

Fermenting In Stainless Steel Soda Kegs  
=====

Cleaning and sterilizing of these has already been discussed. Through out this discussion assume that all pieces and parts mentioned have been cleaned and sterilized.

You will need a proper size wrench to be used for removing the connectors from the keg. If you use pliers or an adjustable wrench you will eventually wear out your connectors. My kegs are 3 and 5 gallon Cornellius Spartan style with ball fittings (as seen on the cover of Zymurgy). For the 5 gallon I use a standard 7/8" wrench and for the 3 gallon I use an 11/16" twelve point deep socket (a wrench would work just as well). These kegs have the single detachable plastic handles and don't interfere with removal of the connectors. People with the full circumference rubber handles my need to use sockets rather than wrenches to get at the connectors.

Note: Before removing any connectors equalize the external and internal pressure of the keg. (ie: open the pressure release until the gas stops hissing out).

Attaching A Blow-Off Tube  
-----

Remove the gas connect from the keg with your wrench and then remove the gas dip tube. This leaves a threaded nub sticking up. The outside diameter of the nub is about 3/8". A piece of 3/8" ID tubing can easily be squished over this nub and firmly attached with a hose clamp. The length of my blow-off tub is about 2 1/2 feet for a 5 gallon keg.

The liquid connector and dip tube can also be removed and replaced with a blow-off tube in the same way. I leave mine in place and have had no problems with it clogging to date. The only side effect is that it can contain yeast deposits which cloud the first cup of beer when it is racked.

Attaching An Air-Lock  
-----

When your beer no longer needs a blow-off tube an air-lock can easily be attached in its place. For this I again use 3/8" ID tubing, but with a length of about 2". One end is affixed to the gas connector nub as described above. The air lock is then slipped into the other end of this short piece of tubing and affixed with a hose clamp.

Racking  
-----

When its time to rack your beer, from settled trub or yeast, you will need to reinstall the gas connector. Reassemble the connector pieces as they were before you disassembled them. Take your wrench and snug down the connector. There is no need for excessive tightening as the rubber O ring holds a great seal. You can tell when a connector has been over tightened as the once round O ring emerges with flattened edges.

If you are using a shortened liquid dip tube for racking then install this into place if not already present. I use a dip tube shortened 1" for primary racking and one that is shortened 1/2" for secondary racking. One could also use a tube shortened by 1 1/2" if expecting large amounts of trub or yeast.

Place a second fully assembled keg next to the first. Purge the air from the second keg with CO2. You will need two liquid disconnects ("beer taps"), a piece of tubing to go between them, and way to stop the flow of beer. Connect one disconnect to the first keg with the piece of tubing attached. Apply pressure with your CO2 tank and run off the beer/yeast/trub until the beer runs clear. I use between 5 and 10 PSI of CO2.

If you have a lot of trub or a lot yeast from a highly active ferment you may find that the first pint is purely yeast/trub. This is why I recommend a shortened liquid dip tube. If you are using a shortened dip tube or are racking from a secondary fermentation/settling tank then you will find that the first cup or two will contain some suspended yeast.

Once you've got a clear flow of beer run some off into a cup to be used for evaluating the beer and to do your hydrometer reading with. Then stop the flow of beer and connect the open end of the tube to the other liquid disconnect. This second liquid disconnect is then connected to the second keg. Restart the flow of beer and open the pressure release on the second keg so the beer will flow freely from one keg to the other.

Now sit down and enjoy that sample of beer while doing your hydrometer reading. When the beer is done racking CO2 will begin to bubble up through the beer in the second keg. If allowed to continue this will get rather violent. Turn off the pressure from your CO2 tank and purge the remaining pressure from the first keg. Remove the disconnects and you're all done.

If you need to connect an air-lock then follow the procedures mentioned above. Otherwise you've got a keg of beer ready to be carbonated and enjoyed.

There are multiple methods of carbonating beer in a soda keg. I won't discuss any of them here. There are also multiple methods of enjoying beer in a soda keg. I'll leave these as an exercise for the reader.

#### Alternate Methods

- - - - -

Another method of connecting blow-off tubes is described in the "Brewers and their gadgets" special issue of Zymurgy. In that article the shell of the connector is screwed back onto the keg without the insides. A 1/2" ID blow-off tube is then placed over the outside of the connector. This achieves the same result but the effective opening for blow off is reduced to 3/16". Therefore this article recommends removing both the gas and liquid connectors

to allow additional capacity for blow-off.

Other Notes

- -----

I initially got into fermenting in stainless steel after mangling my hand on a broken carboy. If you are already into using soda kegs for dispensing your beer then why not go all the way and ferment your beer in them too? Then you can sell of those old carboys and rid yourself of there evil presence.

Yours in Fermentaion Foam,

From: "Tom Childers" <TCHILD@us.oracle.com>  
Subject: Commercialism

I've been a delighted subscriber to this digest for several months now, and am finally getting some equipment together and going for my first batch this weekend. I can't wait to have some real questions and contributions for this fine forum.

But I do have comments on the resurgng flame war focused on Jack Schmidling.

- Everyone except Jack seems to be using Internet for it's intended purpose:  
the dissemination of information without commercial intent. I enjoy hearing about new Guinness packaging, competitions, sources of materials, etc. when the contributor clearly has nothing to gain financially from the posting.
- Jack has referred to his videos far too often with commercial intent. I am a likely purchaser of such a product, but would never buy something produced by a person who so freely violates the spirit of this medium.
- I'm to the point where I will simply bypass entries from Jack. Someone who takes offense at words that are in the dictionary (medical terms, no less!) and has contributed one interesting idea in 30 posting can be safely ignored. Why don't others do the same? This is one annoyance that will go away if no-one pays any attention.

Can we return to the interesting stuff now, and relax our egos a bit? Please?  
There are hundreds of us reading this digest, not just the few knocking heads.  
We are here because we love the art/science/craft/end products of brewing!

Date: 21 Nov 91 18:39:07 EST  
From: Jeff Frane <70670.2067@compuserve.com>  
Subject: Whose Kegs Anyway?

In all this talk about using stainless steel kegs for kettles and fermenters, I've noticed one small detail missing: Most of these kegs belong to someone else! To me, this has two elements, one moral and one political. The first is that, since most kegs are the property of breweries, it's simple theft to cut them up and use them for kettles. While it's true that this is less expensive--for you--than buying a SS kettle from a kitchen supply store, it's \*not\* less expensive for the brewery which has to replace it. Kegs are expensive.

The second element is a little different. For the six years or so that I've been involved in homebrewing, the local brewing industry, both micro- and macro- has been extremely courteous and helpful to all of us. They've always been astonishingly cooperative in providing information and guidance, and in some cases raw materials. I think it's a Bad Idea to turn around and start swiping their kegs. A lot of micros (particularly brewpubs) have a hard time finding and paying for adequate cooperage, and if homebrewers are indiscriminately appropriating these kegs without paying for them, they're going to be having an even harder time. Think about that the next time you try to reserve a pony keg of your favorite micro beer for a company picnic.

I think George Fix's information on converting pony kegs to fermenters is excellent technical information. But, please, be sure you really own those kegs before you take them out of the trade.

To Jack Schmidling: I suspect none of us were offended by the "gutter talk" since we recognized that "anal" was short for "anal retentive" which is a corruption of a psychological term rather than naughty language. Jack, "anus" is not a dirty word. Karl Desch's question about aluminum can hardly be classified as offensive. Remember, there are no stupid questions . . . just stupid answers.

From: IO10676@maine.maine.edu  
Subject: De-labeling Bottles

I realize that a lot of you HBDers never touch bottles, being quite happy to stick with your kegs. I'd like to myself, but a meager grad student's budget doesn't allow it. And for the rest of us who do use bottles, I'm sure most of you have long since de-labeled all the bottles you use. I was in that same condition before a recent cross-country move, but at that time I decided it was silly to transport umpteen cases of bottles when I knew that I could get more after I got settled in at my new location.

My point is that any of us may suddenly have the need to remove a LOT of labels from bottles again, and the new brewers on the digest are probably still in the process of doing this the first time. So, a suggestion and a question for the HBD:

I have found that one of the most effective things for scraping the labels off heavily-glued commercial bottles is a metal-edged windshield ice scraper. The one I have has an apparently brass edge on it, and I got it last winter at a convenience store for about a buck. Works pretty well on my windshield and really well on my bottles. If you live in aa southern clime, you may not be able to get one of these, but I would heartily recommend one to any other dwellers near the Great White North (eh).

And now my question: I've heard that prolonged soaking in the proper chemical will make even the most recalcitrant labels float right off. Problem is, I can't remember what chemical it is. Bleach? Ammonia? Something like that? Anyone know?

Date: Thu, 21 Nov 91 22:42:20 EST  
From: Joshua B. Halpern <jbh@scsla.howard.edu>  
Subject: Boiling (or in computerspeak, flaming) water

The rather long simmering argument between Jack Schmidling and Bob Jones on boiling water should be quickly extinguished and both gents forced to take courses in elementary thermodynamics. To summarize the problem, Schmidling has a pot which sits on top of a forced air melting furnace and he can boil water (7 gals in about 15 minutes). He states that you can't possibly hurt a steel kettle on anything even that hot.

Jones replies that you can't boil anything at 2500 F because the steel melts.

Schmidling counter flames (appropriate to this correspondence) that

1. He measured the temperature of the flame with a thermocouple pyrometer

SS has a higher melting temperature because it contains chromium and chromium melts at a higher temperature

3. Aluminum melts at 1200 C, so you cannot compare the two and
4. Water boils at 212 F and turns into an expanding cooling gas so one can heat in kettles without worrying about the kettle melting.

Well anyhow, just about all of what was said by both parties is irrelevant, and what isn't is only distantly related to the problem.

First of all, at constant pressure (atmospheric in this case), liquid water and steam can only coexist at one temperature, the boiling point, 100 C or 212 F. Thus, you can only have water below 100 C, or (superheated) steam above it. The steam is not an expanding cooling gas, but rather it is carrying energy, in the form of heat, away from the kettle, while that little old melting furnace is pumping it in the other end. If you close the kettle (pressure cooker), then the temperature will increase inside as will the pressure, until the whole thing goes boom. That's why pressure cookers have the little valves which regulate the pressure and keep our kitchens and bodies in one piece. However, as we state in the beginning, at atmospheric pressure, water and steam can only coexist at the boiling point (OK you chemists and physicists, I know about vapor pressure, but these guys need a simple explanation).

So Jack Schmidling is right that he can have a pot full of boiling water on a really hot flame and the boiling water will remain at 100 C, but his picture of what is going on is wrong. It is not the temperature of the flame that matters, but how much energy it can pump into the kettle per unit time that is determining. There is a small caveat that should be

inserted here, before everyone starts using torches to heat their kettles, remember the flame heats the pot, and the heat that is transferred to the pot then flows into the water. If the heat flows into the pot faster than it can be transferred to the water, then the temperature of the bottom of the pot will be much higher than the temperature of the water. Given a hot enough flame and a pot made of a poor, or non-conductor, and you can melt the bottom of the pot. Ordinarily this is not a problem, but with a forced air or oxygen heater, and a stainless steel pot (SS is a relatively poor conductor of heat), interesting things could happen.

The difference between temperature and heat is important, and often badly understood. Temperature is a measure of the average amount of energy per molecule or unit mass. Heat is a form of energy. Thus, a flame can be very hot, but since the gas is not very dense you can do things like put out a candle with your finger, or quickly pass your hand through a gas flame without pain (There is something of a technique to both of these tricks and I am not recommending them to anyone, and accept no responsibility for anyone doing so, but most adults have seen both of these things done). A safer, though less spectacular, way of seeing this is to pass your hand in front of a hair dryer. The dryer produces air at about 80 C or 150 F, but if your hand passes quickly in front of the dryer, its temperature remains at about 98 F or 35 C, because the hot air from the dryer can pass only a bit of heat to your hand. Leave your hand in front of the dryer for a long time, and it will heat up, eventually reaching the temperature of the air coming from the dryer.

What does this have to do with beer? Not much, but on the one hand, I have been enjoying a fine glass of St. Louis Gueuze while writing this, on the other the rate of heating seems to be a bit neglected in the brewing discussions (this is really what the flash pasturization arguments are about)

Many thanks for the Homebrew Digests, although I am not a homebrewer, I enjoy the discussions of beers, and the places to hunt them.

From: agerhardt@ttsi.lonestar.org (Alan Gerhardt)  
Subject: Cleaning SS Fermenters

I would like to thank George for his excellent posting about the use of kegs for fermenters.

I tried his method of removing the ring, etc. last night and his instructions are right on target. I will try a batch in the keg soon.

Sanitation is the only remaining concern at the moment. Every batch I have ever brewed in a glass carboy has left "grunge" deposits on the surface somewhere. I usually use a carboy brush to scrub them off, and examine the carboy closely to make sure I have gotten them all, and then I sanitize the carboy in the usual fashion.

Obviously, examination is virtually impossible in a 15.5 gal keg used as a fermentor. Is chemical cleaning with iodophor, b-brite, or something else adequate for this type of fermenter ?

I would be interested in hearing about the sanitation regimen that anyone is using successfully for this type of fermenter.

Cheers,  
Alan

Date: 22 Nov 91 02:56:53 MST (Fri)  
From: rcd@raven.eklektix.com (Dick Dunn)  
Subject: GLUG!

In HBD 766, Dave Ballard suggests how to get a faster flow out of the carboy (when rinsing) by using a racking tube to vent air up, so that the outflow is smooth.

You can get a good approximation to this by whirling the carboy as you turn it over. It starts a bathtub-emptying sort of eddy; the glug turns to a smooth flow with air coming up the center.

BUT be careful when you give the carboy a swirl, that you don't end up smacking it against something and breaking it!

From: "Spencer W. Thomas" <Spencer.W.Thomas@med.umich.edu>  
Subject: Etiquette and water

I shudder to find myself contributing the non-beer part of this digest. But the recent level has gotten too high for me to keep quiet. I'll keep it short.

Please, when responding to something that is not related to the main point of the digest (today's flood of responses to Jack's comment about the term "anal" come to mind), send mail directly to the "perpetrator". There is absolutely no need to let the rest of us know how smart you are. We already know it. :=) Only when what you have to say is (1) directly related to the point of the digest, and (2) of interest to the other >1000 members of the list, should you reply to the list instead of to the original sender.

\*\* End mini-flame \*\*

Now, for some beer-related stuff: I recently noticed that our city water (Ann Arbor) was smelling strongly of chlorine. I called the water treatment plant and talked to one of their chemists. He said that it wasn't chlorine, but an oxidation product of the chloramine they use for treating the water. It is aggravated by nitrifying bacteria in the distribution system, and occurs mainly when the water temperature is above 14C (summer and fall). In summer it's not so much of a problem because people use more water. As the reaction takes several days, it is most noticeable at the edges of the pressure districts, where the water is "oldest" (2-4 days). Guess where I live?

Guess I'll boil my water.

I also asked for them to send me a water analysis. It hasn't come yet. If you are concerned about the quality or mineral content of your tap water, give the water department a call. They are usually helpful and willing to talk.

Date: Fri, 22 Nov 1991 10:29:22 -0500 (EST)  
From: YATROU@INRS-TELECOM.UQUEBEC.CA (Paul (8238))  
Subject: More about steel vs aluminum

There's been a lot of discussion in the last few digests on the merits of SS over aluminum for boiling wort. Let me add my own experience to this discuddion. Last week I was boiling some water for a mash (my first) in three different pots - 2 SS and 1 aluminum. (I had to do this because the pots are small: 16 Qt SS, 12Qt alum, and 6Qt SS and I needed 5 gal. - Hey, I'm just starting!) Anyway, to make a short story shorter, out of curiosity I tasted the water out of the three pots and the aluminum sample definetly had a metallic taste. Maybe this was all in my mind (does aluminum travel there that fast? == %^). After mashing in an insulated plastic food grade container, I boiled the wort in the same 3 pots.

I also looked at Dave Miller's book (look up "boilers") and he recommends \*not\* using aluminum for precisely this reason : it imparts a slight metallic taste onto the wort.

So I went out to my favorite discount kitchen supplies store and bought a 16Qt enamel pot for my next batch. Given all that, I am not at all worried about my first all-grain batch, "Metallica Pale ale".

(BTW, pop-psyche and gutter-talk, aren't they the same thing?)

>at did) for this reason.

This has got me wondering. I clean my bottles in the dishwasher, using a bit of bleach or B-Brite. I've been told repeatedly that I should not use dishwasher detergent under any conditions and to make sure I don't have one of those additives that keeps the glass from spotting, either. Recent HBD talk has indicated that basic dishwasher detergent is fine for cleaning bottles. Whats the consensus? Maybe someone has a video out there titled, "Bottle Cleaning at Home". ;-0 ;-) ;-0

I don't have a copy of the recipe you used but I've got a batch of Xmas ale made with ginger. It was brewed over a month ago and has been in the bottle 2-3 weeks. I used about 2 oz. of fresh ginger as a finishing ingredient, and yes, the ginger is overpowering. The good news is that it is mellowing with time. Also, ginger will provide a soapy taste. I don't have any experience with vanilla. Give it time; I bet it'll be good.

From: Dave Rose <CHOLM@HUBIO2.HARVARD.EDU>  
Subject: Chimay yeast.

I have recently cultured some Chimay yeast myself. I went about it somewhat differently, streaking the culture out for singles, picking a single into 10ml of liquid media (read "wort"), growing to stationary phase, and then pitching this small culture into a two cup starter. I got visible starter activity in about 12 hours, and when I pitched the starter at around 24 hours I had \*vigorous\* fermentation within 8 hours (maybe sooner, I was asleep).

Two points. First, my experience suggests that the yeast is not inherently slow-growing. However, it is possible that the viability of the yeast in the bottle is low. So, the big difference may be that I am pitching many more viable cells by streaking for singles and making a stationary culture. Incidentally, I find this method (single>>stationary>>starter) works very well; I just set up the starter the night before brewing. With most strains, a stationary culture (one that has been allowed to grow until all the sugar in the culture media is exhausted) is stable at 4C (fridge temp, roughly) for as long as a month. The zymurgy yeast issue, in contrast, suggests that the small culture must be pitched while it is actively growing, which is a little more difficult timing-wise.

Second, there was a suggestion that Chimay yeast is a combination of five strains. I had never heard this, and have no inside information one way or the other. However, the colonies I saw when I struck for singles were very homogeneous, which suggests (but by no means proves) that they are all the same thing. If Chimay \*is\* a mixture, then I have done exactly the wrong thing by streaking for singles. But it didn't look that way to me.

My first trappist ale is fermenting away. I couldn't really find a recipe, so I ended up doing a high-gravity ale with lots of crystal malt and some brown sugar, loosely based on Miller's recipe. Following Miller's advice, I am trying to keep ester production high by fermenting at a rather high temp (~70F), but I don't really have very tight control. I can definitely say that I am getting esters: each day a new fruit emanates from the fermentation lock. Normally I would be concerned, but in trappist ales this is apparently true to style. If anyone is interested I would be glad to pass along the recipe. And any further information on the composition of chimay would be appreciated.

Subject: Window screen

Jack writes:

>A small piece of window screen is rolled several times around the pipe  
and  
>secured with a hose clamp or twisted copper wire. The screen roll  
extends  
>several inches past the end of the pipe and the last inch is bent over  
itself  
>to prevent anything from entering the spigot that has not passed  
through  
>several layers of screen.

All the modern window screens I've seen in my area, are made of some  
mystery  
metal. It doesn't rust, so it's not steel, it oxidizes too easily and  
the  
oxide is too dark to be aluminum. Maybe it's galvanized steel. The  
oxide  
comes off on your hands very easily. Jack's idea is inventive, but I  
would  
recommend against using window screen. As an alternative, you could  
effectively  
build a metal version of the slotted-pipe-in-a-cooler lauter tun by  
capping  
the pipe (don't use lead solder) and cutting a bunch of slots in it.

On another topic: three cheers to the person (sorry) who pointed out that  
industrial coffeemakers could be stainless steel and have built-in heat.

Subject: Cleaning glass carboys

Geoff writes:

>If 1/4 kegs are used - how is the keg cleaned? Glass carboys are enough  
>of a pain, but at least you can see what junk still stuck inside.

I don't use SS kegs (yet), but I have no problems cleaning my carboys. All the gunk is either on the bottom or near the mouth. Immediately after racking, pour in some hot tap water and swirl to loosen the gunk at the bottom. Dump and repeat once or twice and the bottom is clean. Pour a shlug of chlorine bleach in the carboy and fill with hot tap water -- all the way to the top. Let sit for a week. Pour out a few cups and insert carboy brush. I've bent my wire brush handle so it's easy to clean the inside top of the carboy. Careful while pulling out the brush or you will bleach little white dots all over what you are wearing. Dump and rinse with hot tap water. Crystal clean! Of course I sanitize again before using.

From: korz@ihlpl.att.com  
Subject: Window screen revisited

I just had another thought about the screen-around-the-pipe lauter tun. If the only exit for a large diameter container was centrally located, a lot of sugars could be left behind in the grain. The sparge water can sit stagnant at the sides of the tun where there is little "current." I suspect that multiple pipe system (as in the slotted-pipe-in-the-cooler lauter tun) would be more efficient.  
Comments?

From: neilm@juliet.ll.mit.edu ( Neil Mager)  
Subject: No Flames Policy (proposal)

I'd like to make the following No Flames proposal:

HBD No Flames Policy (NFP)

If you feel the urge to enter into a 'heated' discussion with someone, take it to email and out of the digest. If a flame does appear in the digest, email should be used to make the flamer aware of the No Flames Policy. A simple reference to the NFP should suffice without causing a flame war. If someone says something you \*KNOW\* is in error, POLITELY correct them, (and of course, state your source).

All new subscribers should receive a copy so they know the etiquette of the digest.

Thats it. It can be changed, modified, or whatever.  
But let's be the first on our block to adopt such a policy, if not formally, at least in spirit.

Now back to the regularly scheduled brewing discussion.

Date: Fri, 22 Nov 91 16:02:31 EST  
From: "Jack D. Hill" <jdhill@BBN.COM>  
Subject: Pressure Barrels

A friend of mine just started using his new kegging system and lent me his Edme Pressure Barrel. He told me how his first couple of batches with this thing became oxidized after a couple of weeks. He went back to where he bought it and they said he needed a new O-ring (those O-rings get ya every time) . They also suggested that he grease all of the fittings with vaseline. This fixed his oxidation problems but the barrel does not produce beer with a lot of carbonation or thick creamy heads. I understand these barrels are very popular among homebrewers in England where heavy carbonation in their bitters is not desirable, so this makes sense. I prefer this so I plan to use it strictly for English style ales.

Last week I was watching my tape of the Beer Hunter where Michael Jackson talks about beer in England. He describes how beer is barreled while still young, or in his words "still fighting back". They would then insert porous splines into the cork to bleed of CO2 to get the perfect level of carbonation. This technique seemed to be a good idea for this pressure barrel, so last night I racked my porter from the secondary into the barrel (this was done perhaps as much as a week earlier than if I were to bottle). If you've never seen these things before, they have an interesting system of spring loaded pressure release valves and a CO2 injector.

I would be interested to hear if anyone else has been using these barrels and their experiences and tips. My next batch with the barrel will be my first batch using a partial mash. I'll try for a nice bitter. (Sounds like my mother-in-law saying, "Here, have some nice chicken soup.")

From: larryba@microsoft.com  
Subject: DMS and light lagers

Ok, you guru's in Net Land, I need help. I have made several lagers. Both of my light lagers (6lb klages, 2lb munich) have had pretty strong DMS smells when first poured. It is not overwhelming, but it is strong enough to be a aroma defect. I need hints on how to get this down. I don't think it is infection because I have done several light Ale's w/o any problems (klages and wheat). It seems to be limited to Lagers only.

- I do a two step mash + mash out
- I do an open boil for 90 minutes.
- I pitch my aroma hops (if used) after the heat is off.
- The kettle sits, covered, for 10 minutes while I wait for hot break & hops to settle out (set up chiller)
- Chill down takes about 10 minutes (counter flow). Typically the wort starts at around 205f and exits at 65-75f depending upon the supply water.
- I have used a variety of yeasts: Whitbread lager, Wyeast Bavarian and some other lager yeast from a local microbrewery.
- If I do an extended secondary (well, actually I just let the primary carboy sit in the fridge for a month after fermentation stops) the smell seems to dissipate somewhat. If I keg relatively soon after fermentation (1- 3 weeks) the smell seems stronger. I don't have enough batches under my belt to be sure of this.
- I have made three amber/darker lagers and they don't seem to have this problem, but I think it is just masked by the colored malts/hops.

Suggestions I have had so far:

1. Keep the kettle lid off during the steep and chiller prep time to allow more dissipation of the precursors.

Ideas I plan on trying:

1. Skip the steep time and chill as soon as the heat is off. Do a second racking after cooling to ferment temps to get the wort off of the trub.
2. Use an extended secondary (lager in vented tank).
3. Change my malts (any ideas?)
4. Stick to darker bigger beers (ha ha ha)

Any other suggestions, hints about the process?

Thanks, in advance!

Larry Barello

From: Emily Breed 1-415/545-2637 <EMBREED@SFOVMIC1.VNET.IBM.COM>  
Subject: rebottling?

A lack of foresight is taking its toll. We brewed up a batch of spiced ale for Christmas and bottled it in Martinelli's Sparkling Cider bottles (dark green, probably about 23 ounces). Now we've gotten the idea of entering it in the Bay Area Brewoff mentioned in today's HBD. So, my question - is there any chance that opening a few bottles, transferring it (as carefully as possible) to brown 12-oz bottles, maybe adding a little bit of corn sugar, and recapping would work? Would it be able to regain the carbonation it would lose in this process?

Jeers or reassurances will be welcomed!

Emily Breed

Subject: Re: Wrigley Red

Guy D. McConnell writes:...

>While I was in Boulder several months ago, I had Wrigley Red (several  
>actually) at Old Chicago. They had it on tap and I found it quite good.  
They  
>were advertising it as their house beer, "brewed especially for Old  
Chicago".  
>Does anyone know where this beer is brewed and by whom? I got the  
impression  
>that it was brewed in the Chicago area but I'm not sure.

Wrigley Red is brewed at the Boulder Brewery right here in town. The  
Boulder  
Brewery has recently undergone a "re-vitalization" phase over the past  
year and doing contract brews for the local establishments is part of  
that  
effort. They even produce beers for the Walnut Brewery brewpub (most of  
Walnut's Buffalo Gold beer sold at stores and other bars are made under  
contract at the higher capacity Boulder Brewery.) Other contract  
brews you can find around town are Blue Note Ale and something sold at  
the Walrus called Rockies. The Boulder Brewery went through a phase  
where their beer got the reputation of being bland and non-descript - at  
least in comparison to most micro-breweries. They've since made  
improvements  
in brewing recipies (including the use of a new yeast strain) and, in  
my opinion, the beers are a bit better - though still not anything to  
get too excited about. They have also "re-christened" their tasting-  
room and  
made it into a real brewpub - though it's still relatively unknown as  
such.  
I hear they now have real crowds.

Date: 23 Nov 91 01:10:28 MST (Sat)  
From: rcd@raven.eklektix.com (Dick Dunn)  
Subject: prickly pear?

Anyone else out there worked/working with prickly pear fruit for mead (or any other fermented beverage, for that matter)? If so, I'd like to swap notes and info.

There was a story in Zymurgy some time ago about PP mead, and it drove me to make one, in a year when I knew of a store which had oodles of good PP fruit. The result was exquisite. Even the color was amazing; it earned the batch name "Sunset Seduction". Folks compared it to things like good Sauternes (and I was duly flattered). I made it as a sweet still mead.

I've found it difficult to find reasonable quantities of good PP fruit. The problems have been:

- stale, wrinkled fruit
- incredibly high price, > \$1/fruit.
- only a few available in a store at a time

Now, they may be a nuisance to deal with, but they aren't \*that\* bad...

I've

seen them growing wild in abundance. [Why didn't I pick the ones I saw? I didn't have a way to carry them to deal with the thorns; I didn't have a

way to scorch off the thorns; they were in an area where I'm pretty sure "harvesting" would not be allowed.] I don't understand the paucity and the price.

Anybody know where to get them reliably? I'm not looking for specifics like "4th and Drucker in a large sandstone building", since it might be somewhere I can't get to anyway. I'm more looking for ideas on where to find good PP fruit--does it show up in particular gourmet, ethnic, whatever stores? The taste of PP fruit is delicate; it takes a lot of them to give an adequate amount of flavor.

Has anyone else tried a PP mead? If so, did you make it dry/sweet, still/sparkling? Successful?

From: "David C. Douglass" <dcd4f@landau5.phys.Virginia.EDU>  
Subject: Homebrew Digest #766 (November 22, 1991)

Hello, fellow homebrewers,

I don't normally have the time to interact with news groups, but this digest has been quite helpful to my brewing knowledge, so I thought I would return the favor. I have no connection to the Homebrewer's Store.

On the subject of liquid yeast suppliers: I have been using with great success the yeast cultures from the Homebrewer's Store in Washington state, 1-800-TAP-BREW (great prices). The owner Pat Rhodes tells me they have their own yeast lab, so I am sure there is no connection to Wyeast.

He also tells me that a lab at UC Davis (??) measured the rate of infection of commercially available yeasts, checking for lactobacillus. They found a 60 percent infection rate for dry yeasts, and only a 10 percent infection rate for liquid yeasts (this is third hand, so take it with a grain of salt). That seems like a pretty good reason to use liquid yeast.

Anyway, I've enjoyed reading this digest over the past few months, it's a pleasure to follow a group that (usually) responds helpfully and maturely to questions and provocative thoughts.

Subject: Irish brewing?

Howdy Fellow Brewers!

I've been off the list since the 4th of July due to a change of job to a college that only got internet last week. I was amazed at how cut off I felt without it! But it's great to be back and see all the familiar names and pick up new tips (200 batches and I've only scratched the surface...what a great vocation!). First thing I noticed was how much longer the HDBs seem to be now. I was a little disappointed to realize that the difference is largely to be explained in terms of flames and counter-flames. Others have already spoken my mind on that issue.....

What I want to know about is the history of Irish brewing. As a fifth-generation descendant who's been learning about his roots lately, I want to know as much as I can about traditional brewing in Ireland. For example, Guinness: less than 2 centuries old, right? Did it evolve logically, or was it an imported idea (from London, presumably, in the porter tradition). Harp, and especially Guinness Gold, are clearly latecomers to the scene. What about Smithwick's, the bitter which always accompanies Guinness and Harp in an Irish pub? A latecomer as well? One can't help but notice that it's sweeter than most English bitter, and therefore has much in common with Scottish ale. All this to-ing and fro-ing between Ireland and Scotland over the centuries..... 'Course, I can speculate as well as anybody else, but I wonder if anybody actually knows?

Gald to be back,

Rob Bradley  
(bradley@adx.adelphi.edu)

Subject: importing yeast

Does anybody know what the rules are concerning bringing yeast into the US?

I may have an opportunity to get some yeast samples in London. I have brought samples in before (please don't tell), but I'm not sure about the legality.

Subject: Carbonation using Wyeast Irish Stout

In HBD #763, Ken Weiss asks about the experience others have had with carbonation using Wyeast Irish Stout (I believe its #1084).

I just made a porter using said yeast, popped the first bottle in the fridge upon reading Ken's note, and have found the carbonation to be just fine. My yeast was dated October 2. As a side note, the fermentation went significantly faster than normal (3-4 days complete). Aged 3 weeks at 68 F to this point.

From: Tom Dimock <RGG@CORNELLC.cit.cornell.edu>  
Subject: SS kegs / Chilling wort

Alan Gerhardt mentions the difficulty of examining the interior of a SS keg. Difficult, but not impossible - a small bulb on a wire (christmas tree bulb will work) and an examination mirror and you really can look at the inside of a keg. Your local hardware probably has inspection mirrors ( a mirror on a stick - sort of like what the dentist uses) but make sure you've measured your keg hole before you go shopping for one.

I brewed my first batch in my new boiler this weekend. It's an electrically heated converted 15.5 gallon keg. The chiller is a counter-flow chiller made with 24 feet of 1/2" copper. It can take 5 gallons of boiling wort down to pitching temperature (85 F) in four minutes! If people would be interested, I'd be glad to do a series of posts describing the construction of the boiler/chiller combination in some detail.

> ale for Christmas and bottled it in Martinelli's Sparkling Cider  
bottles  
> (dark green, probably about 23 ounces). Now we've gotten the idea of  
> entering it in the Bay Area Brewoff mentioned in today's HBD.  
> [can it be rebottled?]

How about another approach? Wrap the bottle in aluminum foil, then get  
some green cellophane and wrap over that. Tie it up around the neck of  
the  
bottle with a nice red ribbon and bow, and instead of a label, tie a gift  
tag around the neck with the label information writton on by hand. In  
other words, make it look like a Christmas present, and in the process,  
light-proof.

Maybe you could just use wrapping paper, but I'd have more confidence in  
the foil and it'll look snazzier, I think. There's also gold-colored  
foil  
available; try craft stores.

Subject: SS Fermentors, Melting, Aluminum, and Chiller vs Chiller

Someone (I can't remember who) asked a few days ago about using your SS boiling kettle as a fermentor, but wondered how to use the lid. Last time we made a Strawberry Mega-Mead, we didn't think we could get the pureed mess into a carboy, so we just let it cool down in the kettle. I took a garbage bag and cut it open, swiped down one side with alcohol and then put it over the top of the kettle and secured it with a loop of string, using a 3.5" floppy as a tourniquet to tighten it. Results? As one would expect, no metallic flavour. It left a real disgusting ring of blue crap, which looked like it would be a bear to get clean, but it virtually wiped clean. So, the verdict, go ahead and use your SS pot as a primary, provided the level of liquid is not so high as to touch the area where the handles are joined. Many of the cheaper pots have a riveted on handle which is made of a cheaper metal and which will corrode. I should mention that there is no way using a plastic bag in this manner to "aim" any blowoff, so I wouldn't use a 6 gallon SS pot to do a primary for a 5 gallon batch unless you're fermenting in a room with a floor drain!

Greg Pryzby writes:

> For the Samuel Adams fans out there- there Holidays Classic 12 pak is now available. You get 3 Boston Ale, 3 Boston Lager, 3 Winter Lager, 2 Lightship and 1 Canberry Lambic.  
> It is available at the Price Club for \$10.99.

.....  
>Greg Pryzby uunet!virtech!gjp  
>Virtual Technologies, Inc.

Rats...it ain't available around here, but I sure wish it was. When are you virtual guys going to give up on vision and consider the important senses, like smell, feel, and taste? :-)

Jack Schmidling writes:

> It will NEVER melt and all your rhetoric will never change that fact.

I'd like to take you up on this bet, Jack. Calculations and phase diagrams be damned...if I had 30 spare bucks and a video cam (and I don't), I'd be willing to prove to you that you can melt a SS pot while trying to boil water. Now, if you were saying that you couldn't melt it on a home stove, I agree with you, but there are stoves (I like to call blast furnaces on legs) on which you could burn a hole in such a pot. As a fellow brewer here will

also attest, you can burn a hole in one of these pots on your electric stove when the coil burns out (ie melts and explodes).

Re: ALUMINUM

Here, I think Jack is right...not only do you not even have to think about getting the taste of Aluminum in your beer if you don't use it (although I have tasted beers boiled in Aluminum and have yet to detect it), but if it makes you feel safer to play it safe before the scientific facts are in, you will be a healthier person because of peace of mind anyway. However, I would pose the following question:

What does anyone know about the absorption of aluminum into the body from the use of antiperspirants? As most of you know, antiperspirants are based on some reactive aluminum compound (AlCl<sub>3</sub> is one) which readily reacts with water. So, how many of you play it safe here as well? It would be interesting to attempt a study of Alzheimers in the US vs another country where the use of antiperspirant is not as common, although it would be impossible to isolate this as the only difference between the two populations.

Re: COUNTERFLOW vs TUBE-THROUGH-BUCKET-OF-ICE-WATER

I prefer to use my counterflow (partly because I was so "anal" during the construction of it that I feel I MUST use it). Most important to me, though, is that once flow is established, the wort coming out of it is always at the same temperature, so I know exactly how cool it will be. In the bucket of ice- wort through tubing method, the initial wort is REAL cold, and after the ice melts and you are using a bucket of chilled water, the wort is warmer. It's difficult to predict what the final bulk temperature of the wort will be. This is important for me, because I want it to be at pitching temperature so I can pitch and go to bed. I usually will not have time in the morning if I let it warm back up overnight (or cool down further) and try to pitch the next day. If the cold break bothers you, let it settle a little while and rack into another primary. Cold break settles pretty fast.

Subject: Kegs and theft

Before I say anything else - I don't have any kegs at all, so don't go flaming me as a thief.

I just wanted to say: From what I remember, whenever I've gotten a keg of beer from a microbrewery or liquor store I've always had to put a deposit on the keg.

I don't know how much kegs cost the owner, but I'll bet mass distributors and even people at the micros are not charged what I am for the deposit. If you keep the keg and loose your deposit then aren't you only ripping yourself off?

From: "David C. Skeldon" (CCL-F) <dskelton@PICA.ARMY.MIL>  
Subject: Stuck Fermentation

What to do now?

I brewed a batch of beer using the following procedure and then dumped it on the trub from the previous batch. The yeast from the previous batch was WYeast #2007 Lager Yeast. The O.G. was 1.032 @ 72 degrees on 18 November. There were signs of fermentation within 40 minutes, within 12 hours the fermentation was active enough that gunk was being pushed out of my 1 inch blow-off hose. After 32 hours fermentation slowed enough that the airlock was installed and within 48 hours of pitching fermentation had stopped.

All fermentation took place in my basement at 62 degrees. My specific gravity has measured 1.022 @ 62 degrees for three straight days. After the first 1.022 measurement I tried to stir the trub up without introducing too much oxygen and as you can tell from the readings it did not help.

The wort tastes very bad, all I could think of when I tasted it was before I was 18, and someone would give me some beer that had sat out in the sun, got frozen, and the dog pissed in it.

This is only my forth batch so my big question is "What do I do now?"

Procedures:

4lbs light DME  
3/4 cup of 60L Crystal Malt  
1 1/2 oz cascade bittering Hops (pellets)  
1/2 oz cascade finishing Hops (pellets)

Add DME and the cracked crystal malt to 2 gallons of water. (the crystal malt was in a grain bag)

Upon boiling remove the grain bag and add the bittering hops

After boiling for 45 minutes add the finishing hops.

After boiling for 2 minutes remove from heat and cool.

After cooling I added it to the cool water in my carboy and shook the carboy.

Temp of the wort was 72 degrees.

Please respond directly if possible since I get the digest second hand and it may take me a couple extra days to recive the resposnes.

Subject: Delabeling and de-dms-ing

Hey dudes and dudettes,

"Big Dog" Sterling Udell asks:

>And now my question: I've heard that prolonged soaking in the proper  
>chemical will make even the most recalcitrant labels float right off.  
>Problem is, I can't remember what chemical it is. Bleach? Ammonia?  
>Something like that? Anyone know?

Ammonia.

I find that bleach does virtually nothing to the glue used to affix labels to glass, but that a 2-12 hour soak in a moderately-strong ammonia solution (same strength you'd use to clean your kitchen floor after brewing and before your wife comes home :-)) works just fine. However, a bit of elbow grease is required for foil labels such as Miller Lite; the ammonia can't penetrate the foil the way it can the paper.

And the required word of warning: rinse bottles well after the ammonia soak;  
NEVER let ammonia and bleach come into contact with each other.

and from Larry Barello:

>Ok, you guru's in Net Land, I need help. I have made several lagers. Both  
>of my light lagers (6lb klages, 2lb munich) have had pretty strong DMS  
>smells when first poured. It is not overwhelming, but it is strong enough  
>to be a aroma defect. I need hints on how to get this down. I don't think

Larry, this is disturbing, 'cause it does sound as if you are doing everything 'right'. DMS is produced to some degree during your post-boil steep, but my first suspect is the malt. Especially given that you are using Klages, which I have never found to contribute much DMS. Anyone else up there brewing from the same lot of Klages? Any of them having the same problem?

I have avoided using Klages in light lagers because it isn't malty enough to my taste. Part of this was an *absence* of slight notes of DMS, which are acceptable in light lagers and seem to add to the malt character when present in small amounts. The German 2-row varieties work better, IMHO.

My gut feeling (no science here :-)) is that you have a bad batch of malt.

To test this theory, I would induce one of your friends to brew using your ingredients but his/her process (maybe that Richman fellow?) To get around it altogether, use German 2-row in your lagers and use Klages exclusively for wheat beers, steam beers, and light ales.

I really would like to hear how it works out for you.

IBU ERGO SUM,

STEVE

From: eisen@kopf.HQ.Ileaf.COM (Carl West)  
Subject: De-labeling Bottles and pipe caps

I've had reasonable success using an overnight soak with dishwasher detergent, 1 or 2 tablespoons to ~5 gallons. For the foil labels it helps to scratch them up a bit beforehand. My favorite tool for that job is one of those \$tainless \$teel potscrubbers, which tool is also useful for getting the last of the glue off the bottles once the lables are gone.

If you're doing the slotted-pipe-in-a-cooler trick, don't bother putting a cap on it, just smash the end flat with a hammer. It's not like you need a good seal or something :)

From: jeg@desktalk.com (John E. Greene)  
Subject: Hops

I don't know if it is because of the mild weather we have been having here in Los Angeles or what, but my hops have started to grow again. I moved around two months ago and just before I did, I cut down the hop vines, dug up the root and transplanted it at the new house. Now I have a group of vines sprouting up and they are now around 8 inches tall. They are understandably growing very slowly but they show no signs of dying back or giving up. I have a feeling that once the temperatures start to drop in the low 40s they will get the picture that this is not the right time of the year to be growing.

From: mlh@cygnus.ta52.lanl.gov (Michael L. Hall)  
Subject: Removing bottle labels

In response to Sterling Udell's question about which chemicals are best to use for removing bottle labels, let me tell you about my experience:

First of all, I think that the proper chemical to use is ammonia. I have tried this and it works pretty well. However, just plain old \*water\* works about as well. The main thing that is important is time. Don't be in a real hurry to get the labels off and you won't have to work as hard. If you let the bottles soak for about a week or so the labels come off much easier. I filled up a plastic garbage can with bottles and water and some ammonia, and then I cleaned up a couple of bottles every day at lunch. Eventually I had many more bottles than I could use.

One other thing: the ease of removing the labels is VERY brand-dependent. Some brands have labels which will fall off after a day of soaking. St. Pauli Girls and Becks (which are the same type of bottle) do, but they're dark green instead of the preferred brown. They're pretty sturdy bottles, though, and I use them because I store my beer in the dark. The bottles I really like are Dos Equis, but the labels are a \*bitch\* to get off. I usually soak them for a day or two to remove the foil part of the label, and then another week or two to get the gummy paper off (which still requires some scrubbing).

Maybe someone else out there in email-land knows of the perfect brand of bottle to use: one that is dark brown to protect from light, sturdy to protect from breakage by the avid bottler, covered with a label which falls off when looked at, and filled with an inexpensive beer which is very good to drink ;)

Personally, I think that the three brands that I have mentioned come pretty close to achieving this, with the exception that the St. Pauli Girls and Becks are green and the Dos Equis are label-clingers and a little less sturdy.

Hope this helps,

Michael L. Hall  
hall@lanl.gov

From: STROUD%GAIA@leia.polaroid.com  
Subject: New Celis Brewery in Austin, TX

Hi y'all!

A group of six Wort Processors travelled to Houston for the annual Dixie Cup blow-out, then went to Austin with our friends Steve Black and Alan Ford for lots of good beer, good Mexican food, sailing and swimming in Lake Travis, and a visit to the new Celis Brewery. It's the last item I'd like to report on.

Pierre Celis was, until recently, the owner of the De Kluis brewery in Belgium, best known for its classic wit (white) beer Hoegaarden. After Mr. Celis sold the brewery to megacorporation Interbrew, he started looking around for a site in the US at which he could start a new brewery. After considering several other locations in the US, including St. Augustine, Florida, he eventually settled on Austin, Texas.

Wort Processor Steve Black (now living in Austin & working for the U of T) arranged for us to tour the new Celis Brewery, currently under construction. It's located just east of Austin, off of Highway 290 in the Walnut Creek Business Park. Our hosts were Jan Van Gysegem, technical director, head engineer, and brewmaster, and Peter Camps, who basically had the same titles but was subordinate to Jan. Peter is married to Pierre Celis' daughter Christine, who will run the financial end of the business. Pierre Celis was out of town when we were there.

The \$4.5 million brewery is well on the way to completion, with all walls and ceilings up, kettles in place, and fermenters, aging tanks, etc. delivered but not yet installed. Plumbing, electrical, etc. work is all ongoing. The brewing equipment is from JV Northwest and is all brand new, except for the lovely copper kettles which were brought over from Belgium. I believe that Jan said they were purchased from a brewery that had closed some years ago in Grimbergen. They are trying as hard as possible to complete the brewery and get the first batch out the door before Christmas, but that date is not certain.

Initial output of the brewery will be in the 10,000 barrel range, with an installed capacity of about 35,000 barrels. They own enough land so that they can easily expand the brewery's capacity to 50,000+ barrels if necessary.

Three beers are initially planned: Celis White (a wit beer), Celis Gold (a golden ale), and Celis Pale Bock (a true misnomer, this will be a copper colored ale in the De Koninck style. The 'pale bock' name was chosen because of some labelling requirements in Texas regarding the word 'ale' and alcoholic strength. Some marketing person came up with pale bock. I suspect that the fact that Shiner Bock is amazingly popular in that area of Texas may have had something to do with it also.). All three beers will be made using the Hoegaarden yeast; the wit beer will be bottle conditioned and the other two will be pasteurized. All beers will be both bottled and kegged. We were told that the beers will sell for a maximum price of \$5.99/six pack.

Ingredients will mostly be American. Briess will do the malting of the barley for them, although the raw wheat and oats for the wit beer will come from a local source in Luckenback, Texas. They discussed hops, though I didn't take very good notes. I believe that Jan talked about using Willamette and Styrian Goldings, among others. Of course, the wit beer will have both coriander seed and orange peel added. Interestingly, Jan said that both the seed and the peel are totally pulverized in a hammer mill before they are added to the boil.

Although Texas law allows them to do their own distribution, the brewery has decided to use an outside company. They feel that they don't currently have the resources or manpower to do it themselves right now. Initial distribution will be limited to Texas, especially Austin, as well as the other major cities such as Dallas, Houston, and San Antonio. Distribution to other US states will occur at some future date.

I must add that I was impressed by the knowledge and commitment of both Jan & Peter. It was clear upon talking to them that they are planning to make quality products at a competitive price. They are building a beautiful brewery and seem to have located in an area that will support their products. Hopefully they can help wean Texans off of Budswiller and onto good beer, then expand to the rest of the country. I'm looking forward to visiting them again next fall and sampling their products. The guys in Texas have a real treat to look forward to.

From: mcnally@Pa.dec.com  
Subject: DMS

Well, lucky you; I've just been reading Fix's "Brewing Science".

Lager malt is much more susceptible to DMS problems than the more heavily-kilned ale malt. The kilning reduces the precursor to DMS.

The solutions: part of your problem could be that you do a closed chill. The advantages of that may outweigh the disadvantages. Letting the ferment go for a long time is about all you can do.

Do you do decoction or infusion mashing? Because you get some open boil time in a decoction mash, you may get rid of some DMS at that stage. Perhaps Mr. Fix will comment on whether the decoction boil contributes in the removal of DMS.

From: AEW@b30.prime.com  
Subject: DMS

Fellow Homebrewers,

I have been reading this digest for about two months now and last night I had a few friends over to help me with my first batch. I primed my yeast (Whitbread dry ale) in a sanitized 12 oz. bottle with a fermentation lock according to directions given to me by the local brewing supply store. This seemed to work great. I had a good flow of bubbles and the yeast looked active.

After boiling my humble extract wort and chilling it to acceptable fermenting temperatures I uncapped the bottle of yeast and poured it into the carboy with the chilled wort. Most of the yeast/starter liquid poured into the carboy fairly easily, but about 1/2 an inch remained in the bottle. Not wanting to have my carboy open too long, I set the bottle aside and fitted the carboy with a blow by tube and jar.

Here is my question: How do you insure that you get most of the yeast/starter into your wort without it staying in your starter bottle?

This morning my blow by bottle was filled with lovely blow-off foam and was happily bubbling away. I was glad I didn't worry but I still would like to get all of the yeast out of my starter bottles in the future.

Thanks in advance...

P.S. My thanks to all of the contributors of this digest for providing informative conversation that turned a subtle interest of mine into a (so far) enjoyable hobby. <|8^ I am glad however, that I joined before the recent flame wars. These most probably would have turned me off before I ever got started :^(

Subject: Yeast lysing(sp?)

Hello fellow brewers. This is submission #1 for me, however, I have been reading the digest for several months now and have increased my knowledge/technique greatly.

I started an Idia Pale Ale 2 weeks ago, and still havn't had the time to rack to the secondary. (Next batch I'll check my schedule in advance :) My question is how long does the yeast bed remain stable before it breaks down and produces of flavors to the beer? Also, how stongly does this affect the brew? It will be another 2 days yet before I can rack it. Will I just have 5 gallons of fertilizer or if not, should I rack to a secondary for a week or so, or just bottle right away?

Thanks for your help,

Jarrod J Loewen Computer Services

From: YATROU@INRS-TELECOM.UQUEBEC.CA (Paul Yatrou)  
Subject: RE: De-labeling Bottles& Clearing agents

Sterling Udell writes:

>And now my question: I've heard that prolonged soaking in the proper  
>chemical will make even the most recalcitrant labels float right off.  
>Problem is, I can't remember what chemical it is. Bleach? Ammonia?  
>Something like that? Anyone know?

My wife swears by bicarbonate soda (cow brand or equivalent). She de-  
labels  
a dozen wine bottles in a bucket of water with 2-3 tablespoons of soda.  
Leaves them in the bucket for a day or so. Most of the labels fall off  
on their own.  
However, she still has problems with labels which have been heavily glued  
on. I guess the scraper would solve that problem. Bleach doesn't seem to  
work as well; I don't know about ammonia. B. soda also has the advantage  
of being a kinder, gentler de-labler than the other two (on human hands,  
that is).

I have a question: has anyone used polyclar and bentonite to clear beer  
in the 2nd fermentation stage as Miller describes in the chapter on  
clearing?

Did it work?

I don't normally care about chill haze, but my current batch is \*\*  
ETREMELY\*\*

cloudy and I would like to do something about it.

(BTW, sorry about the quip: pop-psyche=gutter talk. I meant  
street-psyche=gutter-talk!)  
(Didn't want to get flamed, now, did I)

**Subject: Soaking labels off bottles**

TSP works good for soaking the labels off bottles. My no-scrub method has been to throw them in a garbage can with 1/4 to 1/2 cup of TSP and let them soak for a week or so. If I don't get around to it in a week, I throw some bleach in to keep the bottles from getting algae on them.

From: Jeff Frane <70670.2067@compuserve.com>  
Subject: Some Tips

Can anybody tell me why my postings take an extra day to get in the digest; I'm sending them via CompuServe mail, true, but a few months ago this didn't cause any noticeable delay. ???

Sterling Udell--The mystery chemical is tri-sodium phosphate (TSP) available in the paint section at your neighborhood megamart. I use no distinct measurement, just enough to make the water soapy to the touch. This soaks off labels, mold, gunk, crap, munge and brown crud from carboys, kegs, bottles, the works. Rinse thoroughly, then sanitize. Voila! If you soak with TSP, you shouldn't need anything more abrasive than a plastic kitchen scrubber to get off the glue. (P.S. Anchor uses some really cheap glue and these are the easiest labels of all to get off.)

On window screens, etc.: I have to agree with korz that this sounds like a very inefficient way of extracting sugars from the grain. From my own experience, I can say that the configuration of the lauter tun and the false bottom have a tremendous impact on extraction. Sugars really do have to be coaxed out; if you give them any opportunity they will stay behind in the grain bed. If cost is a concern here, then the system that Charlie Papazian suggests, with two plastic buckets, is certainly a better solution. The buckets are cheap, and it only requires some long boring minutes with a drill to put an adequate number of holes in the upper bucket.

Dave Rose comments on his Chimay-style beer that he doesn't have adequate control over temperature. A suggestion, if it would help: I use a 20-gallon plastic trashcan for a water bath, with the carboy in the middle. I put in enough water to match the liquid level \*in\* the carboy, then float an aquarium heater (about \$10) on a pad of styrofoam. Admittedly, this is of small help if the room is too warm, but in the fall and winter I've found it easier to find a too-cool space in which to place the fermenter. Several years ago, Zymurgy printed an article on building an elaborate carboy warmer made from an insulated box, heated by light bulbs. I've found the water bath cheaper and easier, and it

doesn't bombard the carboy with light.

Larry Barello: You're at Microsoft? in Seattle? Does this mean you're using

Klages malt? I know some of the European and midwestern malts are more likely to generate DMS than Klages. Switching malt in that case is a good suggestion.

Stupid question No. 1: How sure are you that the aroma is DMS? Have others made the same judgment? I only ask since I have watched judges miscall this particular element. Perhaps you should send me a case of your lager for expert evaluation.

David Douglass recommends The Homebrewer's Store. If this is the same outfit I dealt with several years ago, but lost track of, they have incredible prices on pelletized hops. By the pound. As I recall, I paid about \$9 for a pound of Saaz hops, and \$6 for pounds of domestic hops. I've kept them in the freezer and they are still working beautifully for me.

From: gjfix@utamat.uta.edu (George J Fix)  
Subject: Some Tips  
Subject: Kegs (George Fix)

Jeff in HBD#767 raises some important ethical issues that are worthy of serious consideration. However, as far as kegs are concerned I think we are ok. I am an active member of MBAA-District Texas, and every time a meeting is held in the D/FW metroplex I always give a party at my house for the participants. This usually includes production people from A-B (Houston), Millers (Ft.Worth), and others. I take this opportunity to get feedback on my own beers, as well as my brewing procedures. (Incidentally, these folks disagree with each as much as we do. Every brewer has his or her own style, and this is both natural and desirable!) My "brewhouse" consists of three full kegs (two from A-B and one from Millers). They have been cut and modified to serve as a hot liquor tank, mash tun, and brew kettle, respectively. The first reaction of the visitors is invariably ... "George, what have you done to our kegs!"

However, it is all in good fun. These kegs cost the breweries \$15, and they make draft outlets pay a \$20 deposit for each. The latter (at least down here) charges us \$25 for each if purchased empty. The same is true for half kegs except that each of the above prices is reduced by \$5. This seems like a win-win situation for all. Micros, on the other hand, likely pay more for their kegs, and yet are forced to use the big boy's deposit policy. For this reason we should avoid their kegs. Good point Jeff, I had not thought about this issue before.

I would like to second Jeff's other point about commercial brewing. Chip made a similar point very eloquently in an earlier digest. Commercial brewers deserve respect, and while our beers differ from theirs (as indeed we differ among ourselves), there is still a lot we can learn from them. Moverover, in my opinion, the enemy is not A-B, nor is it ourselves (J.S.included!). The real enemy is the unsavory band of prohibitionists who appear to be gaining in power throughout the country. I am particularly concerned about the disproportionate number on nondrinking alcoholics in this group whose sole mission in life appears to be in inflecting their own problems on everyone else.

I use the following procedure for cleaning kegs:

1. Stop the flow out of the fermenter near the end when it changes from clear to turbid.
2. Release the pressure in the keg, and open it up. Collect some residual yeast for possible repitching; having some sterile beer around is useful for this.
3. Rinse keg with hot water (120F) until visually clean; this can be checked with a small flashlight.
4. Add very hot water (170F) and unchlorinated TSP, and then leave to soak. I sometimes leave it overnight.

5. Rinse with hot water (120F).
6. Fill keg with iodophor solution and leave for at least 15 mins. Diversity claims their product needs only 2 min. contact time, and are probably correct.
7. Remove iodophor solution, then seal and store keg.
8. Rinse keg with approximately 24 oz. of sterile beer just before reuse.

NOTES:

- (i) The CO2 system used for beer transfer is great for pushing the solutions out of the keg.
- (ii) Previous posts noted that stains from metallic water are rust. This is correct. Moreover, they can be removed by a variety of acid solutions, ProKleen being only one. However, the point that should be stressed is that if left unattended these stains can build up and become progressively harder to remove. They obviously do nothing for our beers as well.

Subject: Carbonation using Wyeast Irish Stout

In HBD #763, Ken Weiss asks about the experience others have had with carbonation using Wyeast Irish Stout (I believe its #1084).

I just made a porter using said yeast, popped the first bottle in the fridge upon reading Ken's note, and have found the carbonation to be just fine. My yeast was dated October 2. As a side note, the fermentation went significantly faster than normal (3-4 days complete). Aged 3 weeks at 68 F to this point.

**Subject: steal this keg.**

With regard to Jeff Frane's concern on how people acquire kegs: In Seattle there is "Jon's" recycling. They sell all recycled kegs (SS or Aluminum) for a flat rate of \$10/each. I am certain any large city will have a similar facility. Jon's, unfortunately, doesn't usually carry soda kegs. I phoned around a bit and found a place in Tacoma that claims to, but I have never actually been there.

From: Jeff Frane <70670.2067@compuserve.com>  
Subject: Homebrew Store

I phoned the 800 number for the Homebrew Store and spoke with Pat. He was pretty definite that he was NOT interested in "little orders", but only in fairly large amounts. For example, he seemed interested in my buying a 55# sack of British pale malt and several pounds of hops, but not in any piddly orders like, say, a pound of Saaz. He is also quite a talker, and loaded with information, so be sure and use the 800 number.

Prices ARE good, though. For example, that 55# bag of British malt was at 85 cents/lb. (plus shipping, of course). 2-row Klages was 60 or 65 cents/lb. Saaz and other imported hops (pellets) were at \$12.50/lb. Domestic varieties were \$7.50/lb.

From: ALTENBACH@NSSPA.llnl.gov

Subject: REBOTTLING (RE. Emily Breed question from HBD 767)

On the subject of rebottling beer from champagne bottles to 12 oz bottles for competition entry: this is easily accomplished, especially if the beer

is adequately carbonated in its original bottle. The trick is to get the beer

as cold as possible without freezing in order to

minimize the loss of carbonation during transfer. Leave the full bottles in

a freezer for about one hour, also freeze the 12 oz bottles. Then quickly and quietly transfer contents and cap immediately. You don't need to add more

priming sugar. A bonus from this process is a sediment-free competition entry.

Fill one 12 oz bottle from each champagne bottle, and consume the remainder.

Also, less carbonation will be lost if the champagne bottle has a small head space. Good luck at the Bay Area Brew Off. I'll be there as a judge.

From: zentnerl@ecn.purdue.edu (Lynn Zentner)  
Subject: delabelling bottles

Yesterday, Sterling Udell posted about removing tough labels from bottles.

I liked the metal scraper idea, we will have to try it.

Anyhow, we soak our labels off in an ammonia solution, as suggested somewhere in Papazian. This works very well for most labels, except those stubborn foil ones. A great many labels virtually fall right off in this soln. This is great for us, since we keep a notebook of beer and wine labels from things we've tried. Anyhow, hope this helps. For slightly stubborn labels we want to save, we have found that a nylon thread can be pulled under the label to cut through the glue. This is probably a little too much work though, if all you want is to get rid of labels and throw them out. I highly recommend the ammonia idea, though. We have been very pleased with it. By the way, call me insane, but I LIKE to bottle! Pop some homebrews, set up an assembly line in the kitchen with my husband, and it makes for some pleasant together time. Good luck. Lynn Zentner

From: Jeff Frane <70670.2067@compuserve.com>  
Subject: Whose Kegs Anyway?

>In all this talk about using stainless steel kegs for kettles and fermenters, I've noticed one small detail missing: Most of these kegs belong to someone else! To me, this has two elements, one moral and one political. The first is that, since most kegs are the property of breweries, it's simple theft to cut them up and use them for kettles. While it's true that this is less expensive--for you--than buying a SS kettle from a kitchen supply store, it's \*not\* less expensive for the brewery which has to replace it. Kegs are expensive.

BRAVO! My only regret is that I did not think of this first. I have three "stolen" kegs in my basement but I did recently buy a SS brewpot for my belated penance. I feel a little less guilty because mine are aluminum but your point is well taken, as it should be. It's a bit like pirating videos or software. Come to think of it, it's much worse. It's like stealing hardware.

From: korz@ihlpl.att.com  
Subject: Window screen

Jack writes:

>A small piece of window screen is rolled several times around the pipe and secured with a hose clamp or twisted copper wire. The screen roll extends several inches past the end of the pipe and the last inch is bent over itself to prevent anything from entering the spigot that has not passed through several layers of screen.

<All the modern window screens I've seen in my area, are made of some mystery metal. It doesn't rust, so it's not steel, it oxidizes too easily and the oxide is too dark to be aluminum. Maybe it's galvanized steel. The oxide comes off on your hands very easily. Jack's idea is inventive, but I would recommend against using window screen.

The term "window screen" is more to define the mesh size and type than the specific material. Although I am using "hardware cloth" as it is called, window screen is also available in copper and stainless if you hunt around.

I believe that "hardware cloth" is galvanized steel. I currently am taking a zink supplement with my daily vitamins so I doubt that any zink leaching off the little bit of screen would do anything other than save a few more of my brain cells.

From: korz@ihlpl.att.com  
Subject: Window screen revisited

>I just had another thought about the screen-around-the-pipe lauter tun. If the only exit for a large diameter container was centrally located, a lot of sugars could be left behind in the grain. The sparge water can sit stagnant at the sides of the tun where there is little "current."

That is why it took an intrepid experimenter to risk a batch of beer to check it out. The proof of the pudding is in the eating. That is also why I included my method for checking on the sparge completeness in the article.

However, what actually happened was that my wort was boiling and burning under the false bottom and I lifted it, foolishly thinking that I could put it back in when ready to sparge. The "intrepid experimenter" was actually a victim of his own stupidity but got lucky. Don't knock it till you try it.

I did another batch this weekend this way and got the same results. That makes 4 with only the pipe and screen. BTW, the pipe is 1/4 in and only three inches long and the screen only extends about two inches.

Now that I have my ten gal SS pot, I have advanced the process another step and made sparging much simpler. Instead of retiring the enamel kettle, I am still using it for mashing. BTW, mine has now developed the "creaking handle" syndrome but at least at mash temp, it is easy to lift by the lip with potholders.

I use the SS kettle to heat the sparging water and it runs directly into the mash kettle (moved down to a stool), thence into the jug. The whole business is more or less automatic and needs only a watchful eye.

I start heating the water about an hour before the mash cycle is complete and it takes about that long to come to a boil..... I can't wait to hear from the moms on boiling sparge water.

I did, however, learn about turning wort into baked on enamel. Mom got that one right.

Date: Mon, 25 Nov 91 12:49:10 EST  
From: jm@sead.siemens.com (Jeff Mizener @ Siemens Energy)  
Subject: Need Learned Opinions On Beers To Buy

Gentle Beer Fanciers--

This request has nothing to do with Brewing Beer, per se, but rather with Evaluating Beer. I haven't brewed yet, but I will soon, and would like some experienced and/or learned opinions.

I find there are some commercial beers for sale out there that are not too bad. But that's my taste. I'd like to hear if anyone has anything good to say about popularly priced beers. In other words, if you couldn't brew, and you couldn't spend \$10 for a six of <insert favourite mini/micro brew name here>, what would you buy?

For instance: Coors has a Christmas beer out now. The label says Stout, but if it's a Stout, my name's Porter. In comparison to normal Coors, it's a solid at room temperature, however. And "In My Humble Opinion" it's pretty good. Any Comments?

I lived in Germany for six years and drank 'microbrewery' beer every day (and it was !!CHEAP!!). The selection at my local 'drink-market' was great (almost all in nice, uniform, brown, returnable 0.5L bottles). The problem then was not choosing a good beer, but trying to taste them all in 6 years...

Now, I live in Raleigh, NC. We have "State Liquor" here and although one can buy Beer and Wine in grocery stores, there seems to be a subtle pressure on the part of the Bureaucracy to limit the number of available beers to a Few Major Brands. Or I may have it wrong, it may be that nothing but MilBudLob is acceptable to the consumer here. Remember that this is the same state that let a Chicken Processing Plant go uninspected for 11 years while the ice cream plant next door (and employing only 6 people) was inspected several times over the last 5 years. And this is the state that elected Terry Sanford and Jesse Helms. But the weather's nice and the beaches are clean, so it's not a bad place...

Many of the beer names that I see flashing by on my screen here are not available in my area. Or at least I haven't found them yet. So I'd appreciate hearing about 'national brands' that won't turn my toenails green or empty my wallet.

Thanks.

I'll summarize, so don't post unless you feel it's essential or can't reach me by mail (it happens).

Jeff

From: korz@ihlpl.att.com  
Subject: Label removing

Sterling asks about label removing.

I used to use Washing Soda (Sodium Carbonate) when I used to use bottles. I recall someone else mentioning Washing Soda in a recent post so I'd like to recount an experience I had with Washing Soda:

I found that Washing Soda in hot tap water worked really well to remove labels from bottles, even the foil ones, so I proceeded to do a large number of them at one time. I let the bottles soak for 8 or 10 hours (I don't really recall exactly) and then rinsed them inside and out with plenty of hot water. I proceeded to sanitize as usual, with bleach solution, followed by hot tapwater rinse, and then upside-down into a case lined with paper towels. Everything went fine until I set up to bottle. When the bottles dried, I noticed a white residue on the outside (all over, not just where the label was). If it's on the outside, then it must also be on the inside. No amount of washing could remove the residue, however, I could mechanically rub the residue off. I figured it was either the Sodium Carbonate or the glue or some byproduct of the Sodium Carbonate and glue or Sodium Carbonate and the foil labels. I did quite poorly in chem, so I wasn't sure what it was, but I was pretty sure that the Sodium Carbonate was alkaline. If I soaked the bottles in an acid, maybe it would convert the residue into a soluble salt. I chose lemon juice and it worked. a 4 hour soak in dilute lemon juice followed by a hot water rinse removed the residue.

After all that, I'd like to recommend that you maybe fill your bottles with plain water and cap them before soaking them in the Washing Soda solution (i.e. keep the Washing Soda OUTSIDE the bottles). Maybe someone with more knowledge of Chem could comment on whether my problem was due to the glue or foil or if Sodium Carbonate should be avoided for cleaning glassware.

From: Eric Mintz <ericm@bach>  
Subject: Specific Gravity before and after boil

I'm now on my 7th batch of all-grain brews and I noticed something surprising (to me, anyway :-)) on this last batch. I measured SG before and after the boil for the first time (in the previous batches, I either measured before or after, but not both). I expected the SG to be higher due to the evaporation from the boil, right? WRONG! The SG dropped! The only explanation I could think of is that the trub (before precipitation -- that is, while still in solution) contributed some to the SG. Either that or I screwed up my before-boil measurement :-). Anyone care to take a stab at what's going on here?

Date: Mon, 25 Nov 91 17:04:18 PST  
From: Bruce Mueller <mueller@sdd.hp.com>  
Subject: Thermal properties of materials, polyethylene tubing

Here is data on melting points (deg Fahrenheit) and thermal conductivities (Btu-ft/hr-ft<sup>2</sup>-F):

| Material        | Melting point | Thermal cond. | Comments                          |
|-----------------|---------------|---------------|-----------------------------------|
| Cast iron       | 2000 - 2200   | 18 - 30       |                                   |
| Aluminum alloys | 890 - 1215    | 67 - 128      | Pure Al: higher value, each pair  |
| 304/316 SS      | 1600 - 1700*  | 9.4           | The stainless you'll probably get |
| Glass           | 930 - 2800**  | 0.4 - 0.84    | Pure silica: high values          |

\* Maximum use temperatures: metallurgy is more important than melting point.

\*\* Softening point: these are supercooled liquids, so the viscosity keeps dropping with temperature. No true m.p. exists.

To convert temperatures to deg C, subtract 32 and then divide by 1.8. To convert the thermal conductivities to W-cm/cm<sup>2</sup>-C, multiply by 3.44x10<sup>-4</sup>. There, now whether you prefer metric or English units, you've got it!

By the way, I've heard the comparison that cast iron and stainless steel are comparable insulators to glass. The numbers above say glass is at least ten times better! My source of information: Machine Design 1987 Materials Reference Issue. Now, anyone who wants to do the calculations regarding meltdown of pots can, with the help of a good Chemical/Mechanical Engineering textbook. Oh yeah, it helps if you're an engineer (we still need a few train drivers, right?).

Tubing:

If anyone wants some clear polyethylene tubing at \$0.30/ft, I have some in 20 ft lengths. It's really good for keg hose: no plasticizers to leach. A bit stiff. If you want it, please don't clutter the Digest, order direct via email. This isn't really a commercial; I'd ordered this for fellow QUAFF members, but only a couple came through with \$\$.

Bruce Mueller, Development Engineer Chemist (what a title!)

From: kla!kirkish@Sun.COM (Steve Kirkish)  
Subject: Detergents, Label Removal, and TSP

Boy, what you learn on the HBD. I've found the thread about soap vs. detergent useful for a couple of reasons. First of all, the fact that the soap film kills beer head goes a long way toward explaining why my good 'n bubbly homebrew lacks a good head. I handwash all my glasses (the drought, ya know,) and am thinking about changing my dishwashing brand to something "cleaner". Larry Barello recommends Dawn...any other suggestions? (thanks also to Larry for providing the ingredients to check for.)

Second detergent notion: Sterling Udell (HBD#767) asks:

>I've heard that prolonged soaking in the proper chemical will make even  
>the most recalcitrant labels float right off. Problem is, I can't  
>remember what chemical it is.

In HBD #766, Larry B. mentions Washing Soda (sodium carbonate). I'd like to add my suggestion of TSP (Tri Sodium Phosphate, a powder available at hardware stores) mixed with water. I used a 30+ gallon garbage can to hold the bottles and the solution overnight (had a \*lot\* of bottles). Funny thing: The labels on the crown cap bottles slide off easily; the labels on the screw tops don't. Consistent for different brands. Go figure. Of course, a thorough washing of the bottles should follow.

Now then, to the homebrewing audience: Waddaya think about TSP? Good or bad?

- -- Steve Kirkish

PS: Thanks to all for the pasteurizing info, based on my "Up Yoors Coors" entry. I certainly wouldn't consider removing my yeast (it wouldn't be "real ale", but then again, it probably would be a "real pain!"), but just think: Anchor flash pasteurizes and Coors doesn't, and then compare the flavor. I know the ingredients and process differ, but that flashing, amazingly, can't be all bad.

Subject: Late Boil-up

Damndest thing. In all my year of brewing :) I've never seen anything like it.

OK, everyone knows how much wort likes to boil over when you first start it at 212 degrees. I know this as well as anyone, having suffered through a boilover of what my brewpartner termed "biblical proportions" last spring.

Hopefully everyone knows how to get through this, too. I don't recall who tipped us off to this, but it was someone here on the HBD . . . When the wort forms a head and starts making a run for the edge of the pot, you pour a splash of cold water in it. Puts it right in its place, which is back in the pot.

But this is off the subject. Usually, I have to do this maybe 4 or 5 times - 10 or 12 for a particularly ornery brew - and then the foam breaks up and the wort settles in and boils happily. No problem.

Until tonight. I was boiling up a batch of stout, pretty basic in most respects. I had given the wort the cold-water treatment maybe half a dozen times, and it had started behaving nicely. I went off to do the dishes. At 47 minutes of boil, some innate brewsense told me to look over my shoulder . . . Sure enough, the wort was just making its break. I leaped to the stove, killed the burner, moved the pot, and started it heating again. I cleaned up the spill (not much) and went back to the dishes (i had to clear the sink for wort chilling), but 10 minutes later, the wort did its thing again. This time I was ready with the cold water, but I still didn't understand it.

Anyway, I finished the batch, and it's happily starting its ferment in my closet as I type. But I still don't know why it started boiling up again so late. I'm not excessively experienced - about 20 batches -n but I've NEVER seen this happen before. Has anyone else? Do you have any clue why? Or how to avoid it?

Many thanks . . .

Sterling Udell  
Big Dog Brewing Cooperative - Eastern Division  
"NEVER turn your back on a boiling wort."  
- Big Dog Solstice Stout

P.S.: Thanks also to all who replied about delabeling bottles. About 6 or 8 of you, most of whom advocate ammonia, although a couple espouse bleach or B-Brite as well.

From: <S94WELKE%USUHSB.bitnet@VTVM2.CC.VT.EDU>  
Subject: A review of Sisson's (a brewpub in Baltimore, MD)

Sisson's can be found just south of the Inner Harbor area of Baltimore. It's about six block south of the MD Science Center (from there, go south on Light St. and turn right on Cross, Sisson's is #36, on the right). In a seedy part of town, but aren't all great bars? (maybe not the Top of the Mark). They have three house brews on tap: Marble Golden Ale, Amber Ale, and Stout.

Marble Golden: A pleasingly bitter and creamy textured concoction with strong hop aroma and flavor. The hops definitely are out in front of the malt, but the malt that's there is slightly sweet, yet light and sneaking around in the background. The color is a beautiful gold, and the flavor assertive. The beer's body was just enough to make it swallow well (not something to chew on). I give it a 17 on the 20 point scale. A beer I'll drink again.

Amber: A very malty, somewhat sweet brew. Color was pleasing, kinda rosy; a bit paler than Sam Adams. The aroma was dull, and the flavor nutty with a tiny hint of clove. Hop character was lacking (in my biased hophead opinion) but the body was good (very frothy, nice head, substantial mouthfeel). My wife commented "it coats your tongue," but I thought it was within reason. I gave it a 13.

Stout: Deep brown, moderately bitter and not too sweet. I always end up comparing stouts to Guinness Stout, and I thought this one was less sweet, slgithly more bitter, maltier, and with less body. The head was disappointing. Lots of flavors to sort through: malty with roasted (black patent, even) tones, hints of yeastiness (I thought of once-risen bread dough), and butterscotch. I gave it a 14.

About the place: good bottled beer selection, also an excellent restaurant. They specialize in cajun/creole, but the seafood caught my eye. They have a Gumbo du jour, and a soup, and a pasta. I missed the "Bay Scallops and Linguini with Lobstercream Sauce," but I think i may go back for it. Great dessert menu--don't miss the Black Pearl Pie, sort of a warm cookie (chocolate chip) cut in wedges. If you go, be sure to get tickets for the Monet exhibit at the BMA, closing Jan 16, '92. Worth a day trip from DC.

BTW "the 20 point scale" is from Papazian, p. 318. I used it in hopes of being more objective.

From: Tom Dimock <RGG@CORNELLC.cit.cornell.edu>  
Subject: Bottles and labels

If you want sturdy bottles with labels that come off easily, try to find re-usable bottles. In this area (the northeast) Yeungling brews are my choice. Since the brewery has to remove the labels to re-use the bottles, they don't put them on with the horrible glues that are used for throw-away bottles. Yeungling labels slide right off after three minutes in hot water! Plus the bottles are nice heavy brown long-necks. And the beer that comes in them is fine stuff - my favorite is their porter.

I agree with Michael Hall that Dos Equis labels are the WORST! To me, they are just not worth the effort. Why no leave the labels on, you say? Well, I'm a little anal about that....

I did a Medline search for reviews on the subject of Alzheimers a few days ago so I could track down some reading to refresh my memory on this topic. I won't bore digest readers with the details of recent statistical and molecular genetic findings since this is a beer digest, but it appears that the aluminum issue is one of those things that was blown out of proportion. The genetic component of the disease is what is grabbing the interest of the scientific community since predisposition to Alzheimers may be predictable and possibly treatable in the future through genetic diagnosis and manipulation. That is why the proposed study is irrelevant and as stated "it would be impossible to isolate this as the only difference between the two populations". That is a flaw of the statistical approach which is often revealed by more solid 'real' data. Furthermore, two populations selected for their differences in predisposition to Alzheimers likely have many genetic differences. The study has a bias before it even begins. I just Relax, Don't Worry, Have a Mitchum ... for my friends' sake. ;-)

I agree with all the replies to Larry Bareello wrt DMS problems. It seems that he has all the bases covered except for the malt variable.

Give the bottle a swirl before you pour it into the primary.

> From: Jarrod J Loewen <jloper@ccu.umanitoba.ca>  
> Subject: Yeast lysing(sp?)

Good to hear from another Canadian, eh? Yeast lysis is affected both by time and temperature. A rule of thumb is max. 14 days in primary if you're doing a single-stage fermentation. Racking too late risks oxidation. Once your beer is in the secondary you can relax on the order of months since the yeast carried over in suspension is healthy. I'd recommend bottling soon unless you fermented this batch at cooler temperatures ie. 60F instead of the average 68-72F.

I've noticed this recently as well. It seems that the digest is limited to approximately 50K per issue. Postings appear to be put into a queue as they are received and cut off at 50K (look at the date/time received in the headers). This is another good reason to get the flame noise down to zero.

From: IO10676@maine.maine.edu  
Subject: The Perfect Beer Bottles

In response to my de-labeling question, Michael Hall writes:

Maybe someone else out there in email-land knows of the perfect brand of bottle to use: one that is dark brown to protect from light, sturdy to protect from breakage by the avid bottler, covered with a label which falls off when looked at, and filled with an inexpensive beer which is very good to drink ;)

Personally, I think that the three brands that I have mentioned come pretty close to achieving this, with the exception that the St. Pauli Girls and Becks are green and the Dos Equis are label-clingers and a little less sturdy.

I don't have quite the perfect beer, but I have one that's close. The brand is Wisconsin Club, brewed by Huber, and available in the upper midwest. It has the following good points:

- Sturdy dark brown bottles (12 oz bar bottles)
- Labels come off so easily that the condensation on the outside of the bottle is often sufficient
- CHEAP (I've gotten it for \$6/case!)

Main disadvantage is, as you might expect, the beer isn't that great. But it's no worse than any other industrial swill, suitable for drinking after mowing the lawn, etc.

Or, the TRUE perfect beer, by the preceding definition: Homebrew! :)

> Lager, 2 Lightship, and 1 Cranberry Lambic.

I hope that is Cranberry Lambic and not Cranberry Beer, and that is Cranberry Lambic from 1990. I tasted this year's Cranbery Beer on draught, and it tastes like Samuel Adams Lager with cranberry juice in it. Bleechhhh :-b As you recall, last year I had their Cranberry Lambic (and even their table cards called it a lambic) and it was great (make that GREAT :-) ). A pink foamy head, the taste of fresh soured milk and cranberries, and a deep red color. This year, their is little or no head, the color is a dull yellow/red/orange, it tastes like someone added cranberry juice to the beer. Actually, I tried that last year at home - added cranberry juice to beer - and it tasted just like this year's catastrophe... Even this year's table card says it is a Cranberry Beer, brewed in the lambic style. It's terrible :-p When the waitress brought the beer, I gave her a look of surprise when I saw the beer. She said it was not as good as last year. That was an understatement if I ever heard one...

Sorry that you didn't get a chance to try their Cranberry Lambic - 1990 style. Please pass along my sincerest regrets and condolences to Samuel Adams on the passing away of a great brew...

It is simpler, faster, and better to use a hot butter knife to make the  
holes.  
Drilled holes have little plastic curlycues that are impossible to clean  
out and end up plugging some of the holes. A melted hole is neater.

From: rak@mayo.EDU (Ron Karwoski)  
Subject: Michael Jackson....

This past weekend myself and five other members of our homebrew club had the pleasure of attending a homebrew tasting with Michael Jackson in Minneapolis. Michael did all of the homebrew tasting but we had our hands full tasting all of the brewpub's beer. Sherlock's Home had their own bitter, scottish ale, stout, porter, lager, pale ale, and light on tap. They also had a sweet and dry cider on tap (imported). We missed the winter warmer (xmas beer) by a week. They also feature a number of single malt scotches. The ales were all hand-drawn in the English style. All the beers I sampled were very tasty. The brews were \$3 for a 20 oz. pint. Minnesota doesn't have a surplus of brewpubs but this one is definitely worth trying.

The Beer Hunter was a congenial and entertaining fellow. His talk and comments on the homebrew were well recieved and he signed books for a couple of hours. Does anyone know how this guy got his job and if he needs an assistant?

I'm also dying to try a can of Guinness. Local distributors say it will be a while before it makes to Minnesota, and even longer to Rochester. I'll be in Chicago soon and hopefully I can find it there.

I can recommend a type of bottle that fits this bill almost perfectly. I use IBC brand Root Beer bottles for much of my homebrew. The bottles are brown, sturdy, and have no labels at all on them from the start. It costs less than cheap beer and my 4-year-old son is all too glad to empty them for me. I have also seen A&W Root Beer in this type of bottle but have never used them. This is excellent root beer too. We used to say that IBC stood for "It's Better'n Coke". I bottled my last batch entirely in these bottles.

From: Arthur Delano <ajd@itl.itd.umich.edu>  
Subject: Re: Removing Bottle Labels

mlh@cygnus.ta52.lanl.gov (Michael L. Hall) says:  
] Maybe someone else out there in email-land knows of the perfect  
brand of bottle to use: one that is dark brown to protect from  
light, sturdy to protect from breakage by the avid bottler,  
covered with a label which falls off when looked at, and filled  
with an inexpensive beer which is very good to drink ;)

In my experience, bottles from the Whitbread Brewery in the UK (Whitbread  
Ale, Mackeson's Stout) are gloriously heavy and thick, a rich dark brown  
in  
color, and the labels peel off easily after twenty minutes of soaking in  
hot water. In addition, one of the beers (either the ale or the stout)  
never  
seems to leave a moldy scum, so the first-time washing out is made much  
easier  
as well.

The only real disadvantages are that the beers are expensive, and that  
not  
enough people around here have the class to drink the stuff, so when I  
buy  
bottles from the package store there aren't many Whitbread bottles to be  
had.  
But they fit all your other criteria. If you decide to get a lot of  
Whit-  
bread, I'll help you empty the bottles. (:-->)

**Subject: Homebrew Store**  
Full-Name: Ted Manahan

I want to add my comments on the Homebrew Store and its owner Pat. My only order from this store so far has been as a result of an add in Zymurgy for a 7.5 gallon SS pot. I called to order the pot, and Pat talked me into buying a King Cooker and two beer kits too! Quite a salesman, he is.

The whole deal cost me \$150. I'm pretty happy with the stuff. The SS pot is a little thin, but that's what I expected. The cooker really does the job - it gets as hot as I feel comfortable with. The kits are high quality. I got a partial mash S. German wheat beer (with the special clove flavored yeast) and a full extract pale ale.

Prices are good. Pat likes to talk and has opinions on the 'best' way to brew. He does seem to know of what he speaks.

The Homebrew Store doesn't take Visa. You have to mail your order in. Pat says this keeps prices down. He could be right.

From: Dave Barrett <DAVE.BARRETT@OFFICE.WANG.COM>  
Subject: more on de-labeling

Greatings and Happy Thanksgiving!

On the recent question about removing bottles labels. I don't use TSP or ammonia, I soak the bottles in your standard bleach sterilizing solution for 1 or 2 days. By then most labels have fallen off. What doesn't fall off I can easily get off in about 3 seconds with a 1 1/2" wide putty knife.

Any remaining glue then comes off easily with a plastic scrub pad. I've found that this works well even with those nasty foil labels. But no I have never tried it on a Dos Equises (sp?) bottle so your milage may vary.

As to the recent flame war. I have grown as tired of those who have repsonded to JS with flames, as I have JS. I heartily endorse the "no flames / but if you must flame'em directly with email" policy.

And while I'm here, THANKS ROB!

I'm a bit confused here. I thought the idea was to put this into the bottom of a stainless steel keg so you can heat the mash on a burner. The plastic coating Roger suggests might be a good idea for a lauter tun to be used for a decoction mash but not for steep infusion. I, personally, would avoid plastic (recent heat transfer arguments notwithstanding) so close to the burner. I still contend that "common" window screen should be avoided, but (as someone mentioned) brass screen is available. Al.

>Maybe someone else out there in email-land knows of the perfect  
>brand of bottle to use: one that is dark brown to protect from  
>light, sturdy to protect from breakage by the avid bottler,  
>covered with a label which falls off when looked at, and filled  
>with an inexpensive beer which is very good to drink ;)

My personal favorite bottles are from Anchor. They are sturdy,  
brown, filled with good beer, and the labels come off easily.  
I guess the only drawback is that it's not a cheap beer, but  
then life's too short.....

Many German beers come in those 1/2 liter bottles, which look like  
miniature inverted cylindro-conical fermenters. They are a very  
handy size, since bottling 5 gallons requires only 35-40 of these,  
instead of 50-55 12oz'ers. Some come with foil labels and are really  
a drag to remove, the paper ones come off pretty easily however.  
On the down side, these bottles often aren't accepted in competitions.

I've found that whatever nasty chemical I use to remove labels, it  
gets easier if you use hot water. The glue softens more quickly at  
higher temps.

>Jeff in HBD#767 raises some important ethical issues that are  
>worthy of serious consideration.....

>These kegs cost the breweries \$15, and  
>they make draft outlets pay a \$20 deposit for each. The latter (at least  
>down here) charges us \$25 for each if purchased empty.

I can't recall the source (Maybe Mom told me ;-), but I remember hearing that it cost AB over \$200 for each empty keg, and they charged much smaller deposits so that people would still buy draft beer. The theory being that \$20 was enough to motivate people to return kegs because there wasn't much else you could do with them anyway. Enter the homebrewer.

Is this complete BS?

Given the expense of the raw materials (\$stainless \$steel), and the fact that there are several welds and a valve or two, can kegs actually be manufactured for only \$15, even by the bizillion??

Enquiring minds just gotta know,

From: larryba@microsoft.com  
Subject: Re: De-DMS'ing my brew

1. How do I know it is DMS? Well, in small quantities it smells like malt. In larger quantities (like just after a pour, while the head is still expanding) it smells like creamed corn or when really bad, stewed cabbage/vegetables.
2. There seems to be some confusion regarding malts. One person indicates that Klages (actually Great Western Malting Pale Malt) has \*less\* DMS potential vs continental malts. George Fix specifically mentioned continental malts as having more sulphur compounds and gave me some pointers on how to reduce their influence (a: hops, b: keep kettle vented as long as temp is > 150f). Steven Russle points me in the opposite direction. Bottom line is that I plan on doing, not in the near future, two experiments:

- o re-do the klages pilsner and see if venting the kettle during the steeps (or eliminate the steep) does the trick.

- o Get some german pilsner malts and see if that does the trick.

Given that the GWM pale malt is so cheap when purchased in bulk, I am somewhat motivated in trying to make it work. Actually trying to make Klages work might be futile: already my "german Pils" made with klages taste reminiscent of Bud. Ack!

3. A week ago I posted an article about an experiment in my refer: some starter wort spontaneously fermented and had a unusual smell. Well, I finally identified the smell: BUTTER BITS! Yikes, pure diacetyl. What a smell. Now, if I remember correctly, from Dave Miller ( TCHOHB) that Diacetyl is primarily a yeast byproduct (as apposed to DMS that can be produced by bacteria). Anyone know if there are specific bacterial strains that produce diacetyl? I am mainly interested in ruling out nasty bacterial infections that I need to guard against in my kitchen.

Cheers!

Re: Samuel Adams Holiday Classics

I bought this package with much enthusiasm, primarily because of the Cranberry Lambic. Having never tried a lambic before and REALLY liking Sam Adams (both Ale and Lager, although I prefer the Lager), I anxiously got the beer home and waited for the perfect moment to drink the lambic. Well, I wasn't impressed. In fact, the taste reminded me of what my mouth tastes like the morning after having too much the night before. What went wrong? Is this a typical lambic? I also found the Lightship to be pretty watery (but then again it IS a light beer). Well, at least I got to enjoy the Ales and Lagers.

Cheers,

-Bob

Subject: Irish brewing?

Howdy Fellow Brewers!

I've been off the list since the 4th of July due to a change of job to a college that only got internet last week. I was amazed at how cut off I felt without it! But it's great to be back and see all the familiar names and pick up new tips (200 batches and I've only scratched the surface...what a great vocation!). First thing I noticed was how much longer the HDBs seem to be now. I was a little disappointed to realize that the difference is largely to be explained in terms of flames and counter-flames. Others have already spoken my mind on that issue.....

What I want to know about is the history of Irish brewing. As a fifth-generation descendant who's been learning about his roots lately, I want to know as much as I can about traditional brewing in Ireland. For example, Guinness: less than 2 centuries old, right? Did it evolve logically, or was it an imported idea (from London, presumably, in the porter tradition). Harp, and especially Guinness Gold, are clearly latecomers to the scene. What about Smithwick's, the bitter which always accompanies Guinness and Harp in an Irish pub? A latecomer as well? One can't help but notice that it's sweeter than most English bitter, and therefore has much in common with Scottish ale. All this to-ing and fro-ing between Ireland and Scotland over the centuries..... 'Course, I can speculate as well as anybody else, but I wonder if anybody actually knows?

Gald to be back,

Rob Bradley

Subject: Carbonation using Wyeast Irish Stout

In HBD #763, Ken Weiss asks about the experience others have had with carbonation using Wyeast Irish Stout (I believe its #1084).

I just made a porter using said yeast, popped the first bottle in the fridge upon reading Ken's note, and have found the carbonation to be just fine. My yeast was dated October 2. As a side note, the fermentation went significantly faster than normal (3-4 days complete). Aged 3 weeks at 68 F to this point.

From: Tom Dimock <RGG@CORNELLC.cit.cornell.edu>  
Subject: SS kegs / Chilling wort

Alan Gerhardt mentions the difficulty of examining the interior of a SS keg. Difficult, but not impossible - a small bulb on a wire (christmas tree bulb will work) and an examination mirror and you really can look at the inside of a keg. Your local hardware probably has inspection mirrors ( a mirror on a stick - sort of like what the dentist uses) but make sure you've measured your keg hole before you go shopping for one.

I brewed my first batch in my new boiler this weekend. It's an electrically heated converted 15.5 gallon keg. The chiller is a counter-flow chiller made with 24 feet of 1/2" copper. It can take 5 gallons of boiling wort down to pitching temperature (85 F) in four minutes! If people would be interested, I'd be glad to do a series of posts describing the construction of the boiler/chiller combination in some detail.

> ale for Christmas and bottled it in Martinelli's Sparkling Cider  
bottles  
> (dark green, probably about 23 ounces). Now we've gotten the idea of  
> entering it in the Bay Area Brewoff mentioned in today's HBD.  
> [can it be rebottled?]

How about another approach? Wrap the bottle in aluminum foil, then get  
some green cellophane and wrap over that. Tie it up around the neck of  
the  
bottle with a nice red ribbon and bow, and instead of a label, tie a gift  
tag around the neck with the label information writton on by hand. In  
other words, make it look like a Christmas present, and in the process,  
light-proof.

Maybe you could just use wrapping paper, but I'd have more confidence in  
the foil and it'll look snazzier, I think. There's also gold-colored  
foil  
available; try craft stores.

after the  
>ice melts and you are using a bucket of chilled water, the wort is  
warmer.  
>It's difficult to predict what the final bulk temperature of the wort  
will  
>be.

I'd like to add that depending on your setup, you may not always know  
what the final temp will be, even if you use a standard concentric tube  
counterflow chiller (ie garden hose and copper tubing). I learned this  
the first time I used my 15.5 gal keg boiler, and ended up doing an  
inadvertant, uncontrolled experiment with yeast pitching temperatures.

My boiler is equiped with a ball valve at the bottom, and a compression  
fitting to connect to the heat exchanger. When the boil was over, I

turned on the cold water, let the wort flow, and adjusted the rates to get the desired temperature. I filled and pitched into three carboys in succession. Later, I noticed that carboy #1 began fermenting more quickly and vigorously than #2, which was quicker than #3. The same starter culture was used for all three. Even though it was a stout, the finished beer was markedly different as well.

Upon reflection, the explanation became apparent. As the level in the boiler decreased, the flow rate slowed since it's all gravity fed. The slower flow rate resulted in each successive carboy getting cooler wort, and thus the different yeast behavior. To get consistent pitching temps from carboy to carboy, I must adjust the flow rates during chilling.

Date: Tue, 26 Nov 91 15:53:11 EST  
From: Tom Dimock <RGG@CORNELL.CIT.CORNELL.EDU>  
Subject: Boiler/Chiller Construction - Part 1

Having received several mail files expressing interest in my brewkettle construction, and having been re-assured by G. Fix that my use of an A-B keg doesn't make me a despicable criminal, I will describe the construction of my brewkettle and chiller. Note that I would NOT use a keg from a microbrewer, only A-B or Miller, who will not be hurt by my action.

#### Building a Modern Elektrikal Brew Kettle - Part 1

I'd like to start out by noting that low cost was not my primary goal - although I may not be as over-paid as those Rich men from Microsoft (sorry Darryl, I couldn't resist :-)), I can afford to appease my own desire to have a really NICE brewkettle. The use of a keg was based on the fact that it makes a really great kettle, and only secondarily that they are really cheap.

The first step is to remove the tapping core. This has been very well described by George Fix in recent HBD's, so I won't describe the process in detail. It is important to release the pressure in the keg by pushing down on the ball valve with a big screwdriver. Wrap a towel around it, unless you like being showered with Bud Lite!

The next step is to cut out the top of the keg. The kegs are 16" in diameter, so an 8" hole in the top works quite nicely. I know of at least 5 ways to perform this step.

- 1) Drill a couple of holes in the top and then saw between them with a Sawz-All (a heavy duty version of a hand jig saw, for those of you who are not tool freaks). The stainless steel that the kegs are made of is very tough, so you will need to use carbide blades - the SS will just round off the teeth on a normal hacksaw blade. This is a noisy and expensive way to do it, as you'll probably chew up several blades.
- 2) Use an abrasive blade in a circular saw. The blade is meant to cut in a straight line, so getting it to cut in a circle is a little tricky. You always want to wear eye protection when cutting metal, but if you try this method be sure you have heavy duty eye (and ear) protection. There is a distinct possibility of having the blade bind in the cut and throw you, the saw (which is running), and the keg about quite vigorously. Although others have recommended this method, I think it is too dangerous and cannot recommend it.
- 3) Drill a lot of little holes right next to each other and then bang it out with a hammer. Again the toughness of the steel is a problem, but I have found cobalt drill bits (available in many hardware stores) can stand up to it. Using a 5/32" bit, you'd need to drill about 150 holes, so have a HB handy for when you get thirsty (but not too many - safety first!). This will leave a very rough edge, which you can the even out with a half round bastard (no gutter talk here - that's really what they're called) file, or with an angle grinder if you have one.
- 4) Cut it out with an oxy-acetylene torch. Unfortunately, stainless

cuts very poorly with oxy-acetylene, which leaves you with a lot of slag and crud to clean up with an angle grinder. A file might do it, but slag tends to be harder, so you might just end up using the keg to smooth out the file!

- 5) Take the keg to a welding shop and have them do it with a plasma torch. This is really the right way to do it. You might be able to wangle a barter deal - I've never met a welder who didn't drink beer.

So which way did I do it? Number four, because I own the torch and could borrow the angle grinder. Which would I recommend?

Number 1 - No. Too hard, and because carbide blades are expensive, you wouldn't be saving much money.

Number 2 - No. Too dangerous.

Number 3 - Yes. You can buy the bit and the file for about \$10 and an electric drill should be easy to borrow if you don't own one.

Number 4 - Yes, but only if you already have or can borrow the tools.

Number 5 - Yes.

Now RDWHAHB. Next installment we'll work on the heating elements.

I'd like to thank those whose idea I've used in this project - Bill "Veg" Noon for the basic design of the boiler, and Steve Russell and Tom Strasser for ideas on chiller construction. And of course all of you out there in net-land who have discussed these topics over time.

Tom Dimock-- Flame your kettle, not the net!

From: Mark James Easter <eastern@ccmail.orst.edu>  
Subject: Environment/health concerns about bottle cleaning

I'm responding to peoples comments about the use of chemicals to remove labels from bottles. The candidates seem to be:

- 1) plain old water;
- 2) a weak solution of ammonia;
- 3) a weak solution of chlorine bleach; and
- 4) a weak solution of tri-sodium phosphate (TSP).

I suggest that brewers consider the environmental and health impacts of using chemicals for removing labels. Environmentally, all three of the above chemicals will eventually either biodegrade or react to produce relatively benign substances. Phosphates and ammonia, however, have been directly implicated in stream and lake eutrophication. Sodium (in bleach and TSP) in ground water (from salting highways and industrial sources) is becoming a significant health hazard in urban areas. Exposure to chlorine compounds and ammonia has been implicated in liver and kidney disorders, as well as other health hazards. Why not try plain old water? A little elbow grease will provide good training for the 12 oz. curls we do this for.

While working in a certain "dry" middle eastern country, I (and my compatriots) had to find a way to dispose of illicitly-obtained Heineken bottles without alerting the trash disposal authorities that we had contraband on hand. Our solution was to boil the bottles for about 30 minutes, during which the paper came apart and the glue came off the bottles. We composted the paper mush until it was unreadable (that took several months), or burned it, and broke up the bottles.

From: Jeff Frane <70670.2067@compuserve.com>  
Subject: Irish Beer

Rob Bradley asks about Irish brewing history: My father discovered an interesting piece while doing some research on the politics of food(!). In an apparent attempt to destroy the Irish brewing industry during the height of British oppression (the 18th century?), the English prohibited the importation of hops. Apparently the Irish had little or no hop fields and, according to Henry Hobhouse in *The Seeds of Change*, this resulted in the production of porter. (Hobhouse apparently considered porter to be low in hop usage, which is different from what Terry Foster says. This also fails to take into consideration the importance of the water available for brewing, which definitely had an impact on the production of porter in Dublin (and London, for that matter). ) Given the Irish propensity for smuggling, it's also likely that they were getting their hops somehow, at least enough for porter production.

For no obvious reason, I get the impression that brewing came fairly late to Ireland, and that whiskey played a larger part. It would be interesting to learn whether Ireland raises any barley or hops.

You could probably learn a lot by contacting the Guinness Brewery in Dublin.

Jack Schmidling writes:

> It will NEVER melt and all your rhetoric will never change that fact.

<I'd like to take you up on this bet, Jack. Calculations and phase diagrams be damned...if I had 30 spare bucks and a video cam (and I don't), I'd be willing to prove to you that you can melt a SS pot while trying to boil water.

I will settle for a public admission that you are wrong. I will pay for the kettle if you can melt it on a stove while full of water.

> Now, if you were saying that you couldn't melt it on a home stove, I agree with you, but there are stoves (I like to call blast furnaces on legs) on which you could burn a hole in such a pot.

Prove it.

>As a fellow brewer here will also attest, you can burn a hole in one of these pots on your electric stove when the coil burns out (ie melts and explodes).

That's called spot welding and does not qualify for the bet. Nor does the use of oxygen or a concentrated flame of the type used for cutting.

> What does anyone know about the absorption of aluminum into the body from the use of antiperspirants? As most of you know, antiperspirants are based on some reactive aluminum compound (AlCl<sub>3</sub> is one) which readily reacts with water. So, how many of you play it safe here as well?

Would it surprise anyone to learn that I avoid using underarm stuff with aluminum and make my own baking powder to avoid eating alum?

Re: COUNTERFLOW vs TUBE-THROUGH-BUCKET-OF-ICE-WATER

>In the bucket of ice- wort through tubing method, the initial wort is REAL cold, and after the ice melts and you are using a bucket of chilled water, the wort is warmer.

I am not sure why the creative process must stop with one bag of ice.

I gave up on the ice and hooked the bucket to the water tap with an overflow out to a drain. I would however, like to caution prospective builders of an impass I ran into that makes MINE just about useless.

On the assumption that, more is better, I used 1/4 inch tubing so that I could get 50 ft into my bucket or kettle, depending on how I use it. It turns out that better isn't always practical. Nothing I tried would increase the flow rate above about 20 minutes per gal. Two hours is more than I want to spend chilling wort. Moral.... use 3/8 or 1/2 inch tubing.

The last batch I used it in the emersion mode and it cooled it down in about 30 minutes. Total time was two hours for various reasons but most of that time was while I was getting it ready. I wanted to compare the clarity after comparable settling time and was disappointed in the results.

The emersion chilled wort was far more turbid than what I had previously gotten by the instant chill, flow through.

From: STROUD%GAIA@leia.polaroid.com

>About this video, though:

Here we go again. I have been asked to refrain from plugging my video on the air and I obviously have ceased to do so. However, when I or it am publicly criticized by one who has neither seen the video nor met me, I demand the right to protest.

>Why would someone who has never tasted anyone else's homebrew make a "how-to" homebrew video?

I have tasted Bud and my own homebrew and think lots of people "out there" (the real out there not HBDland) could benefit from my humble experience.

>Why would anyone buy a "how-to" homebrew video from someone who has never tasted someone else's homebrew?

For the same reason that I bought a can of malt and yeast years ago even though I had never tasted homebrew. I took a chance. Furthermore, the prospects in my target market are not quite as hung up as you "experts."

>'Nuff said.

Right. Vote the county dry then move out.

Nuff will be said when you stop bringing it up.

Basically MJ is a journalist who hit upon a novel angle: make a story out of his favourite pastime! He wrote articles about beers, brewers and brewing. The launch of the CAMRA newspaper "What's Brewing" gave him an ideal start. The articles were good, they sold and the rest is history. You don't have anyone in the US doing it. Give it a try. One warning, I believe he works very hard. He has to travel all over the world tasting beers and whiskys wherever he goes. He says it's a tough life but someone has to do it :-)

Subject: De-labeling, bottle sources.

>From all I have heard, sodium carbonate is the best stuff for delabelling, but what happens if it's late at night and you just ran out of sodium carbonate. I have it on good authority that plain old sodium Bicarbonate, baking soda, works well also. About 1/4 box in a sink of warm water does the trick.

As for source of bottles, it really doesn't matter. If the bottles have paper labels, it will be very easy and require a short soak. If they are foil, it will take a little longer (since foil doesn't get soggy), but by just scratching the surface a few times with a fork will significantly speed up the process.

Unless you live in anti-alcohol counties like Montgomery County, MD or states

like Utah, just go to any liquor store that sells longnecks and pay the deposit. Some bars will even save longnecks for you in the original sturdy

box, and you may not even have to pay the deposit.

From: Steve Anthony <steveo@Think.COM>  
Subject: All-grain boil and evaporation

I'm getting ready to do my first all-grain batch and have been reading thru TCJoHB, visualizing the steps and figuring out all the details ahead of time. (It's because it's a small kitchen; I have to be organized or I get inundated with mess quickly). One thing that's caught my eye is the amount of evaporation that is counted on during the boil. While I don't have the book in front of me, I believe the values were something like 1.5q of water to be boiled off.

Now, my house, even in the winter, is plenty humid enough. In the summer, I can't even conceive of adding that ammount of vapor to the house. Perhaps, relative to a shower, it's not that much, but the bathroom has an exhaust fan, and the kitchen doesn't (it has one of those fans that suck up the smoke, filer the grease, and send the air back into the room).

When I do extract or partial grain recipies now, I do use an ajar lid during the boil, and am happy with the results. But when I go to the big leagues...

So my question is, is the evaporation necessary? Can I just start out with less liquid and use a lid to prevent the vast bulk of moisture from escaping? Or is there some more fundamental purpose served by the evaporation? How have others coped (if indeed they felt the need to cope) with this? Any I not relaxing?

Prosit!

From: jmiller@anubis.network.com (Jeff J. Miller)  
Subject: Cost of Kegs

Like many of us, I have been dreaming about opening a brewery/pub/homebrew supply business for some time now. In doing so I've talked extensively with Summit (local brewery - very fine - and Mark is a great guy!) as well as poured through LOTS of industry materials.

Summit buys used kegs and price is dependent upon availability. If he can find enough and can afford them he might see a used keg for only \$30. More likely they end up costing him upwards of \$60 or more. Something to keep in mind is that Summit uses the two prong tap (Hoff-Stevens?) which is being phased out because of the labor involved in filling and cleaning the keg.

If you care to talk about newer kegs with the single point of entry (Miller), you wont find them for sale on the used keg market and if you did they would demand a HIGH price because of there demand.

In looking at adds from Sparten and others it seems clear that the list prices for these kegs is usually well over \$200. Even with bulk order reductions in price, I think were still looking at the breweries shelling out BIG bucks for the keg.

So... looking for a cheap brewpot/fermenter! Check out the used dairy equipment. You can usually pick stuff up for scrap prices.

From: "Jean B. Hunter" <MS3Y@CORNELLA.cit.cornell.edu>  
Subject: DMS and Diacetyl (HBD 769)

Larryba asks if bacteria can make diacetyl. Yes, a Zymomonas infection will produce loads of diacetyl as well as acetaldehyde which is green and fruity smelling. I have been using a pressure cooker (15 lb, 20 minutes) to sterilize my starters right in the starter bottle and have had no trouble with infected starters even if they are stored for months before using.

Re DMS and malt: the sulfur compounds added to malt before kilning to inhibit nitrosamine formation, and any sulfur-containing fungicides used to preserve malt and hops, can be converted to elemental sulfur during wort preparation. During fermentation, the yeast use this sulfur as an electron acceptor, first reducing it to H<sub>2</sub>S, then linking on methyl groups to give methyl sulfides. The problem with sulfur in the wort is that it cannot be eliminated by ventilated boiling and sparging since it's not volatile. The only solutions I can think of are changing yeasts (to a strain less eager to reduce sulfur) or changing malts. Hope there are other approaches, as these are admittedly not very satisfying. Cheers -- Jean

From: key@cs.utk.edu

Subject: Soda Kegging Questions.

Greetings all,

I've been following some of the Soda Kegged Homebrew discussions and think I'm going to try it myself this winter . I've got a supplier for used soda kegs lined up and one of the local brew shops (Brewhaus, here in Knoxville) has everything else I need and a good price on it, except CO2 - they want \$88 for a 5lb (filled).

My questions to the group are:

1) where do you get your tanks and get re-fills? I've talked with local rest. supplier and welding gas company. I've found possible used tanks, but the guy knows nothing about them and I'm worried about certification, etc.

2) I've seen those nifty manifolds in the Foxx catalog and they seem pretty cheap way to have multiple beers on tap if one thing is true: Do you need a regulator per/keg or would having a single regulator between the manifold and the CO2 sufficient (i.e, do you find you have to futzz with the pressures on a per keg basis?)

3) I've seen a little about cleaning and modifying the kegs for Homebrew use: Replace all O-rings and shorten the liquid pickup tube. What other things need to be done other than a good bleach-water cleaning?

4) I think, but don't know, that the beer would stay fresh after you've tapped it part way and then swapped it out for another keg and came back to it a little later. Is there any difference between that and not having tapped it later? I don't have to worry about oxidation...

5) any other hints/tips/admonishments from Soda Keggers?

Thanks for any info,  
Ken Key (key@cs.utk.edu)

**Subject: Returnable Bottles**

Just one more idea on the "perfect bottle" subject. I go down to a friendly bar (The Town Hall in College Park MD) and buy cases of empty Bud Longnecks. They sell 'em for the deposit, which has varied from \$1 to \$2 the times I've done it. It's perfect - you don't have to drink the stuff (it's "pre-consumed"), and they come with a great carrying case. You can get a couple extra cases, sort through them to find the good ones, and return the ugly ones and get your money back.

Subject: Party Balls Make Great Lamps

jimb@mips.com (Jim Bergman) writes:  
] He said he would give me the partyball after it  
was consumed for my homebrewing use. My question is, where do I find the  
rubber seals for it or the batch-latch type cap to re-use this partyball?  
I'm interested in fixing it to add a CO2 cartridge or CO2 tank...

This is kind of irrelevant to the subject, but I found in College that  
party  
balls make great lamps. Cut the plastic base off for a sphere, or cut it  
in half. The two small rubber gaskets get a loop of wire (for hanging)  
threaded through them, and a lamp wire is pushed through one of them. The  
light socket is attached to the wire and attached to the wire loop (so  
that  
pulling on the chain won't pull the light off the wire). A bit of chain  
makes a dandy swag lamp in a seventies style.

Since this has nothing to do with homebrewing, I'll provide an  
ObBrew: A metal colander with high sides makes a great tub for grain  
when  
they are being used as an adjunct to an extract brew; the grain gets  
soaked  
thoroughly and is removed easily; reduces the need to sparge later. If  
you  
live in bachelor's quarters, just be certain to remove the dried-on  
spaghetti  
first.

From: rich@bedford.progress.COM (Rich Lenihan)  
Subject: When yeast gets old and dies...

>From: MIKE LIGAS <LIGAS@SSCvax.CIS.McMaster.CA>

> Yeast lysis is affected both by time  
>and temperature. A rule of thumb is max. 14 days in primary if you're  
doing a  
>single-stage fermentation. Racking too late risks oxidation. Once your  
beer is  
>in the secondary you can relax on the order of months since the yeast  
carried  
>over in suspension is healthy.

But what happens when it falls out of suspension? I observe the  
following  
when I brew:

1. Ferment in primary. Lots of trub falls to bottom.
2. After a few days, rack to secondary. About 1/3 - 1/2 as  
much trub falls to bottom.
3. Rack and bottle. Small amount of sediment in each bottle.

I assume that what falls out of suspension in steps 2 and 3 as well as  
step 1 is "dead yeast" (among other things). I've learned from reading  
(here and elsewhere) and from my own experience that it is more important  
to separate the beer from the dreck in step 1 than in step 2 and 3.  
When I went from single-stage to two-stage fermentation, I noticed fewer  
off-flavors in my beers. The last batch I bottled was in the secondary  
(due to illness and busy-ness) for @ two months. It may be my best  
batch yet. So, to reduce the off-flavors, rack to secondary asap. But,  
what about oxidation? I often get staling or oxidation symptoms in  
my beer after it has been in the bottle > 3 months. I don't think this  
is due to improper aeration of the wort or beer. I've always accepted  
this as a fact of life when dealing with living beer and so I don't worry  
about it too much. Besides, only a few stray bottles make it past the  
3-month point 8-) My point is (finally!), can you really "relax on the  
order of months since the yeast carried over in suspension is healthy"?  
Even living healthy yeast dies eventually. I suspect that the longer  
you expose the beer to the sediment (whether in primary, secondary, or  
bottle) the more you're pushing your luck. This warning does not  
include lagering (which I have no personal experience in), where long  
fermentation periods are needed due to the very low temperatures  
involved.

Also, after several months, will there be enough viable yeast to induce  
carbonation? The last batch I bottled is currently under-carbonated  
for my taste, but it's only been in bottle for 1 week now. Time will  
tell how this beer (and its yeast) will age. In the meantime, am I  
worrying too much or should we factor the life-cycle of our yeasts into  
our brewing schedules?

Subject: perfect bottles

>Maybe someone else out there in email-land knows of the perfect  
>brand of bottle to use: one that is dark brown to protect from  
>light, sturdy to protect from breakage by the avid bottler,  
>covered with a label which falls off when looked at, and filled  
>with an inexpensive beer which is very good to drink ;)

Well, IMHO, the way to go is with Martinelli Sparkling Cider bottles,  
or your typical American champagne bottles.

All mine are green, but talk about sturdy! I've got the cases they come  
in,  
and store that way, so green doesn't bother me. They are 750ml, so they  
pour  
a nice sized glass of beer. They make bottling go REAL quik too. I  
usually  
bottle half in the 750ml bottles, and the rest in 12oz Bud "bar" bottles.

The 750ml work out good to pour one BIG beer, or a couple regular size  
beers.  
Great for parties or monday nite football...

Subject: Bottle Labels, Bottles, & my two cents

Tom Dimock <RGG@CORNELL.CIT.CORNELL.EDU> says:  
>If you want sturdy bottles with labels that come off easily, try to  
find re-usable bottles.

I must concur. I'm sure most of you can recall drinking out of a "bar  
bottle"  
(i.e. BudMilob longneck bottle available in any bluecollar watering hole)  
and  
having the label just fall off in your hand with only a little help from  
the  
water condensing on the bottle's surface.

I believe that you won't have much trouble buying these, from any bar at  
which  
they are served, for the cost that the bar paid for deposit.  
I think that is usually 10 cents a bottle.

Now, has anyone found a ready source of Sam Smith's pint size bottles,  
besides paying \$50+ a case for full ones? I know these bottles are clear  
(ref.  
the light damage bottle thread,) but they look great and are just the  
right  
size for my liking.

Subject: Cost of Kegs (George Fix)

After reading C.R. Saikley's post concerning the actual cost of kegs, I called Mike Adams (a brewer at Miller/FW) about this matter. C.R. is right. The \$15 is a "funny money" figure used in internal accounting. The true cost of the kegs is ten times that amount (and even more for the rubber lined kegs). Mike tells me that the loss of kegs is not big issue with them, however Jeff's original point about ethics is apparantly valid. I stand corrected.

Good News/Bad News: Mike also told me that they are phasing out half kegs for economic reasons associated with filling costs. He feels the other large brewers are going to do the same. This means they will start becoming scarce at draft outlets, and start showing up elsewhere. The scrap price for these kegs should be \$5-\$10. People who live near a commercial brewery might want to inquire.

End of HOMEBREW Digest #770, 11/28/91  
\*\*\*\*\*  
-----

Date: Wed, 27 Nov 91 13:09:12 EST  
From: wbt@cbema.att.com  
Subject: Various

Keg deposits:

I called the local Anheuser-Busch brewery and asked them. I was told the following:

The kegs cost \$70-\$75 each in large quantities; \$150 each bought singly. It is illegal to "refill a container that doesn't belong to you." It was implied that this is a federal law. It is illegal destroy or modify these kegs in any way, as they remain the property of A-B, Miller, etc. There is no method for the breweries to trace their kegs effectively. I.e., so long as you don't invite a federal marshal over to help brew, you're not likely to get caught. A-B locally did prosecute several people a couple years ago for cutting up kegs to make barbecues.

I then asked about returnable bottles. A-B told me that they're a bit different, as they're essentially "community property." That is, the bottles are all the same, and it's not uncommon for A-B to get a bottle from another brewery returned in one of their cases. They just go ahead and use them. Also, the bottles cost them about 2 cents each, and they figure it break-even if the bottle makes five passes through the system before being discarded.

In short, A-B doesn't like the idea of people keeping their kegs, but they don't mind homebrewers using their bottles.

Galvanized screen:

Normal "window screen" and other galvanized products have a zinc-based coating. Zinc itself is not particularly toxic when ingested (please \*don't\* take this at carte blanche to chow down on zinc, folks; it can make you sick, even if it won't kill you). Many vitamins contain zinc \*compounds\* (most commonly zinc oxide, I believe); I'm not sure if metallic zinc is metabolized differently or if zinc poisoning only occurs when a certain threshold concentration is crossed.

However, the galvanizing alloy often contains additions of other nasties, most notably antimony, lead, cadmium, and our old friend, aluminum. I would \*highly\* recommend against using galvanized metal in brewing. Even without the toxicity question, zinc should be readily attacked by the acidic mash, and I would suppose the dissolved zinc ions would affect your beer's flavor.

Subject: Specific Gravity before and after boil

> I expected the SG to be higher due to the evaporation from the boil,  
right?

WRONG! The SG dropped!

>The only explanation I could think of is that the trub (before  
precipitation -- that is, while still in solution) contributed some  
tourn.

the SG. Either that or I screwed up my before-boil measurement :-).

I would suspect the latter. It is easy to do and the former? Well, I  
won't

say what seems obvious. I will leave that to the chemists.

On my last batch, I was stunned to find that the gravity of the first 5  
gals

was only 1.030. I stirred it up and measured again and got 1.040. It  
aparently stratified. The total of eight ended up about 1.030 but boil  
down

yielded 6 gals at 1.045.

From: korz@ihlpl.att.com  
Subject: Re: window screen

>I'm a bit confused here. I thought the idea was to put this into the  
bottom of a stainless steel keg so you can heat the mash on a burner.  
The plastic coating Roger suggests might be a good idea for a lauter  
tun to be used for a decoction mash but not for step infusion.

I can't speak for the follow-on but my original posting was to provide a  
simple, one-kettle system that does everthing. The spiggot-pipe-screen  
goes

into the bottom of your favorite kettle. It is used for a directly  
heated  
mashing cycle and sparging, then later for the boil. I proposed (and  
used)

an enamel/steel kettle for economy and availability but it would also  
work in

a cut down keg or any other kettle..

> I, personally, would avoid plastic (recent heat trasfer arguments  
notwithstanding) so close to the burner.

Yucho!

> I still contend that "common" window screen should be avoided, but (as  
someone mentioned) brass screen is available.

Just a detail, but it's copper not brass. Brass contains zink and would  
be

no better than galvanized steel if zink bothers you.

..... Question .....

I have noticed that ALL of my (5) all grain batches exhibit a head characteristic that Baderbrau calls "webbing". A lacy net of drying foam adheres to the glass as it is being emptied and for hours after.

I just finished the last of my extract beers (2 months old) and it did not exhibit this characteristic nor do I recall that any of them ever did. They have a nice frothy head that lasts till empty but leave the glass sparkling clean.

Is webbing a character to be sought after?

Is it obtainable in extract beer?

Is it unique to all grain beer?

BTW, that last extract beer were the Oxidation control and test sample. The result is still the same after 60 days. No obvious difference in the two.

Just in passing, I do not want to disinter the subject. I will mention that

I had to blend in some current all grain to both to bring the flavor up to current standards.

For those afraid to try all grain, I can simply say that (for me), the quality of my beer has made a quantum leap forward. It was like falling off a log.

I do not doubt that some people can make good beer with extracts but I can now honestly say, I don't think I ever did. All grain brewing takes a bit more time and effort but the satisfaction is immense. Dollar-a-gallon beer is also no small part of the compensation.

From: Todd Enders - WD0BCI <enders@plains.NoDak.edu>  
Subject: Yeast musings...

This is strictly speculation (and therefore subject to enlightenment by those who know more than I on the topic of yeast mutations and metabolism), but I was reviewing my yeast culturing practices, and am wondering if the following scenario might not hold true...

1. Start fresh culture from a known source (like a Wyeast packet).
2. Brew and bottle a batch
3. reculture yeast from dregs of "current" batch.
4. Repeat steps 2 & 3 for several (>5) generations.

I don't believe it's exactly fair to call this yeast the same strain as you started with. Why? Well, consider that by using yeast from the bottle, you would tend to pick up the more attenuative cells that are left in suspension and still active. As one repeats this process over several generations of reculture, one is artificialy selecting a more attenuative population, no?

Could this process be extended in the other direction also? i.e. taking the cells that fall out of fermentation first, again and again over several generations, and develop a \*less\* attenuative "sub-strain". How exactly do breweries develop their own strains? (I know they come up from single cell isolates, but is there really that much difference in a population of *S. cervesae*?) How can you select for traits such as ester production (type and quantity) without doing many long months of test batches? Color me curious :-).

Subject: Draught Guinness in Cans / keg stealing

Last weekend I tried the Draught Guinness in Cans. It was good, but not great, in my opinion. Much lighter in body than the bottled version. It \*did\* taste very much like the on-tap version I've had in two places in Chicago (Dublin, Ireland is another story, I would imagine). I have to agree with Michael Jackson who rates the Draught version with 3 stars and the bottled version with 4 stars. I like my stout THICK. The homebrewed stout I have on tap at home now is about the consistency of bottled Guinness but a little sweeter and it has more roasted barley flavor. I don't have the recipe here at work, but I'm almost positive it's two cans of John Bull unhopped dark, 1/2 lb roasted barley, 1 oz of cascade pellets for the 1hr boil and 1/2 oz of whole cascades in the primary, Wyeast #1084

"Irish Ale" yeast, fermented with blow-off at 68F.

On kegs: I kept a keg I got from a brewpub in town. I forfeited the \$45 deposit, which I'm sure is more than they paid for it. It had the brewpub's label glued on top, partially obscuring the industrial brewery's imprint (Miller Brewing Company, I believe). I purchased the tap and hoses new from Foxx Equipment Company. I plan to use it for beer made specifically for parties (15.5 gal). I think I'll brew in it too as soon as I get replacement bungs and a stopper big enough to fit the bung hole.

>have a  
>white ring around the bottle neck just like the Chimay. My question is  
>did  
>the bacteria take over my brewing basement??

First of all, Chimay should not have any active bacteria in it. It is brewed from cultured yeast. From you post, it was not clear if the Chimay bottle necks had the ring or your "Chimay-style" bottles had the ring. If the original Chimay had a ring, it was bad. In any case, you obviously \*do\* have a bacterial infection in your brewery. Are you using plastic fermenters? I suggest switching to glass carboys (or SS as recently mentioned). Are your racking hoses old? If so, change them. I'm assuming that you are using some kind of sanitizer on everything that comes in contact with your beer. Just think through your procedure carefully and I'll bet you can identify where the weak link is in your sanitation.

From: BAUGHMANKR@CONRAD.APPSTATE.EDU  
Subject: Apology, announcement, copper scrubbers and diacetyl

First a public apology for my flame a couple weeks back. The lesson learned was that honey attracts more flies than vinegar. Jack and I have talked by phone and aired and smoothed over our differences. The situation is this. The flame wars are over. There is no longer any reason to bait anyone in the Digest.

We are here to talk beer.

We are back to normal.

Let's keep it that way.

A measure of Jack's interest in this affair is beheld in the quality of his last several posts. Personally, I look forward to any and all such posts by him, as well as everyone else, in the future. Happy days are here again.

Now on to other matters....

OK. I admit it. I've been worrying!

There was a post a couple months back about how a pot scrubber had added a metallic taste to the finished beer. I responded by pointing in the direction of a stainless steel scrubber. I have since contacted Chore Boy and asked about their scrubbers. That particular brand is made of PURE copper. So if you plan on using the pot scrubber in a mesh bag technique for filtering out hops from the boiler, search out the Chore Boy brand. Pure copper can't impart a metallic taste to beer. If it does, then the commercial boys are in big trouble.

Several people have contacted me about having difficulty with this method. This week-end, for the first time, I too had problems with the siphon becoming stuck towards the bottom of the pot. I was able to continue the siphon by placing the boiler on the bottom of an inverted 5 gallon enamel pot, increasing the 'vertical drop' between the boiler and the fermenter. I also tried rinsing off the mesh bag by holding it under running water for a bit. That seemed to help things as well.

A comment about sparging technique:

> If cost is a  
> concern here, then the system that Charlie Papazian suggests, with two  
> plastic  
> buckets, is certainly a better solution. The buckets are cheap, and it  
> only  
> requires some long boring minutes with a drill to put an adequate  
> number of  
> holes in the upper bucket.

One concern I've always had with the bucket in a bucket lauter tun system is the capillary action that's bound to occur down the sides between the grain and the bucket. Any and all water subject to this phenomenon would miss the grain all together and contribute to a less efficient sparge. Dave Line speaks to this in The Big Book of Brewing and thus recommends using a sparging bag. I've never tested

this but it seems a valid point.

Larry writes concerning his diacetyl problem:

> Now, if I rememeber correctly, from Dave Miller ( TCHOHB)  
> that Diacytal is primarily a yeast byproduct (as apposed to DMS that  
> can be produced by bacteria). Anyone know if there are specific  
> bacterial strains that produce diacytal?

I'm not sure about bacteria but I've always understood that the only method for diacetyl reduction we as homebrewers have is to let the beer rest on the yeast cake for a day or two past primary fermentation. Thus my question is: Did you use a two stage fermentation process for that beer and when did you rack? Perhaps George Fix can speak to this with more authority than I.

Happy Thanksgiving to you all--that most of American of holidays when we asked the Indians over for a big feast and then told them to get the hell off our land!

Cheers,

Subject: Describing beer tastes

I just tried Winterhook ale and would like to know how experienced tasters/judges would describe this beer. I would say it was hoppy, medium body, and not much else. It was a little too bitter for my tastes (hopheads take note). This may be way off from a "professional" opinion, so I'll like to see what they would say. Thanks.

I guess you have the holiday weekend to try it for yourselves.

From: Conn V Copas <C.V.Copas%loughborough.ac.uk@hplb.hpl.hp.com>  
Subject: Posting Recipes

A while back, we had a thread on formats for posting recipes. The issue never got resolved, as far as I am concerned, so I am reviving it for discussion.

My main point is that, whilst I appreciate recipes, there is something I appreciate far more, and that's recipe formulation. The former is data, and the latter is information, so to speak. What this implies is that there are three fundamental questions which every post should consider : (a) What was the recipe trying to achieve ? (b) Why were things done in the way they were done ? (c) How well were these goals met ? I suspect that in many cases we can do without descriptions of the mechanics of mashing, boiling or fermenting.

The best way of illustrating my concerns is to analyse a recent post. No slight intended to the author - it looks like a solid recipe and was interesting enough to have already generated some discussion.

>6 lbs. dark dry malt (M&F)  
>2 lbs. amber dry malt (M&F)  
> .75 lb. roasted barley  
> .5 lb. black patent  
>1 lb. crystal malt  
>2 CUPS (not lbs) Quaker Oats  
>2 oz. fresh Bullions hops (boil)  
> .6 oz. fresh Willamette hops (finish)  
>Whitbread Ale Yeast  
>  
>Add hops in last 5-6 minutes of the boil. All specialty grains should  
>be cracked, first. Soak the specialty grains & Quaker Oats in cold  
>water for 15 minutes, bring to a boil, remove grains with strainer as  
>wort comes to a boil. This has an awful hot-break, and needs to be  
>nursed for about 5 minutes before you can leave it safely. I went  
>light on the Oatmeal because the oils in it tend to be detrimental  
>towards head retention.

>  
>Comments: This beer improves substantially after about 2 weeks in the  
>bottle, as hop aroma subsides and the large amount of roasted barley  
>assumes it's place in the forefront. It's my favorite beer to date,  
>but if I were going to brew it again I might cut back on the roasted  
>barley by about .25 lb, and lessen the boiling hops (either to 1 oz.  
>of Bullions, or 1.5 of some lower alpha hop). Whitbread ale yeast was  
>used because of the low attenuation rate: this stout is NOT sweet,  
>but has lots and lots of body.

>  
One of the first things I noticed about this recipe is that it employs a number of different malts and specialty grains, even for a stout. There are two types of roasted grain, one of which is known to impart a harsher flavour than the other, with each having different effects on the colour of the head. I would love to have known whether this mixture was by design or

by accident. If the former, the possibilities for taste interactions between all this stuff are mindblowing, and I would have liked more details. Comments like "It tastes great, you should try it" are just not enough to stimulate me into replicating it.

Is the recipe too bitter ? Well maybe yes and maybe no. First of all, what sort of style was being aimed for (presumably an Irish type stout ?). What are the brewer's own preferences ? (eg, I regard a beer as being sufficiently bitter when it starts to strip enamel from teeth, and would happily use Bullion in a lager :-). How was the balance between malt and hop ? (a terminal gravity figure would have been useful). What about the serving temperature, which is crucial if one begins to talk about strength of flavour ?

This brew was obviously bottled, but I frequently see other recipes which don't specify, leaving me to guess about comments regarding smoothness and head texture.

Here's some more speculation. Is there a chance that it was the large amount of roasted grain rather than the hops which caused the astringency ?

In which case, maybe it's premature to comment until the brew has aged three months.

Some indication of the water treatment then also becomes useful.

I realise my comments have the potential to intimidate beginning brewers, but

that's not the intention. I'm interested in all recipes, whether they're kits, extract or all-grain. What I'm appealing for is more consideration of

the audience. A simple test which one could apply is this : will other people be able to understand what the recipe was trying to achieve, and has it been persuasive ?

Subject: Not Chimay's Fault!

In HOMEBREW Digest #769, b\_turnbaugh described infection problems after brewing with Chimay yeast cultures, saying:

> ... They have a  
> white ring around the bottle neck just like the Chimay. My question is  
did  
> the bacteria take over my brewing basement??

Sounds like SOMETHING did, but I very much doubt it was related to your Chimay culture. I've used Chimay cultures and worse (*Pediococcus damnosus*, *Brettanomyces bruxellensis*, etc.) in my brewing, and have never seen a white ring around the neck of one of my bottles, except in the imitation lambics where ropiness was deliberately induced. This is not a normal feature of Chimay's inoculum, in my experience.

> ... [fermentation] seems to take a couple of days to get going.

The fact that you mentioned this suggests to me you've formed a hypothesis, and it's one I agree with.

> ... Should I start making quart  
> starters instead of 10oz starters?? Should I get down on my hands and  
knees  
> and scrub everything with clorox??

Sounds like a good start to me, Bob. I'd guess your infection has environmental origins, and that you'll do well both to address the environment, and to get fermentation to take off as quickly as possible to minimize the infection's "contribution" to the finished beer. Good luck!

Subject: Lambic, Schmambic.

In HOMEBREW Digest #769, Bob Hettmansperger noted:

>Re: Samuel Adams Holiday Classics  
>I bought this package with much enthusiasm, primarily because of the  
>Cranberry  
>Lambic. Having never tried a lambic before and REALLY liking Sam  
>Adams ...

Sorry, but you still haven't. I haven't tried the Sam Adams  
"Cranberry Lambic", and probably won't, as I can't support the  
appropriation of the name of a specifically regional style for the  
purpose of marketing a beer made outside the region and with  
different methods. To find out how a lambic really tastes, seek out  
a bottle of Timmerman's, of Mort Subite, Belle Vue, or if all else  
fails, Lindeman's. If in your search, you find a source of  
Cantillon, PLEASE LET ME KNOW!!!

> ... Well, I wasn't impressed. In fact, the taste reminded  
> me of what my mouth tastes like the morning after having too much  
> the night before.

Having participated last night in a vertical tasting of Sierra Nevada  
Celebration Ales ('87 - '91) that somehow led to a horizontal  
tasting (the tasters having lost the ability to remain vertical %\*)  
of single-malt Scotches, I find your analogy painfully descriptive,  
just now. The taste in my mouth is not in the least lambic-like.

> What went wrong? Is this a typical lambic?

Not even close. The term "lambic" covers a wide range of flavors,  
but they are generally sharply sour, with varying degrees of  
fruitiness, and a very clean finish. Some have "horsey" or "mousy"  
flavor notes, but all are clean, clean, clean. I highly recommend  
trying a real lambic -- you'll either love it or loathe it, there  
seems little middle ground. Happy hunting!

From: larryba@microsoft.com  
Subject: Re: TSP vs Washing Soda

I think the only thing special going for Washing Soda is it is dirt cheap.

I don't know what the problem was for the guy who got a white film on his bottles. \*Any\* alkaline environment will eventually etch glass. Washing soda is pretty damn alkaline. Good call on using something acidic to remove the film. Also, an alkaline environment will dissolve aluminum and make aluminum hydroxide/carbonate - i know: i used this technique to make hydrogen bombs, er, ballons in high school. Perhaps that was the source of the film.

TSP is great stuff too. I don't use it simply because I don't have any.

I got the tip on using Washing Soda (primary ingredient in all dish and clothing washing detergents) from a friend of a friend who is a chemist.

Now days, I pretty much just use a squirt of Dawn liquid detergent or the Dishwasher when washing bottles or brewing equipment. TSP and washing soda are pretty hard on my hands and I am too lazy to use gloves.

From: Mike Sharp <msharp@cs.ulowell.edu>  
Subject: Re: cutting a keg

Yet another way to cut a keg is to use an autobody 'zip saw'. Its an air driven saw that uses ~4" diameter abrasive wheels. Its small enough to cut a nice circle in the top of a keg, and if it binds in the cut it won't 'kick', just bind (at least at something less than super industrial air line pressures. I run 120+PSI at 13 SCFM). The down side is that you need to know someone who has one. The tool itself isn't expensive. At least not as tools go, anyway. The 5HP compressor you need to run it is though.

Oh, this saw will cut the top of a keg off in about half an hour if you work at it. It should take 2 or 3 wheels. I believe the wheels are \$1.50ish each at the moment.

From: ithaca!amber!phoebe@uunet.UU.NET (Phoebe Couch)  
Subject: Re: Bottles

I usually use *\*very\** hot water to soak the labels off(sometimes with TSP)  
.  
The glue soften up and you can peel the label off and rinse off the glue  
on the  
other side while the bottles are still warm.  
As for strong sturdy bottles, I like most UK imports:  
Bass ale, Guinness, Mackenson and Watneys, etc,  
As for domestic bottles, Anchors are great.  
Sam Adams labels are harder to remove but the bottles are fairly sturdy.

Caution: never use Fosters, not just because they are green,  
but they tend to break when you cap them.

Last time I needed bottles urgently, I tried to buy them off a street  
people  
in Berkeley ( with a shopping cart full)  
at 25 cents over the california redemption rate for each  
6 pack, but he wouldn't sell them or even negotiate, figures!

From: Henry (H.W.) Troup <HWT@BNR.CA>  
Subject: **Bottles, more Ethics, and On Premises Brewing**

Even in stuff ol' Ontario I've been able to buy bottles from the Brewer's Retail outlets. Sometimes. Although I have a fair stock of bottles, I have a question and a comment. What brands (in Canada) come in non-screw top bottles? Are there any caps that home brewers trust for those bottles?

The comment: one local microbrewery died. Rumour says it was because the Ontario regulations forced them into glass bottles (above 200,000 litres per year?), and they 'lost' too many bottles. Bottles certainly cost more than the 10 cent deposit!

Final question: how do people feel about the 'on premises' brewing places? Do you even have them? 'On premises' means they sell you the materials and rent you the space and use of their equipment. They seem to have microbrewery extract style stuff - with filtering and bottling lines. Cost is between homebrew and commercial beer. Getting very popular, because you don't need to know anything.

Henry Troup - HWT@BNR.CA (Canada) - BNR owns but does not share my opinions

Fm: Jack Schmidling

EASY MASH

(The Sequel)

This was originally posted leaving out a lot of details, some of which,  
I herewith fill in.

As I intend to produce a new - - - - on all grain brewing, I would appreciate any and all CONSTRUCTIVE comments.

I want to develop an all grain process that reduces the cost and effort to the minimum while producing an acceptable beer.

As I have the same aversion to plastic as I do to aluminum and to keep within the budget of most hobbyists, I decided to base the system around the old enameled 8 gal kettle that grandma used for canning.

The same kettle is used for mashing, sparging and again after dumping the spent grains, for the boil. It is never lifted full so the problem of handles falling off is not an issue.

A few simple mods are required to make it fit the process. A small brass spiggot is fitted to the bottom with a short piece of pipe extending several inches toward the center on the inside.

A small piece of window screen is rolled several times around the pipe and secured with a hose clamp or twisted copper wire. The screen roll extends several inches past the end of the pipe and the last inch is bent over itself to prevent anything from entering the spiggot that has not passed through several layers of screen.

Mashing is begun by "doughing in" enough warm (100 degs) tap water to 8 lbs of milled (2 row/6 row) malt to obtain a consistency of oat meal. Let this rest for 30 minutes.

Add enough hot tap water to bring the temp up to 120 degrees using a candy

thermometer to monitor the temp. Hold this temp for 60 minutes by adding heat as necessary. Stir frequently to avoid carmelizing and to distribute the heat.

On a separate burner, bring a couple of quarts of water to a boil.

Increase the heat and add enough boiling water to raise the temperature to 158 degrees. Maintain this temperature for 60 minutes. This can be done by simply adjusting the flame while monitoring the temperature and dilligent stirring.

The preferred method is by decoction. Remove a quart of the mash and bring it to a boil on a separate burner then return it to the mash. Repeat this as often as necessary to maintain the 158 degrees. In spite of the fact that boiling destroys the enzymes, there are other important chemical reactions that take place only by boiling. As only a small portion of the mash is boiled at one time, there will always be enough enzyme activity in the unboiled portion to maintain the process, even on the boiled portions.

Even partial decoction should produce a beer superior to the more common method of dumping hot water into a cooler full of malt and trusting to luck.

After 60 mins at 158, crank up the heat and continue the decoction until 178 degrees is reached. Hold this temp for 30 mins with flame and a few decoctions, then turn off the heat and let it rest while heating water on another burner. If you have control over the hot water heater, you can get it almost hot enough out of the tap. I keep two pans of water going so that one is heating while the other is sparging. You are on you own here.

The level of wort in the kettle should be no more than about an inch above the grain when it settles. Lay a dinner plate on top of the grain to distribute the sparging water and minimize the disturbance of the grain.

Open the spiggot just a trickle and run the wort into a sauce pan or jug till it runs clear. Pour the turbid runoff back into the kettle.

The object of sparging is to extract as much sugar from the grain as possible. The longer it takes, the more efficient the extraction. Adjust the outflow so that it takes at least an hour to obtain 5 gallons. Add the boiling water as necessary to just keep the grain covered.

The first runoff should be about 1.080 and you quit when it gets below 1.010.

The total blend will produce 6 to 7 gallons at about 1.030 which, after boiling will yield 5 to 6 gals at 1.040.

The seven gallons of wort will fit easily into the kettle for the boil.  
A minimal one hour boil will evaporate about a gallon so you can play with the volumes in various ways. You can increase the gravity by more boiling or boil less and have more beer.

Add half of your hops as soon as boiling begins. Save one forth for the end and the remainder at regular intervals during the boil.

After the boil, it is tapped into the primary after cooling, either overnight or with a wort chiller if you have one. I actually draw it of a gallon at a time so that I can shake it vigorously and "glug " it into the primary to oxygenate it prior to pitching yeast.

The kettle seems to be universally available for about \$35 and the rest of the stuff can be had for less than \$5, making it a pretty inexpensive system.

I happen to have a small foundry furnace that I use to boil on and have not actually tried boiling on the kitchen stove but I gather from others that two burners will eventually bring 5 gals to a boil. My furnace will bring 7 gals to a wild boil in about 20 minutes and provides a true "fire-brew". It is made out of a few fire bricks, a small blower and some pipe fittings.

For those afraid to try all grain, I can simply say that (for me), the quality of my beer has made a quantum leap forward and it was like falling off a log.

I do not doubt that some people can make good beer with extracts but I can now honestly say, I don't think I ever did. All grain brewing takes a bit more time and effort but the satisfaction is immense and dollar-a-gallon beer is also no small part of the compensation.

Subject: new masher in town

Hi All,

After successfully brewing nine batches of extract or partial mash beer, both my partner and I have finally decided that we are ready to proceed with an all grain brew. In anticipation of this mementos event I have thoroughly read both Miller and Papazian's instructions on how to prepare an all grain batch. Although I think I have a good grasp of all the steps involved, I was hoping to tap this group's "Keg o' Knowledge" and hopefully gain some insight into problems that are likely to occur but that I as a new masher might not have anticipated.

Thanks in advance,

Subject: Cranberry Stuff

It was suggested that I post this to HBD, so here goes...  
The text originally appeared on another beer related dist. list.  
(fyi, I'm the author of the included text)

--Mike

Hi,

I'm now sitting at home, in a comfy chair, with my keyboard and a glass of Sam Adam's Cranberry Lambic.

The bottle says:

"This Cranberry Beer is our version of a traditional Belgian Lambic. It is made with a top-fermenting yeast and wheat and barley malt. After brewing, this wheat beer is fermented again with fresh cranberries. Pure maple syrup is added to balance the tartness of the fruit. This beer combines the tart dry character of the cranberry with the refreshing taste of wheat beer. A special New England brew for the holidays. Cheers!  
James Koch"

A few comments on the label's claims:

- o wheat malt is not used in a lambic (but I'll concede this point since I've been known to use wheat malt too)
- o there is a lot more than 'top-fermenting yeast' that ferments a lambic. For starters, there is the bacteria *Pediococcus cerevisiae* and the yeast *Brettanomyces lambicus*.
- o maple syrup is definately not used in a traditional lambic.

First, I'll say the nice things:

- o the bottle should be strong enough to use for homebrew
- o I kind of like the color (of the bottle, but the beer's is ok too)
- o the label is on straight (the label's color is nice too)
- o the carbonation is ok
- o if I forget they're trying to market this as a lambic, its an ok, but otherwise unimpressive fruit beer. I prefer a more assertive fruit flavor in a slightly heavier beer.

OK, now the real review:

In no way, shape, or form is this even remotely related to a lambic. The beer tastes like a very light beer (or my tap water) with a slight hint of hops & cranberry/maple. I was rather suprised with the lack of body/character and of the total lack of any lactic sourness. Of course this may be because I'm use to drinking lambics that really are from Belgium. (as a point of reference, my tastes run toward Timmerman's)

I wouldn't bother buying a 12-pack just to get a bottle of this. (of course its too late for me...)

Its my belief that this is, at the very least, a complete misunderstanding of the lambic appellation, or at the worst, a just a shameless marketing scam to sell a few extra beers [again]. You decide.

I'd be intersted in hearing a response from James Koch should anyone have his ear. [hmm, this probably puts me on his black-list doesn't it?]

Of course all of the above is \_my\_ opinion and I'm sure someone will disagree...

Subject: Cutting a keg (Re: Boiler/Chiller Construction - Part 1)

First, I'd like to thank Tom for sharing his experiences in building SS brew gear.

I have a few comments to add to what was said re cutting up kegs...

>From the keyboard of Tom Dimock <RGG@CORNELLC.cit.cornell.edu>

> The next step is to cut out the top of the keg. The kegs are 16"  
> in diameter, so an 8" hole in the top works quite nicely. I know  
> of at least 5 ways to perform this step.

>  
> 1) Drill a couple of holes in the top and then saw between them  
>with a Sawz-All (a heavy duty version of a hand jig saw, for

I did this using a "normal" jig saw and bi-metal blades. Definately a noisy passtime, and I did use up 5 or 6 blades. I tried a SawzAll, but it seemed to shake the top of the keg around too much.

> 2) Use an abrasive blade in a circular saw. The blade is meant to  
>cut in a straight line, so getting it to cut in a circle is a  
>little tricky. You always want to wear eye protection when

I uses some of these blades to "split" a keg (they make great barbequeue grilles too :-). I couldn't picture trying to cut a round hole that way, by any means.

I believe that there are little air powered saws that use 4 inch or so abraasive wheels. Those might do the trick. Anyone?

> 4) Cut it out with an oxy-acetylene torch. Unfortunately, stainless  
>cuts very poorly with oxy-acetylene, which leaves you with a lot  
>of slag and crud to clean up with an angle grinder. A file might  
>do it, but slag tends to be harder, so you might just end up using  
>the keg to smooth out the file!

I tried to cut stainless with a torch, and pretty much made a mess of the metal. The cut was very rough, and, like Tom said, it seemed like I was using the stainless to smooth the file (I didn't have a grinder at the time).

Since then, someone recommended sticking a regular gas welding rod into the cut. I haven't tried it yet, but he said that it will make the cut much cleaner. I'll probably give it a shot when it's time to build a bigger lauter tun (Real Soon Now).

> Tom Dimock-- Flame your kettle, not the net!

From: Frank Tutzauer <COMFRANK@ubvmsb.cc.buffalo.edu>  
Subject: I've got my water analysis and I should...

Like all good brewers, I've finally gotten an analysis of my local water supply. Help me interpret it! For organizational purposes, here's what I'll do: First, I'll list the relevant figures from the analysis. Then, I'll tell you what \*I\* think they mean. I'll probably screw this up, so I want you to point out where I'm in error. (Dammit, Jim, I'm a doctor not a chemist.) Finally, I'll close with more specific questions about what I should do to fix up my brews. When answering, keep in mind that I am (currently) an extract and specialty grain brewer. Also, my guesses about what all this means come from my reading of Burch, Miller, and Charlie II. These are the only sources I own that go into any detail about water. Ok, first the numbers. All figures are in mg/L unless noted otherwise.

Alkalinity 88-100  
Hardness approx 120  
Sulfates 21  
Chlorides 15-25  
Mg approx 8  
Na approx 8  
Ca 30-40  
pH 7.7

Now, my reading of the situation:

First of all, my water does not seem to be chlorinated, but instead is filtered, although I have no idea what filtration system is being used. I think that hardness is really total hardness, and a figure of 120 means that my water is hard. I believe that the temporary hardness is given by the alkalinity, and so my permanent hardness would vary from 20 to 32. Am I correct in believing that the alkalinity is primarily (exclusively?) a measure of the carbonate and bicarbonate content of my water? There is certainly no separate listing for either of these ions. In terms of general brewing, recognizing that what is desirable varies among beer types, I believe that alkalinity is a bit high, calcium and sulfates are a bit low, and magnesium is ok, assuming I get enough from my extracts (which Miller says is usually the case).

Finally, my specific questions:

1. Should I mess with my alkalinity? When I first began brewing, I asked whether I should boil my water for sanitization purposes. Of the quite a few people who responded to me, about half boiled and about half didn't. I decided to refrain from boiling until I got an infection (which I never have).

But now, looking at the alkalinity, I think I might need to boil to get rid of some of it. Miller says that alkalinity in excess of 50 (unless "balanced" by Ca--whatever he means by "balanced") will extract harsh flavors from the hops, and Burch says that the lighter the beer, the harder the water should be (Pilsner Urquell types excepted). And come to think of it, my pale ales and steam beers have turned out quite well and my stouts and porters do have a bit of harshness in the background--not much, but there, particularly at colder serving temps. OTOH, Burch also says that "some" temporary hardness is good for stouts and porters, although he does not define "some". Finally, Miller says that if you boil, after leaving a residual of about 35, one can get rid of the carb and bicarb at a cost of 3 parts Ca to 5 parts carb/bicarb. Doing the arithmetic on my water means I will "use up" ALL of my Ca. So, my question: When should I boil to get rid of the alkalinity, and how do I deal with the calcium loss (see stuff on gypsum, below)?

2. Should I mess with my calcium? Miller says that an optimum Ca range "for all brewing water" is 50-100. I, of course, am a bit lower. I could add gypsum, but in doing so I also increase my sulfates. Miller says sulfates are chemically irrelevant, but both Miller and Charlie say they give a dry, crisp palatte, unless they are "too" high, in which case they give a harsh salty taste. Again, what is "too" high? My sulfates right now are quite low, but by adding gypsum to a 5-gal batch, my calcium and sulfates change as follows:

| gypsum added | Final Ca level | Final SO4 level |
|--------------|----------------|-----------------|
| 0.5 t        | 60-70          | 91              |
| 1.0 t        | 90-100         | 161             |
| 1.5 t        | 120-130        | 231             |
| 2.0 t        | 150-160        | 301             |

I used Miller's numbers for changes. Charlie's are 5 mg/L lower for both Ca and SO4. Many recipes I have seen routinely call for adding 1-2 t gypsum. I have never done so because I figured "What does the recipe maker know about my water?" Last week, though, I had a recipe for an English special bitter that called for 2 t gypsum. I was in a "what, me worry?" mode and decided to add it all. Looking at the numbers above, I may have made a mistake, but it's too late now and I'm going to drink the beer anyway :-). So: When should I change my Ca by adding gypsum, and how much should I add? Should I worry about the increase in sulfates that would result?

Well, there you have it. Thanks for any help. There's a pop song about Boston that's locally corrupted by substituting Buffalo and the Niagara River for Boston and the Charles. Anyway, the song has the line "Well, I love that dirty water--ah, Buffalo you're my home." And the last few days, going over this water report, I just can't seem to get the song out of my mind....

Subject: Yeast musings...

> I don't believe it's exactly fair to call this yeast the same strain as you started with. Why? Well, consider that by using yeast from the bottle, you would tend to pick up the more attenuative cells that are left in suspension and still active. As one repeats this process over several generations of reculture, one is artificialy selecting a more attenuative population, no?

Yes, you have set up an artificial (and natural) selection routine that could select for an infinite numbers of characters, not just attenuation. Some could be good, some could be bad.

To me, the more obvious process would be to take your expensive yeast culture and instead of using it to make beer the first time around, use it to start multiple batches of cultures. You could build it up to sufficient volume to start as many separate cultures as you could use in the time they would go bad in the frige. I am not sure what happens in the frige but if you maintain a sterile environment, you can at least count on the same purity of strain.

From: larryba@microsoft.com  
Subject: Galvanized Mesh

>SS or copper/brass would be a much better choice for long term health.

No doubt but let's not lose sight of the fact that a vast majority of our drinking water moves through galvanized iron pipes. I am the last one to suggest that common usage makes things OK nor am I ignorant of the fact that boiling beer may react differently than cold water but just wanted to make the point.

BTW, brass has far more zink in it than galvanized iron.

Re: Removing Lables

I have found that some of the stubborn lables do not use water soluble glue and will never come off using water and soap. They do however, slide right off with paint thinner such as turpentine. This is expecially true of plastic pop bottles.

HOME BREW HORROR STORY

I brought three liters of homebrew to the family Thanksgiving dinner and was forced to rationalize and excuse one undrinkable bottle. It was, unfortunately, my finest beer.

Early in the week, I chilled down the beer till ice was visible and decanted this into a chilled bottle. As it wasn't quite full and just for good luck, I topped it off with a bit from a currently fermenting batch. I squeezed the (plastic) bottle to expell all the air and let it sit till it got hard and fat. I then refrigerated it till the big show.

It was utterly disgusting. I can't begin to describe the flavors but it was probably all of them.

Unfortunately, I did not sample the bottle before the decanting operation but I have been drinking the same batch for several weeks and it's the best beer I have ever made.

The other samples, also in plastic, were a dark and the clovy stuff, I have described before. I called it Holiday Spice Beer and they loved it.

I was somewhat stunned because the day after I did this, someone posted an article saying that this is SOP for competition entries. This confirmed what I had intuited and thought I invented but something definitely went wrong this time.

I don't have enough facts to prove what the culprit was but I just wanted to point that, even the "Worlds Greatest Brewer" has bad days.

From: Jay Hersh <hersh@expo.lcs.mit.edu>  
Subject: Diacetyl

I had also tasted a few "old" beers that were poorly handled in shipping (or so I believe) and found them to have diacetyl flavors. Some fellow judges (and friends) who were at this particular tasting said they didn't think the diacetyl could be a result of poor handling.

I recently had a vacation in Europe. I brought back a few bottles of Budvar Budweiser, and found that while bottles I had drunk in Europe were fine, some of the ones I had after returning had developed a strong diacetyl component. This seems to confirm my suspicions that handling has some effect.

I thought I saw something from George Fix recently (or maybe it was someone else) on a correlation between poor handling and diacetyl. Was this you George, and if so what were the specifics?? If not does anyone else know about any correlation between diacetyl and handling??

Thanks,

JaH

Date: 29 Nov 91 15:07:29 EST  
From: Jeff Frane <70670.2067@compuserve.com>  
Subject: DMS and Other Stuff

On DMS: I ran across an old American Brewer article by Gary Bauer called "Dat Ol' Debbil DMS: Dimethyl Sulphide". According to Gary, the problem lies with something called S-Methylmethionine (SMM) formed during the germination and kilning stages of malting. SMM "decomposes on heating to form DMS during kilning, wort boiling and hot wort storage." He also says "Two row barley which has a normally lower nitrogen content than six row barley, has been show to produce significantly less SMM during the malting process. European malt has less SMM and DMS than North American and Canadian malt."

According to Bauer: "Beers with hig adjunct ratios or low gravities allow the DMS taste or off-taste to be more detectable, while German beers, all-malt beers, flavorful beers, especially dark beers, make the taste of DMS less discernable at higher levels."

Most significant to Larry and the rest of us: "Kettle boiling hyrdolyzes SMM to DMS which is removed during evaporation. The half life or time need to remove half of the DMS is 40 minutes, so that three-fourths is removed in 90 minutes. Narssis recommends a 100 minute boil to reduce the level of SMM and DMS to acceptable levels in most beers...."

"The following steps should ensure low levels of DMS in the finished beer.

- Boil the entire wort 90 minutes or longer
- Ensure that the boil is vigorous--rolling
- Allow at least 8% evaporation
- Minimize the hot wort standing time
- Rapidly cool the wort"

To Jack Schmidling: What Baderbrau calls "webbing" sounds like what's more commonly referred to as Belgian lace. It's formed from the proteins in the beer and it's not terribly surprising that you didn't see much of it in your extract beers, especially if you weren't using many grain additions. I've found the best way to get a startling amount of lace in an extract beer is to add 2 ounces of flaked barley.

To Todd Enders: Brewers have traditionally used the same yeast over and over for many generations, although nowadays most plate the yeast periodically to check

and see if it has mutated or otherwise strayed from the straight and narrow. I suspect that your theory isn't "wrong" but that the yeast strains are inherently more stable than you give them credit. On the other hand, you might begin to select for a higher degree of flocculation (rather than degrees of attenuation). Just blue skying here.

To Kinney Baughman: Why is the capillary action in the bucket to bucket lauter tun any more a problem there than any other system? The solution is generally to use knives for gradually cut down through the grain bed (in a brewery vessel the knives slowly turn but a similar effect can be achieved by using a kitchen knife at different points). My experience with a grain bag was not salutary, as the bag failed to hold the weight of the wet grain and kept falling into the bucket.

Chuck Coronella: Your neighborhood hardware store should have an adapter that screws into your kitchen faucet like your aerator does currently. This will then snap on a unit that will accept normal garden hose/laundry hose fittings. I used one of these for a long time and only ran into a hassle when my new portable dishwasher turned out to need a different fitting.

Date: 29 Nov 91 14:02:26 MST (Fri)  
From: rcd@raven.eklektix.com (Dick Dunn)  
Subject: more about Prickly Pear (Zymurgy articles)

The main response I got to my earlier inquiry about prickly pear fruit for mead was a handful of inquiries about making it. So...I finally had time to dig up the original Zymurgy article about it. It's Volume 10, No. 2 (Summer 1987) - the "Lena" issue, p. 44. This gives a rapturous account of the qualities of one particular prize-winning PP mead, and a modest amount of information about making it.

Particularly, this article describes boiling the fruit for two hours-- which is one reasonable way to extract the juice. The fruits are a bit stubborn this way; a simple pressing doesn't seem to get much, and they're surprisingly firm. A note about pectin--common wisdom hath it (correctly) that one should not boil most fruits in preparing them for fermentation, since it will bring out and "set" the pectin, leading to a nuisance haze. (Pectinase will mostly solve this...but I digress...) This is not a problem with the PP fruit. While the extracted juice from boiling the fruit looks a little cloudy, it appears to be just a suspension of gruk which settles out early in fermentation.

In fact, a letter in the 14(3) Zymurgy (Fall 1991) Prof. Surfeit column says you \*want\* to boil the fruit and extract the juice, rather than just adding the fruit to the fermenter...dealing with the unboiled pulp is described with terms like "seal snot", "blob from a horror film", "fermentation from hell". The description suggests that something in the fruit pulp enables it to trap bubbles and keep them from bursting. I've no first-hand experience with this, but I'll take it as a valid caution; Charlie knows his stuff.

The original (1987) article says to use 75-100 fruits. That will seem like a lot. (It IS a lot!) You can make it with considerably less...but do keep in mind that the taste is subtle.

Date: Fri, 29 Nov 1991 12:39:06 -0700  
From: hpfcmr.fc.hp.com!hplabs!bnr-vpa!bnr-rsc!crick (Bill Crick)  
Subject: Bitter at bottle, Evaporation, bottles,cases

In response to a few recent inquiries:

Adding Bitterness at bottling:

About trying to add bitterness at bottling by boiling hops in water. I don't think this will work. The bittering resins have limited solubility in water. In wort they bond to something in the wort. I think it is some of the proteins. You may try hop extracts, but I believe these add more aroma, flavour, not bitterness. I've never tried them.

All grain evaporation during boil:

Someone asked about having to boil off a quart of water on all grain beers. It is more like a gallon! Reducing water is difficult. If you are doing an infusion mash, you can reduce the water a bit by adding heat, or adding hotter infusions, but if you go too far, the mash is too thick, and difficult to work with. If you reduce the sparge water much, you reduce your extract, and throw good fermentables out with the spent grain. Its hard to get less than 6 gallons of water for any brew with a reasonable gravity. This means boiling off at least one gallon! Yes that is a lot of humidity! It gets pretty steamy when we boil an all grain beer.

Bottles:

For those of you who like (and know what they are), you can still get stubbies by buying Jamacian "Red Stripe" beer at the booze shop. They only come in sixpacks;-)  
Stubbies are the short fat "ex-standard Canadian beer bottles". At one time, all Canadian beer from all breweries came in the same standard, compact bottle. Then some idiot decided that the way to gain market share was to make a unique bottle, and go on a huge ad campaign explaining that the beer was better because the bottle was a different shape, and that the size of your penis was directly related to the height of your beer bottle, and that you'd never get laid drinking from a short bottle. That's progress! Canadians don't drink beer, they drink Advertising! Not to be outdone, they all abandoned the standard! I like stubbies because they store more densely. I have a place where I can stack 7 cases of stubbies where only 3.75 cases of those @#%&\$^ing long neck abortions will fit!  
The .75 of a case always goes flat after i smash the top part of the necks off of the bottles;-)

Cases: My main problem with my stubbies is that the cardboard cases are falling apart, and the new cases are too tall, and too slim for them. Anyone know where I can get new cases? Cardboard would do, but I'd really like to get some plastic cases.

Cara-Pale malt: What is it? Is it the same as Cara-Pils?

Cheers: Bill Crick Brewius, Ergo Santa!

From: dworkin@habitrail.Solbourne.COM (Dieter Muller)  
Subject: wooden casks

I'm fond of mead, which implies being a brewer of it, in this part of the world. I'm also a member of the SCA. As a result, I'd like to take some of my results to various SCA events. However, bottles aren't real medieval-looking, and a stainless steel soda keg (assuming I had one) is even less so.

So, I've been looking for small wooden casks to put my mead into. I've even (finally!) found a source for them. However, it turns out I have to make a decision: do I want paraffin-lined, charred, or unlined?

I'm pretty sure I don't want the charred casks, since that'll add all sorts of odd flavours. The impression from the catalog was that the unlined might not be liquid-proof. However, I believe paraffin is fat/oil-based. Alcohol, if I remember my organic chemistry from many moons ago correctly, is something of a solvent for fat/oil-based substances. So, if I get paraffin-lined casks, is the lining going to dissolve into the mead? That wouldn't be a particularly positive state of affairs.

Of course, all this assumes I can figure out how to make a decent-tasting still mead....

From: dworkin@habitrail.Solbourne.COM (Dieter Muller)  
Subject: avoiding light-struck beer

Now, as I understand it, the problem with light-struck beer is that light (flourescent, incandescent, or solar) is allowed access to the brew through less-than-opaque bottles. This has the potential of turning a perfectly good brew into something completely non-potable. Apparently this has even happened at competitions, a truly irritating event for the poor brewer involved, if it wasn't his/her/its mishandling that caused the exposure.

So, my question is, why not make the bottles opaque? A good layer of paint, or glueing on foil or heavy paper should do the trick. I'm afraid I don't see the problem from the homebrewer's point of view. I fully understand that this doesn't address the problem with respect to commercial brewers, but then, that's not our problem (by definition of the domain of discourse -- this being the HOMEBREW Digest).

I'm obviously missing something here....

From: Bob\_Konigsberg@3mail.3com.com  
Subject: Cost of Kegs

To respond to all, I called the local Anheuser-Busch distributor, and the Anchor Brewing Company, and was told that 1) The actual cost of the kegs is about \$100, 2) they legally remain (and should be so stamped) as being the property of the brewery, and 3) In some cases of flagrant violation, the brewery has taken legal action against the possessors of these kegs. They also said that homebrewers are not the only people who take and use them.

I also called the local Anheuser-Busch office and brewery to ask about purchase of these kegs and was told that they do sell the old style used kegs, the Golden Gate style, but they have only a few, since microbreweries buy them up. These are the rounded side ones. For further information contact Virgil Cox (Anheuser-Busch St. Louis) at (314) 577-2000.

As far as manufacturers of kegs go,

Hoover Universal usually only makes them to order 40K to 50K per batch, and occasionally has extras, but nothing you can count on. Their phone number is (402) 223-2324. They will entertain orders for about 100 as a minimum, and then only after a large production run. Call Mike Ryan at Hoover.

Spartanburg Steel Products in South Carolina will sell a generic keg to individuals. Prices are \$125 for a 15 gallon 1/2 keg in stainless steel, \$100 for a 7.5 gallon quarter keg or \$95 for a 50 liter (about 13+ gallons) poly keg. Call (803) 585-5211 and ask for Linda.

There is also an outfit called Tosca in Green Bay Wisconsin 701 Bay Beach Rd. Phone # (414) 465-8534 which will re-condition used kegs.

Cheers,

BobK

Subject: free advice for Jack

Here are some comments on Jack's EASYMASH process, for which I expect from him no compensation whatsoever.

No mention is made of the pH of the mash. Where Jack lives, the water chemistry must be appropriate to the type of brewing Jack does. Some, however, might live in places with different water chemistry, and these individuals might be disappointed that they don't get results as good as Jack. The materials for dealing with water chemistry are cheap (pH papers, some gypsum, some calcium carbonate) and the effort is minor.

Though it is true that undermodified lager malt is better handled by decoction, much modern American malt and certainly British ale-style malt is quite well modified. The single-step infusion spurned by Jack is in fact used by most British brewers and many commercial brewers of lagers in America and on the continent. If, however, Jack uses very hot sparge water, he probably is better served by decoction.

Jack contradicts himself when he states first that the object of the sparge is the removal of as much sugar as possible, and then a few sentences later instructing the budding masher to stop sparging when the gravity falls to about 10. Perhaps mention might be made of the reasons for stopping at that point, lest an over-eager masher might continue to sparge and leach unwanted tannins out of the grain.

From: Chuck Coronella <CORONELLRJDS@CHE.UTAH.EDU>  
Subject: Cyser Recipe???

Greetings!! I hope everyone (in the US, that is) had a festive Thanksgiving with plenty of bird and brew.

I want to make a cyser, that is, a mead with with some apple cider. Although I've never made any kind of mead before, I've looked through all my books and through the Cat's Meow to learn about the secrets of mead making. (Actually, I've been saving posts regarding meads for quite a while, now. ;-) Unfortunately, I found only 1 recipe for cyser. Maybe I should break down and get a book on mead. So I want to ask a few questions of anyone with experience making a cyser. (Get ready for a long series of questions.)

1. Is apple juice as good as apple cider for a cyser? It seems like apple cider is kind of hard to find around here. Could I use fresh apples? How, what kind, how much?
2. Is a sweet mead, with more than 3 # honey per gallon, most appropriate? If not, what is the <optimal> amount of honey per gallon?
3. What spices/herbs blend well in a cyser? Cinnamon, ginger, tea, hops, orange peel?
4. Does an ale yeast work well?
5. Are acid blend and yeast nutrient necessary ingredients?

Obviously, I'm asking oodles of questions, but I want my first dabble into the ancient art of mead making to be a success. I feel inspired by the two guys listed in the most recent Zymurgy, who won the "Mead Maker of the year" award, (or some such title,) based on their first attempt at a mead!!!

Thanks for all your help,

Chuck

From: dworkin@habitrail.Solbourne.COM (Dieter Muller)  
Subject: mead yeast - continued

The general gist of recent e-mail, as typified by Mike Zentner (zentner@ecn.purdue.edu):  
: I guess I'd have to ask, what is it that you found undrinkable about  
: your meads, and what are you using as a guide for "brewing" them? I  
: may be better able to tell what might be going wrong for you.

Guide? What guide? Brewing's like cooking -- you look at what you have available, eliminate the obvious incompatibilities (like, say, vinegar and baking soda), and see what you can produce with what's left. ;-)

The basic recipe I used was:

3 pounds (aka 1 quart) of unpasteurized honey  
2 1/2 gallons charcoal-filtered tap water  
1 packet of champagne yeast (Red Star, probably, it's been several months)

Since the honey has been kept in the refrigerator, I used the microwave to return it to the liquid state. The water was somewhat above room temperature, mainly to assist in dissolving the honey. No boiling was done (re: discussions several months about the anti-bacterial qualities of honey, recently refuted).

The yeast was dissolved into some warm water filtered as above.

Once I got everything dissolved, I siphoned from the large kettle/pot into my fermenter (one of those collapsible plastic jerry-can ones), tossed in the yeast, and stuck the airlock on.

Months pass (about four, actually).

The mead has tasted reasonably OK during fermentation, though not quite what I was aiming at. The final product has a definite harshness. Unfortunately, it's kind of hard to describe. Following a suggestion from Dick Dunn, I tried adding a bit of sugar to a glass, and it reduced the harshness a fair amount. However, after doing that I have a slightly harsh, otherwise nearly flavourless drink. This is not quite what I'd had in mind....

To see if the problem is repeatable, I've started another batch. It's been going for about two months now. The only difference in the process was adding some spices -- nutmeg, clove, and (I think) ginger. The samples are tasting very similarly to what the first batch was like, modulo the spices (which are certainly contributing towards getting a flavour/odor closer to what I was expecting).

After reflection on recent notes to the list and private e-mail, some courses of action I'm going to try are (in no particular order):

- use glass fermenters
- use a non-plastic storage after fermentation (hence my questions about wooden casks)
- use a less-attenuative yeast

I suspect that changing yeast will have a lot to do with getting closer to my goal of a sweet still mead. Any suggestions on other

things to try, or a better order of trying the things above?

Thanks.

Dworkin

From: Mike Sharp <msharp@cs.ulowell.edu>  
Subject: Mead

Dieter Muller (dworking@habitrail.Solbourne.com) writes:  
> I've been looking for small wooden casks to put my mead into.  
> I've even (finally!) found a source for them. However, it turns out I  
> have to make a decision: do I want paraffin-lined, charred, or  
> unlined?

You don't want a charred one for mead. An unlined cask will take you at least 3-4 batches to 'break in'. That is, your mead will have an extreme oak flavor for the first few batches. A lined cask would most likely be the best way to go, although then you're just using it for effect. You might as well use a paraffin-lined trash can.

I use a 15gal unlined white American oak barrel for making beer (lambic!). They do seal (either that or my downstairs neighbor is very tollerant) but most places wont guarantee them to do so. You should contact me in about two weeks and we can discuss this process in detail. Anyway, to me, using anything but an unlined cask is pointless. Its a lot of money to spend for just an image. The paraffin linning negates a number of the interesting qualities of a good cask (it breathes just a little, it will lend character and color to its contents, etc).

The Dieter describes his mead as being undrinkable:  
> Months pass (about four, actually).  
Here is the problem. Most long mead tastes like gassoline for at least the first six months, sometimes the first year or two. Put your bottles away and be patient.

> After reflection on recent notes to the list and private e-mail, some  
> courses of action I'm going to try are (in no particular order):  
> - use glass fermenters  
> - use a non-plastic storage after fermentation (hence my  
> questions about wooden casks)  
> - use a less-attenuative yeast

None are bad suggestions. However, none of these will get around the problem of hainvg to age a mead. Since most people have no idea that it takes a *\*long\** time to make a good mead most have the problem you describe. (here I'm assuming you're making a long mead, BTW. It is possible to make a 'quick' mead, but this is much more like making soda -- a quick ferment, bottle it at ~1.040-1.050 and keep it *\*cold\** so it doesn't explode. Don't try this at home kids -- its *\*dangerous\**.)

Finally, just to throw a wrench into your works, I believe long meads were less common in the majority of the 'period'. Why? A history by Lt. Col. Robet Gayre pulished as Brewing Mead: Wassail! In Mazers Of Mead (available from the AHA) is quite well researched and it suggests that mead was consumed on what would be today the sweet side. Its me belief that the majority was more likely a quick mead due to the 1) popularity

2) cost of cellaring 3) general impatience (would 1,000,000 bud drinkers be willing to wait 1-2yrs for their product?). There is some mention in Gayre about mead being consumed straight from the fermenters, etc. I don't have any had primary source for any of this, but should you wish to track some down this book has a rather large bibliography.

How do I know this? My first 30 batches were meads. Then I got hooked on lambics... Now Dawn (S.O.) makes the mead. FWIW, someone will be seeing an entry from me in the AHA nationals. The mead is about 2 years old now & was only really drinkable after about a year.

From: des@swindon.swindon.ingr.com (Desmond Mottram)  
Subject: Easymash, Decoction, British brewing, Yeast

Re Easymash: I also use one vessel for both mash and boil. It's plastic with an immersion heater controlled by a simmerstat. These are obtainable in the UK through homebrew retailers. There are several drawbacks which incline me to getting a 35l Burco boiler sometime.

- It's slow to get up to boil, up to three hours for 5 galls. Once boiling it rolls well while the simmerstat is on, but goes off the boil about every 20 secs.
- It's not large enough to prepare the volume of water required for a 5 gall brew beforehand (I boil first to precipitate bicarbonate).
- You can't use it to heat sparge water, as it's tied up with mashing. You can't start boiling with it until you have finished sparging and washed it out.

Re Decoction : Mike McNally writes:  
> Though it is true that undermodified lager malt is better handled by  
> decoction, much modern American malt and certainly British ale-style  
> malt is quite well modified. The single-step infusion spurned by Jack  
> is in fact used by most British brewers and many commercial brewers of  
> lagers in America and on the continent. If, however, Jack uses very  
> hot sparge water, he probably is better served by decoction.

Yes, most British beer is brewed without decoction. I've been told that decoction is required to digest protein before saccharification begins. This is more likely to be necessary with less-modified, high-nitrogen malt, but many modern malts are high-nitrogen.

Does decoction affect taste at all? I got the impression it was done to prevent protein haze, not to improve flavour. An alternative to boiling a portion of the mash, following the decoction rest, is to raise the temperature gently of the whole mash. This means none of the diastase enzymes gets destroyed and enables a faster, more complete mash.

Re Yeast: I've been impressed by the range of yeasts mentioned on HBD. In the UK many yeasts are available for wine-making but I've found only three for beer-making: real-ale, cheap and lager. How much difference does the yeast strain make to the flavour of the beer? I'd suspect a lot, but haven't got the variety to experiment with.

From: Tom Dimock <RGG@CORNELL.CIT.CORNELL.EDU>  
Subject: Kettle building - Part 2

## Building a Modern Elektrikal Brew Kettle - Part 2

I chose to heat my kettle electrically so that I would be able to brew indoors in my shop. This lets me stay out of the Ithaca weather (which is usually bad) and out of the kitchen, which makes my wife happy. It does require a pretty heavy duty electric supply - mine is a 50 amp 240 volt outlet that normally powers my monster welder. Because I have this heavy duty power source, I configured the kettle with a high setting that will boil 6 gallons of water in less than 20 minutes, and a low setting which is used for the actual boil and which won't scorch my wort.

In order to prepare the kettle for electric heat, we need to mount two 1" pipe fittings into the side of the keg. These can be standard pipe couplings from the hardware store, or if you have a friend who owns a large machine shop (as I do - thanks, Charlie!) you can have custom fittings machined from 304 stainless steel. You need to cut two holes for these fittings fairly low on the side of the keg (about 1" above the seam where the bottom support ring is welded on) so that the elements will be near the bottom of your wort. The holes should be about 6" apart, and slightly elliptical so that the fittings are parallel. I cut these holes using the "lots of little holes and then filing to fit" technique. This was surprisingly easy to do. You can also let the welder cut the holes with his fusion torch, if you're sure he understands what you want.

While we're cutting holes, we also need one dead center in the bottom of the keg to make our drain. This one can be a 3/4" fitting, although if you have a pile of 1" SS fittings (gloat, gloat) you can use one of those.

Now comes the fun part, attaching the fittings to the keg. They can be silver-soldered in (normal solder won't bond to the keg), or they can be welded. Silver solder and the special flux it requires are quite expensive - if you're going to buy them just for this, you might come out cheaper to have them welded in professionally. Twenty-five dollars seems to be the canonical number for the job. If you have someone else weld them in, make sure they are not using welding rods containing Cadmium, as this can make your beer poisonous. TIG welding is the best, and is how mine was done. The two heater fittings should be welded in with their axis parallel to each other and to the floor. The bottom fitting should be welded so that it does not extend into the inside of the keg, so that you can drain the keg completely.

Now you'll notice that the keg won't sit flat on the floor anymore, because of the drain fitting. Don't worry, we're going to give the keg legs. Ah, yes, the legs. I wanted the keg to be up high enough that I could drain from the bottom of the keg directly into a counter-flow chiller and then straight into the carboy. For a five gallon carboy and the chiller I had in mind, this meant that the top of the keg needed to be five feet off the floor. The legs are made out of three 2x4's five feet long (my 2x4's are cherry, but that's another story :-)). The legs get cut as shown in the crude diagram, so that the leg supports the keg and touches it at the top and bottom rings, but is cut back away from the sides of the actual keg. Holes are drilled through the legs and the top and bottom rings of the keg to

take 5/16" carriage bolts. These rings make the keg material look like butter - I mean they are TOUGH metal. A cobalt drill bit is highly recommended. The three legs are spaced evenly around the keg, with one being centered between the two heater fixtures (this will be the back of the finished boiler).

notches for chiller

The chiller will be a six-turn coil of 1/2" copper tubing encased in 1" i.d. plastic tubing, and for that we need six notches into the inside of each leg. The notches should be 1 1/4" wide and deep, and 1/2" apart. Don't cut them yet - in a future installment I'll have some more detail on them.

Next installment - Heating elements and power.

P.S. Since writing this installment, I have wondered about silver solder (see separate post), so that becomes an un-recommendation until I find out a little more.

Date: Monday, 2 December 1991 10:14am ET  
From: joshua.grosse@amail.amdahl.com  
Subject: Going all-grain.

I went all-grain for the first time yesterday. I used a blend of Miller and Papazian methods, made some mistakes, infuriated my wife by consuming the kitchen for a good six hours, and had a mixture of stress and relaxation during the process. I'm looking for advice from experienced all-grain brewers on both technique and, in a couple of cases, product availability.

#### EQUIPMENT

I went with a Thorne Electrim brand "bin" for mashing/boiling. This is a 220 volt thermostatically controlled 7 gallon plastic bucket; a Bruheat clone. I made a Zapap lauter tun, using 6.5 gallon buckets, with a slightly leaky tap at the bottom from a rather rough cut hole. I also purchased a Burch immersion chiller.

#### GRAIN

I was unable to obtain or use a grain-mill. I used a Braun coffee grinder, as there seemed nothing else in the house that would work. I've got a blender, and a Cuisinart with lots of attachments, but I thought the coffee grinder would be the least abominable. I ground 8 lbs of German 2-row (lager/vienna) a 1/4 cup at a time in the thing. Going in very short bursts, I thought I'd be able to crack the grains without making too much flour.

For those of you without grain mills; what do YOU use? What kind of extract rates do you get? I got a lot less than I'd hoped. It seemed I made a mixture of flour and uncracked whole grains. For those with mills; how much do they cost?

#### MASH

I used two left-over PH tests from my old salt-water fish tank to adjust PH during the mash. They were a little TOO wide range (from 5 to 9) but I could tell that I needed to add some gypsum to the mash, and that 1 tsp got me between 5 and 6, anyway.

I couldn't obtain PH papers. Where do you find them? I know the brand name that Miller recommends, but my local homebrew supply and one pharmacy I checked with didn't carry 'em.

I used 2 quarts of water per pound, so 4 gallons of water with the 8 pound

mash. Miller, and other brewers, recommend thin mashes with Bruheat (or my clone) systems. This worked fine, no scorching or burning.

I used the old Iodine test that Miller doesn't like. As Papazian predicts, the mash was done in less than 40 minutes. Miller likes to mash for an hour and a half without testing. I preferred to test.

#### SPARGE

A 4 gallon mash didn't all fit in the lauter-tun at the same time! I ended up taking a lot of run-off out right away in order to stop leakage from between the two buckets! Miller recommended a 5-minute rest for settling; I couldn't. This made the sparging get a little more complicated. I'd forgotten about that gallon of acidified foundation (underlet) water at the bottom of the lauter tun.

I used a total of 3.5 gallons of acidified sparge water; one for the foundation, the rest for rinsing after an hour of recirculating. My wort never went clear; I never saw particulate matter, instead it seemed to remain the same level of cloudiness throughout the recirculation. I tried it both Papazian's way, with the liquid above the grain level, and Miller's, with the liquid just below the grain level -- I believe my coffee grinder may have been at fault.

#### BOIL

The electric boiler never got a really good high ruckus boil. All to the good, because I didn't have to watch for a boil over, yet it was "rolling" gently all through the 90 minute boil. I kept the lid 3/4 on, which seemed to help the rolling, but that obstructed my boiloff. I started with about 6.5 gallons and ended up at about 6, not the 5 I was hoping for.

#### CHILL

The immersion chiller only has a small leak on the input side connections, which I'll fix with teflon tape. It chilled my 6 gallons from boiling to cold in 20 minutes, with some gentle stirring every 5 minutes.

#### EXTRACT

I kept 5 gallons of the 6 gallons for fermenting. Guess what? Starting Gravity was 1.030. Had I had a better method for grinding, and a 5 gallon finish, I would have had 1.047. Papazian says, when you get an extract that's different than what you expect, relax and ferment it. That's what I'm doing.

Subject: Club Coors Party Line

Chris Shenton <chris@endgame.gsfc.nasa.gov> says:  
] Saw this number on a co-worker's whiteboard:  
] I just called up 1-800-627-5888: it's a Coors Club survey -- answer two  
questions by hitting buttons on your touch-tone phone, then speak your  
name  
and address into a recording. Then, supposedly, they send you a coupon  
good  
for a case or something of free beer. Guess which one :-)

Very supposedly. I just called and the recording iterates and reiterates  
that  
they wish they could give out free beer, but can't, that it's illegal,  
etc.

The questions are: What is your age? How many beers a week do you  
drink?  
What brand of beer do you buy? (The possible answers are: Coors, Coors  
Light,  
Budweiser, Miller, and Other). They then ask for your name and address.

ObBrew: When I moved from Boston to Ann Arbor, I discovered that my  
plastic  
bottling bucket had been used to carry tools and cans of extract. I went  
at  
it with a sponge and B-Brite, and again with a carboy brush and more B-  
Brite.  
It's clean and white to the eye, but I can feel scratches, although  
nothing  
deep. Should I worry, or just have a homebrew? (note that I may have  
loaded  
that bucket myself in a fit of stupid haste.)

From: zentner@ecn.purdue.edu (Mike Zentner)  
Subject: New American Wheat?

While visiting relatives over the holiday, I chanced upon a case of the Xmas Sam Adams combination (although it sounds like most people are not happy with it, I haven't tried any yet).

More importantly, though, I happened across something called "Heartland Weiss" from Chicago Brewing Company. I liked it better than the Sam Adams wheat because it did not have as strong of a "wheat beer" flavour. The correct flavour was evident, but so were the rest of the body and flavour elements of beers like Paulaner (although certainly not as good as Paulaner). The head did not linger as long (or as firmly) as the German counterparts, but I'd say this beer is worth a try, anyway. Anyone else tried this?

Or am I completely wrong and this is a really crappy beer? :-)

Now, sorry to revisit this, but here goes, no flames intended:

Jack Schmidling writes:

> Re: COUNTERFLOW vs TUBE-THROUGH-BUCKET-OF-ICE-WATER  
>  
> >In the bucket of ice- wort through tubing method, the initial wort is REAL  
> cold, and after the ice melts and you are using a bucket of chilled water,  
> the wort is warmer.  
>  
> I am not sure why the creative process must stop with one bag of ice.

Jack, the process doesn't stop, but if you'd have read my post, you'd have seen that I want something that will chill wort to exactly pitching temperature so I can get some sleep and not rush the following morning. If I kept adding ice, I'd get something say near 40 F, which I would want to let warm up before pitching. If you want to do this, fine, there are no problems with it. It just doesn't fit into my schedule. I repeat, this is not a flame, just a clarification to anyone who was confused by my original post.

Subject: Getting Bottles

When I needed enough bottles for my first batch of beer, I took all the old beer bottles lying around that were not good (green, screw-top, etc.) to the local drinks store (at the time, Wine & Cheese Cask in Somerville -- Gosh, I miss that place), and traded one-for-one for bottles that fit the bill. I've since bought bottles for the price of deposit from beer stores, and discovered a wonderful thing -- some places will thank you profusely for taking their bottles. Apparently, beer stores which are somewhat indiscriminate about the bottles they refund deposits on will accumulate a large collection of bottles they can't get rid of. If it doesn't bother you and doesn't bother the shop clerk, ask to root around his collection of deposit returns. In my last bottle run, I collected a half case of brown pint bottles for German beers that haven't been sold here for three years. Now they're storing a batch of #4 FrankHaven Red Bitters.

Subject: Microbrews by mail

Hi all. Been lurking here via my second hand copies (thanks John DeCarlo!) for months. Learned a lot. Thanks.

A friend of mine has started a little business sending microbrewed beers monthly to members of "Beer Across America". They ship via UPS in Illinois, and through some private company to Indiana, Wisconsin, Michigan, Kentucky, Iowa, and Missouri. Right now that's the only states he can ship to, but that may change. Details are two six packs (different breweries) per month, cost averages \$14 plus shipping/handling. First shipment will be in January.

For all the details call (800)-854-2337. I'm personally very psyched about this, because I'll be able to buy cases of beer not distributed in Illinois from him! I have no commercial connection here, just thought this crowd would be interested in this.

Subject: Multiple Regulators

Subject: Multiple Regulators Time:10:38 AM Date:12/2/91

>2) I've seen those nifty manifolds in the Foxx catalog and they  
>seem pretty cheap way to have multiple beers on tap if one thing  
>is true: Do you need a regulator per/keg or would having a single  
>regulator between the manifold and the CO2 sufficient (i.e, do you  
>find you have to futzz with the pressures on a per keg basis?)

Depende on the beer! I am set up to dispense 3 kegs (via one of those  
manifolds from Foxx). If they are all homebrew I can get by with one  
pressure  
across all three (normally about 7-10 lbs). However when I put a keg of  
Anchor's Liberty on line, I had lots of foaming problems which I was  
unable to  
correct until I spoke with Mark Carpenter at the brewery. Seems Anchor  
dispenses Liberty at 18-20 lbs! It is a pretty lively beer. Also they  
advise  
a minimum of 10'-12' of 3/16" id hose between the keg and the faucet (my  
brews  
have about 4' of 1/4" hose) or some sort of in-line flow control device.  
So I  
bought a secondary or in-line regulator (range 0-30 lbs) and 15' of 3/  
16"  
beverage hose. The gase comes out of the tank at 20 lbs into the  
manifold  
where it is split between the Liberty and the in-line reg. The in-line  
is set  
for my beers (of which I can dispense 2). Now I have no problem with the  
Liberty. The cost involved the in-line reg. and a 2-line splitter which  
came  
to about \$40.

From: bgros@sensitivity.berkeley.edu (Bryan Gros)  
Subject: Reusing yeast

Glad to see the distinct lack of bitching in the last couple of HBDs.

Last week I made an extract brown ale (short on time these days) and added it to the carboy from which I had just removed a porter. I was a little worried that the stuff on the bottom, presumably containing some of the Wyeast English Brewery Ale yeast, would be damaged by the ~90F wort, but it was almost 2AM, so I siphoned it in anyway.

I was amazed to see bubbles in 10 minutes and a full fermentation in 30 minutes. I had never seen it take off so fast. Unfortunately, I don't drink my beer fast enough to do this often, but I'd like to save some of this yeast.

Would it work to just take some of the trub left after bottling the brown ale, add it to some boiled and cooled extract in a bottle, put an airlock on, and when done, cap it and refrigerate it? Then I just let this warm up and add it to my next batch? or maybe make a starter in a wine bottle? And if this works, how many times can I do this?

Thanks for the help.

Jack talks about bottling brew from a keg for Thanksgiving.

>Early in the week, I chilled down the beer till ice was visible  
>and decanted this into a chilled bottle.

The "till ice was visible" caught my eye. Where was the ice? In the  
beer?  
That's too cold, Jack. You begin to isolate the alcohol from the beer  
when you  
freeze the brew. Perhaps what you bottled was more alcohol than beer and  
so  
tasted very strange. Yes you want the draft to be cold, to retain as  
much CO2  
as it can, but you shouldn't see any ice!

Date: Mon, 2 Dec 91 15:17:00 CST  
From: Mahan\_Stephen@lanmail.ncsc.navy.mil  
Subject: Grain mill rehabilitation

Peripherally on the topic of brewing, I have a query. Last weekend at the flea market I picked up an old grain mill. It looks almost exactly like a friend's Corona. However, it is missing the feed hopper and the grinding plates are coated with rust. I can rig something to act as a hopper (cut out 2-liter/3-liter pop bottle, etc...) but am wondering about how to best clean and preserve the grinding plates.

How about it? Wire brush? Chemicals (Naval Jelly?) Steel wool? Here in Panama City the humidity is extreme (usually 90 % +) and the rust problem is severe. Obviously any type of machine oil is out. I would think that vegetable oils would present problems later in the process, leading to lack of head retention. Also, it would seem that the act of crushing the grains would erode any type of coating quite rapidly, introducing contaminants (horrors) into my wort.

Ah, what we won't do to save a few bucks. Can't beat the prices, though. Grain mill \$7, lever type bench cappers \$5. Surplus copper tubing and brass fittings are pretty cheap, too.

On another topic (galvanized pipe and proportion of zinc) it was stated that brass has far more zinc content than galvanized steel. This is true, but galvanizing is a fancy name for coating the steel (iron) with zinc. The hot dip galvanizing process involves immersing the steel in a bath of molten zinc. Effectively, from the liquid's point of view, the vessel (pipe) is solid zinc.

our  
>drinking water moves through galvanized iron pipes. I am the last one  
to

Yes, but, the insides of the pipes invariably get coated with mineral  
deposits which isolate the water from the zinc.

>  
>BTW, brass has far more zink in it than galvanized iron.

Let's not equate plating with alloys. Galvanized steel is steel plated  
with zinc (plus a few other minor metals as mentioned by others). Brass  
is an alloy and alloys are completely different from their constituent  
metals (hey, there's mercury in "silver" dental fillings). I'm not  
a chemist (help! chemists), but this was explained to me quite some  
time ago by my brewing partner who is a dentist. To the best of my  
recollection, the binding of the metals in an alloy is not exactly  
chemical  
but is quite a bit more than simply mechanical. In most alloys (lead  
solder being a notable exception) the consituent metals lose many of  
the properties they had as elements. I don't know if the zinc in brass  
can enter into beer being boiled in contact with it. Again, help from  
chemists & metallurgists, is needed for a more definitive answer to this  
issue.

As mentioned by someone (sorry) a few days ago, copper is a safe bet  
since at this very moment, there are millions of gallons of beer boiling  
in copper kettles throughout the world. SS, albeit more expensive, is  
another good choice and less reactive than copper.

Subject: Re: Casks

Dworkin asks whether to buy unlined, charred, or paraffin-lined casks. I would go with the paraffin-lined casks. I believe paraffin is related to wax (or IS wax) and I don't think it would be affected by alcohol. I don't know about the charred casks other than they are used by whiskey-makers and possibly Pilsner Urquell (I have a faint recollection of charring of casks from the Beer Hunter -- was that PU? Darryl, did you see the Coopers at work?), but I suspect the flavor produced may not go with mead. I know that Mike Sharp has brewed a pseudo-Lambic in unlined oak, and he said the first batch came out much too "oaky." Subsequent batches were more reasonable, as I recall from Mike's writings. The oaky flavor may or may not be compatible with the mead, but you first need to "run a sacraficial batch through" to lose some of the "oakiness."

Another think I recall from Mike's observations, is that until the wood swells, it will leak, and thus you want to keep the cask full of some liquid between batches.

> do it, as you'll probably chew up several blades.

Other methods for cutting kegs deleted.....

Overall, I thought Tom's description of keg cutting was very well done. I concur that a plasma cutter is the way to go if you can get access to one.

OTOH, I've made a couple of boilers using the Sawz-All, and it wasn't too difficult or costly. I used high speed steel blades (at about 80 cents each), and went through 2-3 blades per keg. You can put quite a bit of force on the saw if the blade speed is kept low. "Feed but no speed" in machinists' lingo.

Drilling the holes was actually harder than cutting, but requires only persistence. If the keg is empty (or nearly), it's not necessary to relieve the pressure before drilling. As soon as the drill breaks thru, the keg will vent and fill the room with the smell of stale Budmilob, but no showers.

I had absolutely no experience working with metal prior to tackling my first keg, and in spite of that it seemed easy enough. It was, however, the second noisiest thing I've ever done!

Building a brewery can be as fun as brewing.

From: BAUGHMANKR@CONRAD.APPSTATE.EDU  
Subject: Sparging bags

>To Kinney Baughman: Why is the capillary action in the bucket to  
>bucket lauter tun any more a problem there than any other system?

It's the water action between the grain mass and the side of the bucket that is the concern. The water in the middle of the bucket makes its way through the bed, rinsing out the sugars with no problem. But the capillary action on the sides allows that portion of the water to slip down the sides missing the grain mass. The coarseness of the sides of the bag reduces capillary action, or so the argument goes.

>My experience with a grain bag was not salutary, as the bag failed to  
>hold the weight of the wet grain and kept falling into the bucket.

That's why I usually put a stainless steel vegetable steamer in the bottom of my lauter tun to support the bag. The vegetable steamer makes a nice false bottom.

From: BAUGHMANKR@CONRAD.APPSTATE.EDU  
Subject: 2-row vs. 6-row

Jack posted the outline for his EASYMASH method and then asked for ways to make it easier. During his discussion of decoction mashing I realized that...

...we haven't had a discussion of the relative merits of single-stage mashing vs upward infusion/decoction mashing in these electronic pages in a while, if ever. To get the ball rolling, I take the position that upward infusion mashing is a waste of time for homebrewers. A single-temperature mash of two-row malt at 150 degrees is simpler and yields a 'better' tasting beer. Decoction mashing is interesting as an exercise in getting back to basics but I wonder, in the end, if it's really worth the extra trouble.

My appeal is to the principle of parsimony, Ockham's Razor: Entities are not to be multiplied beyond necessity. :-)

Commercial brewers find it necessary to perform an upward infusion mash to convert the high levels of adjuncts added to the mash. I've always argued that since homebrewers are not the least bit concerned with adding adjuncts to the mash, why bother with upward infusion mashing? A single stage mash of two-row malt is a heckuvalot easier. The grain is more modified and to my mind that means the malt character is more fully developed and therefore tastes 'better'.

Why make life more difficult than it needs to be? Brother Ockham would be displeased.

Another point of discussion here relates to whether an upward infusion mash is essential to the lager beer style (since that's the style its usually associated with). Why couldn't a single-stage mash of two-row malt yield wort which would be characteristic of the lager style? Isn't the lager/ale distinction one based more on fermentation conditions than mashing conditions?

OK, you guys. The ball's in your court...

Date: Mon, 2 Dec 91 21:53:05 MST  
From: dworkin@habitrail.Solbourne.COM (Dieter Muller)  
Subject: ...of sealing wax and casks...

The most succinct answer to the question of paraffin-lined casks came from Bruce Mueller, mueller@sdd.hp.com:

bruce: Mead, even a strong one at 15% EtOH, won't dissolve paraffin. The  
bruce: stuff is SLIGHTLY soluble in HOT EtOH. Not to worry!

An obvious point that I never thought of was made by Drew Lawson, lawson@bdcd102.nrl.navy.mil:

drew: Suggestion for a test: Do you have one of those wax lined leather  
drew: mugs? If so, you could try filling it with mead, covering it, and  
drew: letting it sit for a day or so. Then taste the results.

Since these mugs come with a guarantee of proofness against any potable fluid (or at least, mine did), that answers the question also.

Tom Denny, dennyt@prism.CS.ORST.EDU, asks:

tom: I'm sorry, but I don't have the answers to your questions raised in  
tom: this  
tom: letter. However, I would love, if your willing, to have the  
tom: address  
tom: of your source for the wooden casks! It sounds like a neat idea!

I don't have the immediate address at hand, but the merchant in question is The Cumberland General Store. I got their catalog by filling out one of those send-us-money-and-we'll-send-you-a-bunch-of-different-catalogs offers. If there's demand, I can look up their street address some evening and send it on.

Their casks come in, I believe, 2, 5, and 10 gallon volumes. Prices for the 2 gallon casks are on the order of \$60. This is all from (vague) memory, but reasonably close.

> local rest. supplier and welding gas company. I've found  
> possible used tanks, but the guy knows nothing about them and  
> I'm worried about certification, etc.

I have no idea where cs.utk.edu is, but if you're near  
a large metropolitan area there is probably a place that sells  
bottled gasses. You might check under "gas" in the yellow  
pages.

In San Diego, we have several, one specializing in  
beverage distribution hardware and supplies. My used 5lb tank  
was \$20, filled. Lasted two years. Don't worry about  
certification per se. If the shop will fill it, that's probably  
good enough.

> 2) I've seen those nifty manifolds in the Foxx catalog and they  
> seem pretty cheap way to have multiple beers on tap if one thing  
> is true: Do you need a regulator per/keg or would having a single  
> regulator between the manifold and the CO2 sufficient (i.e, do you  
> find you have to futzz with the pressures on a per keg basis?)

Depends on what you're trying to do. Carbonating beer  
takes ~30psi, dispensing 5psi (for a typical ale) to maybe  
10psi (for a lager, dispensed cold). If you only do one thing  
at a time, save your money and just move the CO2 line around  
as necessary. Unless the spigot is in constant use, you  
shouldn't have to reconnect to a keg much once it's up to  
pressure until you've dispensed enough to (say) double the  
gas volume in the keg, cutting the pressure roughly in half. I  
cheat up a little on pressure, and extend the range further.

> 3) I've seen a little about cleaning and modifying the kegs for  
> Homebrew use: Replace all O-rings and shorten the liquid pickup  
> tube. What other things need to be done other than a good  
> bleach-water cleaning?

ACK! NO BLEACH!

Bleach eats stainless. Use it sparingly if at all,  
then rinse well. I use boiling water w/ a little detergent,  
followed by more hot water to rinse.

I've never bothered shortening the pickup tubes on my  
kegs. The first mug is chewy. Big deal. I'd hate to waste  
beer!

> 4) I think, but don't know, that the beer would stay fresh  
> after you've tapped it part way and then swapped it out for  
> another keg and came back to it a little later. Is there  
> any difference between that and not having tapped it later?

If you don't tap it, you can't drink it 8<:^). The CO2  
blanket on top keeps it from oxidizing, and the opacity of the

keg keeps it from going skunky, but nothing stops the march of time. Using part of a keg is fine, as long as you dispense w/ CO2, which brings me to...

> I don't have to worry about oxidation...

Well, don't \*worry\*, exactly, 8<:^) but here's some thoughts:

Lay down a bed of CO2 in the keg before racking the beer in. It's heavier than air, and will stay in the bottom a long time. This displaces (or at least dilutes) the oxygen rich mixture we know and love as air, preventing oxidation if the beer splashes its way in.

Beer going bad in a frat house keg is a result of that little pump on top, forcing nice, fresh, oxygen and bacteria rich air in.

> 5) any other hints/tips/admonishments from Soda Keggers?

Get a Foxx Equipment catalog. Saves a lot of money.

Identify your kegs by manufacturer, fitting type, and (if possible) model. This will save you a lot of frustration ordering parts. Try to keep the equipment compatible, as this saves inventory in your parts stock. When ordering gaskets, get spares.

Store empty kegs dry, with ~5psi of CO2 in them. This makes it easy to tell if the seals are good, and keeps nasty things out.

Keep the fittings covered to avoid UV damage (I use a paper bag), and clean them before each use to avoid contamination.

Mark the contents when you store them full; I use a magic marker on the trusty paper bag. Sometimes my memory ain't so good.

>But this is off the subject. Usually, I have to do this maybe 4  
>or 5 times - 10 or 12 for a particularly ornery brew - and then  
>the foam breaks up and the wort settles in and boils happily.

I figured this was worth a question to the digest. I have  
resorted on occasion to the "cold water" method, but dislike it  
since you have to watch out for boil-over again. So I normally  
just use the "blow on" method to reduce the foam. This is tough  
on those who hyperventilate easily, but is great in that you  
don't have to worry about another boil-over happening that batch.

Could someone explain what is happening differently in the two  
situations? Thanks.

>compensation.

While I cannot argue against all-grain brewing, let me just say  
that my experience has been that in brewing as well as in  
cooking, the quality of the ingredients is very important.  
Commercial kits and extracts are of varying quality. If you find  
yourself making an award winning beer with extract, stick to that  
extract as much as you can, since it very likely was produced  
with good ingredients. Of course, it may not be great for other  
styles, but that is another issue.

From: Dean Cookson <cookson@mbunix.mitre.org>  
Subject: Electric mashing bins

Ok, I've been convinced. It's time I try making an all grain beer.

But, now I have to decide what to mash in. I've been thinking of buying a 40qt round plastic cooler, and doing a simple infusion mash (I'm mainly a British ale brewer/drinker), but all this talk about electric mashing bins has be curious. How much do these things run in general, how easy are they to use, and can you boil as well as mash in all of them?? Also, are there any 110 VAC units worth it? I have a gas stove and a gas dryer, so there are no 220 VAC outlets in the house. :-)

Thanks,  
Dean

Subject: Ternary and Quaternary Brazing Alloys for Homebrewing

> From: Tom Dimock <RGG@CORNELLC.cit.cornell.edu>

>

> I am reading my way through the HBD archive, and came across a post in  
> HBD 512 stating that silver solder is 97% lead and 3% silver.

That's a negative. Silver solders aren't really solders; they're silver-copper-zinc alloys. Some alloys contain cadmium, however, so you should check the chemistry of the particular alloy you wish to use.

My Metals Handbook recommends using alloys containing at least 50% silver when joining stainless steel, to prevent selective attack of the brazed joints. If you're working with a 300-series (austenitic) stainless steel, try to use an "extra-low carbon" variety, such as 304-L or 316-ELC.

> Now comes the fun part, attaching the fittings to the keg. They can be  
> silver-soldered in (normal solder won't bond to the keg), or they can  
> be welded.

If welding is affordable, I recommend it over silver-soldering. It will remove any concerns over the long-term integrity of the joint.

> From: Jay Hersh <hersh@expo.lcs.mit.edu>

> Subject: Lace

>

> I get Lace in almost every beer I brew, even ones that are exclusively extract.

I recently discovered the 12 "lost bottles" of our 3rd batch of homebrew; a version of Papazian's Tumultuous Porter (aka Goat Scrotum Ale) bottled last March. We used blackstrap molasses in that one, and combined with the ginger and roast barley in the recipe (extract, BTW), the flavor was initially very bitter/astringent. Well, we *did* manage to kill a case and a half of it, but set the rest aside when a better batch came along.

Anyway, 9 months in the bottle did wonders for this beer. The edge came off the ginger, and the molasses bite has vanished, leaving only the effect of the roast barley and, of course, hops. A very palatable, though somewhat dry, molasses flavor is evident in the finish. The mouth feel is also quite good. An altogether pleasing brew!

More to the point, the beer produces quite a bit of foam when poured (I'd guess it's somewhat overcarbonated; we've had gusher infections and this is nothing like that). After it has time to collapse a bit, the result is a truly fine head, and Belgian Lace to the bottom of the glass.

This also brings to mind a question on aging beer. This porter's initial gravity was about 1.045, so it's not a particularly big beer. Fairly complex mix of dark malts, naturally... but overall not something I would have expected to benefit from such long-term aging. I'd be interested in hearing the experiences others have had with aging homebrew.

> Subject: Re: Galvanized Mesh

> To the best of my  
> recollection, the binding of the metals in an alloy is not exactly  
chemical  
> but is quite a bit more than simply mechanical.

Alloys are solid solutions, like a wort is a solution. Same  
chemistry in a different state of matter.

There is a corrosion phenomenon known as "selective leaching" which is a  
known problem with brasses. The zinc, being more reactive than copper,  
is  
selectively removed from the alloy, leaving only copper behind. This is  
also called "dezincification." I'm uncertain whether the homebrewing  
environment is severe enough to produce this effect to any great depth in  
the metal; I tend to doubt it. In any event, the release rate of zinc  
would be minute in comparison to that of the near-pure zinc of a  
galvanized  
finish.

This reminds me that there was an interesting article about a former Homebrewer of the Year in \_zymurgy\_ a few years back. It discussed how he raises his own barley, malts it himself, ..., and uses wooden kegs. (Did he win with a Belgian Brown?)

Sounded like a lot of work, but there also might be more detail in a Beer & Brewing volume.

You can cut your costs on using expensive laboratory yeast cultures, or use a particular brewery yeast from an unpasteurized and unfiltered brand the same way: culture from the sediment in a bottle. Dave Miller, in The Complete Handbook of Homebrewing, recommends only going ONE generation, to avoid attenuation changes from common mutations, and to avoid problems with bacteria.

The technique is to make some fairly hopped wort and pitch your dregs into it. Both Miller and Papazian (in The Complete Joy..) have methodologies outlined. Miller's book has instructions for making up 3 gallon batches of wort, and using home-canning equipment to store wort for culturing use. Both recommend small containers with fermentation locks.

I use Miller's canned wort, but do my culturing in the bottom of a 5-gallon carboy, that becomes my primary fermenter. I pour off most of the "used" wort when culturing is complete, and then pitch cold wort onto the trub. I use this method with either the original lab culture or with dregs from my first generation. Sanitation is critical, and I swab the bottle, cap, neck, quart canning jar & lid with alcohol. I sanitize the carboy and funnel, fermentation lock etc. with the usual weak (approx 1-5 ppm chlorine) solution and I DON'T rinse. My tap water contains coliform bacteria, even though its chlorinated.

havn't  
>got the variety to experiment with.

In my short (7 batch) experience, I've used three types of yeast and  
tasted  
the results of other HB'ers work with a couple of other types of yeast.  
I've  
decided that the type of yeast affects the final flavour more than any  
other  
ingredient. Assuming a particular recipe, varying the brand of yeast can  
make a drastic difference in the final product, from near-pro-quality to  
not-very-pleasant. I've done this experiment and was pleasantly  
surprised at  
the results, since I've got a variety of yeasts available to me. You  
might  
try a mail order house in the US or elsewhere to gain some variety.

Mark Davidson writes:

> to know so that I can deal with that in my construction article.

#define DISCLAIMER "I know just enough to be unsure of myself"

A quick plunge in the Metals Handbook [Wonderful set-o-books, BTW]  
produced  
the following...

Silver \_solder\_ (the stuff that melts at 450 F) seems to come in two  
basic  
compositions:

Tin-silver ranges from 90-97.5% tin, with the remainder being silver.

Lead-silver [you definately do NOT want this!] is 94.5-98.9 LEAD,  
the remainder being silver.

Silver brazing (which for some reason is often referred to as silver  
"soldering") is a different animal.

The stuff I'm using for stainless work (J.W. Harris Safety-Silv 1370) has  
the following nominal characteristics (BAG-5 is the "official" category)  
:

Silver: 45% Copper: 30% Zinc: 25%

The alloy has a solidus of 1225F, liquidus of 1370F and a working temp.  
range  
of 1370-1550 F. The flux (Stay-Silv "White") is a bit nasty, so be sure  
to  
clean, clean, clean it off before using the "fixture" for food. I'm told  
that  
the "service temperature" for joints made with this alloy is approx. 400  
F.

Another book which I recently uncovered, and is about nothing but  
stainless  
steels, recommends using BAG-4 alloy. It is similar to the above, but has  
[nominally] 40% silver, with the difference being made up of roughly 1.  
5%  
nickel and the remainder additional zinc.

Both of these alloys (according to the info I have) are food safe, and  
contain  
NO cadmium.

The down side of them is cost. I paid \$57 for 5 Troy ounces (the smallest  
size my supplier has in stock) of 1/16" wire. There is a place called  
Small Parts Inc. in Florida (I can look up the address tonight), and I'm  
sure there are others, that carries it in 1 oz. coils for about \$22. I  
went  
with what I have primarily because of availability, and on the advice of

someone who knows more than I do that it would work just as well.

went  
> into the wort this morning.

I've used the Whitbread [dry] Ale yeast quite a few times, and while I  
also  
noticed that it seems mighty "fast-acting", the beers that I've made with  
it have all turned out wonderful.

One other thing about it, is that it seems to do a very good job on high  
gravity beers. I make an 18+ Plato, (7+% alc :-), Knock-Your-Xmas-  
Stockings-Off  
ale, and the whitbread seems quite up to the task. The "pleasant floral/  
fruity"  
aroma carries over a bit into the beer, which, IMHO, adds to it  
immeasurably.

From: krweiss@ucdavis.edu  
Subject: Irish Ale Yeast/carbonation summary

About three weeks ago I posted a message noting some problems I had with bottle carbonation in four batches of beer brewed with Wyeast Irish Ale yeast. I asked for other folks' experience with this yeast.

I got 4 responses. 1 said they had no problem with carbonation. 2 asked to hear the results of my survey. 1 said that he, also, had problems getting beer carbonated when brewed with the Irish Ale yeast.

So, the conclusion is inconclusive... I'll probably still use the yeast, as I really like the flavor it gave to a highly-hopped high gravity beer, but I'll make a point of getting the beer out of the secondary and into bottles within two weeks of the pitching date.

I was in LA over Thanksgiving. My mother-in-law lives about two blocks from Wolfgang Puck's brewery, Eureka. A friend and I dropped in around 3:00 on a Wednesday afternoon to sample a few beers. The guard at the door informed us that lunch service ended at 2:30. "No problem," we said, "We're just here for a beer at the bar." Not only was the bar closed as well, but the bartender behaved as if we were insane for thinking we could get a beer at such an outrageous hour. I mean, really, did we think we were in a BREWERY or something??? If someone can send me a *Pediococcus* culture, maybe I'll drop in on my next trip to LA and spray it around... ;-P What's next? Beer tastings complete with precious little commentaries? "A woodsy little beer with an insouciant nose, and a rascally finish. Unpresumptuous, but sturdy." ARRRGHHH! If I wanted to be associated with pretentious snobby weenies that drink for flavor and not effect, I'd drink wine. Whew, I feel better now.

From: eisen@kopf.HQ.Ileaf.COM (Carl West)  
Subject: Quick and clean culturing from a SN bottle

1. Make or have on hand, a small amount of recently boiled, low gravity wort (~1/2cup) at pitching temp (the microwave is a fine tool for the job, I just do it up in a glass and allow it to cool in the 'wave).
2. Decant the beer leaving about 1/2" of beer in the bottle, and set it aside for later.
3. Flame the lips of the wort container and the SN bottle.
4. Pour enough wort into the bottle to bring the level up to 1".
5. Put an airlock on the bottle and shake it up.
  - 5a. Drink the beer.
6. Shake it up whenever you think of it for the next day or so (keep it aerated).
7. Repeat steps 1 and 3.
8. Add enough recently re-boiled wort to bring the level up to 2".
9. Repeat steps 6,7,and 8, ~doubling the volume until you've got the amount that you want to pitch.

This method worked for me the first time I tried.

From: Kent Dinkel <dinkel@hpmtaa.lvld.hp.com>  
Subject: Priming with DME  
Full-Name: Kent Dinkel

To Dave Ballad (lost your address so I couldn't reply directly),

> If you've already thought of this, I apologize. I'm kinda slow  
> sometimes.

I'm VERY slow MOST of the time and hadn't thought of this. Thanks for  
the  
tip!

-----  
----

To Those Who've Primed with DME,

I tried priming my recent oatmeal stout with 1 cup dark DME instead of 3/  
4  
cup corn sugar. I'm not sure what in the %\$## came over me since I've  
had  
decent results with corn sugar in the past and had plenty of corn sugar  
on  
hand for this batch. Anyway, after a week in the bottle the brew tastes  
quite good for its age (so I'm pretty sure that there's not an infection  
--

at least not one I can taste) but is VERY flat. It has NO head and  
hardly  
any carbonation. Just a slight "ppfftt" when the bottle is opened.  
\*Usually\* I've got decent carbonation by this point -- the beer just  
needs  
further aging for flavor. Although I can't be sure, I'm pretty sure that  
the yeast was doing ok at least until I bottled since the S.G. got down  
to  
1.016 or so (which was approximately the expected result). I believe my  
options for this batch are:

1. Relax (for a couple of months), have (a different) homebrew (until  
this  
one is ready).
2. Put the beer in a warmer place. It's currently in the basement where  
(temp < 60 deg F). I could put it upstairs where (62 deg F < temp <  
68 deg F). However, I'm a little paranoid about getting the beer too  
warm and developing off flavors.
3. Add a LITTLE yeast to each bottle. If this doesn't work, go to 4.
4. Try adding 1/4 tsp corn sugar to each bottle.

My local expert tells me #1 is the preferred option since priming with  
DME  
just takes longer for carbonation to complete. He's usually right,  
however,  
I can be pretty impatient (especially when it comes to waiting for my  
brew)  
and was hoping there was a quicker alternative. Have others who've  
primed  
with DME had the same experience and do you have any recommendations?

Thanks in advance,

Kent "maybe someday I'll get this brewing business figured out and  
quit  
experimenting with EVERY flipping batch" Dinkel

Not bad at all. During a recent trip to Chicago I was able to try the new Pub Draught Guinness. As other readers have confirmed, the head was great! One thing that did surprise me was the large "Pasteurized" stamp on the can. I never realized Guinness was pasteurized.

I also found a beer store with Red Tale Ale. Recalling a recent HBD issue where someone stated it was only available out West, I picked up a six. I found it rather unique and enjoyable.

I've got to get to Chicago more often! We didn't have nearly enough time to check out the many interesting pubs and breweries. If anyone can let me know where I should go next time (pubs with good draught and breweries to tour), please drop me a note.

From: Tom Dimock <RGG@CORNELLC.cit.cornell.edu>  
Subject: Silver Solder summary

Thanks to all who responded. It seems that asking whether "silver solder" has lead in it is like asking whether beer has wheat in it. Silver Solder is a generic name under which fall substances with a large number of compositions. The bottom line is that there are silver solders you can use (95% tin, 5% silver, for example) and ones that you must not (lead and/or cadmium containing compositions, for example). Make sure you know what you're using and that it is safe! They will all be expensive, and the consensus was that they are really finicky to use - they require fairly exact temperature control. If things are either too hot or too cold, the solder just runs off, making expensive little blobs on the floor.

As Henry Troup said - "Heavy metals should not be taken lightly"

Tom Dimock - "Flame your kettle, not the net"

From: "Dr. John" <JELJ@CORNELLA.cit.cornell.edu>  
Subject: Mashing & chilling

Sorry for any extra garbage, haven't posted anything for a while, and apparently the submission address has changed since I last did so.

-----Original message-----

--  
Greetings all,  
Glad to see the flaming being doused (mostly), though I did think that some were warranted. Now that we are back to serious discussions, I though I'd weigh in with a few observations on mashing and chilling.

Jack Schmidling, in #764, in your second "Stuff" posting, you claim that if the boiling of the liquid under the false bottom in a direct-fired mash tun could be controlled, then you would be gaining the benefits of a decoction mash. Then in #771 you talk about boiling puny little quart-sized portions of the mash as though this is decoction mashing.

Jack, you appear to be confused as to just what decoction mashing is. May I suggest that you pick up a copy of Noonan's book and read it, or re-read it if you already have it. Regardless of what any of us may think about the grasp that Noonan has on his material, he does elaborate a procedure for decoction mashing that works (I've used the approach successfully a couple times). I think that once you consult this reference you will be firmly disabused of the notion that either of the approaches you discussed constitute a decoction mash. In fact, the first one (boiling the liquid under the false bottom) would only result in deactivating the enzymes. I'd be interested in hearing what the source of your information on decoction mashing is.

Kinney, in regards to your questioning of the utility of a protein rest, in #773, I think that the modification issue isn't a 2-row v.s. 6-row thing. I beleive that either type of barley can be modified to whatever degree the maltster desires, and that the tradition is for Ale malts to be more fully modified than Lager malts, thus obviating the need for a protein rest in traditional ale mashing. So, it seems to me that the question we need to answer here is how well-modified is the malt we are using? If some of the protein still needs to be dealt with then we need to do a protein rest, if not we don't. I'm a firm beleiver in attempting to brew traditional styles with

their traditional raw materials, and as such will not be easily convinced that the protein rest has no place in homebrewing.

In regards to chilling, Jack, in #770, you mention a very long time to chill a 5 gallon batch through quarter-inch tubing immersed in an ice-water bath. In my system I use 20 or 25 feet (I can't remember which) of quarter-inch copper tubing which I immerse in a 5-gallon bucket of ice water. Takes me about 25-30 minutes to chill 5.25 gallons or so. I simply set up a gravity-feed system where the hot wort flows from a 2-bucket hop-back into the coil and thence into my 25 litre fermenter (where it sits for a couple hours before being racked off the trub, aerated, and pitched). I don't know why your system took so long Jack, maybe the extra tubing, though that doesn't seem to me to be a reasonable explanation.

Mike Zentner, in #773, you seem perplexed as to temperature regulation with an ice-water wort chiller. Now, if you follow Jack's astute suggestion about adding more ice as the initial load melts, then there is only one extra little step you need to make this system work. Hve you got one of those little white plastic things for restricting the flow on plastic tubing? I use one with my setup, and by regulating the flow rate can adjust the temperature of the wort coming out of the chiller. If you require a precise temperature this may not be for you, but if you can live with a close approximation you could simply stick a sanitized thermometer in the outflow occasionally, read the temperature and adjust the flow as necessary.

Given the discussions we've seen about various sanitizing agents and their effects on different materials, I'm convinced that regardless of whatever minor hassles the system gives me, its big advantage is that I can use heat (actually steam since I bake the coil after running some water through it) to sanitize the coil and don't have to worry about what sort of byproducts I'm creating with a chemistry experiment involving copper and bleach (or whatever).

So, what's the scoop with Klages? Is it modified fully enough to get by without a protein rest?  
Ooogy wawa,  
Dr. John

> single-temperature mash of two-row malt at 150 degrees is simpler and  
> yields a 'better' tasting beer. Decoction mashing is interesting as  
> an exercise in getting back to basics but I wonder, in the end, if  
> it's really worth the extra trouble.

Well, I've done both single-temp ("toss in cooler and wait" as we call it) and step (add heat to mash) mashes. I presume that this is what is meant by "upward infusion", so correct me if I'm wrong here. (It could also mean raising the temp by adding more hot water, no?).

Based on personal experience, I'm all in favor of doing a step mash, for a couple of reasons. First of all, I noticed that my extract efficiency jumped up a couple of points, which means I can use less grain for a given beer, or make a higher gravity beer with the equipment available. This isn't entirely insignificant when doing 10 gal. batches.

I have yet to get a real handle on controlling the characteristics of the resulting wort (only done 3 so far...), but I did bang through Noonan to come up with the parameters I've been using, and was under the impression that they would give a pretty good balance of mouth-feel, etc. So far, I've been pleased, although I did increase the water a bit on the last one to help prevent the stuff burning on the bottom of the pot.

The other reason I like doing the step, is that the runoff I get seems to be much cleaner than what I was getting with a simple infusion. I'm not sure that this has anything (or much of anything) to do with the step mash per se, however. No experimental data, but I've been suspecting that I could get a cleaner runoff from a simple infusion by either transferring the mash to a separate vessel for sparging, or giving it a big stir before starting to sparge. In short, it seems that I get a much better filter bed (for whatever reasons) with the step mash.

Comments from the experts on this would be most welcome, BTW.

As far as the "waste of time" goes, hell, I've already blown the whole day, another 1.5 hours isn't going to kill me. :-)

> OK, you guys. The ball's in your court...

Volley... :-)

Subject: Anchor Christmas

Well folks, Anchor's Christmas brew is now available, and this year's batch is very fine. I haven't tried a bottle yet, but sampled the draft at the brewery last night.

It's a spiced ale, and the dominant spice seems to be nutmeg, which asserts itself most notably in the aroma. The brewers were pretty even handed with the spices this year, and the nutmeg is balanced and well integrated with the other flavors. In contrast to some of their previous efforts, this brew has a definite hoppiness as well. It's pretty pricey, two 12 packs set me back \$35.

Ho Ho Ho,

CR

Subject: Silver Solder (revisited)

To Tom Dimock:

Ignore the info on the HBD #512 post about silver solder's containing lead. If you were to go down to the hardware store and look at the silver solder for plumbing, you would see the content as being 97% Tin and 3% Silver. (Sorry, but you can't always trust what you read in the HBD :-). There may be some silver solders that contain lead, but I haven't seen them. Always be sure to read the metal contents. It is always printed on the package.

Side note: I remember reading somewhere that all solder connections on drinking water now must be made with lead-free solder. I know it's all that I use, and I haven't encountered any problems in using it. Works just the same as the old 50-50 lead-tin solder..

BTW: be sure to get the proper flux.

Non-flame on:

Thanks for turning off the flames, folks! It was getting tiresome.

From: Bob Jones <BJONES@NOVA.llnl.gov>  
Subject: Guinness draft in a can

I tried this draft in a can stout the other night. I liked it and thought it was as good as the draft I get in my local pub. The real question I have is how do they release the nitrogen when you open the can? I cut the can open and found a little plastic vessel that obviously holds the gas but I can't figure out the trip mechanism that causes it to release. Only guess I have is it is the difference of pressure between the nitrogen in the small vessel and the can that goes to atmospheric pressure when you open the can. Seems wierd if so. Anyone know for sure. I can't fully enjoy the beer until I know for sure. Engineering minds will never rest.

From: Rob Sama <sama@midway.uchicago.edu>  
Subject: melon wheat beer

I recently (this weekend) tried brewing my second wheat beer. I used 6.6 lbs of pure wheat malt liquid extract, 2.5 lbs of clover honey, water, and one honey dew melon. It seems to be fermenting OK, but the sediment looks awfully funny. There is about a half-inch of white sediment on the very bottom, then about another half inch of what looks like beer just above that, and above that there is about a half-inch of white sediment on the very bottom, then about another half inch of what looks like beer just above that, and above that there is about two inches of green-white shit, on top of which the yeast is fermenting. What the hell? I only used one ounce of hallertau hops, so it couldnt be that, could it? I added the melon by cutting it up, letting it steep in the wort, and then removing it before pouring into the glass carboy. What is that green stuff and will my beer come out ok?

From: "CCVAX::HAPANOWICZ" <HAPANOWICZ%CCVAX.decn@bigvax.alfred.edu>  
Subject: A message from my bottles

A layer formed on the beer surface in the bottles of a recent batch. The layer is very thin and is white. The batch is a cherry beer, based on the "Cherries in the Snow" recipe in TCHOHB. Fermentation went ok, it was aged in the secondary for about 4 weeks with a SG of 1.020 at bottling time. The beer tastes ok, but I think it needs more time to age in the bottle, nice cherry flavor and aroma. I drank a half a bottle the other night and recapped the remainder, Grolsh bottles. The next day the layer spread and covered the entire liquid surface. The only thing I can think of is a mold. Am I correct? The layer does not seem to grow larger in the full bottles. Should I just let this age and go with it? It tastes good at this point, will the aging bring out a mold flavor? Any Ideas?

From: Bruce Mueller <mueller@sdd.hp.com>  
Subject: Silver Solder Compositions

OK, here is a table summarizing about ten silver solder alloys whose compositions are given in the 55th Ed. of the CRC "Handbook of Chemistry and Physics". Note that NONE contain any lead, but about half contained cadmium, which is also a heavy metal (toxic). One contains strictly silver and copper, for those who must worry; it would work, but its liquidus temperature (that is, where it is all molten) is 1635F. The lowest is only 1125F (contains Cd, however).

Metal % Range (weight)

-----  
Ag 34-93  
Cd 0-25  
Cu 7-43  
Ni 0-3.5  
Sn 0-10.5  
Zn 0-30

So you don't have to go looking up what the symbols are, in order:  
silver,  
cadmium, copper, nickel, tin and zinc (with a 'c' is the American spelling;  
German is 'k').

Machine Design's Materials Reference concurs on composition: silver with copper and sometimes zinc (this excludes the rest of the metals listed, but the statement is very brief).

Hope this ends the silver solder controversy!

Subject: Re: Yeasts (addition)

In my previous post, I mentioned better cold break in association with the wort chiller. In formulating an answer to Mark Davidson, I realized that I forgot to mention that using a wort chiller also keeps me from pouring hot wort into the fermenter. Casting aside the fear of restarting the oxidation wars, I feel that chilling the wort to below 80F before pouring eliminated some sherry-like flavors that my beer had. According to the Zymurgy Troubleshooting Issue (VOL 10, # 4), oxidation can cause sherry-like flavors. I concur.

>I am reading my way through the HBD archive, and came across a post in HBD 512 stating that silver solder is 97% lead and 3% silver.

That's still lead solder. It's an alloy used for soldering electronic modules. Someone else can tell you what silver solder is but it is more or less the other way around.

From: joshua.grosse@amail.amdahl.com  
Subject: Going all-grain.

>For those of you without grain mills; what do YOU use?

I will use this as an excuse to post a "commercial" on the mill I made. I

can make a few more, if anyone is interested, send me email. But I warn y'all, it aint cheap. I will post some info on it separatley.

>A 4 gallon mash didn't all fit in the lauter-tun at the same time! I ended up taking a lot of run-off out right away in order to stop leakage from between the two buckets! Miller recommended a 5-minute rest for settling; I couldn't.

>This made the sparging get a little more complicated.

This also made it not-sparging and explains all the problems you ended up with. The mash must be allowed to settle or you can not establish a filter bed and will only get what you got.

I do not understand Miller's idea of allowing the water to drop below the grain level unless he is talking about spray sparging. None of the grain above the water level will get sparged. Furthermore, unless you have a transparent lauter vessel, how would you control it?

Sounds like you had a perfectly miserable time but three cheers for the effort.

Fix those leaks.

Subject: 2-row vs. 6-row

>Jack posted the outline for his EASYMASH method and then asked for ways to make it easier. During his discussion of decoction mashing

I realized that...

>Why make life more difficult than it needs to be? Brother Ockham would be displeased.

Tis a bit inconsistant with "Easy", isn't it. I guess I wanted to make good beer first and then simplify it after I had a target to shoot at.

>Why couldn't a single-stage mash of two-row malt yield wort which would be characteristic of the lager style?

>OK, you guys. The ball's in your court...

I will rise to the "challenge", if such a drastic simplification can be considered a challenge.

On my next batch, I will use a single temp infusion at 150 F in lieu of my 5 step method over a 3 hr time frame. It will be interesting to compare the results.

What is the concensus on the time for the single temp infusion?  
.....

This is from yesterday, I forgot to post it...

I hope this can be taken as reasonable discussion because it is not meant to be confrontational. After all, I did ask for comments.

From: mcnally@Pa.dec.com

>No mention is made of the pH of the mash.

Well, for openers, it is called "Easy Mash" and dealing with pH sort of contradicts that direction. I have also avoided it because I am currently trying to make sense out of the readings I get which are inconsistant with recommendations. I do not know yet whether I am dealing with measurement problems or momilies.

> Where Jack lives, the water chemistry must be appropriate to the type of brewing Jack does.

Blessed with L. Michigan water, you probably have a point. Too bad I don't have access to some nice polluted, mineralized, "Sky Blue Water" :)

>The single-step infusion spurned by Jack is in fact used by most British brewers and many commercial brewers of lagers in America and on the continent.

It is less a matter of spurning than of needing something to do while monitoring the mash.

> If, however, Jack uses very hot sparge water, he probably is better served

by decoction.

As a matter of fact I use boiling water and have some thoughts on that.

..  
Not based on brew tech but just physics.

When boiling water is dribbled on top of one inch of water, on top of six inches of mash, it seems reasonable that, by the time the water gets to where it is extracting sugar, it is probably close to the proper temperature. It hadn't occurred to me to measure the temp at the outflow of the masher but my guess is that it is around 150 F.

>Jack contradicts himself when he states first that the object of the sparge is the removal of as much sugar as possible, and then a few sentences later instructing the budding masher to stop sparging when the gravity falls to about 10. Perhaps mention might be made of the reasons for stopping at that point, lest an over-eager masher might continue to sparge and leach unwanted tannins out of the grain.

It was just a reference point for instructional purposes. The reasons are spelled out in the tech pubs. The actual number, according to Noonan is 1.008 but I suffer from a propensity to round off.

From: grumpy!cr@uunet.UU.NET (C.R. Saikley)  
Subject: All Grain Questions

>From: joshua.grosse@amail.amdahl.com

>I went all-grain for the first time yesterday.

Congrats, brewing from grain is extremely rewarding, and I would recommend that any experienced extract brewer give it a try. The magical process of turning grains into beer is truly gratifying.

>I was unable to obtain or use a grain-mill.

>For those of you without grain mills; what do YOU use? What kind of extract

>rates do you get? I got a lot less than I'd hoped. It seemed I made a mixture of flour and uncracked whole grains. For those with mills; how much

>do they cost?

It's unfortunate that you couldn't get access to a decent mill. A coffee grinder or Cuisinart just isn't going to give you a good crush. This can cause the problems you experienced with poor extract and cloudy runoff. It can also cause a stuck mash, which fortunately you avoided.

The Corona grain mill is the old standby. It's hand cranked, but can be connected to a power drill to make life easier. The crush is far from perfect, but it can be made to work OK. A new one will set you back about \$40. Many homebrew shops carry them. Try Williams Brewing in San Leandro CA.

Another option is to have your supplier crack your grain. A decent homebrew shop will have a two roller mill, which should give you a much better crush than a Corona can. It usually costs no more than 4-5 cents/pound extra to get your grain cracked, and some suppliers will do it free. Cracked grain doesn't keep well, so you'll want to brew ASAP after milling. If you live in an area where you must mail order your grain, having it pre cracked is not a good idea.

>I couldn't obtain PH papers. Where do you find them? I know the brand name

>that Miller recommends, but my local homebrew supply and one pharmacy I checked with didn't carry 'em.

I've never had much luck with pH papers either. Especially with darker brews, the color of the wort can obscure the color of the paper, making it difficult to read. A cheap digital pH meter can be had for \$40 from Edmund Scientific. This same meter can cost \$80-90 in homebrew supply shops. It's got a single point calibration, so you need a standard buffer solution to calibrate it. It's accurate to 0.2 pH (the catalog doesn't specify whether this is +/- 0.1, or +/- 0.2), which is generally close enough for brewing. More accurate meters cost hundreds of \$\$\$.

>I used the old Iodine test that Miller doesn't like. As Papazian predicts,

>the mash was done in less than 40 minutes. Miller likes to mash for an hour

>and a half without testing. I preferred to test.

Dr. Michael Lewis at UC Davis claims that with Klages malt and a hot mash (160F) the conversion will be complete in under 5 minutes. I've mashed for as little as 20 minutes and gotten good results. The Marin Brewing Co. routinely mashes for 35 minutes (because it takes that long to heat the sparge water) and FWIW they took 4 medals at this years Great American Beer Fest. Given that, Miller's recommendation of 90 minutes seems excessive.

>The electric boiler never got a really good high ruckus boil.

The advantages of a good rolling boil are several. This topic is thoroughly covered in many places, so I won't go into that here. Suffice to say that a strong boil is highly desirable.

It seems that nearly everyone's first all grain brew is time consuming, messy, and fraught with mistakes - I know mine was. Fear not, for with a little experience, things will flow much more smoothly and your results will likely improve.

Cheers,  
CR

From: martin@daw\_302.hf.intel.com (martin wilde)  
Subject: Brewing Techniques

A good book to pick up is the one titled "Brewing Better Lager Beer". I don't remember the author right now, but it is the green book of beer brewing. Although it is slighted towards lager brewing, there are many, many, many tips which can be used in ale brewing.

Some of these are (and some from other sources):

- A step mash: 30 minutes at 116 degrees and then 60 minutes at 150-158 (depending on the dextrin content you desire) will reduce chill haze which is prevalent in single step infusion mashes. I have also read in the all grain addition of Zymurgy this aids in taste and body (cuts done on harsh offtones). Even 2 Row lager grain benefits from this. Yes I know the British for decades have done infusion mashes on 2 Row Klages and Pale Ale malts, but it doesn't mean its the best method... Maybe the simplest...
- A 90 minute mash is required for full color development.
- The sparge must be maintained at a constant temperature.
- Recycle the extract from the sparge a couple of times (2-3 quarts). This helps in extracting the extract. The slower the sparge, the better the extract collection. When the SP of the extract is below 1010, quit collecting. Use brewing water if more water is necessary in the brewpot.
- After collecting the extract, get it boiling as soon as possible when using the step mash or decotation mash methods.
- A Rolling boil throughout. Have the lid off for at least 30 minutes. This removes some of the bad hop flavors, acids and other foul odors which results from boiling the hopped wort.
- DO NOT aerate the wort while it is cooling, this leads to oxidation.
- Have the yeast in the carboy prior to putting the chilled wort in. This way the yeast is off and running. This is a big plus if your are using a starter culture and pitching at full krausen.
- Use starter cultures. It is a beautiful sight to behold when your wort starts blowing off after 8-12 hours and bubbles form after 4 hours.
- Aerate the heck out of the wort and yeast in the carboy. I found it beneficial to take the carboy for a ride after filling. Something about those bumpy rodes that aerates it really good!!!
- When brewing with extracts, instead of adding water to the carboy, add the water to the brewpot (assuming you have a large enough pot). This way the water will be boiled and sanitized during the boil. One less thing to go wrong.

I hope some of these help...

>story is on this? If silver solder can result in free lead, I'd like  
>to know so that I can deal with that in my construction article.

A fellow brewer, Lou Curcio, checked with one of our metallurgists and  
submits:

The term silver solder is a misnomer, it should be called silver brazing.  
(The difference between soldering and brazing has to do with the liquidus  
temperature). The filler metals in silver brazing contain about 50%  
silver,  
30% copper, and the balance is zinc. (Some fillers contain cadmium, but  
they  
are not recommended for food processing.) There is no lead in silver  
brazing.  
The AWS (American Welding Society) classification of these fillers are  
BAg-4  
through BAg-8.

Subject: Re: How yeast affects flavor

Desmond writes:

>Re Yeast: I've been impressed by the range of yeasts mentioned on HBD.  
In  
>the UK many yeasts are available for wine-making but I've found only  
three  
>for beer-making: real-ale, cheap and lager. How much difference does the  
>yeast strain make to the flavour of the beer? I'd suspect a lot, but  
havn't  
>got the variety to experiment with.

In my opinion, yeast makes a BIG difference. Bigger than which brand of  
extract you use! Different yeasts produce differing amounts of esters  
and  
other by-products, such as diacetyl, phenols, etc. My biggest increases  
in beer quality were: 1) switching to Wyeast (from Muntona (M&F), Doric,  
and  
Edme) and using a wort chiller (better cold break). In addition to  
flavors,  
with Wyeast, you have better control over attenuation (single strain  
yeasts  
have more reproducible attenuation characteristics) so you can make your  
Scotch Ale taste like McEwans, for example. I suggest you call Wyeast  
Labs  
at (503)352-7844 and ask them if they have a distributor in the UK. If  
not, maybe you could be it!

Good luck.

Subject: decoction mashing

I believe that I read somewhere (great reference, eh?) that decoction mashing was developed back when there were no thermometers (or at least they were scarce) so brewers relied on boiling a known percentage of their mash to control the temperature of the mash. However, I tend to believe (more weasel words) that the mash process used does affect the final flavor. Why else would Pilsner Urquell use a triple decoction mash in this day and age? All this is strictly my gut feelings based on the knowledge of the processes involved -- I've never made the same recipe using the three methods and then compared them side-by-side.

From: AEW@b30.prime.com  
Subject: Cranberry Lambic, Bottles

Fellow Homebrewers,

In the past few HBD's there have been several posts about Sam Adams Cranberry Lambic. Here's my 2 cents worth:

From what I have heard (From the local package store and a friend who recently toured the Sam Adams brewery) there were three batches of Cranberry Lambic Brewed. One batch made its way into the 12-pack case, one into Kegs and the third into all lambic six-packs. All three batches are significantly different in taste! (I don't know if they are different in recipe.) The kegged version is much lighter tasting than the six-pack version. I have not yet bought a 12-pack, but have heard from a friend that has had all three that it is somewhere in between the two others. The six-packs were available in the Boston area about three weeks ago and sold like hot cakes! I'm glad a friend picked up a couple :-). I enjoyed the brew in that packaging/batch.

On another note I prefer Whitbread Ale bottles for their good balance of taste, bottle color and label removability. I consider the taste worth the price too!

From: IO10676@maine.maine.edu  
Subject: Cranberry Lambic, Bottles

I guess everybody has The Batch From Hell sooner or later, and it looks like this Solstice Stout is fixing to be mine. Some of you may recall that this is the one that boiled over after 45 minutes of good behavior. Well, now the fermentation has refused to start, and I'm at a loss. I'm almost ready to start worrying here, folks.

After I got it in the fermenter last Monday evening, I added a starter made from 2 packets of Red Star ale yeast. It was a good starter, too; the yeast were clearly off and running. This sort of thing usually gets me a visible ferment by the next morning, but not this time. So, just to help it along, I dumped in another packet of Red Star before I had to leave.

That afternoon I was leaving straight from work to the airport to visit family for Thanksgiving, so I hoped it was just being a little slow. I got back home last night and found that no ferment was going on, and no evidence was extant that one had. I took a gravity reading and found it essentially unchanged from its initial reading of 1.056. I tasted the sample, also, and it definitely was unfermented. I made up one more Red Star starter then last night, dumped it in, and moved the fermenter out of its 55-60 degree closet and into my living room, hoping a little heat would kick-start it.

It's still doing nothing, and despite a couple bottles of Big Dog's best Hexham Brown Ale, I'm starting to worry. Have any of you ever had a ferment that simply would not start? This is a very new thing for me, and in my experience is completely out of character for Red Star ale, usually quite a vigorous strain. I know the yeast was good, as it did fine in the starter. The fermenter was well rinsed and did not smell of chlorine. No great temperature shocks have occurred. I just don't know.

As far as I can tell from the smell, it's not infected yet. Is there anything I can do, besides wait and hope? Please e-mail me directly with any suggestions!

Thanks . . .

From: dworkin@habitrail.Solbourne.COM (Dieter Muller)  
Subject: cask source

Here's the information on wooden casks from the Cumberland General Store:

Paraffin-lined Oak:

| Gallons | Diameter | x Height  | Price    |
|---------|----------|-----------|----------|
| 5       | 10.5''   | x 17.25'' | \$44.20  |
| 10      | 12.5''   | x 22''    | \$56.90  |
| 15      | 14''     | x 17''    | \$71.00  |
| 30      | 18''     | x 29.25'' | \$103.50 |

Charred Oak:

|   |        |           |         |
|---|--------|-----------|---------|
| 1 | 7.5''  | x 8''     | \$59.18 |
| 2 | 8''    | x 10.5''  | \$63.90 |
| 5 | 10.5'' | x 17.25'' | \$91.73 |

Paraffin-lined Basswood:

|    |        |           |         |
|----|--------|-----------|---------|
| 5  | 10.5'' | x 16.5''  | \$35.90 |
| 15 | 14''   | x 23.25'' | \$51.80 |
| 30 | 18.5'' | x 29.25'' | \$84.80 |

Shipping to Colorado would be somewhere between \$5 and \$12, depending on UPS or USPS and the weight of the barrel. Obviously, your mileage will vary. I find it kind of surprising that you can mail a 30 gallon cask....

They also have oak water kegs (paraffin-lined, hinged top), rain barrels (40 gallon, oak or basswood, paraffin-lined), and nail kegs (pine, not lined, not rated for liquid).

Obviously, it was too late at night when I read this originally, since I don't even have the option of unlined. I'm considering getting one of the paraffin-lined, and one of the charred, just to see what the effects of the linings are.

They have lots of interesting other wooden things like bungs, faucets, etc. Also, there's a beer & wine-making section. It's kinda like a Whole Earth catalog, but oriented mainly on pioneer-like things.

Their address:

Cumberland General Store, Inc.  
Route 3, Box 81  
Crossville TN 38555

The catalog has a \$3.00 price tag on it, I don't know how serious they are about enforcing the price.

Subject: re: Cranberry Stuff

Mike Sharp <msharp@cs.ulowell.edu> writes, among other things about Samuel Adams Cranberry Lambic:

> o wheat malt is not used in a lambic (but I'll concede this point  
> since I've been known to use wheat malt too)

Not true...wheat is likely to be up to perhaps 1/3 of a lambic.

> o maple syrup is definately not used in a traditional lambic.

True, but there may be a non-malt sugar added to the lambics with fruit.

..  
I seem to think it would be the equivalent of invert sugar but I'm about 900 miles from my reference books. Anyway, they do add some "sugar for sugar's sake". Maple is hardly traditional, but it is mostly sugar which won't contribute anything to the body.

Mike goes on with one of the best examples of "damning with faint praise" I've ever seen (!)...and on the subject of Samuel Adams (the most over-marketed small brewery in the US) I'll not even attempt to gainsay him.

> ...The beer tastes like a very light beer (or my tap water)  
> with a slight hint of hops & cranberry/maple. I was rather  
> suprised with the lack of body/character and of the total  
> lack of any lactic sourness...

I'd be glad to hear other comments on fruited beers. My sense agrees with Mike (and with the way the fruited lambics are made) - that these should be rather more substantial than average.

I've been using an electric bin for mash and boil for nearly a year now.  
It  
is easy to use and I'm pretty pleased with it. But it does have  
disadvantages  
that make me feel I shall move on sometime. I did mention some a couple  
of  
digests ago, but to re-cap briefly, worst disadvantage first:

- Mine is slow to boil (3 hours for 5 galls) and goes off the boil every  
20  
secs when the simmerstat cuts out.
- You can't use it to heat sparge water whilst it's tied up mashing.
- You can't begin the boil as you sparge, as you have to clean the bin  
out  
first.
- It heats from the bottom, so you have to stir it up every 30 mins or  
so  
to avoid uneven mashing.

Nevertheless I like it and don't think I've wasted my money.

Not a chance! You'll never rest. Once satisfied with one brew, you'll  
think  
"now how about trying..." It's more than a life's work getting them all  
right. That's half the fun! The other half is consuming the product of  
course :-))))) The hard bit is having the patience to change only one  
variable at a time.

> and uses wooden kegs. (Did he win with a Belgian Brown?)

This was Mike Matucheski. He gave a talk at the last AHA conf. The article is in the summer '89 issue. He did win the Belgian category a few years ago with a beer he calls 'Goudenband'. His brew seems to be exclusively Belgian in character and he uses bottle cultured yeast (apparently obtained on one of his \_many\_ visits). He brought a few samples of his stuff to the unofficial lambic tasting (at the last conf.). It wasn't bad, but I would definately say it was horsey. This is a common character in Belgian lambics. Its the aroma you'd be into if you were a conoseur of horse sweat. Finally, Mike is making the conference beer for this year. Its a Framboise (did I let the cat out of the bag?). If nothing else, it'll be an eye opener for many people.

Subject: Wine/beer snobbery?

In Digest No. 774, Ken Weiss writes:

> What's next? Beer tastings complete with precious little commentaries?  
"A  
> woodsy little beerwith an insouciant nose, and a rascally finish.  
> Unpresumptuous, butsturdy." ARRRGHHH! If I wanted to be associated with  
> pretentious snobby weenies that drink for flavor and not effect, I'd  
drink  
> wine. Whew, I feel better now.

Not to start another flame (we've had enough, on other subjects), but I'd respectfully point out that to stereotype wine-lovers as "pretentious snobby weenies" is no more accurate than to stereotype beer-lovers as "fat, burping slobs."

I know Ken's tongue is visibly in his cheek here, but it bears occasional repeating that a lot of folks enjoy wine, beer and other fermented fluids (thanks, Martin!) as adjacent stopping points along a continuous spectrum.  
As a wine lover AND home brewer, I've got no problem with that.

But in these troubled times, when there are dark forces out there who would be happy to see a modern version of the failed experiment Prohibition return, I'd respectfully suggest that we ought to be seeking common cause among those who favor beer, wine or spirits, or any combination.

Subject: Re: re: rE...Re-using yeast

Bryan Gros writes:

-----  
:I was amazed to see bubbles in 10 minutes and a full fermentation  
:in 30 minutes. I had never seen it take off so fast. Unfortunately,  
:I don't drink my beer fast enough to do this often, but I'd like  
:to save some of this yeast.

Quite a few of us would like to re-use yeast that we've had good results with (to cut down the cost, among other reasons). But not all of us have the chance or time (or energy?) to brew successive batches so that we can repitch off the sediment in the secondary of the previous batch. There's always the technique for propagating some of the trub in sterile wort and using it within a week or so, but what if you need more time?

Now here's my question/suggestion:

-----  
What about culturing yeast from your own bottles?  
This is regularly done with Chimays and other imported beers, granted you don't have any other source for getting these yeasts.  
Could the same method be used here? Or is there a problem with culturing from such a small sample such a long time after it's been active (infections, mutations, or just plain old weakened yeasties).  
Maybe you can culture from several bottles-worth to increase the size. Presumably, recapping the empty bottles and storing them in the fridge a day or two until you have enough will not hurt the yeast.

This would allow you weeks/months before starting a new batch. Also you have the benefit of "tasting" the results of the yeast before you use it.

Has anyone tried this?

From: "Andy Wilcox" <andy@eng.ufl.edu>  
Subject: SS Bud Kegs (again)

After several months of not brewing, I'm ready to jump back in again. During the break, I've happened across several of the 15gal SS Kegs. I'd like to set up the "ultimate" all grain brewing system with these. Just as a preliminary guess, I'm thinking of using one for a boiling vat (natural gas powered), one for a lauter tun, and another for a fermenter.

I'd be very interested in hearing about what kinds of gas fired multiple keg systems that ya'll are using.

From: bliss@csrd.uiuc.edu (Brian Bliss)  
Subject: boil overs

All of my extract beers seem to foam over to a great extent, but my all grain batches come to a nice rolling boil without ever foaming up at all. Until last weekend, that is. I added .5 lb roasted barley to 1.5 gal water, brought to 152F, and added 2 tsp of amylase enzyme to do a partial mash. I let it sit for 20 min, turned on the heat, brought to a boil, and added 2 cans JB dark extract. It came to a boil without ever foaming over.

I never tried using amylase enzyme before. I hypothesize that it is the unconverted starches in the wort that cause the boil over, and that when I do the full mash of an all-grain beer, or at least a very complete partial mash, these are eliminated. Handy stuff, that amylase.

>since you have to watch out for boil-over again. So I normally  
>just use the "blow on" method to reduce the foam. This is tough  
>on those who hyperventilate easily, but is great in that you  
>don't have to worry about another boil-over happening that batch.

Boil over is caused by the formation of a viscous film of protein on the surface of the soon-to-boil wort. When the steam escapes upward at the onset of the boil, it blows a big wort-bubble all over creation. To prevent boil-over, I skim the creamy head of protein that forms in the pre-boil stage several times. Haven't had boil-over in years.

Boil-over usually doesn't occur after that initial 'steam-break'. I've always assumed that this is because the rolling action of the boil prevents another film of protein from forming. The cold water method may fail sometimes because the protein probably skims over again. The cold water would have returned the wort to a pre-boil temperature, preventing the rolling action of the wort which will thereafter prevent the wort-bubble action.

At least, that would be my guess.

And, no, this doesn't affect the head retention of my beers. There's plenty of protein left in the wort for that.

As for mesh:

A non-metal source of mesh is 'no-see um' mosquito netting from an outdoors hiking/camping shop. It easily withstands boiling temperatures.

And just when you thought the solder thread had run its course:

Is there a problem with antinomy in solder? Some lead-free solders contain 5%. Seems like someone had a disparaging attitude toward antinomy a couple issues back.

Sure is nice to have the Digest back to normal.

Bob Jones wrote in HBD 774:

> The real question I have is how do they release the nitrogen when you  
> open  
> the can?

Bob, I also wondered about this. I believe I have it figured out.

(This is all IMHO based on examining the can).  
At the factory, I believe they put a small quantity of liquid nitrogen  
into the plastic reservoir. The edges of the reservoir are sealed, but  
the  
small hole in the center is not. Before this liquid can boil off, they  
fill  
the can with beer, add CO2 and seal it. When the beer is poured in the  
can,  
it cannot enter the plastic dome because the nitrogen is bubbling out.  
When  
the can is pressurized, the beer presses down on the dome causing it to  
seal  
and trap the nitrogen. When the beer is opened, the center of the dome  
pops  
up, allowing the now gaseous nitrogen to jet into the beer. It is really  
a neat idea.

<Beer exerting pressure>

\_\_|<sup>—</sup>||<sup>—</sup>|\_\_ (side view of circular dome)

^^ The edges are always sealed  
^^ pressure causes this junction to seal against the base.

Subject: WYeast #1084 Irish Ale yeast

In response to the question on (lack of) carbonation using Wyeast Irish Ale yeast, I have never had this problem. I used it in an Irish sweet stout and it produced quite a nice, creamy head. I currently have another stout in the secondary and the yeast in it is now thrice pitched Irish Ale yeast. I used it first in my Christmas beer, saved the dregs from the secondary, pitched it into my "Yellowdog Mild", saved the dregs again, and then pitched into the current stout. I have noticed that the primary fermentation has gotten less vigorous each time. The first time (Christmas beer), I had some blowoff even though I was fermenting 5 gallons in a 7 gallon carboy. The second use yielded about a 4" - 5" kraeusen, and this batch only rose up about 1". It still ferments well (starting gravity on my current batch was 1.051 and was down to 1.016 after 4 days when I racked it) and I still have had no carbonation problems. The Christmas beer has a thick, brown head that lasts until the glass is empty. This yeast is my personal favorite. Just another data point for your survey.

From: man@kato.att.com

Subject: Sanitizing Kegs

After reading George Fix's posts about SS fermenters, I thought of a few questions.

George said that sometimes boiling water wasn't good, because high iron content would be a problem. Someone else contradicted this, I believe, but that isn't important. My question is this:

Can I take a 15 gal Bud keg and put it on my King Kooker and put, say, 2 gallons of distilled water in it. Then boil it all out and let the steam sanitize the fermenter ? Remember, Bud kegs are NOT rubber or plastic lined on the outside, they are all metal. My water supply could probably be used, but distilled could be used for problem water supplies.

Any comments ? For me, with my flame thrower burner, this makes a very easy way to sterilize without any chemicals.

BTW, my local beer distributor sold me three 15gal Bud kegs for \$10 each. I plan to use 2 as fermenters and 1 as a combo masher/boiler (and maybe a lauter tun) to make 12 gallon batches.

Subject: Priming with DME syrup

Kent Dinkel got flat beer because he didn't use enough DME. One cup of DME has only 0.8 cup of malt extract solids, only 3/4 of which is actually fermentable. So, about 3/5 of a cup (less than 2/3 cup, by my primitive math)

is fermentable. To get the same carbonation you would get from 3/4 cup corn sugar, you would need to use 1-1/4 cup of any syrup.

From: arf@ddsw1.mcs.com (Jack Schmidling)  
Subject: GRAINMILL

To: Homebrew Digest  
Fm: Jack Schmidling

SUBJECT: Milling Grain

WARNING!!! This could be construed as a COMMERCIAL, close your eyes for ten seconds if it offends you.

Do it NOW, or forever hold your fingers.

.....

Anyone who uses whole grains quickly realizes that makeshift grinders and food processors are all but totally unsatisfactory for milling malt. They create vast amounts of flour that make clear beer virtually impossible. They leave large amounts of grain untouched or merely broken. They pulverize the husks, which severely limits the quality of the filter bed when sparging. They are only used because nothing else is available that fits the budget of even the affluent home brewer.

I just finished making a real grain MILL. This is not a grinder, blender, slicer or shredder. It is a genuine roller mill. It crushes malt, leaving ALL of the husk in tact and a minimum of flour. Not one grain can get through it without being properly milled. It does exactly what a malt mill is supposed to do.

I built it out of surplus parts and a weekend's worth of labor. There are enough parts left at the surplus house to make about 5 more. If anyone is interested, I could build/sell them for about \$200.

Send me email and I will provide further details to anyone interested.

.....COMMERCIAL DISCALIMER.....

I included the cost to avoid being inundated with email from bargain hunters.

js

P.S. I will ignore all flames, private or public.

From: grumpy!cr@uunet.UU.NET (C.R. Saikley)  
Subject: Priming Experiments

The recent talk about the merits of priming with DME vs. corn sugar reminds me of an experiment I did some time ago. I split a single 5 gallon batch into 3 smaller batches at bottling time, and primed them as follows :

Batch A - 1/4 cup corn sugar (remember it's 1/3 of 5 gals)

Batch B - 1/3 cup DME

Batch C - 16 fl oz of sterile wort

The sterile (all grain) wort was pulled out of the original brew just prior to pitching. I kept it in a sterile jar in the fridge for the 3 weeks between brewing and bottling.

About one month after bottling, I conducted a blind tasting with 5 knowledgeable homebrewers and simply asked for preferences. The results were unanimous. All 5 liked batch C the best. Much to my surprise, 4 of the 5 liked batch A better than B.

Carbonation levels were very close in all three batches, but batch C had a much finer bead, and was described by some as "smoother" than the others. I don't recall why A was preferred over B, and my notes aren't handy.

Admittedly, this is all pretty crude and in no way conclusive, but it at least suggests that our homebrews may benefit from priming with wort rather than sugar or DME. Anyone else out there experimented along these lines???

From: rcd@raven.eklektix.com (Dick Dunn)  
Subject: notes from a tour of Anchor

It's been quite a few years since I last got to tour the Anchor Brewery, but I finally got there again today. I figure a bunch of this stuff is of interest to homebrewers, since Anchor is really the paragon of small breweries in the US...in some sense they're the most significant American brewery if you're considering criteria other than size. I don't want to spend too much bandwidth here, so I'll keep it pretty terse. (Ask if you want more detail.) If you are in the Bay area, go take the Anchor tour. Don't fuss at me; just go do it! Be sure to call ahead; you need reservations.

Overall brewery stuff: 3 vessels--mash tun, lauter tun, brew kettle--all beautiful copper. Brewery is a showplace. Brewhouse 110 bbl capacity. (This is a brewer's barrel - 31 gal.) 37 employees. 1990 production 68k bbl; 1991 production est 75k bbl. (not bad growth!)

Current beers: 6 were presented for tasting after the tour; notes such as I gathered:

Wheat: about 70% wheat malt, rest pale malt, alcohol 3% wt  
Steam: 3.9% alc, combination pale and crystal, all Northern Brewer hops. They formerly used mixture of hops (I recall Galena mentioned on earlier tour), now only NB  
Liberty Ale: all pale malt, only Cascade hops, alc 4.5%  
Porter: mix of pale, crystal, chocolate malt. Forgot to ask about hops  
Old Foghorn: barleywine, 7%  
Christmas: spiced brown ale, fairly strong (but < OF)

Brewing process (Steam typical): 3 day primary ferment, 3 weeks in secondary, krauesened, then centrifuged, filtered (diatomaceous earth), flash pasteurized (170F for ~15 sec) and bottled. Liberty Ale is dry hopped.

Misc notes:

All alc given by weight; multiply by 1.25 for volume figure

All barley malt is from 2-row.

Oxygen - chemist says they end up with about 250 ppb in bottle. Bottling process is careful to let the beer foam up a bit, thus headspace is CO2.

They do reculture their yeast--carefully! (Usual commercial procedure--wash, adjust pH?) They're watching it for mutation all along. They don't reculture from Old Foghorn because of the strength.

I asked about the current "cold filtering" (and not pasteurizing) hype that's currently the rage for television beers. They say it's a process developed by Sapporo, licensed in US. Very expensive, for large breweries only. Also some doubt whether their beers would make it through the filter without removing a lot of interesting stuff, let alone clogging the filter.

Old Foghorn may be available in bottle again sometime early next year.  
The bottling line can now handle it; the problem is switching it between the two bottle sizes. (Background: Since the very first OF, Fritz has insisted that it go in the little "nip" ~ 6 oz bottles because of the strength. This is a massive vexation at all stages of bottling/handling.) The new bottling machines are said to be able to handle the bottles, so let's hope. Meanwhile, it's available on tap here and there...nirvana.

I was really struck by how much different Liberty Ale tastes fresh from the tap as compared to bottles. On tap, it seems more like a cross between Sierra Nevada Pale Ale and Celebration - the Cascades really come through in a way they never have in the bottle.

Anchor is an inspiring place to visit--both from the brewing standpoint and because it's a business run the way a business should be: They all know what they're doing; they believe in it; they don't cut corners; they are out to do the best job they can, and they do. If you want to learn about brewing, this is one of a couple places to start.

> > since I've been known to use wheat malt too)  
>  
> Not true...wheat is likely to be up to perhaps 1/3 of a lambic.

My statement has confused more than a few people. Lambics do not contain  
wheat MALT they do contain UNmalted wheat. In fact, up to 40% of the  
mash is UNmalted wheat. Of course some of the pencil pushers are moving  
toward replacing part of this with rice or corn....

>  
> > o maple syrup is definately not used in a traditional lambic.  
>  
> True, but there may be a non-malt sugar added to the lambics with  
fruit...

The only time I've heard of non-malt sugar being added is when making a  
Faro.

I'm sure some producers do it, and it would seem likely that Lindeman's  
with their soda-pop sweetness probably is one, but it is not  
traditionally  
done. Of course many producers are abandoning whole fruit and going to  
syrups so who is to say whats happening now. (again, thank the bottom  
line  
for this)

Subject: Re: Cranberry Lambic

Hello

On the subject of decoction vs infusion mashes, Al Korz asks why would PU use a triple decoction mash? The malt that PU uses is specially made for them and is apparently extremely under modified.

Dave Miller tells me that many of the German breweries are now using single step infusions instead of decoction mashes in order to save on energy costs.

Fred Eckhart recommends using a protein rest even for pale ales, so last summer I tried two batches of bitter, one with a protein rest and one using my usual method of a single infusion at 153F. I couldn't detect any difference between the two batches. However, I always let the trub settle overnight in my fridge before racking to a second carboy, I then dump the wort through a funnel into another carboy and pitch the yeast starter. This seems to aerate the wort pretty well so that I always get a reasonably short lag time, even though the temperature is low (about 50-45 F) at pitching time. Using this method I always get a bright beer regardless of wether or not I use a protein rest.

Subject: Guinness in a can (again)

Boy, did I screw up! Yesterday I posted a "how I think it works" on the new Guinness in a can. Last night I examined the carbonation device more closely and realized my last posting was quite incorrect.

Previously, I had cut into the can from the side and did not totally remove the cartridge. Last night I took it apart. It is a sealed plastic container with only one pinhole. I suspect that the pinhole is not completely drilled through at canning time. They may just leave a very thin membrane. I suspect they pre-charge these cartridges with Nitrogen and keep them frozen. At temperatures low enough to keep the nitrogen liquid and not boiling, the membrane wouldn't be under much stress. When the can is at drinking temperature and opened, the membrane would rupture, releasing the Nitrogen...

Subject: Removing plastic keg odour?

I recently invested in a plastic keg, I think its called a Eurokeg \_ Its a six gallon barrel shaped vessel. The problem is that is has a very strong plastic/chemical odour. How do I get rid of this smell? I tried soaking it overnight with a 10% bleach solution, but the smell still persists. The manufacturer recommends using SPG chemical cleaner, which my local homebrew store doesn't stock. Is SPG just a cleaner or will it also help remove the smell? Some have recommended sodium bicarbonate - I'll try that tonight, but I somehow don't think it will work. Any ideas? Also -what is the smell - unpolymerized monomers perhaps?

Subject: Silver Solder

The concern over antimony in silver solder should be laid to rest. Ingesting small amounts of antimony is harmless. Pewter contains antimony, and acid foods can leach small amounts of it. The real danger lies in inhaling it. Antimony in the lungs is deadly, in the stomach is not. I am talking of course of trace amounts.

BTW, Anheuser-Busch does NOT want people taking their kegs, and has in some flagrant cases, taken legal action.

Subject: Avoiding Boil Overs

>>From: IO10676@maine.maine.edu

>>When the wort forms a head and starts making a run for the edge  
>>of the pot, you pour a splash of cold water in it. Puts it  
>>right in its place, which is back in the pot.

>And Martin sez:

>>I figured this was worth a question to the digest. I have  
>>resorted on occasion to the "cold water" method, but dislike it  
>>since you have to watch out for boil-over again. So I normally  
>>just use the "blow on" method to reduce the foam. This is tough  
>>on those who hyperventilate easily, but is great in that you  
>>don't have to worry about another boil-over happening that batch.

To which Kinney adds :

>Boil over is caused by the formation of a viscous film of protein on  
>the surface of the soon-to-boil wort. When the steam escapes upward  
>at the onset of the boil, it blows a big wort-bubble all over  
>creation. To prevent boil-over, I skim the creamy head of protein  
>that forms in the pre-boil stage several times. Haven't had boil-over  
>in years.

Another technique to minimize the chance of boiling over is to  
add a portion of your bittering hops before the boil commences.  
A common practice in commercial breweries is to add about 10% of  
the kettle hops for this purpose. I've tried it at home, and it  
definitely helps. You can still have a boil over, but it's less  
likely.

If Kinney's hypothesis is true, I'd speculate that the mechanical  
action of the hops floating around on the surface breaks up the  
viscous film.

>  
> Has anyone tried this?

Yes, I do this routinely. I buy a package of Wyeast and brew a batch with it.

I'm very anal with this batch (ooh, there's that word again. I guess we're just an anal bunch huh? :-). I save a sixer of this batch to use as fuel for

yeast starters (I always use about a pint starter). I use the yeast sediment in the bottom of one bottle to make a yeast starter. That gives me seven batches for the price of one Wyeast packet. I just used up the last bottle

from a sixer of British Ale yeast. That bottle was over a year old and had been stored at room temperature which can get up near 80F in the summer

(I'm in the Central Valley of Calif. which gets mighty toasty in the summer!).

Note that all succeeding batches after the first are first repitchings so there are no issues dealing with mutations and such. Oh, and the resulting

beer from that last bottle was good too :-). Using this method I can keep several strains of yeast around and at hand to brew with.

Subject: The extra ingredient in a can of Guinness draught.

I have yet to have a can of draught Guinness but I just remembered an article on the mechanism behind the can. After some hunting I tracked it down. I was debating on submitting a copy of this to the list but I decided that no one would turn me in. In any case I'll give a plug for the publication NEW SCIENTIST, its a weekly publication from Britian that covers the latest developments in science, engineering, technology etc. Check out an issue at your local library or buy a copy at a newsstand.

Here goes enjoy a Guinness while reading New Scientist :^)

The article is titled:

"The extra ingredient in a can of draught Guinness"  
NEW SCIENTIST, 22 July 1989 p. 34

Written by Andy Coghlan

"Guinness, the maker of the black, creamy beer for which Ireland is famous, has mangaged the impossible. The company has succeeded in canning a form of Guinness that, until recently, was available only on draught in public houses and restaurants.

The world's seven million Guinness lovers have a choice betwen two products: draught Guinness, a thick, smooth stout with a creamy-white head and Guinness Extra, which is available in bottles and cans. Guinness Extra has a coarser texture than draught Guinness and a head that is less smooth and creamy.

According to Alan Frage, the product development director at Guinness, the majority of people who drink draught Guinness do not drink Guinness Extra. "We knew that draught Guinness in cans would give them the opportunity to enjoy their favourite brand at home as well as in the pub," he said.

Forage and his colleagues began working to solve this problem in 1984. After four years of development work costing 5 million pounds, Forage and his team had perfected a tiny diaphragm, made of plastic, that cracked the problem.

They tested more than 100 different techniques before settling on the so-called "in-can-system". People who buy draught Guinness in cans, which have been available throughout Britian since March, will find this system if they slice open the empty can. The device, which sits on the base of the tin, helps to mimic the tap in the pub.

Draught Guinness owes its creamy texture to a surge of bubbles in the beer as it passes through a series of tiny holes in the special dispensing tap. The tap has a system of tiny holes which creates pressure differentials.

These differentials force the gases out of solution and produce a "surge". Unfortunately, the gasses wil remain in solution if people simply pour Guinness from the barrel into a glass.

The new system essentially mimics this process from the inside of a can. The device is a plastic chamber with a minute hole at the top, which sits on the base of the cans.

For the system to work, the pressure in the can must exceed atmospheric pressure. The canners fill the can with beer that is cold enough, at between 0 C and 1 C, to retain gas that would bubble out of solution at higher temperatures.

The canners put 440 milliliters of Guinness in a can that can hold 500 milliliters, in order to leave enough room for the creamy head to form.

They also "dose" the beer with extra nitrogen, which raises the pressure when the can is opened.

Once the lid is on, the pressures in the can and inside the chamber reach an equilibrium that forces beer and gas into the device. When someone

opens the can of beer by pulling the ring-pull, it initiates the same process that happens in a tap for Draught Guinness.

As the ring-pull comes off, the resulting drop in pressure forces beer and gas out of the chamber through the tiny hole, creating small, stable bubbles.

As the bubbles rise up through the liquid, they act as centres where other bubbles form. This is what causes the characteristic surge. The

number of bubbles created and the small diameter of the bubble dictates the

density of the head of the drink and its creaminess. The smaller the bubbles, the creamier the texture, says Forage,

The only remaining problems for the designers related to the canning process. They had to invent a filling device that expels oxygen from the can, because the gas impairs the flavor of the beer.

Now, Guinness has patented the system and owns the registered designs of all the engineering equipment that is unique to the packaging line.

The secret for drinkers, says Forage, is to make sure that the can is cooled in the refrigerator for two hours before serving. Otherwise, the

beer bubbles out uncontrollably as too much gas has come out of solution to

create excessive pressure. He says that the product is selling much better

than expected"

From: Bob Jones <BJONES@NOVA.llnl.gov>  
Subject: Mead Making goes Hi-Tech

!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!  
!!!!!!!!!!!!!!!!!!!!!!!!!!!!

Following is a (rather lengthy) post Micah gave me to post for him. He regularly reads the HBD that I give him via footnet. I think he feels guilty for being a HBD reader only. This contribution is solely his. I am merely acting as a conduit for his ideas and opinions.

Bob Jones  
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!  
!!!!!!!!!!!!!!!!!!!!!!!!!!!!

In an effort to put useful information on this net I am posting this draft of a mead making article that I'm doing. Hopefully it contains some answers to various questions about mead that I've seen posted.

WASSAIL Micah Millspaw 12/4

The oldest of beverages ,the newest of techniques. High tech has come to mead making.

Because of the commitment of time involved, many people are quite hesitant about getting into mead making. Generally it takes less equipment and the ingredients are cheaper than is needed for brewing. Someone who is extract brewing is already covered (equipment wise) to be a mead maker.

To those veteran mead makers out there, you know the time and effort (mostly time) spent on a mead can be exceptionally rewarding. On the other hand something could go wrong and unnoticed for a year or more and that can be very disappointing. The amount of time we put into a mead can make the loss seem much worse than the loss of a batch of beer. It is also possible to radically reduce the length of time it takes to produce a consumable mead/ melomel/ methiglin.

Let us consider some ways of reducing or eliminating the chance of disaster striking your mead. These efforts should also shorten the fermentation time.

Meads are known to have long, slow fermentation times (1-4 months is common). This long term ferment tends to tie up a carboy that might be used more productively (for beer maybe?). The reason that it takes a long time to ferment out is that honey is woefully lacking in the nutrients that yeast needs to effectively metabolize the mead wort.

The cure is to add yeast nutrients. Yeasts like ammonium salts, these are those little white crystals available at most homebrew shops. These will do the job of sustaining the yeast ,but there are some nasty side effects. If too much of the ammonia salt crystals are used their taste and aroma will remain in your mead(yuk). The only way to get rid of the ammonia taste/smell is to age it out, this often takes years. Fortunately there are better yeast nutrients. The best that I have used so far is bacto nitrogen base yeast nutrient from DIFCO. This nutrient is available from pharmaceutical and laboratory supply houses. The difco has no flavor/ aroma side effects but is rather expensive, the plus is a small amount will do lot. Detailed information for amounts to use should be provided when you purchase the nutrient. Recently a yeast nutrient for meads became available from Great Fermentations of Santa Rosa which they claim will ferment out a mead in three weeks at 70 degrees F. I have used this nutrient several times and have found that if the temperature is maintained it is possible to ferment out in three

to four weeks. This nutrient is reasonably priced and is easy to get.

Having addressed the need for yeast nutrients, it is a good idea to have some yeast to go with them. Liquid culture wine and champagne yeasts of high quality are easily obtainable. Many dried yeasts are also of interest to the mead maker. One of the most important features of a yeast to the mead maker is alcohol survivability. Meads in general and especially high gravity meads have alcohol levels far exceeding that of most beers.

Prise de mousse (*S. bayanus*) and Pasteur champagne (*S. cerevisiae*) are excellent for traditional and high original gravity meads. Epernay, a wine yeast is very complimentary to melomels (fruit meads). Most wine yeasts are entirely adequate for mead making. Try a few different ones if you're looking for something unique in flavor. It is possible to use ale or lager yeasts (I've tried both) to ferment mead, I've been less satisfied with the results (flavor) when compared to meads made with wine or champagne yeasts.

Some mead makers like to use "killer yeasts", these are identified by the letter K preceding a name or number. The killer yeasts work well in conjunction with other *Saccharomyces* yeasts. The "killers" function is to eliminate competing wild yeasts. It is not normally necessary to use this type of yeast unless you choose not to boil your mead wort. (the not boiling is part of an ancient process and will not be discussed here)

It is important to prepare a yeast starter so as to have enough yeast ferment your mead. As there is a great deal of information available

about making yeast starters, I'll not go over it much. The only suggestion that I will give is to use confectioners sugar instead of dry malt extract in your starter, this removes the chance of strange flavors in traditional meads.

The properly prepared yeast in conjunction with the essential yeast nutrients should result in a vigorous 3-4 week ferment. It is important to allow adequate headspace in the fermenter and the blow off method is recommended.

After your mead has reached the desired specific gravity, it should be racked into a soda keg. Kegging the mead gives you control over carbonation levels and oxygen exposure problems. It is also possible to arrest the fermentation at a desired point by kegging and sub-micron filtration. I have had good luck adding fruit concentrates and essences to filtered meads. They are very stable compared to bottle conditioned fruit meads.

A clean soda keg should be blanketed with CO<sub>2</sub> prior to racking in order to limit oxygen exposure. Fermented meads are very susceptible to oxidation. Oxidation will result in some very unsatisfactory flavors in the finished product.

Decide if your mead is to be sparkling or still (flat). If the mead is to be still, rack into the keg, put on the lid and seal it with as low a pressure as possible (I recommend filtration). If the mead is to be sparkling I strongly recommend force carbonation. I've found that using "methode champenoise" with mead to be unpredictable and usually unsatisfactory. Rack into the soda keg, seal it then pressure up to 30-40 psi and set it aside for a while. Mead seems to be slow to absorb carbonation (compared to beer) and since mead should improve with reasonable aging this will all work out nicely.

What to do with a 5 gallon keg of mead? It is possible to put it on draft in your home. The drawback is that the mead when present in large amounts could overwhelm you. The option is to counter-pressure bottle from the keg. Most counter-pressure fillers allow you to purge the bottle with CO<sub>2</sub> prior to filling. Removing the normal atmosphere from the bottle is absolutely necessary to limit oxygen exposure. The mead that you're putting into the bottle should be a finished and stable product and you don't want the oxygen to ruin your efforts.

Before bottling, sample the kegged mead to ascertain its conditioning; age, carbonation level, etc...Cool the keg of mead down to

35-40 degrees F. so as to improve it ability to hold CO2 in solution.  
Clean your bottles and fill them up. Enjoy.

Micah Millspaw

From: Bob Jones <BJONES@NOVA.llnl.gov>  
Subject: Multi-keg Brewerys

Reply to Andy Wilcox's request for info on multi-keg brewing systems.

I use 3 of the 15 gal AB kegs. Their functions are : hot liquor tank, mash tun and kettle. All three are natural gas fired. I built a stand that supports the hot liquor tank and the kettle. The mash tun sits on a short stand on the floor. A mag drive pump moves the mash liquid from the mash tun to the kettle. I have essentially taken the classic four level brewery and made it two levels by employing a pump. Makes everything easy to look into without a ladder. I use an immersion cooler to cool the wort in the kettle before transfer to the carboys at ground level. The unique thing about my brewery is that the whole system is two kegs wide ( about 3 feet) and five feet tall. The mash tun is placed under the stand for storage when not in use. My wife even made me a cover for the brewery so it can be covered when not in use. I set out to design the most compact, flexible, efficient brewery that I could conceive of when I designed it. It has worked extremely well for about 8 years with few modifications. I did add the gas fired stand for step mashing a few years ago. I had been brewing 5 gal batches on the kitchen stove for about 5 years and was ready to get out of the house and in the garage. I only do step mashes for lagers but I always do a 170 mash out for all brews. I think this improves the mash efficiency and makes the beer more stable when bottled.

Good luck on your brewery. Bob Jones

From: hartman@varian.varian.com (John Hartman)  
Subject: Crushed Grain Stability, pH Meters, and Copper Scrubbers

Greetings All--

- --Stability of Crushed Grain--

I was wondering if some of the more experienced grain brewers can tell me just how long I can expect my crushed grain to keep if it's kept in a cool dry place, like say wrapped in paper and stowed in food grade plastic. How long have you kept crushed grain before using it?

- --pH meter sources--

If you interested in pH meters, I have two sources besides Edmund Scientific. The first source is:

Omega Engineering Inc.  
P.O. Box 4047  
Stamford, CT 06907  
FAX: (203)359-7700  
Phone Orders: 800-826-6342 (Visa, MasterCard, or American Express)

Here's their product:

Litmustik High Performance pH Tester, Model PHH-1X

Range: 0 to 14 pH  
Resolution: 0.1 pH  
Accuracy: +-0.2 pH  
Battery 4 x 1.4V  
Battery Life 1000 hrs (it keeps going and going and ... ;-))  
Operating Temperature Range: 0 to 50 C  
Dimensions: 5.91" H x 1.26"  
Weight 0.13 lbs.  
Cost: \$44.

It comes with batteries too. It's basically a pocket-sized meter featuring an "easy to read" LCD display and "single point calibration". I have no affiliation with them nor have I purchased or used one (yet ;-)). I called in and asked for a catalog. I received 50 lbs. of catalogs for all sorts of laboratory instrumentation, which is regrettable. Everything else in the catalogs is expensive with the exception of this meter. They don't look like they are exactly interested in us small fry so if you call to order play it cool. The other source is a familiar one--William's Brewing:

William's Brewing  
P.O. Box 2195  
San Leandro, CA 94577  
PHONE Orders: 510-895-2379  
FAX Orders: 510-895-2745  
Brewing Advice: 510-895-2744

Their newest catalog now features a pH meter very similar to the one above. It too is a handheld electronic meter with +-0.2 pH accuracy, comes with batteries and costs \$40. No I haven't bought this one either, nor am I affiliated. William's also sells 250 ml of pH 4.01 calibrating solution for \$6.90 which can be used to adjust their meter. I suspect you can use it to calibrate the Omega meter as well.

- --Copper Scrubbers--

I had trouble the first time I used one as a siphon filter. I placed it in a cheese cloth bag and attached it to the end of my vinyl hose with a sturdy rubber band. After one gallon of wort had passed through, the siphon came to a complete stop. Upon closer inspection the cheese cloth was found to be completely covered with a very fine film of trub. Furthermore the rubberband was constricting the flow as the vinyl had softened up in the hot wort. (I use a counter flow chiller). This effectively prevent any further flow through the siphon. Since then I've abandoned the cheese cloth and gone with just the scrubber loosely bound with a rubberband. It works quite well now with whole hops. I haven't tried it with pellet hops though. I know that I'm letting some of the trub silt through this way but most of it is caught by the hops which act as a filter themselves as the wort drains.

Cheers, thank you for not flaming, and have a nice day,  
John E. Hartman (hartman@varian.varian.com)

Subject: Now About That Wheat ...

In HOMEBREW Digest #775, the famed Dick Dunn said:

>Mike Sharp <msharp@cs.ulowell.edu> writes, among other things about Samuel

>Adams Cranberry Lambic:

>

>> o wheat malt is not used in a lambic (but I'll concede this point  
>> since I've been known to use wheat malt too)

>

>Not true...wheat is likely to be up to perhaps 1/3 of a lambic.

Important point, Dick: UNMALTED wheat is from 20% to 60% of every commercial lambic recipe I've seen. I know of no lambic brewer using wheat malt. That was the distinction Mike was drawing.

>> o maple syrup is definately not used in a traditional lambic.

>

>True, but there may be a non-malt sugar added to the lambics with fruit.

..

Mike's argument turns on the question of traditional usage of the term "lambic" (which has come to be a regional appellation in all but law, implying a very specific set of traditional practices and ingredients). Within the traditional definition of the style, fruits are acceptable adjuncts; maple syrup is not. I have no big hamburger with using maple syrup in beer, but don't call it "lambic".

>... Maple is hardly traditional, but it is mostly sugar which  
> won't contribute anything to the body.

But it WILL contribute to the flavor!

Sorry to nitpick, but the issue here is a brewery ripping off the name of a "hot" style to sell a beer that has very little in common with beers having a legitimate claim to the title. Mike was pointing out that neither their methods nor results corresponded to the accepted usage of the term, and from what I saw in Belgium and have read in the literature, I have to agree with him!

From: Conn V Copas <C.V.Copas@loughborough.ac.uk@hplb.hpl.hp.com>  
Subject: Yeast culturing and Whitbread

A note of caution. The majority of my efforts at culturing from commercial brews (Guinness, Coopers, draught Flowers Original) have resulted in mildly infected starters. Given nutrient and oxygen, most showed reasonably short lag phases, and I don't attribute my problems to poor technique. As reinforcement, I recently read an interview with one of the Bass Worthington technical staff, who expressed horror at the idea of home brewers attempting to culture from any bottle of White Shield older than a couple of months. And then of course there was the Zymurgy special yeast issue which concluded that uninfected dried yeast is the exception rather than the norm.

What all this leads to is that maybe every starter should be considered for disinfection procedures. I don't have the resources or the patience for separating colonies on agar, so have tended to opt for chemical warfare, namely, acidification followed by sulphiting. Wheeler recommends using mineral acids (sulphuric in my case) to achieve a pH of 2.5, held for 6 hours. The sediment is then strained off into a new starter medium. Winemakers typically employ the equivalent of 1/4 teaspoon sodium met per gall, and presume that 24 hours ejects most of the volatile sulphur compounds.

I'm a fraction confused about the mechanism of these techniques, ie, whether they inhibit bacterial growth, or kill existing cells. This has implications for the sequence of use. If the former, they should be applied prior to pitching into the starter, in order to give the yeast a competitive edge. On the other hand, sulphite is an anti-oxidant, so maybe the best sequence is acidify the dregs of the starter bottle, culture, then hit with sulphite after the yeast has gone anaerobic. Opinions anyone? In either case, I presume a starter culture at the aerobic phase is ultimately required.

More musings. After heroic efforts to attain an uninfected Flowers culture, I recently read that it is probably the Whitbread 'B' strain anyway. Roger Protz, in the latest issue of "Whats Brewing", slags this strain off as lacking character and as having acclimatised in some unspecified fashion to worts containing wheat adjuncts. For what its worth, he believes Whitbread's practices of using up to 15% unmalted wheat flour, or malted wheat, result in undesirably 'glutinous' brews. I sometimes wonder whether CAMRA's politics may interfere with its sensory capabilities, but that's another story. The yeast itself, according to G. Fix, is a mixture of 3 strains, and I'm wondering whether any of the aforementioned disinfectant treatments are likely to change the balance. And does it have any resemblance to the

dried Whitbread yeast available in the US ?

Subject: Legality of importing beer (Scott Welker)

In HBD 775, Rich Steuven writes:  
>Truth, Fiction, or Urban Legend:

All beers imported into the US are required to be pasteurized  
and/or to have chemicals such as \_formaldehyde\_ added to them.

Of course, adding formaldehyde would violate the Reinheitsgebott (beer  
purity law) of Germany. While the law is no longer fully enforced, it's  
largely followed (anyone know of any negative examples here?). So  
leaving out the nasty chemicals appears legal, thank goodness, because  
my existence would be a pretty sorry one without German beer!

That part about pasteurizing, though, that may be true. I'm skeptical,  
however...when I lived in Japan, many beers claimed to be "draft", which  
my limited ability to read Japanese interpreted as "mechanically  
purified",  
i.e. filtered. Several of those beers are available here (sadly, not  
Yebisu).

Subject: SA Cranberry 'lambic' batches

From what I have heard (From the local package store and a friend who recently toured the Sam Adams brewery) there were three batches of Cranberry Lambic Brewed. One batch made its way into the 12-pack case, one into Kegs and the third into all lambic six-packs. All three batches are significantly different in taste! (I don't know if they are different in recipe.) The kegged version is much lighter tasting than the six-pack version. I have not yet bought a 12-pack, but have heard from a friend that has had all three that it is somewhere in between the two others. The six-packs were available in

Did they explain why the kegs version of Samuel Adams Cranberry Beer is so horrible - lager beer with cranberry juice... :-b

Last year's version was very good. This year's is terrible.

About adding Coca-Cola to the brewing process and then wanting to try it with ginger ale. That may very well be the secret to brewing a ginger beer - flat ginger ale! The sugar is already there, and the flavor too, and you could substitute some of the water you use with some ginger ale soda...

**Subject: re: Kitchen Aid grain mill**

Ted asked about using Kitchen Aid's (formaly Hobart) grain mill attachment instead of a corona style mill. I looked at this when I was looking for a mill, and at \$145 for the kitchen aid attachment, it hardly seemed worthwhile. I bought a Corona from Alt Bev for \$41.

One thing I have yet to do however is figure out how to easily attach the Corona to the Kitchen Aid; it should be easy but I haven't had the time. The problem with using a drill is that it's hard on the drill to turn that slowly under load (at least mine gets real hot) and hard on me controlling the speed. I use the hand crank at the moment. Works fine.

From: 105277@essdp2.lanl.gov (GEOFF REEVES)  
Subject: A quote for the season

Here's a little something to stir warm memories. It's from Thomas Hardy's "The Return of the Native" which I've been reading lately. It describes a Christmas scene which seems appropriate even though in this case the carolers are serenading two newlyweds.

[Wildeve, their host] produced a stone jar, which threw a warm halo over matters at once.

'That's a drop of the right sort, I can see,' said Grandfer Cantel, with the air of a man too well-mannered to show any hurry to taste it.

'Yes,' said Wildeve, 'tis some old mead. I hope you will like it.'

'O ay!' replied the guests, in the hearty tones natural when the words demanded by politeness coincide with those of deepest feeling. 'There isn't a prettier drink under the sun.'

'I'll take my oath there isn't,' added Grandfer Cantel. 'All that can be said against mead is that 'tis rather heady, and apt to lie about a man a good while. But to-morrow's Sunday, thank God.'

'I feel'd for all the world like some bold soldier after I had some once,' said Christian.

'You shall feel so again,' said Wildeve, with condescension.

'Cups or glasses, gentlemen?'

'Well, if you don't mind, we'll have the beaker and pass 'en round; 'tis better than heling it out in dribbles.'

'Jown the slippery glasses,' said Grandfer Cantel. 'What's the good of a thing that you can't put down in the ashes to warm, hey, neighbours; that's what I ask?'

'Right, Grandfer,' said Sam; and the mead then circulated.

Best Wishes for the Season  
Geoff

Subject: Controlling boilovers

I thought I would add to the ongoing thread on techniques to control initial kettle boilovers. I keep a spray bottle of water handy and just spray that foam away. I use a 1 quart size sprayer and can adjust the spray nozzle for max effect. Get a new one, their cheap(ie don't clean out a window cleaner bottle). This has worked well for me for a long time.

If I am going for a lighter flavored brew I might skim the scum that forms the second time around. My experience with adding hops before the boil is it causes MORE foam up. I always wait about 10-15 minutes before first hop addition.

Subject: STUFF

To: Homebrew Digest  
Fm: Jack Schmidling

From: "Dr. John" <JELJ@CORNELLA.cit.cornell.edu>  
Subject: Mashing & chilling

Your arrogance makes responding in kind irresistable.

>Jack Schmidling, in #764, in your second "Stuff" posting, you claim that if the boiling of the liquid under the false bottom in a direct-fired mash tun could be controlled, then you would be gaining the benefits of a decoction mash. Then in #771 you talk about boiling puny little quart-sized portions of the mash as though this is decoction mashing.

If you took the trouble to understand the article instead of looking for something to flame, you would note that the number of quart-sized portions actually brought to a boil, represent a significant proportion of the total mash volume.

> Jack, you appear to be confused as to just what decoction mashing is. May I suggest that you pick up a copy of Noonan's book and read it, or re-read it if you already have it.

Again, if you took the trouble to read the article, you would note that I even quote from Noonan in it and many other articles I have written.

>In fact, the first one (boiling the liquid under the false bottom) would only result in deactivating the enzymes.

I would be most interested in knowing just what the difference is in wort boiled under and within the mash and that boiled separately.

> I'd be interested in hearing what the source of your information on decoction mashing is.

I used your favorite reference and added a little common sense and came up with a much simpler method that seems to do pretty much the same thing. If you find that beyond your own abilities or inclinations, that is your problem.

From: martin@daw\_302.hf.intel.com (martin wilde)  
Subject: Brewing Techniques

> - Recycle the extract from the sparge a couple of times (2-3 quarts). This helps in extracting the extract.

This has the "ear feel" of a momily.

Just how does recycling, highly saturated wort, improve extraction?

The intuitive purpose of recycling the initial runoff is to

keep the cloudy stuff out of the wort.

> - After collecting the extract, get it boiling as soon as possible when using the step mash or decoction mash methods.

This one has possibilities of being true, I just don't happen to know what they are. I have often contemplated putting off the boil till the next day. What is the problem? ... particularly in the case of decoction, where the wort would be pretty well sterilized/pasturized.

From: BAUGHMANKR@CONRAD.APPSTATE.EDU  
Subject: Boil-over

>Boil over is caused by the formation of a viscous film of protein on the surface of the soon-to-boil wort..... To prevent boil-over, I skim the creamy head of protein that forms in the pre-boil stage several times. Haven't had boil-over in years. Boil-over usually doesn't occur after that initial 'steam-break'.

I recently had a great debate on the true meaning of the aphorism, "A watched pot never boils", I lost by general consensus but.....

The most obvious reason for the boil over is that the liquid is too hot.

If one simply turns the flame down when nearing the boil point, a most amazing thing happens.....

I too, skim the foam but given enough heat, nothing will stop a boil over.

From: joshua.grosse@amail.amdahl.com  
Subject: Sparging discussions

In HBD 775, Jack Schmidling commented on my too-small lautering tun problems:

>>A 4 gallon mash didn't all fit in the lauter-tun at the same time! I ended  
>>up taking a lot of run-off out right away in order to stop leakage from  
>>between the two buckets! Miller recommended a 5-minute rest for settling; I  
>>couldn't.  
>>  
>>This made the sparging get a little more complicated.

>This also made it not-sparging and explains all the problems you ended up  
>with. The mash must be allowed to settle or you can not establish a filter  
>bed and will only get what you got.

It did settle, but only after I'd drawn off a gallon or two, which was then recirculated.

>Fix those leaks.

That would take larger buckets!

And, C.R. Saikley writes:

>Another option is to have your supplier crack your grain. A decent  
>homebrew shop will have a two roller mill, which should give you a  
>much better crush than a Corona can. It usually costs no more than  
>4-5 cents/pound extra to get your grain cracked, and some suppliers  
>will do it free. Cracked grain doesn't keep well, so you'll want to  
>brew ASAP after milling. If you live in an area where you must mail  
>order your grain, having it pre cracked is not a good idea.

Interesting. I've no easy access to a homebrew shop that has a mill. As I live in an area with homebrew stores that don't offer milling service. Andy (ak35+@andrew.cmu.edu) recommends mail-order precrush.

>I've never had much luck with pH papers either. ...

Spencer Thomas (spencer.w.thomas@med.umich.edu) recommends obtaining pH papers at a photographic supply store.

>>The electric boiler never got a really good high ruckus boil.  
>  
>The advantages of a good rolling boil are several. This topic is thoroughly  
>covered in many places, so I won't go into that here. Suffice to say  
>that a strong boil is highly desirable.

It does roll, however, and I stirred frequently, and Irish Moss really helped the hot break.

>Fear not, for with a little experience, things will flow much more smoothly  
>and your results will likely improve.

Thanks, C.R.

In HBD 776, Kurt Swanson asked:

>I've always wondered why underletting is necessary in sparging... I've always  
>done it, but never knew why... Miller doesn't say why, just that it should be  
>done... Any ideas?

Both Miller and Papazian recommend foundation water in order to avoid clogging your lauter tun strainer. If the mash is placed there with air under the strainer, its more likely to cause stuck runoff.

From: Jim White <JWHITE@maine.maine.edu>  
Subject: Family discord !

A few nights ago I was roasting some pale grain malt, in preparation for another batch. The wonderful odor of the roasting barley was beginning to permeate the kitchen when my 14 yr old son dashed into the kitchen and began opening windows. As he proceeded with the window opening, he was making subtle comments about my activity, such as...

"That's really gross, Dad !"  
"Can't you do that in the basement?"

A while later, my wife returned from walking our dog, and immediately commented about the 'vile' odor.

Needless to say, I sensed a pattern. It also brought to mind how much the family also dislikes the smell of boiling hops. During the summer I can open the house to the environs, but during the winter we struggle to maintain a dramatic temperature differential betwixt the inside and outside, so opening windows is not always prudent. This, of course, exacerbates family disunity as the pungent hop odor is trapped within.

Now, I happen to like the smells of roasting barley, boiling hops, and fermenting beer. However, I stand alone against a united family in this respect. Anyone else have this problem?

I have been toying w/the idea of installing a cheap stove, and sink in the basement so I can brew sans harassment. Just another home brewing expense that I, currently, find difficult to justify.

Date: Fri, 6 Dec 91 18:41:48 CST  
From: gjfix@utam.uta.edu (George J Fix)  
**Subject: Soda keg types**  
Subject: Availability of Legal Kegs (George Fix)

I checked with a few scrap metal outlets and have found they are awash in beer kegs. One location was checked, and at least 25% of the kegs could with some effort on our part be rendered serviceable. The majority, on the other hand, were badly stained. While this is obviously not "corrosion", and theoretically can be removed, this is a task I will gladly leave to others. In any case, this looks like a viable option for cheap kegs.

Another possibility is a company called Sabco (formerly Save a Barrel). They sell cleaned and tested kegs (half and full) for \$20. Totally reconditioned kegs go for \$35-50 depending on the keg type and fittings. They will sell one keg at a time, and all keg prices are the same independent of the number of kegs purchased. Call Bob Suber at 419-531-5347 if interested.

Incidentally, Sabco uses the term "Hoff-Stevens keg" for what I normally call "Golden Gate". These are the kegs with the wooden bungs in the side. They do use the modern single prong (Sankey) tap. This is the one with the ss ring. I believe they will also install the older double prong (Hoff-Stevens) tap as a special order.

I personally went ahead and purchased the half kegs I have been using these last few years as fermenters directly from Miller Brewing.

The data on lost kegs in recent posts can be misleading. While some commercial brewers do spend big \$ on missing kegs, it is not because they are being converted into barbecue pits or homebrewing equipment. The vast majority are lost due to trade conditions. It is not uncommon for kegs to be accidentally sent to the wrong brewery. Most of these are scraped. One of the reasons Millers went to rubber lined kegs is so they could be easily distinguished from A-B and Coors. (The rubber also provides fantastic insulation). I have been told their keg loss has plummeted since that switch.

I have also talked to several micros about the keg loss problem. Many have been badly hurt by it. For example, Don Thompson, owner of the now defunct Reinheitsbot Br. Co. of Plano, Tx., tells me that he lost over half his kegs

(all purchased new) because they were accidently sent to another brewery,  
and  
then apparantly disappeared. Our newest micro ( Dallas Br. Co.) has used  
only  
the old Golden Gate kegs with the Hoff-Steven fittings so this would not  
happen  
to them.

Subject: Hubris/Nemesis

A few weeks ago, fellow Portlander Al Marshall reported on batches of bottled beer lost to mold and suggested the Portland weather might be responsible. As I recall, I poo-poo'd the notion, mentioning that I lived in the same clammy neighborhood and had never had any such problems. Well, sic semper tyrannis, or whatever. For reasons not much advanced over laziness, on November 6th I bottled half a ten-gallon batch, saving the rest for a more convenient time. The other night, as I set out to bottle the rest I discovered a layer of scum covering the entire surface of the beer in the carboy. The beer smelled wonderful as it glugged down the drain and I was deeply depressed as my partner (who was due half the batch) walked off with an entire case of the good stuff.

At any rate, let this be a lesson to me. The beer should have been bottled a month ago and clearly sitting in the carboy in the basement left it vulnerable to mold spores. It seemed obvious to me that bottling the beer--even if I could have peeled away the mold--would have been an exercise in futility. The beer might have ended up okay in the bottle, but it seemed more likely that mold spores would have been carried over and I would have ended up with two cases of moldy beer. Maybe not, but who wants to expend the effort on those odds?

Hmmph.

I'm going to be brewing an abbey-style ale next weekend with some Belgian yeast I got today from WYeast (no, it's not yet on the market, but soon, very soon). Any constructive suggestions (malts and hops?) would be appreciated. What do any of you know about biere de garde? I've heard rumors of a particular yeast strain; Dave Logsdon thinks the French breweries probably use a wine yeast, especially given the very high gravities of the beers. Anyone know for sure, or know how these beers differ from abbey beers?

**Subject: Avoiding boilovers**

To add yet another way to avoid boilovers to the several that have recently gone before:

I found a great way to avoid boilovers quite by accident. I boil on two burners on an electric stove (my brewkettle is short and fat so it fits over two burners). It takes quite a while for the boil to commence once I crank up the temperature settings to maximum. During this time, between the "steam break" and the boil, a head forms on the surface (kind of a scary one -- looks like it could take off and boil over any minute. Then an ever so slight boil begins and it seems that the resulting agitation causes the boilover head to drop. The boil finally gets strong and never spills over.

All that to say: if you keep the heat down on while initiating the boil, it shouldn't boil over.

Oh yea, I forgot to mention this and it is germane to the above recommendation: I don't cover the brew kettle until the roling boil begins. If I cover it beforehand, it boils over!

> build/sell them for about \$200.  
>

A Corona grain mill can be had for \$40-\$45. I have one and it works great.  
If you can't make high quality brew with grains crushed with this inexpensive mill, then you'd best blame the ingredients or your procedures.... cause it isn't the mill's fault.

I believe the (above) poster could do we subscribers a service by posting his design and parts list with sufficient detail that we may build one, and I challenge him to do so. I believe this selfless act would be more inline with the non-commercial intent of this list.

From: Paul Bigelow <bigelow@waterloo.hp.com>  
Subject: Soda Pop

The topic of exploding pop bottles was well flogged on the digest several months ago, but I humbly submit (OK, maybe not so humbly :-), that my technique is the best I've found so far.

For soda pop makers the spectre of exploding bottles is always a paramount worry, since there is a very real danger of physical injury. My family just finished off the last of a batch of cherry coke I made about three months ago, and I was able to relax throughout that period with zero worries.

I looked at the ingredients for soda pop:

1. Carbonated water
2. Sugar (for sweetening)
3. Flavorings

In restaurant soda fountains, the latter two are combined as syrup, and the carbonation is provided as bottled CO2. The homebrewer without an expensive kegging setup, instead uses yeast and sugar to provide carbonation. The danger is that yeast, being rather stupid, can't tell the difference between the sugar provided for carbonation, and the sugar provided for sweetening.

The secret to zero worries is to keep the sweetening sugar out of reach of the yeast, until just before serving. In the case of my cherry coke batch, I bought the syrup from my local homebrew store, and made up just the carbonated water. Back when I could still get Hires root-beer extract, I added the flavoring at bottling time, but not the extra sugar.

My recipe for carbonated water is simple:

5 U.S. gallons of water  
1.5 cups sugar

1 teaspoon dry bread yeast (rehydrated)

I fill each bottle 2/3 full, screw on the top, and leave for one or two weeks. Each weekend I measure and add the syrup to a few bottles, top them off with water and stick them in the fridge. This is a very quick operation. I had experimented with adding dry sugar, but this caused an excessive amount of foaming.

I have to admit that I have not yet tried making up my own sugar syrup without the preservatives that come in commercial syrup. However based on what I read in cookbooks, a heavy sugar syrup is unlikely to grow anything, and if I feel paranoid, I could always keep my syrup in the fridge.

From: Rob Nelson <70206.1316@compuserve.com>  
Subject: Evil Incarnate

Greetings and felicitations of the season.

My brewing partner, Mr. Jack Hagens and I would like some input / advice on a barley wine we are brewing. According to all we have spoken to, this batch may just reduce our petroleum dependance. Our recipe used the first runnings only from 15 lbs of Muton & Fison British Pale Malt and 10 lbs of Marris Otter British Pale malt plus a lb of Marris Otter crystal thrown in for good measure. Jack mashed the M&F in a stiff mash at 158 degrees single infusion. I step-mashed the other grains 122/140/153 degrees. The combined runnings were boiled for 4.5 hours with 1 oz hoppings every 30 minutes (Goldings/Fuggles alternated). An ounce of Goldings was added at the end of the boil for a 15 minute simmer.

The resulting concoction had a starting gravity of (hang onto your seats folks) 1.148! That's right. One point one four eight! Comments from other brewers, both amateur and professional ranged from "Oh my God!" to "Marry me and have my children!" Our questions concern yeast / fermentation management and dry hopping. Here is our seat of the pants plan.

We pitched a Wyeast 1028 London Ale starter (1 quart) at high krausen. Blow off began in 12 hours and subsided in 5 days. As of today, (day 6) we're still perking merrily at the rate of a bubble per second. Temperature of the fermentation is 65 degrees. We've modified one of those orange rubber carboy caps to accept a racking tube and airlock at the same time. We melted the racking tube shut on both ends to prevent airborne contaminants. We will wait until fermentation dies down to a bubble every 5 seconds, then every time Jack walks by the carboy, he'll give a gentle swirl of the sediment. This is yeast phase one. Some calculations have revealed that our hopping rates may have been too low so here is phase two.

We plan to make a 2 quart starter of 1 cup DME, 1 oz Eroica pellets and some yeast slurry from the Pike Place Brewery in Seattle Wa. This yeast has successfully taken a 1.085 wort down to 1.015 with the occasional CO2 rousing at their brewery. (BTW, their "Old Bawdy" barley wine will be a real winner this year). We figure that the extra hops will add needed bitterness and that the PP yeast should start things back up when the London Ale begins to fade.

Phase three will involve another starter of similar hopping and gravity but with liquid champagne yeast. With luck, we hope to chew this down to 1.030 or so for a strength of 14% or so.

So, the questions: Anybody out there ever tried something like this?  
Will  
hopping the starters help? What is the max alcohol tolerance of  
champagne  
yeast? Does the light in the refrigerator really go out when you close  
the  
door? Have we lost our minds?

Thanks in advance,

Rob Nelson

From: dworkin@habitrail.Solbourne.COM (Dieter Muller)  
Subject: off-flavoured mead, the continuing saga

I was at a revel last night, and the master of the house provided some home-made wine for the company to enjoy. I tried a spot of it, and it had the exact same harsh tang as my mead. Of course, I immediately asked him how he'd made it. It turns out that the only commonality between how he made his wine and I made my mead was that we both used champagne yeast. He also pointed out that the harsh tang usually ages out in a year or so.

Therefore, I think the next batch is *\*definitely\** going to be made with a milder wine yeast. Anyone know what they use for Spatlese?

From: TSAMSEL@ISDRES.ER.USGS.GOV  
Subject: re: Family discord

Well, Saturday I got home and found the house empty and I assumed that I had enough time to brew up an extract batch, since my family was off at the library, shopping, etc. I decided to do a partial mash of a pound of Munich, ground the grain (slightly ) in a coffee grinder (yup, I'll get a Corona) tied it off in cheesecloth and began to do what i term "instinctual mashing".

As luck would have it, the family came home WITH a new puppy. Thus the kitchen was turned into chaos. I wasn't able to doc my steps and rests and after I added the extract and completed the hopping and the boil, I find the laundry/ brewery downstairs full of (laundry).

So I must wait 45 minutes to decant the wort into the carboy which has been in the freezer, partially filled with H2O. I finally get the carboy loaded and lo behold, there is a rather impressive cold break AND the wort is at a pitchable temp. So I pitched.....

Notes: How does one brew all-grain with out interruption and still have a familial unit?

I hope this batch turns out OK...

From: zentner@ecn.purdue.edu (Michael Zentner)  
Subject: boilover & thermodynamics

Early in the Stuff post, Jack writes:

```
> I used your favorite reference and added a little common
> ^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^
> sense and came up with a much simpler method that seems to
> ^^^^^^
```

Uh oh!

And later writes:

```
> The most obvious reason for the boil over is that the liquid
> is too hot.
>
> If one simply turns the flame down when nearing the boil
> point, a most amazing thing happens.....
>
> I too, skim the foam but given enough heat, nothing will
> stop a boil over.
```

Wrong, wrong, wrong. Boiling water is boiling water, and, except in the case of either high pressure or serious, fast overheating (you know, Jack, the kind of heat that melts a pot?), boiling water will be at whatever temperature atmospheric pressure by you will allow (which may be a pretty low temperature indeed, if you brew where your head is (in the clouds)). Changing the flame on your stove will not change the temperature of boiling water.

Now, that said, the rest of your post on this subject has some validity, but not for the reason you state. I can maintain a very vigorous boil without boilover after the initial rise in foam has subsided. I wish I could explain why sometimes wort will foam again after the initial foam up, but I can't. While changing your flame intensity, you may increase or decrease the rate of boiling, the temperature remains the same. It is true that a lower rate of boiling will make less foam less quickly, and you may avoid boilover this way, but it has almost nothing to do with temperature.

Solution: I don't worry about boilover anymore, because I boil 5 gallon batches in a 10 gallon pot. Plenty of time to catch the mess before it oozes over the edge.

and  
> fermenting beer. However, I stand alone against a united family in  
this  
> respect. Anyone else have this problem?

Me.

Except that I'm in a slightly different position where I still live at  
home  
and nobody else can STAND brewing beer. I'd wanted to brew more this  
weekend,  
but good old Mom said "no way, your father will be home." So, after  
saying  
"seig heil," I found something else to keep me busy.

Funny though, Mom would gladly DRINK the stuff (dad's a tee-totaller).

They used to go away on weekends, but now that it is colder, they're  
staying home. I've considered boiling the wort on the gas grill on the  
back porch - I've also considered waiting until spring when they won't be  
around as much.

It's frustrating, but they charge me very little for rent leaving me with  
few options.

> I have been toying w/the idea of installing a cheap stove, and sink  
in the  
> basement so I can brew sans harrassment. Just another home brewing  
expense  
> that I, currently, find difficult to justify.

Here's another reason why not to do so: It probably won't help. My  
cousin  
Tom had to give up brewing for a variety of reasons - one being that his  
wife and kids could not stand the smell coming from the basement. The  
only good thing to come from all that is that I got another carboy and a  
box of bottles for free.

Subject: Pasteurized imports

In HBD 775, Rich Steuven writes:

>Truth, Fiction, or Urban Legend:

All beers imported into the US are required to be pasteurized  
and/or to have chemicals such as \_formaldehyde\_ added to them.

Well, I don't have any hard knowledge on this, but my gut feeling is that  
it is  
total fiction. We all know that beers don't have to be pasteurized. As  
proof,  
consider the bottle conditioned Bavarian Weizens or Belgian trappists  
(Chimay &  
Orval) that have live yeast in them.

Would anyone here suggest that either of these have formaldehyde added?

Not

me. The Weizens adhere to the same Reinheitsgebot as the rest of the  
German  
beers and I am HIGHLY sceptical that the monks are adding formaldehyde to  
any  
of their beers. As far as I know or can tell, the Orval and Chimay ales  
that  
we get in the US are the exact same beers that are sold in Europe.

> champagne  
> yeast?

Wow, another recipe most likely worthy of being named BrainDeath!

Must you? Must you have done this? Must you have done this and live so far away from me so that I will probably never get to taste this potion?

Seriously though, the Champagne yeast should have no problems standing up to an alcohol content of 14%. If I were to create such a potent brew I might just have started with that. I find your ideas quite interesting however. It sounds rather intriguing to use a London Ale yeast first to establish some of the character that that strain provides. The high alcohol content will, of course, eventually kill off the beer yeasts as the alcohol rises above 8 to 10 percent.

> Does the light in the refrigerator really go out when you close the  
> door? Have we lost our minds?

Yes and No. Not necessarily in that order. :-)

If I ever get off my butt and build a Mash-Tun From Hell (not [TM] Dan Hall and Mike Sharp, but probably should be :-)) then I would LOVE to attempt a barleywine. Maybe for next year's Christmas Brew! Yeah, that's the ticket! "Olde Saint Nick Barleywine" One bottle and you'll be slidin' down the chimney!

From: wiley@wiley.b11.ingr.com (Dave Wiley)  
Subject: To decoct or not

In every other mashing technique I've read about, letting the grains boil for any length of time is considered major bad news. However, in decoction mashing large fractions of the mash (1/3 - 1/2) get boiled. It seems like this would lead to a major astringency problem.

Not to ramble on and on, but I know from two experiences (one intentional and the other, er, otherwise) that boiling grains does lead to obvious and disastrous off-flavors. On the other hand, Noonan is a fairly on-the-ball kind of guy and he recommends decoction mashing - not to mention several hundred years of German tradition. What's the deal?

Subject: Mill Power

In response to Greg Roody on his problems with using a drill motor to power a Corona I use a Makita 1/2 inch drill motor to power mine. It is mounted and supported on a stand that has four legs high enough to fit a standard 5 gal bucket under. I increased that hopper size by taping two coffee cans together. Hold about 3-4 pounds of grain. The drill is adjustable in speed and you can lock the trigger on and walk away. The drill cost about \$100 and can crack many many pounds and never get warm . You can even use the drill for drilling holes, that how I justified it to my wife. I hesitated to put together a grinder type mill for fear it would cause all types of stuck mash problems. It works much better than I ever would have guessed. In fact I think I get better extract from my grinder than the roller mill I use to get my grain cracked with. You can tune the grinder while it is running to optimize the grind. Works for me.

You advocate boiling the liquid under the false bottom as a means of achieving decoction mash. I only skimmed through Noonan's book, but I recall him writing that one must boil what he referred to as the thickest part of the mash each time. Do you know why he claims that the thickest mash portion be boiled, and what would be the difference in boiling just the thin mash under the false bottom?

This is one I've wondered about too. I did this to my last batch. A friend wanted to watch me do an all-grain session, and he was supposed to be at my house at or before noon. He didn't arrive until 2:30, and left at 4. So much

for learning all-grain. Anyway, I left the runnings covered overnight in my kitchen, and boiled, cooled, and pitched the next day. I've called this batch Procrastination Porter, and I taste no obvious defects. There's a letter to Professor Surfeit in the latest Zymurgy asking the very same thing, and Surfeit recommends against doing it, claiming nasties will take up residence in the wort. I believe that's true, but how many of those nasty will survive a 90 minute boil?

See if your guess and mine coincide. I figured premix meant that the  
syrup and carbonated water are together in the bag or keg, i.e. it's  
already  
soda. And I figured post mix means the bag or keg contains only soda  
syrup,  
and the carbonated water is added at the soda dispenser.

Yes. Primarily my wife objects to the smell of malt, which  
pervades the house during a vigorous wort boil.

What do I do?

- 1) Boil when my wife isn't there.
- 2) Turn on all exhaust fans near stove.
- 3) Put a bunch of spices in a small amount of water and gently  
simmer (cinnamon and cloves are good). This is an old trick  
used to mask odors and masks the malt fairly well.

I was going to express the same sentiment about this the last time Jack  
posted  
information about his grain mill. Two hundred dollars is a lot of money  
for a  
grain mill, and if it's like other real grain mills, it's heavy,  
therefore  
shipping it from Chicago would add significantly more dollars to the  
cost.  
How about it Jack? You shared info about your mash/lauter tun idea. Tell  
us  
how we can make our own. Maybe we might still want to buy some of the  
parts  
from you, if we can't find them locally.

controlling  
>the speed. I use the hand crank at the moment. Works fine.

I've had both problems. I first tried using a cordless variable speed  
drill,  
but it gave up (overheated and shut down) after about 4 pounds of grain  
were  
milled. I now use a fixed speed corded drill, and it works fine, but  
goes  
like a raped ape. I don't see any problems from this though. The grain  
is  
cracked properly, and fast! I once read that sustained high speed does  
bad  
things to the Corona grain mill's bearing surfaces (such as they are).  
However, at light speed (or is that Lite speed?) the process is over just  
like  
that (it takes longer to stop and reload the high-hopper).

Well someone (forget the name) spoke about making sour mashes at the  
AHA conference this summer. One of the techniques was to let the mash sit  
before boiling. Times were greater than 1 day, but I expect that even 1  
day  
could produce some souring, depending on temperature and storage  
conditions.

Subject: Legal beer imports II; Coke mix vs premix; Foul odors (Scott Welker)

In HBD 771, I asked for examples of beer imported from Germany that did not conform to the Reihheitsgebott. Thanks to John DeCarlo and Chip Hitchcock, who pointed out MOST beers are modified before being sent from Germany (by adding noxious chemicals). Their sources were Miller and a Sam Adams ad, respectively. You learn something every day. I think the filtration of Japanese beer leaves the issue open, because the beer could be unnecessarily pasteurized to comply with US law. Now I'm even more curious.

Also in HBD 771, Ken Key writes:

>He said they're going to continue to use the 5 gallon  
>kegs for post mix (whatever that means exactly - I have guesses)  
>with the bags being premix.

Doesn't "premix" refer to the fact that soda fountains just add the sweetened syrup base of the various soft drinks to a single supply of carbonated H2O? If so, it follows that "postmix" would be complete Coke, with no need for mixing. Cheaper for small joints to set up that way, I'm sure.

And, Jim White writes:

>Now, I happen to like the smells of roasting barley, boiling hops, and fermenting beer. However, I stand alone against a united family in this respect. Anyone else have this problem?

Not me! And my wife (lucky me) loves these smells too. The only person who ever said otherwise dislikes beer altogether. Could it be that we like to smell what we like to taste? I read that the biochemical workings of smell and taste are very similar (and we smell most of what we taste, too), which seems to support this theory. Anyone out there love the smell of something they hate the taste of or vice versa?

More from Jim:

>I have been toying w/the idea of installing a cheap stove, and sink in the basement so I can brew sans harrassment. Just another home brewing expense that I, currently, find difficult to justify.

Jim, to quote Heinlein: "In a family argument, if it turns out you are right-- apologize immediately!"

From: pierce@chips.com (John Pierce)  
Subject: New brews (to me...)

While not exactly homebrew, I thought I'd comment on a couple of new microbrews I gotta chance to try recently...

I was back east over Turkey-day, and got a hold of a couple of brews I've never seen out west here. (back east means N.H. and Vermont to me)

First was a 6-pak of "Frank Jones India Pale Ale" from [New-Hampshire | Vermont]. Tasted like it had sat on the shelf too long, but wasn't bad.

Kinda reminded me of Sam Adams the way it tastes out here... (S.A. always tastes better in Boston to me than it does in California).

Second was Catamount Amber from White River Junction, VT. Had it on draught in Hanover N.H. and it was great. Got a 6-er in a small town in the middle of nowhere, VT. and it was OK. Very much reminded me of Sierra Nevada Pale Ale or Santa Cruz Brewing Co. Lighthouse Amber (my two regular favorites).

Thirdly, we stopped by the Centennial Brewery in Boston for lunch one day and had their Stout and their Bitter. The stout was pretty good but had traces of an oftaste that ruined the bitter. These off tastes were similar to those from numerous short-lived extract-brewing micros out thisaway that seemed to have contamination problems.

Finally, after getting back to the left coast, I discovered my favorite brew-pub (aforementioned S.C. Brewing Co / Front Street Pub) has released their annual holiday brew, "Hoppy Holiday". Darker than previous years, and closer to Sierra Nevada's Celebration Ale in style, very nice spicy characteristic to the hopping. Barmaid said something about lotsa Chinook hops contributing to the spiciness. Bay area readers note: They told me they are running low on this only one week after release!

Cheers! (no, we didn't stop there, just drove by ;-)

From: roscoe@sunwise.UWaterloo.ca (Ross Haywood)  
Subject: Food grade materials

There has been some discussion in the last few weeks over the suitability of various materials for the construction of brewing kettles, lauter tuns etc.

I constructed a stainless steel brew kettle with standard copper immersion heaters and an associate assures me that I will most certainly expire in the near future due to the ingestion of ?copper sulfates??. It seems to me that commercial brew kettles were all copper in the past I reply. Not so says he- they were copper outside but stainless inside.

Other materials that have been mentioned in this forum are silver solder, and galvanized sheet metal (I'm reasonably sure that galvanized is a no-no).

So, who out there has the definitive answer on the selection of materials for beer making equipment?  
Ross.

> will be at whatever temperature atmospheric pressure by you will allow.  
..

"Too hot" implies "at too high of a temperature" in common use. Mike is correct; the wort boils at whatever temperature it boils at, and you can't exceed that temperature. A boilover doesn't happen because the wort is "too hot."

What I believe was meant, though, is that the rate of heat input to the wort was too high. Since the temperature can't rise, the wort boils faster and therefore evolves steam at a higher rate; more bubbles per second. That's bound to aggravate an impending boilover. A more correct way to state this is "the liquid is being heated too quickly."

That's why leaving the lid on a kettle (reducing heat loss from the top) tends to cause boilovers; it eliminates a source of heat loss and thus increases the boiling rate. Adding cold water can stop a boilover by absorbing some of the extra heat in the wort, reducing the boiling rate. If you have a gas burner, turning down the flame is an option; those of us using electric burners will find it easier to move the pot partially off the burner to slow the boil until the foam has subsided.

Stirring and skimming are another approach; they break up the surface film so that the escaping steam doesn't form bubbles, and burst the bubbles already formed. combines both the mechanical and thermal approaches.

From: Mark J. Easter <easterm@ccmail.orst.edu>  
Subject: Removing Labels

I submitted a comment a week or so ago about environmental and health considerations in label removal. My memory has been known to fail me in the past, so I decided to actually test again (perish the thought!) the label removal procedure that I advocated, that of soaking or boiling the bottles. Here's the results:

Overnight soak in cold water in the bathtub: I put in about four tablespoons of mild detergent in a solution of cold water. The technique removed or softened all bottle labels except Dos Equis. The sample bottles included Bud long necks, Henry Weinhardts, (Long Live) Guinness Extra Stout, Sierra Nevada Pale Ale, Michelob long necks, and a few miscellaneous others. The Michelob and Bud bottles had to be scrubbed a little bit. Washing in mild detergent removed all traces of the glue.

Boiling the bottles: I was able to put almost a case of bottles in my canning boiler. After filling them all up with water and topping off the boiler, I put it on a high flame. The water reached boiling temperature in about 25 minutes. I boiled for 20 minutes, and then left the lid on and let them soak overnight. The sample included all of the above. The results were nearly identical, except that I did not have to wash all of the bottles in detergent- the glue had come off of about 1/2 of the bottles. I had to scrape labels off of a few bud and michelob bottles.

Seems like the soak technique might be the most economical and least energy-intensive. Has anybody else had similar experience?

Thanks to all for comments I got in direct EMAIL on the last submission.

Subject: boilover & thermodynamics

>Changing the flame on your stove will not change the temperature of boiling water.

Poor choice of words but I suspect most people will understand that if you reduce the heat [under the water] you will reduce the chances of a boil over.

> While changing your flame intensity, you may increase or decrease the rate of boiling, the temperature remains the same. It is true that a lower rate of boiling will make less foam less quickly, and you may avoid boilover this way, but it has almost nothing to do with temperature.

It has to do with the RATE of temperature INCREASE. I one approaches the foam over point with a reduced flame, it will not foam over. After a gentle boil is achieved, full heat can be applied without a boil over.

>Solution: I don't worry about boilover anymore, because I boil 5 gallon batches in a 10 gallon pot. Plenty of time to catch the mess before it oozes over the edge.

Yeh, except that I am so greedy that as soon as I got my 10 gal kettle, I started increasing the batch size. I now put 8 gals of wort in my ten gal pot.

I never actually had a boilover until this weekend. It was 60 out and I mis-calculated the time and was in the wrong place at that critical moment.

It makes searching for previous posts, and archiving by subject, much easier. You've used "STUFF" for a subject line about 15 times now, and when I'm looking for something you wrote in the past, I don't know which "STUFF" it was.

I also responded by saying it is a problem without a good solution. My mailer only allows a one word subject. In the interests of saving bandwidth, I typically respond to several topics in each posting. No matter which one I chose for the subject, the others would be lost in a search. The only alternative is Misc and this seems equally problematical.

When I post an original article, it ALWAYS has an identifying Subject.

Sorry, suggestions would be more helpful than just repeating the criticism.

>You advocate boiling the liquid under the false bottom as a means of achieving decoction mash. I only skimmed through Noonan's book, but I recall him writing that one must boil what he referred to as the thickest part of the mash each time. Do you know why he claims that the thickest mash portion be boiled, and what would be the difference in boiling just the thin mash under the false bottom?

Well, far be it from me :) to criticize the work of an expert but one of the things I dislike the most about Noonan's writing is his lack of clarity on many issues. After reading parts over many times, I go away totally confused. In this case, he gives equally reasons for boiling both the thick and the thin mash but the circumstances for doing which are cloudy enough to make it meaningless.

Furthermore, as I actually do a thick mash decoction, the fact that some of the thin mash is boiling seems to cover both bases.

>Anyway, I left the runnings covered overnight in my kitchen, and boiled, cooled, and pitched the next day. I've called this batch Procrastination Porter, and I taste no obvious defects. There's a letter to Professor Surfeit in the latest Zymurgy asking the very same thing, and Surfeit recommends against doing it, claiming nasties will take up residence in the wort. I believe that's true, but how many of those nasty will survive a 90 minute boil?

Premusming further that, the mash was over 150 degs, when covered for the night. How would they get in, in the first place? I could believe a chemical reaction could affect the taste, but infection? Bah!

>Interesting. I've no easy access to a homebrew shop that has a mill.  
>As I live in an area with homebrew stores that don't offer milling  
>service. Andy (ak35+@andrew.cmu.edu) recommends mail-order precrush.

Imagine that, homebrewers actually disagreeing on methods!! :-)

Let me clarify what I meant in the original posting.

I'm sure that with proper treatment by conscientious suppliers and shippers, mail ordering cracked grains is possible. If you've found a source that can reliably get precrushed grains to you in good condition, and you're satisfied with the results, more power to you. If you haven't yet identified that source, beware that shipping cracked grains is a risky proposition. Given that crushed malt doesn't keep well, and that shipping exposes it to unknown conditions, you may not be happy with the results. Time, temperature, and moisture all take their toll.

Perhaps someone out there has identified a good source for mail order precrushed malt. Anyone???

Subject: Decoct, not halfcoct

>Not to ramble on and on, but I know from two experiences (one  
>intentional and the other, er, otherwise) that boiling grains does lead  
>to obvious and disastrous off-flavors. On the other hand, Noonan is a  
>fairly on-the-ball kind of guy and he recommends decoction mashing - not  
>to mention several hundred years of German tradition. What's the deal?

Unless I missed the boat, you don't boil the grains, you bring them to a  
boil,  
i.e. you heat them to just before boiling, then add them back into the  
mash.

While still a higher heat less astringency will be created while  
enzymatic  
activity in at least that portion of the mash will be de-activated.  
Also from what I understand you end having brought 1/3 - 1/2 of the mash  
to a  
a boil, but not all at once, but rather in steps, so that only a small  
portion  
of the grain is actually de-activated at any one time. This still leaves  
plenty  
of grain with active enzymes throughout the entire mash.

From: Jeff Frane <70670.2067@compuserve.com>  
Subject: Sour mashes & such like

There has been a thread here about mashing one day, and then boiling the wort on the following day. Several people have commented that either a decoction mash or the wort boil would sterilize the wort and protect from off-flavors. As Jay Hersh notes, this is essentially the procedure for achieving sour mashes, and even one day is enough to start the process given the correct temperatures. What's important to note is: boiling will kill microorganisms but will not kill off-flavors (or toxins for that matter) already introduced into the brew by those microorganisms. And, no, this doesn't mean that every single batch of beer with a one-day lagtime between mashing and boiling will produce sour beer, just that it considerably increases the odds of spoilage.

On Corona mills: You would be amazed at how frequently these show up a garage sales and flea markets for about \$10, putting them well within the reach of most brewers. With care, they will produce a very nicely cracked grist. It's true that they can be motorized--although I've never felt the need, since it takes me about 20 minutes to crack enough grain for a 10-gallon batch by hand--but a friend who used a drill to power his says that the plates no longer run smoothly against each other but instead wobble. A roller mill is a great thing but \$200?! You'd be better off spending the money on a SS kettle or on more malts!

On pasteurization, etc.: I think this idea has been pretty well dismissed by everyone here. The State of Oregon used to have a law requiring pasteurization of beer (which was pretty much ignored by people like Sierra Nevada, not to mention Cooper's, Chimay, etc.). The battle over dismissal of this OLCC rule was led by (ta da!) Coors, who had obvious interests in repeal. I think you will find that most laws about alcohol content, etc. in beers are state laws and that the federal BATF gets involved in other silly rules. Such as not being able to use the word "Christmas" on an alcoholic beverage or not being able to use someone's name on the label unless a picture accompanies it. ???!

I'm intrigued to follow the discussion of boilovers. Most of the solutions seem

pretty sensible; I've used most of them at one time or another. Turning  
down the  
heat just as the first, violent surge occurs helps a lot, as does  
stirring with  
a long spoon at the same time. What interests me most, though, is that no  
one  
has mentioned an increase in activity when hops are added. I've never  
seen a  
concise explanation of this phenomenon but have observed it in countless  
brews.  
I've always warned new brewers not to walk away from a boiling kettle,  
\*particularly\* if they've just tossed in some hops. Anyhow, virtually  
every  
boilover I've ever witnessed or heard of had to do with inattention. Best  
not to  
wander off too long no matter what's going on with the boil.

Subject: STUFF (Ha! just kidding)

First, bad news. My favorite brew glass, purchased from the Boston Wort Processors at the AHA conference this past summer, was broken today by my mother-in-law. Bummer. To be truthful, it's amazing it survived as long as it did, but still.....Geez, I wonder what the ol' bat will get me for xmas ;-)

I just obtained a used Coke keg. Everything I know about kegs I've learned from this digest, and of course I haven't paid all that much attention, since I didn't have a keg. What would be nice is if there was a "howto keg" write-up, with, for example, what to replace, how to clean, how to fill, how to carbonate, how to serve, how to store, and what not to do. I know all of that info has been in the HD at some point. Has anyone put it in any sort of order? There's nothing about it in the archives; would be a nice thing to have there, though.

> Miller and a Sam Adams ad, respectively.

Well, there you have it, then... This sounds just like the rest of the  
utter nonsense that Jim Koch talks in his radio adverts. Like where  
he claims Sam Adams brews in weeks what "the leading import" brews in  
"three hours". As homebrewers we must all know that no one can  
possibly brew anything in as little as three hours. Not even the Dutch  
or the Japanese have perfected explosive fermentation, to my knowledge.  
He also talks about how they won first prize at the GABF three years  
in succession as if these were the most recent three, neglecting to  
mention that the last time was in 1986 (or maybe 1987, depending on  
whether  
my memory serves me correctly).

Since hearing Jim's advertising campaign, I've actually been avoiding  
drinking Samuel Adams beers. Having my intelligence insulted in this  
way certainly does not endear me to his company or their products...

And as for Miller... that's like believing General Motors if they told  
you that the wheels drop off Toyotas at speeds above 30 mph.

Subject: Grain Mill

This is a first submission on this quaint system and I don't like the odds of success...but I can offer some ideas on a grain mill. I built one for home use using pretty simple techniques. All aluminum, and using a junk gear drive motor (slow but it can turn the house) double roller crusher, does 1# per min. At first I used a 1/2 drill motor which worked if you started the drill before loading the grain and kept it going. It was a lot faster than the gear unit. The advantage of the crusher over the grinder is that the grain husks are not shredded and do not contribute to off flavors. You also get guaranteed 100% grain cracking and in addition, relatively few "fines" are generated. As a result yields are high and the grain bed is quite uniform. I have never had a stuck bed as I did with a Corona on occasion. There is a minimum of machine work involved, cutting plate aluminum, drilling and tapping, a bit of lathe work on the rollers. I don't know what a machine shop would charge to do the work, but alternatives are the local high schools and community colleges offering shop courses. A bit of barter for a case or two with either a student or the instructor might turn the trick...it worked for me. I'll be happy to furnish sketches to interested folk, just send a SASE.

From: rich@trevor.att.com

Subject: undercarbonation - causes and fixes ???

I recently brewed an extract-based pale ale type beer. Three weeks after bottling, there is still very little carbonation in the beer. I am trying to figure out what went wrong as well as how I might repair the current batch.

Some of the details of this batch include:

- used Wyeast American yeast (first time I used Wyeast)
- in primary for 5 days
- in secondary for 2 1/2 weeks
- used 3/4 cup priming sugar (no, I did not forget it)
- added 1 T. of dissolved Knox gelatin before bottling
- added 1/2 gal of boiled water before bottling to increase volume to 5 gallons. The water was cooled for a while before adding it to the beer, though it may have still been quite hot. I didn't check temperatures. I've done this before and given the small(?) volume of water added, I didn't think it would be a problem.
- the bottles were well rinsed after sterilizing them with a mild Clorox solution.

I remember seeing something on this digest once before about beer sitting in the secondary too long and leading to undercarbonation. Anybody know anything about this?

Even though this beer isn't too bad flat, might anyone be able to suggest how I can fix the current batch to make it better?

Thanks for your help,  
/rich kempinski

Date: Tue, 10 Dec 91 21:30:05 EST  
From: "Dr. John" <JELJ@CORNELLA.cit.cornell.edu>  
Subject: Well, excuuuuuse me! :-)

Greetings all,

I'd like to start with an apology of sorts, seems that the wording of my post in #774 was, shall we say, unfortunate in some regards. I've worked things out privately with Jack, but want to take this opportunity to redeem myself publicly, lest any of you are left with the impression that I am indeed arrogant.

So, being among the most recently Schmidled (or is that Schmidified :-))

of the HBD'ers, I'd like to offer a few thoughts as to how we might steer the HBD back to the kinder and gentler digest of old.

Unfortunately,

it seems that I fell into the trap that all too many posters have lately, namely adopting a somewhat belligerent tone in responding to what I perceived, and still perceive in part, as factual errors, or inconsistencies, in a couple of Jack's postings. I'd like to suggest that any of us who are tempted to fire off responses to Jack, or anyone else for that matter, that could be construed as inflammatory take the time, and expend the effort, to choose our words more carefully. I submit

that the digest will be much better served if we all take the time to send out well-reasoned, and carefully-written, postings, rather than simply

cranking up our blowtorches. Hell, Jack might even come around if we tone things down; though I'm not exactly suggesting he'll become affable, or anything like that, for to do so would most likely cause my veracity to be seriously questioned :-).

In the interest of helping start the process, at least in a small way, I'd like to restate the gist of my posting in #774.

Jack Schmidling, in #764 in your second "STUFF" posting, you suggest that

if the boiling of the liquid under the false bottom in a direct-fired mash

tun could be controlled, one could thus achieve the benefits of a decoction

mash. Then in #771 you refer to boiling an unspecified number (which, based on my mashing experiences, I infer to be a small number) of quart-sized portions of the mash as decoction mashing.

Both of these approaches seem contrary to the decoction procedures which Noonan elucidates in "Brewing Lager Beer." Regardless of what any of us thinks about Noonan's grasp on his material, the fact remains that his book is, to my knowledge, the only thorough English-language treatment

of decoction mashing, and, in my experience, his procedures do work.

I encourage you to read, or reread as the case may be, Noonan. When you do, you will note, on page 109, that Noonan states, in no uncertain terms, that by boiling the liquid portion of the mash you will likely be decimating your mash's enzymes, rather than achieving the desirable results of a decoction mash. As to the quart-sized portions, I assume that during a one hour conversion rest you will only need to reset your mash temperature 2, or at most, 3 times, and thus would not be boiling enough of the mash to accomplish what you would if you did a decoction of the size necessary to boost the temperature from protein rest to conversion rest. If you have other sources of information on decoction mashing, I, and I assume a few other HBD readers, would be grateful if you would post the references and help us expand the information base on which we can draw.

I hope, and expect, that this partial recantation will be sufficient to rekindle the discussion of decoction mashing without igniting any flames. As a practitioner of traditional brewing techniques, when I can find the time and gain the acquiescence of my family, I am always interested in learning of other brewers' approaches, in hopes of garnering some useful information to improve my own brewing procedures.

In closing, I'd just like to observe that flaming is a two-way street. If each of us practices some self-restraint on our pyromaniacal tendencies we can, before long, restore the digest to its past glory.  
Ooogy wawa,  
Dr. John

P.S. I'd still like to know what you all think about using Klages in a single temperature infusion mash. I'm thinking about doing so this Friday night, and would like to hear of any experiences along these lines that anyone cares to recount.

From: carr@ascc01.att.com  
Subject: Homebrew transport

Howdy,

Regarding the transport of homebrew on commercial flights, I have had some problems flying from here in North Carolina home to Minnesota with homebrews in my carry-on. They stopped me at the xray machine and asked me if those were bottles in my bag, to which I replied "yes". They then asked me to take them out, and if they were beer, to which I nervously answered "yes" again. At this point there are several of them eyeing the plain brown bottles with liquid in them with the mysterious bottle cap "Raleigh Brewing Co." (doesn't exist). They then asked me if it was home-made beer and I began to play dumb and pretend I didn't know what they were talking about, "can you really make beer at home?", and claim that a friend gave them to me.

I ended up weaseling out of it and they let me go, with the homebrew ( a couple bottles ). They said it was some law regarding interstate taxes and that bringing home-made beer over state lines was illegal. I don't know if this is a federal thing or just another asinine North Carolina liquor law.

Many guest at my wedding last spring received bottles of our Wedding Weiss and had no trouble transporting it when they had it in their checked-on baggage, instead of carrying them on. I also have gotten away with it in my carry-on by bringing homebrew bottles that I left the original labels on, so that they look like commercial beer.

I don't know about mailing homebrew, and am very curious as I will be mailing xmas brew presents across the U.S. soon. Anyone with experience in this willing to share?

As a point of interest, I understood that the Bier de Garde brewed at the Catamount brewery was not brewed by the Catamount staff. I hope that one of the "in" east coasters will clarify this a bit.

Whatever can you mean? ;-) Fortunately, I like both. But in regards to the aromas that emanate from the brewing process, a few notes. First off, my wife doesn't like beer, but she does like the aroma of making beer, so I'm off the hook there. (Still have to clean up after myself, however.) Next, I used to live two miles from the Van Nuys AB plant, and I drove by it twice every day, and often on weekends. I often would get comments about how it smelled bad from passengers. Curiously, I could often turn them around by mentioning how it smelled like oatmeal to me. By reminding them of some familiar smell that they have happy associations with (well, hopefully), I could influence their feelings on the matter. It seems that people often immediately believe that anything they can smell is bad; it is my belief that this kind of thinking is responsible for the rise in bland lagers and dry beer.

There are, of course, many variables, but as a generalization, high gravity (and therefore high alcohol) beers will last 2 years or more if treated carefully: cool temperatures and no light. Good sanitation procedures should obviate the first item in your list, good capping practice the second, and I would only expect that the evolution process to take more than a few years or else we all would have been overrun by such beings long ago. ;-) Seriously, I've had a vertical tasting of Bigfeet (that sounds pretty bad, doesn't it?), and the 5 year old version was clearly on the downward slope, but the three year old was marvelous.

> you HB'ers across the pond ever hear of the guy?

Michael Jackson mentioned this, but was concerned about how serious Mr. Thomas (a co-Beer Writers Guild member with MJ) was about this yeast, as he was only using it to "finish" the beer. Seems that the yeast is quite feeble and produces a variety of "interesting" esters; it's too weird (and too weak) to ferment out a batch by itself. Jackson suggested that this might be a grand marketing ploy, but did not deign to rebuke it until he felt more certain about the matter.

From: abirenbo@rigel.hac.com (Aaron Birenboim)  
Subject: Berliner Weisse / Sour mash

i have seen a few postings about a sour mash thread....  
somehow i have missed it. perhaps one of my attempts to  
get the following posted worked, but i keep on getting bounced  
mail...

well.... heres my post.... AGAIN!

\*\*\*\*\*8

I plan to try to emulate Berliner Weisse, and have been asking around  
for suggestions at to how to do this.

It appears that Berliner Weisse can be emulated from a sour mashed  
wheat beer recipe. My recollection of general opinion is to use  
stale hops. Papazian suggests 1-2HBU.

1) Hops... Can i make stale hops by just setting some nice  
leaf out in a bowl in my apt? Shoule i keep the hops  
in the dark while aging? I have some Mt. hood,  
alpha = 2.8, is this a good choice?  
Martin L. sent a recipe using 2 oz. low  
alpha hops for the boil, PLUS a 2 OZ! finish.  
Unfortunately i have not has a berliner weisse  
for YEARS, and i do not remember the bitterness.  
I think it was low, so i will most likely  
go with the stale hops.

3) Souring...Papazian suggests adding 1/2 lb malt to the mash  
AFTER the mash is complete and cooled to 130 F.  
Let this sit 15-24 hours and it should smell nice and  
putrid. Then sparge and boil as usual.  
Martin L. said one Berliner-weisse like brew he  
liked pitched a buttermilk culture called Staph.  
Lacticus along with the yeast. This scares me  
since the strength of the culture relative to my  
yeast is an unknown, and it will be hard to control  
sourness.

Another gentleman cultured the dregs from a bottle  
of Berliner Weisse, and got a nice sour flavor,  
plus the "white ring" sign of infection.

I might try this, except that I CAN'T FIND ANY  
BERLINER WEISSE! Does anybody know where i could  
Berliner Weisse in the denver area???

BTW... the fact that a sour beer resulted from  
simply culturing Berliner Weisse dregs seems  
to indicate that they actually do pitch souring  
bacteria (yeast??) into the beer AFTER the boil.  
However, i do not know if this will be the best  
method for a homebrewer.

I have an idea to combine the two methods...  
After the mash cools to about 130F, throw in  
some whey from old sour cream. This might be  
a better way to start souring than just adding  
cracked malt.

Is there a way to know when to start sparging if i use

the sour mash method? I imagine that the souring might cause a drop in pH. perhaps i will know that souring is complete after the pH drops a certain amount?

Please let me know about your sour mash / Berliner Weisse experiences!

Subject: Reply to Flaming Sam Adams.

In response to Paul Jasper's flame of Sam Adams, I have this to say: Paul, you must admit Sam Adams Beers are at least 10 times better than any Bud, Coors, Miller etc product. I personally am very delighted the SA beer exists. I'm sure SA is partially responsible for getting people to try other non CoBudMilob beers. If a CoBudMilob drinker tries SA and likes it, he may try Catamount, Anchor, or Sierra Nevada etc. I'm definitely for any product that will open more minds to different beer styles.

As far as the advertising saying SA brews in weeks what the leading import brews in 3 hours, could it be they are referring to quantity (final output in 1 day because of the size of brewery). I agree the ad may be misleading. Paul, please UPS me any SA you do not wish to consume.

Dry hopping: I recently made a batch of German Pils. I dry hopped half of the batch (1 oz of Saaz in cheese cloth in a keg for 7 days). What a pleasant hop aroma! For those of you who have not tried dry hopping, give it a go. Definitely one of the best hop aroma beers I've made. Mmmmmmm.. Time for a refill.

From: zepf@Central.Sun.COM (Tom Zepf)  
Subject: Crushed Mail Order

I have ordered pre-crushed grains from William's and from Great Fermentations of Santa Rosa. I've been pleased with the resulting beer brewed from both sources. I've tasted the grains and they seem fresh to me.

GFSR ships grains in a double paper bag, but the grains are very nicely crushed and there isn't a lot of "flour". Because the bag is not air (or moisture) tight, I feel better about brewing with it as soon as possible. I'm pretty sure the grains are milled to order.

William's ships the grains in 1 lb. sealed plastic bags. The grains usually contain a little "flour", but I don't think any husks are involved as I haven't detected any unusual husky or tannin notes. I would guess that William's crushes in batches, but the plastic bags probably do a pretty good job of protecting the grain. I've kept the William's grain down in my basement for over an month and brewed with it with no detectable problems.

I'm hoping to get a Carona for Christmas so I don't have to make beer with ingredients in 1 lb. increments.

From: PEPKE@SCRI1.SCRI.FSU.EDU (Eric Pepke)  
Subject: Boiling Over

When you boil wort, at least two things happen:

- 1) The water turns to steam, whose vapor pressure exceeds the atmospheric pressure.
- 2) Dissolved oxygen and other gases are driven off.

In my experience, the dissolved gases are responsible for most boilovers. Unlike steam, which tends to form in large bubbles around local hot spots and nucleation sites, the dissolved gases come out as small bubbles in many places at once. The small bubbles are better at making the foam that causes most boilovers.

Fortunately, once the gases have been driven off, there is much less problem. If you do extract brewing, you can boil all your brewing water before adding the extract. If you do all-grain brewing, it's much more difficult--even if you are very careful to keep the hot runoff from splashing, it will still absorb a fair amount of oxygen. The solution is to be very careful about adding heat when it starts to fizz. This is better for the flavor, too, as you don't really want the oxygen reacting very much with the other stuff in the wort.

**Subject: Removing bottle labels**  
Full-Name: Kent Dinkel

There have been a few discussions about removing labels from bottles. I soak my bottles overnight in the bathtub or large bucket with ~ 1/2 cup of borax. The next morning, most of the labels are floating in the tub. Those that aren't already floating peel off pretty easily. Applying a \*little\* elbow grease with an abrasive sponge easily removes any residual glue and/or label from the bottles.

I can't say that this works for all bottle and labels -- I primarily use Bud long-neck bar bottles (pretty sturdy suckers available at .05\$/bottle from the local liquor store) and Grolsh bottles.

The bottles aren't sanitary yet, but I won't be mistaken for serving Bud to my friends!

From: JPJ@b30.prime.com  
Subject: Sam Adams Cream Stout

Subject: Sam Adams Brewery, Sam Adams Cream Stout

Greeting, HB's...

I recently went on a tour of the Sam Adams Brewery -- I highly recommend this tour! I found out quite a bit about their brewing processes, as well as sampling their lager, ale, and lightship on tap -- as if I don't know what they taste like, but free beer is free beer, and Oh, is Sam good on tap \*)

After leaving the Sam Adams brewery, we made our way somewhat carefully through the friendly streets of Jamaica Plain to a local pub called Doyle's. Doyle's, as well as another pub whose name escapes me right now (also in G. Boston) has the distinction of being the first to be able to sell Sam Adams products before the general public can get its hands on them. So, it was my great fortune to be able to sample, on tap, Sam Adams Cream Stout. The rep at the brewery said they're still working on it, but I think it's perfect. Smooth, flavorful, and only 3.25 a pint... They also had some Cranberry Lambic on tap, but it was not as good as the 6-pack version. If you get a chance, make a trip down to Doyle's (preferably during the day) and sample this great brew.

For those of you unable to make the trip, I guess you'll just have to wait 8(

Subject: Oxidation, odiferous brewing, barleysine and shipping.

Oh well, I can't correct the subject line typo. Actually, barleysine is a type of audio output filtered through a high gravity beer. [grin]

Oxidation.

I have tasted oxidized beer and try to avoid it at all costs. I was musing on the cask conditioning of British Bitters, and began to wonder how they avoid oxidation of the beer in the cask after the cask is no longer full. I mean, the stuff might be around for a few days. Any thoughts?

Brewing Smells.

My wife dislikes the odors associated with brewing, too. She has found that a bottle of \*very\* good wine will keep her calm during the process. My cost per bottle just went up! [wide grin]

Keeping Barleywine.

Don't worry about aging that barleywine. It will last for years.

Shipping.

I have spoken with the Bureau of Alcohol, Tobacco and Firearms a couple of times and they assure me, and read to me from the regs, that it is NOT illegal to ship alcohol via UPS, or any other non-Postal Service carrier. The Postal Service is not allowed to ship it, but there is absolutely no law that would forbid any other carrier from doing so. Virtually all of the carriers say they will not ship it except from one dealer to another. Of course, you don't have to tell them what's in the (well, very well packed) box. I have discovered that the airlines will ship alcohol, but at a dear price.

This B.S. of UPS and others not carrying our homebrew is stupid. I urge a letter writing campaign to their corporate offices. I'll try to get an address.

Subject: Crushed Grain by Mail Time:8:45 AMDate:12/11/91  
CR asks:  
>Perhaps someone out there has identified a good source  
>for mail order precrushed malt. Anyone???

When I was doing extracts with the odd addition of specialty malt I bought mine from William's Brewing in San Leandro, CA. They seal all their perishables in sturdy plastic bags. Their crush was very nice and the quality of the grains are good. For small quantities like this they are a fine choice. I cannot speak on their wares for all-grain batches.

I expect that a corona mill would be a better way to go for the isolated brewer, unless you can find a mail order house who will bundle your grains into your specific recipe and then grind and ship for 24 hour delivery (which would be expensive, yes?). The \$45 for the mill would be paid for by the better price reflected in large volume grain purchases.

Date: 11 Dec 91 14:07:06 EST  
From: AEW@b30.prime.com  
Subject: Sam\_Adams\_Ads

In HBD #779 paul@melody.Rational.COM (Paul Jasper) writes:  
> Well, there you have it, then... This sounds just like the rest of the  
> utter nonsense that Jim Koch talks in his radio adverts. Like where  
> he claims Sam Adams brews in weeks what "the leading import" brews in  
> "three hours". As homebrewers we must all know that no one can  
> possibly brew anything in as little as three hours.  
This ad also confused me a little when I first heard it, but last Saturday when I toured the brewery (Great tour!) the tour guide made this statement using his own words and the meaning of it came clear. What Jim Koch is referring to is the total volume of beer produced by his breweries in a year compared to the volume of beer produced by (still unnamed) major Brewer in 3 hours. I don't think he is claiming anything about the time it takes to make any particular batch.

Paul also writes:  
> He also talks about how they won first prize at the GABF three years  
> in succession as if these were the most recent three, neglecting to  
> mention that the last time was in 1986 (or maybe 1987, depending on  
> whether  
> my memory serves me correctly).  
According to the tour guide at the brewery, Sam Adams didn't submit an entry after winning three years straight in order to give other (smaller/home) brewers a chance at the award. The following year they did enter and win again, afterwards the award was phased out for the new GOLD/SILVER/BRONZE medal system. Not only has Sam Adams beer won three times in a row, but EVERY time it has entered that category.

Paul Continues:  
> Since hearing Jim's advertising campaign, I've actually been avoiding  
> drinking Samuel Adams beers. Having my intelligence insulted in this  
> way certainly does not endear me to his company or their products...  
I personally enjoy the Sam Adams ads here in Boston, Jim has such a sense of humor that he modifies the ads for local appeal. In one ad he even changes the familiar phrase to: 'With a head so thick you can float Mark Parento on it.' (Mark Parento is a local D.J.) Even if I didn't like the commercials, it seems a shame to let this stop me from enjoying Sam Adams or any other fine Microbrewery beer. It certainly beats drinking MilBudiken just because their ads lack character and therefore don't offend anyone.

I am in no way affiliated with the Boston Beer Company. (Brewers of Sam Adams brand beers)

If you do not agree with my views, please direct response to the below e-mail address and save the HBD the flame war.

Subject: bunratty meade

Hey now- Has anyone tried Bunratty Meade? I was leafing through a copy of the Irish Echo and came upon an add for the stuff. It says it's made from white wine, honey, and herbs and has an alcohol content of 14.7% (didn't say volume or weight, I assume volume). I called the distributor for more info and spoke with a very nice woman who said they are based in NJ and that they've been selling the stuff as quick as they can get it from Ireland (it's produced at Bunratty Castle). There's two choices of bottles: a standard glass one and a really nice looking white stone bottle that has the label fired onto it.

I should have my hands on some by the weekend, so I'll give a report next week. If you want to call on your own, the number is 1-800-4-CAMELOT.

Subject: priming for American Light Lager?

I've got this batch of weasel water that turned out surprisingly well, but now it's ready for bottling. This is a brew designed \*especially\* for those Bud drinkers back home at xmas - so I DO NOT want to alter the lovely absence of flavor.

Would rather not use corn sugar (I've done side by side comparisons of corn sugar and krauseueu audusned beers. Krauseueu audusning wins.). So, to minimize flavor alterations as much as possible, what's the most likely candidate for priming?

From: Jeff Frane <70670.2067@compuserve.com>  
Subject: Barleywines, shipping & ?

Steven Boege asks about aging barleywines. Curiously, last night I split a nip of Thomas Hardy with Liz. The beer was of 1986 vintage. I drank one bottle that year: awful! tasted just like cough syrup. I drank one bottle in 1989 or 1990 and it was definitely better. Last night's was superb, wonderfully rich and complex. Virtually no carbonation, which has been true of other British barleywines I've tasted. I also have bottles of 1985 Old Foghorn, 1989 Old Knucklehead, and 1988 Blind Jack (mine own). I sample all of these from time to time; while still very good, none have changed as dramatically as the Thomas Hardy. (As memory serves, the TH is about OG 1114, all pale malt, with two kinds of hops, two yeast additions during fermentation and one at bottling. I guarantee from my tasting that the beer was very sweet when it went into the bottle but it definitely dries out over time.)

Also in answer to Boege: that very case of Old Foghorn I'm still into came back from San Francisco on the plane in 1985. I know of other homebrewers that have brought cases of beer with them in the luggage compartment without adverse effects. When I have to ship beer (either commercial or homecrafted) I pack them in a very sturdy box, lined with a garbage bag in case of leakage. My best packing material turned out to be some heavy cardboard tubes found at work (not unlike big solid toilet paper rolls). The box usually has a piece of styrofoam on the bottom, then the bottles are slid down into vertical tubes and stuffed at the top with newspaper. More newspaper or styrofoam chips (if available) are stuffed all around the tubes and across the top of the whole shebang. I ship via UPS and either send it through the mailroom here at work (UPS never asks them what's in the boxes), or tell the UPS clerk it's perishable food. If asked if it contained alcohol, I would lie.

To Jack Schmidling: Are you under the assumption that 150 degrees of heat will kill many microorganisms, other than yeast? Remind me not to eat any of your home-canned foods. !! CAN WE GET SOME DATA FROM GEORGE FIX HERE!!! GEORGE, HOW ABOUT SOME DOPE ON WORT SPOILAGE, ETC.?? if you've got the time.

To Jay Hersh: (I'm going to have to start keeping copies of my beer texts here at work!) As \*my\* memory serves, the decoction mash \*does\* call for boiling the mash section, not just bringing it to a boil. I have to admit that decoction mashing never made much sense: most are two or three-step decoctions and while it's true that you never boil more than one-third of the mash at a time, how do you know it's the same one-third (bloody unlikely) and that you won't somehow destroy all the enzymes? Nevertheless, it works. I did it twice deliberately, the second time using something the Germans developed in the 30's with a typically long and complicated name, basically meaning short hot mash--for light lagers. (I also did it once because the Bruheat died and I needed another way of raising the temperature of the mash: a problem not unlike the original brewers who developed the system). Some of these damn things, like the triple decoction used in Pilsen, go on for twelve hours or so. Noonan's argument in favor of decoction is based on (as I recall) two arguments: 1. An increase in extract, which was something like 1 or 2 points better with decoction than infusion (whoeee!) and 2. a highly-disputable contention that "true" lager flavor can only come from decoction. (Ha!)

Dr. John: UC Davis' Michael Lewis (beerguru) not only claims that one can do a single-step infusion of Klages but that any homebrewer who tries to do anything else is a fool. Lewis' contention is that accurate temperature changes are impossible for a homebrewer to achieve consistently, so why bother?... Lewis' opinions aside, I know from experience and from watching microbreweries that it is possible and that it will produce a good beer. For me, the problem with Klages is not in conversion or in chill hazes, but in getting any malt profile out of the stuff. I would strongly recommend using an addition of CaraPils and some caramel malt.

JPaul: Without being able to translate the damn things (your attempts sounded fine to me), I'd suggest the language was Flemish. I don't think there's a language called "Belgian", but recall that the country is divided into French and Flemish language groups. A truly weird country, really, as one can tell by drinking their beer.

From: korz@ihlpl.att.com  
Subject: Re: What is cold break?

Recently, I received a question via email that may be of interest to other beginners. The question was "what is cold break?"

First of all, there's no reason to avoid posting naive questions to the HBD. Have you ever seen a post like: "well, that was a dumb question..." Of course not. So don't be afraid. If you've got a question, probably 25+ other people have the same question... there's over 1000 subscribers to HBD and a large number of them are beginners.

On to your question. Cold break is two things which are related:

- 1) the "trub" (pronounced TROOB and meaning beer-related sediment) that forms when you cool your sweet wort after boiling (i.e. "you should rack your beer off the cold break"), and
- 2) the "process" or "stage" of the brewing process during which this sediment comes out of solution (i.e. "I had an incredible cold break").

The yeast that sinks to the bottom of the fermentor when it dies or runs out of sugar and goes dormant is also trub, so there's two sources for trub: 1) the cold break and 2) the yeast that comes out of solution. Trub may also contain some fermentation byproducts, but I'll leave that to others to post.

What's in cold break? Well, I'm not a chemist and have not researched this too much, but I believe that it is mostly proteins and product of tannins reacting with proteins. The tannins are from the husks of the grains. They are why you should never boil grains and why oversparging (sparging is the process of pouring hot water over your mashed grains to extract the sugars -- too much of this or too hot a sparge water and you extract too much of the tannins from the husks) is discouraged.

Why get rid of it? Off flavors are one reason -- I noticed an definite improvement in my beer since starting to use a wort chiller and part of that improvement is no doubt due to my leaving most of the cold break in the kettle. (Another reason for the improvement is the fact that I no longer pour the HOT wort into the fermenter -- I wait for it to cool. This reduces oxidation and got rid of the sherry-like flavor in my beer. Another reason to get rid of your cold break is to minimize chill haze in your final product. Chill haze is the product of tannins and proteins which becomes visible only when you chill the beer. Notice that the quick chilling of the wort does exactly that and then you leave it behind in the kettle.

One final note, the quicker you chill, the better the cold break (the more cold break (trub) you create).

One way to get cold break and to cool your wort without a wort chiller, is to use ice. I used to do this before I built a chiller. I would boil 4 gallons of tapwater on the previous day and then fill up four plastic milk jugs and put them in the fridge. The morning of the brewing, I would move one into the freezer. 8 hours later, the freezer jug would be partly frozen. I would boil the extract in only 2 gallons of water and then after the boil, pour the icewater into the kettle. This gave me a pretty good cold break. One chilled, boiled gallon in the fermenter

followed by the (now 80F) wort and then topped off by more chilled, boiled water. The improvement you get from this procedure will inspire you to build a chiller. It did for me. Note that when you go to full (5 gallon) boils, you will get an improvement in hop-oil extraction because your boil will be of a lower specific gravity.

Subject: grain cracking

The subject has been tossed back and forth about milling.

Goshums, geewhilikers! At \$10 per can, extracts are pretty expensive. At 80 cents a pound for grain, after about 8 brewings with all-grain the differential pays for the mill! Save up your pennies and buy a Corona grain mill--that's my advice. I got mine from a second hand store in a little town, but even at \$45 new, it's not a bad deal. I couldn't do without it now.

From: florianb@chip.cna.tek.com  
Subject: grain brewing in the family

The question came up on how to grain brew without interruptions and still maintain a family.

I am married to a wonderful woman, have a daughter 4.5 and a son 1.5, and have been all-grain brewing for several years. Maybe I can advise.

First, it helps if your spouse likes good beer and doesn't mind the smell.

Of course if you have kids, the smell of beer brewing is lovely compared to the smell coming from the back seat of the car on any extended trip.

Second, you need to be set up for all-grain brewing. Have the right equipment and plenty of room in the kitchen. A nice big brew pot is *\*mandatory\**, as well as a grain mill or some source of pre-cracked grains.

A rolling pin doesn't cut it if you are concerned with time. Also, use hop bags to avoid problems with siphoning the wort.

Third, you have to get your method down. I was disappointed to see how long it took to do all-grain brewing in the beginning. This was before I figured out how to largely reduce certain portions of the brewing time. Now, I can start an all-grain batch at 2:00 pm and have it finished by 7:00 pm. This, even taking time out for certain activities while the kids are napping in the afternoon...

Now what are these methods? I use a three-step process of mashing. The method is based on Papazian's method, but with some condensations. I dough-in with warm water, then add enough 130 F water right out of the tap to bring the mash up to 122. This remains for 30 minutes for a protein rest, on the stovetop. Next, I add sufficient boiling water to bring the brew up to 155 F for the saccharification, which lasts at least one hour, again on the stovetop (LO). After this step, I skip the mash-out (which never amounted to any difference for me anyway). I put 2 quarts/# *\*boiling\** water into the picnic cooler/mash tun, then add the mash all at once. I stir it and leave it 30 minutes. A simple re-circulation of a gallon or so and the wort comes out clear. Then I run it all out at once, starting the boil as soon as I have 3 or so gallons. The boil takes 1.5 hours. I also use a copper tube chiller.

Altogether, this process just doesn't take much more time than extract brewing. Honest! But during the idle periods, I take the opportunity to do family things, change my spark plugs, chop wood, go to town, or whatever I like. The timing just isn't that critical, so interruptions aren't a big deal.

Finally, I have found that my 4.5-year-old is fascinated by the brewing process. I usually let her play in the grains as I am weighing them out. She likes to stick Peter Pan, horses, or whatever underneath the grains and pretend lots of stuff. That's fine by me. Now my 1.5-year-old son is getting into the act, with spillage happening usually. That's fine too. Kids are only young once.

Hope this helps. One of these days, I plan to write a note on my condensed all-grain process. Just maybe, one of these days.

From: Bruce Mueller <mueller@sdd.hp.com>  
Subject: Copper

I take offense (professionally) to non-chemists/toxicologists commenting about such matters! It's as bad as non-lawyers or non-doctors practicing those disciplines.

To quote the eminent Merck Index regarding copper's toxicity:  
"Copper itself probably has little or no toxicity, although there are conflicting reports in the literature. Soluble salts, notably copper sulfate, are strong irritants to skin, mucous membranes."

Now, as to cupric sulfate (form referred to above) pentahydrate (that means it comes "packaged" in 5 water molecules), Merck gives the LD50 (the amount to kill half the rats), oral, as 960 mg/kg. For a 70kg (average male, big beer belly means more, female typ. less), that would be 67 grams! I dare say you'd NEVER form a concentration anywhere near that high at any reasonable wort pH. Now, if you acidified to pH 1 with mixed sulfuric/nitric or nitric/hydrochloric acids, I'd be worried. Suffice it to say your beer would taste absolutely AWFUL way before you'd have any effects. Besides, the copper would kill off the yeast: little critters are MUCH more susceptible to copper than humans.

By the way, though unrelated to beer, bluestone, the common name for cupric sulfate pentahydrate is a GREAT cure for really bad athlete's foot. Talk to a podiatrist about it. It is irritating, but not nearly as bad as the fungus!

If my interchangeable use of copper and cupric is annoying, sorry. The current recommended usage is copper(II); the old is cupric. Merck goes way back, so they use the old form.

**Subject: Grainmills**

I remember faintly of someone who built a grain mill from an old grocery store checkout conveyor. That reminded me that a good friend of mine (who, by the way, owes me a favor for all the homebrew I've pumped into him!) works for a company that engineers custom conveyor systems for industry. The way he explained it once, the systems are built from stock parts. Maybe he would have some leads on used conveyor parts or sources for new parts. I'll ask him. Meanwhile, keep an eye out for store checkout conveyors on sale!

Subject: Places to buy beer

I'll be in the Bay area for the holidays. I probably won't get a chance to visit any brewpubs due to lack of transportation. What I'm looking for is a place to buy fresh bottled beer, ie Sierra Nevada, Anchor beers, etc.

Does anyone know of a good store fairly close to Hercules, CA (East Bay)?

Last year when I was out there, I found some in a grocery store, but not every grocery store had beers other than BudMiller. Also the age of the beer there was questionable. This is my big chance to taste these wonderful beers as I can't get them in Alabama. Please help! :-)

Subject: Priming with dry malt extract

Jack writes:

>One of the problems I have found with dry extract is that  
>there is always some undissolved residue in the bottom of the  
>primer making me wonder what is in the last few bottles.

Putting dry extract in your priming bucket is not a good idea --  
it is an invitation for bacterial and wild yeast infection.  
I believe that what the original poster meant was what I have  
always done: boil the 1 or 1.25 cups of DME in 16 oz of water  
to kill bacteria and wild yeasts. Besides that, dry extract  
does not dissolve easily in cold liquids, as you have already  
found out.

[At the end of all this is some new business...]

From: "Dr. John" <JELJ@CORNELLA.cit.cornell.edu>  
Subject: Well, excuuuuuse me! :-)

> In the interest of helping start the process, at least in a small way,  
I'd  
like to restate the gist of my posting in #774.

Rather than re-invent the wheel, the following are my (JS) comments from  
email, sans personal stuff....

> What you perceived as arrogance wasn't intended that way,

We both seem to have a "tone of voice" problem. Sorry if I misread you.

> I have reread the article in question, and I beg to differ. I see no  
indication of the number of portions brought to a boil. If we limit our  
discussion here to only those "decoctions" which are boiled during the  
conversion rest, we probably don't need more than 2, or at most 3, for  
temperature maintenance during a 60-minute conversion rest.

I guess you would have to read between the lines and actually do the  
procedure to get the full meaning. There are two 60 min "rests" and a  
30  
minute "rest". Furthermore, the time required to bring each step to  
temperature adds another hour or more. The number of quart sized  
"decoctions" is considerable. Possibly, more than the whole batch size.

I also, used the term "partial decoction" in describing my process to  
indicate that it is a hybrid technique and not necessarily by the book.

>An acid rest, I presume. Might it not be easier, and more expeditious,  
to  
accomplish the acidification with gypsum (when appropriate) or lactic  
acid?

Reinheightsgbot prevails at the JSP Brewery. I even use organically  
grown  
grain.

>And why not do something about the chlorine which so many of us find in  
our  
tap water, or is that taken care of by using the hot water?

I either use previously boiled water or set out the dough-in water the  
night  
before to de-chlorinate. It is very critical to get it out before  
mixing  
with the grain as it will combine with the organics and form  
nitrosamines.

>A protein rest, I presume. Any particular reason you chose 120 degrees?  
Some authors (Miller, p.117; Noonan, p.112; to name two) imply that 122 degrees is optimal. Is an hour really necessary? I've had good luck with 30 minutes for all-barley-malt beers, and 45 minutes for wheat beers.

First of all, controlling temp throughout the mash to 2 degs, is beyond anything I am capable of doing. It would be just as useless to have changed the number to 122 as to really attempt to do it.

This may seem a bit arbitrary and even bazzare but someone posted the profile that came with a computer controlled, electronic masher he just purchased and I simply used it as a starting point.

>But if ease is the overriding concern wouldn't it be simpler to use a stiff mash and additions of heat and boiling water for temperature maintenance?

No doubt. I was trying to get the word out while working on the process. I am really pushing the enamel kettle, screen and pipe system as an inexpensive and effective way to get into whole grain. You will note the first article on the subject totally avoided discussing the process because I didn't know where I was going with it. I wanted to do everything right and then back off to simplify it. I needed a target to shoot at.

> I must say that I remain unconvinced that your procedure does "pretty much the same thing" as a true decoction mash.

Perhaps, [some of the same things], would have been a better choice of words. I would also like to point out that (if I didn't in the article) that boiling under the false bottom is to be avoided because of the risk of burning whatever is under it. Furthermore, I no longer use a false bottom so it is not even relevant.  
.....

NOW, on to new business.....

Last weekend I brewed up a batch with the same ingredients as my standard "generic ale" and did a "single" temp infusion.

The bottom line is that I lost about 5 points in starting gravity and a gallon of wort for other reasons, so the loss is a bit more than 5. The good news is that I finished by tea time instead of the usual, watching the kettle boil with dinner in my hand.

I put single in quotes because it became obvious during the infusion that this is not a valid test. As it took about an hour to bring the mash from room temp to 154 degs, one could hardly call it a single temperature. It spent enough time around the key rest temperatures to have had some influence on the end results, if these rest temps really do have a purpose.

I suspect that a true single temp infusion would yield an even greater delta in the SG.  
.....

I think the jury (mine anyway) is still out on the boiling sparge water issue. I think most of the references do not take into consideration the heat losses in a small batch.

For example, with boiling water going in, the temp of the wort coming out of the mash kettle is about 130 degs. This of course depends on the rate of sparging but the experts say the slower the better so the heat problem gets worse as the sparge time increases.

Unfortunately, I did not have the sense to measure the temp of the water on top of or within the mash but I would not be surprised to find it nowhere near boiling and just about where we want it. I seem to have a problem remembering more than one thing at a time but I will measure it next time.

In the meantime, this is what my intuition is based on....

There is about 3 gallons of water in the mash and an inch of water on top. The boiling water dribbles into a small soup bowl that is nested in the grain and the rim is just below or at the water level. Only the water in the bowl is near boiling and it is all downhill from there to 130 degs.

At the very worst, it seems like we might get something like a mash-out while sparging, whatever that might be worth.

Date: Wed, 11 Dec 91 17:14:32 EST  
From: "Dr. John" <JELJ@CORNELLA.cit.cornell.edu>  
Subject: HBD no. 779 (12-11-91)

Seasons Greetings all,

First, I'd like to thank those of you who e-mailed me regarding my questioning of the suitability of Klages for a single temperature infusion mash. I've decided that I'll go ahead with it, and deal with any haze, if necessary, at bottling time.

Regarding today's digest (#779):

Ross Haywood:

I don't have the definitive answer, but suspect that brewing predates the discovery of the "recipe" for stainless steel. I suspect that your friend is mistaken, and that there are indeed quite a few copper-only kettles in breweries around the world, and probably were quite a few more in days gone by.

Norm Pyle (and TSAMSEL):

With a 4-year old and a 1-year old sharing the house with me and my wife, interruptions are inevitable. I try to schedule the stages of my brewups around those that I can forecast, and just go with the flow on the rest. I'm going to try a new approach, for me, this Friday--nighttime brewing. Shouldn't be so many interruptions after the boys are in their jammies and safely tucked in for the night.

Steve Boege:

I think that the 25 years is a reference to Thomas Hardy Ale. Rumour has it that you don't even want to consider drinking this stuff till it is at least 5 years old. If you are confident in your sanitation procedures

I wouldn't think that you'd have much to worry about if you aged your barleywine for 5 years, though you might want to taste one every 6 months or so just to make sure it isn't going off :-). I've got some pretty elderly brews lurking in my basement, from a few batches I made 2-1/2 to 3 years ago, and they are mostly still quite drinkable. And most of these were from OGs of ~ 1.050.

If you can fit the case "under the seat in front of you or in the overhead compartment" there doesn't seem to be any reason that they should hassle you. When I was living out west, family members brought me half-cases of beer from "God's Country" (Wisconsin for those of you who may be wondering) a couple times with no problems (they carried it on).

Jack Schmidling:

I, for one, appreciated the tone of your posting today. Noonan does have a tendency to wander occasionally, and on a first reading even seems to contradict himself from time to time. But, I've found that after a few rereadings I can usually ferret out at least the seeds of some useful information to build on. From my readings of Noonan I've concluded that you want to boil, to the extent possible, only the thickest part of the mash for all but the final decoction. The point of the final decoction is to halt any further enzymatic activity, and this is when you want to boil the thinnest portion, as this is where the enzymes are reputedly lurking.

Jay Hersh:

Maybe you are only halfway in the water :-). Noonan does indeed instruct us to boil the decoction, for up to 45 minutes in some cases,

prior to returning it to the main mash. With the enzymes mostly in the liquid part and the thick part being boiled (except for the final decoction) there isn't too much degradation of enzymatic activity. Now, on the question of astringency arising from decoctions, I'm at a loss, but hope someone else has some good information. It hasn't been a problem for me in the decoction-mashed beers I've made, but I'd sure like to know why this is. Anyone out there who knows?

Jeff Frane:

Glad to know that I'm not the only one around who actually enjoys cranking the old Corona by hand. Hell, it's some of the only exercise I get :-).

Russ Gelinias:

Any chance that you can track down the date on that Times article? I'd like to read it, but a quick perusal of Monday and Tuesday's issues failed to uncover it for me.

Rich Kempinski:

Clorax, eh? Is this stuff any relation to that cute little booger who "speaks for the trees?" :-)

Ooogy wawa,  
Dr. John

Subject: How do you develop a yeast culture? Discussion?

After tasting a variety of homebrews at a recent homebrewers party, I am finally convinced that yeast really matters (that is, the quality and type -- especially liquid vs. dry)! After you experience the odors and aftertastes dry yeast imparts to the brew, you can recognise a beer brewed with dry yeast in a New York minute.

All that to say that I am going to start experimenting with liquid yeast in future batches. From the discussions in this newsgroup, that suggests to me that I will probably end up culturing yeast to squeeze more than one batch of beer out of it. The discussions I've read so far agree that you can only use a few generations of propagated yeast before it begins to degenerate.

My question is this: how did the brewmeisters in the "olden days" (i.e. before availability of high-tech equipment) culture their yeast? My understanding is that they didn't even know what did the fermenting until the late 1800s. At some point, they had to begin with wild yeast. Then, from that, they cultured an ale or lager. Then there are several other important attributes of the yeast to culture (e.g. attenuation level, etc.). Anyone know the history of yeast culturing and, much more importantly to us pragmatics, how we can do it at home? Finally, has anyone out there had any luck with local wild yeasts (like the Belgians did)?

From: Darren Evans-Young <DARREN@UA1VM.UA.EDU>  
Subject: Copper scrubber clogging

Regarding the use of copper scrubbers...

I quit using copper and started using the plastic version due to definite metallic tastes in my brews. But the following still applies:

I had been using the copper scrubber with a muslin bag over it for many batches. As my procedures became more streamlined, I found that the bag started getting clogged. I have since discovered why. After the boil, I would immediately start siphoning through my counterflow chiller. There was so much particulate matter floating in the wort, it would clog up my pickup. Solution: After the boil, I give a good circular swirl with my spoon, cover the pot and let it sit for at least 15-30 minutes. This gives the protein goop time to settle while I drink another homebrew.

After that time, I start siphoning and all I get is clear wort...no more clogging! So if you're having that problem, let your wort sit for a bit before you start siphoning.

Subject: Fwd: STUFF

Details are up to you but here is enough to get you started...

GRAIN MILL

[21 lines of ad copy explaining what a grain mill is deleted]

.....

The mill consists of two 1.5 in rollers, driven by a 1/30 HP electric motor. The motor drives one of the rollers through a set of reduction pullies at a speed of about 300 RPM. The other is driven by rubber friction rings from the first. It is designed to stall in the event of unwitting attempts to mill fingers. It will smart but not much more.

The rollers are 12 inches long and have meshing teeth running their entire length. In cross section, they look like fine toothed gears. However, the rollers are spaced about .05 inch apart so the teeth do not actually mesh. Their purpose is to pull the grain through the rollers. The spacing assures that the grain will only be crushed enough to expose the contents without tearing the hulls.

The assembly is mounted on a plywood base, 18 inches square. It is intended to sit on a table, with the business end hanging over the edge.

Operation consists of slowly pouring the grain into a hopper and catching the milled product in a pan or bucket underneath. It takes less than a minute to mill a pound of grain. It could be made to work much faster but I was more concerned about safety than speed.

The product that emerges looks like a picture out of a text book on brewing. This is normally only obtainable through a series of rollers whose spacing gets progressively closer. By using the toothed rollers, we are able to achieve the same results in one step.

[ pricing information deleted ]  
arf@ddsw1.mcs.com

----- end forwarded message -----

Jack says that the rollers are expensive and he will only purchase them to order. Rather than making you go to all this trouble, Jack, feel free to simply E-mail me the address and phone number of your supplier, and I'll take care of it myself. I'll even post the answer to the net so that you don't have to get flamed about wasting bandwidth.

Oh, and if you want to send me schematics of your grain mill (C.O.D., of course), my address is:

Peter Berger

5373 Beeler St.  
Pittsburgh, PA 15217

Like I said, I don't have \$200 to spend, and I wouldn't want to put you to the trouble of building me one when I can do it myself. If mailing the schematics is too much trouble, however, I can give you a fax number which will pass them on to me. Of course, if you need to fax it from Kinko's or something I'll pay the cost.

From: FWALTER%RULUPI@ccmail.sunysb.edu  
Subject: Transporting Homebrew

I've had no trouble checking a case of homebrew with United. I do get differing reactions from the agent. Some say OK, others want assurance that nothing will leak, and then proceed to put the case in double plastic bags. But it's always gotten there with me.

Carryon is a different matter. I've been able to carry on small boxes (a dozen bottles) with no question; on another occasion I was requested to prove that the bottles contained beer (by drinking it then and there). On that occasion, only 5 bottles got where they were going.

Your best bet is to call the airline. You shouldn't necessarily believe them, but...

Fred Walter

Date: Thu, 12 Dec 1991 02:46 EST  
From: FWALTER%RULUPI@ccmail.sunysb.edu  
Subject: comments on homebrewing

Last night I made a batch of beer. Nothing unusual - it was batch number 54 (I average about 10 batches a year) - but it was my first since subscribing to HBD. Until October I'd never realized there was so much to worry about!

Actually, I started 2 days ago. I boiled 4 gallons of water. May as well get the chlorine out. I presume there's nothing left alive in there. My mentor when I started brewing out in Boulder, Colonel John, suggested this. I poured the water into gallon plastic milk jugs, put them in a cold water bath, and left them overnight in the basement, chilled to about 40F.

I sterilize with bleach. Rather than measuring a teaspoon per 5 gallons (or whatever is lethal to the wee beeties), I just pour a bit in and then fill the carboy with water. It hasn't failed yet. Why take chances with sanitation?

The temperature in the basement has dropped below 60F, so it's lager season. I'm an extract brewer - perhaps I'm lazy, but extract beer is easy and tastes great anyway. I crushed some crystal malt (I wanted 4 oz, poured 6, and decided to use it all because it was easier than trying to put it back in through the small hole in the bag) with a rolling pin on a cookie sheet. Works fine, even for the harder grains like black patent and roasted barley, and keeps those beer-mug-lifting muscles in shape. My 4 year old daughter can crack crystal.

I dumped the cracked malt into 1.5 gal water in my 4 gal pot (the most expensive item in my brewery), brought things to a boil, and strained out the grains with a kitchen strainer. Got most of them. Then I added about 6 lb of dry malt extract to the wort. This is messy. Is there a good way of pouring dry malt extract into hot wort? Too fast and the wort splashes out of the pot; too slow and the extract absorbs the steam and sticks to the bag. The stuff in cans at least comes sticky, and can be forced into the pot with a rubber scraper.

I subscribe to the principle that a watched pot never boils (I have lost some while not looking). As boil approaches, stir occasionally, and be prepared to

lift the pot off the stove (I hate electric stoves - gas provides much more responsive temperature control). I do have boilover problems with my Dopplebock  
- 2 gallons of water and 12 lb of extract in the pot leaves little head space.

I found some old hops in the freezer. They've been in there since August. Didn't smell as aromatic as they should, so I pitched 2 oz rather than 1 for bittering. The wort smelled fine, and not too bitter (my family, too, dislikes the smell). I tossed in an ounce of fresh hop pellets at T-2m for aroma.

Then I carried the pot of wort to the basement, dumped a gallon of cold water in the carboy, and proceeded to sparge the wort into the carboy. By my calculations, 200F wort + 40F water, in roughly a 2:3 proportion, gives a final temperature of 90-100F. My hand tells me its lukewarm too. Who needs fancy wort chillers? So I pitched the yeast. Red Star. One package. Hasn't failed me yet. Tonight it is bubbling nicely.

The carboy is clear glass - my basement has fluorescent lights. Should I worry?

I've given up on measuring the original gravity. Beer clearly stratifies, and I see no point adding potential contaminants by stirring things up. If I need the OG, I can estimate it from the materials used, I suppose. But then, my friends have never inquired about the gravity.

In a week or so I'll dump 60 bottles in the sink, pour in too much bleach, and let them soak overnight prior to bottling. I get a contaminated bottle maybe once every fifth batch. I'll also throw in some labelled bottles. Soaking overnight in bleach will remove almost anything (except Sam Adams labels). If the labels don't float off, I grab a plastic dish scrubber and scrub. Wet paper isn't very strong. I use only brown tall neck bottles, mostly Coors, Piels, and Olympia. It's cheap, and refreshing on a hot summer day. You don't always want a ((your favorite brew here)). I also use Sam Adams bottles, although they are thinner, lighter in color, and, I suspect, not as strong.

Should I worry? Most HBD writers seem far more serious about their avocation. I make beer it because it's fun, costs less, and tastes great. I don't care it it could pass for brand X, or if I used the wrong style of hops. Only one of my batches was my best ever, but all were very good. Haven't made one even close to undrinkable yet (I'm convinced the trick is all in the sanitation).

I think I'll continue not to worry about anything I read in HBD.

Cheers,  
Fred Walter

Subject: RE: Artichokes and beer

For the longest time I thought medical school wasn't doing me any good,  
that

I wasn't learning anything. Boy, how wrong I was!

There is a certain chemical (still undiscovered by medical science) in  
artichokes that make everything taste sweet. The chemical supposedly  
interacts

with certain neurons in certain types of taste buds that shifts your  
perception

of tastes toward the sweet sided. To prove this theory, eat an artichoke  
before drinking a glass of plain water. It will taste sweet...

Now I've got to go to a pathology lecture. Oh, well, duty calls...

Subject: Zymurgy gadget issue

A question for those of you who have purchased the Zymurgy special issue "Homebrewers and their gadgets". Did you find it useful? By participating in Homebrew, have I already read about all the 'gadgets' that they cover in this issue?

How about the grain issue? I'm currently an extract with 'grain tea' brewer but want to venture into all grain soon. Is it a 'must read'?

I don't want to buy them if it will be repeat reading.

Thanks,

John

From: Robin Garr <76702.764@compuserve.com>  
Subject: Transporting homebrew

With regard to Mike Carr's comments and request for information on carrying homebrew on board commercial flights and shipping brew interstate, a couple of thoughts:

\* I have repeatedly been assured by BATF officials that there is NO federal law prohibiting individuals from sending alcohol across state lines. The feds took themselves out of that business after Repeal.

\* Complicating the situation, however, is that each of the 50 states has its own rules regarding the receipt of alcohol by its citizens from non-commercial sources. Some ban it, some merely would seek to tax it, and some don't care.

\* In any case, you cannot legally send alcohol via the United States Postal Service. I assume this is the result of Congressional blue-noses. The law provides fines and prison time; I seriously doubt that this would be enforced against individuals mailing small amounts for private consumption, and the chances are that you could do it without being found out. It's probably not a good idea, however, and the least that would happen in case of discovery is confiscation. :-(

\* Most of the private mail services, like UPS, won't knowingly accept alcohol for shipment between individuals, but this is a matter of their own policy and not (no matter what their agents may try to tell you) a matter of law. In practice, most home brewers ship their goods, carefully packaged, via UPS, not identifying them as beer and accepting the reality that any claims for loss will be rejected. Some folks like to use smirking euphemisms like "yeast cultures" on the address form, but I think this risks probing questions. I like "non-perishable food gifts" myself. It's not a lie.

\* Finally, I have often carried homebrew on commercial flights without incident. The security folks DO want to know about unmarked bottles, and this is reasonable. But remember, it's LEGAL to brew, and it's LEGAL to give it to friends. Don't be furtive, be forthright. "Yes, this is home-brewed beer, and it is legal." Remember, the security authorities (besides being minimum-wage rent-a-cops of limited education) are more likely to be worried about a nervous passenger who's obviously lying about something than they are about a brewer who's toting something that he has every right to tote.

From: dbreiden@mentor.cc.purdue.edu  
Subject: Carry-on beer on commercial flights

I was rather concerned with the prospect of transporting homebrew and brew in general last spring. When I asked for help form the digest, the scariest story I heard came from Pete Soper (whatever happened to him anyway?) who spent a long time in an airport talking to security people and their superiors and more superiors before someone finally called the tower. Someone in the tower told them all to quit being stupid. The line was that if the bottles are sealed and stay sealed --- no problem.

>From that, I surmise that if some person chose to question your claim that the liquid is beer (home brewed or not) then you would have to prove it --- I don't know. Oh, in addition, Pete found that the bottles of homwbrew with HOMEMADE labels did not get questioned -- even when he explicitly told the security folks that those contained homebrew as well.

On to MY experience. Armed with this story and the knowledge that I was doing nothing wrong, I went to the airport plenty early in case of hassles. At the Indianapolis airport, one person asked me if those were bottles in my carry on. I responded in the affirmative. No one bothered me after that. I had no trouble in the Minneapolis airport.

Coming home, I had 12 bottles of microbrewed beer AND 6 little bottles of Old Knucklehead barleywine. (Quite a load for carry on!) In the Portland airport, a guy asked me if I had a case of beer in my pack. I answered thatr I only had a half case (honest! I forgot about the little bottles for a moment!) -- the guy nodded and left me alone. In Detroit (didn't pass through Minneapolis on the way home) no one raised eyebrows or anything.

I think the one thing you can be sure of when you pack beer as carry-on is that your mileage WILL vary. Someone, somewhere, once found an authoritative reference to the legality of this, but I don't know where, who, what, etc. about that -- it wouldn't hurt to be armed with this, a little extra time, and a good deal of politeness when you travel. Another option is to check it through -- I've nto done it; it sounds a bit nerve racking. But you could get more home that way!

From: Gordon Baldwin <hpubvwa.nsr.hp.com!sherpa2!gbaldwin>  
Subject: Re: Bunratty Meade

My wife and I tried Bunratty Meade when we were in Ireland 4 years ago. The Bunratty Castle has a fun mideavel (sp?) dinner, in which they serve their Meade. It is heavier than I am use to ( I make a mead using 10-15Lb honey for a 5 gallon batch). I didn't know it was made with white wine, but that would explain some of the flavor. It has a kind of cheap wine overtone to the normal mead flavor. I was a bit dissapointed by the flavor at first because it was not what I was ready for, but after a couple of glasses I adjusted and I found it quit enjoyable %-).

Right next to Bunratty is Durty Nellies. This pub has been around since the castle was built. (or so I was told) We sat in the corner by piano and sang show tunes with the local Irish. I don't know many pints of Guinness I drank, but the only one I had to pay for was the first %-).

The only problem with Ireland was it was the only place in europe that we had a language problem. We were with friends from Cork and when they drink they get very hard to understand.

From: R\_GELINAS@UNHH.UNH.EDU (Russ Gelinias)  
Subject: cold break, mash out

I'd like to second the opinion that "beginners" shouldn't feel shy about asking "dumb" questions. Discussions of "simple" processes like cold break often lead to more in-depth analysis of brewing. I've also run into more than a couple of "experts" who could benefit from a discussion of the simpler brewing concepts, but would never ask about them. So jump right in.

Florian (with the great family attitude!) said he doesn't mash out. I've never mashed out either, but was wondering if maybe I should. I suppose if you are trying for an exact OG/FG then it might matter, but I'm not all that concerned. Should I be?

BTW, there are a couple more definitions of cold break:  
(n) Any vacation time in New England in the winter.  
(n) When the cold you picked up from your vacation in New England in the winter finally starts to go away.

**Subject: Traveling with Homebrew**

Another data point on carrying HB on airlines . . .

Last summer I flew from Des Moines to Key West to visit family, and I carried 16 bottles of HB in mychecked baggage. Packed securely, of course - I wrapped it in umpteen layers of newspaper and surrounded it on all sides by clothes. It probably would've been a good idea to put it in a plastic bag too, but I didn't think of it.

Anyway, it arrived just fine, and the airlines gave me no trouble. I don't know about carry-on, but HB in checked baggage seems to be just fine.

> Jack. Some of us are just interested in how you put YOUR two plates  
> together and connected it to a drive.

Actually, I was under the impression that Jack had built a roller mill,  
not  
a grinder. The difference is that a roller mill allows the plates to be  
positioned at a known distance from each other and they won't touch each  
other. I've seen a couple of roller mills and, while I think it would be  
easy enough for Jack to describe the basic design, I also think that the  
metal working involved could be non-trivial.

Subject: Bad Apples

I don't know if this is the right place to ask this question, but I imagine that I'll find out soon enough :-)

I have made an attempt at apple cider. I pressed a whole mess of apples and created about 10 gal. of cider. Aprox 3 gal went to instant consumption (it was really good). And the remaining 7 gallons went into a couple of carboys. I added ale yeast (i think Whitbred), yeast nutrient, ??? acid and couple of other things that the guy at the beer supply shop told me to.

I picked these ingredients up from the wine making shelf. Anyhow- the fermentation went crazy for about 2.5 weeks (lots of bubbles) and it kept filling up my blow-off bucket. While kegging another batch of real beer I kegged this stuff too, as the gravity was almost 1.008 or so. I had a taste at this time and it tasted like vinegar (blech!)

The guy at the shop mentioned som sort of sucrose that might help. Sorry about the ramblin' but here is my question. Is there any thing I can do to save this stuff? I had hopes of being able to have a nice glass of hard cider sometime this winter. If saving this stuff is hopeless does anybody know what to do with ~7gal of apple vinegar? :-)

Date: 12 Dec 91 15:19:18 EST  
From: AEW@b30.prime.com  
Subject: English Bitter Extract recipes

Fellow Brewers:

I recently brewed an all-extract batch using the following recipe based roughly on the recipe for 'Beginner's Bitter' From Miller's book.

- 4.3 Lbs. Light Unhopped Malt Extract
- 1.0 Lbs. Light Unhopped Spray Malt
- 1.0 cup Dark Brown Shugar
- 2.0 oz. Fugles hop pellets (Boil)
- 1.0 oz. Fugles hop pellets (20 min steep post-boil)
- 3/4 cup Corn Shugar (Priming)
- Whitbread Ale Yeast (Dry)

This was a 5 gal. batch. For my first try the clerk at the local brewing supply store recommended Light Extract instead of amber. I should probably have insisted on Amber since I like Darker Beers, but this was my first batch and I took his advise. The beer has been bottled for a while and upon tasting it, I have come to two conclusions: 1) The beer is too light for what I am used to calling bitter. (I am using my memories of Whitbread Bitter on tap in Cambridge, England for comparison.) This I can almost certainly attribute to the Light malt, next batch I will certianly use the Amber. 2) The Alcohol content (according to my two hygrometer readings is about 6.5%) seems to be a major portion of the aroma and flavor. I want to almost say that this beer tastes 'cidery' but risk showing my inexperience in tasting homebrews by saying this. Whatever I call it, I want to get more towards a true English Bitter beer with my next batch (although I'm sure that I will have no trouble drinking the two cases that this batch made :-)

Here are my questions for the experienced brewers out there:

- 1) Are my assumptions about Light vs. Amber malt correct?
- 2) Should I eliminate/reduce the spray malt to reduce the alcohol taste/content? and will this effect flavor considerably?
- 3) Could the Brown Shugar (Cane Based) be giving me the Cidery taste, and If so what would I substitute? Mollasses? How much?  
Or, better yet...
- 4) Does someone have a good recipe for an all extract English bitter? I have seen several Bitter kits at the local store. Which ones are recommended?

Any suggestions are welcome. I think that this recipe deserves another batch and I want to give it a fair shake. Many thanks in advance.

From: Jay Hersh <hersh@expo.lcs.mit.edu>  
Subject: Sam Adams claims

Keep in mind, that when Sam Adams was winning the "Best Beer in America" it was a poll of attendees at the GABF. They used tactics like having sexy women distribute cool stuff (hats, coasters, etc..). Also since their beer's name started with an A for Adams, they were next to the door, so everyone entering the GABF would inevitably start there, meaning that while you didn't get to taste every beer, you probably tasted Sam Adams.

Well the uproar over this became deafening, so 2 years ago (think it was 2) the AHA finally eliminated the attendee poll and began a blind panel judging in a per style fashion according to AHA/HWBTA guidelines. Of course there's a pretty low category to beers present ratio, so it's still not such an incredible feat to win, but I believe Sam Adams Lager has only won one silver since the category judging began.

This doesn't mean I don't like the stuff, but I do cringe at some of their ads.

From: mlevy@unssun.nevada.edu (Marcel Levy)  
Subject: planes&Corsendonk

An answer to the question about the Corsendonk label: the last two lines are a kind of Flemish I haven't seen before. The first line seem like a dialect of French, and you're probably right about that one.

The second line "Ambachtelyk Bier" doesn't refer to the abbey. I think "ambacht," the root word, means "avocation." At least, that's what I think it means in Dutch. So read it as "professional beer," or "beer made by artisans."

Yes, the third line is talking about their yeast ("gist") but I don't know what "Levende" means. Wait. On second thought, that's "live." Duh. Yeah, that's live yeast in the bottle. Hope that helps.

Planes, beer and bureaucrats: I've carried my beer on, checked it in and flown into Europe with it. I haven't had any problems (might be luck). I would suggest carry-on as being less risky, but then I only had one or two bottles in my backpack, and maybe the customs folks expect that sort of thing from students. My one experiment with checked baggage and beer suggests that either the cargo hold is pressurized, or that the bottles can stand it.

But I would recommend carry-on, because baggage handlers are not known for their deft caress.

From: "Dr. John" <JELJ@CORNELLA.cit.cornell.edu>  
Subject: Corona grain mills

Greetings,

Just because "we" only use Corona mills for crushing malt doesn't mean that there aren't other uses, and other sources for this handy little implement. I got mine at the food co-op in Moscow, Idaho, about three years ago. At the time I saved about \$15 or \$20 compared to the going prices from homebrew suppliers, Seems like this was, and probably still is, a rather high-markup item for them, but that doesn't mean that you have to pay it. Anyone who is contemplating buying a mill should look through the yellow pages, if your town doesn't have a food co-op perhaps it has a farm supply store, which might also carry the Corona, or a similar brand since these things are also useful for cracking the corn before you feed it to your chickens.

Ooogy wawa,  
Dr. John

Date: Friday, Noon, GMT  
Subject: Hello and Achtung

Hello everyone. I've got a few things on my mind. First, a reminder that requests, deletions, changes, and subscriptions (except automated ones) will not be handled until the end of December, as I am away until then. I'm in Scotland, and have been sampling lots of wonderful brews in the local pubs, and will be in London soon for a few more days. I was able to handle some requests this week (and send this message) courtesy of HP in South Queensferry, but I expect to have no network access between 12/14 and 12/24.

Second, perhaps more important, I received the following ominous message from the system administrator at one of HP's main network gateways:

```
> According to our records, mail from rdg@hpfcmi.fc.hp.com, routed via  
> hp-cv.cv.hp.com from hpfcrdg.fc.hp.com, accounted for over 400MB of the  
> Internet traffic arriving on hp-cv during November. This makes hpfcrdg  
the  
> second heaviest sender of packets to hp-cv -- right behind our *full*  
news  
> feed.  
>  
> This kind of volume tends to attract management attention, etc, etc...  
.
```

In other words, digest traffic is getting out of hand, and people are noticing. I'm afraid that the time is coming where we're going to have to figure out how to reduce the volume. The problem is *\*not\** with the content of the digest; The size of the digest is limited to 50k, 5 days a week, so please do not think I am asking you to submit fewer articles, as that would not do any good. The real problem is the number of addresses on the list, and how delivery is optimized (not at all). So, I will be thinking about how to distribute the load more efficiently in the next month or so. Perhaps just having more redistribution points would help enormously.

I just wanted to make everyone aware of this situation, and get you thinking on how you can help. Relax and don't worry about it. I'll keep you informed. My goal is to keep the digest operating, no matter what constraints are imposed, and the first priority is to appease whatever administrators or bean counters necessary without impacting delivery of the digest.

Rob Gardner

Date: Thu, 12 Dec 1991 15:37 EDT  
From: BAUGHMANKR@CONRAD.APPSTATE.EDU  
Subject: Sam Adams. The REAL story.

Sorry. I can't let the disinformation below pass without comment:

>According to the tour guide at the brewery, Sam Adams didn't submit  
>an entry after winning three years straight in order to give other  
^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^

>(smaller/home) brewers a chance at the award. The following year  
^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^

(Haven't seen such disingenuous prattle since Reagan claimed his  
policies were responsible for the destruction of the Berlin Wall.)

>they did enter and win again, afterwards the award was phased out  
>for the new GOLD/SILVER/BRONZE medal system. Not only has Sam Adams  
>beer won three times in a row, but EVERY time it has entered that  
>category.

I don't want this to sound like a flame. I'm just speaking the facts.  
I attended the GABF the year Sam Adams won the first award. Let me  
describe the situation.

First, Koch hired a couple of dozen GORGEOUS females, ALL wearing  
leotards, ALL sporting Sam Adams hats, ALL working the crowd with  
pitchers of Sam Adams, ALL coming up to the predominantly male crowd  
asking, "Here. Have you tried the beer with body?" Then, "How about  
a free Samuel Adams hat?"

In case you haven't been to the GABF. Here's the set-up. It's in a  
huge room. You could put 3 or 4 basketball courts in there. Around  
the walls are the various booths, manned (personned?) by  
representatives of the small breweries, pouring out 2 oz samples to  
whomever stops by. The first thing to note, is that there is no way  
to hit them all. If you did, you'd be staggering drunk by the end of  
the night. If you drank a particular unknown breweries beer that  
night it's because you happened by that table at a time when your  
glass was empty. They don't run you down and pour beer down your  
throat. At least 99.9% of them don't.

At the end of the night, as everyone stumbles out the door, you're  
asked to write down the name of best beer you drank that night. You  
get the picture by now. It's late. You have a GREAT buzz going.  
You're not sure about the best beer you tasted but you sure as hell  
remember the best boobs you saw that night! What was the name? Oh,  
yeah. I'll just look at my hat. Never mind. They're a couple  
hundred of them being worn at the moment. I'll look at the guy's  
behind me. Those folks sure are nice! And the women are so damned  
good looking. No doubt about it. Sam Adams is the best beer I drank  
tonight.

It's plain and simple. Sam Adams keeps getting voted best beer in  
America because Jim Koch is a great marketer. Not because he brews  
the best beer in America.

Obviously, the brewing community was a BIT upset by a couple of years  
of such shameful commercialism. Maybe he did skip a year. I don't  
know. But next in old Jim's bag of tricks was to hold his national  
beer distributors convention at -- guess when -- the same time as the  
GABF at -- guess where -- the same place where they have the GABF.  
Free tickets to all his distributors AND THEIR FAMILIES to attend the

GABF. Guess who they vote for? With 2 to 300 different beers to choose from, you don't have to stuff the box long before you come out the clear winner in that kind of "democratic" election.

So sure they phased out the popular vote and went to the gold, silver, bronze format judged by a panel of experts. They phased out the popular vote precisely because Jim wouldn't play by the rules, unwritten but categorically understood by the rest of the brewing community. The man has no shame.

I was indeed touched to hear that Koch says he quit entering his beer to give the rest of the brewing world "a chance". The only chance he gave was the opportunity to have every beer stand on its own against the competition with no stuffing of the ballot boxes or his organized army working the crowd to an unfair advantage. In actuality, Koch is a pariah at that event and he "don't get no respect" from any of the brewers. He sells breasts not brew.

I tip my hat to the man (cough! cough!). He's a good businessman. He and Donald Trump would bed well together. But remember, he doesn't even brew his blue ribbon beer. He CONTRACTS it. The BEST beer in America, 'brewed' by the Boston Brewing Company of Pittsburg, Pennsylvania. Say what??!! Isn't something missing from this picture!! Like a brewery??

It's better than Budmiller, no doubt. It's even as good as Heineken, St. Pauli Girl, Beck's and all the rest of the faceless-lagers-brewed-for-America-to-American-tastes-and-don't-taste-anything-like-their-European-counterparts that come in from overseas. Furthermore, it isn't offensive which is the key to selling anything in the mass beer market of America. Brew a beer that doesn't offend anyone, have a near-naked woman drink it in front of you and you'll sell millions of gallons of the stuff.

Anyway, that's how he did it. I'm glad he gets people trying different beers. I'm glad he supposedly opens people's eyes to the alternatives to Budmiller et al. Me? I throw my hat into the ring with the honest small brewers of America. I don't buy Sam Adams products. I have limited amounts of money. And Jim Krook has more than his share.

Sergeant Friday. Over and out.

From: dinsdale@chtm.eece.unm.edu (Don McDaniel)  
Subject: Single-step mashing of Klages

Dr. John's idea of usings Klages in a single step infusion has occurred to me as well. I have been using Klages in a two stage infusion for lagers and imported two-row pale ale malts in a single-step infusion for ales.

The matrix recently posted for Redhook ales reveals that they use Klages as the base malt for all their products. They've got some fine products. This led me to wonder about switching to Klages for ales. Doing so would save me about \$.20 per pound and more importantly require me to keep less malt in the garage. The question now is: does Redhook use tradiditional single-step mashing or do they find they need a protein rest. I suspect the former. Maybe the person who posted the matrix or some other resident of the Emerald City can find out for us. Certainly, if it's good enough for Redhook, it's good enough for me.

Subject: grainmill idea?

I just had a stray thought... Has anyone tried rigging a hopper above the rollers on a cheap hand-cranked pasta machine to crack grain?

The rollers are steel, and adjustable from pretty far apart to really close together. I just don't know if they'd "grab" the grains and run them through or not.

If this works, it should provide a superior crush to a Corona at a similar or even lower cost. I've got a pasta machine, and next time I brew (soon, I hope, as Thanksgiving parties wiped out my inventory) I'll try cracking some crystal with the pasta maker and see what happens.

Subject: Thomas Hardy's Ale

There's been talk recently of how long barleywines will keep, so I thought I'd add my two cents.

The Celebrator staff recently did a tasting of eight of the last nine vintages of Thomas Hardy's. The importer was kind enough to send them to us. (No Kidding. Free beer - in the mail! It's a tough job.....[gloat,gloat]) My notes aren't handy, but if memory serves, the 87 was the unanimous favorite. The 86 had soured (very nasty, undrinkable) and earlier batches were over the hill. This calls into question the brewer's assertion that TH will improve for 25 years.

And now, at the risk of commercialism.....

For a more complete account of this hedonistic event, see the Dec/Jan issue of the Celebrator.

Please direct all flames to me personally,

From: objy!server!bobm@Sun.COM (Bob Muller)  
Subject: Re: Boiling Over

I've been following this thread with real interest, and I think I'm beginning to see commonalities between the theories. First, my own experience.

When I first started extract brewing about 10 years ago, I had boilovers about 1 batch out of every 3 (I won't tell you about the landlord's reaction to the drip pan on the stove when I moved out!-). Over time, I found a way that works and haven't had any boilovers since. I bring the water to a boil, then heat and dissolve the malt and other ingredients in the boiling water. Never had another boilover.

So what's the deal? I think Jack's explanation makes sense--there's something about the rate of increase in wort temperature that reduces boilover. I think Eric's explanation makes sense--the dissolved gases (primarily oxygen/nitrogen?) make bubbles that foam. I think a prior post (sorry, don't have the name) makes sense--the proteins in the wort make a film that promotes the boilover. I think the posts about adding water to the boil and lowering the temperature briefly at the boil all make sense. How to reconcile all these?

Food chemists please correct me. The boilover is clearly a foaming phenomenon, the same stuff that makes souffles souffle and gives brew a head.

A foam requires at least two things, gas and liquid. The liquid forms a structure around the bubbles that allows the bubbles to persist in an ever-expanding structure that stabilizes to whatever extent the liquid's structure permits. Now, a nice protein foam like egg or malt proteins would seem ideal to promote a nice stable foam--and it does, both for souffless and beer. Complex carbohydrates may also be a good foaming agent, I'm not sure. Example: the new Guinness. This uses nitrogen to produce very small bubbles, which combine with the protein/carbs in the beer to form the smooth, creamy, stable head. My guess is that the rate of release of bubbles is important, the size of the bubbles is important, and the nature of the foaming agent is important in determining the stability of the foam.

So, my theory is that (1) slowing the temperature rise to boiling in a wort produces bubbles at a slower rate, reducing the amount of foam (this is Jack's observation); (2) boiling the water before adding the malt extract drives off the gases that make the smaller bubbles that form the foam, thus reducing the malt's ability to cause foam; and (3) skimming off the coagulating proteins will reduce the amount of foaming agent in the wort, reducing the amount of foam; (4) dumping in cold water reduces the rate of bubble production and disturbs the formation of the protein film that promotes foaming, at least temporarily, but this is enough to destabilize the foam (and this applies to lowering the temperature when the foaming occurs, it lets the foam destabilize by reducing foam production).

Subject: Mash tun design

#####  
Following is another contribution from Micah Millspaw on mash tun design. These contributions are his alone. I am merely acting as a conduit for his ideas and opinions.  
Bob Jones  
#####

I've built IMHO a very efficient mash/lauter tun. This is the result of many years of brewing and four earlier mash tuns. I usually do single temp. infusion or step infusion mashes so my equipment is set up accordingly. This mash/lauter vessel is made from a SS keg(15.5) and can easily mash and sparge 50# of grain. I have brewed at least 150 gallons using it and had no stuck mashes or any large problems at all. It is not insulated as SS is a poor thermal conductor and the grain is a large thermal mass,I lose about 3 degrees F over 2 hours. I've built into this mash tun some interesting features which might be of use to others who are planning on building or modifying their mash tuns.

- 1) the false bottom is a piece of 10 gauge perforated SS sheet metal with 3/32 holes in it. This is a pricey item but it is worth the cost.
- 2) the tun can be gravity filled with strike water from the bottom up. IMHO this makes for uniform heating of the grain without stirring, also dry pockets of grain are totally eliminated.
- 3) Spray sparging over the grain bed Bob Jones has come up with a flow control ( but I haven't installed it yet) that will maintain the level of sparge water over the grain bed.
- 4) most importantly, a vent tube that runs from the top (outside) of the tun to under the false bottom. I believe that this vent prevents a set mash caused by a sort of vapor lock, where the wort cannot flow out because no air can flow in. It has been my experience that venting under the false bottom works very well, this is my third mash/lauter tun to use this. However too finely crushed grain can still cause problems that no mash tun will fix.

On the topic of boil overs, I have a hood with a two speed fan above my kettle. Since the installation of this hood I have had no boil over problems and have had much more vigorous boils.

EUREKA! Please note, multiple title. Thanks for all the helpful mail.  
Again we prove the value of honey over vinigar.

From: Jeff Frane <70670.2067@compuserve.com>

>To Jack Schmidling: Are you under the assumption that 150 degrees of  
heat  
will kill many microorganisms, other than yeast?

Yes, as a matter of fact it will kill MOST of them. That is why milk  
and  
many other products are pasturized at 150.

> Remind me not to eat any of your home-canned foods.

Home canned foods are processed for long-term storage, not overnight as  
in  
the situation we are here discussing.

Most of the concern in canned goods is with botulism spores that can  
even  
survive an hour in boiling water. That is why pressure cookers are  
used.

You may rest assured that whatever gets into a 150 deg batch of wort,  
will  
not be worth worrying about in the morning. If the big B spores get it,  
boiling won't help anyway. Fortunately, the ones I have talked to, say  
they  
don't like beer.

From: Conn Copas <C.V.Copas@loughborough.ac.uk>  
Subject: Casks, decoction, wort chilling

>I have tasted oxidized beer and try to avoid it at all costs. I was  
musing  
>on the cask conditioning of British Bitters, and began to wonder how  
they  
>avoid oxidation of the beer in the cask after the cask is no longer  
full.  
>I mean, the stuff might be around for a few days. Any thoughts?

Depends how well the cask is sealed and consequently whether oxygen fills  
the  
ullage space. Most casks have an inlet which is sealed by a wooden peg,  
and  
which is somewhat permeable. The short answer is that the beer does  
deteriorate  
and is better fresh. Apart from the problem of oxygenation, the brew also  
loses  
condition as dissolved CO2 transfers into the ullage. The brew is pumped  
out by  
hand, so dispensing pressure is not an issue. One solution to all this is  
to  
maintain a blanket of CO2 as the brew is drawn off. CAMRA objects to this  
practice on the grounds that it isn't natural/traditional, and there is a  
possibility of the brew becoming artificially overcarbonated. This is one  
of  
the few areas where I object to CAMRA ...

Re decoction mashes, Hough et al talk about clarification benefits.  
Apparently,  
the theory goes that raising the grain to boiling extracts residual  
starch,  
which then becomes converted.

Re using chilled water to hasten cold breaks, Wheeler throws cold water  
on this  
idea in his latest book :-). The theory isn't presented at all clearly,  
but I  
believe the basic concept is that trub formation involves an equilibrium,  
ie,  
wort at a given temperature can support a certain  
concentration of dissolved trub. By increasing the volume, a larger  
absolute  
amount of trub remains in solution. Conclusion : it is better to chill  
the  
smaller volume using a heat exchanger.

Papazian sez that while commercial brewers remove hot/cold break material from the wort prior to fermentation, homebrewers need not worry. Note that C.P. recommends a blow-off tube.

Miller recommends that you settle the wort and rack it, but you can pitch before racking the next day. Miller says that leaving the hot/cold break material will cause high levels of fusel alcohols to be produced, and says that this will occur during the respiration phase due to the yeast using the trub for oxygen instead of the oxygen from your aeration efforts. Note that Miller does not recommend blow-off tubes.

His "beginner's guide" section has you rack from boiler to fermenter, then to a carboy, then back to the fermenter. Too many steps, I think. Also, I use liquid yeasts and starters. With ale yeasts, this means I get a VERY short lag, if I waited until the next day, it would be far too late. Miller is a lager maker, where even with starters, the lag is long enough to pitch then wait for settling to occur.

Papazian may be right, in that, the blow-off may expel fusel alcohols that are produced by fermenting on top of hot/cold break material. I'm for blending the two bibles together -- and here's what I do (or did) as of my last batch:

I use an immersion chiller to get to room temp, in the open electric masher/boiler. Then, I remove the chiller and cover the boiler with a sanitized cover. After cleaning up everything else, I go get my carboy where the starter has been working. I remove the fermentation lock, pour off the used wort, leaving the slurry behind, and then rack the batch of wort from the boiler onto the yeast in the carboy. I cap, slosh around, then use a blow-off tube.

Yes, I get some trub formation over the next few hours. But I've not left a fresh batch of wort sit around for bacteria and wild yeast to feast on. I use a blow-off tube to remove any excess fusel alcohols, and I don't worry.

From: "John Cotterill" <johnc@hprpcd.rose.hp.com>  
**Subject: Liquid Starters**  
Full-Name: "John Cotterill"

I began using liquid yeasts about 5 batches ago. The first surprise was how long it took to get a serious fermentation started (over 2 days!). At first I thought it was just an older yeast, but the second batch did the same thing. Since then, I have been adding the liquid from the package to a little (very) sterile water and malt put into a bottle with an air lock on it. After a few days, I can pitch this into my batch and have a fermentation that starts within about eight hours.

My process is very inexact, I just add, "oh, about this much malt to about this much water." My only real concern is not to put so much malt in the the final alcohol content in the starter kills the yeast. What do other people do? Do you boil hops into the starter mixture? Are there any rules of thumb for how much malt to use?

By the way, my second surprise was how good beer tastes using liquid yeast and how it gives me another degree of freedom for keying in on the ideal recipe.

Subject: Half-coct decoct

> Noonan does indeed  
>instruct us to boil the decoction, for up to 45 minutes in some cases,

OK, but I wasn't actually basing my impressions on Noonan. I was basing it on what I had (perhaps mistakenly) thought to be traditional German and Czech decoction brewing. Darryl Richman had a more complete tour of the PU brewery, and I don't have his article here, so perhaps he can comment on his recollections. It is certainly possible that in my questioning of our tour guide and the museum curator at the Bamberg brewing museum (a former brewer who spoke no English, and I not enough German) that I didn't make my questions clear, or misunderstood the answers.

BTW If you're in Bavaria make the trip to Bamberg. There is a great brewing museum in a monastery overlooking the town. Lots of local brewpubs making tasty Rauhbiere, and a lot of other great local breweries. Unfortunately we skipped Kulmbach, though some Kulmbach beers were available in Bamberg. Also while not as great a brewing town Nurnberg is nearby and is quite a quaint little town with a hilltop fortress and old city walls dating from the medieval ages.

Sorry I'm not Norm Hardy, and I don't have my notes handy. A bunch of people (Wort Processors) are after me for a complete tour write-up but I'm too busy.

Subject: Grain Mills

I like my grain mill.....  
Grain mills are very helpful in the sense that you can bulk order grains for a significantly lower price and if you and all your friends order the price even goes lower...  
I have only had my grain mill for 3 batches but it has nearly paid for itself in the amount I saved ordering 5-10 lb bags of grain.  
A grain mill isn't necessary but is sure helpful and couldn't do without it now.

.Brian Midura  
P.S. If you think they are too expensive and have friends that homebrew you can all pitch in and it is less of an economic burden on each person.

The question of cargo-hold pressurization comes up in various contexts both in and out of the HBD. The cargo-holds of all commercial jets are pressurized to the same pressure as the passenger cabin. This is why they can carry pets down there.

In any case, even if you took your beer into the vacuum of space it would be the same as if the pressure inside the bottle increased by about 15 psi. I should think most beer bottles could manage this much pressure increment.

Beer in space? Hmm... Has anyone sent some little yeastlies up in the shuttle to see if they'll still ferment?

Subject: Beer Places in Seattle

Two \*interesting\* taverns in Seattle are Murphy's Pub and The Blue Moon. They are both on NE 39th, west of Univ of Wash. Murhpy's is really in Wallingford, The Blue moon is just the other side of I5 from campus.

Murphy's is an Irish pub with excellent live music most evenings. They have Guinness and other British beers on tap. Don't remember which others, I haven't been there in at least 5 years (I don't live in Seattle any more). One of the local NPR/APR radio stations, KPLU does a Saturday morning live variety show from Murphy's with music, skits etc. Similar to West Coast Weekend on KQED in SF or Prarie Home Companion, but better than West Coast Weekend (IMHO) and more focused on Irish/Celtic music than PHC. The host(ess) of the Seattle show and several of the guests have appeared on PHC. Not relevant to beer, but Seattle has a thriving folk/bluegrass scene.

Somewhat further in the same direction, between Wallingford and Ballard in Phiney Ridge is the new location of Red Hook, home of Ballard Bitter, Red Hook, Winterhook etc. I went on a tour in their old Ballard location when my sister was up visiting and had a wonderful time. They only had tours on Saturday mornings (they brew every other day) and you needed reservations. Don't know if policies have changed. You can get cool tee shirts like the winterhook shirt i happen to be wearing and they give you as much beer on tap as you can drink before noon.

The Blue Moon is a funky, bohemian place that has been there for over 50 years. They have local micros on tap: the various red hooks and grants, probably many others by now but it's been a while ;-). They used to have different events on different nights: opera night, grateful dead night, free peanut night etc. i watched the reagan/mondale ferraro/bush debates there ;-)

Near Boeing, Ranier brewery also has tours, although they HARDLY qualify as a micro!

Have Fun!

- --kt

PS there is also an excellent homebrew supply store in pike place market, so your 'friend' could bring you back supplies ;-)

>quite a few more in days gone by.

I'm no anthropologist or metallurgy/historian, but I'd say we're  
on pretty safe turf to claim that brewing predates stainless steel.  
In fact, I think it's safe to say that brewing predates written  
language. The oldest known recipes come from the Sumerians and are  
written in Cuneiform, the oldest known written language. They'd  
already figured out how to make beer by the time they'd figured  
out how to write about it. As far as I know, there are no "recipes"  
for stainless steel in Cuneiform. :+]

There are anthropologists out there who espouse the theory that  
humans made the transition from hunter-gatherers to an agrarian  
society in order to have a more reliable supply of grains for  
beer making. I guess they were the first to go all-grain!

Chai Yo,  
CR

"We brewers don't make beer, we just get all the  
ingredients together and the beer makes itself."

Subject: lifetime of beers

It may be of interest to report that I recently drank a bottle of Gale's Prize Old Ale that had lain with my wine for 12 years. It was superb and was superior to but of kindred character to a Thomas Hardy's Ale. The Gale Prize Old Ale came in corked bottles of 9 3/4 fl.oz. capacity, and an old CAMRA guide described it as the last commercial beer in England to come in corked bottles. Can someone tell me if it is still being brewed, and if so, in what kind of bottles does it come. Mine is a lovely brown pressed glass with a charming inscription. Peter Gaspar

Subject: lifetime of beers  
Subject: Wort Spoilage (George Fix)

Jeff Frane's comments about wort spoilage appear to me to be right on target. This is an area which many homebrewers take lightly since the damage to the finished beer is usually not as serious as it is with other types of infection. Nevertheless, problems from wort spoilage are apparently somewhat common. What is particularly frustrating is to be evaluating a beer in a competition where the brewer has clearly used a well designed recipe with high quality brewing materials, yet have the overall effect compromised by minor (but invariably unpleasant) effects of wort spoilage.

The most dangerous wort spoilers are from a broad class of gram negative bacteria generally called coliforms. What they have in common (other than the Gram stain) is a strong propensity to produce various sulfur compounds (DMS, H<sub>2</sub>S, and misc. mercaptans). The effect is different from the malt derived DMS cited in other posts, and has the unmistakable aroma of cooked corn. (This flavoring is totally unrelated to the use of corn as a cereal adjunct). Most is scrubbed out in the fermentation, but residual flavoring recalling rotten vegetables can remain in the finished beer.

Two points deserve emphasis. First, effects can occur with only moderate levels of infection. In experiments I did in preparing my book, it was found that infections as low as 1000 cells per milliliter can be relevant. (E.Coli from ATCC was used in these experiments). Recalling that there are roughly 10,000,000 yeast cells per ml. in a normal pitching, this amounts to one coliform to every 10,000 yeast cells, hardly a massive infection.

The second point is that the sulfur compounds produced have very low flavor thresholds. For example, the DMS/H<sub>2</sub>S/mercaptan mixture produced by coliforms is typically detectable at 10-20 micrograms per liter (parts per billion if you like!). This is in striking contrast to esters, diacetyl, etc. whose thresholds are measured in milligrams per liter (ppm). Powerful stuff this.

The coliforms are inactivated at 140F, so wort held at 150F is theoretically safe. Nevertheless, I feel that Jeff's concerns are well founded. First, 150F is cutting it close to the danger point. Second, there is always the possibility

that bacteria will find thermal protection inside protein particles or in some other place.

There is one other wort spoiler that is unwelcome in most beers, but is welcome in sour mashing. These are thermally resistant strains of lactobacillus. In fact, it is my view that the real challenge for sour mash brewers is to promote the lactos while keeping the coliform count low. If done well with the right recipe, this can lead to refreshing and snappy flavors a la Berliner weisse (when it is fresh!). In most beers, on the other hand, it will lead to an unacceptable sourness.

As a practical matter, our best defense against wort infection is keeping our brewing equipment clean. A variety of cleaners work well (e.g., TSP, B-Brite, washing soda, etc.). What is apparently important is not the cleaner used, but rather making sure that the equipment is cleaned in a timely manner after use.

I am very sympathetic to the "no chemical" approach to sanitation. Indeed, some of the flavors imparted by residual chemicals can make rotten vegetables sound pretty good! As a personal matter, on the other hand, I simply do not trust myself to do an adequate job at for example cleaning using hot water and a cloth alone. Moreover, enough is known about the chemical cleaners and sanitizers that they can be totally neutralized after use using the appropriate procedures.

From: man@kato.att.com  
Subject: boiling

Since I moved my brewing outdoors, I have had experiences that none of you have mentioned. When I brewed indoors, it took 1.5 hours minimum to boil down 6.5 gal of wort to 5.5 gal. So far, I have made 2 batches outdoors. One batch was 6.5 gal pre-boil and the other was > 8 gal pre-boil. In both cases, I boiled it to under 5 gal in 1 hour. I am using a King Kooker jet propane burner, but I keep it at a setting so it just does boil. Does anyone else experience this? My 8 gallon batch had an extra 1.5 gal of water added to the kettle after the sparge. I figured this would fix the problem, but I still had to add > .5 gal of water to make a 5.5 gal batch.

Jack:

On this intimidation theory. I don't but it, but then I don't know for sure, either. Why don't we do this: Will anyone who got a free copy under the pretention of posting a review please step forward and explain yourself? Now, give them a week. If Jack has a larger list than those who respond, I suggest he post them after the week is over. Then we will see who is fessin' up.

Jack:

On the STUFF postings. You said you didn't separate your posts to save bandwidth (sic). But you continue to post ads and EASY MASH techniques and INTIMIDATION posts to both the HBD and rec.crafts.brewing. This is a terrible waste of bandwidth. You essentially send these posts to r.c.b twice. I suggest you only post these to one place (your choice, but HBD would let you get to everyone) and then with the extra bandwidth, you can separate your posts and keep the threads going with meaningful subject lines.

From: Frank Tutzauer <COMFRANK@ubvmsb.cc.buffalo.edu>  
Subject: culturing yeast

In HBD 781, Eric Mintz asks to start a discussion about yeast culturing. I've finally read the yeast special issue of zymurgy, and I'd like to second his suggestion. From my own standpoint, I would like to build up a collection of various yeasts that I can use as needed. Although cost is one consideration, my main reason for wanting to do this is that my only source of liquid yeast is mail order and I'm tired of having to coordinate brewing around shipping concerns. So far, I have cultured yeast from the bottom of my own bottles, but: (a) I don't want to push it past one or two generations, and (b) if I want to drink that last bottle but I'm not ready to brew then I'm S.O.L. :-)

So...I'm considering two options. First, slants, agar, and petri dishes, as detailed in several of the zymurgy articles; and, second, a yeast bank involving glycerin (?) and sticking the yeastie boys in the deep freeze. I know a lot of you use slants, but does anyone have experience with the yeast bank? The cost seems reasonable. Alternative Beverages sells a yeast bank for about 6\$ (U.S). The kit comes with 5 culture tubes, 4 ounces of "freeze shield", an eye dropper, and a storage container. Additional freeze shield and culture tubes are available. I don't know much about chemical glassware, but I suspect the petri dishes, etc., would cost a bit more.

Some more questions:

1. How does the yeast bank compare to slants, etc.
2. What's a good source of inoculation loops, agar, etc., for non-chemists?
3. How long can the cultures in the various systems be kept?
4. How many batches do you get out of one strain?
5. How much refrigerator/freezer space is needed?
6. In either system, does the yeast degrade/improve over time?
7. What problems/pitfalls have you encountered? What advantages?

I thank you and my yeast thank you.

Young fermented cider is usually very tart due to its acidity (you don't  
need  
to add acid crystals). It is unlikely to be vinegar-like from the  
activities  
of acetobacter at this early in the game. Acetobacter spoilage results  
primarily  
from the conversion of ethanol to acetic acid and therefore must occur  
after  
fermentation. Spoilage is also a slow process unless you deliberately  
inoculate

your beer/wine/mead with a high titre of acetobacter. It's probably worth your while to save your cider and see what it is like in 3 months. I also noticed that you did not include a sulfite treatment of your cider 24 hours prior to pitching the yeast. Judicious sulfiting is good insurance against microbial contamination of ciders and wines and will circumvent acetobacter problems.

> From: Mike Dobres <DOBRES%DUVM@pucc.PRINCETON.EDU>  
> Subject: What makes top top or bottom bottom  
> Just curious-What makes top fermenting yeast float more than bottom fermenting yeast? Perhaps something to do with cell/cytoplasmic density or CO2 retained by cell - I dunno - Any ideas?

A good question and the answer may at first seem contrary to simple logic. Ale yeast flocculate (stick together in multicellular aggregates) much more efficiently than lager strains. This is due to their bearing a higher concentration of various cell surface adhesion molecules, the details of which are unimportant. One would think that larger cell aggregates would fall out of suspension faster and settle to the bottom, but that would only be true when the liquid is still. The turbulence produced during active fermentation moves the yeast through the beer and as ale yeast aggregates it forms a sticky yeast mass which can cling together at the surface of the beer producing a luxurious thick yeast foam. Hence the description "top fermenting". This phenomenon of aggregated material being pushed to the surface by turbulence where it aggregates further is also seen during the boiling of your wort when the proteinaceous scum forms.

Although what I described above is generally true for ale versus lager yeast the top vs. bottom fermenting delineation is not an accurate one to employ in defining an ale versus a lager. Many ale strains exhibit varying degrees of flocculation and the same applies to lager strains. What is more important in our definition is the temperature at which the fermentation takes place. Lagers are fermented cold (40-55F) and aged colder (32-40F) and ales are fermented at warmer temperatures (60-70F). The levels of products (esters, acetaldehyde, phenols, diacetyl) of fermentation which account for much of the personality of a given beer style are strongly affected by the temperature of fermentation. Irregardless of extent of flocculation, lager yeast are more active at lower temperatures.

From: bradley@adx.adelphi.edu (Robert Bradley)  
Subject: What is Canadian 2-row?

(Sung to the tune of 'Poor Lonesome Cowboy':)  
I'm a poor lonesome Hoser and a long way from home....

Does anybody know what Canada Malting's 2-row malt is? In recent private correspondence, Dr. John described Klages to me as "2-row with the enzymatic properties of 6-row". This seems to describe the stuff I brewed with back in the good ol' days when I was still living in Toronto. You used to be able to get 100 lb. bags in quantity  $\geq 6$  at the Canada Malting plant for \$29 a pop, and Jake McKay sold 'em in quantity 1 for \$36 at Fuggles and Goldings (does anybody out there know how Jake is and if F&G is still in business?). I understand that the breweries used to use the self-same stuff. This would have been a good thing for corn-brews like Blue (reputed to be 44% corn!), but Viv Jones, then brewmaster of Upper Canada, complained in 1988 that the stuff was too enzymatic (!!!) and that UC was having to use some imported stuff in order to keep the final gravity up.

So my question: is CM 2-row Klages? Partly or completely?  
And does anyone know where a poor expatriate banished to the wilds of Long Island could find some, even if it's not at the incredible price of .29/lb? (How much is that in real money?)

By the by, I almost always used a one-step infusion mash with the stuff. (I seem to recall Viv Jones saying Upper Canada did the same.) I never got a haze at room temperature, but chill haze was sometimes a problem. On the other hand, I sometimes got chill haze with a step-mash, so I can't reject the null hypothesis.

In #781, Jack Schmidling says:  
> it took an hour to bring the mash from room temp to 154 degs ...

If you want a "true" infusion mash and would also like to save time, just strike with hot liquor. You'll have to fine-tune for your own equipment and methods, but I bring about 3 gals. water to about 162 degs and then add 8 lb. grain. The temperature settles at  $\geq 150$  and I can adjust upward with a little boiling water if need be. (PS: this may not seem like a very stiff mash, but I'm using a bruheat with a hanging grain bag...there's about 1 gal. below the grain.)

Also, Jack, I urge you to collect more data points before concluding that a single-step mash gives a lower yield. In my experience there has been no difference.

Finally, let me put in my two cents in favour of the Corona grinder (mine is a Polish look-alike). True, it's not a mill and it 'scrapes' instead of crushing, but it does a decent job with very little flour if you set it just barely fine enough to break all grains. There's no need to spend a lot of money, and you get freshly ground grain. However, I don't buy Florian's argument that it pays for itself compared to the cost of brewing with extract: Saving money is not the reason to brew from grain...love or lunacy are the only things that could justify investing an extra 3-6 hours in each batch. (Well, OK, better beer is another reason.)

Happy Holidays, all,  
Rob (bradley@adx.adelphi.edu)

Subject: airlines transport

I had an experience similar to others in trying to hand carry a couple of bottles (unlabeled champagne) in a briefcase aboard a flight from the Colorado Springs airport. Xray picked up the bottles, the attendant insisted upon examining them. I told him they were homemade beer. "How do I know, if you want to open one and show me (?) that will do." Since I had no way to open and recap I declined. He told me if I could get the airline to agree to carry the stuff he would let it through. A hurried trip back to check in, query to the supervisor, "Could I put the bottles in my checked baggage?" No. "What if I had just put them in before checking the bags?" "That would be ok, but you didn't. Now we know you've got them and you can't prove what's in them." I left the bottles at the checkin counter, they put my name on them and on return a week later, surprise, they were still there unopened! I did not take this as commentary on the quality of my brewing. On a later trip, not wanting to risk breakage, I took a couple of similar bottles, this time with reglued Budwater lables on the champagne glass. Same procedure at Xray, attendant examined the bottles, no questions.  
Draw your own conclusions.

Subject: Kraeusening

Kraeusening

I have a question regarding Kraeusening my medium to heavy bodied ales. I tried this on my last batch using the formula outlined in Papazian. It is only very slightly carbonated (but still very drinkable, of course!). According to Burch, I should raise the S.G. by .005-.006 which I believe makes Charlie's formula low by a factor of two. In any case, I need some help from you Kraeuseners.

The Details: Extract/Mash recipe with I.G.=1.040 , Edme ale yeast, two weeks in closed plastic fermenter, racked and bottled with 1.4 quarts of gyle.

Thanks,

Andy Hays

Subject: On Mashing & the Menage

In HOMEBREW Digest #778, Ted Amsel outlined a familiar scenario:

> I got home and found the house empty ... I decided to do a partial mash  
> ...  
> ... the family came home WITH a new puppy. Thus the kitchen was  
> turned into chaos.

There oughta be a law, Ted.

> How does one brew all-grain with out interruption and still have a  
> familial unit?

If you ever find a really good answer, would you send word? One thing that I can pretty well count on is just at that moment where it's critical that nothing be stirred up and that I be able to work quickly (like, when starting the siphon to rack the cooled wort to the carboy), a veritable Panzer Division of kids & animals will stream through, and generally stop to (loudly) discuss matters right in the middle of the "brewery", until I bellow. Sometimes it's not even that easy to quell the riot -- I recall attempting to explain, as tactfully as I could, the importance of bottle sanitation to a depressed French psychiatrist who was sure that she was being very helpful to me by processing the bottles through with barely a sidelong glance at the bleach solution. Amazingly, no infection developed, but I sweated bullets

until the last bottle of that batch was gone. Recently an entirely new dimension of the problem has developed: spectators! Call me a grump, if you will, but I generally prefer to work alone. That way I can truly focus on what I'm doing, and I'm less likely to end up in one of those awkward positions where something must be done NOW, but the tool needed to do it is filthy. Recently everyone I've ever met (brewers excepted, of course) seems to have decided that, Gee Whiz, wouldn't it be a grand thing to come and see Martin brew. I suppose that would be fine, but they usually bring their kids to play with my kids (swelling the Panzer

ranks), and the last two such events have begun with the guest walking right in and calling the sheriff, most recently because someone shot a hole in their car as they were turning into my driveway (no, it's not THAT kind of neighborhood)(And that story's actually a good deal weirder than I've made it sound -- I'll tell it to you some evening, over a brew)

I don't think the problem's as much families as it is Karma. Disasters that would NEVER happen when I'm raking up the leaves (ugh) seem to know when I'm brewing. I had a realtor call me while I was brewing a batch of porter to say someone was finally making an offer on the money-pit I'd been trying to unload for over a year, and that the papers were even then being faxed to a location a few miles from me. I could just make it there

and back during starch conversion. Halfway there, the water pump on my truck blew ... (the porter turned out fine, despite a VERY long rest).

Subject: bottle fillers

Is there some reason a bottle filler isn't considered a necessary piece of equipment for brewing?

I siphoned my wort from my brewpot to my primary with the bent-tube technique. It went okay. I racked from my primary to my priming container, and from there into my bottles, using a bottle filler. (I sometimes think of this as a "bottling wand". It's a stiff plastic tube, a little more than a foot long, with a gizmo at one end. The weight of the wort/beer holds the gizmo closed, unless you press it down against, e.g., the bottom of a bottle. This thing attaches to the lower end of the siphon tube.)

Siphoning was a thousand percent easier with the bottle filler! To stop siphoning, all I needed to do was lift the "wand". Very simple, very straightforward to control exactly how much beer gets in the bottle.

Do people not talk about bottle fillers because there's a problem? Or because they're so wonderful, no one would consider siphoning without one?

From: Brian Capouch <brianc@zeta.saintjoe.EDU>  
Subject: Best size for counterflow chiller

I'm putting together a little brewery, and I found out, somewhat at the last minute, that my heat exchanger is not going to work as I'd planned.

So I need to make a "quick-and-dirty" counterflow chiller. My question is this: would 1/4" or 3/8" tubing make the better mousetrap? Intuition tells me that the 1/4" would allow a much greater wort-to-coolant surface area, since there'd be more wort (relatively) on the outsides of the tubing than in the center. That would be at the expense of throughput, but I'd rather have cool wort exiting slowly than hot wort exiting fast.

Is that logic good?

Thanks.

Subject: flame Koch, not his beer

Uh, Kinney, I think the subject line about covers it. Jim Koch is a shameless marketer, as you say, but he makes good beer. There *\*is\** a brewery in Boston, although some (most?) of the beer is contracted out to Pittsburg. One of the Boston brewers will probably set this straight. I don't think that Sam Adams lager is a "faceless, non-offensive beer". It sure seems to have a lot more character than Becks or Heineken, and I know people who don't like it ("it's too strong"). That's not to say that there's not a number of microbrews (and homebrews) that blow Sam away. The point is that Koch's *\*beer\**, for the most part, is a flavorful quality brew. Koch's *\*attitude\** is something completely different.

Subject: Rolling Grain Mill, under \$40

Whoof, I think I've begun the redeeming process of discarding my semi-yupster lifestyle. Last weekend, I transformed my oh-so-trendy-at-the-time hand crank pasta maker into:

>>>>>A ROLLING GRAIN MILL<<<<<

But you know, it did make good pasta - actually GREAT pasta. Oh well, now it performs a far greater service.

This is my story:

All this recent talk about grain mills got me thinking how the budget brewer could build such a gadget. After discarding a bunch of my own ideas, reading over Jack Schmidling's design (which was well done BTW. Hats off to Jack.), my eyes lit upon the dusty Atlas hand-cranked pasta machine. So, they've pretty much done the engineering for you. Pasta machines have two opposing rollers to flatten the dough and an adjustable gap. After an afternoon of tinkering, the result is a hand powered rolling grain mill with an adjustable gap that works just as fast, if not faster, as my Corona Mill. Total cost: under 40 bucks. Man, I tell ya - I doubt I'll ever use the Corona Mill again.

1. Buy a pasta maker, or sneak one out of a trendy friend's kitchen. You can buy pasta makers at most kitchen stores, dept. stores, etc. They run between \$35-40. Out here in NJ, I got mine at Fortunoff's in the Willowbrook mall.

2. Modifying the pasta maker. No disassembly required. Now, it's time to take the shine off the pasta rollers. (Otherwise the grain sits & spins) Get a grinding wheel bit for a power drill. I got mine for about 3 bucks at my local hardware store. They've got all sorts of geometries. Mine looked like a pink stone teardrop. Anything will work if it takes the shine off the stainless steel.

Take that power drill (If you don't know how to operate one, watch an old episode of "Mission Impossible.") and grind the begezzus out of those shiny, smooth, adjustable rollers. You don't need to dig. Press just enough to make a rough surface. Go back & forth in a lengthwise pattern. Turn the crank, repeat again, all the way around.

3. You're done. Have fun. Put in some grain and try out your new rolling mill. Iterate on the grinding as necessary.

I made a hopper from a old pizza box. This'll take all the grain you can put through it.

A pasta machine - makes a great Xmas gift for the brewer in your life. :  
-)

IOn HBD #782, Rob Gardner writes

> In other words, digest traffic is getting out of hand, and people  
> are noticing. I'm afraid that the time is coming where we're going to  
have  
> to figure out how to reduce the volume.

I get the digest by direct mail, but I could pick it up from newsgroup  
rec.crafts.brewing. I don't find the rest of rec.crafts.brewing that  
interesting, and I was never sure how consistent this cross-posting  
would be, but I would be willing to switch.

If you or somebody else would be willing to consistently send the  
digest to rec.crafts.brewing, maybe we could keep the direct mailing  
at a lower level.

One of the pasta machine makers has a grain mill. It looks much like  
the pasta machine, but the roller are scored to "grab" the grains.  
Since it is intended to make flour, a simple modification would be  
necessary  
to crush malt. The cost is high, close to \$100 I recall, so I have  
not used one.

From: Donald Oconnor <oconnor@chemistry.UCSC.EDU>  
Subject: pasta mill

Ken Weiss inquired about using a pasta maker/cutter as a grain mill. I tried this a couple of years ago. It doesn't work. Can't pull the grain through.

Commercial roller mills have very large rollers, 6" diameter. Pasta rollers

are only an inch or so in diameter. That's probably the problem. A large

roller leaves essentially a long feed area into the cracking region. Pasta

rollers are also very smooth; I'm not sure about commercial ones. Does anyone

know if commercial rollers are roughened or what? Commercial rollers are used

to make chicken feed among other things.

Date: Mon, 16 Dec 91 12:13:27 EST  
From: Tom Dimock <RGG@CORNELLC.cit.cornell.edu>  
Subject: Carbonation and Grain Mills

Rich Kempinski asked in HBD 779 about rescuing an under-carbonated batch. I had one of these (batch #1...) and ended up pouring all of the bottles back into my priming bucket, adding fresh priming sugar and a fresh yeast starter and then re-bottling. A pain in the a-- to do, but it did result in a pretty good ale.

A Dietz wants to prime without sugar to preserve flavor. The best way to make sure you don't change the flavor is to save some of your sweet wort (I have never done this, but have seen writeups of using 3 pints for a five gallon batch) under sanitary conditions and then using it for priming. Don't remember where I saw that, but it was a split batch comparison of using sugar, DME, and sweet wort. The sweet wort won hands down. I'm gonna try this one myself one of these batches.

On roller mills - the reference in HBD 780 to building a roller mill using the rollers from a grocery store checkout came from a small book on building your own brewery. I don't remember the exact title, but it was xerox style publishing and probably isn't available any more. I do recall that the rollers were 4" in diameter, and that there was a provision for adjusting the spacing. Although there was a picture of the device, it conveyed very little useful information on how to build it. For example, there was NO indication of how the rollers were powered.

In doing some serious "wetware simulations" (i.e. kicking back with a homebrew and thinking about it), I came up with several unknowns. First, what are the critical factors in getting the grain to feed. My simulations very easily showed the grains just sitting on the rollers with not enough traction to get sucked in. Jack S has dealt with this on small diameter rollers (1.5") through (I think) longitudinal serrations cut into the rollers. I am fairly sure that the rollers on a pasta machine would not work for this reason. The 4" rollers are probably big enough to work with smooth surfaces. Do we have any Industrial Process engineers out there who could calculate for us the minimum roller size for a smooth roller to work effectively on the grains we use?

My second unknown was roller spacing. Is there a specific spacing which guarantees a good crush, or does this vary with the grain? Would adjustable spacing be required? That would make the construction a bit harder.

What data can people come up with? Measurements of commercial mills that work?

BTW - My series on keg boilers is coming along -- Part 3 got stuck in the push down stack, but should escape soon....

**Subject: Iodophor Anyone?**  
Full-Name: "John Cotterill"

In several previous posts, the use of Iodophor from Diversity Chemical was recommended for sterilizing stainless steel. I talked to the local rep here, and they only sell the stuff in a crate of 4 1-gallon containers. I asked if I could get a 1 gallon sample, but he seemed very resistant (I think if I pushed hard enough I could get it). I got to thinking that many of you out there might like to get a hold of single gallon also. The stuff costs \$55.13 for the box of 4 1-gallon containers. I would be willing to buy the case, take a gallon for my use, and sell the other 3 to anyone who wants a gallon or more. I'll sell it for what it costs me plus whatever it costs to ship it to you (provided the stuff can be shipped legally). If there is some interest, please e-mail me and I'll get the process in motion.

Subject: Fwd: STUFF

>I E-mailed Jack Schmidling and explained that I had access to a metalshop, and requested detailed instructions on how to build my own grain mill. Here is the response I received. I have edited it, but retain a copy of the full text for all interested parties.

I would suggest that interested parties request the text from me rather than a pirated copy. I have made significant enough changes that make your copy totally obsolete. It runs far better at 120 rpm and the ideal spacing seems to be around .020. I have also developed a hand cranked version that works amazingly well.

In regard to the rest of your sarcasm, I suggest you try honey instead of vinegar.

From: krweiss@ucdavis.edu  
Subject: grainmill idea?

>I just had a stray thought... Has anyone tried rigging a hopper above the rollers on a cheap hand-cranked pasta machine to crack grain?

>The rollers are steel, and adjustable from pretty far apart to really close together. I just don't know if they'd "grab" the grains and run them through or not.

Don't bother, it won't work unless you run it through several times at progressively closer spacings. That is why roller mills have multiple sets of rollers and also why they are so expensive. That is also why the one I made has, what amounts to teeth on the rollers to grab the grain. The rollers on my pasta machine are so smooth that I doubt it would work at any spacing.

From: man@kato.att.com  
Subject: boiling

>Since I moved my brewing outdoors, I have had experiences that none of you have mentioned. When I brewed indoors, it took 1.5 hours minimum to boil down 6.5 gal of wort to 5.5 gal. So far, I have made 2 batches outdoors. One batch was 6.5 gal pre-boil and the other was > 8 gal pre-boil. In both cases, I boiled it to under 5 gal in 1 hour.

Consider it a blessing. You can start out with more wort at a lower sg and end up with more beer. I typically get 1.5 gal per hour boil off on my furnace.

>Jack:

On the STUFF postings. You said you didn't separate your posts to save bandwidth (sic). But you continue to post ads and EASY MASH techniques and INTIMIDATION posts to both the HBD and rec.crafts.brewing. This is a terrible waste of bandwidth.

First of all, I have not seen HBD on rcb for quite some time, so it does not appear to be redundant. Secondly, as there seems to be a different ambience on HBD, I frequently re-phrase postings or leave some things out of HBD articles. They are not the same.

From: larryba@microsoft.com

Subject: Re: pasta (grain) mills

I tired it, it doesn't work. The pasta mill rollers are too small in diameter to "grab" the grain. The Seattle Brew Brothers have a mill with rolls made from 4" pipe (ends welded, shaft installed, outside turned true, about a foot long) and it seems to work very well. Only one roll is driven, the other free-wheels, you have to get the undriven one spinning slightly before dumping in the grain. It will eat a fifty pound sack in about a minute. Very impressive.

From: "John A. Palkovic" <scientist@lupulus.ssc.gov>  
Subject: de-arf program, water quality

I have written a filter that removes certain postings from the HBD. It runs on unix computers. It only needs a handful of unix utilities. You can attain a copy via anonymous ftp from lupulus.ssc.gov. Look for pub/de-arf.shar. I have tested this script on SunOS 4.1.1 and Ultrix 4.2. I hear that it also works on a Unix-PC. For those without anon. ftp access, I will mail a copy on demand.

I figure only one person will flame me for writing this. :-) My own opinion is that it makes the HBD a lot easier to read, and it merely automates what I have been doing manually for months. Since it is written in sh, you can hack it to your heart's content, and perhaps improve it.

Now for something homebrew related. In his book, Papazian says (p. 79)

... information about the contents of your drinking water supply is available at no cost from your local water department

What exactly should I ask my water dept.? Should I call or write? Is there a law that says they have to supply this info at no cost?

I have other questions about water, but I'll leave it at that for now.

Katy lauds a few of my neighborhood taverns:

Date: Fri, 13 Dec 91 10:39:43 -0800  
>From: ktk@nas.nasa.gov (Katy T. Kislitzin)  
Subject: Beer Places in Seattle

Two \*interesting\* taverns in Seattle are Murphy's Pub and The Blue Moon. They are both on NE 39th,

Make that N 45th St.

west of Univ of Wash. Murhpy's is really in Wallingford, [...]

Murphy's is an Irish pub with excellent live music most evenings.

Slight correction: Murphy's WAS an Irish pub with etc., etc., as they've lost their lease, and so are temporarily without a home. Happily, they are resuming work on a new site just down the street. No clue as to when they'll reopen, alas, but it shouldn't be more than a couple more months (he said, hopefully).

Couple of notes on your other mentioned places:

The Blue Moon is smoky as all hell, and drenched with attitude (albeit an alternative attitude). Monday evenings (Opera Night) are good, since the music frightens away many regulars; Thursday is Dead Night, if that's your pint. Actually, I suppose every night is Dead Night there. Dress down.

The Red Hook Brewery keeps an attached brewpub, the "Trolleyman." It's smoke-free, but a bit lacking in the ambience department, unless you like to drink in your Mom's living room. They have live muzak on Monday nights.

Four taps, including one rotating of a cask-conditioned variety. Good place if you don't mind young-upwardly-mobile types, or can ignore same for good beer sans secondhand smoke. Beware: closes ungodly early (c. 10-11pm).

From: Patrick\_Waara.WBST129@xerox.com  
Subject: Re: boil overs

I'm way behind in my digest reading, but I haven't seen anyone mention the method I use to avoid boil overs, so I thought I'd share it. What I do is let the wort foam up near the top of my brew pot as it begins to boil. Once it gets close to the top (not too close as I'm try to avoid a boil over afterall), I remove the wort from the burner. I then let it set until the foam subsides (a minute or so). When the foam has gone down, such that I can see the wort, I return it to the burner. I watch it as it quickly returns to a rolling boil and rarely will it foam up again. If the foam does rise up again (usually meaning the boil wasn't going strongly enough before I removed it from the heat the first time), I simply repeat the procedure. I've used this method for my last 24 batches and haven't had a boil over yet.

Subject: Re-using Yeast

I need some expert opinion on re-using yeast. Approximately a month ago, I saved from my primary frementer two scoops of the dregs. The yeast for this batch was Wyeast American Ale. I put the dregs into a sanitized plastic container. I covered the dregs with a few inches of fremented homebrew and stored it in the fridge.

The question is, will I be able to use this yeast for my next batch? Should I use a low gravity starter to get the yeast active or can I simply dump the contents into the chilled wort. Would it be worthwhile to sepearate the trub from the yeast sediment? I recall reading a post in the HBD about this, but I was unsuccessful in attempt to find it. Does anyone remember the subject line or the issue number? What "things" should I look for, or smell, in able to determine if it is infected. Or has it been stored too long to reuse?

BTW, the yeast was used for an IPA and is planned to be pitched into a brown ale. Thanks in advance for your help.

From: Jeff Frane <70670.2067@compuserve.com>  
Subject: Pilsen Mash

On Decoction Mashing:

The following is from H. Lloyd Hind's Brewing Science & Practice, Volume II, written in the 1930s, during a chapter on decoction mashing: "It is then heated to the boiling point, again at the rate of about 1-1/2°F a minute, and boiled for times which may vary from 1/4 hour for pale beers to 3/4 hour for dark, when it is pumped back to the mash tun."

He specifically spells out the variant employed at Pilsen:

"Only two vessels are used, a combined mash and lauter tun and a copper. The mash is made at the rate of 6 to 6.3 hectos per 100 kg. . . . to give a first wort of 12.5 or about 1.050. The initial rise of temperature given for each mash [below] is secured by pumping an appropriate proportion of the main mash from the mash tun to the copper, where sufficient boiling liquor or boiling mash, as the case may be, had been retained to give the required increase. The starred figures represent temperatures in the mash tun. The others are temperatures in the copper.

Hydration cold

Confusing, ain't it?

To Peter Gaspar: Gale's is available here in Oregon, for a good bit of money. It may be in a pint bottle; think it's with standard crown cap. Hmm, on reflection the bottle might be embossed. I will check if you want. I think it definitely needs time in the bottle. Your 12 year old may be optimum. One I tasted was definitely too young. Ooog.

To George Fix: Thanks for answering the call on sour mashes. I know about the resilience of coliforms from working in a bacteriology lab in a food processing plant. Some of the spinach we were testing had gone through the dryers (very, very hot dryers) in clumps and the levels inside the clumps were astronomical.

Subject: Counterflow chiller size

Brian Capouch asks about sizes for the tubing in counterflow chillers... Everyone I know who has used 1/4" tubing has regretted it. They are just too slow. 3/8" is better. Now if you're into brewing fast, my counterflow chiller is made using 25' of 1/2" tubing, and it will take 5 gallons of boiling wort down to 80 F in under five minutes. My boiler drains from the bottom - it might be difficult to start 1/2" as a siphon. For general guidelines, I'd say about 16-18' of 3/8". Other opinions?

>put so much malt in the the final alcohol content in the starter  
>kills the yeast. What do other people do? Do you boil hops  
>into the starter mixture? Are there any rules of thumb for how  
>much malt to use?

Lots of good questions <grin>.

The Wyeast liquid yeast packets recommend a starter of 1.020 SG  
wort. No mention is made of hops, though. I don't know of any  
good reason to put hops in your starter, but there might be some.

If you use dry malt extract, such that 1 lb. in 1 gallon gives  
1.040 SG, then a 1 pint starter would use:

1 lb. 1  
----- = ---- lb. = 1 oz.  
8 pints/gal \* 2 (reducing the 1.040 to 1.020) 16

>gets in the bottle.

Well, I stopped using mine because there is no way to control exactly how much beer gets in the bottle. The volume taken up by the filler itself leaves \*way too much\* headspace in the bottle. So I have to top off each bottle separately from a small pitcher. Way too much work.

Now if there was a bottle filler with a manual switch controlled from the top, so I could fill the bottle as much as I wanted, it would have the advantages of both systems.

From: pyle@intellistor.com (Norm Pyle)  
Subject: Yeast herds, Berghoff Bock, Rambling

Frank Tutzauer's yeast culturing discussion got me thinking about this concept of only using one or two "generations" of a particular strain to avoid promulgating a bad characteristic or two. Do this make sense? You actually have dozens, hundreds, thousands, of generations of the yeast in a single batch, no? I mean you start off with a small number of yeast cells and by the time your beer is at full-krausen, you've got lots and lots, right? I'm not disputing the claim that one shouldn't keep reusing a batch of yeast, I'm just curious about this. Is a generation considered to be a "herd" (MOO! :-)) of yeast that hasn't gone dormant, therefore each time a "herd" of yeast runs out of food, that is considered to be a "generation"?

Last night I picked up a six-pack of an American bock brewed by Berghoff. They claim to brew in the old-world German style, blah, blah, blah. The beer was good, not great. The only other beer I have to compare in that range is Paulaner Salvator, a double bock. The Salvator is clearly more alcoholic, as I would expect, but it is also much smoother tasting. The Berghoff has a slightly unpleasant edge to it that I can't really put my finger on, except to say that I've tasted other beers with it. I don't think it is skunky, although the beer is packaged in green bottles. Have others tried this brew? What was your impression? I'm looking for a detailed description because I'm trying to hone my beer evaluation skills a bit, and this is a bit of a stumper for me.

Martin Lodahl's brewing woes amused me, but I can relate. Believe me, I can relate. Kinney Baughman's Jim Koch gripes amused me, but I like the beer. I hear you Kinney, but I let it roll off like water on a duck's back, 'cause I know its just marketing (something close to lawyering).

I'd also be willing to pick up the digest on rec.crafts.brewing if that's what it takes. Good plan, Fritz.

Happy Holidays!!!

Subject: Clarification on rolling grain mill instructions

In yesterdays posting regarding a pasta maker into grain mill, I wrote:

>Put in some grain and try out your new rolling mill. Iterate on the grinding  
>as necessary.

This should say: "Test the mill with some grain. Use a gap appropriate for your grain. If the grain fails to be forced between the rollers, go back and resurface the rollers until you have a rougher texture. Continue this process as necessary."

You will have good cracking with only one pass (not iteratively as the first posting seemed to say). Accept no substitutes.

Cheers,  
-A Dietz

From: bickham@msc2.msc.cornell.edu (Scott Bickham)  
Subject: grain mills

While shopping for cookware gifts yesterday, I found a mill that grinds using three grooved rollers with an adjustable spacing. The rollers are about 4" in length and located at the vertices of an inverted triangle. The retail price ( which this establishment sells at ) was around \$80. A bit pricey compared to a Corona, but much better than \$200 for a homemade one. I think the manufacturer is Mikasa or something that sounds similar.

>the tubing than in the center. That would be at the expense of  
>throughput, but I'd rather have cool wort exiting slowly than hot wort  
>exiting fast.

All the above intuitions are correct. In fact I shared them when I designed the first version of the counter-flow chiller that I sell. I chose 5/16" OD tubing for that model. 95% of the time it works fine. It's a little slower on the siphon (@ 30 minutes) but very efficient. However, it's too efficient for big, high gravity brews and the cold-break is so pronounced that some people complained that it clogged the siphon. Two years ago I switched to using 3/8" tubing. With a strong water flow it works fine. From my kitchen sink, I found that on the average the water exiting the chiller was about 10 degrees warmer than the smaller pipe. If the wort coming out is too warm there are two things you can do. (1) Use a pinch clamp on the end of the exit hose to slow down the flow of wort. (2) Try to connect to an outside faucet. The outside faucet at my house generates about three times the flow of water than does my kitchen sink. No one has yet to complain of a clogged chiller with the larger tubing, BTW.

The other thing to remember is to keep the water housing of the chiller as small as possible. Heat exchangers are more efficient the more the coolant turns over.

Tom Dimock observes:

>On roller mills - the reference in HBD 780 to building a roller  
>mill using the rollers from a grocery store checkout came from a  
>small book on building your own brewery.

That's Bill Owens' book, How to Build a Small Brewery. It's still being published. Overall a good book. And at \$5.00 or so, a good value for the info.

>In doing some serious "wetware simulations" (i.e. kicking back with  
>a homebrew and thinking about it), I came up with several unknowns.

Your allusion to 'wetware' caused me to think about the possibility of using the pasta machine as a wet-mill roller. Wet-mills are touted as the best possible solution to the mill problem. They crush the grains while generating absolutely no powder. Conjecture tells me that the wet grains would be 'tackier' and would pass through the smoother rollers of the pasta machine. That could save roughing up the rollers so that the machine could still serve that function. It's probably easier on the machine anyway.

OK you kitchen tinkerers. Get to it and try it out. I don't have a pasta maker (yet). After some homemade lasagna at a friends house a month ago using her own pasta, I admit to thoughts of purchasing one. Now if it can double as a wet-mill roller.....

>the tubing than in the center. That would be at the expense of  
>throughput, but I'd rather have cool wort exiting slowly than hot wort  
>exiting fast.

>Is that logic good?

Well, I thought it was good logic too but I was wrong. I made a wort  
chiller  
from 1/4" tubing immersed in ice water. It worked great as far as  
cooling the  
wort goes, but it had several other problems, namely the throughput was  
way too  
slow and on top of that it clogged. It took about an hour to cool the  
first  
3 or so gallons of a 5 gallon batch. At that point the thing clogged and  
I had  
to run some boiling water through to clean the clog and finish the  
cooling.

A slow throughput is one thing but over an hour is too long for me. I  
tried  
increasing the flow by raising the bucket (I sat it on top of the fridge)  
but that didn't help much. I am going to do one of two things to solve  
this  
problem, either shorten the length of my current copper coil or go out  
and buy  
some bigger stuff, I havn't decided yet which is better. From feeling  
the wort  
coller as it is now, the wort seemed to be cool about half way through  
the tubing  
so I can probably cut down the length by about 1/3 (it is about 30' now I  
think).  
This should increase the flow by 50% if I remember correctly. Of course  
to solve the  
clogging problem, I may keep the length and go to the 3/8 tube. Or as a  
third  
alternative I could cut the tube I have now in half a connect a Y to it.  
This  
should double the flow. Actually if I could remember all the fluid  
dynamics  
and thermodynamics I learned in college I could figure out exactly how  
long and  
how big my tube needs to be, but that is too much work so I will just  
guess.

Later,

Bill

From: Arthur Delano <ajd@itl.itd.umich.edu>  
Subject: Phil's Philler -- review

Since there have been some questions about bottle fillers on the Digest, I thot' I'd throw in my two cents worth.

I've always bottled with a bottling bucket, with a spigot attached (no stopped siphonings for me!) and a length of 3/8" dia. tubing leading to the bottles. After two batches of this setup, having to pinch the hose and dribble beer all over the floor between bottles was getting to me, and I wanted a filler.

The brew store had a Phil's Philler, which is a brass mechanism about the twelve inches when collapsed, and an additional half inch when extended. The wide end (containing, I suspect, the valve) fits inside a 3/8" tube very snugly; no problems with slippage. The wide end is 3" long. The narrow part has a bevelled end and the tubing is thin. When the mechanism is fully extended, a pinhole can be seen in the narrow tube just before it meets the wide tube.

After the bottling setup is prepared, the philler is inserted in a bottle and pressed against the bottom (there are about 2-3" of the filler over the height of a 12 oz. bottle; I've used it with 28 oz. bottles with no trouble, however). The bevelled edge keeps the beer from damming up; the beer swirls around and fills the bottle with very little bubbling. The philler can be held at various positions between fully open (compressed) and fully closed (extended) and regulate the flow of beer; helpful during the end of the fill when the beer is going up the neck.

The niftiest part of the mechanism is as follows: when the fill is complete, you simply remove the philler, and the beer remains at the level it was while the philler was in. This is because the valve is above the fill line, and the pinhole is an air bleed, thus the beer inside the tube inside the bottle remains when the philler is removed; the only displacement is the volume of the metal and not its contents. Brilliant.

Now for the downside. Despite claims that the mechanism is stickproof, I've overfilled my share of bottles when gravity could not overcome stiction. (a small spring would help immensely, but would probably increase the price a great deal). An interim solution I've found is to use two hands, one on the large tube and one on the small. This is less work than trying to pinch off a siphon tube and aim for the next bottle, but is hard on the knees if your bucket is on the table and your bottles are on the ground. A bit of practice is necessary to get a consistent fill level on all your bottles, and if the flow is stopped before the bottle is full, a surge of air will percolate through the bottle. (I've found this to be not much, tho' it is annoying). Lastly, this gadget retails for \$9.00 or so. I wouldn't have paid that much for it, but I would pay \$4.00.

It has speeded up -- and even more importantly, made neater -- my bottling

procedure by a great deal. I'm glad I have it.

AjD    ajd@itl.itd.umich.edu

ps. It was gotten for \$4.00 by introducing a friend to brewing and  
getting a  
\$5 discount at Modern Brewer in Cambridge, MA. \$9.00 minus \$5.00  
discount  
equals \$4.00 paid. :->

Subject: Followup to my Erroneous Seattle Post

Well, having been out of the Seattle area for many years, i should have known better than to try and say anything about it, but I had such good times there drinking beer that i couldn't resist ;-)

anyway, here are some corrections and additions:

Murphy's is closed for further notice.

The blue Moon is on N 45th St, on the same side of I-5 as the U of W campus.

The Trolleyman/Red Hook Brewery is in Fremont, not Phinney Ridge.

Next time on Phinney Ridge, try the 74th St. Ale House at 74th & Greenwood.

They have numerous micros on tap and an occasional cider. It's a good fallback if the Trolleyman is full.

The name of the homebrew supply store is:

It is Libery Malt Supply Co.  
1418 Western Ave.  
Seattle, Wa. 98101  
(206)-622-1880

Some other places to try:

The Red Door (in Fremont, at N 34th & Fremont Ave N, just north of the bridge) lots of micros; a good alternate to the Trolleyman  
Cooper's Ale House (Lake City Way at about 80th; once again lots of micros

Thanks go to Paul Brownlow (paul@pilchuck.data-io.com) and Rick Noah Zucker (noah@cs.washington.edu)

>help from you Kraeuseners.

>The Details: Extract/Mash recipe with I.G.=1.040 , Edme ale yeast,  
>two weeks in closed plastic fermenter, racked and bottled with 1.4  
quarts  
>of gyle.

I've been using this method for 4-5 years now, and have found that although CP's formula has its limitations, it's pretty good. As I recall (if brewing books were at here at work, I'd never get anything done!), the amount of gyle suggested is directly proportional to the amount of green beer, and inversely proportional to the OG of the gyle. It works out to 48oz of 1.040 gyle in 5 gallons. If the gravity goes up to 1.080, the quantity drops to 24oz.

Now, what this formula fails to account for, is that not all 1.040 worts are created equal. The ratio of fermentables to nonfermentables varies considerably, and thus the amount of carbonation varies also.

If one were so inclined, a formula could be developed based on both OG (original gravity) and TG (terminal gravity), which gets around this problem, but has some of its own. To determine the amount of gyle to hold back for priming, you'd have to be able to predict the TG beforehand (difficult, especially if it's a new recipe), or hold back extra and only use what's called for after measuring the TG (read wasted beer!). Based on all of that, I've been content to use CP's numbers with an adjustment to account for the fact that my worts are typically very rich in unfermentables (mash temps ~158F).

Another consideration is that beers primed with gyle generally take longer to carbonate than those primed with sugar. Regarding Andy's problem, it could be that all that is required is a little more time. I've got some questions :

1. How long has the beer been in the bottle???
2. What was the final yield???
3. What proportion of the wort sugars came from the extract vs. the mash???
4. What was the mash temp?

All of these factors will influence the CO2 level. If I had to venture a guess, I'd suspect that time is the most likely. Perhaps waiting another week or two will solve the problem.

Cheers,  
CR

Date: 17-Dec-91 Time: 01:38 PM Msg: EXT02402

Hi folks,

My fiance loves the smell of making beer. I tend to do it on a weekend day when he has to work, because he invariably comes over (just when the pot is starting to boil over), unbraids my hair and plays with it (over the cooking proto-beer, and I shed lots :( ) and does nuzzly things while telling me how wonderful I am to make him beer. While this is going on, the pot boils over, and I smack him good. When he comes home and beer has been made in his absence, (my preferred course of action) he bounds across the room exclaiming my virtues to the skies, and says how great it is to come home to the smell of home cooked beer.

When I lived in Williamsburg, VA, we could smell the Anheuser-Busch folks making beer, and after people figured out what it was they just said, "oh, Busch is making beer. Hey, maybe we should go over to Busch (gardens) tomorrow for the free tour. We can ride the monorail and see THE RUMBLE OF HOOFBEATS THE RATTLE OF CHAINS again." No one ever said it smelled bad. We always associated the smell with free beer.

Subject: Grain Crushing

Has anyone used the KitchenAid grain mill? I have never seen it and I wonder whether it cuts our mustard.

Also, the diagrams I have seen of professional roller mills have three sets of rollers. Each successive set has a smaller gap between the rollers.

My guess is that the three roller set design improves the throughput of the mill more than it defines final crush quality. Further, I guess is that if we homebrewers are willing to let crushing take a little longer per pound, a pasta maker with roughed up rollers could be just the ticket. Now to motorize it...

Does anybody know differently?

**Subject: Re: Bottle Fillers**

Paul asks:

>Do people not talk about bottle fillers because there's a problem? Or  
>because they're so wonderful, no one would consider siphoning without  
>one?

Bottling wands are discussed occasionally. Usually, however, not until someone has a problem with bottling. I would not bottle without one -- they are great. On the one that I have, the gizmo at the end is orange and contains a spring to shut off the flow. I intend to bottle (instead of kegging) the batch currently in the primary since it is a ginger/orange/cinnamon/nutmeg ale and not for everyday consumption. I want to save the kegs for the everyday beers.

>There *\*is\** a  
>brewery in Boston, although some (most?) of the beer is contracted  
>out to Pittsburg. One of the Boston brewers will probably set this  
>straight.

The SA that we get on the West Coast is brewed in Portland (That's Oregon, not Maine, silly), by the Blitz-Weinhard Brewery. When I toured that brewery in July, the generally uninformed tourguide claimed he knew nothing of this, which was consistent. When I mentioned it to the two guys serving in the hospitality room, their eyes got wide and they started whispering as if it were some well kept secret that I had just divulged. They eventually admitted that SA was made there, but said they had been instructed not to talk about it. Since Jim Koch admits that SA is contract brewed, I could only conclude that BW didn't want their loyal fans to know that they were making "Boston" Lager.

BOO! Ha! I'm not afraid! BOO! BOO BOO BOO :- ) :- ) :- )

Ok Jackaroo! I'll tell you what I thought of "THE VIDEO". I'll even  
tell everyone on the net, so hold onto your shorts, cause here we go!

While visiting a friend to whom you sent a sample, we drank some  
exceptional  
homebrew, and watched your video. So...

The video as a whole to approach a first attempt at brewing is good. It  
in  
fact kinda parralleled my first expierience. I think it would be helpful  
to  
get a first time brewer off the ground. But now, syrup and sugar, yuck!

The overall flow was good, as were the cute little light signs you used  
to  
tell times and ingredient measurements.

However, here are a few things I noticed that you might want to change.

Get rid of the fruit flies! The "By the way, those are fruit flies" sure  
didn't  
do much to reinforce the first rule, sanitation.

I don't know about other brewers, but I stay away from wooden spoons, as  
is  
seen in the video. A stainless steel spoon, or even plastic would be  
better.  
Who knows what is hiding in the porous wood!

Clean your stove. It looked like somebody had cooked a splattering  
hamburger  
before you decided to brew.

You should make your kitchen look like one of those TV cooking shows.  
The only thing visible in the kitchen should be brewing stuff. Especially  
inside the refridgerator. Unless maybe you want to show some beer time  
munchies next to the beer...

Lose the advertisement for that Baderbrau stuff. I've never seen the stuff before, and didn't care for the big advertising spot, even if everyone does have thier price. A quik tour was fun, but not the big ad.

To sanitize the bottles, did I miss something? The only part I remember was in the rootbeer part, where Marilyn poured the solution from bottle to bottle. Isn't it better to soak those bottles to insure sanitation??? Did I miss something when I checked the barbeque???

So, are these flames? No, they're just a few minor recomendations. Were the flame wars justified? Yes and no. It is hard to visualize exactly what is going on across a keyboard. I think many flames would only have beed sparks, had the video been viewed.

Jack, I'll give you a fairly solid "B". It was good, and would prove helpful to a new brewer. But, there are odds and ends that need tying up. Your working on citizenship now, so we'll give you a "Acceptable" in that catagory :-)

..).

Yes. Plain and simple. Since you aren't mashing, you don't have to worry about pH, minerals, etc. Some might say: "Hey! If you're making a Burton Ale, don't you want to make your water have the same mineral profile as the wells in the Trent river valley?" Well, yes and no... it depends. It depends on your extract. If you have an extract that was made in Burton upon Trent, I suspect that they did not remove any of the minerals prior to making the wort that became the extract. When they evaporated away the water, they left behind the minerals. The minerals should still be in the extract. However, one of my favorite extracts, the one I use for my favorite Bitter, is Munton & Fison Old Ale Kit. But when I use a can of this extract and add 1.5 to 3 lbs of light dried extract, plus some boiling hops and dryhops, I add 1/3 oz Burton Water

Salts from Wines Inc. to my 5 gal of relatively soft Chicago water. Oops... I forgot to mention the Brewer's Choice British Ale yeast from Wyeast Labs (#1028, I believe). I'm slowly approaching what I remember of the Ales I drank on tap in England, but my memory is fading and getting clouded by the bottled versions I get here. The bottom line is, you can use distilled water for extract brewing, but you may want to optionally add minerals to taste.

John writes:

>What exactly should I ask my water dept.? Should I call or write? Is  
>there a law that says they have to supply this info at no cost?

I called my water dept when I lived in Hickory Hills, IL and asked for "the latest water analysis report." They sent me one within a few days. It contained everything I had expected -- all the minerals, etc. When I moved to Palos Hills, IL (the next suburb south of Hickory Hills), I did the same, but got a different animal entirely. What they sent me was six or so bacterial counts. Not what I had expected. I haven't tried again, explaining that I want mineral concentrations.

Hmmm... <dialing>... Hello? ....

Well, I just got around to it. The lady at the water department wasn't sure, so she transferred me to the Palos Hills Commissioner of Public Works!

Imagine that! As soon as I said "mineral content," he said "oh, yeah -

-  
you want a Chicago water analysis." I asked if that will be just like the water out of the tap in Palos and he said yes. After a few minutes of discussion, I found out that Hickory Hills used to blend Chicago and well water. I had noticed that some months the water would stain the sink and on other months it would not. That explains that. So when you talk to your Water Dept rep, ask if your water is blended and if the ratio changes from month to month.

The Commish said I should get the analysis in a day or two.

dishes, as  
> detailed in several of the zymurgy articles; and, second, a yeast bank  
> involving glycerin (?) and sticking the yeastie boys in the deep  
freeze.

I have used, and continue to use, the yeast bank. I find it pretty easy,  
and the thawed yeast can be built up into a viable culture. Be warned  
that the yeast seems somewhat weak upon thawing. I suspect that many  
cells are killed by this process. However, once you have built up a few  
of them they work just as well as the original batch.

The process that seems to work best for me involves using three stages  
of starter - two tablespoons, 0.5 cup, and .75 quart. This takes four or  
five days from thawing the yeast until it is ready to pitch.

I found that the original five test tubes were not enough - buy extras.  
I like to keep five tubes of each yeast type.

I have a batch of lager going in my garage as I type this. The yeast is  
about six months old, Bavarian Lager. I expect it to turn out well!

Ahh and if you are the complete ex-Yuppie ("Grumpy"?) <Grown-Up...> you might even have the "Pasta-EZE" motor drive for said pasta machine! These sell for about \$35-40 too, just like the pasta maker itself. (You get the pasta maker for Xmas one year, use it once, put it away, get the motor for Xmas the next year, and actually use the thing about 10-20 times til you get bored!). Seriously, tho. The motor drive works great, and saves muchos sore shoulders if you are a wimp.

From: Bob Jones <BJONES@NOVA.llnl.gov>  
Subject: Holiday Ale Recipe

Here is a Pale Ale Recipe I brewed for the Xmas holidays. It is in the style of American Pale Ale very similar to SN Celebration ale of about 1988. This is a big, hoppy brew, loaded with aromatic cascade hop fragrance, It has that front of the mouth bitterness that can only be achieved with dry hopping, so don't skip it if you really want to duplicate this flavor profile.

Crying Goat Ale

Batch size 11 gals.

19 lb - 2 row klages  
3 lb - Munich malt  
2 lb - 40l crystal malt  
1.5 lb - Home toasted 2 row klages (350 deg for 40 min). Age a couple weeks before use.  
2 lb - wheat malt  
2 oz - N. Brewer hops (AA 6.9)  
6 oz - Cascade hops (AA 5.1)  
1 t - Gypsum (in mash)  
2 t - Irish moss (last 30 min of boil)  
Chico Ale yeast (wyeast 1056, keep temp at about 65-68 for primary fermentation)  
1.5 Cups corn sugar to prime

Brewing specifics :

90 min boil  
2 oz N. Brewer for 80 min  
2 oz Cascade at end of boil for 10 min steep  
4 oz Cascade dry hop (after 1 weeks, rack and add to secondary)

Mash specifics :

Single temp infusion mash for 90 @ 155 deg  
170 deg mash out for 10 min  
sparge 11 gals @ 168 deg

From: Bob Jones <BJONES@NOVA.llnl.gov>  
Subject: Homebrew Competition (2nd post)

Dear Fellow Homebrewer:

You are invited to participate in the 1992 Bay Area Brew-off homebrew competition. This years competition is hosted by The Draught Board homebrew club. The competition will be held at Lyons Brewery Depot in Dublin, Ca. on Jan 25, 1992. Entries will be received the week of Jan. 10-17 at Lyons Brewery. Entry deadline is Jan. 17, 1992. Mail or deliver your entries to Lyons Brewery Depot, 7294 San Ramon Road, Dublin, Ca. 94568. Entries consist of 2 - 12 oz. bottles. Entry fee is \$5.00 per entry. One entry per category. Label each entry with category and sub category if needed, your name, address, phone number and club affiliation.

The catagories for this years competition will be as follows:

Dry Stout  
Porter  
Pale Ale - Sub Cat. are Classic Pale Ale, India Pale Ale, American Pale Ale  
Amber Lager - Steam style  
Barley Wine  
Mead - Sub Cat. are Traditional, Melomel, Cyser, Metheglin (all still and sparkling)  
Holiday Beer - Spiced, herbed or other special beer brewed for the Christmas holidays.

This is always a fun get together for homebrewers. I look forward to seeing you all there.

If you want additional details on the catagory definitions or have general questions about the competition call Bob Jones (510)743-9519 or email to BJONES@NOVA.LLNL.GOV

See you at the competition,

Bob Jones

From: cjh@vallance.HQ.Ileaf.COM (Chip Hitchcock)  
Subject: re Kraeusening

The numbers quoted from Burch seem to me to be high. Consider (numbers from various sources):

1. 1# extract/gallon yields 45 points (average).
2. extract is 15% water, so 1# spray/gallon yields 53 points.
3. a cup of spray or cornsugar is .4#.
4. common recommendation for a 5-gallon batch is 3/4 cup cornsugar
5. This is .06#/gallon. multiply by 53 (points/#spray/gallon) gives 3.2 points (assuming cornsugar gives the same SG/weight as malt sugars, which seems reasonable).

malts vary somewhat in their %fermentables, and yeasts vary widely in %attenuation, but if we take 70% as a mean, 3.2 points of corn sugar have the same amount of fermentables as 4.5 points of malt sugars. You might juggle the above figures to get up to needing 5 points from malt, but 6 seems unlikely.

(I'm doing this from memory, so I'm not sure about the above ]constant[s---but the one I'm most unsure of is #1, and I'm sure it's not low---if it's high Burch's figures are even further off).

For a completed batch, we already know the attenuation in points. This gives, for instance

$$3.2 = \frac{(\text{change in SG}) * (\text{quarts of gyle})}{20 + (\text{quarts of gyle})}$$

(assuming a 5-gallon (= 20 quarts) batch and an attempt at the canonical amount of priming). This becomes

$$\text{quarts of gyle} = 64 / ((\text{change in SG}) - 3.2)$$

If your SG dropped 28 points (~70%), you should put in 2.6 quarts of gyle.

Note that this formula uses the /change/ in SG---not sure what P uses. I'd

have expected a physics teacher produce a correct formula (the one I used to date certainly would have)....

Note also that Miller, who doesn't think much of krauesening (probably because it affects the flavor more in lagers, which he admits to preferring), suggests two quarts of gyle in a batch.

On the other hand, I have been krauesening ESB (which should have low carbonation) with ~16 oz gyle in a 1/2-batch and getting results---sometimes much too much carbonation for the style. I've found that carbonation is very sensitive to factors like the type of yeast and the amount that remains suspended, even when you prime with corn sugar; I once used Polyclar (to get a blanket of CO2) when racking a stout, and it took several months to get any head at all. I would look at other factors (temperature during the first few weeks after priming, time since priming, etc.) before substantially increasing the priming.

Date: Tue, 17 Dec 91 16:54:32 PST  
From: Richard Childers <rchilder@us.oracle.com>  
Subject: Blitz-Weinhard, Schmidling, et caet

Well, first off, while I've been reading this for about a year or so now, I've never had anything useful to say, until now, but wished to thank all those whom have made their experience, knowledge, and conjecture freely available to all whom cared to partake.

I was up in Portland, attending classes at Sequent, and had the opportunity to tour the Blitz-Weinhard Brewery. It was a waste of time, alas. I wish to save anyone else so inclined, from wasting their time.

First off, the tour is totally isolated from the brewery. OK, maybe that's necessary to maintain sterility ... but I think the whole tour exists, not for the benefit of the tourists, but for the benefit of Blitz-Weinhard.

The tour takes place in an isolated and out-of-use corner of the brewery, and said corner is quite sealed off from the brewery proper. You are allowed to gaze at some shiny metal vats that aren't particularly well-labeled as to their functional relationship to the process, including the original brewery vat, or one of them - which, incidentally, looked much like a large water heater, making me wonder if it might be possible to start up a microbrewery with a few well-sanitized, yet discarded, water heaters. That's about the most valuable factoid I carried away from the tour.

Better than half of the time allotted to the tour was spent in the panelled office of Henry Weinhard, Senior, watching a movie that didn't spend a second in fifteen minutes discussing how beer was made, preferring to replay old advertisements, many of which relied heavily upon the antagonism that exists between California and Oregon to promote their brew as a local product. Which is amusing, as I recall all too clearly how Henry Weinhard's Private Reserve was, um, ladelled down the throats of California consumers as the choice beer of Real Beer Drinkers Everywhere, a few years back, when it came out. Divide and conquer is not only a political strategy - it is a marketing gimmick, too.

The film did mention that a large percentage of their product relied upon the inclusion of the finest rice and corn, along with choice hops and barley. My interpretation of this is that, while they malt their own grains, they have

also found it convenient to manufacture their own corn starch onsite, but find it sells better if they refer to such as 'grains' instead of 'starches'. From my understanding of the brewing process, while a small amount of corn starch may prove beneficial immediately before bottling, it is not a major ingredient of beers in general. At Blitz-Weinhard, corn and rice starch are fillers, not pre-bottling additives.

If they made that corner into a beer-making museum, dedicated to the history of brewing in the Pacific Northwest, self-guided tours, everything neatly labelled, lots of colored flowcharts detailing things, maybe a few photographs of microscopic yeast doing their thing and some chemical formulae for those so inclined, it would be great. They have some fine equipment in there. Alas, nobody seems to regard it as of any importance except as props for Blitz PR. It's really too bad. That corner of the building lies empty and unseen almost all day, every day, 365 days a year, except for three half-hour slots a day.

Summary : don't waste your time unless you like to drink cheap beer and tour empty buildings. You'll learn more brewing one batch and messing it up. ) -:

Now that I've said that, I wish to address one other small issue ...

Subject: Re: GRAINMILL

>Since this forum is a place for sharing (knowledge, ideas, experience...) why don't you just tell us how you made it.

Past experience says that a long posting would have been received with little enthusiasm, by enough readers, that the whole objective would have been lost in endless flames.

If you took the trouble to send for the information offered through email, you would now know how it was made.

Gee, Jack, that's funny. I sent you private mail in response to this ad - oh, I'm sorry, it wasn't an ad, you were sharing information - suggesting that you do the very same thing that about half a hundred others must have asked, in my absence - that you cease and desist your commerce, but that you really ought to post a diagram of the Damned Thing - and I didn't get any diagrams. All I got were some comments about how there were 'no laws here, just hallway monitors.' Remember ?

However, as I happen to have a foundry and machine shop in my basement, it is a little like asking a brain surgeon how he fixed that tumor.

If you can't explain it to a five-year-old, you don't understand it. Maybe

in subsequent issues of HDB yet to be perused I will see the plans, but I doubt it. My grandfather was one of the finest machinists in Texas during the 1930s, rumor has it, and while I'm no machinist, I know how to draft plans, read blueprints and schematics, and quite a bit else. Most everyone else reading this is similarly highly qualified to pursue a wide range of occupations. Don't you think it's about time you quit pretending you were a brain surgeon amongst natives from farthest Borneo ?

And, yes, I can explain network administration and multiprocessing to a five-year-old.

I apologize for publicizing this, but I tried private email and it didn't make a dent. If you don't stop, I'll probably just page past your name as I see it, and ignore you as yet another marginally intelligent poltroon with more text than sense or courtesy, better ignored as a bandwastroid. It's unfortunate that you can't freely share of your designs and ideas without trying to make a buck, but I don't pay people to change my tires and I don't buy things I can make - from you or anyone else.

This is a noncommercial channel. Please respect it or leave.

Subject: Of Skimming and Cold Breaks....

As a result of some dicussion, in this forum re: boilovers, I decided to skim the thick brown mass that forms on the top of the (beginning to boil) wort.

Also, as a result of recent Miller readings, I decided to REALLY chill the wort to cause a massive cold break to settle out.

After running the wort through my chiller, (25 ft of coiled copper sitting amidst a bucket of snow). I then transferred the wort to my auxiliary chiller ..... December. The pot sat outside (properly covered) overnight with the air temp around 11 F. In the morning I brought it back inside, (though I didn't open the pot, I could hear/feel sloshing so it wasn't completely frozen). That evening I siphoned into my primary and pitched the yeast.

I expected a huge mass of cold break material to have settled out with the quick chilling and prolonged intense cooling. Though I'm not absolutely positive I can identify cold break material, there was little mass of yuch at the bottom of the bucket. What gives? Could this be because of the skimming?  
Is the thick mass of foam that forms at the beginning of the boil the same material that forms the cold break?

Jim White

On New Years Day, I'm getting a new (auxiliary) Wort Chiller !

Hops contain a natural anti-bacterial agent. Putting hops in your starter will help prevent infection.

John writes:  
>What exactly should I ask my water dept.? Should I call or write? Is  
>there a law that says they have to supply this info at no cost?

If you don't have public water (I have private well water), there are usually plenty of labs around which do water analysis, but you have to know what to ask them to test for. There's an article in the Winter Zymurgy, Beer from Water, which discusses how the water mineral content effects your beer. The following books have good material on water content:

D.E. Briggs, J.S. Hough, R. Stephens, T.W. Wong, Malting and Brewing Science, Volume 1, Malt and Sweet Wort, Second Edition, Chapman and Hall, New York, 1981.

Dave Miller, The Complete Handbook of Home Brewing, Garden Way Publishing, Pownal, Vermont, 1988.

Gregory Noonan, Brewing Lager Beer, Brewers Publications, American Homebrewers Association, Boulder, CO, 1986.

Subject: Re: Sam Adams Breweries

To build on Jim Jedrey`s message:

According to a reliable source, much of the Sam Adams Ale is brewed by FX Matt in Utica, NY (home of Matt`s, Utica Club, Saranac 1888, etc). FX Matt brews contract beer for several microbreweries. Me thinks that they may be shipping from Utica as well, since much of the keg ale that we get here in Rochester tastes very fresh. There is also the Sam Adams brew pub in Philadelphia, which was brewing ales for on site consumption last time I was there. I can`t say for sure that the Philly brew pub is owned by Jim Koch, but it displays the familiar Sam Adams logo.

Papazian suggests bittering hops to help inhibit bacterial growth. I  
don't  
know how much it really helps though.

Subject: Jim Koch on the radio

This morning as I was driving in (details of which might find their way to alt.peeves at some point) WFNX in Lynn had Jim Koch on the radio.

For the past several days, FNX has been "giving away" slots for this tour they will be taking of the Jamaica Plain brewery, so having Koch in was part of the big promo and hype.

I wish I could tell you that this was an interview laden with introspective, detailed questions. But it wasn't.

A few points of interest (and don't flame the messenger please):

Koch says that Sam Adams is still technically a micro-brewery but that it is the "biggest pygmy" in the forest.

Koch says he is the 6th oldest son in a row (through the generations) to be a brewer.

When describing the taste of Sam Adams, he said some people might find it too heavy but that everyone "grows up" eventually.

He also said that the worst that could happen is that if the brewery failed and went broke he'd wind up with having free beer for the rest of his life. I'd like to know how that works out.

And, the last thing I remember, is that he says Sam Adams brews in three locations: Boston for the East, Pittsburgh for the Midwest, and Oregon for the West. He does this so that the beer may be fresh - he wants it to be delivered no more than 24 hours after it's finished. If this is true, I wonder how he gets it to Japan (where he says it is sold over TV)?

From: otten@cs.wm.edu (John Otten)  
Subject: Another Bottle Filling Technique

With all of the various methods of bottle filling discussed lately, I have yet to see the method that I use. So, here is another one...

I do both the primary and secondary fermentations in the plastic bucket (i.e. I pitch the yeast and let it sit for a week or two). When it comes time to bottle, I boil up some water with priming sugar (about a pint of water with 3/4 sugar) and then add another pint of water to cool it a bit.

I pour this solution into a 5 gallon plastic water bag (like we used to carry water in on camping trips) -Sanitized of course- and then siphon the beer in after it. It seems that the siphon action mixes the priming solution with the rest of the wort ok. Then, I attach a spigot to the opening in the bag (it usually comes with one), and fill the bottles. Every now and then (every three or four batches) I need to add some air to the bag as I get towards the end to help with the flow, but not every time I bottle. I do this by tilting the bag so the wort is away from the spigot and then just opening it.

I didn't come up with this idea. It was suggested to me by the store that sold my first beer making kit. As the bag and spigot were only about \$3.00, I went for it. It works well for me...

From: joshua.grosse@amail.amdahl.com  
Subject: Cuisinart pasta machine

With all the discussion of using pasta makers for grain mills, and the latest discussion of Corona and other mills instigated by my attempts at using a coffee grinder, I thought I'd add in my own comments. I've got a Cuisinart pasta extruder attachment. It uses the food processor motor to drive a feed screw, like the Corona, to force the pasta through extrusion plates. The thing came with six plates to make a wide variety of pasta.

All I need is a way to fabricate the business end of a grain mill that could be fastened to the pasta machine. The hopper could hold about 1.5 lbs of malt. Any suggestions?

Subject: Big time bitter

I've got a brew that has such a bitter finish that it's virtually undrinkable, and I \*like\* bitter. It has one 3.3 lb. can of hopped extract, and about 15AAU of whole hops, with 1.5 oz of 9.6 AAU hops steeped for 3 minutes. So it should be somewhat bitter, but this is something else! The beer smells somewhat young, but not "off". It starts somewhat sweet, has normal carbonation, tastes fine, but then WHAM! you get his intense bitter flavor that sticks on your tongue for hours! It's not really like a normal hops bitter flavor either; it's not crisp, it's heavy. One odd thing is that it's taken a month for the bottles to clear; usually they clear in a week or so. Clearing hasn't had any effect on the bitterness. The hops were not really fresh, but they didn't seem bad either. The ferment with Whitbread dry yeast went normally. There are no indications of any infection, unless that's what this bitterness is all about.

So what gives?

From: "William F. Pemberton" <wfp5p@euclid.acc.Virginia.EDU>  
Subject: More on Chillers

With the different designs for chillers showing up, I figured I'd share my experiences for another data point.

The counterflow chiller that I use is made from 3/8" OD copper tubing inside a 3/4" ID garden hose. There is about 20 feet of copper tubing in this thing.

I have never had a problem with clogging and this thing is FAST. The way I currently brew involves transferring the hot wort from the first floor down to basement level. The drop is about 10 feet, so the flow rate is very high. This chiller has no problems dropping the wort from boil to less than 70 degrees. The total transfer time is usually in the 10-15 minute range.

> If one were so inclined, a formula could be developed based on both  
> OG (original gravity) and TG (terminal gravity), which gets around  
> this problem, but has some of its own. To determine the amount of gyle

A while back I made a "graphic aid" which allowed me to select the  
proper ammount of wort to save based on desired CO2 pressure and O.G.  
without having to crank through the math every time I wanted to brew. I  
didn't make any allowance for % fermentables (that would take another  
axis :-), but I suppose that it wouldn't be hard to include such data and  
make a nomograph, sort of like:

```

% fermentables
|
| / / / / / |
| / / / / / |
Atm. | / / / / / | Orig. Gravity
pressure | / / / / / |
| / / / / |

```

(quantity along the lines)

I'll tinker with it sometime over the coming week or two, and if I can  
come up with a really nice looking graph, I'll make the PostScript  
available  
somehow.

I derived my "numbers" from Noonan, BTW, and although I don't have them  
handy to make a comparison, they seem pretty much in agreement with what  
other people have been reporting. [read that: " I did it right" :-) ]  
My latest batch of 80-weight only needed 1 pint/five gallons, but I "keg"  
so the required pressure is lower.

Subject: Chicago beers

Talk about Chicago beers in #784:

Berghoff's is a big and boistroous German restaurant in the Loop. No trip to Chicago would be complete without a lunch at the Berghoff before or after a visit to the Art Institute (two blocks away). They have their "own" beer, brewed under licence by Heilemann's to the north in Wisconsin.

It's available on draught in the restaurant and in the bottle at many local stores. I recall regular and dark...maybe bock is seasonal, maybe a synonym for dark. At any rate, Norm is correct, and perhaps a trifle too generous, wehn he describes it as "good, but not great". Like Augsburger (also from Wisconsin) and the Lowenbrau brewed under licence by you-know-who, Berghoff beers claim to be old-world style but are actually a compromise, having more body than North American beers but neither the bitterness nor the purity of German lagers. And yes, they do taste mass produced. Save your money.

Baderbrau [umlaut over the second 'a'], to my limited knowledge, was the first micro in the Chicago area. They seem to have opened up shortly before I moved there in Sept. 1989. Their basic lager is pretty damn good. I would compare it to Sam Adams lager (it seems it's once again OK to admit that I drink the stuff from time to time). Probably better than Sam Adams, IMHO, when it's fresh. Full-bodied, all grain, plenty of hallertuaer hops.

Cheers,  
Rob (bradley@adx.adelphi.edu)

I don't think you could still use the pasta machine for pasta if you did  
this. You'd have to clean up with water. Apparently, if you get a pasta  
machine wet the noodle dough will stick to it for years after. I dunno  
why,  
but you're supposed to clean those things by just waiting for the bits of  
dough to harden, and brushing them clean.

>> of gyle.

I can't speak directly about kraeusening with gyle. I have primed  
cider and cyser with sweet cider, and your numbers are approx in line  
with what I calculated to achieve the same weight sugar as 3/4 C corn  
sugar (5 oz I think) assuming that all weight in excess of the weight  
of water was due to sugar. I used 5 C of 1.045 cider (modulo memory  
lapse) for 5 gals. It worked reasonably well, though it was a wee bit  
less carbonated than I had hoped, but this is exacerbated by the lack  
of body remaining after Champ. yeast have done their worst. The  
assumption of all excess weight being fermentable is generally less  
reasonable for wort. I prime beers with dry malt extract rather than  
corn sugar (due to allergic friends) and I usually use about 1-1.5 C  
for ales, and they seem to carbonate more slowly. Others have  
said here that gyle works better than dry malt ext.

Then korz@ihlpl.att.com writes:

>Yes. Plain and simple. Since you aren't mashing, you don't have to  
>worry about pH, minerals, etc. .... The bottom line is, you can use  
>distilled water for extract brewing, but you may want to  
>optionally add minerals to taste.

I both agree and disagree with this comment. I used distilled water for a long time, and I found that I was consistently ending up with high final gravities. For example, for an O.G. of 1.040, I'd finish at 1.022! When I switched to tap water, this problem went away... thus I am assuming the distilled water was the problem. I figure there just isn't enough nutrients in distilled water to keep the yeast going for very long. Whether or not there are sufficient nutrients in your extract I suppose depends on the extract. Apparently the extracts I used were not sufficient (I don't recall what those brands were right now...). So, I'm convinced that if you are going to use distilled water you should add nutrients --- not just for taste, but for proper fermentation.

From: zentner@ecn.purdue.edu (Michael Zentner)  
Subject: bottling wands

The topic is back, and I'd thought I'd cast one opinion of dissent. I don't think these are a miracle tool. I don't like using a spigoted bucket for bottling because of sanitation hassles incurred by always having to take the spigot off. I don't even like using a plastic bucket for bottling because of sanitation worries. My bottling wand does not form a perfect seal when it's supposed to be "off". There is as much, if not more aeration with the use of the wand by the initial rush into the bottle than there is with my siphoning technique.

I simply like to have a spare carboy around where I can combine the wort and priming solution and siphon from there into the bottles. This way, the only plastic used is the siphon, which I am much less apt to scratch than the bucket or spigot. The speed for bottling is about the same either way. I used the wand for 3 or 4 batches before I decided to nix the idea.

That said, I'm not saying that because you use a wand your're doing anything wrong. I'm just saying that not everyone thinks it's such a great idea, and bottling by both methods can be equally as efficient.

Mike Zentner    zentner@ecn.purdue.edu

PS- Maybe I feel this way because I never have lost a siphon.

From: pierce@chips.com (John Pierce)  
Subject: Yeast propagation forever??

I was talking to the chief assistant brewer at my local brewpub the other night, and he told me that they have been re-pitching their yeast directly from one batch to the next for well over 200 batches now. They brew 217 gallon batches, using open primary fermentors (brewing a range of lagers) and "just throw a bucketload of yeast from the last batch into the next.

I have NEVER had a contaminated or otherwise off-tasting beer in this establishment in the 5 years they've been brewing. (couple of times a couple of years ago, their beer was under-carbonated, but thats the ONLY flaw I've ever noticed).

They are brewing continuously, I guess that helps keep the strain consistant. Also, he said they only use the yeast from their regular amber and lager's, and not anything from any of the specialty's (stouts, barleywines, etc).

Date: 18 December 1991 1:14:14 pm  
From: pencin@parcplace.com (Russ Pencin)  
Subject: Infusion, Mash-out, Sparge Efficiency

I had been out of town for several weeks, so I am posting several observations that may or may not be relevant at this time. If so, please ignore them.

1). INFUSION

I attended the Advance Brewing Science class at UC Davis in September. Dr.

Lewis is an amazing individual to say the least. The key word in the description of this class was "SCIENCE". The class was aimed at personnel of

major breweries who need to understand the process and procedures used to produce consistent product. The main point of the mashing lecture was to scientifically explain why a single step infusion accomplished at 153 degrees

in fact produced a more consistent product than one produced via a step infusion starting at 122 degrees rising to 155 degrees. The chemistry of this

process was presented in excruciating detail. The bottom line was that because

current malting techniques produce a malt that is highly convertible and that

the protein molecules are locked in a matrix that is only broken by protease

enzymes, that a single-step infusion at 153 degrees will produce the optimum

starch conversion without releasing the protein from its matrix. The absolute

requirement here was that the grain be "struck" so that all the grain ended at

exactly the strike temperature expected and stayed there for the entire mash.

He gave several formulas for calculating the temperature of the strike and

several "techniques" of providing consistent mix of strike water and grain. (

i.e. don't just dump the water onto the grains, instead create two even flows

of materials such that every grain gets hit and mixed with an equivalent stream

of hot water. Not easily accomplished at home alone, but quite simple if brewing with a friend. He/she pours the grain in a fine stream, you

pour the

water to meet just above the water line in the mash tun)

I have used this technique for the last 5 batches of brew using 3 different

grain types. 2 row Klages, 2 row Muton/Fison English, and American Munich

malt. In each case I use my Auto-Mash(tm) preheated to 153 degrees and strike

with 158 degree water. The advantage to the Auto-Mash(tm) is that it provides

both a stirrer and a +-1 degree water jacketed temperature control. The resulting wort has been nothing short of spectacular!. The Klages and English

complete conversion between 45 and 55 minutes, the Munich is done in 40-

45

minutes. The "efficiencies" I have obtained consistantly are Klages 1.034, M/S English 1.032, Munich 1.032. The beers from these mashes do have a slight chill haze, but this disipates in less that a week in the fridge ( I only bottle ). I will never do a step infusion again, even if it is dead simple with the Auto-Mash(tm) because the results from the single-step process are quicker, clearer, and easier to sparge ( no, I don't know why, the run-off just seems to clear quicker and run more smoothly).

2) Mash-out, Sparge Efficiency  
I couldn't help but grin at the "non-use" of the mash-out by many HB's. I in fact never used a mash-out (170 degree temp rise) until after the UC class. After hearing the lecture on conversion and all of the chemistry involved, I had a discussion with Dr. Lewis about the degradation of crystal malts at mash temperatures. What I now do is mash my base grains to conversion. At conversion I add the Crystal and any other specialty grains ( all finely ground ) to the mash and start my mash-out temperature rise ( 1 degree a minute to 170 degrees ), allowing the mash to mash-out at 170 for 10 minutes. I the ladle the grains into my picnic cooler/ slotted pipe sparger and take ALL of the initial run-off after recycling about two quarts to get clarity. Once the initial run-off is collected I add ~4 gallons of 170 degree water to the tun and stir the H--- out of it for three minutes. Let is settle for 5 mins, recycle about two quarts to set the bed again and take the run-off to the boiler. This procededure has boosted my "efficiency" on an average by 1.005 per pound of grain.

My real point here is that adding the Specialty grains during mash-out temp rise has added a whole new dimension to the flavor/aroma profile of my beers. I don't know about you, but one of the constant comments on my score sheets from competition since I went to all grain has been: 'Needs more malt, not much malt aroma". I now get that heavenly crystal aroma and that pleasing residual sweetness that I so loved from the extract brews that added "steeped crystal" liquid to the boil. I haven't had an opportunity to enter these new beers in competition yet, the Lyons Bay Area Brew-off Competition will be the first. I'll post my results.

From: bradley@adx.adelphi.edu (Robert Bradley)  
Subject: mashing and sparging in a BruHeat

What follows is a copy of some info I shared with a fellow HBDer who is the proud owner of a new BruHeat bucket. I actually own an "Electrim Bin". As near as I know it's identical to a BruHeat, except that mine is 110 volts (and therefore slower in getting liquids to boil).

I use a hanging grain bag with the trade-name Brewbits. If you want to try to make one: it's cylindrical, with a nylon(?) mesh on the bottom which is fairly fine and an impervious material making up the side. The diameter is perhaps an inch or two less than the interior diameter of the bruheat. There are four loops at the mouth, and you hang the thing by passing a string through the loops and tying it around the mouth of the bucket. On my bucket, there is a rim right at the top, and another a couple of inches down, so I have two positions for the bag: "down", with the string at the lip of the bucket, and "up" with the string futher down pulling the loops up higher. (I hope this all makes sense :-)

To make average strength beer with a single stage infusion mash:

To make an 8 lb. batch: set the bag to down, add 3 gal. water, raise temp to about 162 (72 C), add grain. Temperature outside the bag should be good, add a little boiling water to get inside temp to 150-155 range. Hold 60-90 min. Raise temp to 175. Heat off. Raise bag to up position. Drain the wort below the bag and pass it all back through, then 2 1/2 gal sparge water, also at 175. (As you have already realized, you can't do everything in the bruheat...my compromise is to heat sparge water in the pot I used to use for extract brewing). When sparging is done, get rid of the bag and spent grains, and perform boil in the bruheat. I just throw the hops in loose, and I therefore have to pour the contents out. If you use a hop bag, you could just drain the wort through the tap.

Further details added the next day:

The Brewbits was purchased at a Wine-Art store in Toronto; sorry I can't be more helpful than that...mail order across the border is a bit of a hassle, though not out of the question. Wine-Art is a national chain, based in Vancouver....perhaps they do mail order. I've not seen it anywhere else, but a similar item without that trade-name may well be available somewhere.

\*\*\*\* If any of you HBDeers know where such a bag can be found, please tell Jay Marshall (marshall@sweetpea.jsc.nasa.gov) \*\*\*\*

As I said yesterday, the bag can be hung in one of two positions. When "down", there's room for about 1 gallon of liquid below the bag; just enough to keep it safely above the heating element. This leaves approx 2 gal (sure, 2.25 if you like) to combine with the grian in the bag. When "up", there's room for maybe 2 gallons below the grain. So you have to let wort out of the tap a couple of times during the sparge. I sometimes boil the first 2 gallons in the same pot I heated the sparge water in, so as to save some time on the boil (i.e. I combine it with the rest of the wort in the bruheat once the sparging's done).

Happy sparging!

Rob (bradley@adx.adelphi.edu)

> This would allow you weeks/months before starting a new batch.  
> Also you have the benefit of "tasting" the results of the yeast  
> before you use it.  
>  
> Has anyone tried this?  
>

In a word, yes. I brewed up a batch of beer a few years ago only to find that I had no yeast in the house to pitch into it. What to do? Following the Golden Rule of Homebrewing I immediately tried to relax and poured myself a homebrew. It wasn't until then that I realized that the stuff at the bottom of the bottle that I didn't want in my glass was just the stuff I wanted in my ready-to-ferment beer so I poured it into the carboy. Granted this isn't the optimal way to start a batch of beer. I didn't sanitize the bottle neck and I didn't make a starter culture. But - it worked! It took a while to get started but the beer came out fine with no contamination or yeast-related problems. In fact the only problem was that an uninspired recipe made an uninspiring beer.

>From: "John A. Palkovic" <scientist@lupulus.ssc.gov>

In his book, Papazian says (p. 79)

... information about the contents of your drinking water supply is available at no cost from your local water department

What exactly should I ask my water dept.? Should I call or write? Is there a law that says they have to supply this info at no cost?

I called the City of Richland (WA) and after three iterations with the city's central switchboard, I finally talked to someone who knew the answers. He supplied me with photocopies of the mineral content as well as the halocarbon report (doesn't have anything to do with homebrewing, but I was curious!). You might want to be a little more specific about which minerals you want to know about. The report I got told me all about minerals like Cd, Pb, Hg, etc. It did state what the hardness was (as CaCO<sub>3</sub>), but didn't include anything about either Mg or SO<sub>4</sub>. The gentleman I spoke with was a little apologetic about the hardness of the city water -- medium hard, until I told him that to a homebrewer this is just fine. After looking at the report, and comparing to the latest Zymurgy article, I would need to add a little gypsum to duplicate the hard waters used by major European brewers (Pils Urquell excepted).

As for cost, I just asked for the report and it was sent. No one mentioned any costs. Perhaps your city will be as nice.

From: ek@chem.UCSD.EDU (Ed Kesicki)  
Subject: pasta machines/Video critique

Let me tell you a story about an experience I had with a hand-cranked pasta maker. My Italian-American mother has had one of these since I can remember; one day in the 1970's, my friend and I thought it would be fun to put little army men through the rollers. Well, it *was* fun--really flattened those guys. However, it also broke the machine; somehow the rollers got pulled apart permanently. And my mother was really P.O'd (she still mentions it from time to time).

Anyway, I don't mean to say that crushing little plastic army men is the same as crushing malt, but I just thought I'd warn you that these pasta makers are not indestructible. I think, however, that you will know if you are using too much force to crank the thing; we really had to use a lot of force to get those guys to go thru.

About the Jack S. video: I saw it, and I liked it. It seemed to give all the basic info for a beginning extract brew. My roommate and I have brewed 13 batches since April, so the video was a little too basic for our needs. I found nothing too offensive in it, however, except the guy from Baderbrau Brewery who said "malt, hops, water, and yeast" about a thousand times--very annoying. And oh yes--the fruit flies--I had forgotten about them--thanks, Robert.

One minor point for you amateur geographers: The city where a lot of Sam Adams is brewed is called Pittsburgh, not Pittsburg--I know, I grew up there.

From: abirenbo@rigel.hac.com (Aaron Birenboim)  
Subject: Lactobacilus (sour mash)

Well, I'm giving sour mashing another try. My first attempt produced a nasty infection, but NOT lactic acid producing bacteria. I am going to give it another try, but this time i plan to try to give the lactic acid producers a boost.

I do not have culturing equipment (yet!), and i have found "buttermilk starter" hard to find. I do have a plentiful supply of "acidopholis". This is commonly found in stores to help people with digestion problems.

All acidopholis products mention "Lactobacillus acidopholis" on the label, but many are mentioning strains. Here is a partial list of the beasties i saw mentioned, and product name where i remember it.

Solgar multi-acidopholis  
L. Bifidus  
L. Bulgaricus

bio-flora  
L. Acidopholis 49  
SF77

do these numbers mean anything? This is the product i bought since the inactive ingredient is barley malt. I assume malt was the culturing media... hence these beasties should be able to metabolize beer wort.

Natures Life : Lactobacillus Acidopholis strain #3208  
once again, does this number really mean something in the real world?

Natrin Digesta-lac  
L. Bulgaricus

other brands listed :  
L. Casei  
L. Bifidus

One bottle mentioned that L. Bulgaricus is synonymous with L. delbreuickii. yes... delbreuickii (sp?) as in hefe-weizen yeast. I wonder how and if Lactobacillus delbreuickii and Saccharomonococcus (sp?) delbreuickii are related?

Could a person who knows a bit about microbiology shed some light on the subject?

I plan to run my mash thursday night, and boil fri night or sat morning.  
I need to brew soon, since my Wyeast starter has already fermented out, and is in the fridge. I will need a new starter friday.

Subject: Busted WYeast Packet

Hey all,

My brewing partner (Tom Strasser -- strasser@raj3.tn.cornell.edu) and I just popped a package of WYeast (#2308 -- Munich Lager -- dated 4/91) and at the same time that the inner seal popped, the \*outer\* seal ruptured as well, shooting out some of the precious yeastily fluids. Well, we were unsure of what to do but decided that whatever it was, we should probably do it right away. We made a real dilute starter (like 1.010-1.015) and dumped in what remained.

First of all: what would \*you\* do? We couldn't get more 2308 as the brewshop in town doesn't carry it. Is it hopelessly naive to think that it's salvageable? Secondly, how should we assess the starter before committing it to a whole 5 gallon batch? This is a tough one, since we plan to brew several batches from it. Our plan is to go with it, as long as it appears to be a normal starter: looks, smells and tastes OK.

Anyone ever have this happen to them before (I would suspect the ever-luckless Martin Lodahl :-)? Just in case, watch out for 2308s of that lot, i.e., have a spare handy.

Yours in the Suds,

STEVE

ps by the way, the fluids that did shoot out tasted sweet. So either the inner and outer packets mixed right away or else the sugar solution is the outer one. (despite previous net statements to the contrary)

From: tony@spss.com (Tony Babinec)  
Subject: Berghoff

At the turn of the century, Berghoff was brewed in Fort Wayne, Indiana. I don't know what all happened to that brewery, but through the years it changed hands. Until recently, they brewed Ballantine's India Pale Ale (yum!) there and other beers such as Falstaff. To my knowledge, the Fort Wayne brewery is now closed. See the old Berghoff can amongst Oldenberg's breweriana collection in Ft. Mitchell, Kentucky, outside Cincinnati.

Meanwhile, the Berghoff restaurant in downtown Chicago is a thriving establishment popular with both locals and out-of-towners. On the premises is the Berghoff stand-up bar, with both a beautiful bar and inlaid woodwork behind the bar. The stand-up bar was, like McSorley's in New York, an all-male club until circa 1970, and of course now is open to the general public.

In the time I've been drinking its beer, it has served a light (Dortmund) and a dark (American Dark). In local stores, you'd find a seasonal bottled bock (American Bock), which cannot be compared in gravity or flavor to the great German bocks or doppelbocks. Berghoff beer served on tap on the premises, and found regionally in bottles, is brewed at the Berghoff-Huber brewery in Monroe, Wisconsin, formerly the Huber brewery. Huber brewed a coupled dozen regional beers, and is perhaps best regarded for launching Augsberger, since sold to Strohs. Berghoff-Huber is the source of such collector beers as Harley-Davidson Heavy beer and Foecking (get it?) beer.

The news for the general beer public is that Berghoff has bought and refurbished the defunct Siebens brewery in the River North area of Chicago on west Ontario. Siebens was selling a reasonable quantity of its brewpub beer, which was generally okay, but it sunk for a number of business reasons (the board got rid of the founder, the restaurant concept varied, was pricy, and indifferently executed, etc.). Berghoff bought the place, refurbished the inside, and is brewing there. On tap on recent visits were: light lager, dark lager, Maerzen, as well as several ales, including an amber ale, a porter, and a stout. The beer is brewed on premise; the kettles are visible just behind the great bar. I can't comment on the restaurant operation, as I haven't eaten there yet. But, Berghoff is to be congratulated for running what so far appears to be a good beer operation.

I toured Blitz-Weinhard a couple of years ago, with similar experiences. After the tour, I asked the guide where they made their malt, since I had not seen anything like that anywhere. He had no clue what I was talking about. Sort of like "Malt? What is that?". Another guide that he asked for help told us that their malt was made by an independent malting company in Vancouver, WA, across the river.

Maybe that has changed, but more likely it is a case of different tour guides telling different stories.

Date: Thu, 19 Dec 91 9:55:26 CST  
From: tony@spss.com (Tony Babinec)  
Subject: russ gelinas brews very bitter beer

In a recent HBD, Russ Gelinas describes a batch of beer from: one can of hopped (!) extract, an addition of 15 AAU of bittering hops, and 1.5 ounces of late hops. Assuming the usual 5 gallon batch, and a boil of at least 45 minutes to 1 hour, that's a lot of hops, even for a hophead!

One can of extract in a 5 gallon batch will produce a beer of starting gravity of about 1025-30. By comparison, English ordinary bitters come in at about 1035-1038. However, the English bitter will have 20-25 BUs bitterness, which translated to AAUs is somewhere around 6-8 AAUs. So, Russ's beer has somewhat less SG than a bitter, but twice the hops, the effect of which is too much bitterness. So, an obvious adjustment in the next batch is to lessen the hops. Also, why use hopped extract? Use unhopped extract and perform the hopping yourself, which affords you more control.

There isn't much you can do about the current hoppy batch, other than age and refrigerate it. Some hoppiness might go away, but the older the beer, the more likely oxidation will take place, which makes the beer less drinkable.

At the expense of a second can of extract, you can brew a beer of greater gravity, which will enable you to add more hops without such a dramatic effect on malt-hop balance. Don't substitute too much sugar for malt, as sugar will completely ferment out, giving rise to thinness, a cidery flavor, and perhaps too much alcohol for the style.

Subject: Cold break

Jim White writes concerning cold breaks:

>I expected a huge mass of cold break material to have settled out with  
the  
>quick chilling and prolonged intense cooling. Though I'm not absolutely  
>positive I can identify cold break material, there was little mass of  
yuch  
>at the bottom of the bucket. What gives? Could this be because of the  
skimming?  
>Is the thick mass of foam that forms at the beginning of the boil the  
>same material that forms the cold break?

I read a study in a technical brewing journal that concluded that  
"quick chilling" is defined by shocking the wort cool, as in a few  
seconds, not chilling the entire mass quickly, as in ten minutes.  
This is one of the technical reasons why I like counter-flow chillers,  
BTW. Taking the wort temp down close to freezing probably had little  
effect on the break. But if you do this after bottling, it will have  
an effect on the clearing of chill haze (also the result of proteins).  
It takes a couple of weeks though.

The thick mass of foam forming at the beginning of the boil is  
predominantly proteinaceous material, the same stuff that forms the  
cold break. That being the case, I think skimming does lessen the  
amount of cold break.

>beforehand (difficult, especially if it's a new recipe), or hold back  
>extra and only use what's called for after measuring the TG (read  
>wasted beer!).

Not if you rack away from the trub before pitching! I've found that I  
have

to leave some liquid behind after what I consider a safe settling time  
(given temperature and equipment) to avoid picking up lightly-settled  
trub.

After racking, I pour off everything remaining that will pour easily into  
a

sterile container, refrigerate, and decant after a few days (sometimes  
more

than once). This is wort that couldn't be salvaged otherwise, it's being  
kept a short enough time that it's not likely to pick up an infection at  
~2C (if I think it might, I can always measure what I need and boil it),  
and the trub settles much more thoroughly in a few days and is unlikely  
(from all comments I've seen) to affect the flavor in the absence of  
yeast.

I've been short of gyle for bitter, which I've tried to make  
less-carbonated; for a standard batch you might have to save a little  
more

(look at what you poured off and estimate amount needed versus amount on  
hand \* % liquid).

Subject: re: Re: Liquid Starters

John DeCarlo stated:

>I don't know of any

>good reason to put hops in your starter, but there might be some.

The reason that leaps to mind is to take advantage of the anti-bacterial properties of hops. It should help to keep those non-yeast beasties down.

I hope someone will check me on this, I think that while the bitterness and aroma of the hops decrease with age, their anti-bacterial-ness remains relatively intact. If so, it seems like a good use for old hops.

Date: Thu, 19 Dec 91 13:35:40 EST  
From: otten@cs.wm.edu (John Otten)  
Subject: Great Deal on SS pot???

I was poking around one of the local Oriental Markets last night, and I noticed some large stainless steel pots they were selling. There was the number 27 followed by a Korean symbol (which I guess was the word for liter or quart), and the handle looped from one side to the other (like on a bucket). The thing that caught my eye the most though was the price-  
\$45!!!. And that included the lid, and a whole bunch of accessories that looked like steaming racks & stuff. I guess the whole thing was a kind of all purpose food steamer/kettle/(and hopefully brewpot).

However... The metal was thin. It looked sturdy enough, but when I read about others and their SS brewpots, I figure they are talking about the pots that are about 3/16" thick. The thickness of the pots I saw was about the same as one of those spun aluminum pots & pans that you can get at K-mart for about \$3.50 (about 1/32" ?). I think that the pot is plenty durable enough to hold 5 gallons of wort, but I would be concerned about scorching the bottom of the pot while boiling. I use my electric stove for the boiling (not a blast furnace like several other readers :-), so I am not too worried about this.

ANYWAY, I am wondering if others have seen/used pots with metal this thin, and whether they had (or didn't have) problems. I will probably go buy it anyway, as right now I use a 4 gallon enamel pot to brew, and that doesn't seem to be much thicker...

ALSO... I noticed 1 lb bags of dried malt for \$1.95. My brewing supply store charges \$12.00 for a 3 lb bag. Is this the same sort of malt!?!?!?!?

If this is good news for SS pot hunters, remember, you heard it here first! :-)

John

Subject: holiday beers

Date: 19-Dec-91 Time: 03:25 PM Msg: EXT02440

Hi there brew folks,  
this was taken directly from the Wednesday, December 18, 1991 NY Times.  
It's  
an article (mentioned yesterday in the HBD) about seasonal holiday beers.  
Enjoy.

FOR CHRISTMAS TOASTING TIME, HAVE A BEER, BUT NOT JUST ANY

By Florence Fabricant

For that holiday spirit, this may be the year for beer. With Champagne  
prices  
through the roof (and eggnog full of fat), beer certainly suits leaner  
times.

But not just any beer. And certainly not an ordinary six-pack of  
something  
industrial -- suitable when your team has won, perhaps, but not for  
Yuletide  
toasting. For the holidays, there are other, more appropriate choices:  
the  
seasonal Christmas brews. If you consider the special Christmas bottles  
of  
Coca-Cola, the special Christmas blend from Starbuck's Coffee -- even the  
Christmas brandy made by Germain-Robin in California -- it makes sense  
that  
brewers are also cashing in on Christmas.

Still, these beers represent something more than a marketer's dreams.  
They're  
part of a venerable beer-making tradition that is being revived around  
the  
country with great success.

"Beers for the season are a staple in Europe and even some of the big  
breweries in America used to make them," said Paul Shipman, the president  
of  
the Red Hook Ale Brewery, a micro brewery in Seattle, which has been  
making  
Winterhook, a rich, full-bodied seasonal ale, since 1986. "This year, we  
increased our production by 50 percent and probably could have sold even  
more," Mr. Shipman said.

Like all of the Christmas beers, Winterhook goes on sale in November; by  
Christmas, the stores are usually sold out. Traditionally, before beer  
making  
became industrialized, these were the first beers brewed in the fall.

Holiday beers and ales are typically dark, rich and full bodied -- the  
better  
to complement heavier, spicier holiday and winter food. And brewers often  
use

special yeasts, hops and malts for these products.

"All the malt in Winterhook came from one farmer who malted the barley especially for us," Mr. Shipman said.

Another characteristic of these brews is a higher alcohol content, usually 5 to 7 percent, than the beers and ales made the rest of the year. One Christmas beer, Samichlaus (Santa Claus) from Switzerland, is made with 14 percent, better to sip by the fire than at the beach.

Many of the American micro breweries that now make these seasonal beers are inspired by English-style ales like Samuel Smith's Winter Welcome. D. L. Geary's Hampshire Special Ale, made in Portland, Me., is one such ale, with a robust flavor and an alcohol content of 7 percent.

>From Mexico comes the dark Noche Buena, made by Moctezuma, the company better known for Dos Equis and Superior. There are also entries from Norway, the Netherlands, Belgium, Denmark and Germany. The Swiss Samichlaus is made once a year on Dec. 6 (St. Nicholas Day), then not released for sale until the following November.

At his Eureka Brewery in Los Angeles, Wolfgang Puck, a co-owner, made a Christmas lager for the first time this year. "It's the kind of malty amber beer I remember," he said. "It goes with the heavier food like venison we tend to serve at this time of year." Eureka's Christmas beer is only served on tap in the restaurant and is not bottled for retail sale.

Beyond just showing holly on the six-pack, what sets all these beers apart is their limited availability. It's partly marketing, to be sure, but these beers are definitely different from the regular lines. "It's fun for our customers to have something different, and it helps keep people interested in a season when things are slower," said Marcia King, the president of the New England Brewing Company in Norwalk, Conn., which makes Holiday Ale.

At the Adolph Coors Brewing Company (a company not usually known for distinctive-tasting brews), the brewmaster had concocted a special beer just for the owners to have at Christmas. "Then, at one point," said Gina Freize, a spokeswoman for the company, "they began sharing it with the employees. Six years ago, we began making enough to share with the whole state of Colorado."

For the last four years, Coors Winterfest has been sold nationally. With production now up to around 4.5 million bottles, it dwarfs the quantities of most of the winter beers made by the micro breweries. For some breweries both large, like Coors and small like D. L. Geary, a winter beer is the only seasonal beer they make.

But in the centuries before yeasts were understood, temperatures controlled and pasteurization a standard practice, beer making was strictly a seasonal activity, with various beers made for different times.

No beer was made during the summer, as the hot weather could spoil the beer because there was no refrigeration. Beer making would get under way in the fall, after the harvest when the heat had faded.

"These customs are at the root of brewing," said Michael Jackson, the author of "The New World Guide to Beer" (Running Press, 1988). "The fact that you're not constrained by the seasons doesn't mean you can't celebrate them."

#### BREWS FROM NEAR AND FAR

Here are just a few of the Christmas beers out now. Many, the fruits of micro-breweries, are sold only in specific parts of the country. Most are available until the end of the year or through mid-January.

Anchor Brewing Special Ale -- Anchor Brewing Company, San Francisco, Calif.

This medium-amber ale makes a good head and has a toasty aroma and rich, mellow slightly winy flavor. Available nationally.

Catamount Christmas Ale -- Catamount Brewing Company, White River Junction,

Vt. This medium-amber ale combines the bitter flavor of hops with hints of walnuts and coffee. Available in the Northeast.

Hampshire Special Ale -- D. L. Geary Brewing Company, Portland Me. With a tealike aroma, this medium amber ale has a bitter flavor mellowed by malty sweetness. Available in the Northeast.

New England Holiday Ale -- New England Brewing Company Norwalk, Conn. This ale

is a deep, reddish amber with a spicy bouquet and slightly bitter taste with cinnamon and nutmeg seasoning. Available in Connecticut and Massachusetts.

Samichlaus Bier -- Brauerei Hurlimann, Zurich. This dark, strong (14 percent alcohol), rich and malty-sweet lager is excellent to drink with chocolate desserts. Available nationwide in major cities.

Samuel Adams Winter Lager -- Boston Beer Company, Boston. This medium amber

beer is full-bodied and mellow with a pleasantly bitter finish. Available nationally in major cities.

Samuel Smith Winter Welcome Ale -- Samuel Smith Brewery, Tadcaster, Yorkshire,

England. A medium amber ale with a rich, malty aroma and a full bodied, tangy

flavor. Available nationally.

Seasons Best -- F. X. Matt Brewing Company, Utica, N.Y. This light amber beer has a malty aroma and a fairly bland flavor. Available in New York and New Jersey.

Sierra Nevada Celebration Ale -- Sierra Nevada Brewing Company Chico, Calif. This is a medium amber ale with a fruity aroma and an excellently balanced flavor that combines the bitterness of hops with the sweetness of malted barley. Available nationally.

Winterfest Beer -- Coors Brewing Company, Golden, Colo. A relatively light-bodied medium amber beer with a moderately rich flavor and a nice, bitter hoppy finish. Available nationally.

Winterhook Christmas Ale -- Red Hook Ale Brewery, Seattle, Wash. This fullbodied, medium amber ale keeps a good, creamy head, has a toasty coffee aroma and a rich flavor. Available in the Rockies and Pacific Northwest.

[...]

Ahh yes, the joys of industrial beer tours! It is part chemical factory  
and part make-the-world-safe-for-stupid-tourists. The average tour  
is definitely NOT for the knowledgable brewer.

I've toured Pabst (before they were bought); A-B plants in Colorado and  
New Hampshire; Schiltz; Miller; and Coors. Plus a dozen brewpubs.

The guiding principles of industrial beer tours are:

- 1) the guide knows less than you do
- 2) the tours never go to the interesting areas (culture lab, granaries,  
etc)
- 3) you will have to listen to company sales propoganda
- 4) a recent addition is listening to the "safe drinking" lecture
- 5) you will be herded from site to site quickly
- 6) you only get 2 beers at the end :-(

I've set up an in-depth tour at Coors for the Colorado Springs homebrew  
club  
for early February. I'll report back if this non-standard tour goes  
well.

For what it is worth, Ken Pavechevich, founder and CEO makes a big issue out of claiming the use of only Saaz hops.

Also for what it is worth, I added 1/2 oz of Saaz to my last batch at the end of the boil. This is addition to the "standard" 1 oz of Chinook. It will be interesting to see I can tell the difference.

From: zentner@ecn.purdue.edu (Michael Zentner)  
Subject: bottling wands

> There is as much, if not more aeration with the use of the wand by the initial rush into the bottle than there is with my siphoning technique.

After the drubbing I got over aeration and oxidation, I noticed this immediately. The simple cure is to lift the bottle to reduce the "head" and tilt it till the end is covered. You can then put it back down and continue the process in the normal fashion.

It's a little extra work, but if one is an oxidation freak, it beats the other tricks I have seen so far.

.....

Fining.

I gave up on waiting for my beer to clear and have fined 4 batches with gelatin. The speed with which this stuff works is mind boggling. After 30 days, my all grain generic beer, is still so hazy that about all I can see through it is a flash light. Three days after fining, it is sparkingly clear. This was even true on one batch, only a week after pitching.

I rationalize that my beer is still Reinheitsgbot because the gelatin is

only a temporary resident.

According to Noonan, gelatin will only work at temperatures below 55 degs.

It happens to be almost that cold in my basement these days but can anyone refute this seeming momily?

I would also be interested in any comments on taste/flavor or other effects of fining with gelatin. Yeh, I know, it ain't Kosher. Or is it if you leave it behind by racking?

From: "Rad Equipment" <rad\_equipment@rad-mac1.ucsf.EDU>  
Subject: Anchor Date Code

Subject: Anchor Date Code Time:4:03 PMDate:12/19/91  
New Anchor Bottling Date Code

Jim Homer requested I investigate this for you all...

I spoke with Mark Carpenter, brewmaster at Anchor Brewing Company, about the new date code that they are using since they changed their label to a dual design, putting the government warning on the back of the bottle. If you are still getting bottles with single labels, the beer is older than October, 1991.

The new date code replaces the clock-face which used to show the bottling month as one of 12 small notches around the main label. A three character code is now included on the new back label of the bottle. The code works like this:

The first character is always numeric and represents the last digit of the year. Currently you are seeing a "1" in this spot.

The second character is always alpha and represents the month by using the first letter in a month which has not previously been used. So:

January = J  
February = F  
March = M  
April = A  
May = Y  
June = U  
July = L  
August = G  
September = S  
October = 0  
November = N  
December = D

The third character in the code is either alpha or numeric and tells the day of the month. The first 26 days are represented by the alphabet with the remaining days listed as:

27th thru 29th = 7 thru 9  
30th = 3  
31st = 1

They didn't use 0 (zero) for the 30th because the labeler makes it's "O's" (letter O) the same way it makes it's "0's" (zeros).

So today's (12/19/91) bottling reads: 1DS

This code was originally created by Fritz Maytag for use on his PC to identify file dates with 3 characters.

Happy Holidays to all!

From: hartman@varian.varian.com (John Hartman)  
Subject: Scrubber + Pellets = Trubble, Cold Break

- --Copper Scrubbers revisited--

This is a follow-up to a post regarding the use of copper scrubbers in HBD #776. In that post I pointed out that the use of cheese cloth over a copper pot scrubber at the end of my siphon had caused severe blockages. I have since learned that the real problem is not the cheese cloth but the combination of the pot scrubber and pellet hops. The last batch I made I used up some old pellet hops for the boil. I usually use whole hops from Freshops. I experienced blockage once again but without any cheese cloth. I conclude that using pellet hops is incompatible with the use of the scrubber as a filter.

On the other hand, using the scrubber with whole hops does work quite well.

- --Whither Coldbreak--

I'd like to solicit opinions on cold break. I've never really seen the phenomenon in over 20 batches. Mind you I always see the dramatic formation of hot break as the brew approaches boiling. Upon cooling though I see no precipitation. When I switched to a counter-flow chiller, part of the motivation was to improve my beers by producing the alleged cold break. While the chiller has improved my beers, I only see the slightest clouding of the once hot, clear wort as it exits the chiller. Originally I was racking into a temporary container so that I could rack off this 'cold break' before fermentation. But there was no cold break, so I now counter-flow/siphon directly into the fermenter, which is actually a lot less work. The output of the chiller is typically 60F. So what gives? Where is the cold break I hear so much about? Any insight here would be greatly appreciated.

By the way, for the longest time I would siphon into my fermenter in the Brewing Room (read kitchen) and then carry it to the Fermentation Room (read Basement). One day after a few home brews I finally decided to just go ahead and drill a hole right through the floor and on into the basement. I installed a racking tube and have since been siphoning directly to the basement. Well fellow brewers, this technique has worked quite well. It has had the added benefits of improving the strength/speed of the siphon and of allowing me to brew up to 15 gallons conveniently. I would recommend this to others with the caveat that one should be prepared to explain to non-brewers just why one would do such a thing. My girlfriend seems to enjoy pointing it out to her friends as if to confirm her suspicions of what I'm not sure. Well

I guess I've wasted too much bandwidth already, so I'll close by simply wishing all happy holidays.

John

Subject: King Gambrinus?

Who was King Gambrinus?

There have been many beer-related pictures of a person wearing a crown.

Somehow Gambrinus has become a sort of "patron saint" of brewers.  
Many breweries have taken their name from him or put up statues  
claiming to be in his likeness.

I've heard/read several proported explanations about who this, possibly  
mythical, person was. The stories say King Gambrinus was one of:

- 1) a real [English, Dutch] king
- 2) a mythical [English, Dutch] king
- 3) a corruption of a Dutch brewer's name (Jan Primus)
- 4) a distant relative of Charlie Papazian ;-)

Does anyone have a better/truer story? Who was this guy?!?

From: whg@tellab5.tellabs.com (Walter H. Gude)  
Subject: Pre-crushed grain

With all the talk about grain mills and the many references to grain not keeping well after crushing, I've been wondering how you can tell when pre-crushed grain has been around too long? What tastes will "stale grain" impart to my beer. For instance, I have a half of a pound of crystal that I milled at the brew store about a month ago. It's been in a closed (hopefully sealed) zip-lock bag in my vegetable crisper since I used the first half. How can I tell if its "bad"? It still tastes ok. Will crushed grain get moldy?

Inquiring minds want to know.

Subject: Immersion Chiller...

Someone asked about the Immersion Chiller from the Home Brewery, whether it was big enough to do the job. I just bought it for \$29.95. The first thing I'll is its much bigger than it looked in the ad. From the picture, it looked to be about six inches in diameter. As it came it was about 8 loops each about 10" in diameter. That works out to about 50 feet of tubing. This just barely fit in my brewpot so I play around with it to make it 10 coils of 9" diameter. I boiled three gallons of water just to test it. It took the water from 100C to about 32C in five minutes at a very slow flow rate from the faucet before I got bored and put it away.

For the tinkers among you you may be able to get the 50' of tubing and the connectors for less. But if your like me and your time budget has more constraints than your monetary one, I'd say this is a deal.

I'm in no way connected with the Home Brewery, just a satisfied customer.

From: R\_GELINAS@UNHH.UNH.EDU (Russ Gelinias)  
Subject: bitter brew

I guess I wasn't exactly clear wrt. my undrinkable bitter brew. I said it had a can of hopped extract and 15 AAU of hops, which by itself, would make for too bitter a brew. But it also had 4+ lbs. of amber dried malt, and a lb. of crystal. So that's 7.3+ lbs of malt and 1 lb of crystal, with 15 AAU plus whatever was in the extract worth of hops. The extract was an amber, so I doubt it had more than 10 AAU in it, more likely closer to 5. Still a hoppy batch, but I've made them that hoppy before, and they were fine. This one is lousy, if I do say so myself. It doesn't taste like hops, that's what's confusing me. Centennial hops, fwiw. I'm starting to wonder if that can of extract was bad.....it seemed ok. I'm stumped.

Subject: BORNEO

(This post is not really beer related)

Richard Childers writes (to JS):

>Don't you think it's about time you quit pretending you were  
>a brain surgeon amongst natives from farthest Borneo ?

I object. There are many things natives from Borneo could teach us about living off the land without destroying it at the same time. My wife and I lived for a week with a native tribe on Siberut, an island off the W. coast of Sumatra. These people are very similar to the native tribes of Borneo (they are both proto-Malay people). They have managed to survive on a tiny island for thousands of years by cultivating sago (a tropical root) and hunting tiny tree monkeys for food. They have \*NOT\* hunted these animals to extinction as our ancestors have on occasion - just enough to survive.

The sad thing is that both the Mentawais people of Siberut and the people of Borneo are threatened by Indonesia's indiscriminate logging and transmigration policies. It won't be long before the lifestyle of these people change forever (for the worse).

BTW, they also happen to ferment some pretty wild fluids too ;-)

My last day at work, so I won't be readin' HBD until 92. So, Merry Xmas, Hoppy New Year, and enjoy those Christmas batches...

Subject: burst Wyeast

In HBD 786, Steve Russell bemoans his burst Wyeast package. Moments before I read his post, UPS delivered my latest batch of ingredients from Alternative Beverages. Moments after I read his post, I called Alt. Bev. because they had left out a package of hops. The guy on the other end of the phone noticed that I had ordered Wyeast and told me a few things about burst outer seals. The beer gods must read the HBD because I didn't bring up the subject, he did. Anyway, he told me the following tidbits: First, he's had a lot of complaints about just this problem. Second, he spoke to Wyeast, and they told him that they are redesigning the package and rewriting the directions. Finally, he said that the reason they break is because when you slap the package your hand puts too much force on too big an area. He suggests using the bottom of a beer bottle to break the inner seal. The beer bottle is about the same size as the inner packet, so force is applied at just the right points. Also, the concavity of the bottle helps. Now this guy's not a physicist, but he does work for a homebrew supplier, and his advice seems reasonable. I'll try it on my next batch.

>Subject: Infusion, Mash-out, Sparge Efficiency

in this post Russ describes a single step mash procedure produced after listening to lectures by Dr. Lewis at UCDavis. He now uses a 1-step mash at 153F.

I believe that this may be a very good procedure, but I'd like more detail about how to deal with adjuncts/specialty grains.

Here is Russ's mash-out specialty grain procedure:

> What I now do is mash my base grains to conversion. At conversion  
>I add the Crystal and any other specialty grains ( all finely ground)  
>to the mash and start my mash-out temperature rise ( 1 degree a minute  
to 170  
>degrees ), allowing the mash to mash-out at 170 for 10 minutes. I the  
ladle  
>the grains into my picnic cooler/ slotted pipe sparger and take ALL of  
the  
>initial run-off after recycling about two quarts to get clarity. Once  
the  
>initial run-off is collected I add ~4 gallons of 170 degree water to the  
tun  
>and stir the H--- out of it for three minutes. Let is settle for 5 mins,  
>recycle about two quarts to set the bed again and take the run-off to  
the  
>boiler.

Can I use this single step infusion with fermentable adjunct like barley flakes, wheat flakes, cracked wheat or oats (cooked) ? If so... how much adjunct might i get away with?

How about roasted barley.... I do not even know if it is really fermentable.

I can see that unfermentable specialty grains like crystal or chocolate malt would be better added before mash out.

Subject: Phil's Philler

A follow up to Arthur Delano's review of Phil's Philler:

The sticking of the shutoff mechanism is a \*big\* problem. This sticking has a lot to do with putting a little bit of horizontal force on the lower brass tube (the one that bottoms out in the bottle). If you could carefully suspend the filler in space without hitting the lip of the bottle as you pulled up, the problem would be less acute. In the heat and mess of bottling, this is not a very practical suggestion... but it does explain why the user thinks the filler works great when he "plays" with it, and then has trouble using it on real bottles.

A problem not mentioned by A.D.: BY THE VERY NATURE OF ITS DESIGN THE DEVICE APPEARS TO AERATE THE \*&#\$ OUT OF THE FINISHED BEER.

I cannot accuse Phil of false advertising, because all he claims is that the filler fills bottles right up to the lip and shuts off by pulling it out of the bottle. The downsides are "in between the lines".

I tried Phil's as an alternative to the red-tipped plastic bottling wand. The wands are prone to leaking due to seating problems between the spring-loaded rod enclosed by the tip and the tip. Phil gives you a different kind of leakage problem and aerates the beer more in the bargain. I am back to kegging when I can and bottling with the wand when I must.

From: Mark J. Easter <eastern@ccmail.orst.edu>  
Subject: Pasta machines, wet milling

Feliz Navidad, Ya'll;

In HBD #785 (Dec 19, 1991), on the subject of "wet milling" malted grains in a pasta machine prior to mashing, Ken Weiss writes:

>I don't think you could still use the pasta machine for  
>pasta if you did this. You'd have to clean up with water.  
>Apparently, if you get a pasta machine wet the noodle  
>dough will stick to it for years after. I dunno why, but  
>you're supposed to clean those things by just waiting for  
>the bits of dough to harden, and brushing them clean.

This has been my experience with pasta machines. The first time I used mine I did not read the directions thoroughly...and washed the thing off with hot water and detergent. The problem I had was \*rust\* on some of the visible mechanisms (I'm afraid of what happened to the internal, invisible parts of the machine). Anyway, we dried the machine thoroughly by setting it near the woodstove and then cranked it liberally. The machine works fine, now, however we had real problems with pasta sticking to the rollers for the first several batches after that experience. After reading the instruction manual (who would have thought of this?), we found that one should \*never\* wash the machine in water, just let the leftover pasta dry out and brush it loose. One is supposed to heat the machine (with rubber feet removed) to temperatures above 140 dF if one is concerned about bacterial contamination.

I tried my machine on \*dry\* malted barley and wheat. It worked relatively well on the barley- it seemed to provide a good "crush" while leaving the hulls intact, however the wheat kernals just tended to break into two pieces. I suppose a second grind at finer setting might help crush the pieces. Quite a lot of flour was evident in the grind. I'm a real amateur when it comes to evaluating a quality grind, so I'm not a good final authority on the subject. The grind was also extremely slow. One might need to "rough up" the rollers (I recall somebody else mentioning this in the HBD) to facilitate passage of the malt through the rollers, a procedure that would probably render the machine useless for pasta. As somebody who loves homemade pasta as much as homebrewed beer, this would be a heartbreaking exercise.

Joyeux Noel- I'll be enjoying "Cherry Fever Stout" ala Papazian this season and I'll raise a glass to my fellow homebrewers.

Subject: Re: bottling wands

Mike writes:

>The topic is back, and I'd thought I'd cast one opinion of dissent.  
>I don't think these are a miracle tool. I don't like using a  
>spigoted bucket for bottling because of sanitation hassles incurred  
>by always having to take the spigot off. I don't even like using  
>a plastic bucket for bottling because of sanitation worries. My  
>bottling wand does not form a perfect seal when it's supposed to  
>be "off". There is as much, if not more aeration with the use of  
>the wand by the initial rush into the bottle than there is with my  
>siphoning technique.

I used to (and soon again will for my (late) Christmas Ale) use a bottling wand attached to the end of my siphon hose. After very few batches, my orange plastic gizmo also had leakage in the "off" position, but it was a drop every few seconds and I would normally put the wand in the next bottle while capping the current one. The initial rush can be reduced by raising the bottle and wand closer (not above!) the level of the beer in the priming vessel. As I'm sure you're aware, the rate of the transfer is dependent on the difference in the height of the liquid levels. One the end of the wand is submerged in beer, I lowered it to fill faster.

>

>I simply like to have a spare carboy around where I can combine the  
>>wort and priming solution and siphon from there into the bottles.

Agreed. I used a spare carboy for a priming vessel also.

>

>That said, I'm not saying that because you use a wand your're doing  
>anything wrong. I'm just saying that not everyone thinks it's such  
>a great idea, and bottling by both methods can be equally as efficient.

Agreed again. It's not so much that I strongly disagree with you Mike, it's just an opportunity for me to mention the "level differential vs. flow rate" hint and to mention that I had the same leakage problem. Maybe a better wand is the answer. "Phil's Philler" mentioned recently sounds like a step in the right direction, but I think I would like it better if they put a return spring into it (currently "off" is a result of gravity as

I understand it). I'll probably buy one anyway.

Al.

Subject: Percise bottling, Xmas beers.

Many thanks to Ms. Katman for her reproducing that NY times article on Christmas brews. The Catamount Christmas Ale is certainly a delicious brew, as is the Sam Adams Winter Lager and, dare I say it, the Coors Winterfest. Sure wish the Red Hook stuff was available on the East coast.

On Bottling,

Since I can't see, I have been constantly plagued with the problem of how to tell when the bottle is full enough. Usually, I just fill until overflowing, (on the dishwasher front, in its down position), and then pour a little out. Not especially precise, you will admit. If my wife is so included, (one in ten batches), shw helps me and the bottles are all filled just right. I got an idea today and called Cole-Parmer. I spoke with a product specialist and found that they have just what I need. I can connect a batch controller to a peristoltic pump. It will measure to within a quarter milliliter or so. I can tell it to put exactly 282.5 mills in a bottle, touch a foot pedal, and the pump will do just that. No spilling, no guessing, no hassle ... except for the price. (Damn, did he have to mention THAT!) The setup would cost \$1750. That's right, no decimal point after the 7, or even the 5.

But what the heck. Hobbies are money sinks anyway. Just another thing to save for. Now, does anyone have an idea for the same basic thing that might cost just a little less?

I know, I could keg, but that's not possible now. The price isn't bad, but the space for the extra icebox is. I wonder if I could find a used, repairable commercial bottle filler?

Thanks for any thoughts. Dan Graham

Subject: umlauts, bottle fillers, dried malt and SS pots

Re: "Baderbrau [umlaut over the second 'a']"  
German typographic convention allows one to type an "e" next to a letter that normally has an umlaut over it: "Fuehrer" for example. On the other hand, American typographic convention allows one to drip all diacriticals entirely with no apologies. I don't know from German myself, but learned how to type in German this summer when working with a visiting German professor. This is entirely FYI, of course.

Re: Richard.Stueven@Corp.Sun.COM  
> I bottle right out of the spigot.  
You're not the first person to point out that this can be done. I got so used to using Papazian at his word that I never thought beer could simply be poured in very carefully. (P, by the way, prescribes a pinched-hose technique which I reported worked poorly).

Re: otten@cs.wm.edu (John Otten)  
> [About using a thin-walled pot]  
We've had little problem with scorched wort, but have had some, using a thin-bottomed steel pot. I may use a metal spacer (available in some kitchen stores) between the electric burner and the pot next time.  
When I was shopping for a pot, I found that the stores often had no markings on the pots, indicating that they were steel or aluminum. Had I planned ahead, I would've brought a magnet with me. I settled for tapping on the pot; if it rang well, it was probably steel; if it thudded or rang mutely, it was probably aluminum. "Probably" is important; has anybody else had this problem when they were bargain-pot-shopping?

> ALSO... I noticed 1 lb bags of dried malt for \$1.95. My brewing supply store charges \$12.00 for a 3 lb bag. Is this the same sort of malt!?!?!?  
Where do you live? (!?)

From: mcallist@netcom.com (Ron Mc Allister)  
Subject: umlauts, bottle fillers, dried malt and SS pots

Greetings, and Happy holidays!

I am in the process of designing an automated masher, using a PC for process control, statistical and recipes. This is a very exciting project, as it allows me to roll my electronic, programming and beer making into a REAL worthwile system.

Here's my latest plan:

- 1.) 55Gal Steel drum, cut along its axis, kinda like those BBQ's folks make for BIG picnics, but not to be cut in the center, more twoards one side.
- 2.) This will make foom for:  
A SS 15Gal Keg , straight sided type to be suspended in the drum (a keg within a drum).
- 3.) The SS keg sits on 4 wheels, and is slowly rotated by a motor arrangement on top driving a rubber wheel bearing down on the Keg
- 4.) The Drum is filled with enough water to cover the keg 3/4.
- 5.) Water heater elements on either end of the drum, controlled by the computer.

Why this plan ?

After looking at Zymurgy and ads for the "Auto-Masher", and reading Miller's excellent book (The complete handbook of home brewing) to find out that he recommends 1.33 qt of water /# malt, I realized that a system like auto-mash would have a hard time stirring the mash. I will be doing step mashing, making many mashes and varying very exactly time, temperature, ph etc.. to provide optimum control. Someday, it will be incoroprated into my "mini-micro-pilot-brewer" wherein total automation will be employed.

The Q (finally)

The rotating barrel idea is a bit more work, but AM I ON THE RIGHT TRACK ? Any suggestions would be helpful. Thankyou.

Merry Xmas!  
Ronan (The Barbarian) "Barbaric Brew".

Subject: Berghoff

I was at the Berghoff for lunch the day after Thanksgiving. While they were selling the Wisconsin brewed beer you mentioned, they were also selling brewpub like products, presumably from their newly opened brewpub. I had the weizen, which appeared to be unfiltered. Others at my table had an Alt and a Winter Warmer type beer. They were also offering a porter.

While an ale brew-pub combined with German food is a little odd, the beers were certainly of better quality than the contract brewed (Huber?) lagers you mention.

Subject: Conveyor mill

I just spoke with my friend who works for a company that engineers custom conveyors for industry. It seems that, yes, they do use off-the-shelf parts and then piece them together. I asked if there's any possibility that we (brewers) could use parts from his company's suppliers for making a grain mill. It turns out that he has had some experience in this area also (he worked for a company that made coal crushing equipment). He said that there's no way the parts they use could build a mill for the \$100-200 I suggested -- often just the bearings they use are \$100 each. Oh, well... back to the old drawing board.:^(

Subject: STUFF and undercarbonation

I finally got around to reading a weeks worth of hbd's (the week before last's - I've still got a week's worth to read and need the disk space)...

> my mailer only allows a one word subject

hey - it used to be that fortran identifiers were limited to 6 characters, and that didn't stop the early NA hacker from giving their library routines meaningful names (sarcasm intended). Take, for instance `dmxv()`, which translates to double-precision, matrix times vector. Now if you adopt the convention that R stands for response, G is for all-grain, T is for temperature, and Y for yeast, then "RG>TY1007" could be construed as "response concerning a batch of all-grain ale fermented at a high temperature with wyeast 1007 german ale..."

> Three weeks after bottling, there is still ver little  
> carbonation in the beer...

At the risk of oxidizing it somewhat, try shaking the whole case of bottles. It should carbonate in another week.

From: ALTENBACH@CHERRY.llnl.gov  
Subject: SS POT ON ELECTRIC STOVE

In HBD 786 John Otten is considering brewing with a stainless steel pot on his electric stove. I have a thin cheap SS pot and a heavy duty restaurant grade pot (Volrath) and recommend the latter if you can afford it. The cheapo works ok, but is easily dented and will scorch somewhat. The heavy duty pot is a fine piece of equipment that should last as long as you still like beer (lifetime). But BEWARE: using a shiny SS pot for extended boiling on a conventional electric stove can easily damage the stove. The heat reflected off the pot and back to the stove is so great as to warp the burners and rings, especially if you use two burners simultaneously. You can also scorch the stove surface very easily. I had to replace the main burner on my electric stove and my wife will never forget how I violated her domain. Fortunately she kicked me out of the kitchen into a dedicated brewing area (formerly laundry room). When upgrading your equipment to stainless steel, leave the stove behind and also get yourself a blast furnace (or at least a propane burner).

Subject: SS POT ON ELECTRIC STOVE

Greetings. Has anyone ever devised a hydrometer that floats in the secondary vessel continuously - maybe with a DC voltage proportional to the SG? Any Ideas would be appreciated. Also, can one accurately measure the weight of a wort with a triple-beam scale to determine SG?

I left a posting yesterday giving sketchy details of an automated mash project I am working on. This hydrometer will eventually be interfaced to the sparger to obtain "real-time" readings of degrees of extract, etc.

Also, anyone have any experiences with a PH sensor that is rugged, low-cost, accurate? only a transducer is necessary.... I will also integrate this into the control loop.

From: bliss@csrd.uiuc.edu (Brian Bliss)  
Subject: amylase

For the last few mashes I've been adding a tablespoon or two of amylase enzyme to my mashes, half at the start, and the rest halfway through. Will this make a difference, or is it just a drop in the bucket compared to the amount of amylase already in the barley malt? How much of it is alpha-amylase, and how much is beta-amylase, and is this proportion different from that in the barley malt?

Dad told me that he is now raising specialy corn (for which he gets a premium) from which they make this stuff. How many bushels were sacrificed for this little 1 oz. bottle? is \$1.95 way too expensive for it?

Someone recommended adding a little to the wort after picthing to get a drier beer. well, I found out that this works. In fact, it works too well for my taste. My guinea-pig batch of extract stout is way to dry, overcarbonated for the amount of priming sugar used (I guess becace some extra sugars were formed after bottling), and gives me a slight stomach ache when I drink it.

>luckless Martin Lodahl :-) ??

OUCH! Direct hit ... 8-0 Yeast everywhere ...

Yes, as a matter of fact, I did have this happen, about a year and a half or so ago. Quite a few people had the same experience at the same time, and after noting a couple of postings to that effect, Pete Soper (from whom we haven't heard in too long; Pete, you're greatly missed!) began collecting stats and contacted WYeast. They responded very quickly, immediately dumping the packaging that was the source of the trouble. My retailer unhesitatingly replaced my burst packet, and while I was there making the exchange, another patron told how he'd started a packet and left for work, finding yeast sprayed all over his kitchen when he returned.

When my packet burst, I didn't handle it with as much aplomb as Steve did. Fearing contamination, I just dumped the stuff and resorted to the packet of dry yeast I keep on hand for such exigencies. Then it was Edme, now it's Whitbread. And the beer turned out fine, but not as tasty as it would have been, I'd like to think ...

Subject: How Did You Know, Stephen?

A possible water saving idea:

An effective wort chiller may be constructed for those who are concerned about water conservation. For those "do-it-yer selfers". This is a forced air system and might be overkill, but we are on our 6th yr. of drought here (sheesh) and trying to minimize waste. I used what I had available. Improvise, Improvise, Improve !

1. Coil 15' of copper tubing around a section of 6" stovepipe used as a form, then slip a piece of 8" stovepipe around the whole arrangement and wrap another 20 or so feet of tubing back up the other direction towards the start of the tube.
2. Remove the stovepipe forms.
3. Obtain a length of 10" galvanized stovepipe 1' longer than the coils and slide the coils inside.
4. Secure the coils to the inside of the 8" stovepipe with straps and rivets or screws. (Plumbers tape works fine).
5. Mount a circular piece of 1/2" plywood to the end opposite tubing connections to act as a mounting plate for the blower. Use 4 little "L" brackets.
6. Find a powerfull fan or impeller type blower and mount on plywood. An ideal type is one of those 110VAC leaf blowers, or something with that kind of force. (Use ear plugs when using).
7. Add connections to complete. Store filled with sanitizing solution.
8. Use only food-safe solder for connections if solder used.

From: Robb Holmes <RHOLMES@uga.cc.uga.edu>  
Subject: Winning Blue Ribbons ( bad beer of old)

Back in the mid-70's, I drank a lot of --uh-- beer, I suppose, since it tasted too bad to be water. It cost about seven cents a bottle, using one can (2.2 lb.) of Blue Ribbon malt syrup and, if memory serves, about four pounds of sugar, stretching the wort to about seven gallons. Of course, it was awful, but I drank it anyway.

I got back into brewing last March, and I'm still not a great brewer, but I've been amazed to discover that, using good ingredients and reasonable attention to sanitation, it's possible to brew a very tasty ale or stout.

I recently found one grocery store that still carries Premier Malt Syrup, which appears to be the same as the old Blue Ribbon. I immediately whipped a batch for old times' sake: three cans of Premier hopped light and no sugar (except one cup Dextrose for priming). I noticed this batch fermented faster than any other I've seen, and this in November, with reasonably cool weathr.

This batch does not taste infected, and it's not overly cidery, so it's a big improvement over the crimes I used to commit with Blue Ribbon. Still, there's a certain flavor about the beer that I don't like (although my wife prefers it to the very hoppy ales I usually brew). Sorry, I don't know how to describe the flavor, other than to say it was what was left when you took away the cideriness and infection that were typical of beer made with Blue Ribbon way back them.

Has anyone ever undertaken a study of Blue Ribbon/Premier? I'm curious how others describe the flavor of beer made with this malt syrup, and if anyone knows why it produces the same, consistent off flavors.

Any replies/opinions on this subject will be appreciaed.

In Homebrew digest # 784, Kenney Baughman writes:

>The other thing to remember is to keep the water housing of the  
>chiller as small as possible. Heat exchangers are more efficient the  
>more the coolant turns over.

In more scientific terms, you get better heat exchange when the coolant flow is turbulent. This means the "reynolds number" is much larger than, say, 10000. It would be possible to estimate the reynolds number for a wort chiller of given dimension if we knew the pressure drop between inlet and outlet. Since plumbing water pressure tends to be a function of position ;-), it is hard to say what the correct dimensions should be. Here in Texas (near Dallas), my water pressure is a hell of a lot more than it was in Warrenville, IL, near Chicago.

Happy brewyear,

-John

Subject: Berghof and Huber

Hmmmm, my info may be dated but as I understand it, the Berghof owns the old Huber brewery. They don't contract it, they do it themselves. (Does this qualify as homebrewing?)

Quick history, Huber used to make three basic labels: Huber, Rhineland, and Augsburger. Of these, Augsburger was really good. So Huber goes belly up and sells the Augsburger name off to Stroh's. Stroh's turns Auggies into an average beer. Berghof buys Huber to make their house label. (They may have been contracting with Huber before, I'd have to check.) So now Berghof beer is available throughout the midwest (in both dark and light.) Michael Jackson is actually quite enthusiastic about the light. Huber and Rhineland are also being brewed again.

Anyone in Chicago know the story for sure?

Subject: bunratty meade

Hey now- Well, I managed to get my hands on a bottle of Bunratty Meade last weekend. The bottle is beautiful white stone with a cork. The back label has some pretty interesting information, including that in Ireland it is customary for a new bride and groom to drink meade for a fortnight/lunar cycle after their wedding, thus deriving the term honeymoon. You learn something every day...

The label also says that the stuff can be consumed cold before, during, or after dinner or warmed as a toddy type of thing. I had it cold. Really interesting flavors. It's supposedly made with white wine which lends a little flavor right off. The remaining taste is very alcoholic (14.7% volume) and mostly honey. My girlfriend's comment was that it tasted like "honey with rubbing alcohol dumped in it." It took me quite a while to finish a wine glass full and provided quite a warm fuzzy feeling. I definately wouldn't want to drink it in any great quantity.

I would suggest trying some if you can find it. It's only about 15 bucks, and if all else fails the bottle makes a nice vase or lamp or something. I guess you could probably bottle your own meade in it if you have a cork-thingamabob. I wouldn't fly to Ireland for it or anything, but it's not bad overall...

Subject: bunratty meade

Hey now- Well, I managed to get my hands on a bottle of Bunratty Meade last weekend. The bottle is beautiful white stone with a cork. The back label has some pretty interesting information, including that in Ireland it is customary for a new bride and groom to drink meade for a fortnight/lunar cycle after their wedding, thus deriving the term honeymoon. You learn something every day...

The label also says that the stuff can be consumed cold before, during, or after dinner or warmed as a toddy type of thing. I had it cold. Really interesting flavors. It's supposedly made with white wine which lends a little flavor right off. The remaining taste is very alcoholic (14.7% volume) and mostly honey. My girlfriend's comment was that it tasted like "honey with rubbing alcohol dumped in it." It took me quite a while to finish a wine glass full and provided quite a warm fuzzy feeling. I definately wouldn't want to drink it in any great quantity.

I would suggest trying some if you can find it. It's only about 15 bucks, and if all else fails the bottle makes a nice vase or lamp or something. Subject: Gelatin

Hi,

Jack S. asks whether Noonan is correct that gelatin will only work below 55 degs. I have used gelatin finings at temperatures up to at least 70 degs and it seems to work OK. For what its worth though I've found that isinglass works better for me, and since I mostly make English style bitters and ales I feel that its a more "authentic" way to go. I've never noticed any taste/flavour effects when using either gelatin or isinglass. I once made a wheat beer that wouldn't clear with either isinglass or gelatin, so I used a combination of polyclar and a bentonite slurry. This cleared the beer of practically everything, haze, flavour, mouth feel, head, (everything). In some cases I guess its best to just leave the beer cloudy.

Subject: finings

Jack asks:

>I would also be interested in any comments on taste/flavor or other effects  
>of fining with gelatin. Yeh, I know, it ain't Kosher. Or is it if you leave  
>it behind by racking?

I've never used geletin. I have, however, used Irish Moss, which is a particular type of seaweed. I've noticed no detectable flavor difference, but have noticed a reduction in head retention along with the primary result of finings, namely crystal-clear beer. The loss of head retention would support those who suggest that protein is crucial for head retention, since the Irish Moss (added at the end of the boil) helps precipitate out more proteins.

I don't think that the use of any kind of finings is allowed by Reinheitsgebot, but I've stopped worrying about that a long time ago. In my humble opinion, I like Ales much more than Lagers and I feel that whatever it takes to make my beer look and taste the way I like it, as long as it's natural (i.e. not artificial flavor, etc.) meets my purity law.

Somewhere, I've got some really interesting info on finings. I've already checked my files, it's not here at work. What I faintly recall is that finings work in one of two ways, and most of them work electrostatically. For those who are unfamiliar with finings, they are clarifying agents which include: geletin, Irish Moss, Polyclar and Isinglas (sp?). I may have missed a few. Rather than rely on my memory, I'll try to look for my notes on finings at home and then post them after (or during) the holidays.

Subject: Jockey Boxes (re: Dan Graham)

Dan, you mentioned that you would like to keg your brews (to avoid the hassles involved with bottling without being able to see), but don't have a spare fridge. I assume you want the fridge to chill the beer and not lager it.

If that's the case, you can buy or build a "jockey box". This is a large cooler with stainless steel or copper cooling coils/plates in it which you fill with ice. You then hook the output of your keg to the input on the jockey box, and the beer gets cooled as it passes through the coils; there are standard bar taps on the output of the box. This way you only cool the beer by the glass/pitcher. Note this isn't necessarily practical if all you want is one glass, but at a party it can save you a lot of hassle trying to keep kegs cool. I've seen these with one to three tap lines built into the same box. One of the last issues of Zymurgy had an article on how to build one, or you can buy them from a supplier such as Rapids.

In any case, it's cheaper than the pump.

By the way, how do you prevent boil overs?

Enjoy.

Arthur writes:

>When I was shopping for a pot, I found that the stores often had no markings  
>on the pots, indicating that they were steel or aluminum. Had I planned  
>ahead, I would've brought a magnet with me.

Most varieties of Stainless Steel are not ferromagnetic. I simply bought mine from Rapids for ~\$90 (lid is extra), which is not a bargain, but, I know what I'm getting (SS), it's heavy gauge, and it's handles are sturdily attached. Bargains do not always meet all of these three criteria.

Ronan--

The rolling keg idea for agitation is novel, but since you didn't mention otherwise, I will assume you will be measuring the temp of the bath and not the mash. You should really measure the mash temp, which (as far as I can think of offhand) means either mounting a temp probe into the end of the keg (with a swivel connector so your sensor cable doesn't get all twisted up) or abandoning the rolling-keg idea. Maybe you should go with a paddle agitator as is commonly used, although I realize this is what you're trying to avoid. Good luck, and please report on your progress.

From: synchro!chuck@uunet.UU.NET  
Subject: Cool Books

During my latest trip to London, I bought a pile of books at the CAMRA booth at the Old Ale Festival. I wanted to recommend some of them to my fellow homebrewers. All of these are available at a discount to CAMRA members.

Good Beer Guide 1992 A classic, and a must for every beer traveller.

Good Pub Food Visiting some of these pubs has completely changed my opinion of English food.

Beer, Bed & Breakfast You can plan an entire vacation just visiting some of these inns.

The Real Ale Drinker's Almanac Lists the ingredients for nearly all of the

real ales produced in Britain & Ireland.

The Best Pubs in London There is a book for every major ale city and region in Britain.

The London Drinker The monthly newsletter of the London branches, lists festivals & events in the London area.

I also want to put in a plug for CAMRA itself. In the past I have taken issue

with their overzealous and restrictive definition of what is "real" ale. What

I learned on this trip is that CAMRA is as much a social as an advocacy organization. Nearly every interesting beer lover and homebrewer that I met

was a member. I was surprised how quickly these guys were willing to accept

me as a fellow beer lover & expert.

After the obligatory Budweiser jokes, we would get into discussions of mashing

techniques, the influence of British ale on American microbrews, or unusual

hop varieties (including 'special' hops). No CAMRA member ever gave me any

attitude, and all were genuinely interested in the American brewing renaissance. If you ever get a chance to visit Britain, join CAMRA and stock

up on some good books, then go looking for a beer festival or other CAMRA event.

I wish there were similar books and organizations on the continent.

From: Jeff Frane <70670.2067@compuserve.com>  
Subject: Flying--but big--beer glasses

British pub owners are having a hard time of it, apparently. The government has issued orders that beer glasses be large enough to hold a full pint even when a decent head is added. According to a wire-service article in the local paper, a pint of bitter can run as high as \$3.50 in London. They ought to try drinking at some of our local pubs that charge that much and only give you 16 ounces (British pints are 20!).

Then, too, the Daily Telegraph had a filler, titled "Beer glass plea": "Serving beer in shatter-proof glasses, which disintegrate into harmless cubes when broken, would prevent many of the disfiguring injuries suffered in pub brawls, claims an article published today in the British Medical Journal."

Sounds like a fun place to drink.

To Brian Bliss: Malted barley is \*LOADED\* with enzymes. There's no reason in the world why you need to add amylase.

Nick: Do what you can. I've tasted some remarkably fine lagers that were made without refrigerators. 40F isn't bad at all, especially if you can keep the main ferment down around 50.

>Let me tell you a story.... my friend and I thought it would  
be fun to put little army men through the rollers. Well, it \*was\* fun-  
really flattened those guys. However, it also broke the machine;  
somehow the rollers got pulled apart permanently.

I was so impressed by the mod to the pasta machine that I got real  
depressed  
for not thinking of it first. Then I remembered why I didn't try to use  
mine.

Our previous video was on re-cycling paper into all sorts of neat things  
including paper and post cards. Well, guess what we tried to use for  
smoothing out the post cards? And guess what we can't use for making  
pasta  
anymore?

The crank on the Atlas (the most popular model around here) is held into  
the  
roller by nothing more than friction (wishful thinking) and will  
permanently  
slip once this joint is over stressed. I have had mine apart 3 times  
and  
thought I fixed it each time but it never lasted. The only cure I see  
is to  
have it tack welded together and I will probably never get around to  
doing  
it.

Now the question is, can I use my malt mill for a pasta machine?

Subject: Beer as Carry-On Baggage

I've never had any problem carrying beer on the train. I generally carry a case or two when going north to visit folks. I have even exchanged full for empty in mid-trip, with a sister who lives up in Raleigh, hitting the ground for a very brief visit.

If your beer is hyper-active, please line your cases with a plastic trash bag to contain the excitement.

More than two cases will not fit conveniently on the shelf in a roomette.

At least one baggage man is also a home-brewer.

Cases of empties can be packed with clothes for and tightly tied closed. They can then be shipped as baggage; the key phrase is ``passenger states no prohibited articles''. The contents are dirty clothes, if they ask for details. Limit three pieces, so a suitcase means that you can only ship two cases of empties.

From: GC Woods <gcw@garage.att.com>  
Subject: Tucson Brewpubs/Electric Dave

While on a business trip to Tucson, AZ recently I was drinking "Electric Dave's Ale" at the hotel and the bartender said "to enjoy it now because Dave just got busted for selling pot". So now we know what the "Electric" part of the brew really was!!

The two brewpubs in Tucson are Gentle Ben Brewing and San Francisco Bar and Grill Brewpub. Gentle Ben's is located across from the university - the beer was drinkable, but nothing special. The two things I did enjoy was the price (\$2.25/pint) and they had Anchor X-mas on tap (nutmeg and clover are the strongest flavors I noticed). The place was almost empty (tues/weds), but have large crowds/band on weekends. Atmosphere is basic college pub.

The San Francisco Brewpub brewing operation was shutdown while I was there and no one would say why? They did have plenty of other micro and imports (like Guinness) to make up for the loss. There was an extensive menu with normal bar food and also the weird combinations that many brewpubs like to look fancy with. The atmosphere is fancy sports bar with many TV's scattered around. One great thing they do have is 25 cent oysters during happy hour on weekdays, but the cowboys at the bar where a little shocked when I ordered 40 after the first 4 I ate were excellent.

Subject: First mash

Well I finally got around to it, and tried a small (3gal) infusion mash.

I tried to use the picnic cooler to do the mash, but the strike water only got me up to about 148F so I ended up doing it in the kettle in the oven, a la Miller, at ~155.

pH5.2, 5# pale malt. .5# chocolate malt (~62L, pre fudge-factor)

Dumped the mess back into the cooler to sparge, stopped taking the runnings when they started tasting `husky'. (got about 22 points/#/gal)

90 min boil, skimming for the first 30 min, no boilover.  
Hops in a bag for 60 min. More hops in another bag for 15 min.

Immersion chiller, 212F->75F in 8 min, not much obvious cold break.

Oops, starter gone bad, have a homebrew, pour some wort onto the dregs, airlock, and stick in the corner of the heated waterbed.

Pour the wort into 5gal carboy, bung.

Next morning:

Pour the `starter' into the 3gal, rack wort off 1" trub, top up with boiled and cooled water. Shake. Airlock. Cross fingers. Go to work.

Tool notes:

Instead of using a slotted Cu pipe, I took a piece of soft plastic tubing and punched little holes up and down its length with a leather punch. It certainly allowed a good flow for sparging (is there such a thing as too much flow?). It needs a little weight to make sure it stays down near the bottom.

I used the legs from a pair of the SO's pantyhose as hops bags, they seemed to work well, but I had to trim the edges on the plastic stirring spoon to avoid getting runs :^) Not having to deal with the hops really seems to have sped up the chilling operation.

The (inevitable) questions:

What sort of effect did sitting around at 146F-148F for 20 min have?

Should I have pre-heated the cooler? How?

What's a good size cooler for up to 10# of malt?  
(this was the SO's 54 quart cooler, too big.)

Date: Mon, 23 Dec 91 15:41:22 PST  
From: dannet!bruce@uunet.UU.NET (Bruce T. Hill)  
Subject: A Recipe for Homebrew (circa 1930)

Greetings!

My sister-in-law's mother gave this following recipe to me. It dates back to the 1930's. They grew up in a predominantly Polish part of Chicago where it was traditional to make home-made beer for festive occasions (like Christmas!). The recipe is pretty rough by our modern homebrewing standards, but it shows that the homebrewing spirit was alive and well several decades ago.

Reprinted verbatim from a yellowed sheet of paper:

.....  
.....

INGREDIENTS FOR 6 GALLONSEQUIPMENT

- 1 - 3 Lb. can Hop Flavored Malt Syrup
- 1 - 6, 8, 10 or 12 gallon crock
- 3 Lbs. Corn Sugar
- 1 Tester and 1 Filter Float
- 1 - Package Settler
- 6 ft. Siphon Hose
- 1 - Cake Fleischmann's Yeast
- 1 Bottle Filler, 1 Capper, 1 Box of Bottle Caps

METHOD

- 1. Bring one gallon water to boiling point using a pan large enough to hold water, malt syrup and corn sugar. Add malt syrup and stir until mixed. Stir in corn sugar slowly until dissolved. Settler should be mixed in with sugar at this time for best results.
- 2. Place crock on box or chair (not on floor), pour in three gallons of luke warm water, then add hot ingredients. Now add sufficient luke warm water to make 5 and 1/2 gallons of liquid in the 6 gallon crock.
- 3. Dissolve yeast in cup of luke warm water and 1 teaspoon sugar. Allow mixture to stand until yeast starts working, usually within 1/2 hour. Add the working yeast to mixture in crock and stir until mixed throughly.
- 4. Place lid or cloth over crock and allow to set 48 to 72 hours in warm weather and somewhat longer in cold weather, or until it has finished working.
- 5. After 2 or 3 days foam will rise to top of crock. Do not skim this as it is the hops and malt working. If skimmed it will lose some of its flavor.
- 6. It should now be ready to bottle. Siphon into bottles, being careful not to place end of hose near bottom of crock. A Filter Float will prevent this.
- 7. In case the mixture is left in crock too long, add 1/2 teaspoon of sugar to each bottle. Store in warm place. It should be ready to drink within 7 to 10 days, at which time store in a cool place, or refrigerate.

HELPFUL HINTS

-----

1. Wash crock in strong Purex water. Sweeten crock by letting set 1/2 to one hour filled with water and baking soda.
2. Wash bottles clean with soda water but do not use soapy water. Turn bottles upside down to drain, in rack or case.
3. Soak bottle caps in water long enough to soften cork before bottling to make capping easier. Use warm water.
4. Chill before serving. When pouring, slant bottle and glass and pour slowly to prevent clouding.
5. If it is cloudy or tastes gritty, you have disturbed the sediment by shaking it up or by pouring too fast.
6. If it tastes "flat" you either bottled it too late, or did not allow it to age long enough.
7. If it tends to foam up or tastes "airy", you bottled it too soon. The mixture had not completed.
8. Use of tester. Tester is accurate when it is kept at uniform 65 or 70. The tester will settle the first day between 3 and 6. This is the approximate alcohol content. When the tester settles to 1/2% or the red line "B" it is ready to bottle. If the test settles to "W" it means it is too flat. Taste to determine if it has turned sour. If not, then add one teaspoon of sugar to the quart or 1/2 teaspoon to the pint before capping, to restore life to it. In the event it has soured, it is spoiled.

.....  
 .....

Comments: That last sentence sums up the attitude of the author -- "relax, don't worry". Any ideas why it is recommended to "sweeten the crock" with a baking soda solution? The tester (hydrometer) "B" and "W" graduations, what do they mean? Why not put the crock on the floor? What is a Filter Float? Bottle Caps with cork seals -- definitely ancient.

Wishing you all a "Hoppy Holiday",

Bruce Hill

P.S. Keep up the good work Rob! I expect a full report of your recent trip :-)

From: srussell@snoopy.msc.cornell.edu (Stephen Russell)  
Subject: Burst WYeast Packet, revisited

THE BURST WYEAST 2308...REVISITED

For those who were wondering about the WYeast package whose outer seal we inadvertently burst (see HBD #786), the answer is that after 3 1/2 days in the starter, \*nothing\* had happened. Fortunately, one of my fellow members in the Ithaca Brewers' Union (Mike Lelivelt -- utb@cornella.cit.cornell.edu) came to my rescue with a slant he had made up earlier. That particular starter is going gung-ho after 1 1/4 days. Which is good timing, considering that we are brewing a Munich Dunkel today.

There's one advantage about being in a homebrew club!

Thanks to all who offered advice/condolences...Frank Tutzauer, Edson Smith, and especially, Mike. I owe him a beer (and plan to pay up at Goose Island on Sunday night...join us if you're in the Chicago area!)

Why not a recipe? One particular one comes to mind for some reason....:-)

"BURST BUBBLES, NO TROUBLES" MUNICH DUNKEL

6 lbs Klages  
1.5 lbs Vienna  
1 lb light Munich  
1 lb dark Munich  
1.5 lbs dark crystal  
0.2 lbs chocolate malt

Doughed in at 90F and temperature raised to 155F over 60 minutes.  
Saccharification rest 1 hour at 155F.  
Heated to mashout over 10 min and held 5 min. Mashout at 164F.  
OG: 1.059 Expected FG: 1.014-1.016  
Sparge water acidified to pH 6.0 with lactic acid.

1/2 oz Hersbrucker plugs (2.9% alpha) 60 min  
1/2 oz Northern Brewer plugs (7.5%) 60 min  
1 oz Hersbrucker plugs 30 min  
1/2 oz Hersbrucker plugs 15 min  
1/2 oz Tettnanger leaf hops dry hop

1/2 tsp Irish Moss at 30 min

WYeast #2308 Munich Lager

We plan to ferment at 45-50F for 2 weeks  
then remove from refrigerator for 2-3 days for diacetyl rest  
then lager at 35-40F for 2-3 weeks (dry hop here)

Serve lightly chilled (48F) with a selection of sausages, cheese, and black radishes...whoops! wrong forum :-)

IBU ERGO SUM,

STEVE

>should be. Here in Texas (near Dallas), my water pressure is a hell of  
>a lot more than it was in Warrenville, IL, near Chicago.

Right, but there's a little more to consider. If you have a very small  
coolant flow area per wort flow area, keep in mind that the increased  
efficiency will cause the coolant to very quickly rise to the  
temperature of the wort, not vice versa. Therefore, in order to get  
the wort temperature down, you'll really have to be cranking the  
coolant throughput. With my water pressure, it is very unlikely I'd  
be able to achieve the desired degree of cooling unless the wort flow  
rate was throttled down quite a bit too. Put another way, if you're  
planning on a specific coolant area per unit area of wort flow, there  
is an optimal length of tubing to use, beyond which no additional  
temperature drop will be gained. Make sure that with your chosen  
flow "areas" that the length of tubing along with water flow rates  
approximately makes sense to get the degree of cooling you want.  
Also, keep in mind that regardless of what degree of turbulence you  
have in the coolant side, most homebrewers will not have turbulent  
flow in their wort, making this the limiting transfer rate. For  
example, if I use 1" vs 3/8" tubing for the wort, and the flow is  
laminar, it will take a lot "longer" for the heat to leave the center  
streamlines in the larger diameter case, requiring a longer tube.

From: Brew Free or Die! 24-Dec-1991 0935 <hall@buffa.enet.dec.com>  
Subject: Re: A Recipe for Homebrew (circa 1930)

In HBD #788, Bruce Hill favored us with a home brew recipe from the 1930s.  
He stated that it was traditional to make home-made beer for festive occasions.  
Methinks that in the early thirties, tomorrow would have been considered occasion enough. 8^)

I think I can help with some of your questions, Bruce. I too was given some old beer recipes, with a bit more explanations given.

>Comments: That last sentence sums up the attitude of the author -- "relax, >don't worry". Any ideas why it is recommended to "sweeten the crock" with >a baking soda solution? The tester (hydrometer) "B" and "W" graduations, >what do they mean? Why not put the crock on the floor? >What is a Filter Float? Bottle Caps with cork seals -- definitely ancient.

I think the point of the baking soda to 'sweeten the crock' is simply to remove any off smells that may have developed in an unused crock. Being somewhat porous, if the crock wasn't previously cleaned well, or simply sat unused, it may have gotten a kind of punky smell. The universal cure for this seems to be old Arm and Hammer, you know, a box in the refrigerator and all that.

The "B" graduation on the tester means bottle, as in "time to". Back in the daring and adventurous 'old days', Grandpa didn't ferment beer out completely and then add a measured amount of priming sugar. He let the beer ferment until there was just the right amount of fermentation left, that is, the tester said 'bottle' and he bottled and he \*liked\* it. None of this fancy schmancy Balling or Plato or S.G. or fiddledeedee.

The "W"? You got me. "Wasted". "Whoops". "Where've You Been?"

The crock not on the floor? Need some elevation, to facilitate siphoning later.

My old homebrew directions describe something that has got to be your Filter Float. Take a board and cut out a circle slightly narrower than the opening of the crock. Drill a hole in the middle large enough to fit a siphon hose into. Pound four nails into the board near the outside edge, equally spaced

around the circumference, such that the points of the nails extend about an inch and a half beyond the bottom. Place the siphon hose into the hole in the center, with the hose extending slightly beyond the bottom of the board, and float this device on top of the beer. It will allow siphoning of the beer near the top, away from the sludge at the bottom, and the nails will prevent the board from 'bottoming out' and picking up the sludge. Voila!

Happy Holidays fellow brewers, and good brewing in '92!

Subject: Re: A Recipe for Homebrew (circa 1930)

Sounds like a nice light brew. Did Fleischmann make a brewers yeast or was it their off-the-shelf bakers yeast.

The baking soda is used to neutralize the acidity of the Purex, which I think was and still is a chlorine bleach. Rinsing with the baking soda should sweeten any residual sourness left by sterilizing with bleach.

> 4) a distant relative of Charlie Papazian ;-)  
>  
>Does anyone have a better/truer story? Who was this guy?!?

Having just returned recently from that lovely little brewing town, Plzen  
in Czechoslovakia I can tell you a little more about Gambrinus.  
There is a brewery named Gambrinus in Plzen. Seems he was a king.  
He was one of the kings of Bohemia, the western (non-slovak) half of  
Czechoslovakia. This region has always been pretty closely tied to  
Bavaria  
in it's brewing traditions. I don't know a lot of specifics about the  
king,  
but him and King Wencislaus (sp??) also of Bohemia, were big favrotes  
among  
the brewers in the area. I believe one of them was responsible for the  
laws  
that made it a crime punishable by death to export rhizomes (hop  
rootings)  
of the fabled Saaz (named for the Tzatek region of Bohemia, just north of  
Plzen) hops.

good King JaH :-)

From: Jay Hersh <herhsh@expo.lcs.mit.edu>  
Subject: Al vs SS testing

One of the more ingenious testing means I saw exploited the density difference in these two metals. I think you'll need a CRC handbook to find the densities, but if you want to make sure the pot you have is indeed SS you can submerge it in water, check the displacement (probably best to use metric). Then weigh it, and divide the weight by the volume to get the density.

If I recall the old discussion, the densities of Al and SS are significantly different that it should be pretty apparent if you've got the wrong one. Keep you're receipts :-). ....

Subject: Irish Moss & Head Retention

Hmmm I have been using Irish Moss for years with no resulting loss in head retention. I also use a yeast nutrient. The yeast nutrient is made from dead yeast which is dried and ground up. This works under the theory that the best (most complete) source of trace nutrients the yeast need to maintain proper cell growth and maintenance is already in other yeast..

While some may claim this is an evil alien additive, I think since it is just

from yeast to begin with it's OK. This may counteract any negative effects

from Irish Moss, though I have been using Irish Moss longer than I've used

the yeast nutrient, and don't recall any negative effects way back then.

Subject: Jockey Boxes (re: Dan Graham)

>I assume you want the fridge to chill the beer and not lager it.

>If that's the case, you can buy or build a "jockey box". This is a large cooler with stainless steel or copper cooling coils/plates in it which you fill with ice.

There is a much simpler device available. Come to think of it, it might be what's in the jockey box. It's a flat aluminum plate about 8x12x1 with a serpentine path inside and in/out hose fittings. You put it in a dishpan full of ice and hook the beer to it. It is incredibly efficient. When you tap a beer, the ice looks like it is running down a drain. It is even convenient for a couple of glasses. One tray of cubes will chill several.

BTW, it also makes a great wort chiller but like everything else made of aluminum, I consigned mine to the recycle bin. But for those who don't mind losing a few brain cells, I highly recommend it.

BTW... btw, in case it isn't obvious, wort chillers make great beer coolers but because of their capacity, only useful for parties.

.....SPARGE WATER MOMILY.....

The experts all agree that the temperature of sparge water should be around 170 degs F for maximal extraction. I think, however, that we have a problem extrapolating a commercial process to home brewing and if a homebrewer uses water at 170F, he will not achieve the same results.

First of all, most commercial brewers sparge with a shower-like sprayer that impinges directly on the malt. In the typical homebrew setup, we are dribbling the water on a layer of water (1" typically) above the mash. This is done to avoid disturbing the filter bed with a stream of water. I take this one step further and place a small bowl in the mash to receive the water and distribute it evenly.

We are, in effect, dribbling water into a three gallon bucket of water and the temperature profile thus created is far from what is desired for efficient sparging if we start with water at 170F.

On my last batch, I sparged with boiling water (as usual) but this time, I took careful temperature measurements and here are the results.

|                          |     |
|--------------------------|-----|
| Sparge water:            | 210 |
| Center of bowl:          | 155 |
| Surface, midway to edge: | 140 |
| Surface at edge:         | 139 |
| Edge, 2" below surface:  | 135 |
| Wort outflow:            | 135 |

The level is maintained to assure that the bowl top is below the water surface. The edge is the edge of the mash kettle.

Nowhere does the water temp even approach the desired 170F. Clearly, using boiling water to sparge in this fashion is not only NOT going to cause any problems but it is NOT even hot enough, if 170F is what is desired.

Solving this problem presents a real challenge to the homebrewer. In my case, I have 7 gallons of water boiling that is gravity fed to the mash tun and it is a terribly convenient way of sparging. The thought of coming up with enough pressure (at the "proper" temp) to drive a spray, gives me a headache.

The good news is that the beer tastes great anyway and perhaps the only effect is using a little more malt per gallon to compensate for the less than ideal efficiency.

Subject: pitching starters

I've been using Wyeast for the last 6 or 7 batches, and I've regularly made a starter. Now that I've used liquid yeast for a while, I've got some questions about pitching starters (not to be confused with starting pitchers-- that's another sport altogether!). My questions are these. Assuming you can perfectly time your starter to coincide with your brewing: (a) When should you pitch (i.e., when in terms of how far along the starter is)? and (b) What should you pitch? Let's consider "when" first. My references on this are mixed. Paul Farnsworth, in the yeast special image of zymurgy, says you should pitch after the starter has become "opaque" and before the yeast "begins to settle out" (p. 35). The Wyeast package says to pitch after about 12 hours, at high kraeusen. Finally, Miller (p. 94) says to let the starter ferment completely out, pitching the slurry on the bottom. I have tried all three methods, but so many other variables were also changing that I'm not sure which is best. From a practical standpoint, I end up more toward the Miller side, but for no reason other than I want to give the yeastie boys plenty of time and have tended to err on the side of too much time. So, what is YOUR experience?

Second question: What should you pitch? It seems to me that there are two options: pitching the entire starter, and decanting and pitching only the slurry. Miller decants and pitches slurry, since he lets his starter ferment completely out. Farnsworth doesn't say what he does, but I assume he pitches the entire starter since there is no slurry. Wyeast makes no recommendation (at least not on their package). I don't buy arguments about the starter altering the flavor of your beer. Afterall, it's only 2-4 cups of plain-vanilla wort. I don't see how it could alter the flavor much more than adding 2-4 cups of water. On the other hand, it seems to me that there are millions of yeasties still in suspension, so I figure why not put them into the wort too. Again, I've done it both ways and don't know which is better. What do YOU think?

Now, if Nolan Ryan and Roger Clemens used liquid yeast, you would get starting pitchers pitching starters!

From: "DRCV06::GRAHAM" <graham@drcv06.decnnet@drcvax.af.mil>  
Subject: Beer Hunter / pitching starters.

Second thing first: I, also, have tried several different methods of pitching as to when and what to pitch. I've seen, rather, tasted, no detectable difference. I suppose this issue will be religious with some, but I think it really doesn't make much difference. I usually can't brew exactly when I wanted to, so the starter more often than not ferments out.

Always seems to work just fine. Actually, I now usually do the yeast caking thing a la Fr. Barleywine.

Beer Hunter:

Wow! I am so underwhelmed I cannot believe it! I didn't see this series the first time it was on Discovery, so I tuned in Monday evening with great anticipation. What a pile of spent grain! Talk about bad signal to noise ratios, I think it was 100:1. Now, realize that I'm blind, so I'm reviewing this from a "talking" perspective, only. There was so little actual information that I thought I was watching [listening to] Wings.

Tuesday's episode on British brewing was a total disaster to me. Sure, the real ale information was interesting, but so much about British brewing was not even mentioned. I thought that most of the half hour was completely wasted. Oh well, I'll stick to Jackson's books, they are far, far better.

From: Jeff Frane <70670.2067@compuserve.com>  
Subject: Hi! Krausen

Frank Tutzauer asks about pitching yeast:

Herewith the "Official" Wyeast stance on when to pitch! Fresh from the as-yet-not-quite-written pages of The Yeast Book. This also happens to coincide with my anecdotal evidence. You will get much more vigorous and rapid fermentation if you pitch at "high krausen", which is as Paul Farnsworth apparently described it in Zymurgy: "opaque". Sometime around 18 hours (give or take a few) after the last pitching, the yeast will be in their most useful phase. Think of it as your own biorhythm. Personally, I'm at my peak at about 9 a.m., and am the most willing then to begin projects, think, write, etc. At about 3 p.m., on the other hand, all I want to do is take a nap. Yeast cells are just like me, vigorous at some times and lazy as hell at others. The idea is to catch them at their figurative 9 a.m.

I used to use the Dave Miller approach, assuming I was increasing my pitching volume, until Dave Logsdon cautioned me about pitching at high krausen. I listen to people once in a while, and tried it several days later. The difference in lag time was astonishing, and I strongly recommend it.

In reference to Frank's second question: actually, even when the yeast is at high krausen there is a slurry. At least, that's been my personal experience. I bung in the entire thing, starter wort and all. I'm with Frank: there's no way that wort is going to affect the flavor the beer negatively, and there's no way I'm going to waste those little yeasties!

-----

Date: Thu, 26 Dec 91 14:19:14 EST  
From: Jay Hersh <hersh@expo.lcs.mit.edu>  
Subject: pitching starters

My approach is to try to pitch the yeast while still actively fermenting, either at high krausen, or just past. Of course this means I pitch the whole starter, not just the slurry. My thinking behind this is as follows. Since the starter was aerated, when the yeast in it is at high krausen, or just past, then it has finished consuming the dissolved oxygen and therefore is no longer reproducing. This means that the yeast population is at it's maximum (in the starter) and that the yeast are actively fermenting. Tossing this into the wort means that it will hit the wort in a ferment phase, so it will initially start to ferment the wort, thus laying down a blanket of CO2 over the wort. Upon discovering dissolved oxygen in the wort it will go back into a reproduction phase and reproduce until the supply of dissolved oxygen is used up, then they will switch back over to fermentation again.

I think (and seem to observe) that this has a few benefits. I seem to get CO2 activity from the airlock right away in the fermenter, indicating that the yeast are indeed laying down a CO2 blanket over the beer. I have very short times to high krausen (and associated blowoff) in the fermenter, usually less than 24 hours, often as little as 2-6 dependent upon yeast strain and pitching rate.

I have sometimes pitched the starter before high krausen. The only difference I note here is that the time to krausen in the fermenter is usually longer. I assume this is because there was fewer yeast cells in the starter since it hadn't reached it's reproduction peak yet.

So in summary I always pitch when active unless something happens to prevent my brewing at the planned time (pitching the slurry if it's not too long since vigorous fermentation ceased still works well), and I have always had good results. I don't think the timing of when to pitch is that incredibly critical, I think the critical factor is adding a large supply of healthy active yeast.

From: hpfcmr.fc.hp.com!hplabs!uunet!bnr-vpa!bnr-rsc!crick (Bill Crick)  
Subject: Bottle fillers, grain mills

Bottle fillers: I found them way too slow. They doubled bottling time. We just use a siphon, and a pinch clamp. After a few thousand bottles, you get real good a clamping suddenly just when the beer starts to race up the bottle neck. At least my wife has She has run the siphon on the bottling line for the last few thousand. She has also learned to transfer the tube from one bottle to the next without breaking the liquid in the tube, so she moves a full tube from one bottle to the next. Less air in the beer.

Grain mills: I think the commercial mills use three sets of rollers to minimize production of fine grist. The first rollers are spaced rather far apart, and anything small enough after the first set, is screened out, and hence isn't recrushed. Only the stuff above spec goes to the second rollers which are closer together. Ditto for the third rollers.  
I also think they screen the real fine stuff out and don't use it for mashing?

Date: Thu, 26 Dec 91 16:29:53 PST  
From: "Tom Childers" <TCHILD@us.oracle.com>  
Subject: Precise Bottling/Automated Bottle Fillers

(Let's see if I can get this post out THIS time])  
In HBD 787, Dan Graham asks about an automatic bottle-filling device.  
What a great opportunity for some creative design/engineering work] Here  
are  
some thoughts.

One approach would be to add some kind of sensor near the top of a  
bottling  
wand, right at the height that you want the beer level to reach in the  
bottle.  
The sensor would need to fit inside the mouth of the bottle, and have an  
adjustable height to work in a variety of bottle types. The sensor would  
either shut a valve in the wand, or turn off a pump that transfers the  
beer  
from the priming container to the wand.

You might be able to construct a wand with an automatic cut-off valve.  
A small cylindrical float around the wand, connected to a valve in the  
upper  
part of the wand, should do the trick. Of course, the float height would  
have to be adjustable, to accomodate different sized bottles.  
Unfortunately,  
the float could stick while transferring some of the "meatier" brews,  
like  
the 1.148 leviathan mentioned a few issues ago...

The second solution requires a friend with some electrical engineering  
background. Build a bottling wand driven by a small electric pump, then  
add  
two copper contacts to the wand at the desired fluid level. Connect  
these  
two contacts to a transistor/IC circuit that will switch off the pump  
when  
fluid comes in contact with the two pieces of copper. Circuits to sense  
a  
fluid contact are not hard to design, and are based on the principle that  
water-based solutions (like beer) are slightly conductive to electricity.  
The  
circuit would need to switch off the pump when the beer rises to the  
right  
level and causes a small electric current flow between the copper  
contacts.

I'm pretty sure that there are circuit diagrams for this kind of thing in  
at  
least one of the electrical hobbyist books available from Howard W. Sams  
Publications. Radio Shack may have even had a kit for building one about  
20 years ago. And someone with more electrical engineering background  
than  
I have should be able to design one without too much trouble. You ought  
to  
be able to build an "automatic electric bottling wand" for under \$100.

From: tomm@pet.med.ge.com (Thomas Manteufel 5-4257)  
Subject: query: Oxidation and Crystal Malt

Here's a question for the experts: We all know that pouring hot wort through an atmosphere containing oxygen (like ours does) produces oxidation and off-flavors due to chemical interaction with oils from the hops. How much interaction is there with sugars and other flavors from the grains? Like many other beginning-to-intermediate brewers, I steep my crystal malt at 170F for half an hour, and then pour this through a strainer into the brew kettle. The last batch I made had a lot of crystal (1.5 #) but the taste was not what I would call "sweet". It tastes very "grainy". Did pouring the hot steep water oxidize it? If so, not having a lauter tun (yet), what is the best way to transfer this to the brew kettle sans grains? Should I invest in a grain bag (and would it hold cracked crystal)?

Thank You for any useful information,

Thomas Manteufel IOFB

>water at 170F, he will not achieve the same results.  
>  
>First of all, most commercial brewers sparge with a shower-like sprayer  
>that  
>impinges directly on the malt.

I've wondered about this. Intuatively, I figured that a shower-like  
sprayer  
would be the best way to evenly distribute the sparge water and minimize  
the  
disruption of the grain bed, and planned to include such a device in a  
lauter  
tun I've been planning to build. However, wouldn't spraying the sparge  
water  
oxygenate it? Wouldn't the resulting oxygenated water create oxygenated  
wort, which at temperatures above 80F, would quickly produce oxidized  
wort?

Now... what do all of you think about this?

Subject: Beer Hunter

Dan Graham writes that he thought the Beer Hunter was a bad show and a waste of time. Granted, some of the episodes were better than others and, in terms of brewing information, I would place the British episode in fourth or fifth place out of the six. I even pulled out my Beer Hunter

Videos (obviously, I was inspired enough to buy them from the Discovery Channel)

an re-viewed the British episode. You're right Dan, there's not a lot of information for us brewers, but I don't think that these videos were targeted towards people of our level of beer knowledge. On the other hand,

I love British and Belgian beers \*passionately\* and I could watch the Beer Hunter Videos once a month forever -- never growing tired of them.

I think they are worth every penny I paid for them and also used my

purchase

of the videos as my vote that the Discovery Channel should create more episodes.

From: shenton@cpstnd3.alliant.com (Chris Shenton)  
Subject: Fermentation times versus vessel size

I've done a few wheat beers semi-recently and noticed something odd in the last 2-3 batches. I did 10 gallon batches, then split into two carboys, one a 5-gallon, the other a 7-gallon. The larger one -- which was not filled all the way to the top -- finished in a week or so as usual. The smaller, filled all the way up to the neck, is on it's third week.

Both were pitched from the same 750ml starter, and they both look and smell fine. The fermentation still looks fine: lots of fine bubbles at the neck, yeast sediment on the bottom...

The first time I noticed this, I suspected inadequate rinsing of the bleach, so this time, I was extra thorough. Both times, the large carboy finished well before the small one.

Any ideas? Thanks.

From: psrc@sewer.att.com (Paul S R Chisholm)  
Subject: summary of bottle filling discussions

Well, I'm glad my posting started a lot of discussion! Here's a summary of the follow-up articles in rec.crafts.brewing. Similar (partially identical!) discussion appeared in the Homebrew Digest. HBD also had some positive and negative reviews of Phil's Philler. This has a hole at the top and a hole at the bottom, so you can withdraw the wand without taking out the beer and increasing the headspace.

Some people Worry (for shame!-) that a bottle filler causes more oxidation (because of spraying through the smaller opening, rather than through the whole opening at the end of the siphon tube, I guess). The solution is to tilt the bottle at the beginning, and stick the end of the bottling wand into the bottom "corner" of the bottle. The wand's end is soon covered with beer, and no amount of spraying will cause any extra air to be mixed in with the beer. Also, if the end of the wand (or siphon tube, or whatever) isn't much lower than the end of the siphon tube in the priming carboy (or whatever), the beer will be siphoned slowly, at low pressure, reducing spraying. (This works for any bottle filling procedure.)

Another problem is the bottle filler has beer in it. When you lift the filler from the bottle, that beer doesn't go into the bottle, and the headspace is greatly increased. Even if you fill the bottle almost full, the resulting headspace is larger than some people consider optimal. You can fill the bottle, move the filler to the top of the bottle, and press the tip of the filler to drizzle enough beer down the side of the bottle to reduce the head space.

There are two kinds of fillers. One kind has a spring. The other has a stopper that's held down by the weight of the beer. The latter is slower. Does that mean oxidation is less of a problem? I expect it's easier to finish filling (using the side-of-the-bottle trick) with a springless filler.

My take on all this is that there are ways to use a bottle filler to reduce problems (and reduce Worry). I didn't find enough evidence of problems to bottle my beer without a bottle filler.

Here are some of the articles. (I generally quote the first person who raises a particular point.)

From: kswanson@casbah.acns.nwu.edu (Kurt Swanson)

> Bottle fillers are guilty of 2 things, that the bent tube technique is not:

> Keep you're receipts :-). ....

As I recall, the density difference is about a factor of 3. Don't  
bother trying to measure by displacement because it will be difficult  
to get an accurate measure in a vessel with such a large diameter.  
Just estimate the thickness of the metal used (use one of those  
devices that clamps around whatever you're trying to measure...even  
a suitably modified compass will work). Then you know the diameter of  
the pot as well as the height, account for the bottom as well and  
calculate the volume of material. Weigh it and you then have the  
density. Compare the weight with what a similar amount of aluminum  
would weigh, and if your pot is more than twice that weight, you can  
be pretty sure it isn't aluminum.

Re: Information Wanted

Hi All!

I just bought a used roto-keg for \$10. This thing has absolutely the worst CO2 system ever invented. They actually expect an "O" ring to hold in the pressure of a "powerlet". Needless to say, it doesn't.

I have a couple of questions to put to the group.

- 1) Is there an "improved" powerlet system for this keg?
- 2) Is there a standard gas fitting which is designed to go into the hole for the powerlet system?

Thanks in advance!

From: arf@ddswl.mcs.com (Jack Schmidling)  
Subject: Beer Hunter

To: Homebrew Digest  
Fm: Jack Schmidling

Now that the "Beer Hunter" series has spent itself on Discovery, it seems a critical review is in order.

The most serious criticism is that there is simply too much fluff, what we call "waterfalls", coming back to the same scene, over and over to fill in for voice-over.

The brewery stuff goes by in a flash but we get singing and dancing ad nausiam. The bus trip to the barley field was a classic in killing time to fill out the segment.

He seems a little uncomfortable as an actor. I have the same problem and am sensitized to it in others.

I really got tired of watching him DRINK beer.

I am NOT saying that it isn't worth watching, uninteresting or shlocko; it's just not what I, as a homebrewer, had hoped for or as a producer/director expected from someone so highly touted. Like so many other series, this one could have been improved greatly by editing down to a one hour show.

Finally, I find it amazing that one would pay for advertising of a video tape that was being screened in the same time slot. Why would anyone buy it as opposed to just taping it? I suspect a deal was cut for rights to screen it at no cost, in return for free ad, with Discovery getting a piece of the tape sales, if any.

From: larryba@microsoft.com  
Subject: Superior Products

A couple of weeks ago someone mentioned Superior Products as having a clearance on Volrath pots. I called them up and got a copy of the flyer and noticed some other bargains in there that might be of interest to the HBD crowd. On page 45 there is a two tap beer draught arm for \$79. Two new faucets alone cost more than this unit. The two faucets are mounted in a SS arm that stands about 10-12 inches high.

Also on page 45 is a pressure regulator. It states it is a nitrogen regulator with two gauges, but then they mentioned it being used for beer. Sounds like a CO2 regulator to me. \$23.50

Last item, also on pg 45 is a Beer Brute: a plastic barrel with Beer draught tap (on top) and hardware to hold your CO2 bottle. It is designed for holding a pony keg and ice for a party. Looks like a bargain at \$75.

If you have money to burn they have lots of other cool goodies in the flyer: large industrial refers (great for lagering/fermenting), industrial strength stock pot burners (\$\$\$), SS shelving, sinks, etc. Dial thermometers (\$4.90), Beer Tapster (like beer brute, but industrial with a built in refer - \$700) Great theater pop corn maker (\$375).

Anyway, the flyer was pretty cool: 1-800-328-9800, it is fun to thumb through it and dream of great parties and breweries.

With regard to temperature, Jack indicated that the largest heat losses were from the transfer from the pot to the bowl on top of his grain bed. When planning such a device for the home, keep in mind that a fine spray has a much larger surface area per volume of water than does a straight pour of water. This allows very rapid heat loss when the temperature difference of the water and the air is great. On an industrial scale, I suspect that the air temperature around the spray is much higher than that of the home (due to the volume of the spray) and such problems are not as important as at home. At any rate, fill a plant mister with boiling water and spray it at your face sometime to convince yourself that the finer the spray, the more cooling will take place between outlet and destination.

From: zentner@ecn.purdue.edu (Michael Zentner)  
Subject: In defense of the Beer Hunter...

Lots of people write that the series was lacking practical information for homebrewers. Well, I don't think the series was ever aimed at brewers. I'm sure Discovery wouldn't even air a brewing series because of lack of audience.

I personally thought it was great. To me, brewing is a lot more than conversion sparging, etc... I enjoy the product as well. I like to see how other people enjoy their beer. I think the little historical ditties are great information....for fun, not how-to knowledge. I love the bit about cooking with beer. It's great to learn the customs associated with the beverage, both old and new (that Anchor trip, for example). I realize some of you are mainly concerned with the science of the process, but for others of us, that's only 50%.

From: mm@lectroid.sw.stratus.com (Michael Mahler)  
Subject: Oxidation of wort

Just curious. I started my second batch of brew, this time an Octoberfest kit.

In Papazzian's New Joys of Homebrewing, he says that you should oxinate the bijeebers outa the wort so the yeast has plenty of oxidation to munch on and here y'all are saying that this is really bad.

What I did was use a sterilized racking tube and mixed up the wort really well, whipping up the surface a bit (not too much). It was at about 80 degrees. I also used the rack to add the cold water to the primary fermenter which already had the wort poured into it.

I did this with my first batch as well, and it tastes pretty damn good!

So what's the poop?

-----

Date: Mon, 30 Dec 1991 11:13:35 EST  
From: RWINTERS@LEDA.HQ.NASA.GOV (Rob Winters)  
Subject: beginner's questions

I've made a couple of kits thus far. Since they behaved very differently, I'd thought I'd solicit some opinions as to why.

The first kit was a fairly simple TrueBrew porter kit. It fermented wildly for about 48 hours, and fermentation had stopped completely within about 4-5 days. I bottled it after a week. It came out pretty well, and was deemed fairly drinkable by the masses.

The second kit was a TrueBrew "Maestro Series" India Pale Ale kit. It included such components as crystal malt, boiling hops and dry hops, and oak chips for the ferment. The sg of the wort was supposed to get to 1.054-1.056, but mine only made it to 1.049. I didn't have anything handy with which to adjust it upwards. It seemed to ferment well, and the fermentation gradually slowed until it was very slow after about 8 days. However, it never seemed to stop. The airlock bubbling interval slowed from every second (day 1) to every 45 seconds or so (day 6), and never got any slower. I finally gave up and bottled it after 13 days, even though the airlock was still ticking over like a darkroom timer every 45 seconds.

The sg was still up at 1.017, even though the kit said it would be down to 1.012 after seven to ten days. It seemed to have leveled out at that mark.

After a week in the bottle, I haven't had any explosions, but I'm wondering if I've got 2 cases of Canada Dry(tm) India Pale Ale on my hands. I'm going to chill one and find out, but on to the questions:

Why d'yer think my wort didn't make it to the sg that the kit predicted? Too low a temp or not enough time processing the crystal malt, perhaps? Do these kits (or specific ingredients) have a shelf life that I should be concerned with?

Why did this batch not seem to want to ferment out? Temperature? The air temp was 72degF, if my heat pump is working. Not enough oxygen at the start?

Should I have ignored the kit instructions and waited for zero acitivity?

Why did my ending sg come out above the kit's prediction? Will too high a temp processing the crystal malt result in unfermentable sugars? Was it just plain not done yet?

I also have questions about storage and shelf life. How should homebrew be stored? Is the basement floor good enough, or should it be refrigerated? I still have porter that has been basement floored for about a year. Is it good, or is it time to wash the bottles for another batch? I didn't see any mention of these issues in Papazian's book or the kits' directions.

There seems to be some debate going on about head space at the moment. I realize that excessive head space will mean excessive oxygen

which will tend to spoil the brew. Won't insufficient head space result in broken bottles, because there's nothing to compress as the beer primes?

Thanks for any help!

strainer  
>into the brew kettle.

One of the things that happens during boiling is that it drives off  
dissolved  
oxygen. I don't think that you will get oxidation reactions to a  
significant  
degree from pouring a partial mash through a strainer. Also since this is  
only  
a portion of the wort any effect will be diluted.

I'd relax on this one,

JaH

From: eisen@kopf.HQ.Ileaf.COM (Carl West)  
Subject: Scum Skimming

The best tool I've found for skimming during the boil is a conventional strainer. Slotted spoons have too much impervious surface area so that the liquid flowing off carries the scum away as well.

Someday I'll get around to making a skimming `paddle' out of some screening (of nylon or some appropriate metal) that fits the curve of my kettle.

I saw your original posting and found it quite humorous. I felt  
pretty  
sure that the lady in question was your wife. I wish her well in her  
business  
endeavor. Will she do mailorders at all? If so, I will write/phone for  
a  
catalog. It seems to me that the humor level in the Digest has fallen  
quite  
a bit in the past several weeks (months?). Perhaps it's just holiday  
stress  
and/or not enough homebrew. I offer this humble suggestion; If you take  
offense  
to something written in the Digest, take several homebrews and then re-  
read it.  
The humor might just emerge. Anyway, Hoppy New Beer!

Date: Mon, 30 Dec 91 14:56:27 EST

From: randy@rdr.com

Subject: Some questions about mashing from a first-time masher

I'm what I would consider an intermediate brewer (about 10-12 batches of mostly-extract brews, a few of which have been quite good). I'm setting up to attempt my first full-mash brew in a week or so, and I've found a lot of conflicting information in my sources. Maybe someone here can help me out.

The two books I'm referring to are Papizan's "Complete Joy of Homebrewing" and Dave Line's "Brewing Beers Like the Ones You Buy". A few questions:

1) In Line's book, his procedure for a step mash suggests doing the "protein rest" or first stage at 55C (131F), but Papaizan suggests 50C (122F). Who's right? Does it really matter?

2) The recipe I'm using from Line's book (for a light pilsner, a Heinekin clone), he calls for 5.5 lbs of "lager malt". What kind of malt is this? 2-row or 6-row? Unmodified, modified, or highly modified?

3) In Papaizan's book, he says that 2-row barley has a LOWER enzyme content than 6-row. But in my catalogue for the Home Brewery, they tell me that 2-row barley has HIGHER enzyme content than 6-row. Line's book didn't mention it. What's the deal?

4) In the same recipe in Line's book, he calls for 14oz. of "flaked rice". My local home brew shop has rice extract solids. How much of this extract would correspond to 14oz of flaked rice? (I understand that the rice solids go into the boil while the flaked rice goes into the mash). How about using regular white rice or rice grits?

5) For the second stage of the mash (the actual starch conversion), I've heard of times anywhere from 15 minutes to 1.5 hours. I understand that this can change depending on what kind of beer you make and what temperature you mash at, but what's a good rule of thumb? What's the usefulness of using tincture of iodine to test for starch conversion?

I'm really not trying to be anal about this (there's that word again), but there's a lot of information to process and I never seem to hear the same story twice.

Please send me information by e-mail to this address (randy%rdr.com@uu.psi.com) or if that doesn't work try randy@id.com.

Thanks!

Randy
