A mashed wort takes about 1 day to prepare, as against 1 hour for extract. From then on there is no difference. You do not spend 1 day solid, there are several periods of an hour or two when the brew takes care of itself.

> - How much more water do we use? Do we have to condition the water?

About 1/4 to 1/3 more. Yes, always condition, even for extract beers if you want to get the best out of them.

> - How about \$\$ investment in equipment (minimum required) ?

Assuming you already have a fermenter, hydrometer, syphon and either bottles or barrel, without which you cannot even brew extract beers, you will also need IMHO (please adjust UK # to US \$):

Absolute minimum:

- Mash tun & boiler. In the UK a combined unit is available for #38. You can spend twice or more for separate units.
- Thermometer, another #1-2.

Pretty indispensable:

Water treatment salts, pH papers, stirrer, sparge/hop bag. These will set you back #5-10 more.

Luxuries:

Cooler (luxury in the UK anyway :-)), sparge water heater.

> - Is the final per bottle cost less, or more?  
>

It works out around the same. For 35 pints the malt will cost about #3.50, hops #1.00, other bits and bobs are negligible but the electricity isn't, add another #1.0 for this, and we have #5.50. Extract kits cost #5-7.

There is no doubt in my mind that it is worth it, as the results are wonderful :-)))))). Extract is OK :-| but not great.

From: "Dr. John" <JELJ@CORNELLA.cit.cornell.edu>  
Subject: Less taste, etc.

Greetings all,

A few issues back there was a brief discussion about Miller (the alleged beer, not the author) and how they get away with the clear bottles. Perhaps the fact that they are so stingy with the hops allows them to avoid the problems usually associated with clear bottles :-).

In today's (#658) digest Mark W. Castleman asks about the August "Schnell" brewery in New Ulm, MN. This is a new one to me, the only brewery there that I know of is August Schell. I assume that you could simply pick up the phone and call information to get the number and then call the brewery to inquire as to their schedule for tours. Jackson, in the "Pocket Guide to Beer" says that this may be the prettiest location of any having a brewery in the U.S. And, they make good beer, especially their pilsner (one of the best interpretations of the continental pilsner style brewed in the U.S., imho).

Lastly, if dextrans don't add to the perceived body of a beer, then does anyone have an explanation for why relatively low temperatures for the starch conversion rest (i.e. something like a range of 145 to 149 degrees F) produce such thin beers? Miller (the author not the alleged beer) claims in TCHOHB that the peptidases (the enzymes that break down small proteins, which are the ones we want?) are most active in the range of 113 to 122 degrees F, so it seems that they would be relatively inactive in the 140's and probably aren't the explanation. So, what's the story?

Ein prosit,

Dr. John

From: David J. Sylvester <sylveste@wsfasb.crd.ge.com>  
Subject: Fast ferment

Hi,

I have never tried posting here before and don't even know if this will get through. If it does I would greatly appreciate an e-mail response as time is a factor here. Here's my story:

I made a 5-gallon batch of wheat beer 5 days ago using 2 1/2 lbs of lighth DME, 1 cup of wheat malt, 4 cups of corn sugar and some hops. I cracked the malt and boiled in 1 1/2 gal of water, strained out the malt, added the sugars and about 2/3 of an ounce of hops. Boiled for 10 minutes adding the rest of the hops in the last minute. For no other reason than curiosity, I started the yeast (red Star ale) in a bottle with 1 cup warm water and 2 tsp. corn sugar. The yeast was working like mad after a few minutes.

Here's where I made my first mistake. I poured the wort into the fermenter, which had 3 1/2 gal cold water, and added the yeast. The wort temperature was 40 deg cels (105 deg fahr). I sealed the fermenter, got some bubbling for a few minutes, and the fermenting stopped dead!

I figured that temperature was the problem, so I placed the fermenter in a refrigerator. About 4 hours later fermentation had resumed and was vigorous for about two days. It stopped bubbling by Tuesday. Ready to bottle, I opened the fermenter and saw bubbles rising from the beer. I decided to error on the side of caution so I siphoned to a secondary and resealed. No bubbles. (I repeat, no bubbles, that is).

I thought that perhaps the fermenter was not sealed well, so I replaced the air lock with a better one. No bubbles. Now I (may have) made my second mistake. I added more yeast (same brand - Red Star). After 12 hours (it is now Thursday morning) no bubbles.

My concern is with too much yeast affecting the taste. Should I siphon into another fermenter to remove the yeast at the bottom, leave it alone? I plan on letting it sit for another week before bottling anyway.

I also realize I should be testing SG. I would appreciate any insights. Hate to lose 5-gallons for any reason. Thanx in advance.

Dave Sylvester.

I haven't been fooling around with fruit in beer; however, I do make a mead ale based on the recipe in Dave Miller's book to which I like adding fruit. The first time I made it I had some blueberries around that had seen better days, so I added them; the amount I added (less than a pound) didn't lead to a noticeably blueberry flavor, but it did produce a beautiful pink-purple color. The next time I made this (which I do partly because honey is cheaper than malt extract and quicker than mashing grains), it was the middle of winter, and fresh berries of any kind would have been pretty expensive and also possibly flavorless, so I used what I had around, which was:

12 ounces of frozen strawberries  
1 bag of cranberries  
some currant syrup (Someone brought this to a party once for putting on ice cream, but not very much of it ever got used for that because the seeds were too much of a nuisance.)

The only one of these berries which made an identifiable contribution to the flavor was the strawberries. I suspect that it is also the strawberries that produced the noticeably brown tint to the red color (all these berries are red, so you can't tell where the red came from).

It is true that honey has less flavor than malt, so you might want to use more than 12 ounces if you were trying to flavor a lager, but you definitely can get results with less than eight pounds.

(The mulberries from the tree in the back yard are dropping all over the place; I'm going to try using them in a mead ale this weekend. I expect that they will contribute more to the color than the flavor, but you can't beat the price.)

Laura

Subject: O2

There's an interesting letter in the latest Zymurgy (Summer). It is a short treatise on how yeast need oxygen to reproduce. What I found most interesting was that the highest need for oxygen came some 10-14 hours after pitching. It was implied that this delayed O2 need was because all the original O2 in the wort had been used up in those 12 or so hours. In those cases where there is a long delay before active ferment, as with some liquid yeasts, it might be worth giving the wort a splashing stir with a stainless spoon at the 12 hour mark. Comments?

Speaking of yeast, I just pitched the dregs from the secondary of one batch into the next batch. The dregs had been refridgerated in a clean glass jug for a day. Active ferment started in 18 hours (it's Wyeast Irish Ale, btw), a little longer than I expected, possibly because of the cooling. The first batch was oatmeal stout, the second is an Irish Red Ale. A black and tan, of sorts!

Subject: Cider Status

My first fermenting attempt (cider) has been fermenting for 10 days now. I followed my local supplier's instructions: add 1.5 cups of sugar to a gallon of cider and a packet of Red Star Champagne yeast. It had a vigorous ferment for the first 6 days or so; it glubbed every 2 or 3 seconds. Now it glubs 1 - 2 times a minute. Could anyone tell me what is happening at this stage? Should I bottle now, rack it to a new jug and ferment some more, or just let it go in the same jug a while longer? I don't have any testing equipment - playing this one by ear.

Any help is greatly appreciated!

A good idea even if you're not priming in thre keg. I  
bet B-brite tastes terrible, tho I haven't confirmed this  
8<:^).

> The other

> possibility is the tanks leaked at the seals in the poppets or the main  
lid

pressurizing to

> 5 lbs. with CO2, then I checked for leaks and had none (at that time).

Unlikely. If it held pressure before you put beer in,  
it probably would after. If the yeast conked out, the priming  
sugar will leave the beer sweet. If you can't taste it, try  
taking an SG measurement; if it's higher than your FG, that's  
what happened.

> 2. After these two tanks came up flat, I artificially carbonated them.

> [...]

> So I ran the CO2 up to 35+ lbs for 2 days and then

> foam city when I draw a glass from the tap!

Sounds like your feed pressure might be too high still.  
Ales should dispense at about 5PSI, lagers at 7-10. Try venting  
the tanks and reseting your regulator.

> FYI - I'm running 3/16" tubing from the quick-disconnect fitting (Pepsi  
> style tanks) up to the faucet (through wall mount) all of about 1 foot  
in

> length. I'm running 5/16" tubing from the CO2 tank outside the fridge  
> about 4 feet to the tanks.

Look into the fittings at the door. If there is a tiny  
little orifice there, that could foam your beer. The other  
possibility is that the beer in the outside hose may be  
warming up in the tube, which will also foam it. If the second  
glass dispenses OK, that would be my guess. I keep my  
dispensers inside the fridge for just that reason; prevents

spoilage too.

> This is my first submission to the digest, I hope I didn't over do it.

  You're doing fine!

From: <S94TAYLO%USUHSB.BITNET@CUNYVM.CUNY.EDU>  
Subject: Strawberry beer

I have brewed four batches of strawberry beer, so I can comment on results.  
As was suggested in the last HBD, strawberries don't impart a strong flavor in the finished product. All my batches have used 8 pints (about 1 lb. each) of fresh strawberries from the store, and the results have been a subtle taste at best. The one distinct character in my latest beer has been a "late aftertaste" of strawberry jam, like you were sucking on a spoonful of the stuff. I kind of like it. Crystal malt (about one pound in this last batch) which adds sweetness, helps to bring out the essence of the fruit. I suspect that much of the essence was "scrubbed out" by the fermentation.  
I wonder if adding pasteurized fruit after most of the brewing is finished would help. One other important ingredient was pectic enzyme, as the pasteurization sets the pectin very well. This results in a very nice looking crystal clear beer with a pink-amber hue. Here is the latest recipe (my best):

- 1 can (3.3 lb) M&F amber hopped syrup
- 3.5 lb. dry light malt, unhopped
- 1 lb. crushed crystal malt, steeped by whatever method you choose
- 1 oz. Northern Brewer leaf hops, (alpha=8.0%) 1 hour boil
- 2.5 gal. preboiled water, 1 gal. of it for steeping the crystal
- 8 pints fresh strawberries, washed, stemmed, pureed
- 2.5 gal. bottled water, chilled to near freezing, for cooling hot wort
- Ale yeast starter (see below)

Yeast Starter-

1 quart of water and 1 cup of dry malt extract, boiled and cooled to below 90 F. Add 4-7 gm packets of Red Star Ale yeast, and agitate. Let 'er rip for about two hours (or conveniently as long as it takes to do the rest of the batch, it you do this first). Add to cooled wort. The beer was actively fermenting in less than four hours, one loooooong (like 12 hours) glub, if you measure that way.

Brewing Specifics-

Steep crystal in 1 gal water for a while, then "rinse" in remaining 1.5 gal. brewing water. Add first steep to brewpot, and add malt and hops, boil for 1 hour. Remove hops, and cool in sink of cold water. DISREGARD LAST SENTENCE!! Turn down heat to very low flame and add pureed strawberries, heat for 15-20 minutes. Now remove hops and cool in the sink. Dump in primary fermenter and add the cold bottled water. The temp should be around 65-70. Dump in the yeast. The next day or sooner, add about 4 tablespoons of pectic enzyme, just right into the beer. Rack after 3-4 days.  
Bottle with 3/4 cup corn sugar.  
OG-Who cares  
FG-1.008 (this is pretty low)

Indeed most strawberries on the market are blah, bland.  
Not to offend those readers from California, but strawberries from  
California (esp. Southern California) taste like, \*nothing\*.

Strawberries from the Northwest are sweet, juicy, and have a  
strong strawberry flavor (if they don't rot because of the rain).  
I hope to use the freshest berries, straight from the garden.

The proof is in the bottle - I hope to report, in a couple of months,  
on my strawberry experiment.

I'm still looking for suggestions/experiences.

Thanks, but you're making me blush! I haven't seen the article myself  
yet;  
the vagaries of the post office may mean that I won't see it until I get  
to  
the conference. I hope they picked some good photos.

> I do have a question however: at what temperature is the wort when the  
> yeast (one of three interestingly enough) is pitched? The article did  
> mention 41f as the fermentation but didn't state the pitching temp.

They pitch at 5C (41F). They use a lot of freshly harvested yeast that  
hasn't had a chance to use up its glycogen reserves and so they get a  
very good start.

I just received a letter from the brewmaster at Pilsner Urquell who  
guided  
me around. PU is going to be upgrading their fermenting and lagering  
cellars  
to all stainless open primaries and cylindroconical fermenters. All of  
the  
oaken barrels are being removed. They are working to improve the shelf  
life of their beer, and intend to begin canning it as well.

--Darryl Richman

From: PEPKE@SCRI1.SCRI.FSU.EDU (Eric Pepke)  
Subject: Re: All grain brewing ?

Jim White asks about all-grain brewing:

- Is the final brew, in general, superior to an extract brew? If so, why?

This is a matter of deep religious conviction. Holy wars have been fought over it, and the streets are lined with the heads of those who dared to ask this question. Nevertheless...

You get much more control over the process of all-grain brewing. First of all, you get to choose from a large variety of malts. By varying the strike temperatures and the rest times and by choosing the method of mashing, you get to control the amounts of what kinds of sugars are present in the wort.

These are all variables. Skillful manipulation of these variables can result in an exquisite product. Sloppy manipulation can result in junk. It's a lot like cooking. I happen to like Campbell's Cream of Mushroom Soup a lot. No doubt a skillful cook could make something which is much better, and no doubt a poor cook could make something which is much worse.

That having been said, my second all-grain beer was the best beer I have ever tasted. In my experience, it is much easier to get a complex flavor with all-grain brewing. There is never any need to add yeast nutrient or heading agents. I have not seen any need to age the beer more than the minimum amount of time needed to get the carbonation; with extract brews there is often a kind of harshness which ages out that I assume is due to the high temperatures needed to concentrate the extract.

Anecdote: There is a local brewpub which, up until a few months ago, made a series of largely uninteresting beers. A while back they had a specialty ale which was delicious. I finally cornered the brewmaster and he admitted that it was essentially the same recipe as one of their uninteresting beers using an all-grain rather than an extract process.

- What kind of time commitment are we talking about to wort creation?

Quite a lot. I basically commit an entire weekend to brewing a batch of all-grain beer: one day to mash and sparge, the next to boil. Depending on the style of mashing you want to do and the results you want to get, a mash can take anywhere from 1.5 to 4 hours, requiring anything from occasional checking to almost constant supervision. Sparging takes a couple of hours if you don't screw up and get a stuck mash which requires resetting.

- How much more water do we use? Do we have to condition the water?

You don't use any more water, really. The only extra water is that lost during a full wort boil rather than a partial wort boil. I don't know about conditioning the water except as you normally would for the style of beer.

You do have to be a little careful about the pH of the mash.

- How about \$\$ investment in equipment (minimum required) ?

Lessee--I use my boiling kettles for mashing, stovetop or decoction. I use a meat grinder for crushing the malt. Before I used a meat grinder I used a rolling pin and a large quantity of elbow grease. I use a Gott 5 gal. cooler for a lauter tun; I think that was about \$16. The screen at the bottom is a metal vegetable steamer (about \$3?) with a hacked up cheap plastic bowl to make a good seal. That's about it. Even before I had the cooler I was making excellent beer using an ad-hoc arrangement of buckets, spaghetti cookers, and sieves.

With a full wort boil you can't really cool it by mixing it with cold water, so it's more important to have a wort chiller to get a good cold break. I use an immersion chiller which I made myself out of copper tubing. I guess the parts cost about \$15 or so for the tubing, hose to the faucet, and faucet attachment.

- Is the final per bottle cost less, or more?

If you buy the grain by the pound bag and extract by the can at the local shop, the cost is about the same. If you buy the grain in bulk (25 lb or more), the cost is quite a bit lower, even lower than if you buy the extract in bulk. Of course it takes more time, but worrying about the dollar value of time spent on a hobby causes ulcers.

Subject: AHA conference, BG Jazz

For those of you who are coming to the AHA conference in Manchester, you might want to know that the Boston Globe Jazz Festival is happening the same week, in Boston of course, about 60 min. from Manchester. The festival runs from June 17 to June 23, with a number of free concerts. The main concert is June 23 at 3:00 on the Boston Common, and is free. For more info: (617) 523-4047 (the area code might be 508).

Re. Manchester stuff: Well, there isn't really alot. There's the Boston Trading Co. bar near the convention center. There's an Irish Pub (can't remember the name) that has good tap brews (Guinness, Double Diamond, Harp,...). Go about 20 blocks north on Elm st. from the conference center, turn right on Bridge St. (after big Numerica bldg.), then turn right after 1 (??) blocks on Kosciuscko (sp?) street. Nearby also is the Salty Dog Tavern. I haven't been in there in a long time. It was your average Budswiller joint; it may be better now, probably not. In the same area is the High 5 restaraunt/hotel. It has a bar at the top, really nice view of the city. Recommended for the view.

There's not much in "downtown" Manchester. Head for South Willow St. and the "Mall of New Hampshire" (!) if you need to spend \$\$, or head for the Daniel Webster Highway North. Ask for directions.

If you continue past Bridge St. on Elm, after a few more blocks you'll find the North End Superette on your left. That's where you'll want to go to buy beer. Some NH liquor stores also sell (high alcohol) brews.

There's lots of places to eat. Cafe Pavone is very good Italian near the river near Bridge and Elm. Very affordable. Check the yellow pages for other places.

FYI: The city is cut in half by the Merrimac River. Rt. 293 follows the river. Rt. 93 goes around the east side of the city. Most of the "good" stuff in on the east side of the river, "da west side, dere" is home to a large Franco-American population, and is almost a seperate city. The conference in near the river, on the east side.

My apologies to those of you who are not going to the conference, and couldn't care less about Manchester. To those who are going, I hope this helps, and I'll see you there.

Oh yeah, don't even \*think\* of swimming in the Merrimac river; it's been seriously polluted for years.

From: Dave Barrett <DAVE.BARRETT@OFFICE.WANG.COM>  
Subject: British Isles Brewers

There has recently been quite a few requests for information of breweries to visit in Britian. I have a book written by CAMRA's Roger Protz that claims to have "tasting notes and ingredients of all cask-conditioned real ales brewed in the British Isles". Its quite a book. It covers England, Scotland, Ireland (sort of), Wales, Isle of Man, and Guernsey. For each brewery Protz gives the name, address, phone number, and whether or not they have a reception center and/or brewery tours. The information he gives on the beers is very complete. It includes OG, ABV, ingredients (often with porportions), and tasting notes (which are broken down into nose, palate, and comments)

For example the entry on the Pitfield Brewery (I chose this one because there has been a lot of request about London in particular) and one of their beers read:

Pitfield Brewery  
8 Pitfield Street, N1 6HA  
Tel: 01-739 3701

Independently owned  
Reception centre - yes (Ship and Blue Ball, Bundry Street, E2)  
Brewery tours - by arrangement

Pitfield Bitter  
OG 1038 ABV 3.7%  
Ingredients: pale malt (90%), crystal malt (7%), wheat malt (3%),  
Goldings whole hops  
Tasting notes  
nose - Rich grain and hint of Stilton  
palate - Pleasing malt in the mouth, light, hoppy finish  
Comment - Excellent, quaffable, copper-coloured bitter

In short this is a great book for finding out where to go, and as source of recipes. My wife had a friend purchase my copy in England (thanks Jean!), the price printed on the cover is 6 pounds 95. If you're interested the info you need is:

Subject: Re: Primitive brewing

Mashing over an open fire - fascinating. Though I do think that cracking the grain with a plank is a bit much - they did have mills then, after all.

My own .02\$ added to this is that, being of Lithuanian descent and a homebrewer, I often get explanations from people my grandparents' age about how brewing used to be done down on the farm by their parents and grandparents.

The accounts I get are confused and varied, but it seems that mashing (or maybe fermentation - I'm not sure) used to be done in huge (this ain't no 5 gal. batch here) wooden casks, lined with straw, with a hole in the bottom. After the mash (and/or fermentation) was done, the hole was unplugged and the straw acted like a sieve. One thing seems for sure, though, this farm-brew did not receive a secondary ferment, nor was it carbonated. Ah, the days of yore

From: hersh@expo.lcs.mit.edu  
Subject: Dextrin Malt and Mashing

Well I don't know how much this applies, but having been to this date a mostly extract brewer I was always a little dissapointed with the body/mouthfeel of extract brews finding them usually a little on the thin side.

Once I began to use malto-dextrin in my beers I noticed a substantial improvement in the mouthfeel/body. So my empirical experience is that malto-dextrin has an effect on this.

Now I don't know how malto-dextrin relates to Cara-Pils or dextrin malt grains. I would however like to know if anyone does know how these relate, as I have been following the all grain discussions more closely lately and having taken over Steve Strouds (of Wort Processors fame) old apartment (affectionately now know as the Wort House) I plan to begin all grain brewing.

Date: Thu, 13 Jun 91 13:35:10 PDT  
From: Martin A. Lodahl <pbmoss!malodah@PacBell.COM>  
Subject: Why Do We Mash? (long!)

In HOMEBREW Digest #658, Jim White asked one of the most thought-provoking questions I've seen in a long time:

> I've read much discussion, in this digest, regarding various chillers,  
> mashing tubs, temperature control ..... etc, related to all grain  
> brewing.  
>  
> I'd like to solicit some opinions about whether or not it's worth  
> the (seeming) effort involved.

I really feel that this is a question everyone eventually decides for himself, and the answer has a great deal to do with why we brew in the first place. That it takes more time and effort is unquestionably true. It's also true that some equipment is required that the syrup brewer isn't troubled with, but the magnitude of this requirement is not great. That it produces better beer is not necessarily true, but in my experience, generally seems to be the case. What's incontestably true is that mashing places you in intimate contact with a part of brewing the extract brewer has hired someone else to do, a part of brewing many of us find fascinating and intensely satisfying. Seeing a mash convert is almost a magical experience; tasting the growing sugar content as the mash progresses and smelling that great brothy aroma is a pleasure I, for one, wouldn't choose to give up. From that perspective, all the fiddling with equipment and process is anything BUT a nuisance! If I felt completely locked into my present process, I'd be looking around for something else to do. With brewing, there's always another variable to control, always something new to try, always something to be learned. And on a practical level, the degree of control mashing affords over the characteristics of the final wort cannot be duplicated when using extracts, as the recent investigation of unadvertised non-malt sugar content in some extracts has made clear. A vitally important component in the quality of your beer is in someone else's hands. I realize that a case could be made that from this perspective, we should be growing & malting our own barley. Who knows? Maybe some day, we will! But to address your specific questions:

> - Is the final brew, in general, superior to an extract brew? If so, why?

In general, yes, in my observation. A very good brewer can make very good beer using very good extracts, but that same brewer will usually make better beer mashing. In some styles, where precise control over fermentability is important, the difference can be surprising. Most of the time, however, the "80/20" rule seems to apply: 80% of your effort will be required to produce the last 20% of beer quality.

> - What kind of time commitment are we talking about to wort creation?

This was debated here a few months ago, a debate that opened my eyes to just how variable an answer to this could be. I've said above that I enjoy the process, so it's not surprising that I manage to make it take all day to produce a 5-gallon batch. As I've never done an all-extract batch, and only my first batch was extract-and-specialty grains, I really don't have a good baseline to judge the time increase. Consider it significant. If you'd rather not take

the time, don't.

> - How much more water do we use? Do we have to condition the water?

The only increase in water use I can imagine is in cleaning the extra vessel (lauter tun), and a small amount lost in the longer boils made possible by not using extract. Required water treatment may actually be less, in terms of time and effort, if your water doesn't need to be preboiled to remove temporary hardness. Since the whole wort volume will be boiled, preboiling for sanitation is not an issue. Some pH and mineral adjustment is usually required, but is not burdensome.

> - How about \$\$ investment in equipment (minimum required) ?

You'll need a kettle capable of boiling all the wort. 33-qt enameled steel canning kettles are under \$30. You'll need a lauter tun of some sort, appropriate to the mashing scheme you prefer to use. I do a stovetop step-mash, and my lauter tun is made from a 7-gallon plastic wastebasket, the bottom of a discarded plastic soap pail, a drum tap, and a jellymaker's straining bag. The cost is certainly under \$20. An insulated cooler would work better and cost more. The other piece of equipment is a wort chiller, of either the immersion or counterflow design. I made my latest immersion chiller for about \$25. From there you could get fancy; I recirculate ice water through my chiller, but I got the pump free.

> - Is the final per bottle cost less, or more?

Less, if you consider only materials. Factor in the capital cost (see above) and it'll be more for quite a while. In fact, about the time you've used the equipment enough to recover your investment, parts will begin to break. I've replaced my chiller (destroyed in an unusually hard freeze) and most of my lauter tun. But the cost difference is piddling. And after all, isn't the purpose of a hobby (or a passion) to spend without guilt?

> I'm relatively new to the list ...

Welcome!

> ... and I suspect this subject has been discussed  
> many times in the past ...

It hasn't, actually, and I don't understand why not.

> ... but I'd like to know, 'Why do you brew how you brew'?

Because I enjoy brewing that way, and it produces beer that I like. Thanks for asking.

Subject: Beer bellies, cholesterol and imagination.

Get out your salt shaker ... here it comes.

Cholesterol is a uniquely animal product. It is found in meats, butter, cheese, etc. Unless you are making a rather exotic beer, such as putting real cream in your cream stout, your beer will not contain any cholesterol.

Your beer will contain calories. Pure alcohol has 6.96 calories per gram, and the rest of the stuff in the beer, mostly carbohydrates have about 4 calories per gram. A quick look at Bowes & Church shows that beer has about the same calories as a soft drink, (non diet).

Three beers or three Cokes ... about the same caloric content ... but much more nutrition in the beer ... a health food.

Sugar is one of the worst things you can put into your body. From that standpoint, a beer is far, far better than a soda. Y'know, this sounds interesting ... I think I'll start a "Beer is a health food" campaign.

Let's see now, if you replaced all sugar with beer, and all cholesterol with beer, you'd drink about three pints a day ... yeah, sounds great! Come to think of it, pizza is a health food, too. Bread, tomatoes, onions, peppers, mushrooms, cheese ... a real health food. Beer and pizza .. what will they think of next!

From: olson@antares.cs.Virginia.EDU  
Subject: sparging -- cloudy runnings

Fellow relaxers,

Reading HBD has gotten me interested in mashing, and my last two batches have been partial mashes (3 lbs grain) following the directions in Miller's TCHBoHB. The mash itself is tons o' fun, and the magical transformation from grainy to sweet does, as promised, make you feel like a wizard. Then comes the part that gives me trouble -- the sparge. Miller says to recirculate the first runnings once, then sparge and "let the clear wort fall into your boiler". Other things I've read call for you to recirculate until the wort clears. Unfortunately, my worts never run clear. Last night I recirculated for a full hour, with negligible improvement after the first 20 minutes or so. The wort was turbid enough that a spoon stuck into it faded to invisibility an inch or two below the surface. My questions are:

1) Am I being too compulsive about this? Should the wort really run "crystal clear", as per Miller?

2) If it should, what am I doing wrong? Following Miller, I use the straining basket from a 2-gallon spaghetti cooker to hold the grains, and smooth the grain out with a spoon to form a slightly concave surface. I pour recirculated wort (and later, sparge water) gently over the depression, so as not to mess up the bed too much. I keep the rate of sparging low, so that most of the liquid goes through the bed to the bottom of the strainer rather than oozing out through the sides. There doesn't seem to be a lot I can do to get better filtering from the grain bed, except to mash more grain :-). The quality of the crush is, of course, a prime suspect. Not having a Corona (it's on order), I buy my grains pre-crushed from the folks at The Home Brewery, who use an industrial 2-roller mill. One presumes they do it right, since the owners are dedicated mashers themselves. There are a significant number of whole and half husks in the grist, but I do notice a small amount of whitish dust at the bottom of the bag -- I've been assuming it's crushed malt, which Miller says is OK. Could that be the culprit? I try to discard it at mash-in, but you can't get it all...

Any advice appreciated!

>From: tamulis@gauss.math.nwu.edu (Andrius Tamulis)

If you get to Europe, check out one of the many open-light or open-air museums. These are large parks that have been filled with old buildings that would otherwise have been torn down. In particular, just about every farm house I looked at, regardless of how small or primitive, included a corner that had a large copper pot built into it, over a fire. These pots were generally in the 15-20 gallon range.

Andrius description matches some old recipes I have read, where straw is placed in a tun and then crushed grain placed on top of it. Alternate infusions of warm and boiling water are then added and strained off, and this is then boiled and left to cool, and then yeast (barm) is added the next day. In fact, the farmers often used a device to hang onto their yeast culture that had pieces of wood strung on a knotted rope, like a large necklace. With a tremendous surface area, the yeast could hide in the nooks and crannies until the next batch was brewed.

From: darryl@ism.isc.com (Darryl Richman)  
Subject: costs of mashing

Regarding the cost issues between grain and extract, most of the responses have put them on a par, especially when you consider amortization of the equipment. I disagree with that, but I do buy grains and hops in bulk. I've calculated it before and the ingredients cost per bottle of beer is in the 7-8 cents range. (E.g., 7 lbs. 2 row malt @ .40/lb., 1 lb. crystal @ .55/lb., 2 oz. hops @ .20/oz. -> \$3.75 / 5 gal \* 1 gal / 10 bottles -> 7.5c / bottle.) If you've got some storage space in your garage, you can buy barrels of grain at these prices. Fortunately, we've got a maltster locally that is cooperative.

As for equipment costs, I spent about \$25 on an immersion chiller I built. The two kegs I cut up to cook in were each \$10 deposit. The 80 quart Coleman cooler I use as a lauter tun was about \$40 on sale. The gas fittings for setting up the two dead water heaters I use to cook with cost about \$15. There's probably another \$25 in assorted things that I haven't included. I did pay \$200 for a big, used chest freezer, and another \$60 for the thermostat (of course, the Hunter unit that everyone has been talking about is a great deal at \$20). But these were later additions to my brewing gear. This lets me brew in 15 gallon batches. For lower gravity beers I can produce as much as 25 gallons (for example, English Mild) and for higher ones (e.g., barleywines), as little as 10. The limiting factor right now is my mashtun/boiler size.

I personally think that mashing is great. It takes me about 6 hours to brew a simple beer like a bitter, longer for more complex ones. Of course, the first couple of times, expect to spend a long day-- I've yet to see an all-grain brewery come online that didn't have some bugs to be worked around.

From: dbreiden@mentor.cc.purdue.edu  
Subject: Miller Genuine Draft

Last night I wanted something light and thin, so I bummed a Miller GD from my roommate. It's a pretty good beer for when you want an American style beer. Anyhow, I was looking at the label and recalling the stuff I've heard about Miller brewing and the treatment of hops. On the label, the words "No additives or preservatives" are boldly displayed. And of course, the ingredients are not listed, they simply say "Contains malt, hops, yeast, and water. Selective listing indeed. So I was thinking, "If they treat the hops, wouldn't that result in an additive?"

In the course of this thinking, I once again got to thinking what a shame it is that ingredients need not be given for beers. I really wish I could see what is in the beer I'm drinking. When enjoying an American beer, I'd like to know for sure if they use corn sugar, or corn syrup, or rice, or whatever. But my thinking just got me sort of frustrated. So I had another beer and quit thinking about it.

So anyhow, why is it that Miller can proudly proclaim that they put no additives in their beer when, apparently, their hops are goofed up to prevent skunking?

Hello,  
Having made strawberry wine and cordial (no strawberry beer or mead yet) and tasted strawberry eau de vie, it seems that the strawberry taste is not strong enough to go through the fermentation process. The wine smells strongly of strawbs and is a lovely brownish red color, but it really doesn't taste much of strawberries. It is a generically fruity tasting wine. The eau de vie doesn't taste like anything but alcohol. It smells nice though. I guess all but the smell-producing components get left on the other side of the distill. The cordial (soak sliced or mashed berries in vodka for a month then add sugar syrup or honey to taste) tastes of strawberries. Raspberries give things a stronger taste and color. I expect the strong malt flavor would overpower the subtle strawberry.

Subject: Re: Xingu beer  
Newsgroups: rec.food.drink

> Has anyone ever had this S. American beer? What is its area of  
distribution?  
> And does it come in cans?

Xingu - pronounced 'SHIN goo' comes from the Caccador Brewery,  
State of Santa Catarina, Brazil (~600 miles southwest of Rio).  
It is an Indian recipe converted to a brew of barley, water,  
hops, and yeast. The grain is roasted by open fire malting.  
It is a black, dense, opaque, LAGER beer. It is brewed on site,  
using Brazilian hops and barley. The brew was developed by  
Alan D. Eames. Brazil used to brew quite a few great 'black' or  
'escura' lagers. Unfortunately, these have been discontinued in  
favor of lager production by the majors (Brahma, Kaiser, and  
Antartica). The Indian tribes along the Xingu river and it's  
tributaries (Amazon area) still brew these beers. Their  
process is basically malted grains, lupine herbs, and airborne  
yeasts - with the women chewing the grain and spitting the mash  
into pots, the resulting 'mash' being cooked over open fires  
and giving the beer it's 'blackness' from the smoke - and lagered  
in underground clay pots.  
Eames took their recipe and converted it to a commercial process.  
The resulting brew pours and looks like a stout but tastes like  
a lager. It is BLACK. It has ~4 % alcohol by volume.

It is distributed by Caparra Sales Co., Randolph, MA  
(617) 986-2337. Maine artist Eric Green painted the Xingu  
label, based on antique maps of the Xingu river region and  
included a Txukahamei warrior with a lip disk.

Subject: Beer and Cholesterol

Vijay Vaidyanathan asks about beer and cholesterol.

>Having just been diagnosed as having a "Cholestoral Problem"  
>(specifically, too little "good Cholestoral" and too much "bad  
>Cholestoral"), my wife has suggested that Beer may not be the best  
>thing for me. On the other hand, I can think of no reason that  
>Beer can contribute (or aggravate) a cholestoral problem.

First, let me say that I am sorry to hear about your problem. You will probably have to change your lifestyle in terms of diet and exercise, and that is difficult for some to do. I am no expert on cholesterol, but I have done a little research on it since it is a problem in my family. My understanding is that a cholesterol problem is caused or aggravated by ingesting saturated fats from foods, especially those which come from animals, but also from certain plants.

Usually people with this problem are told to eliminate butter, whole milk, coconut, palm oil, etc. from their diets, and eliminate or reduce the eating of pork, beef, eggs (especially the yolks) etc. On the other hand, they are encouraged to substitute for the above: margarine, low fat or skim milk, chicken, turkey, fish; and should eat lots of fruit and vegetables. They should also reduce or eliminate fried foods (fried potatoes, french fries, etc.) and cook with vegetable oil instead of butter or lard (actually olive oil is even better because it is a monosaturated oil which helps reduce blood cholesterol.

Beer does not contain saturated fats, so it can not cause or aggravate blood cholesterol levels to any significant degree directly. But, it may in some cases, indirectly! How? Read on.

>On the other hand my wife claims that "Beer gives you a Belly" ...  
>what exactly is it in Beer that gives you the infamous "beer  
>Belly".

Does beer really give you a "beer" belly? I know several beer drinkers, some have "beer" bellies, some do not. I had a friend who spent his life working as a brewer for Miller (the beer, not the infamous author). He is dead now, not of a cholesterol related problem, but of diabetes. But he one time told me that he felt that the "beer" belly was a result not of the "beer" that people drank, but of what they ate (potato chips, peanuts, etc.) while they were drinking beer.

I know of no scientific study to support this, but it makes some "horse" sense to me. Add to that the fact that these same people may also be "couch potatoes" who are ingesting all of this stuff while watching some sporting event on TV, instead of participating in one themselves, and it could be that beer really contributes very little to the "beer" belly.

This is what I meant above by beer contributing indirectly to higher levels of cholesterol. What are you eating when you drink beer?

Now, before anyone flames me, let me say that I mean for the "indirect" connection between beer and cholesterol to be taken lightly (i.e. with a grain of salt substitute!). But, it might be \*FOOD\* for thought. (You can flame me for the bad pun.)

Finally, let me say again that I am no expert. Before deciding on your own diet (or changes to it), talk to a real expert.

I hope that controlling your cholesterol levels is a manageable project for you.

David Huyink

From: Martin A. Lodahl <pbmoss!malodah@PacBell.COM>  
Subject: Liquid vs. Dried Yeast

In HOMEBREW Digest #659, Ifor Wyn Williams notes:

> Many people have strong views about the relative merits of fresh  
> yeast, liquid yeast, dried yeast, freeze dried yeast, ... etc. One  
> thing that has puzzled me for a long time is that for a given quantity  
> and strain of yeast, how does the manner in which the yeast has been  
> stored affect the resulting beer?

It's not the storage as much as it is the processing required. It's hard on yeast to be dried out and rehydrated. Many are killed by the process, so in the interests of viability, strain selection stresses "ruggedness" rather than ideal brewing characteristics. Additionally, there seems frequently to be a question of contamination in dry yeasts, which is not a necessary attribute of the process, but rather symptomatic of "relaxed" QA on the part of the producers. There have been several excellent articles on this subject in Zymurgy in the last couple of years.

A liquid culture, however, is no guarantee of quality. We've come to feel that it is, because for most of us, the liquid yeast cultures we're most familiar with is the Wyeast "Brewers' Choice" line, which is most certainly an outstanding product in every sense.

Subject: To mash, or to extract ...

I love it! Nothing like getting into a subject where religious fervor is involved. To mash or to extract is a wonderful way to explore the reasons and pleasures of homebrewing in the first place.

I'm nearly blind. For that reason, I've stuck to just extracts. That is, extracts plus adjunct grains, oatmeal and anything else I can imagine. There is no question that all grain beers have the potential to be the best in my opinion. That being said, notice that nearly half the recipes in The Winner's Circle are extract based.

I believe that part of the reason people get better results from all grain brews than from extract based recipes is that they take more care with their all grain exploits. I do full wort boils with my extracts and adjuncts and take care to condition the water if needed.

I'm terribly picky about the extracts I use and try to follow the best of techniques, whatever that is. It's sort of like using fresh grape juice versus juice extracts in winemaking. You will get good results from the extracts if you pay attention to detail. You will get wonderful results from the fresh juice if, again, you pay attention to detail.

There are more details to pay attention to in all grain brewing, and if I could see better, I'd delight in paying attention to each one. However, even with the limits of extracts, spectacular beers may be produced.

One of the things I like best about this list is that there is no stratification among this group. All grain brewers seem not to look down on us extract types, and we, or at least I, don't act like the mashers are hoyty-toyty.

Is all grain cheaper than extract? Maybe, but with the recent price increases all of the distributors seem to have inflicted on us, I think Catamount Porter or Sam Adams Boston Ale may almost be cheaper. But so what? I have as much fun making beer as I do drinking it.

Now, what I really want to talk about is dehydrated beer. It comes in a can, you just add beer...

From: srussell@snoopy.msc.cornell.edu (Stephen Russell)  
Subject: maltiness, body, kudos, and a brewery tour

Greetin's,

One thing that often puzzles me is how to impart malt aroma into beers. It is straightforward that to impart hop aroma one uses finishing hops;

however, malt aroma is much more subtle and difficult to attain.

Munich malt usually does the trick, but plenty of beers that sure-as-hell don't have any of this malt in them (such as British ales and pale, fairly dry Pilseners) have a great deal of maltiness in their aroma.

What's the secret? What yeasts tend to promote maltiness? What would you

alter in your mashing schedule and/or recipes to assist? I've used toasted

and Munich malts with some success, but want to know more.....

BTW, one impression I have is that if you leave a beer sit, the hop aroma dies faster than the malt aroma. Is this what you find as well, or have

I been tasting too many in one sitting?

As for the great dextrin 'n body debate, I have read Miller and agree that he, at least, is convinced that it's proteins and not dextrans that con-

tribute to body. However, I continually see other sources (Zymurgy articles,

other books, etc.) that attribute body to dextrans. Since I was trained as an

all-grain brewer by using Miller's book, I tend to trust him the most, but

am still far from convinced.

For one, body may strictly-speaking be defined as "palate fullness", but it is also considered a measure of viscosity. And it would take many thorough experiments to convince me that sugars don't make aqueous solutions

more viscous. But perhaps the effect is negligible compared to what the medium-sized protein molecules do, or maybe I'm making a perceptual mistake.

Well, there is a simple experiment one could perform (by "one" here, I mean someone less lazy than myself!). Take two mashes with the same malt,

run them through the same protein rest schedule (thereby insuring identical

protein compositions) and then saccharify one at a high temp (66C, say) and

one at a low temp (62C, say). The former will be more dextrinous and therefore

less fermentable, the latter more saccharinous and fermentable. Both should

still have (roughly) the same initial gravity. Ferment each under the same

conditions using the same yeast. The former will have a higher final gravity.

Which one will have more body???? Maybe one of you has an idea from your own

experiences even if you haven't performed this exact experiment.

More discussion on this topic would be helpful, since controlling body

to beer is a common goal. Besides, we haven't had a good flame in a while (remember cleaning wort chillers? recipe copyrights? beer and your health? and so on, and so on.....)

I would also like to ditto Norm Hardy's comments from yesterday; kudos to Darryl Richman for the fine article about his visit to the Pilsner Urquell brewery in the latest Zymurgy. (Please don't strain your arm patting yourself on the back again, Darryl! I couldn't live with myself.)

BTW, I've received several inquiries about our club's (the Ithaca Brewers' Union) trip to Vernon Valley, NJ, the last weekend of July. We will get an owner-guided tour of the Clement Brewing Company and participate in the theme park's Germanfest. There are still plenty of openings, so if any more of you are interested, please send e-mail to me directly. (srussell@snoopy.msc.cornell.edu)

From: cjh@vallance.HQ.Ileaf.COM (Chip Hitchcock)  
Subject: re Beer and Cholestorol ?? Beer Bellies.

GROSSLY SIMPLIFIED EXPLANATION:

Most sugars are chains or rings of 6 carbon atoms. You and yeast go through similar processes to get energy from sugar: break in half, rearrange, break off 1/3 as CO<sub>2</sub>, what's left is ethanol (or an ethanol-oid stub, C<sub>20</sub>..).

This only gets the small part of the energy that can be released without additional oxygen. Us aerobic types can run ethanoloids through a slow burn that turns C<sub>20</sub> into (CO<sub>2</sub>)<sub>x2</sub>, releasing lots more energy---enough that if you drink a lot, or eat lots of sugar, you'll find (after you come down) that most of it has been stored as fat (long carbon chains) rather than burned, since most of us don't run marathons while drinking and so don't need the energy. When we do need the energy, the fat gets unzipped 2 carbons at a time and you get back the ethanoloid to be burned.

There is a third path for the ethanoloid, before or after it's been stored as fat: pound 3 of them together, lose a carbon, and you get a Y-shaped 5-carbon ]chain[. Hook 6 of these together, kick them so they make

a multi-ring shape I'm not going to try to show in ASCII, and you get cholesterol. (Boo! Hiss!) This is why plant oils can be preferable to animal fats; the chains have occasional extra bonds which plants can make and unmake and animals (including us) can't, so you get the taste/feel of fat without as much of the raw material for cholesterol.

Very few foods have significant amounts of cholesterol in them, so "cholesterol-free" is misleading (the FDC is now taking on this issue); what matters is not just the fat content but its type. There are other complications, e.g. egg yolks do have significant amounts of cholesterol, but (a) they have other nutrients some of us may not get enough of, (b) eggs are a cheaper source of protein (in terms of energy & plant foods to make) than most other animal-deriveds, and (c) some part of the cholesterol appears to be in a complex form which is actually beneficial (it's believed to scavenge loose cholesterol) or at least not harmful.

The arguments over eggs are typical: there are still disagreements about the effects of almost any dietary factor you care to name. (Large quantities of salt were on everybody's hit list the last time I looked, but even that may have changed....) The metabolic pathways are massively more complicated than I describe, and it's not clear what overall effect you can expect from a given diet; not nearly enough Framingham-style research (examining large populations over many years, tracking diets and sorting by every conceivable variable) has been done. The arguments with the loudest plurality are now pointing toward complex carbohydrates (i.e., starches) as the best source for the bulk of the calories we consume, but nobody knows the effects of all the other things you eat or drink; cf arguments that moderate (definition varying) drinking can reduce tension (e.g., blood pressure) enough to be, on the balance, a life-extender.

This isn't a matter of RDWHaH, but the issue of what you should eat and what you should weigh is much bigger than how much beer you're drinking,

and it depends on many more factors. Teetotalers can have a "beer bellies"; their livers might be in better condition but their overall health may not be as good as that of occasional drinkers who aren't as obviously overweight. It's arguable that the key to health, now that we don't have to gorge or starve with the seasons, is moderation. Homebrewers /can/ be good at this; I've seen a lot of beer around Wort Processors meetings and haven't noticed anyone being unsociably drunk.

This may not seem very informative---but the one thing I'm sure of is that absolutely certain answers are very likely to be wrong (cf. Clarke's 3rd Law).

Final note: making cholesterol is not a nasty trick our body pulls on us. Cholesterol is needed in cell walls; also, many hormones (sex, growth, etc.) are very close relatives of cholesterol, having the same multi-ring base with slightly different ornaments (usually 1-2 carbons or 1 oxygen) in varying locations to differentiate them.

A common argument is that our total fat intake and our net calorie balance (intake vs used) have become much higher in the last few generations than they were in most of our evolution, and that cholesterol problems are a consequence of this. It's argued that the "peasant" diet (mostly grains, with occasional meat for a treat or flavoring) is similar to that of our distant ancestors and our closest relatives (e.g., Australopithecus and chimpanzees), and hence is the one that our metabolisms are best designed-for. The judges aren't all back, and the issue is complicated by all of the separate economic interests trying to sell us the food they've produced.

From: grumpy!cr@uunet.UU.NET (C.R. Saikley)  
Subject: Cost of Brew

Greetings fellow brewers. I've returned from a recent net-hiatus, and hope to be able to participate in the hbd more frequently again.

Anyway, I tuned into the discussion of all grain vs. extract brewing and wanted to add my two cents. Basically I think that Martin covered the questions very thoroughly, but I'd like to add some of my thoughts to the following question.

> - Is the final per bottle cost less, or more?

I don't really buy the "well-it's-a-hobby-so-why-do-you-care-how-much-it-costs" attitude. Cost may not be of concern to some, but not everyone is that fortunate.

Grain brewing can be *\*much\** cheaper than extract, provided that you can get a good price break on ingredients. Some friends of mine recently pooled their resources and bought one ton of malt. They got a deal. I often get my grain from a nearby microbrewery for the bargain basement price of \$0.23 per pound! If you can work out an arrangement with other members of your homebrew club and with a supplier, you will save bucks. As an example, here is a breakdown of a recent brew. It was very inexpensive, simple and above all delicious.

|                      |           |         |
|----------------------|-----------|---------|
| 28 lbs Klages malt   | 0.23 X 28 | \$ 6.44 |
| 3 oz Northern Brewer | 3.00      |         |
| Sierra Nevada Yeast  | free      |         |
| Propane              | ~1.00     |         |

Total 10.44

This yielded five cases of beer for about \$2.00 per case. Granted the price would increase for a brew with lots of specialty malts. Nonetheless, you won't get anywhere near \$2.00 per case for even the simplest extract brew. Of course not everyone will be able to get grains for \$0.23 per pound, but as they say, here is another data point.

From: Jeff La Coss <jlacoss@ISI.EDU>  
Subject: Why Punts? well...

Wine bottles have punts for (at least two reasons)

1) Tradition - recall that glass bottles were hand-blown until relatively recently. When the hot glob o' glass is pulled from the oven, it is blown into a small globe to start working it into shape. During further shaping operations, the globe was set onto the end of a carbon rod (a "punty") to support it while being spun. Since bottles always looked that way.....

2) Punts DO make the bottle bottom stronger - the glass is in compression rather than SHEAR.

It was recognized early on that the punt had advantages - secondary fermentation isn't always desirable, but it occurred frequently in wines. Secondary fermentation was first used by Dom (Father) Perignon as an experiment. Champagne bottles were and still are made of HEAVY glass to prevent them from exploding while being racked to collect the dead yeast. Crown (pop-bottle) caps are used also for pressure relief during racking - they are replaced with the cork&wire affair after the yeast has been removed from the bottle.

From: IOCONNOR@SUNRISE.ACS.SYR.EDU  
Subject: Supplies

Just a few thoughts on purchasing supplies.

Often there are new folks who want to know where to get supplies. Prices are certainly a concern and so is freshness. IMHO the best place to buy stuff is through a local shop, if you have one.

I've compared most of the prices at mine, and they seem to be not only cheaper, but there is no shipping since you pick it up yourself. The added benefit of purchasing from a shop in person is that you can shoot the bull with the owner who is usually a pretty good brewer him/herself.

I like to patronize mine shop owner because he's so damn helpful--he even gives his home phone number out so if you have a problem you can call. I dont think that that can be done with the catalog ones!

If you dont have a local shop, or the prices at your local shop are so outrageous, then the catalogs is the place to go, otherwise i'd go with a local. I see my visits as an adventure. It's not like going to the supermarket--I have to spend at least half an hour, even if I buy one thing!

Well, as the "Torch" used to say in the "Fantastic Four," "Flame on!"

Date: Fri, 14 Jun 91 16:56:07 PDT  
From: gschultz@cheetah.llnl.gov (Gene Schultz)  
Subject: Recipes for brewing wheat beer from extract

Responding to R. Tidd's request for recipes for brewing wheat beer with extract, I offer two very simple recipes:

1. 1 can (3.75 lb.) of Telford's Wheat Beer extract  
2 cups of granulated sugar  
3/4 oz. of Saaz hops  
1 package of Wyeast London Ale yeast

Bring two gallons of water to a boil, then add extract. Add sugar. Add 1/2 oz. Saaz hops to the boil for 30 minutes. Remove heat. Add 1/4 oz. Saaz hops for aroma. Add cool water to bring wort volume to four gallons. Cool to 75 - 80 degrees. Transfer to primary and pitch yeast.

Comments:

Ridiculously simple, but very nice and light. Most people who don't like wheat beers like this one, and many people think that this is a commercial product, not homebrew! The Telford's extract is probably the major factor in the success of this recipe--done just right. You need to put in some sugar to bring up the level of fermentables, but don't put in too much, or you'll get a cidery taste. Don't follow Telford's instructions, which say that this kit can make five gallons--too watery.

2. 1 can (3.75 lb.) of Telford's Wheat Beer extract  
2 cups of granulated sugar  
1 oz. of Saaz hops  
1 lb. of cracked wheat malt  
1 package of Wyeast Bavarian Wheat Ale yeast

Steep the cracked wheat in about two quarts of water at a constant temperature of 170 degrees for 30 minutes. Drain and save liquid. Bring two gallons of water to a boil, then add extract and wheat mash. Add sugar. Add 3/4 oz. Saaz hops to the boil for 30 minutes. Remove heat. Add 1/4 oz. Saaz hops for aroma. Add cool water to bring wort volume to four gallons. Cool to 75 - 80 degrees. Transfer to primary and pitch yeast.

Comments:

I just tried this recipe, so I can't comment about the results. I steeped the cracked wheat malt to get even more of a wheat taste. It will be interesting to see if the Bavarian Wheat Ale yeast will enhance the flavor. This batch should be thicker and darker than the batch resulting from the first recipe.

From: BAUGHMANKR@CONRAD.APPSTATE.EDU  
Subject: Manchester; All-grain vs. Extract

For those of you planning to go to Manchester, why don't we all try to get together at some point during the conference and drink a few beers face to face without these computer terminals in the way?! You can all find me at the equipment expo. Dave Wills of Freshops and I will have a table displaying our product lines. I'll be the tall, skinny, 6'8" guy with curly hair. All Longnecks, Stubbies, and everyone in between are encouraged to stop by and say hello.

My two cents on the extract vs. grain discussion:

I started out in extracts. Then became a strictly all-grain brewer for years. Now I "go both ways". For lagers and light ales, I prefer all-grain because the flavors are more subtle and are easier to control if I mash. But for heavy porters, stouts, and barley wines, I now just use a light malt extract for the fermentables and steep crystal, chocolate, dextrin malts or roasted barley for flavor, depending on the recipe. I've found that the darker malts over-power any residual extract tang that might be present in the kit and gives me a full-bodied, robust beer in less time than it takes to mash.

See ya'll at the conference.

Subject: Processing Homegrown Hops

I just learned that a friend of mine has hops growing in his garden. They were obtained from Oregon or Washington by a friend of his that did not have a place to plant them. They have been unattended for a couple of years.

Is there a good source of information on taking care of and processing hop plants?

Is it worth the effort?

How do I go about determining what type they are?

John Mireley

From: pmh@media-lab.media.mit.edu  
Subject: beer bellies & exercise

It seems obvious to me that the size of one's beer belly is inversely related to the amount of exercise undertaken. When I was a student at Oxford I drank upwards of 8 pints of real ale a night but because I was rowing 2-3 hours a day I never got much of a belly. Nowadays, I don't drink nearly as much as I used to (and the beer's not as good or as fattening), but because I don't exercise as much, I'm starting to look like I'm expecting. Time to get back in a boat or something cause I'm not stopping the beer intake!

From: caa@com2serv.c2s.mn.org (Charles Anderson)  
Subject: CatUs Meow

I'm sort of a novice homebrewer, I've made a few batches that have turned out pretty good, and I've made some mead that preliminary indications show should taste pretty damn good even if the bottles didn't seal tight enough for it to come out sparkling like it should be (it's mildly fizzy).

But now I'd like to try some partial mashes and do some full grain mashes.

I was wondering about grain mills I've tried the bowling pin craking method for some speciality grains that I've added to some of my extract brews along with using a mortar & pestle but the latter creates too much dust, the former is a pain in the a\*\*. I've got a catalog from Great fermentations that has a grain mill listed at 49.95 but it doesn't say what type of mill this is...does anyone know? Is it a Corona Grain mill, if not is it better than the Corona.

Also on the lookout for Cheap extract & grains, I recently got a catalog (of sorts) from Green Acres it has 58lp pails of Briess extracts listed at \$82.80 this comes out to \$1.42 per pound add shipping and it'll be around \$1.60 this extract comes in (what they call) brewers gold, sparkling amber, traditional dark, and Bavarian wheat.

They also seem to have pretty good prices on grains at about \$1 a pound for the 20lb range and \$.80 for the 50lb range (actual range is from \$.

62  
to \$.86 per pound)

> BTW, when I printed the PostScript directly from my Unix  
> machine to the Apple LaserWriter, it came out 'Catus Meow'. When  
> I transferred to the Mac and printed it out, it came out  
> properly. Anyone else notice this?"

I did notice this it actually came out CatUs Meow, you will also not that just about everyplace in the text that there is supposed to be a ' you get a U. This is because the Mac has outputted (is that a real word?) the code it wants to print the value of the ' (it's actually an accent grave symbol not a right quote) which has a value of 213 which gets the high bit stripped off of it and comes out as 85 which is a capital U. This happens with the copyright symbol too. I posted a short perl script right after the recipe book was made available that converts the charaters

with thier high bits set into quoted octal /325 for the above character. Here it is again....if you don't have perl you should get it but if you can't a short C program to do the same thing should be relatively easy to do. (this should all be on one line)

```
perl -e 'while(<>)[s/[ /200- /377 ]/sprintf("///%3o",ord($&))/ge;print;]'  
recipe-file | lpr
```

Sorry for rambling so.

I don't think a cloudy sparge is too serious. I've also tried re-circulating this through the grains, and also experienced little improvement. But the resulting beers have cleared perfectly well, and tasted fine.

Dave Line in his Big Book of Brewing says never on any account tip the tun at the end of sparging to extract the last part of the mash below the tap, as it is full of gunk and will spoil the beer. I just couldn't bring myself to junk 1/2 gall of potential beer, so I tipped the tun, Sure enough it was full of gunk. I strained it and re-circulated it. It still came out cloudy, so I fermented it anyway. There was nothing wrong with the beer at all! It cleared bright quickly and tasted fine. Can someone say whether this really is inadvisable in their experience, not opinion.

I suspect the cause of the cloudiness is powder in the malt. I've had two consecutive batches from the same supplier, one full of powder and one without but with too many whole grains. I don't think the cracking/crushing is as consistent as it should be. I also got widely varying amounts of sugar from these two batches. Far less came out of the batch with too many whole grains, barely 60% extraction. So I'd rather have a bit more powder and more sugar for my money, than a wort that is clear because there is nothing in it.

Lastly - this may be sacrelige - but who is Miller? I'm from the UK and have never heard of him. Our brewing gurus are Dave Line and (recently) Graham Wheeler of CAMRA. Can someone please mail me the title of his book(s) with publisher, date and ISBN if possible.

Thanks,

>From: dbreiden@mentor.cc.purdue.edu

Last night I wanted something light and thin, so I bummed a Miller GD from my roommate. It's a pretty good beer for when you want an American style beer. Anyhow, I was looking at the label and recalling the stuff I've heard about Miller brewing and the treatment of hops. On the label, the words "No additives or preservatives" are boldy displayed. And of course, the ingredients are not listed, they simply say "Contains malt, hops, yeast, and water. Selective listing indeed. So I was thinking, "If they treat the hops, wouldn't that result in an additive?"

That's interesting, because I was "forced" to drink one the other day on a Delta flight (they don't carry any imported beers!). So my parched mouth succumbed to the temptation. One thing I noticed was the head of this beer. They must be adding some sort of heading agent as the head was much more creamy and long lasting than those I'm used to. In fact I thought "Gee this stuff is lingering too long." The foam that did stick to the sides of the cup never did subside, even after the beer was long gone. After that experience I can't imagine there is only malt, hops, yeast, and water in the beer.

From: Brian D. Moore <bemo@spacsun.rice.edu>  
Subject: Sucrose to Invert?

Reading yet another book on winemaking, I have come across a procedure to, supposedly, convert sucrose to invert sugar. I figure posting here would be the quickest way to test/deflate the procedure. "The Winemaker's Companion" by Turner and Berry suggests that it is possible to accomplish the conversion by boiling the sugar with 1 tsp. citric acid, which I suppose is to perform the same conversion as the yeast's 'invertase' enzyme. Does this, in fact, work? It is not mentioned in Berry's more famous work, and the books appear to be equally old. Should this practice be restricted to winemaking, or does the presence of citric acid not affect beerbrewing unduly?

From: Tom Dimock <RGG@CORNELLC.cit.cornell.edu>  
Subject: Bellies and Beer

If my personal experience is any indication, you can drink more beer at the same time you are reducing both your cholesterol and your "beer belly".

A year ago I had a cholesterol count of 220 (not really bad, but needs attention according to my doctor). I have seriously reduced my fat intake,

but because I work eight minutes walk from the Chapter House (owned by James and Laurie Clement, who brew four-star beers in their brewery at Vernon Valley, N.J.) I have been drinking more and better beer. This year

I am 10 lbs lighter (all off my belly) and my cholesterol is down to 134. So cut out the junk food (and ice cream and chocolate, sigh...), stop worrying, and have a homebrew!!

-----

Date: Mon, 17 Jun 91 13:44:38 EDT  
From: hersh@expo.lcs.mit.edu  
Subject: Cholesterol, Strawberries, Brew Bags

I am in a similar situation to Ken W., in that I partake of beers on a regular basis (say a pint a night with dinner most nights, more on the weekends), and have an excellent cholesterol level (good ratio, high good, low bad). As for mental acuity, what's that?? :-)

On strawberries, I made a strawberry/blueberry mead a while back that I think is just now coming into drinking age. The strawberries can be smelled and also impart a present but not overwhelming flavor. I'll have to double check the recipe, but I recall being surprised that I could taste the strawberries as much as I did, since I did not add an overwhelming amount, however the taste is not that strong overall.

Everything I've heard about these Brew Bags is that they are a gimmick. An awful contraption that leads people to believe that they can make beer at home as if it were cake mix, and produces beer that most homebrewers would do a spit take with. All indications are that this is a disservice to homebrewing in that more often than not the quality of the product is so poor as to dissuade people from believing that they can make good beer themselves. CAVEAT: I have never tried these myself, only read a number of reviews by others, so perhaps I'm totally wrong (it happened once before, but fortunately there were no witnesses :-)), but I'm not about to go toss \$30 to try it, after all I have lots of homebrewing equipment so I don't need no steenkin bags...

>>nice view of the city. Recommended for the view.

The name of the Irish Pub is The Wild Rover (or is that the Red Rover?).  
It is on some Greek sounding name that starts with the letter K. Sorry  
for the vagueness, Manchester is still a foreign town to me. Never  
been there, but my wife has and she says it is a great place to meet and  
drink good beer. The description for the Salty Dog is pretty accurate.  
It is basically a college hangout place.

Portsmouth has a new brewpub called the "Portsmouth Brewery." Portsmouth  
is a seacoast town which is 45 to 60 minutes from Manchester. They had a  
wheat beer, pale ale, and a brown ale on tap. The wheat and pale ale had  
a good flavor, though a little cloudy. The brown ale was lacking in  
taste,  
I thought. I definitely recommend it, besides Portsmouth is a lot more  
interesting than Manchester. There are other decent bars and pubs in  
Portsmouth but I don't remember the names. If you want more information  
just  
e-mail me and I'll ask my wife (she is the native). I'll post a summary  
if there is enough interest. Hurry cuz time is running out.

From: MIKE LIGAS <LIGAS@SSCvax.CIS.McMaster.CA>  
Subject: CABA Promo.

Due to the encouraging response to my recent posting about the Canadian Amateur Brewers Association (CABA) in which I asked interested brewers to E-mail me directly for information, I have decided to post this letter about the CABA directly to HD. A common question I have been getting is "Can Americans join up?". The answer is a definitive YES. The CABA is much like the AHA in its scope of interest and activities, as the following letter describes.

\*\*\*\*\*  
\*\*\*\*\*

#### WHAT IS CABA?

The Canadian Amateur Brewers Association (CABA) is a non-profit organization whose purpose is to promote homebrewing as an enjoyable hobby through educational publications, events, and other activities.

#### HOW CAN CABA HELP ME?

The Canadian Amateur Brewers Association is dedicated to improving the skills and knowledge of its members. Members are invited to participate in the special events organized including the annual conference, frequent competitions and special seminars.

#### HOW LONG HAS CABA BEEN AROUND AND WHAT HAS IT DONE?

CABA was started in 1984 as a forum for homebrewers, both novice and experienced, to exchange ideas, skills and their love of homebrewing. Since then annual conferences, competitions and tastings have been organized.

CABA produces a newsletter every two months to keep its members informed of recent events, club news, and a members forum which allows members to voice concerns, ask questions and to get answers.

CABA has also had mail in competitions, and is at present planning judging training seminars to be part of an ongoing educational program.

In October of 1990, the first Board of Directors was elected from the membership. The Board is currently registering the organization as a non-profit group.

For less than the savings from a single batch of homebrew, you can enroll in the only national club in Canada which will help you brew better beer.

THE BENEFITS OF JOINING CABA

Newsletter every two months    Annual Conference  
Annual Spring Competition Fall Mail-in Competition  
Judge training/Tasting seminar Discounts at retailers  
Members Forum

A greater variety of regional activities across Canada will be planned as CABA's membership increases.

HOW DO I SUBSCRIBE?

To become a member of the CABA mail a cheque/money order for \$15 made out to CABA, to the following address:

CABA  
19 Cheshire Dr.  
Islington, Ontario  
M9B 2N7

Please include the following information on a separate sheet of paper:

NAME  
ADDRESS  
POSTAL CODE  
HOME PHONE (include area code)

It would also be appreciated if you could provide the following information:

I started brewing in 19\_\_.

I brew with: [please check appropriate line(s)]

From: Doug Dreger <dreger@seismo.gps.caltech.edu>  
Subject: Weizen Beer

I was wondering if anyone has been successful in making a weizen with a medium to strong clove taste? The local brewpub offers a wheat beer that doesn't even have a hint of cloves and several homebrewing friends make very good wheat beers that have negligible clove taste. My HBing friends use the wyeast wheat beer yeast. I don't know what the brewpub uses.

Anyway I want to make a weizen with a strong clove taste. I propose to mash 6 lbs of wheat malt with 4 lbs of klagges, add about 1.5 oz's of medium alpha hops and the wyeast wheat beer yeast. My question what else can I do to help develop the clove taste. Does fermentation temperature play a role? I am planning on fermenting in my refridge at about 55 to 60 degrees.

Thanks  
Doug

Hah, hah, hah! Betcha those clay pots never saw a drop of Clorox solution.  
Let alone the, ah, interesting character that pre-chewed mash lends to the final brew. Father Barleywine, what do you think of that? I can see the recipe in 'The Cat's Meow, 2nd edition':

XINGU THUNDERF\*\*K

5 pounds Amazon maize  
5 pounds winter wheat  
Lots of lupine herbs

Chew grains thoroughly. Get your family and friends to help. Spit into malting vessel, and cook over an open fire, making sure you expose the mash to the smoke....

Leave wort outside for 3 days, after which time you may then bury your fermentation vessels until final gravity reaches 1.005. Don't worry about the scum at the top of the vessels, draw beer from the bottom and enjoy!

Actually, I wonder what this stuff tastes like? I'd love to see M. Jackson cruise around native lands, sampling folk brews.

I somehow find myself in the unenviable position of saying this but...

M. Bass writes:

> The foam that did stick to the sides of the cup never did subside, even  
> after the beer was long gone. After that experience I can't imagine  
> there is only malt, hops, yeast, and water in the beer.

Why not, Good German beers exhibit exactly this type of behavior when poured in a "beer clean" glass. I've brewed many a homebrew that exhibited nice smooth carbonation, excellent head, and left a lace. While they may choose to brew swill for marketing reasons, the skills of the brewers at places like Miller and Anheuser Busch are actually quite good. It takes a lot of skill to create a product that while brewed at several different plants across the country, tastes the same everywhere, state to state, month to month, year to year. It's just so sad they choose to exercise this enviable skill in the pursuit of thoroughly lackluster beer.

Also Tim Dimock says:

> So cut out the junk food (and ice cream and chocolate, sigh...), stop  
> worrying, and have a homebrew!!  
Tim I must be some kind of alien, cause I eat chocolate every day, and while I moderate my consumption of ice cream in recent years, I still eat it an average of 1-2 times per week, yet I have the lowest cholesterol of anyone I know (self satisfied smirk). I think a good exercise regiment, and otherwise reasonable diet help a bit.

This has been my experience with the Wyeast culture;  
it's actually two yeasts: *S. Delbruckii* (the weizen yeast) and  
*S. cerevasii* (?) (top fermenting ale yeast). They use a  
mixture because they're afraid *S. Delbruckii* alone would be  
too intense for most folks.

If the fermentation temperature is too low, I think  
the ale yeast takes over. *S. Delbruckii* is just not as  
vigorous a yeast as most, and doesn't compete well. I've had  
good wheat beer made with it; the secret seems to be to  
ferment it warm (70F+).

An easier way is to get ahold of MeV #033, a pure  
weizen yeast culture.

In my quest for the elusive clove aroma, I've done  
some rather extreme things. My first weizen was 100% wheat  
extract (Ireks) using the Wyeast, and had very little wheat  
character. My second was the same wort (but double strength; I  
call it a "doppelweizen") with the MeV yeast, and it is  
incredible. LOTS of wheat character.

To further isolate variables, I'm brewing a barleywine  
with lite malt extract with the yeast from the secondary, to  
see just what it takes to get the taste. I'll report when it's  
ready to drink.

Hang in there. It *can* be done.

From: eisen@kopf.HQ.Ileaf.COM (Carl West x4449)  
Subject: bellies, wheat, long head

The trouble with beer, wine, etc. is that the calories add to my mass and the alcohol adds to my inertia, and the combination adds to my belly.

Is there any difference between weizen, weissbier, and wheat beer? or are these all names for the same thing? A friend of mine had some weissbier in germany and loved it. She says she'll do nearly anything ;-) for me if I'd make some for her.

Michael Bass commented on the suspicious the longevity of the head on his Miller Genuine Draft. I've got a batch of extract brew that leaves head on the side of the glass 'til the next day (by which time it's dried out). I added no heading agents, just amber extract (forgot what kind), Saaz hops, water, and Whitbread Ale Yeast. Unless the extract had stuff in it that wasn't on the lable, we can't conclude for sure that Miller is dicking around with heading agents.

I think your proposed fermentation temperature is too low. The wheat beer yeast is an ale yeast, and should be fermented warm. Personally, I try to ferment my wheat beers above 70 degrees. The warmer the ferment (within reason), the more clove esters you'll get.

Your recipe looks about right to me. For a Bavarian Weizen you want 50-60% wheat malt. Depending on your mash/sparge system, your beer may come out a bit too strong with 10 lbs. of grain. You might also think about adding/substituting a little Munich malt for more maltiness and a touch of color.

Definitely use the Wyeast wheat beer yeast. It is the key to the clove aroma. If you can't get that, try Vierka lager yeast (dry). When fermented warm, it also produces a marked clove aroma.

At the end of fermentation, the Bavarians lager their Weizen beers for at least 3 weeks below 40 degrees. I have never tried \*not\* doing this, so I don't know how important it is.

At last month's meeting of the Brews Brothers, a few of us had a mini tasting of commercial (German) Weizen beers. We were all struck by the wide range of flavors among the various brands. The Paulaner was rather sweet and clove, while the Spaten had a very strong sour/tangy note to it. (Of course, who knows how old these beers were and what atrocities they'd been subjected to?) I drank a Pinkus last night, and it seemed somewhere in-between. Personally, I go for sweet and clove.

Good luck!

Subject: 4-vinyl guaiacol

From: Doug Dreger <dreger@seismo.gps.caltech.edu>

>I was wondering if anyone has been successful in making a weizen with  
>a medium to strong clove taste? The local brewpub offers a wheat beer  
>that doesn't even have a hint of cloves and several homebrewing friends  
>make very good wheat beers that have negligible clove taste. My HBing  
>friends use the wyeast wheat beer yeast. I don't know what the brewpub  
uses.

The clove taste in Bavarian wheat beers comes from a compound called  
4-vinyl guaiacol. It is produced by *Saccharomyces Delbruckii*, which is  
the yeast strain used for wheat beers in Germany. American wheat beers  
typically don't use a *Delbruckii* strain, and consequently don't have the  
clove taste.

Wyeast #3056 is a mixed strain. It has both *S. Cerevisiae* and *S.*  
*Delbruckii*.

Like your friends, I found it produced no clove character. I'd suggest  
trying MeV Lab's wheat beer yeast (#033). A friend used it recently with  
very good results. His first batch was a standard weizen and had distinct  
clove tastes with very pronounced banana esters. He later pitched the  
dregs from the first batch into a second. The second batch was a dunkel  
wiezen. The banana esters were very strong and the clove taste diminished  
substantially. I'm a little sketchy on the details of the fermentation,  
so I don't know what's attributable to what. At any rate, they were both  
good beers, and had more clove than any brew fermented with Wyeast that  
I've encountered.

On Sunday I made a wheat beer using MeV #033 myself. Thusfar all I can  
say  
is it's a slow starter. I pitched a 1.5 liter starter into 15 gallons  
early Sunday evening, but there was still no activity late Monday night.  
Have others out there found it to be a slow starter also???

"

The thinking of the Big Brewers seems to be something along the lines  
of, "if you put it in and then took it out, it's as if you didn't  
put it in". This thinking is quite common on the cellaring end of  
the process, where adsorbants like polyvinylpyrrolidone, silica  
gel, or Bentonite are added and later filtered out. My  
understanding is that after the chemical treatment of the hops,  
what's left is just the iso-alpha acids, so they don't really  
need to mention the reagents or intermediate products ...

Subject: Great advert...

Perusing the latest issue of Classic and Sportscar (a delightful issue,  
BTW),  
I ran across a great advert for Theakston. It is a centerspread with  
nought  
but moody a photograph filling about eighty percent of the pages, and a  
hand  
pump with Theakston badge and the words "Brewers in Masham, North  
Yorkshire  
since 1827. Best Bitter, XB and Old Peculier."

The photo is of some bags of hops with the brewery name on, and the  
brewer  
tending a long feedpipe into a brewing square. The caption on the photo  
reads  
"The suppliers want this hop filter for their museum. We need it for our  
beer."

I think I just added a third brewery tour to my must list this September.

Cheers...Gary

From: jbergmann@aqlan.ssc.af.mil  
Subject: New Book, Germany

Howdy All,

I've got two major topics. First is a new book called The Absolute Beginners Manual on Homebrewing Beer, or 'The Beer Book' for short. It is written by my recently retired Base Commander, Col. Dave Vogl. He was Base Commander of Maxwell AFB, Al. since 1988, retired yesterday.

Anyway, like the title says, this book is for BEGINNERS!!!. It is perfect for that person who is still hesitant about starting homebrewing or may be slightly intimidated by Papazian or Miller. (I know I was; after first reading TCJoHB, then Miller's book, I wondered if I was going to have to drag out my college organic chem books :-). The book deals exclusively with extract brewing, although he does mention the more advanced all-grain process (about 1 page worth). There are sections on ingredients, equipment, soda pop, a couple of recipes (the Recipe for Fun is super...), and several good charts and conversion tables.

Again I stress that this is for beginners and those who are probably worrying too much about getting started. It would make a perfect gift for these types of people. You can request a copy by writeing to:

The Beer Book Price is \$10.00 + \$1.00  
329 Center Drive for shipping and handling.  
Montgomery, Al. 36113

- - - - -

On a totally unrelated note, I just received orders to Germany :-). As a result, I will probably be putting my homebrewing on hold for about 4 years. If anyone has Norm Hardy's six(?) part posting on German beers and stuff, I would be most grateful for a copy. I will be arriving there just in time for Bad Dierkeim (sp?) and then it will be off to OktoberFest. I will think about y'all while I'm there. Really... ;-).

Thanks for all the info over the past year and the introduction to a wonderful pasttime.

That's what you do, but read on...

> If I don't cut the tube, will I just be able to suck the sediment  
> off the  
> bottom with the first few glasses?

Yes.

> If I suck the sediment out too early  
> will I have problems carbonating? (I definately prefer natural  
carbonation).

No. The yeasts in suspension do all the work; the ones  
on the bottom just sort of lounge around (hey, what would  
\*you\* do in a bathtub full of beer? 8<:^)

> the

Personally, I would recommend NOT cutting the tube, unless you can  
easily get a replacement. I purchased a used (for homebrew) soda kegging  
setup, and the previous owner had already cut the tube off. By doing  
this,  
there is always about 1 quart of beer wasted. If you artificially  
carbonate, there is no sediment, but there is wasted beer. With primed  
kegs,  
the first glass of beer pulls out most of the yeast anyway, so why cut?  
Just be sure that is what you really want to do, because once you cut  
it, you can't make it longer again without replacing it.

Since CO2 is cheaper than dextrose or malt, I always artificially  
carbonate - plus I feel the beer has a slightly 'cleaner' taste than  
when primed (less yeast in suspension?), and the beer is ready to drink  
sooner.

From: zentner@ecn.purdue.edu (Michael Zentner)  
Subject: Cholesterol...and who does what

I was going to stay clear of this discussion, but I feel like I have to add to the following, from Jay Hersh:

>Tim I must be some kind of alien, cause I eat chocolate every day, and while I  
>moderate my consumption of ice cream in recent years, I still eat it an average  
>of 1-2 times per week, yet I have the lowest cholesterol of anyone I know (self  
>satisfied smirk). I think a good exercise regiment, and otherwise reasonable  
>diet help a bit.

with which I agree, except that it seems like everyone has overlooked one thing. Another important factor affecting your cholesterol level is genetics. Just because one guy can get away with eating chocolate all the time does not mean another guy with exactly the same exercise habits can get away with the same diet. Also, it seems that given you have high cholesterol, your potential for developing cholesterol related diseases is also somewhat governed by genetics. Maybe some of the Med people on the list can comment on the validity of this. I take it as an extrapolation from statistics on smokers, where not every chain smoker develops lung cancer.

And then there's the happiness factor. It just seems that people who are never happy tend to age rapidly. You can be afraid of ingesting/  
inhaling/  
coming in contact with everything around you for one reason or another. Maybe it's just me, but if I can't do some of the things that "aren't good for me", I'd likely not have much fun, and not be very happy either. Ultimately, beer is not good for you. You can get all the good stuff from  
beer (vitamins,proteins, etc...) by ingesting malt/yeast/hops in other forms which would probably be healthier than beer, but there's the beer enjoyment factor. I guess my point is, sure, exercise and eat sensibly, but obsessing on "clean living" can't be good for most people...so once in a while, eat that steak and have the chocolate pie. I'd rather trade the enjoyment for the few extra years.

From: CHARRIS@MAX.U.WASHINGTON.EDU  
Subject: homegrown hops alpha% ???

Many of my homebrewing cohorts grow their own hops as our Pacific Northwest climate makes this an easy horticultural challenge. I have gotten as much as 5 lbs. (dried weight!) of hops from 2 prolific Hallertaur and Northern Brewer vines in my yard.

The question that often comes up, is whether there is any way for the home hopgrower to measure, or even crudely estimate, the alpha% of our homegrown cones?

At present, most of us just guess using the lower end of the published range for the strain that we "believe" was the source of our original rhizomes. But since some of these vigorous vines are of questionable heritage we'd like something a little better.

Any suggestions?

Subject: Hop Bags & Scott Yeest

I was talking with a fellow brewer last night and he mentioned using a muslin bag to keep his hops in during the boil. I got to thinking about this and was wondering what effect this would have on extraction rates with regards to bitterness. I was under the impression that the mechanical action of the boil was necessary to optimize extraction of alpha acids in the hops. Wouldn't the bag interfere with this? I would be most curious to see this discussed. Same person mentioned using a new (to me anyway) brand fo ale yeast made by Scott (sp?). It is supposed to be a \*very\* clean fermenter that produces a minimum of fermentation by-products. From what it sounds like, this would be ideal for summer brewing condition (for those of us without refrigerator space). Has anyone out there used this stuff? Care to comment?

mill,  
> if not is it better than the Corona.

I've got a copy of Great Fermentations of Santa Rosa's 1991 catalog  
(they're just a couple of miles from me), and the only mill that I can  
find listed is the "Corona Grain Mill" (\$49.95). Do you have the  
catalog for "Great Fermentations of Marin"?

Also, if you crush your own grain, do it far away from where you  
boil the wort, bottle, etc.. The grain husks contain acetic acid  
bacteria (or is it lactic acid bacteria?), and you may not want to take  
the chance of contamination via grain dust in the air.

> spit take with. All indications are that this is a disservice to  
homebrewing

Actually, a "bag o'beer" is what got me started in homebrewing.  
Someone gave me one as a present, and it turned out OK, although very  
flat (even by British standards). It did, however, have a slightly tart  
taste that increased with time (read: probable acetic acid bacteria  
contamination). You are probably right in saying that the produced beer  
is "not good".

However, I suspect that all of the books/kits/recipes that call for  
half malt/half cane sugar are doing a larger disservice. I've seen bad  
recipes, etc. a lot more often than I've seen brew bags (I've only seen  
the brew bags carried in only one store).

Subject: lambic tasting

I had the pleasure of attending the Belgium lambic (and similar beer) tasting at the AHA conference last night. I'm too ignorant of the style to post any kind of in-depth beer review; I'll leave that to someone who took notes (you know who you are). Of course ignorance won't stop me from saying \*something\* about it.

There were maybe 25 people in attendance, four people to each bottle, which gave each of us a good portion. We sampled geuze (sp?), kriek, framboise, Belgium brown ales, and some homebrewed lambic-style beer. An educated and interested group of tasters made for a very enjoyable and informative session. The homebrews were very good, some were extremely close to the real thing. I never thought I would hear a homebrew \*praised\* for having a "horse-blanket" aroma!

Kudos to Mike Sharp for organizing the tasting and to Dan Hall (BFD!) for helping out.

My one taste observation is a unique sensation I noticed as I was driving home: my mouth felt extremely clean, as opposed to the way it can feel after a night of drinking "normal" beer. I would guess this is because the acidity of the lambics cuts through the residual sugar that would normally be left on your teeth. I can still feel the effect today! Belgium mouthwash!?

Subject: Corn

Has anybody ever used corn starch in brewing? Papazian says that corn starch can be added directly into the boil, without any sort of pre-cooking. We are trying some lighter-bodied beers and it seems that corn starch would be a cheap substitute for corn sugar.

A possibly unrelated note on cider making: it seems that the addition of some acid blend to the mix allows for a much greater amount of sugar to be put in, while maintaining proper "tartness" (as opposed to "dryness").

Subject: rabbits & hops

It seems that rabbits like hops.

Sometime yesterday the local rabbits got to my hop plants. The Hallertaur is now 4 inches high, and the Bullion and Cascade are missing leaves from about 4" to 18" off the ground. The Saaz wasn't touched. When I get home tonight, I'm fencing in whatever's left.

Hmm..."Saaz, the anti-bunny hop"

Y'know, I'm kinda surprised that noone has marketed a hops bag with the name "The Hop Sock". Or maybe I just missed it.

Subject: **Straining pellet hops**

I used to use only flower hops for my brews. I could run the wort through a hopback and get it crystal clear before pitching (i.e. no trub). But I have recently switched to pellets, and the old hopback technique doesn't work. How do you filter out all the hops from the wort without having to wait hours for the tiny bits to settle out?

From: mike\_schrempp%42@hp4200.desk.hp.com  
Subject: more on mashing

As a newer masher, I'm still in the process of getting my process smoothed out, but I have some comments regarding Jim's mashing vs extract that haven't come up yet.

The bottom line, in my opinion, is to do it. Trying mashing can be cheap, fun, and enlightening. Your contribution is time and patience.

On Quality: I've noticed better CONTROL of my beer. By choosing mashing temperature, you can cause your finished beer to be sweeter (hotter mash) or less sweet (cooler mash). The place that made your extract had to make this choice when they mashed for their extract. Their choice, not yours, and since a hotter (sweeter) mash is quicker, economics may push the extract makers this way. Controlling the temperature is easy with the correct, cheap equipment.

On time: Plan a full day for your first brew. For my full mashes, I start early on a Sunday, get the mash started and read the paper while it works. My personal time breakdown for beginners would look like this:

Crushing the grains - don't, buy pre crushed. As a beginner this not the best

way to start the day.

45 minutes - getting the mash water hot

10 minutes - getting the grains and mash water mixed (Mash-in)

30 minutes - protein rest/ph adjust. A cool temperature rest. I believe this

is good for beginners even if it's not needed because it gives you a chance to work with the mash, see the volume, use the thermometer, etc. This will be good practice when it comes time to raise the mash to starch conversion temperature, etc. Also, play with those damn ph papers for a while, then throw them away when you can't make them work and hope everything will be okay as is and don't sweat it. Beer was invented before ph was.

15 minutes - raising mash to starch conversion temperature. For the beginner,

shoot for the middle of the mashing range (63C 145F) and take anything close (58-67C 136-152). Don't sweat it. The only danger is overheating.

2 hours - starch conversion. Depending on your temperature this can actually

take anywhere from 15 minutes (hot mash/sweet beer) to 2 hours (cool mash/dry beer). During most of this time you are reading the paper. Do the iodine test often to see what the hell it's all about, not just when you think the mash is done. I usually do it the first time during the protein rest just to reassure myself I know what I'm doing. If you are doing a low temperature mash you may get bored after an hour and decide to raise the temperature some more to speed things up. WOW, now you're doing a two step mash.

30 minutes - raise temperature to 75C (167) to kill enzymes and stop the mash.

90 minutes - sparge. The first 45 minutes are spent recycling the wort (remember

to keep it hot) and worrying about why it won't clear, the next 45 minutes are spent rinsing the grains with hot clear water. If the sparge stops running, don't stir it, stab it with a knife to get the sparge water down into the grain bed. Expect low yield, about 25SG points per pound per gallon.

120 minutes - boiling the wort. It might not really take this long, depending on

how much sparge water you used. I advise stopping the sparge early to keep the blood pressure down. You'll know what I mean when you sparge the first time.

60 minutes - cooling the wort in the sink (in the pot, of course).

15 minutes - racking into the carboy, leaving the hops behind.

That it, and all in less than 9 hours. Not bad for the beginner.

On Equipment: You need a big enough pot (not necessarily 10 gallons). I use one

of those enameled pot. I think about 3-4 gallons will do for the beginner.

(when the pot is full, the sparge is over!).

For a grain strainer (only advanced brewers need to call it a lauter tun)

you can get by with one of those steamers or make a two bucket version.

I

built (read "drilled") my first 2 bucket thing while my first mash was converting. I think I spent about \$10 for 2 buckets and a spigot.

You can mash in your boiling pot, with the pot in an oven on low, but I think

it's easier to use a picnic cooler. I'll assume that everyone has a picnic

cooler of some kind. Wash the cooler (no need to sanitize, you'll be boiling

everything later) and throw in the dry grains. Add the mash water and you're

done. When it comes time to raise the mash temperature, it all comes out and

goes back into the pot on the stove, then back into the cooler. I'd say any

picnic cooler will do, but I use one of those 3 gallon Gott water jugs. If you

go with one of these, it can be the outer bucket of your strainer and it has

a built in spigot. It also keeps your grain bed hot during the sparge, which

is a very good thing.

Well, I think I've stretched this out as long as I can.

GO FOR IT!

Mike Schrempp

> made by Scott (sp?). It is supposed to be a \*very\* clean fermenter  
> that produces a minimum of fermentation by-products ...  
> Has anyone out there used this stuff? Care to comment?

Howdy, Oran! What he might be referring to is Lallemand yeast, now being distributed by a company named Scott. It's dry yeast, sold in bulk to the brewpub/microbrewery industry, and it is indeed clean and predictable, and not particularly attenuative. I recently had tastes of two otherwise-identical batches, one fermented with Lallemand and the other with reused Sierra Nevada ale yeast. The difference was amazing, and most felt in Sierra Nevada's favor. Nevertheless, one of my first orders of business when I get back from vacation is to make up a pale ale, fermented with the small stock of Lallemand I've been hoarding since March, and dry-hopped with Chinooks.

another  
>beer and quit thinking about it.

One way to find out what ingreddients they use is to contact the nearest  
brewery of the beer in question. I have found that the brewers use corn,  
rice, and whatever else. The magic words to look for are "cereal grains."  
"

This usually indicates (IMHO) that the brewer is using rice or corn. They  
use these items to stretch the malt grains thus using the same amount of  
the more expensive grains and making more beer. The problem is if the  
drinker has a problem with the other grains. Example: my friend is  
allergic to corn and cannot drink most beers because of that. So, he  
is constantly looking at the ingredient list for those magic words.

Subject: Brewpubs, and the lack thereof, in LA

In response to Laura's request for info on LA brewpubs:

When I moved down here four long years ago to attend grad school there were exactly zero brewpubs in the LA area. Pretty depressing having moved here from Seattle.

Well things aren't quite so bad for anyone traveling to Southern California today, but not great either. I don't know of anything in the Anaheim/Garden Grove area in particular, but here are the options I am familiar with:

Gorky's: faux-Russian food and beer joint in two locations, Downtown LA, in amongst the warehouses, E.8th Street and about Maple Street (can't miss it) and Hollywood, just North Hollywood Blvd. on Cahuenga Blvd. Pretty good "Red" Ale.

Eureka: very, very trendy Wolfgang Puck restaurant and brewery. Very large, very metallic, and very pretentious. The unfiltered-pilsner is however a nice Czech-styled beer. Located at 1845 S. Bundy Drive in West LA. Find this location then go around the block, the entrance is on the other side.

Alpine Village: a strange sort collection of things German in the middle of nowhere (Carson). Location of the Oktoberfest celebration in LA. They brew beer all year but I am not sure where it is available past their two month long Oktoberfest, perhaps in the restaurant. I drink it at a local, Santa Monica, pub. It's located just off the Harbor Freeway (110) at Torrence Blvd. in Carson.

There's also a place in Pasadena called something like The Rose and Thistle(?) which I haven't been to. Hope you enjoy your vist. Also, I hope another posting lists brewpubs I don't yet know of.

From: David Taylor <DAVID@phillip.edu.au>  
Subject: Extremely important information

Gooday

A few tips and comments:

Dave Line mentions 'torrefied barley' as contributing to loose mashes and easier sparging, while contributing a slight grainy taste. It's really just barley (unmalted) that's been popped like popcorn. I made some once in a microwave which gives clean heat without toasting the grains. The barley had to be on a glass or ceramic plate as the plastic u-wave proof bowl I tried came out with grain melted into its base. It took 8 - 10 mins before most of the grain had popped. At the time I only had dried yeast so poor yeast performance masked any finer flavours. It may be worth a try if your mashes run too slow, and with the better yeast cultures available today.

Does everyone know the fastest way to empty a bottle? I don't mean to stick a straw in it! I mean when you're washing dozens of bottles for your next batch. It was demonstrated many years ago by Professor Julius Sumner Miller on 'Why Is It So'. He had two flagons (~4.5litre) full of water, one he gave to his stooge, the other he held. On the signal the stooge started pouring and shaking the flagon; Prof JSM held his neck down and gave it a swirl - the water whirlpooled out the neck and emptied in much less time. I've always swirled water out of bottles since - it's fun just to watch it work - and to think how much sooner you'll be emptying bottles of brew into a glass!

As a fuzz-faced home brewer, what is it about not shaving in the morning that makes a bloke want to brew beer? Anyone any ideas?.... Eh Charlie?

And a similarly demographic question - most homebrewers who read HBD are computer literate and have technical abilities. We have access (a privilege I feel) to this fast, worldwide network on which we piggyback our homebrew discussions. I'm just wondering if brewers with net access are different or better than those without? I recall the atmosphere of ignorance that I laboured in when I started, compared to the immediate information available in HBD and via email. Has this been discussed before? Could it be the subject of a future editorial by Charlie P.?

Some day some unique styles may evolve:- Bit-Bucket-Bock? Klages-Kluge-Ale?  
Megabyte-Memory-Malt-Liquor? Program-Counter-Porter? Stack-Overflow-Stout?

Bye now

Subject: Thursday night at the Nationals...

Hi -

Even though I live twenty minutes from the venue, schedules permitted me only Thursday night (Club Night) at the National Conference. What a blast! A buffet dinner (with beer available of course) gave me a chance to meet with several nice folks from Michigan and my home club. The remainder of the evening was spent roaming a large room full of people and tables - both somewhat full of homebrew 8') The brews were generally excellent, as was the camaraderie. I met many of the "legends of homebrewing", who were all very friendly and approachable - just folks. Just plain fun.

I would heartily recommend the experience. In fact, I probably will go to one sometime - all of it - even though it will be much further away.

Cheers...Gary

>From: <S94TAYLO%USUHSB.BITNET@CUNYVM.CUNY.EDU>  
Subject: Half-Full Bottles

Over the few years that I have been brewing, I have heard many stories about how a large headspace turns into an exploding bottle. The most outlandish one is that yeast is inhibited by pressure generated during conditioning, and if the headspace is short, the yeast dies out faster, hence less carbonation. More headspace, yeast carbonates longer. I don't buy it! This version assumes (I believe, incorrectly) that there is "too much" priming sugar at bottling time, and you are just counting on the yeast to die off just in time.

The way I think it happens is based on simple stoichiometry of biochemical pathways. When a molecule of glucose (or any other monosaccharide) is metabolized in the absence of oxygen, two (2) molecules of CO<sub>2</sub> are produced. When the same molecule is metabolized in the PRESENCE of O<sub>2</sub>, as in early fermentation (bad use of that word, sorry), SIX, count 'em, six molecules of CO<sub>2</sub>. When you bottle with almost no headspace, there is almost no O<sub>2</sub>, and so every sugar molecule makes only 2 molecules of CO<sub>2</sub>. However, when you have a large headspace, there is lots of oxygen in the bottle, which is used to make way too much CO<sub>2</sub>. The other danger is that air compresses, and compressed air propels glass around the room or wherever the bottle is when the glass fails. Beer doesn't compress, so when glass fails with no headspace, it just goes "crik", and kind of runs onto the floor. These messages are just too damned long, and I need a beer.

>From: Dave Speed <dspeed@sactoh0.SAC.CA.US>  
Subject: Stainless Equipment Questions

Greetings !

I have two questions concerning stainless steel equipment which is used by home brewers.

First, I saw an ad in Zymurgy from an outfit in Seattle that makes 15.5 gallon brewing kettles from SS kegs. They advertise a price of \$65 for these. I've also heard mention from several here about their own keg kettles.

As I've never torn up a keg to see the internals, I wonder at what is involved. I have more that the normal complement of tools (incl oxy-act torch and high speed grinders), but know from personal experience that stainless steel is difficult to work.

I'd like to hear comments from folks who have trod this path before me.

Second, I moved from bottles to kegs rather quickly and now have a small collection of used pin-type connector 5 gal kegs. I am experiencing a problem with rust in these kegs, something that I did not think could happen. After cleaning a keg and before use (sometimes up to 2 weeks), I stored the keg full of sanitizing solution (bleach and water). Now I am experiencing something that sure looks like rust on the inside of the rounded top part of the keg. One other keg appears to have a small "spot" of rust down on the rounded bottom paer (again, inside the keg).

The sides appear to be stainless, the top and bottom are not so obvious. I'm not a metallurgist, but have delt with more than my fair share of stainless. Neither of these kegs was manufactured by Corneilus; one is Firestone, and one is ToteSystems.

Is this a fatal problem in a keg ? Would it do the same with beer in the keg (given the acidic nature of beer) ? Can it be \*fixed\* ? Should it be fixed, or should the units be retired ? I'd like to hear of others experiences along these lines.

BTW, I am relatively new to the digest, and would like to say that this has been a useful group for me. Please keep the signal to noise ratio high.

Dave

>From: Richard.Stueven@Corp.Sun.COM (Richard Stueven)  
**Subject: Re: Half filled bottles**

>My housemates and I were not able to come up with a good  
>explanation for why a capped half bottle of beer is a dangerous  
>thing. So I ask, why is a half full bottle of beer more likely to  
>explode than an almost full one? What about almost empty bottles?  
>What about completely full ones?

Here's my understanding of the Mechanics of Carbonation:

If a bottle has too much headspace (the space between the beer and the cap), the CO2 will all end up in the headspace. This means that the partial pressure of the CO2 will not be great enough to force the CO2 to remain dissolved in the beer. Result: flat beer.

If a bottle has too little headspace, too much of the CO2 will remain in the beer (here's where I get a little hazy) somehow shutting down the yeast's production of CO2. Result: flat beer.

(I know that last bit sounds counterintuitive, but I'm sure I read it in TCHoHB.)

Miller et.al. claim that the best fill level is 0.5-1.0 inches of headspace.

If anyone has better information, please pass it along...I was trying to explain this to a friend just yesterday.

have fun

>From: Mark.Nevar@hp-1sd.cos.hp.com  
Subject: King Kooker, Rye malt

In the Summer '91 issue of Zymurgy there is a review of the King Kooker. Basically, it is a 125,000 BTU jet cooker and is very sturdy. Several mail order houses stock the item for sale to us brewers. I have wanted to get one for when I upgrade my brewery from partial mashes to full mashes. Anyway, I called the company, Metal Fusion Inc. in Louisiana (504) 469-6431 to find a local distributor (NJ), but they said they didn't know of one. They didn't check or anything, but they didn't know one off the top of their head. They did offer to ship me one direct, however. So, for \$49.99 (\$40.00 for unit, \$6.24 shipping, and \$3.75 COD (no charges, I could have sent a check, but that was another delay)), they are shipping a unit to me. This is the same unit that Alternative Beverage charges \$56.95 for, before shipping and handling (Winter 1990 catalog). It comes with a baffle to divert the flame (no hot spots). AB sells the non-baffle model for 48.95. Metal Fusion has dealt with brewers before. They knew what one to suggest when I mentioned the intended use.

Also in the Summer Zymurgy was an ad for a place that offered malted rye for a dollar something a pound. With the recent discussion on rye, I'm suprised no one has mentioned it. My issue is home, so if anyone needs the number email me and I'll post it.

>thoroughly lackluster beer.

I second your sadness. Hopefully, the increasing popularity of beers with flavor, brewed abroad as well as at our fine U.S. micro-breweries, will increase their availability. It has already made a mark on the north side of Chicago, where you can find much better beers on tap and beers like Sierra Nevada, Sam Smith's, Fuller's, and Pilsner Urquell in bottles at many bars. Last Saturday, I went on a midnight cruise on one of the big commercial yachts: Old Style and Miller (I think) on tap and Bud and Bud Light in bottles. That's it. I had club soda. It's cheaper and to me, tastes the same.

Now on to my point. On the topic of U.S. beers tasting the same everywhere,

I'd like to add another data point. I had Miller and another U.S. beer in

Canada two years ago. Definitely *\*not\** the same flavor! I thought they weren't bad at all. They actually had flavor. Has anyone had a similar experience? By the way, try Labatt's from Canada and Labatt's purchased here side-by-side. Another big difference!

<FLAME OFF> -- sorry.

Kieran> In Germany I will be in ... Munich July 22-26 or so. Any onfo on  
Kieran> places to go etc, would be greatly appreciated. Thanks!

I recommend the Schneiderweisskeller on Marienplatz. Try their weissbier  
and especially the Aventinus weizenbock. Ummm... I also very much enjoyed  
their brotsuppe (bread soup).

Fairly recently opened is the Paulaner Brauhaus, a brewpub serving an  
\*unfiltered\* Helles, which had a bit more zing to it than the usual  
Munchener Helles, and a real fine Weissbier. It's at Kapuzinerplatz, a  
little  
outside of the altstadt, near the Goetheplatz U-bahn station.

I also braved the Hofbrauhaus to try their Maibock: excellent bock --  
worth  
the trouble if they have it. Stay away from the tourists; sit at a table  
with the Bavarians.

I'm sure others will urge you to go to Andechs, so I won't bother here..  
. :-)

Hit any and all of the biergartens -- they should be lovely this time of  
year. Why aren't there any of these bits-of-paradise in the US??? :-)

Bis spaeter!

>From: JWHITE@maine.maine.edu (Jim White)  
Subject: All Grain vs Extracts - Long.

The following is a summary of the many responses that I received to my posting regarding, All Grain Brewing (HBD #658). I'd like to thank all the respondees, both those who sent me mail, and those that followed up to the HBD. I am resolved to attempt an all grain brew this fall/winter.

During the course of this summarization I will be using quotes and paraphrasing w/o necessarily crediting the source. If this offends, then I can send (upon request) my complete file of responses, and those interested can find the sources. I apologize in advance for this lack of credit, but in this informal forum, it seems unnecessary.

Questions and responses:

> Is the final brew, in general, superior to an extract brew? Is so, why?

Responses ranged from , 'yeah, I think so' to being a 'matter of deep religious conviction'.

Generally speaking, respondees enthusiastically supported grain brewing over extracts. The brew resultant for and all grain mash can be described as:

- More complex
- More body, aroma
- Better head retention
- Full of malt tastes and character.
- No off flavors associated with extracts.
- Less harshness.

Flavor, however, may not be the reason why all grain brewers do all grain brewing. Many brewers simply like the control, and feeling of 'really' brewing your own. These's also the risk! Some (paraphrased) responses...

'Mashing puts you in intimate contact with the part of brewing the extract brewer has hired someone else to do... Fascinating and intensely satisfying..  
..Seeing the mash convert is almost magical.'

'... it's the way to make better beer....it gives you complete control over the ingredients...'

'..you can control... the variety of malts....strike temperatures.... mashing

methodology..... amounts and kinds of sugars present. Skillful manipulation of these variables can result in an exquisite product..... Sloppy manipulation can result in junk...'

However, some theorized that the higher quality is attributable to factors other than grain.

'... notice that nearly 1/2 of the recipes in the Winners Circle are extract based...'

'... the reason people get better results from.. grain..than extract... is because they take more care...'

'..whether it's the grain.... or the increase in experience and concentration.. .. I cannot say...'

> What kind of time commitment are we talking about to wort creation?

Most everybody said, 'All day'. Here are some samples.

'.... I enjoy the process, so it's not surprising that I make it last all day'.

' I basically commit and entire weekend to brewing a batch of all-grain beer.'

'A mashed wort takes about 1 day to prepare.....(but) you don't take a solid day..... there are several long periods where the brew takes care of itself.'

' ... I started at 7 am and put it in the carboy at 4 pm.'

One helpful response broke down each step and they added up to 8h 45m.

> How much water is used? Does it need conditioning.

Not exactly sure why I asked this question, as (in Maine) there's almost as much water as there is winter. In any event noone seemed particularly concerned about it. Most condition the water, but state one should do this even with extract brews.

Here goes;

' ...only increase is cleaning.... the lauter tun. Required conditioning may be less..... some PH and mineral adjustment is usually required, but not cumbersome.'

'You do have to be a little careful about the pH of the mash.'

'About 1/4-1/3 more (water is used).... Always condition, even for extract brews'

'I do full wort boils with my extracts and always condition the water.'

'Big additional water use is for chilling..... I fill my bathtub w/ water ... and put my kettle in it..... I then bucket water to the yard.... water plants.....'

'.... get the pH down to a mashable level.....otherwise you lose efficiency.'

> How about the \$\$ investment in equipment?

This started a bit of tongue-in-cheek dialogue re: whether or not we should be worrying about the cost of a hobby.

Enamel steel canning kettle- \$ 30  
Lauter-tun (Zapap) - 10  
Wort chiller- 25 Homemade from Cu tubing and fittings.

Buy the grain pre-crushed, was one pretty good idea. I also liked the idea of the bathtub wort chiller.

> Is the final cost per bottle less, or more?

'Less if you consider only materials..... factor in equipment and it'll be more. Isn't the purpose of a hobby to spend w/o guilt.'

'Worrying about the dollar value of time spent on a hobby causes ulcers'

'It works out about the same.'

'So what?'

'50 % savings (over extracts).'

'Grain CAN be cheaper than extracts, providing you can get a price break  
on  
the ingredients.'

There you go ! Some late (today) responses may not be included. Is there  
anything else left to say? Thanx again.

Jim White

>From: cjh@vallance.HQ.Ileaf.COM (Chip Hitchcock)  
Subject: re Half filled bottles

Where did you hear that half-filled bottles are dangerous? Homebrewing is still built up out of lore as much as certain knowledge, so there's a lot of misinformation wandering around---you have to pay attention to sources and ignore random rumors. I can't draw a precise curve of pressure

vs time, but I would be very surprised if the peak pressure in a partly-filled bottle were higher than in a full bottle.

wrt filling, I've started following Miller's advice to leave only ~.5"

headspace to minimize oxidation (by leaving less O2 in the bottle). He also

suggests laying the caps on the bottles (for cleanliness) but not crimping

for a while so the first bit of CO2 will flush out the air in the headspace. This sounds like another lore-based idea; a quick calculation:

```
.75 cup corn sugar x .4#/cup x 454 gm/# / 180gm/mole = .7567 moles
x 2 (molecules CO2 released for every molecule of sugar )
x 22.4 (liters/mole at 273K)
x 293/273 (crxn to room temp---293K=20C)
/ 50 bottles (guesstimate of 5 gallon batch)
= .728 l CO2/bottle
/ ~3 days to [carbonate[
```

= 10 ml/hour average, so a headspace of a few ml could be flushed out quickly---IFF the yeast starts chewing up the corn sugar at full speed immediately instead of needing time to multiply. Any guesses on this one?

These numbers also say that a half-bottle should generate 364ml of CO2;

that's just about 12 volume ounces, so if none of the CO2 dissolved before

it was all generated (not likely), you'd get about 2 atmospheres, ~29 psi,

in the 6-ounce headspace of a half bottle. That's not a lot of pressure in a reusable bottle; you're more likely to get flat beer because there's not enough pressure to persuade all of the CO2 to dissolve.

It's nice to know enough biochemistry to follow just what the yeasts are

doing, but you can get a lot of useful estimates about the rest of brewing

just from knowing a little chemistry and/or physics. (Note that the above figures wouldn't be approved by a strict instructor; the figure of .4#/cup

is imprecise enough that the answer shouldn't have more than one significant figure, but we'd still find something on the close order of the above results.)

Subject: L.A. Brewpubs

It's surprising how often this L.A. brewpubs request gets passed around the HBD. Check the recent archives, I've posted a couple of replies myself. Don't have the time right now, so I'll just add a couple of notes to Mark Schweitzer's posting.

He already mentioned Goriky's and Eureka.

> There's also a place in Pasadena called something like The Rose and  
> Thistle(?) which I haven't been to.

This is the Crown City Brewery, near the corner of Del Mar and Fair Oaks in Pasadena. Worth checking out, although the beers are good but variable. I don't know of any Rose and Thistle, but I'll be back there for 4th of July, so I'll see if there's a new pub. Also check out the Loch Ness Monster Pub (N. Fair Oaks, check the Yellow Pages) and the John Bull (S. Fair Oaks, across the street from Gerlach's Liquors), both decent pubs with tasty beers on tap.

>From: Tom Hamilton <tlh@ISI.EDU>  
Subject: la brewpubs

I e-mailed this off yesterday to the unnamed inquirer of la area brewpubs but since there seems to be others interested.....

The closest brewpubs to Anaheim are in Fullerton near the CSU Fullerton campus (forget the name, never been there) and Belmont Brewing in Long Beach. Mediocre beer, bland atmosphere. Other LA area brewpubs include, Alpine Village Hofbrau in Torrance, good German style lagers and good German food in the Alpine Village restaurant. Gorky's in downtown LA, various ales of various qualities, fun atmosphere, lousy neighborhood (the Hollywood location doesn't actually brew on the premises and the people are alot snottier). Eureka in West LA (Wolfgang Pucks place), ultra chee chee but fun to see the place. Supposedly Wolfman spent over ten mil just to build the place. Only one style of lager on tap but filtered and unfiltered. Good stuff. Supposedly brewing a dark soon. Crown City in Pasadena, never been there but I've heard good things. Angeles Brewing in I think Chatsworth? Again I've never been there but they do brew the Rhino Chasers amber which is available locally in six packs. Pretty decent stuff. If you are heading south out of LA, try heritage brewing in Dana Point, good beer in a nice beach town. Manhattan Beach brewing is supposed to be opening up soon too.

Try to pick up a California Celebrator free "brewspaper" as it has a complete list of all California breweries and their ph #s and addresses.

If you need more help, info or opinions,,,,,,,  
tlh@venera.isi.edu  
Tom Hamilton  
University of Southern California  
Information Sciences Institute

ps. try picking up a celebrator at the beverage warehouse in Culver City at Culver Blvd. and McConnell. They have a very good selection of domestic micros and interesting imports albeit stored in the warm LA air under the fluorescents.

pps. almost forgot. I heard a Gorky's add last night on the radio mentioning \$1 16 oz. ales from around 6pm till midnite. mon-thu.

>From: dbreiden@mentor.cc.purdue.edu  
Subject: Miller Brewing co.

I seem to have started something with my question about additive to  
Miller GD.  
Let me point something out:

1. The label proudly claims: No additives or preservatives.
2. There is no ingredient list -- there is a statement that the beer contains barley malt, yeast, hops, and water -- but doesn't say whether or not those are the ONLY ingredients.

So -- anything we might call an additive, Miller Brewing can call an ingredient. Brilliant eh? "Oh, that 30% corn syrup in the recipe? Well, in these parts we call that an INGREDIENT -- it ain't no additive!"

>From: srussell@snoopy.msc.cornell.edu (Stephen Russell)  
Subject: Quite the conference

Greetings and salutations, all....

Just returned from NH and the AHA conference, first one I ever attended, and let me tell you, good times were had by all. The seminars and speakers and banquets were fine, but best of all were meeting all the homebrewers from around the U.S. and Canada. I sure hope you can make it to one someday, as it really is an awesome experience.

Among the highlights of note to readers of this digest.....Mike Sharp really outdid himself with the lambic tasting. I am slow to develop a taste for this style, but I did enjoy sampling commercial and homemade varieties. Even Charlie P. brews the stuff (and should keep working at it). Martin Lodahl supplied Mike with a photo album of the Cantillon (sp?) brewery in Belgium. Russ Gelinias, who was in my "quartet" with Pete Soper and Dwight Beebe, said it all last week, but it's worth repeating anyhow. Thanks, Mike!

Kinney Baughman is quite the party animal, and was easily the tallest person at the conference. This has to change; rumor has it that Manute Bol has a great recipe for Sudanese beer, if only we can get him to brew it. Kinney went up to the Vermont Pub and Brewery to brew with Greg "Extracellular Slime" Noonan on Saturday; perhaps he could post what he brewed and how it went??

Of course, the funniest moment was when we (Tom Strasser and myself) saw the HBD's own Darryl Richman eating breakfast with Charlie Papazian on Wednesday morning. To give you an idea of the sacred importance of this Digest as compared to the American Homebrewers Association, we marched straight up to their table and said "Aren't you Darryl Richman?" and proceeded to introduce ourselves to Darryl, talk about random brewing stuff and the Digest, and otherwise completely blow off old C.P. Well, sure, we finally got around to introducing ourselves to the "Big Cheese" himself, who is indeed a nice guy in his own right (and deserving of far better company than us, as is Darryl), but ya know, sometimes you just have to seize the moment.

Carpe diem, dudes!

Perhaps the source of this "half filled bottles are bombs" rumor is the  
old  
priming technique that modern brewers now avoid; a small measure of sugar  
in each bottle. In that case, the volume of CO2 generated in each bottle  
would be the same regardless of whether the bottle was full or half-  
full;  
the only difference would be how much of the CO2 was dissolved in the  
liquid. The half-full bottles could not dissolve as much CO2 as the full  
bottles, so more CO2 would remain as gas, and pressure in the bottle  
would increase.

If this guess is right, then those of us who mix the priming sugar with  
the  
beer before bottling should never have to worry about partly-filled  
bottles exploding; for us, the volume of CO2 produced during conditioning  
is proportional to the amount of liquid, so that underfilled bottles  
should  
actually develop less pressure than full ones.

From: Jean Hunter <MS3Y@CORNELLA.cit.cornell.edu>  
Subject: Re: Rust in stainless kettles (HBD 665)

Rust in a stainless kettle? Yes, unfortunately. The bleach/water solution generates active oxygen and leaves a chloride residue. The oxygen is what combines with your steel to make rust, and the chloride is a powerful catalyst for rusting (which is why things rust much faster in seawater than fresh water). I don't know what grade of stainless is used for kegs (can anyone tell me? would it be #304?) but I've seen rust on #316 stainless, the most corrosion-resistant, at mechanical stress points on a stirrer used in saturated KCl solution.

I recommend that you try to remove the rust deposit and buff out the pits. The keg should be fine after that. To prevent future rust switch to a different sanitizer. I have heard that chlorine bleach solutions lose their sanitizing power after a few days anyway. Happy brewing -- Jean

From: Michael Mays <MAYS@jhuvms.hcf.jhu.edu>  
Subject: RE Half-filled Bottles

Hi there,

I am a pre-novice brewer (OK, I have never brewed a batch of beer in my life, ...yet). But I do know a little chemistry. With regards to the half filled bottle controversy I believe Chip Hitchcock (HBD665) is on the right path. The amount of CO<sub>2</sub> produced is going to be a function of the amount of sugar (corn syrup) in the bottle. I do not believe that ~29 psi (gauge) pressure is a normal pressure for a bottle of beer (it seems a little high to me) but I would not subject returnable bottles to those pressures. Not all of the sugar is consumed I believed. And as mentioned some of the CO<sub>2</sub> is dissolved in the beer.

To within a headspace of 0.25-1.5 inch (or more formally oz), the volume of the headspace doesn't dominate the finale pressure of the bottled brew. As I understand it with such a headspace, the pressure of the CO<sub>2</sub>, the ethyl alcohol (EtOH) content and the type of yeast will control the pressure. The CO<sub>2</sub> and EtOH concentrations are the feedback to the yeast which tell it to stop growing. So when a certain concentration of these chemicals are reached the yeast stops (slows down) production. But given a much larger headspace of 6oz the yeast may eat up all the sugar before the CO<sub>2</sub> and EtOH reach their limiting (desired) concentrations and hence a 'flatter' beer. The mechanism of Richard Stueven (HBD665) also comes into play at this point.

Al Taylor (HBD665) points out that in aerobic 'metabolization' of any six carbon sugar, six molecules of CO<sub>2</sub> would be produce. This is true, but I thought yeast was an anaerobe. Interesting though is that 6oz of air (1.2oz of O<sub>2</sub>: 0.002 moles) would produce an increase of 3.7psi under such 'ideal' aerobic conditions. The number of moles of sugar used is about 0.015 moles/bottle. If you add 0.075 cups too much of corn syrup (hard to see if using a 1 cup measuring cup) you are introducing a potential equivalent pressure increase in terms of ideal anaerobic CO<sub>2</sub> production. Also, beer does compress, only very little. And hence when it decompresses, it moves only very little. The net effect is the same as described by Al.

Well thats what I think,  
Michael Mays  
Mays@jhuvms.bitnet

> based...'

Notice that they nearly all use Wyeast liquid yeast.

I just tried two batches using Wyeast: Munich beer (using the Munich beer  
yeast), which is fermenting away in my fridge at 32 F (also my first all  
grain batch), and an extract/specialty grain stout/porter (using German  
Ale yeast), which is fermenting in a garbage can of water at 75F.  
(My roommate keeps turning the A.C. off, and opening the windows).  
The amazing thing is that they seem to be fermenting at the same rate!  
i.e. It's been nearly 3 weeks, and the Ale still has Krausen on it.  
I can see why the Munich beer is going slowly in the cold (in fact,  
it's going quite well for 32 F), but the Ale ...

cheers!

From: hersh@expo.lcs.mit.edu  
Subject: Rabbits & Hops

From the "Gods Honest Truth" category

When I was a senior at the University of Rochester one of the most bizarre incidents I have ever been witness to occurred. I was hanging with my girlfriend and her roommate in the lounge of their suite. They were taking care of their roommates bunny while their roommate was away. They let the bunny out of the cage to roam around the suite. The 3 of us had just opened a few Molson Golden, and mine was about 1/4 full. I set it down on the floor next to my chair, and to the absolute amazement of all of us, the bunny hopped on over, grabbed the top of the bottle with it's little bunny teeth, tossed it's head back, thus emptying the bottle in one gulp, dropped the bottle and hopped away.

Now I know I wasn't crazy or halucinating as 2 other people saw this happen and burst out laughing with me at the same time. Me being the fiend I am tried to get the Rabbit to repeat this behavior so we could video tape it and get it on David Letterman's Stupid Pet Tricks. Well we couldn't get the rabbit to drink from the bottle again, but we did notice it loved beer, especially a hoppy beer like Molson's Golden. BTW My girlfriends roommate never found out about this, she didn't have much of a sense of humor :-)...

I've heard that cutting off the lower 1-2 feet of leaves keeps animals away and helps prevent mold or fungus from getting to the plants.

Date: Mon, 24 Jun 91 14:25:03 EDT  
From: hersh@expo.lcs.mit.edu  
Subject: consistency, extract vs. grain

Al:

Notice I said state to state, not country to country. I'm sure Canadian tastes being different, and these beers having to be rproduced by law in Canada, in the province they're consumed in, they are surely brewed to different recipes there.

My observations/feelings on the extract vs grain issue are these;

- 1) Lots of Competition winners are extracts
- 2) Most of the brewers I know who make grain beers make GREAT beer most of the time
- 3) The more experienced brewers I know who make extract beers make GREAT beer most of the time

I would summarize it like this:

While it is possible to make really good beers with extracts, it takes a little more skill/knowledge/care to do so. I think the AVERAGE grain brewer makes better beers than the AVERAGE extract brewer. I also think the AVERAGE grain brewer has more experience and puts more time/care into the brew than the AVERAGE extract brewer. My experience/observation indicates that the choice of grain/extract is less critical than the skill of the brewer, though I think that grain brewers tend to be exposed to more of the variables of the brewing process and perhaps learn a little more than extract brewers do (again ON THE AVERAGE, BASED ON MY EXPERIENCE).

Enough of these sweeping, useless generalization s that will almost surely getr me into trouble :-)...

>I'd like to add another data point. I had Miller and another U.S. beer  
in  
>Canada two years ago. Definately \*not\* the same flavor! I thought they  
>weren't bad at all. They actually had flavor. Has anyone had a similar  
>experience? By the way, try Labatt's from Canada and Labatt's purchased  
>here side-by-side. Another big difference!

If you look carefully at a bottle of Miller, Bud, etc. purchased in  
Canada  
you will see (in small print) "brewed under license from Miller (or A-B)  
by Labatts (or Molson)" (or words to this effect). IMHO, Canadian  
Miller,  
Bud, etc. taste just like any other brew from Labatts or Molsons (e.g.  
Blue, Export, Canadian, etc.). In effect, large, commercial Canadian  
breweries produce a wide range of almost identical tasting beers with  
nationwide consistency in the same way that large, commercial American  
breweries do; it's just that the generic taste differs from one side of  
the border to the other.

I'll bet that the U.S. versions of Labatts products bear (depending on  
local laws, of course) a similar "brewed under license" statement  
crediting Miller or someone with producing the flavour you know so  
well south of the border... :-)

This doesn't have a lot to do with beer, but I thought it may make some drinkers happier!....

A popular science TV programme here in the UK made several very interesting points/claims about Cholesterol..

1. It is extremely difficult to reduce your Cholesterol level. In one survey, a large number of people who were regularly counseled by a dietician only managed to reduce their Cholesterol levels by an average of 5%.
2. Drugs to reduce Cholesterol levels do not have an overall effect on the mortality of their users. Their side effects cause an increase in suicides and an increased susceptibility to fatal accidents!
3. There is no evidence demonstrating that someone who manages to reduce their cholesterol level by dieting is less likely to suffer heart disease or live longer.

Basically, they claimed that controlling your diet to reduce Cholesterol in order to avoid heart disease was only sensible for a small number of genetically susceptible people. Different people are susceptible to different causes of heart disease.

I find that being anxious about diet does me no good at all :-) --- just drink away and enjoy!

I don't know for sure what's in "Burton Salts", but my supplier believes it's nothing more than the appropriate mix of Calcium and Magnesium sulphate. According to "Home Brewing" by Graham Wheeler, water quality similar to Burton-on-Trent may be achieved by adding 1000mg/l Calcium Sulphate (Gypsum), 150mg/l Magnesium Sulphate (Epsom salts) and 60mg/l Sodium Chloride (common salt) to soft water.

Hi There,

Since I am claiming to be a chemist I thought I should correct the last paragraph of my posting in HBD666. For the aerobic 'metabolization' described, the pressure increase would be zero since each CO<sub>2</sub> molecule produced replaces a O<sub>2</sub> molecule consumed.

On the subject of Canadian beer. When I was in Magog, Quebec for a few weeks a few years ago, I asked a few Canadians why their beer tasted different/better. No one was an authority but the most popular opinions were: People in the United States would not drink a 'real' beer with flavor and The beer brewed for us Southerners had to be brewed to different standards to satisfy some governmental (US) body.

As a general rule, you don't want to soak stainless steel in chlorine bleach. Stainless steel is subject to a phenomenon known as "stress corrosion cracking" wherein stainless steel under stress in a chlorine environment will develop tiny cracks along the metal grain boundaries in the high-stress zones.

Unfortunately, I have had practical experience with this phenomenon. Some time ago I had a favorite stainless steel thermos bottle that I hauled to work every day loaded with coffee. After many years of use the interior had acquired a coffee lacquer coating that was pretty unsanitary looking. Being a homebrewer, I figured nothing would be better at sanitizing my scummy thermos bottle than bleach. So I decided to soak the thermos overnight in bleach. I figured that stress corrosion cracks require high chlorine concentrations and would take months to develop. Since I was using common household bleach (full strength) and only soaking overnight I should be safe. Boy was I wrong. The next day my favorite (actually my only) thermos bottle had no vacuum and was ruined. Lesson learned. Nowadays, I use bleach to sanitize my stainless brewpot and *\*RINSE THOROUGHLY\** before storing.

You have rust stains? Try some fine grade ("00" or "000") steel wool.

Subject: Miller's Cold Filtering

Greetings,

Today Kieran (IOCONNOR) asks "what the \*@#\$ is 'cold filtered'?" Well, I do know someone that works at Miller (just down the road from you Kieran, in Fulton) and the best that I can figure is that they have ceramic lined pipes that the genuine draft goes through to the bottling plant and the beer is passed through ceramic filters. Also, the bottle filler is enclosed in a 'clean room' with people in white suits and hats and booties. They even have to step in some sort of alcohol bath before entering the filler room. Oh, and they do not pasturize the beer.

All this says to me that instead of pasturizing to kill all of the potential nasty beatsies they filter them out and pay very close attention

to sanitization. In fact I heard that they recently pitched something like 1600 (or maybe there is one more zero) cases that didn't pass the bio type

qc. The net result is that they work hard to make their beer clean enough to last without pasturization. They call it genuine draft because they don't pasturize keg beer either, it goes straight from the filler to the cooler and remains cold (supposedly) until serving.

Oh the price people pay to ensure that their alcoholic beverages have the same lack of flavor every time!

On a related topic, has anyone had any Miller 100% Barley Draft? I think that it is cold filtered too but has no 'cereal' (so they say). I had some a while ago and it was the most flavorful thing that Miller has ever put out (which isn't saying much).

G'Day,

Joe

From: MC2331S@ACAD.DRAKE.EDU

Subject: Consistency

Another bit of anecdotal evidence on beers tasting different here than on their home turf. Two years ago I took the Carlsberg tour in Copenhagen. I

was told that the Carlsberg, Tuborg, Elephant etc. which is shipped here to the

USA is made according to a completely different recipe than the stuff made in

Denmark for domestic consumption. A-B imports the stuff, but doesn't do anything other than bottle it. The guide said that the US Carlsberg is made with much

less malt and hops, but a higher alcohol content.

On a seperate note: what is the best way to condition bottles of lager? We have a batch of Irish Lager in the fridge right now and will be

racking it soon. Do we put the bottles in the closet or the fridge or somewherein between?

From: mcnally@Pa.dec.com  
Subject: pre-pitching oxidation (oxygenation?)

I've got a batch of sweet stout just getting going in the fermentor. Because the packet of Wyeast (Irish Ale) was slow to start, I didn't have time to give it a second feeding in some starter wort. To offset the low pitching rate, I decided to aerate the wort more vigorously than usual. After cooling, I racked into a carboy which sat overnight in my newly-built swamp chiller (a sort of idiotic extension to the wet T-shirt mechanism) at about 60 degrees. The next morning, I sterilized my fermentor and began racking the wort (sans break material) into it. So far, nothing unusual; I always do this, and use the Dave Miller technique of aiming the racking hose such that the wort fans out over the inside surface of the fermentor. This time, however, I stopped the flow after about a gallon, put some clean (not sterilized, but I'm not worried) saran wrap over the top, picked it up, and shook the heck out of it. The result was a two-inch layer of foam on the wort. I then pitched the yeast over this and finished racking. The beer is now off to a start.

I think I'll probably do this in future whether I've pre-cultured the yeast or not. Comments? Of course, I wouldn't try this in a plastic bucket fermentor :-). (My old bucket is now part of my swamp chiller, along with a little pump, a fan, and a Hunter AirStat.)

From: adams@bostech.com  
Subject: Cold filtered

Kieren asked about cold filtering...

A lot of the microbrews (at least Catamount, I know for sure) use the process that Miller has made famous as "Cold Filtering". Apparently, most of the big commercial breweries heat up the fermented beer in order to kill off the suspended yeast. This avoids ugly sediment and beer grenades. A cooler way (sorry, couldn't resist) is to pump the beer from the fermentation tank through a filter which, I think, is partially made of diatomaceous (sp?) earth. The filter clarifies the beer significantly, in addition to pulling out the remaining yeasties. It has obvious advantages over any process that involves heating up the fermented product.

What I can't figure out is why the average Miller drinker would see the ads and say "Cold filtered? That must be better than heat pasteurized." Then again the average Miller drinker doesn't know what hops are either...

Dave

From: hplabs!bmr-vpa!bmr-rsc!crick (Bill Crick)  
Subject: Half bottle carbonation

Someone asked about half filled bottles creating too much carbonation. I don't know if the final pressure is higher, ( I liked the O2 explanation , but there certainly is higher apparent carbonation when you open it. When I make Ginger beer, I always put the last bit in a black champagne bottle. I use this one to wake up guests who have gotten dulled to the bang the normal ones make. The less liquid in the black bottle, the more pop it has. I recently had a batch where the black one only had about 5oz. of beer in it (26oz. bottle). The regular champagne bottles make a boom, like a shotgun when set off, and the corks are gone for about 4 seconds. The black one in the last batch cracked like a high caliber rifle, and the cork was probably in flight for over 5 seconds. Also the partially full bottle usually shoots its entire contents 10-15 feet into the air, where the full ones seldom gush higher than about 4-5 feet. There is a definite correlation: The emptier the bottle, the louder, and the further the cork and the bottle contents go.

Bill Crick Brewius, Ergo Sum.

Subject: Re: consistency

I guess I wasn't clear in expressing my comment. I was well aware of the fact that "Canadian" Miller was brewed in Canada (under licence of ... etc. -- just like Lowenbrau brewed under licence by Miller -- Aside: Miller's ad campaign where they shipped a keg to Germany to pass inspection is a complete farce: I don't think any German could drink U.S. Lowenbrau without spitting up). I believe the Labatt's purchased in the U.S., however, has a big "IMPORTED FROM CANADA" on it, but I could be wrong. I won't even mention that Moosehead is not even sold in Canada -- oops, I guess I just did! I did notice, Jay, that you had stopped at the state level, the point I wanted to make was related, though.

The point is, that it's interesting that a reasonable tasting product can be poured out of a can labeled "Miller," while at the same time a relatively lousy tasting product can come out of a bottle labeled "Labatt's." I understand there is/was a price-gouging lawsuit against the American brands in Canada. I believe that their defense was that they do not advertise in Canada and the low cost was due to this reason (if my memory serves me correctly, the last time I was in Toronto, 24 cans of Canadian beer was approaching 30 \$CDN, whereas a case of an American brand was on the order of 19 \$CDN). My explanation for Labatt's tasting bad in the U.S. has always been that it needed to be pasteurized to be sold here. Keeping their beer fresh was the reason I was told that Coors did not used to be sold east of the Mississippi -- I believe Coors now says that it ships their beer under refridgeration, but I've seen cases of Coors stacked in the aisles of the store, so what gives? I know that beer purchased in Canada used to spoil in a few months if not refridgerated. Beer in Alberta used to always be stored in walk-in coolers and only came in bottles, but on my most recent trip to Calgary (1988) and my last trip to Vancouver (1990), they cans and the cans were stacked in the aisles of the store. Have they started pasteurizing?

Al.

From: Martin A. Lodahl <pbmoss!malodah@PacBell.COM>  
Subject: Cold Filtering, and the Conference

In HOMEBREW Digest #666 (the Issue of the Beast 8-), Kieran O'Connor asked a very cogent question:

> --what the \*#\$\$ is "cold filtered"?

A marketing ploy. Virtually every commercial brewer filters their beer, and virtually all do so cold, to (try to) remove chill-haze before bottling. A lot of other stuff is stripped out as well, but their process is calibrated for that. Bottled beers labeled "draft" can't, by law, be pasteurized, so they must be very finely filtered to eliminate possible biological contamination; Coors, for example, has done this for years with all their beers. Miller marketeers saw an opportunity, and like A-B with their beechwood aging, made marketing hay on a technique imposed on them by other parts of their process.

And to all of you posting glowing reports of what must have been an outstanding conference: YOU CAN'T IMAGINE HOW JEALOUS I AM!! Maybe next year. And in Mike Sharp's report on the Lambic Net (the only traffic there in weeks, it seems) I note that Phil Moeller, a fellow GCBA member, was there; so I'm sure I'll hear all about it at least once more ...

Speaking of Mike and lambics, if you thought that he'd done a huge amount of advance work to make his tastings go so well, you're right!

Date: Tue, 25 Jun 91 16:05:24 PDT  
From: Martin A. Lodahl <pbmoss!malodah@PacBell.COM>  
Subject: Ullage

My first batch was, to be charitable, sub-optimal. Among my many sins in producing that batch was wildly inconsistent ullage, ranging from 1/8" to 2+". I noticed that the sound made in lifting a crown would vary considerably, roughly proportional to the headspace. Bottles with lots of ullage roared "PSSSSST!!", while those with less were more reserved. Then I bought a copy of Miller, and have used his recommended (small) headspace ever since, without further reflection.

Until this year's nationals. The bottles I sent in never had less than 1/2" nor more than 3/4" ullage, but some judges seemed to find this uncomfortably small. Several commented on the "overflow", and one made the curious remark that though it was rather full, it didn't gush. I've never noticed a correlation between fill and gushing.

Perhaps the answer is that if you're entering contests, it's a good idea to tailor both the bottles you use and the way you fill them to the apparent tastes of the judges ...

From: Mike Fertsch <FERTSCH@adc1.adc.ray.com>  
Subject: Winners Circle (Grain vs Extract)

Let me put in my 2 cents on the "Winner's Circle" recipes and the Grain vs Extract discussion. I agree that there are as many extract recipes in this book as grain recipes. This may indicate that extract beers are as "good" as grain beers.

OTOH, most of these recipes are OLD. All-grain brewing has become popular only in the last few years. I estimate that three or four years ago, 80 percent of all competition ENTRIES were extract beers. I'm surprised that only 50 percent of the WINNERS are extract. The simple fact that 50 percent of the beers in this book are extract beers does not tell us much about quality of grain or extract recipes. Winners from recent competitions (check Zymurgy) are almost exclusively all-grain beers. I guess that more than half of today's entries are all-grain beers.

I conclude that looking at competition winners tells us about the popular fads in brewing. It is difficult to determine good versus bad sources of fermentable sugar.

I've been judging homebrews for a long time (5 years, I think?!). Homebrew has improved significantly since then. IMHO, the beers that won competitions a few years ago would not do well today. I'd think twice about blindly adopting recipes from Winners Circle. I should know, I have a few swill recipes in the Winners Circle book.

From: prs@titan.HQ.Ileaf.COM (Paul Schmidt)  
Subject: Flavors

I haven't brewed anything yet (perhaps later this summer or early fall?), and I'm trying to get an idea of what kind of beer to try first.

I've been reading lots of descriptions of beer flavors (hoppy, sweet, esters, etc.) but I don't really know what they all mean. Can someone post a description of the major flavor 'spectrums', and name a commercially available beer that would represent the presence or absence of that particular flavor? For example, I understand that Molson Golden is a hoppy beer; is there a similarly-flavored beer without as much hops that I could try next to it? And so forth...?

Thanks in advance!

From: kla!kirkish@Sun.COM (Steve Kirkish)  
Subject: What's \*in\* that beer?

I've been reading with interest the recent entries about Big-Breweries' and their alleged additives, creating a chemical soup that tastes almost, but not completely, unlike beer ;-). I dug out my 1988 copy of CAMRA's "Good Beer Guide" (a definitive guide, IMHO, and indispensable in the UK...) and turned to page 144 for an entry entitled "Foreign Bodies", by Roger Protz. He mentions in particular Miller Lite, "described as 'the nearest thing to an empty glass'", and discusses how American legislation (at one time) forced the makers to list their ingredients: "propylene glycol alginate, water, barley malt, corn syrup, chemically modified hop extracts (there ya go), yeast, amyloglucosidase, carbon dioxide (!), papain enzyme (clarifier, I believe), liquid sugar, potassium metabisulphite, and Emkamalt". Public outcries forced Miller to drop it's use of additives, the report goes on to say. It is brewed under license in Britain by Courage. The author considers this to be a happy example of what the British big-brewers should follow.

He goes on to describe the effects of these and other additives (available from your local chemistry set): propylene glycol alginate is added to lager and keg beers to lend a "commercially attractive but fake head"; amyloglucosidase and aspergillus niger are used to balance enzyme deficiencies; hypochlorite, bleach, ozone, gibberellic acid and bromate can speed germination and starch extraction; and silicone anti-foam reduces the yeast head in fermentation vessels to "squeeze in more liquid".

The upshot is to not only make beer drinkers aware of what might be in that bottle, but to also suggest that ingredients go back on the label. If ya got nothing to hide, why not show it?

Fortunately, these additives are not necessary to the taste of a homebrew, and their probably not cost effective. I am no chemist, but I have a feeling that most of the ingredients above might be organic extracts and most may not be unhealthy. As the cartoon at the end of the article states, with the bartender telling a guy at the bar with a "Gents" room beyond, "Not many people hang on to it long enough to worry about the ingredients".

So, don't worry, relax, have a homebrew!  
(And apologies and thanks to CAMRA and Roger Protz for the excerpts.)

From: hersh@expo.lcs.mit.edu  
Subject: Cold Filtering Debunked

Gee what is cold filtering you ask??  
Well in just about any brewery larger than your kitchen the beer is filtered prior to bottling or serving. Since Miller brews Lager beers the beer is already cold. A typical step before filtering is cold conditioning, where the beer is "aged", basically let sit at temperatures in the low 30s. This can also be known as lagering, though cold conditioning is typically for just long enough to let yeast sediment out of solution, while lagering can go on for many months. Either way the beer is cold at this point, and from what I understand keeping it cold during bottling helps the CO2 stay in solution.

So as far as I can determine, cold filtering is something Miller has done for as long as they've used filters, made lager, and bottled it. It's just a new name for something that a lot of breweries do. Miller probably trademarked it first though so no one else can use it.

As far as "clean" room procedures, many other brewers use some or all of these techniques (clean rooms with microbial air filters, sterilant bath before entering filter room, etc..)

Oh yeah, the reason some brewers don't pasteurize is cause they use a finer (and more \$\$) filter that gets out not just the yeast, but also bacteria, which are smaller.

On a related note, Joe mentioned Miller 100% Barley Draft, well Matt's of Utica has been making Saranac, an all-malt American Pilsener for some time. While other Matt's products (except the contract brews) are pretty much swill the Saranac is respectable American pilsener.

From: grumpy!cr@uunet.UU.NET (C.R. Saikley)  
Subject: Cold Filtering

Just to add to the discussion of cold filtering.....

I recently heard that those wily Japanese brewers, the very ones who pioneered the "cold filtering" process, were adding a small number (~1000) of yeast cells back into each bottle of cold filtered brew. The idea being that these yeasts would consume whatever oxygen was introduced during the bottling process, thereby increasing the shelf life. Now imagine that, filtering out all the yeast, then adding some back in! All this for the sake of producing a consistently bland beer and keeping it consistently bland longer.

Pass the Sierra Nevada please,

From: RJS153%SYSU@ISS1.AF.MIL  
Subject: Help with Mabi brew

Hi All!

A friend of mine is from Puerto Rico, and he wants to make a native brew from Puerto Rico called "Mabi". Mabi is a mildly alcoholic brew that uses the bark from some tree, possibly the Mabi tree. The wort (I'm new to this, so forgive me if I use the wrong terms) also has cane sugar, and a sample of someone else's Mabi already brewed. My guess is that this is where the yeast comes from. Mabi is a real quick fermenter, something on the order of five days, or only three days if they put it in the sun. We're in Ohio, so there are not a lot of Mabi brewers in the neighborhood. He needs to either find some Mabi-style yeast or get a substitute. What type of yeast could he substitute?

Any help you can provide is appreciated. If we ever get this off the ground, I'll be sure to tell everyone how it turns out.

From: Marty Albin <martya@sdd.hp.com>  
Subject: coatings on kegs

Sorrtly to post this, but mail bounced and I hastily discarded the alternate address.

> Am looking for a source for some form of paint or coating to apply  
> to my SS barrels/kegs that will provide better heat transfer.  
> I have heard of such coatings, and seen photos of containers with a  
> gray coating on their bottom surfaces.

To the outside or the inside? If you want to put it on the inside, you'd be wasting your effort. Direct contact with the fluid in question is as good as it gets.

If you want to put it on the outside, there are some paints you might try, but they wouldn't be much use unless you want to cool the keg in orbit or something.

A coating can increase heat transfer by radiation, one of the three normal mechanisms (the other two being conduction, where heat flows within a stationary medium, like a metal; and convection, where heat is carried by a fluid in motion), but at the expense of the other mechanisms. If you turned your keg into a perfect black body (100% emissivity) you would get only a microscopic increase in heat transfer at the kinds of temperatures normally encountered in brewing.

Radiative heat transfer varies with the fourth power of temperature, so things like stars and white-hot pieces of metal lose most of their heat by radiation, but things like kegs lose most of their heat by convection. In a vacuum, there isn't anything to convect or conduct to, so all heat transfer is by radiation. This is why it's so hard to cool the space shuttle, and why thermos bottles have a vacuum insulator.

If you could increase the surface area of the outside of the keg (by welding on fins, say) you could increase convection somewhat. To get optimum effect, you'd need fins on the inside too.

I assume in all this that you're trying to find a way to chill kegs quickly. There's another approach: in-line chillers called cold plates. The idea is you store the beer warm but run it thru a refrigerator or ice chest to cool it on the way to the tap. Foxx Equipment sells these for about \$125, but you could make your own for half that. I've seen them used, and they really work.

A wort chiller stuck inside might work too, but you'd risk contaminating the keg, and you'd lose some carbonation.

If you figure something out, let us know! I'd like to save some time at parties.

Subject: Aerating worts

Mike McNally offered his experience with oxygenating wort prior to pitching and asked for comments. Here's mine:

First, I like to use the term aerating to preclude any confusion with oxidation which we all know is undesirable.

Like Mike, my primary reference is Miller. I used to fan the wort over the sides of the primary when racking to aerate the wort. With this method, I experienced a variety of problems with long lags, slow or stuck ferments, and high terminal gravities. So I tried something akin to what Mike described. I rack to a carboy after cooling and allow to sit over night for trub settling. In the morning, I rack to my plastic-bucket primary and pitch. I don't generally bother with the fanning procedure anymore. I take my OG reading right in the bucket and then use the hydrometer (which is of course already sanitized) and whip the hell out of the wort. I do this for a couple of minutes until my arm gets fatigued and there is a good head of foam on the wort. I then seal it, put the fermentation lock on it and let it go.

This procedure has solved all the aforementioned fermentation difficulties. The past seven batches in which I've used this method have all resulted in quick, clean ferments without any signs of infection (the additional exposure to bacteria from the whipping is small and I feel is more than offset by the shorter lags).

I also apply this to the preparation of starters. The ten minute boil is sufficient to drive off most or all the oxygen. Vigorous swirling in the starter bottle before fitting the fermentation lock results in much faster takeoff times.

 From: jlf@poplar.cray.com (John Freeman)  
 Subject: Mashing time

I thought I'd add my two cents worth to the discussion of mashing times. I drew up this PERT chart long ago to determine what could be done in parallel. I have mashed in as little as 3 1/2 hours - I had no homebrew to drink while I was doing it... With homebrew, it takes a little longer.

I tried to draw this to scale, each column representing about three minutes, each task placed approximately where it belongs in time. The straight line represents the critical path, the things you cannot hurry: heating, mashing, boiling, cooling. One of the best speedups you can make is to sparge into your boiler while applying heat (at J).

- A. Clean mash tun, measure mash water.
- B. Heat mash water.
- C. Assemble grains, scale, grain mill, etc.
- D. Crack grains.
- E. Mash.
- F. Clean up from cracking.
- G. Relax.
- H. Measure and heat sparge water.
- I. Clean and set up sparge equipment.
- J. Sparge into boiler.
- K. Heat wort to boil.
- L. Weigh hops.
- M. Boil wort.
- N. Clean up sparge equipment.
- O. Proof yeast (dry) or take wort sample for yeast starters.
- P. Add hops to boil.
- Q. Clean and set up wort chiller.
- R. Chill wort.
- S. Put hydrometer and thermometer in wort.
- T. Put away materials.
- U. Clean boiler, strainer, etc.
- V. Pitch Yeast.
- W. Clean wort chiller.
- X. Relax. Relax. Relax.

Subject: Beer Tastes

Paul Schmidt (prs@titan.hq.ileaf.com) asks about examples of commercial beers with specific tastes; he mentions "hoppy", "sweet", "estery". Here's a couple of suggestions:

hoppy - Samuel Adams Lager is amazing. It's like sticking your head in a hops basket. Try drinking it straight from the bottle. I don't know, it must shoot the hops right up your nose.

sweet - Any of the scotch ales, like McEwans. They're apparently brewed with crippled yeast to produce sweet diacetyl flavors. The only trouble is finding a fresh bottle. McEwans in particular is in clear glass and tends to go off.

estery - Anchor Liberty Ale is very fruity for a commercial beer. This is typical for an "ale" style but still strange to the American palate, if there is such a thing.

Well, I like my Sierra Nevada too, but rumor has it that these guys (AB,  
Miller, Kirin, etc.) are in business to make money!

I feel the same way in the grocery seeing all the people buying Coke/  
Pepsi  
by the gallon instead of fruit juice -- especially for kids!

I think that very little of the cost of typical beers and soft drinks is  
in  
the ingredients, and most is in packaging, distribution, advertising,  
(and  
profit). Correct me if I'm wrong, but this seems to be "the American  
way".

All the more reason to "brew it yourself".

Cheers,

Mark Sandrock

P.S. I sometimes tease my kids when they want me to buy them pop (which I  
do on occasion). "Coke, the REAL thing, artificial color, artificial  
flavor,  
artificial sweetener, right!" I say, "Fruit juice, the REAL thing!"

From: bryan@tekgen.bv.tek.com

Subject: Oxygenating Wort

I recently ran a test on the effects of oxygenating the cooled wort prior to pitching the yeast. I brewed what turned out to be about 8 1/2 gallons of a Pale Ale (O.G. of 57) in a 10 gallon pot. 5 gallons went in 1 fermenter

and 3 1/2 gallons went in another. While transferring the wort, I gave it a stir regularly to ensure the same density of wort went into both carboys.

When transferring the cooled wort into the 5 gal carboy, I stopped at 3 or 4 points and gave the carboy a good shake. The carboy would have several

inches of foam on top when I was done shaking it. The carboy with 3 1/2 gallons I shook only once, at the end. I had a starter made and pitched a generous amount of Wyeast American yeast into each.

At 8 days the measured gravity was 20 for the carboy with a minimal amount

of oxygenating and 14 for the carboy with lots of oxygenating. In general the carboy with lots of oxygenating had a much more vigorous fermentation,  
(visual observation).

Date: Thu, 27 Jun 91 12:45:22 PDT  
From: grumpy!cr@uunet.UU.NET (C.R. Saikley)  
Subject: Overdo the O2

I thought I'd share my method for oxygenating (as opposed to aerating or oxidizing) my wort. Since I'm somewhat of a fanatic, I'm sure some of you will find it amusing.

My brewing environment is rather hostile. I brew outside for several reasons, but this has the disadvantage of putting me amidst several fruit trees. There are always oranges, lemons, figs, or tangerines on the ground spewing spores everywhere. Add to this the algae laden fish pond and you've got a microbial zoo. Under these conditions, I'm forced to do everything I can to minimize exposure of fertile wort to the elements.

When I lived elsewhere, I employed the afore-mentioned technique of vigorously shaking a partly filled carboy to aerate it thoroughly. That no longer works. When you do that, you are also putting whatever critters are in the air in intimate contact with your wort. In my zoo, this is enough to cause infection related off flavors in the beer. In the spirit of overkill, here is my solution :

Place a T fitting on the \*cool\* side of the counter-flow wort chiller. Connect one side of the T to a tank of medical grade oxygen!!! Connect the other side (via some tubing) to one of those orange colored plastic carboy caps with two tubes sticking out of it. In the cap's other tube place a stem thermometer so that the stem sticks right into the flow of wort. When it's all set up, you turn on the valves in the right sequence, and you get cooled oxygenated wort at the right temperature into the carboy without exposing it to the environment. The chilling, oxygenating, transferring system is completely closed. Besides being really cool, it works very well. The yeast really takes off.

Alan Kornblum, the brewing chemist at Anchor, informed me that most commercial breweries aerate their wort rather than oxygenate. This is primarily because excess oxygen can cause yeast mutations and it's easier to not overdo it if you avoid pure oxygen. I seldom repitch my yeast, so mutations aren't a big concern.

To be used only under adult supervision.....8-]

Subject: 1/2 batches

Howdy,

Disclaimer first: I'm a novice home brewer. Now that that's out of the way, here's my question. A buddy of mine has gotten good results by using

2 homebrew kits in one 5 gallon batch of beer. I think this was recommended

in "Joy of Homebrewing". It seems to me what one changes by putting in 2

cans of "good stuff" instead of one, is the ratio of "good stuff" to water.

Can one accomplish the same thing by putting in one brew kit and half the

normal amount of water. I hope so.

-----

Date: Thu, 27 Jun 91 17:29:32 EDT  
From: Pete Soper <soper@encore.com>  
Subject: re: half-filled bottles

Two considerations:

1. It is the rapid expansion of the headspace gas that propels broken glass.

The bigger the starting volume (and pressure of course), the more energy available to shove a piece of glass into your body.

2. Thermal expansion of beer will cause the bottle and/or cap to fail if

you use too little headspace and the beer then warms up enough.

This has been repeated periodically in "Zymurgy", in the Digest, etc.  
Item

one is a serious safety issue that beginning brewers should pay special attention to. Item two is just a heart breaker that you'll observe if you go too far with minimizing headspace.

> Subject: Aerating worts

> Like Mike, my primary reference is Miller. I used to fan the wort  
> over the sides of the primary when racking to aerate the wort.  
> With this method, I experienced a variety of problems with long  
> lags, slow or stuck ferments, and high terminal gravities. So

Since writing his book, Dave Miller has changed his ideas on wort  
aeration. At a meeting of the St. Louis Brews a while back he  
suggested  
aerating the wort every half hour or so after pitching for at least  
several hours.

More recently he has been experimenting with a homemade version of the  
'Happy Yeast Air Infusion System' reviewed in the Winter 1990  
\_Zymurgy\_.

This uses an aquarium pump to pump air through a filter and into the  
wort. According to the review, the manufacturer suggests aerating for  
five hours.

Subject: Winner's Circle Beers

In the last two special issues of *\_Zymurgy\_*, the Winner's Circle column has published statistics about the entries to the national homebrew competition. Here are excerpts:

1989 Based on data from over 850 entries  
Entered      Placed 1, 2, or 3  
Extract      28%    22%  
Partial Mash    23%    18%  
All-Grain    49%    60%

1990 Based on data from 1548 entries  
Entered      Placed 1, 2, or 3  
Extract      22%    20%  
Partial Mash    27%    20%  
All-Grain    51%    60%

Of course, in interpreting the numbers one must take into account that more experienced brewers may be more likely to submit all-grain beers.

Howdy Brewfreaks!

Well as ya'll know I'm fairly new to homebrewing...cooked my first batch and its in the bottles now. Everything is going according to plan. I popped the top on one and its smells and tastes ok....the thing is that the first try I used a "kit" you know open the can..boil..add sugar etc..which is fine. for the first time..but I want to branch out (i'm allready hooked on the hobby :) the deal is the 2 suppliers who I got catalogs from really have a limited inventory..as far as supplies go...I won't mention any names... but one starts with a O and is from Ill. the other is from NC...what I would like to know is there a mail order supplier who stocks it all...I want to continue with extracts...but eventually I want to try some grain recipes. . any help would be greatly appreciated...you guys have been really helpful thanks again to ya'll!!! direct e-mail is fine.

Bill

From: hplabs!bnr-vpa!bnr-rsc!crick (Bill Crick)  
Subject: halfers, taste differences

I sent an article in on the carbonation levels of half bottles, but it seems to take my posts a long time to show up? It must be flying around on someones disk god know wherre?

I always bottle that last half bottle, and have never had any blow up, but I have noticed that they are more prone to excessive foaming when being poured.  
IE: Their apparent carbonation is higher.

Regarding differences between beer tastes in different countries, I have noticed that most Canadian beers taste different as you travel from province to province. I was told this is due to local market preferences? Note that we don't have a free trade agreement inside Canada, so beer sold in a province must be brewed in that province! It seems a bit silly to have to travel to the states to sample several Canadian beers that it is not legal for me to buy in Ontario? Of course that's not the only silly thing I can think of that is unique to Canada.

Most American brands sold in Canada are brewed under licensce by a Canadian brewery. I believe most Canadian brands sold in the US are Imported from Canada, and sold as such. I've never tasted them to compare to the sold in Canada versions. I'm always amazed how many places sell Molson Golden on tap in the states!

That would have been my choice as well. Harpoon Lager is also pretty heavily hopped for a medium-light lager.

>sweet - Any of the scotch ales, like McEwans. They're apparently brewed  
> with crippled yeast to produce sweet diacetyl flavors. The  
> only trouble is finding a fresh bottle. McEwans in particular  
> is in clear glass and tends to go off.

Sam Adams Double Bock is a fairly sweet beer. Anybody at the Conference get to try "Wee Heavy" on Friday night? Now that was sweet, not to mention having a "hit me over the head with a stick" alcohol content!

>estery - Anchor Liberty Ale is very fruity for a commercial  
> beer. This is typical for an "ale" style but still strange to  
> the American palate, if there is such a thing.

You want fruity? Try the new (you guessed it!) Samuel Adams Wheat Beer (!! ) due to hit the stores in a couple of weeks. It's light and crisp, a good thirst quencher, with an incredible banana ester. I hope it's as good in a bottle as it was straight out of the conditioning tank at the brewery.

During the Saturday brewery crawl at the AHA conference we visited the Boston Beer Co. and Jim Koch (he pronounces it "Cook") himself served as tour guide. When he was done discussing the brewery operations, he grabbed a stack of plastic cups and said "Anybody wanna try some beer?" (silly question :- ) He then proceeded to open the spigot on the "bright beer tank" and pour a glass for everybody who wanted one.

If someone out there was in attendance and taking notes, maybe you could pass along some of the comments Jim made about the yeast he uses for the Wheat Beer? It's pretty amazing stuff. Anybody out there know Fred Eckhardt personally? I know he was taking notes. Now if we could get him on the net...

I always used to think Jim Koch was a marketing slime type, probably because I get to hear his commercials on Boston radio all the time. After talking beer with him at the brewery, I've found a new respect for him and his products.

Try the wheat beer. I thought it was pretty amazing. It smells more like real bananas than real bananas do! :- ) Your mileage may vary.

My first batch was a 'short' batch by mistake (didn't measure the H2O correctly) and I ended up with about 3 or 3.5 gallons for my 5 gallon extract recipe. I was GREAT! Quite strong, and it was very flavorful.

One problem - it was so good, it didn't last long! Also, you really couldn't drink more than 1 or 2 at a time due to the alcohol content, or you'd really get @#\$(\*(%# :-).

I haven't tried the two-cans-of-extract for one batch method yet, but that seems like the best of both worlds (full batch, but very strong at the same time). I may make my next batch in a similar manner.

From: R\_GELINAS@UNHH.UNH.EDU (Russ Gelinias)  
Subject: hoppt

Someone said to smell Sam Adams Lager straight from the bottle for an example of a hops aroma. I agree, but Sam Adams Stock Ale has even \*more\* hops aroma, almost too much for me, and I like hops alot. The hops do seem to be more easily sniffed from the bottle. Maybe the small nostril-sized (more or less) opening helps concentrate the aroma for a good sniff. I always take a good sniff from the open bottle before I pour off any beer.

From: Alex\_M.\_Stein.osbu\_south@xerox.com  
Subject: Re: Homebrew Digest #669 (June 28, 1991)

Tom Nolan (nolan@lhevax.DNET.NASA.GOV) described Sam Adams Lager as "like putting your head in a hop basket." Strange, that's how I used to think of Liberty Ale, which we get in LA both in bottled form on on draft in several of the finer drinking establishments.

And then, I went to the Anchor brewery and drank fresh Liberty Ale. It was as if I'd died and gone to hop heaven. I've never tasted anything so fragrant and wonderful and ... hoppy. Highly recommended. But then, I'm a big-time hophead.

Alex Stein  
astein.osbu\_south@xerox.com

PS: Unfortunately, I find it hard to drink "normal" Liberty Ale now, since the intense hoppiness seems to fade and, although I still love it, I can't help but compare it to the fresh unbelievably hoppy Liberty Ale I had at the brewery.

From: Rick Myers <hp-bsd!hpctdpe!rcm>  
**Subject: Near Beer**  
Full-Name: Rick Myers

Somebody recently asked about non-alcoholic brewing. I thought for sure that somebody would mention the article in latest issue (July) of Popular Mechanics! I will recap that article here, since it has some good info in it...

There are four methods currently used to make beer devoid of alcohol:

- a) vacuum distillation
- b) diffusion or reverse osmosis
- c) "stupid" yeast that ferments only 1% of the fermentables in the wort
- d) arrested fermentation

The fourth method, arrested fermentation, seems to produce the best tasting non-alcoholic beer, according to PM's tasting panel. The top three brews used the arrested fermentation method.

PM's rating were:

Outstanding

- 1. Clausthaler(Binding)
- 2. Haake Beck(Beck)
- 3. Sharp's(Miller)

Recommended

- 4. Pabst N.A.(Pabst)
- 5. Buckler(Heineken)

Drinkable

- 6. O'Doul's(Anheuser-Busch)
- 7. Old Milwaukee N.A.(Stroh)
- 8. Texas Select(San Antonio)
- 9. Birell(Hurlimann)
- 10. Kaliber(Guinness)
- 11. NA(San Antonio)
- 12. Goetz Pale Near Beer(Pearl)
- 13. Moussy(Cardinal)

Poor

- 14. Texas Light Dark(San Antonio)
- 15. Kingsbury(Heilemann)
- 16. Hamm's N.A.(Pabst)
- 17. Texas Light(San Antonio)

I thought the 'Drinkable' category amusing, as I don't find any of those listed in that category as being drinkable...

> many ways of retrieving these files, but I still get the changed  
characters.

Yes. The authors to "uuencode" the file after they compress it  
(not vice-versa!), and stick it somewhere where we can ftp it.  
This is standard stuff for files with special characters in them,  
such as raster images, or the output from "compress".

> At 8 days the measured gravity was 20 for the carboy with a minimal  
amount  
> of oxygenating and 14 for the carboy with lots of oxygenating. In  
general  
> the carboy with lots of oxygenating had a much more vigorous  
fermentation,  
> (visual observation).

Please be sure to tell us if the final gravity for the less-oxygenated  
wort is the same, even if it takes longer to get there...

On the same note, in trying to get my orange-ginger mead to carbonate,  
I took both cases and shook them last night. Did I pull a SNAFU?  
It's a dry mead, OG 1.088, FG .998, so fermentation stopped from lack  
of fermentables. I added 3/4 cup of corn sugar for bottling.  
It's been a month or two since bottling, and it spent 2.5 months  
fermenting.

BTW, it's the same mead that had a "soapy" taste to it when  
it was fermenting. From the responses we got here, I thought  
the taste was from not peeling the ginger. When fermentation finally  
stopped, it was totally clear a day later, and the soapy taste was  
completely gone. I must conclude that the taste was from the yeast  
(M & F champagne yeast, If I remember correctly).

cheers!

bb

Date: Fri, 28 Jun 1991 13:29 EST  
From: BAUGHMANKR@CONRAD.APPSTATE.EDU  
Subject: Conference observations & comments

Greetings one and all:

I just got back from the New Hampshire Conference and am catching up on all the Digests that came in while I was gone.

I thought the New Hampshire Conference was another resounding success. This makes my fifth national conference and I can't think of another event that I enjoy as much. A motel full of homebrewing freaks, each anxious to talk and share their latest and greatest brews. That's about as close to homebrew heaven as a poor old country boy like me can get. That goes for you city boys, too. :-)

It was great to put faces to some of the e-mail addresses I've been seeing for the last year. Mike Sharp gave a great Belgian lambic beer tasting. I found out too late to actually participate but I did wander around and grabbed a few sips from the ever-generous crowd. I played basketball in Belgium 13 years ago so I had already sampled most of the beers that were served in Manchester. I always love to see the look on someone's face as they sample these precious bottles of God's nectar for the first time! I even found Charlie Papazian's horse blanket krieg surprisingly close to style.

A few more observations: (because I can't resist!!)

I met Jay Hersh for the first time around 3:00 a.m. in his room. He's the only man I've ever seen who can read an issue of Zymurgy while fast asleep!

The Cornell contingent was well-represented. The Cornell site must have more homebrewers per site than any other node on the net. They may be quiet on the Net but they spent the majority of homebrew club night plying me with beers and stories. Then they sent me off stumbling to my room. Thanks, guys! It was great! You may talk with a funny accent but you make superb beers! BTW, Dr. Beebe, I'm Master Baughman to you. :-)

Darryl Richman, thanks to the fame and quality of his responses on the Digest, was as popular a personage as the inimitable Charlie P. All week long, one could hear, "Are YOU Darryl Richman?!!!!!" echoing through the halls. Oh, the price of fame and notoriety.....

Martin Lodahl wasn't there to spout his memorable impressions of the beer in hand but someone had brought along his picture. I'm not sure how much money Martin had to pay him to do it, but it was barely worth the price! Sorry you missed the framboise tasting, Martin. I'd love to have heard your impressions of some of those beers.

Pete Soper was there to help me prove once again that the culture and breeding of the south shines like a beacon through the murky darkness and cultural depravity of those lands beyond the Mason Dixon and Mississippi River. But, hey, we understand that you can't help where you were born. :-)

I talked with Russ Gelinas for a while at the framboise tasting. But we didn't drink enough to break through his calm, even temper so I have no lurid tales to tell of him terrorizing the night!

As for me, I maintained my usual calm, unassuming disposition, maintaining sobriety at all times, preaching moderation in all things, and only saw the sun rise twice.

Now on to various and sundry comments from the last 10 HBD's:

You can make the pick-up tube in a keg longer after cutting it by attaching a short length of siphon hose to the bottom. It's a good idea to change it every now and then.

A nice way to get the effect of boiling hops loose in the pot with the convenience of putting them in a hop bag is to line the boiling pot with either a sparging bag or a BIG mesh bag, one that allows you to fold back the top along the rim of the pot. You might need to weigh down the big mesh bag with a circle of copper tubing. When the boil is over, pull the bag out of the pot, taking with it the hops and a fair amount of trub. However, I STILL say use the pot scrubber in a hop bag routine. It's simpler and works great.

As for a quick way to empty carboys: Stick your siphon hose or a long length of copper tubing into the carboy and pour. I guess this is a variation of the soda straw in a bottle technique. I just discovered it about a year ago and slapped myself (ouch!) for not having realized it earlier.

Mike Schremp seemed to imply that when mashing in a picnic cooler, one can recover the mash water, heat it up on the stove, and then return the water to the cooler to boost the temperature. BE CAREFUL!!!!!!! The mash water contains all the enzymes and if you bring that water to a boil, you will destroy all the enzymes and thus kill the starch conversion process.

Treating water with Burton Salts:

If you're brewing with extracts, forget the water salts. The extracts already contain all the minerals and salts that you will need for that beer. If you're making an all-grain beer, it's better to get your water tested at your local water plant or give them a call for the ion content of the water if you're already on their system. Adjust your water according to beer you're trying to make. In general, soft water for lagers. Hard water for English type ales.

An interesting aside here. Pere Theodore of Chimay fame told me that the water at the monastery is extremely soft and they make their ales without treating it at all.

Still on the subject of water treatment, watch out for the transcripts of the Manchester conference. Greg Noonan gave a great workshop, in particular giving references to easily obtained kits that allow the testing of your water in your own home.

Clean your boiling pots, Bruheats, and coffee pots of stains by boiling a little bit of B-Brite in them. The more I use that stuff, the more uses I find for it.

To increase heat transfer in your 15 gallon keg-converted boilers: Find a fifty gallon drum. Cut the top foot or two off with a metal cutting blade on a circular saw (or take it to a welder). Then cut a circle out of the other end of the barrel, just big enough to fit the keg/boiler through. The idea here is to make a jacket that goes around the keg which traps much of the heat that would otherwise escape to the air and slip this jacket around the boiler during the boil. You'll also need to cut a couple of 1" x 5" holes around the top of the fifty-gallon drum to allow the gases from the burner to escape.

I entirely agree with Mike McNally's observation that one should aerate the wort in the carboy by sloshing the beer around while it's filling. I've been advocating that for my BrewCap customers for the last five or six years. It's especially important to aerate the wort well in the BrewCap since it is a closed fermentation system. The idea of connecting a T-fitting in-line with an aquarium pump pumping air into the cool wort sounds like a great idea. I can't wait to give it a try.

Cheers ya'll,

Kinney Baughman | Beer is my business and  
baughmankr@conrad.appstate.edu | I'm late for work.

From: randy@grebyn.com (Randy Tidd)  
Subject: Need info on Keg hardware

I have a question about Kegging my homebrew -- but my subscription to this forum isn't currently active, so I'd appreciate a reply via e-mail.

I recently acquired one of the old-fashioned aluminum kegs, one of the Aheiser Busch "Golden Gate Kegs"; these are the ones with the bung hole in the middle of the side, and taps on the top and bottom. What I need is the hardware to use it -- replacement bungs, and a tapper system. The tapper system will have to be a 2-piece one, with the pump for the top tap hole and a spigot for the bottom tap hole.

Can anyone give me any pointers? I asked my local homebrew shop and the guys at 1-800-321-BREW and neither could help me out. One guy mentioned a place in Kansas called Foxx, but I have no way of knowing what their phone number is or even if they still exist. Any tips on this company would also be appreciated.

Again, please send the info via e-mail to randy@grebyn.com.

Thanks!

Randy Tidd

**Subject: Need info on Keg hardware**

Problem - How to extend standard 5 gallon all-grain mash recipes to 7 gallon volume.

Variables -

- \* Conflicting information!!! I recently followed a ZYMURGY recipe from the Yeast Special Issue that used 15-20 lbs. of grain & I still only produced 6 gallons.
- \* 99% of all published recipes appear to target 5 gallon batches, regardless of the contents used.
- \* The '1 quart of water to 1 pound of grain' rule of thumb doesn't seem to help. Is more sparge water the answer?

Questions -

- \* What are some tried-and-true 'extender' techniques for increasing water content but not diluting the beer for an all-grain mash.

thanks.... Tim.Weil@f131.n109.z1.fidonet.org

From: D\_KRUS@UNHH.UNH.EDU (Daniel L. Krus)  
Subject: RE: US formulations of imported beers.

Bob makes reference to Beck's American beer being different than their European version. I can personally attest to this. My sister is a flight attendant for NorthWest Airlines and she has brought me back a couple of 5L kegs. This beer is MUCH better than the American version. It has much more flavor and is much smoother, almost creamy. European Beck's is a superb beer.

From: msharp@hawk.ulowell.edu (Mike Sharp)  
Subject: Lambic experiment update

Hello All,

I heard from Martin Lodhal that some of you have been wondering about the lambic experiments. So here goes...

Currently there are three test batches. I've made two and Martin has made one.

Test Batch #1 --

Started back in January. This is 60% malt 40% malted wheat fermented in a 15 gallon oak primary and a 15 gallon oak secondary.

This was inoculated with Wyeast bavarian wheat (it seemed like the thing to do at the time) followed by *Pediococcus cerevisiae* and then *Brettanomyces bruxellensis*.

Test Batch #2 --

Started about 1 (2?) months ago. Again, a 60%/40% mix, but fermented in glass this time. Wyeast European was used for the ferment, followed by *Pedio* and *Brett* as with #1.

Martin's batch --

ummm, I'm not sure what he did... probably something simmilar. He'll have to tell you when he gets back from vaccation.

A few weeks before the conference (AHA) I made a pseudo-gueuze by blending

my two test batches 50/50. It is currently a redish-golden-wierd color. Sort of like a light honey with just a hint of red. Carbonation is extremely

slight, but its been increasing as the *Brett.* works at what is left of the

fermentables. The nose is mostly of oak, but not unpleasantly so. The taste is a combination of oak, lactic acid, and a sort of subtle fruityness.

There is a subtle hint of hops (if you look for it) as well as a slight malty flavor too. There isn't any one dominant flavor, many different ones.

I think this turned out remarkable well given (a) a new oak barrel and (b) having almost no clue about making this when I started. Of course this

really won't be ready for a year or so, but its already showing promise.

I can hardly wait to start the next batches given the result of these batches.

I should be adding some Moreno cherries to a few gallons of test batch #1 in a week or two, and once my \_28\_ gallon brewery is functional (gloat) I'll be back to using the cask. (it took me 20 straight hours the last time I made a batch in the cask -- I'm a fanatic, but not crazy enough to do that again).

As for the tasting at the conference, I think it went very well. You'd be

hard pressed (I was) to assemble that many lambics/flanders browns outside

of Belguim. The final lineup was Liefman's Goudenband, Timmerman's Kriek & Framboise, St. Louis Gueuze, Mort Subite Kriek, Alexander Rodenbach

(the 150 aniversary beer, not the gran cru), Lindeman's Framboise,

homemade gueuze from Mike Matucheski, homebrew kriek-substance from Charlie Papazian, assorted trappists from Darryl Richman (I think), and probably a few others I'm forgetting. Both tastings lasted about 2 hours, proceeded at a rather relaxed pace, and were very informal. Pictures of Cantillon (thanks to Martin) were passed about. The list of reservations reads like a HBD,CI\$,AHA whos-who. I think we need to do this again next year... (it was interesting to see how many of the 'good people' I pulled away from the opening ceremonies)

Current cultures for making lambics: (I'm keeping them)

Pediococcus cerevisiae

Brettanomyces bruxellensis & lambicus

Saccaromyces globosus

I have two others, but they're not going anywhere until I figure out if they're `safe'.

I'll be experementing with a line of 'Belgian kits' sometime soon. A supplier at the conference told me about them & will hopefully be shipping me a few for testing. I'm particularly interested in if (& how) they have the same lactic acid character, or if they result in just a standard fruit ale. Stay tuned for more info.

Finally, every month or so I create a 'best of' collection of lambic notes that appeared on my mailing list. For those of you who want to keep up w/o the daily junk-mail this might be a viable route. Note that I have two such 'best of's at the moment (a third is due) and each is about 800 lines.

Subject: US/Canadian beers, good wishes for the summer.

Happy Canada Day, fellow homebrewers!

I'm about to sign off the list for the summer: vacation, conferences, moving.  
I'll be sure to get back on after Labour Day. The first 14 months has been great; I look forward to many, many more.

On the subject of US beers in Canada and vice versa:

Canadian main-line beers are almost comically consistent: 5% alcohol by volume and a FG of 1010, no matter who makes 'em and what they're called. This means that they start at 1048 or so and we may ball-park the \*real\* residual extract at 40%. Needless to say, you need a \*few\* hops to balance that much sugar. Even a beer like Blue - a sop to the contemporary palate, being about 1/3 adjunct (legend puts it as high as 4/9!) and relatively sweet - has been hopped to an extent you wouldn't find in Miller or Bud. Therefore, Canadian Miller and Bud, which are brewed under licence, are very little like the original, as they match typical Canadian specs.

Did I hear some innocent soul ask why they would bother to brew beer named Miller or Bud that's nothing like the original number? Simple: for a modest licence fee, the Canadian breweries cash in on decades of American beer commercials which we Canucks have watched on cable.

Canadian beers in the US, on the other hand, are imports. I won't promise that the Blue and Golden we get down here is exactly the same as the stuff in Canada, but Moosehead is typically Canadian - 5%, 1010 and a fair hop bite. (Caveat: beers brewed by the big Canadian brewers are often sufficiently bitter, but virtually never have decent flavour/aroma characteristics.)

Moosehead segues nicely into the province-to-province trade issue. I grew up in Quebec and lived for 8 years in Ontario. I never tasted Moosehead until I moved to Chicago. 9 Canadian provinces (tiny Prince Edward Island is the exception) have a simple law - brew your beer here or it will be treated like Becks and Newkie Brown: an import, available only in provincial liquor stores. This is just one example of the sort of inefficiency built into the Canadian economy by decades of pork-barrel politics aimed at keeping as many workers in the "regions" of Canada as possible, instead of flooding to the big urban centers. The result is that even a beer like Blue, which is available everywhere, is brewed in different provinces with different water, different brewing kettles, different size batches, and so on. Moosehead, BTW, is brewed in Nova Scotia and New Brunswick and apparently sells better in the US than in Canada.

A closing note for residents of/visitors to Ontario. According to the brewmaster at Molson's Toronto brewery in '88 (maybe '87), Molson's was the only brewer selling 100% malt beers at regular prices. They

make 4 all-malt brews: Lowenbrau (under licence) and Porter (decent sweet stout) are premium-priced, but Molson Stock Ale and Export Light are regular priced. Export Light is a misnomer - it should be called Stock Light, as it's the dilute formulation of Molson Stock Ale. At 4%/vol and 1010 with a good hop bite, it's a reasonable alternative to the usual mind-numbing 5% stuff we Canadians grew up swilling. Molson Stock Ale - 5% and 1012 with real bitterness - is just about the last example of a Canadian traditional ale, the sort of thing 'real' Canadians drank until the 1960s. Even IPA has now been yuppied up.

The foregoing is not meant to imply that the big breweries are the whole story. Ontario has provided fertile ground for micros and brewpubs, ranging from the excellent to the atrocious, over the past few years. I'll drink a few pints of Wellington County (they make real ale a la CAMRA, available in pubs only) and sup some Brick and Upper Canada while I'm home, but the case of beer in my trunk when I cross the border will be Molson Stock Ale.

Have a great summer,

Rob

**Subject: hop flavor**

regarding tom's (nolan@lhevax.dnet.nasa.gov) request for info on tastes. I feel its important when considering beer taste, but not often said out loud to beginners, to understand the difference between 'bitterness' and hop flavor. hops, depending on how you use them, can add either. beers can be very bitter but not taste like hops (but the bitterness is from the hops). taste any english bitter for a bitter taste. for hop flavor- try spaten!

From: polstra!jdp@uunet.UU.NET (John Polstra)  
Subject: Water Treatment for Lagers

In HBD #670, baughmankr@conrad.appstate.edu (Kinney Baughman) had plenty of interesting stuff to say (I loved the technique for emptying a carboy), but I am responding here to his comments about water treatment:

> Adjust your water according to beer you're trying to make. In general,  
> soft water for lagers. Hard water for English type ales.

This is the common wisdom and it's what I used to do, too. But further study has convinced me that "soft water for lagers" is bad advice. (Actually, what is usually advised is "soft water for \*pale\* lagers," and I'll assume that's what Kinney really meant.)

Where does this idea come from? It seems to stem from the following line of reasoning:

1. The greatest pale lagers in the world come from Pilsen.
2. The water in Pilsen is extremely soft.
3. Therefore, soft water should be used for pale lagers.

Makes sense, eh, so what's wrong here? What is wrong is that this line of reasoning does not take into account the brewing \*process\* that is used in Pilsen. It turns out that the brewers of Pilsen were not able to brew good pale lagers until 1842, when they first began using an acid rest during the mash to compensate for their soft water. [1]

The acid rest is a rest at around 95 degrees F which is done before the protein rest. As its name implies, the acid rest has the effect of lowering the pH of the mash. It is necessary in Pilsen only because the water is so soft there. If the water had the proper level of calcium ions in it (and not too much carbonate) then the pH would settle out at a good value on its own.

You're not going to get the best results in making a pale lager with soft water unless you either add an acid rest to your mash schedule or treat the water appropriately to bring the calcium level up. In my opinion, treating the water is a whole lot easier and more reliable.

The key to treating soft water is getting the calcium level up to 50-100 parts per million. This will (again, assuming you don't have a lot of carbonate ions in your water) cause the mash pH to be correct and will make an astounding difference in the amount of extract you get from a given amount of grain. It will also shorten the starch conversion time by an amazing amount. Consider the following table from [2], which describes five mashes with identical ingredients except for the water treatment:

| CaSO4 | CaCO3 | pH   | Conversion Time |
|-------|-------|------|-----------------|
| 0     | 0     | 5.95 | 45              |
| 0     | 50    | 6.15 | 60              |
| 125   | 0     | 5.65 | 15              |
| 250   | 0     | 5.35 | 10              |
| 125   | 50    | 5.75 | 30              |

Here, concentrations of CaSO4 (gypsum) and CaCO3 (calcium carbonate) are given in parts per million, and conversion times are given in minutes. The article goes on to state:

These examples show how strongly the composition of the brewing water affects the mash. Similar results have been reported for commercial brews, however, the conversion times tend to be lower than those reported in Table 1 ... Conversion times of 20 minutes are considered bad in commercial brewing since they can yield unpredictable carbohydrate profiles.

Those who are used to doing 2-hour mashes, take note!

By the way, 125 ppm of CaSO<sub>4</sub> adds 29 ppm of calcium to the water, while 250 ppm of CaSO<sub>4</sub> adds 58 ppm of calcium.

I started systematically treating my brewing water about nine months ago, and I have noticed a real improvement in extract efficiency. Brews that used to take 10 lbs. of grain now need only a little over 8 lbs. Mash conversion times have dropped noticeably, as well.

I generally use a mix of gypsum and calcium chloride to treat my ultra-soft Seattle water. When I want to accentuate the hops, I use more gypsum and less calcium chloride; when I want a softer or sweeter flavor, I shift the balance in the other direction. In any case, I make sure that the total calcium ends up in the 50-100 ppm range.

Enough of my rambling. Here are the references:

From: polstra!norm@uunet.UU.NET (Norm Hardy)  
Subject: Aphids aphids everywhere and not a hop to drink

Here in the summer(?) of wet Seattle, my hops are slowly growing. But, the aphids grow even faster.

Here is what I have tried, but I would like to hear how others' are dealing with pests:

Although I have used Diazinon to kill the suckers (and lady bugs too), I prefer softer methods. Lately I have been setting the garden hose on stun (spray) and manually knocking the aphids (and spider mites) off the leaves. Not only is it a wet process, but lengthy as the foliage on the Herzbruchers is extensive (some leaves are 12 inches across the longest span). But it works, on the short term as I have to do it again two days later. Most of the problem is located on the back side of the leaves.

My botanical neighbor purchased a bag of 1500 lady bugs for her garden, and some naturally came over to check out the hops. But they appear to have flown away home.

Lace flies are also trying to eat the aphids but they don't appear to put a dent in the supply. They merely tell me where the concentrations are.

Any other HBD hop growers out there want to share?

> in a hops basket. Try drinking it straight from the bottle.  
> I don't know, it must shoot the hops right up your nose.

I agree, but would be more specific and say Sam Adams Lager has a \*lot\* of hop \*bouquet\* AND quite a bit of hop flavor. Sierra Nevada Pale Ale also has quite a big hop nose and taste. Anchor Liberty Ale has quite a bit of hop flavor/bitterness but a little less hop nose (if I remember correctly). I'd also like to add that, in my opinion, the 1990 Sam Adams Christmas beer (I forget the actual name) was just as hoppy in nose and palate but had a bit more maltiness -- a more well balanced beer than the Boston Lager. I wish it would be available year-round.

>sweet - Any of the scotch ales, like McEwans. They're apparently brewed  
> with crippled yeast to produce sweet diacetyl flavors. The  
> only trouble is finding a fresh bottle. McEwans in particular  
> is in clear glass and tends to go off.

If I recall correctly, I get my McEwans (Scotch Ale and Export) in brown bottles (Chicago Metro Area). I would add Sheaf Stout (by Tooth's) to sweet beers and Mackeson's XXX Stout is also pretty sweet. Compare to Guinness Extra Stout which is a dry stout (especially in the bottle -- note that Guinness on Draft is a very different beer than in the bottle).

I would recommend Samuel Smith's Pale Ale for diacetyl flavor, but it's not as sweet as the beers mentioned above.

>estery - Anchor Liberty Ale is very fruity for a commercial  
> beer. This is typical for an "ale" style but still strange to  
> the American palate, if there is such a thing.

The fruitiest beer I've ever tasted is Orval Trappiste Ale. A cross between banana and (forgive me) bubble gum. I've heard that, on one occasion, a person got a hold of a very bad bottle of Orval. If it tastes awful, you got one too.

Finally, I would like to dispute Paul's contention that Molson Golden is a hoppy beer. Paul-- once you try Sam Adams, Liberty Ale, and SNPA, you may feel compelled to write a retraction ;^), but you don't have to.

Here's to beer with flavor! (I'll drink to that!)

Al.

From: Tom Dimock <RGG@CORNELLC.cit.cornell.edu>  
Subject: Cornell Homebrewers

In HBD #670 Kinney Baughman remarks "The Cornell site must have more homebrewers per site than any other node on the net." Probably true, and I just wanted to give a little credit to those responsible. Steve Russell ("primary fermenter"), Dwight Beebe ("chief brewing fool"), and the rest of the membership of the IBU make it hard to NOT be a homebrewer.

You walk into the Chapter House on IBU meeting night (either on purpose or by accident) and here are 30 or so loud and lively people who have brought their own beers to a bar with some of the best brews available! Not only that, but the owners are enthusiastically participating, rather than chasing them out or calling the police. Showing the slightest bit of interest gets you a fast intro to the art of homebrewing (complete with samples), a trial subscription to their excellent newsletter, and an offer of an experienced brewer to help you through your first batch! It also didn't hurt that at my first meeting the guest of honor was no less than Michael Jackson!

Well, you might be able to walk away at that point, but then you start getting E-mail from Steve about everything from upcoming IBU events to blowing up dead whales with half a ton of dynamite. And every time you go into the Chapter House James or Laurie Clement or someone from the club wants to know how you're doing.... Next thing you know, there's five gallons of brew bubbling away in the kitchen, and the HBD has become the high point of your working day.

So thanks, IBU, for getting me into this; I'm looking forward to sharing my attempts and helping get someone else into this silly sport!

Well, what you really get is improving the ratio of "good stuff"  
(i.e., malt) to "bad stuff" (i.e., sugar). By eliminating the  
sugar from your recipe, you get a more full-bodied and better  
tasting brew (IMHO) (certainly it will be "maltier" :-).

Yes, you can brew a 2.5 to 3 gallon batch with one can. In fact,  
that kind of approach is now showing up on the kit directions.  
The latest \_zymurgy\_ had a review of a kit designed for 3 gallons  
that said just use the can and don't add any sugar. Good going,  
I say. The fewer kits that advocate using sugar the better.

Well,

It is worth a minor note here that there is a \*big\* difference (IMHO) between using a "kit" and using malt extract. A "kit" is usually in a can and is formulated to make a certain type of beer, often containing the hops as well.

Many of us who brew with extract only buy light malt extract and add additional grains to achieve the pale ale, stout, whatever. I can heartily recommend this method and haven't bought a "kit" in over a year. But it does make it more important to condition your water, though all I have ever used is gypsum.

First, Brian Bliss replies to someone else:

>Yes. The authors to "uuencode" the file after they compress it  
>(not vice-versa!), and stick it somewhere where we can ftp it.  
>This is standard stuff for files with special characters in them,  
>such as raster images, or the output from "compress".

If you ftp'd the files with binary set and they uncompressed,  
the reason you're getting a U instead of ' is not because of  
the ftp link. You do not have to uuencode something to use  
ftp. As one of the authors explained to me, he had a similar  
problem because of the printer connection to his computer not  
supporting the "higher" bits, or something like that. The  
character ' is not represented in ascii in the postscript file.  
Apparently, the printer is only getting part of the information.

If you're as dumb as me :-)) and tried to vi the file to put  
a manual feed instruction (it looked like the "book" was formatted  
for printing out on two sided pages) in there and then wrote the file,  
you'll also find that vi strips non-ascii characters and  
replaces ' with U. I have fixed this problem and gotten it to  
print out two sided, though, for anyone interested and willing  
to sit next to the printer feeding in pages.

Subject: Rob B's Canada Posting

Wait Rob, don't go away just yet, you can't post something so long and informative on Canadian beers and then go away without answering a few follow-up questions.

Specifically when you quote alcohol contents, are you doign it by Volume (what the rest of the world uses) or by Weight (what we fools in the US use). When you call something a mind numbing 5% (assuming it's by volume) that's the equivalent of ~4.2% which is not very different from many US beers. Of course if you've already adjusted to US for the sake of the posting and just forgot to mention it, then to quote Emily Latella, "Oh never mind...."

It's true. Many of the prepared fruit juices say "100% natural", and, if you read the fine print, "10% fruit juice". As I understand it, one could sell sawdust and call it 100% natural, so that phrase is exquisitely meaningless. High fructose corn syrup is not a "naturally" occurring substance to my knowledge.

A little more "truth in advertising" would be wonderful, including listing of ingredients on ALL products intended for human consumption. (And animal consumption for that matter!)

Subject: Peristaltic pumps

Has anyone considered using a peristaltic pump to move their worts between containers during chilling, racking, and bottling? These simple pumps are used in medical applications like heart-lung machines because of their gentle action. It would be nice not to have to raise and lower heavy containers full of wort, and perhaps do away altogether with the frustrations of siphoning.

What say?

In HBD #? (I forgot the number :-()), Ken Ellinwood writes:

>Does anyone know what varieties and proportions of hops are used  
>to brew Sierra Nevada PaA friend and I are interested in  
>brewing a copy-cat version. Thanks in advance,

I was at the Sierra Nevada brewery last month for a tour. At the end, the tour guide showed me the brewsheet they use for the Pale Ale (I took notes, of course). I don't have them here so I can't give all the details, however I do remember the type of hops used. For bittering, they use an "experimental high-alpha Cascade" and for steep they use regular Cascade. No one there was completely familiar with the process (it was Saturday) so I couldn't get any real information on the experimental Cascade (like, what is the alpha analysis).

For what it's worth...

In HBD #671, I wrote:

> By the way, 125 ppm of CaSO4 adds 29 ppm of calcium to the water, while  
> 250 ppm of CaSO4 adds 58 ppm of calcium.

That's not quite right. Actually 125 ppm of \*gypsum\* adds 29 ppm of calcium to the water, while 250 ppm of \*gypsum\* adds 58 ppm of calcium. Gypsum is calcium sulphate dihydrate, or CaSO4 \* 2H2O.

In the article I was referring to, the author said he added X amount of "CaSO4". I don't know whether he was using gypsum, or really using the anhydrous form of calcium sulphate.

125 ppm of anhydrous calcium sulphate (CaSO4) adds 37 ppm of calcium, while 250 ppm of anhydrous calcium sulphate adds 74 ppm.

More than you ever wanted to know about water treatment ...

Subject: Possible Aphid cure.

Norm Hardy asks about the critters munching at his hops. My organic gardening friends and I use this combination:

1/2 gallon white vinegar  
1 bulb garlic, all cloves peeled and crushed  
1 bottle cayenne pepper

Mix it all together and let stand for two weeks. Strain and spray on your garden. I know, it sounds \*strong\*. It is, don't eat it, just spray it on the hops. It doesn't work for all pests, but it keeps many away, and the rabbits, too.

Subject: Zymurgy @ 3AM, Harvesting Hops

Hey folks, I just moved into Steve Stroud's former residence and inherited his hop plants. They have flowers on them, some quite sizeable, and I'm wondering about harvesting them. What should I look for to know when to harvest them?? Any special technique, or is just pulling them off OK?? Will the vines continue to flower throughout the season or do they flower just once??

When they are big, green, and have decreased slightly in springiness when you squeeze them, it is time to pick them. You will know for sure next time, because when you let them go too long, they turn into a dried out brown.

Just pull them off (some people say to squeeze them off with thumb & forefinger). But be gentle, since all of the good stuff is the light, powdery yellow stuff inside. After picking, dry them to gain consistency in your weight measurements (last year, my 12 oz. wet dried down to 3 oz.).

The vine you have picked from will not flower again. It can be removed. You should have some fresh vines which are climbing up the existing ones; these will get their own flowers, so effectively you get multiple harvests. Last year, I had three separate harvests off of mine.

I haven't heard of a good way of characterizing the alpha of homegrown, so I just use mine for aromatics.

Subject: Wort Aeration notes...

Way back when I was taking HS Chemistry, I noticed that the teacher put brass extensions on the faucets, and they had an extra short arm that stuck out horizontally. Each end had "grips" for holding rubber/plastic hose. It turns out that when unobstructed, the extra arm aerated water as it passed. When this was obstructed, the water ran "clear." So, naturally, now I view this as one possible means of aerating wort: rack through the pipe. It should be easy to clean, and it aerates quite non-violently. Also, the teacher at one point turned on the water, let it run down the drain, and hooked a hose between the extra arm, and a bottle of ethanol, which of course, made the alcohol boil at room temp. Thus, we have a new method at allowing those who fear the germs of their mouth to be able to start suction in racking, with little anxiety.

..

My only problem now is: where do I get one of these? Am I going to have to go back to my HS to steal one?

Kurt...RDWHAHB!!!  
Your first suggestion is a wonderful idea. If it's possible to automate  
the  
process of subscribing and unsubscribing then HBD should go for it.  
However,  
your second suggestion may not be the most sensitive approach. We should  
be  
glad to see the keen interest shown by homebrewers who pursue a  
subscription  
to HBD with persistence. As posted in a recent HBD, Rob has been away  
recently  
and has been unable to attend to the growing list of requests. I'm sure  
that  
things will cool down now that he's back. I myself am relying on copies  
from a  
friend. I myself am guilty of sending an annoying "sign me up" directly  
to the  
forum after receiving no action from the request line. Had I received  
'annoying little "don't send that message to the whole group"' letters, I  
would  
have abandoned my interest in HBD. You guys are a friendly lot, and this  
is one  
thing that makes HBD fairly unique and thoroughly enjoyable.

I raise a beer to you Rob and apologize if you and others found my zeal  
annoying. Keep up the good work.

Relax, Jay, I don't leave til Friday morning. Wouldn't miss the  
fireworks  
and bar-b-q for anything. After all, this is only my second 4th of July  
:-)

> Specifically when you quote alcohol contents, are you doign it by  
Volume (what  
> the rest of the world uses) or by Weight (what we fools in the US use)  
.

Methinks (me fears!) I may have egg on my face. Canadian regular beer IS  
5%  
by VOLUME. There are stronger ones: Brador, Labatt's Extra Stock (called  
"Hi-Test" in BC), and a truly excellent beer called Upper Canada  
Rebellion  
(available in Ontario only) are all  $\geq$  6%.

I know that mainline US beers tend to be 4-4.4%. If this is indeed  
by weight, then you are absolutely right: that's about the same as 5%  
by volume. One of the (few) points of pride Canadians have with respect  
to their Southern cousins is the belief (promulgated as much by American  
tourists as our own kin) that our beer is stronger. Cruel man! Are you  
going to shatter one of my cherished adolescent myths?

As was noted in most of the requests and a subsequent post to the Digest,  
the recent flurry of non-brewing traffic (like this message here, for  
instance...) was caused by a lack of response to the homebrew\_request  
address. Said lack of response was due to Rob Gardner's vacation  
(imagine,  
the nerve of the man!), Rob is back, non-brewing traffic has dropped off  
sharply, so let's just drop it, OK?

But, as long as I'm here posting pure noise, I think it's been too long  
since we had a "Thanks, Rob" thread. Rob, I really appreciate the time  
and  
effort you put into keeping this digest going. Thanks!

From: IOCONNOR@SUNRISE.ACS.SYR.EDU  
Subject: How to subscribe to the Digest.

In response to the suggestion to annoy people who send to the list instead of to the "homebrew request" address for a subscription.

If you are on BITNET, then the listserv method is better than homebrew request. It is automated, and you can get on and off whenever you want to--especially if you will be away, and don't want a lot of mail. It takes about 30 seconds to subscribe via listserv.

For a vax machine type this:

```
$ send listserv@UA1VM subscribe beer-l "Your name"
```

to get off the list:

```
$ send listserv@UA1VM unsubscribe beer-l
```

For an IBM mainframe:

Tell listserv at UA1VM subscribe beer-l "Your name"

to get off the list:

Tell listserv at UA1VM unsubscribe beer-l

Any local "listserv" can be substituted for UA1VM, for example, I use SUVVM, and SUVVM forwards the message to UA1VM.

N.B.--If you subscribed to the list via homebrew request, you \*cannot\* get off the list via "unsubscribe." They are two separate mailers.

BTW Someone told me Rob was on vacation and thats why it took so long to get people on and off the list. True?

Kieran

Date: Wed, 3 Jul 91 14:25:18 CDT  
From: bliss@csrd.uiuc.edu (Brian Bliss)  
Subject: hydrometer readings, corn sugar, and hop pest repellent

On hydrometer readings:

>Specifically when you quote alcohol contents, are you doing it by Volume (what  
>the rest of the world uses) or by Weight (what we fools in the US use).  
When  
>you call something a mind numbing 5% (assuming it's by volume) that's  
the  
>equivalent of ~4.2% which is not very different from many US beers. Of  
course

from this I deduce that pure alcohol has a S.G of  $4.2/5.0 = .84$   
anybody with a bottle of everclear (and hydrometer) care to verify this?

hypothetically, assume that you have 1.040 S.G unfermented wort,  
with 5% potential alcohol (an approximation to the best of my memory),  
and anything non-water is 100% fermentable. It ferments  
completely - nothing left but alcohol and water (very hypothetical).  
It should now have a S.G. of  $.95 * 1.000 + .05 * .840 = .992$ , not 1.000  
A hydrometer calculation would indicate that that you have lost  
.048 S.G, and have an alcohol content of 6%, not 5%!

If the hydrometer manufacturers compensate for this,  
the label on the scale "potential % alcohol" is erroneous.

What they can adjust for is "% by weight" or "% by volume".  
I would assume that hydrometer readings are calibrated for weight,  
means you are weighing the stuff, but they could calibrate the  
potential alcohol scale for volume. It's calibrated for weight,  
is it not? If not, the rest of my argument is in error.

Note that  $4.2/5 \sim 5/6$ .

```
original potential alcohol:5 %  
final potential alcohol:  -1 %  
-----  
unadjusted alcohol content:6 % by weight  
adjusted for error in F.G: 5 % by weight  
    6 % by volume
```

You should always be able to multiply by 5/6 to get the  
% alcohol by weight, adjusted for the error in taking the  
final gravity. all equations are linear.

i.e. if the "potential % alcohol" scale on your hydrometer is  
adjusted for weight, it is really giving you % alcohol by volume  
after you subtract.

disclaimer: I don't have a hydrometer here in front of me,  
if 1.040 S.G. is not 5% potential alcohol by weight, the  
calculations will need to be re-done.

.....  
On corn syrup:

>High fructose corn syrup is not a "naturally" occurring

>substance to my knowledge.

Isn't it just corn starch that has been converted to sugar by the same malting process we homebrewers use? Is that not "natural"?

.....  
On hop pest-repellent:

>1/2 gallon white vinegar  
>1 bulb garlic, all cloves peeled and crushed  
>1 bottle cayenne pepper

Add a bottle of beer, an onion, and soak your brats!

I hope it doesn't impart a permanent off-flavor to the hops!  
(It's all water-soluble, it should wash away).  
You can always try electric fences...

The ultimate guide I used for a similar trip was Michael Jackson's Pocket Guide to Beer. Jackson includes directions, addresses, telephone numbers, etc. of breweries and drinking establishments. I used it as my primary guidebook. Another thing which I stumbled across was an association of Brewery-Hotels in Germany. I believe you could get more information on this association by contacting one of its members, such as Zum Uriege Brewpub in Dusseldorf or Hirsch Hotel in Ottoburen. Ottoburen was a particular highlight - besides the magnificent medieval monastary ("\*\*\*\*" - Michelin Guidebook) one cannot miss the hotel's swimming pool which is heated by the brewery's brew-kettles.

> Barry Rein  
> BREIN@gpvax.jpl.nasa.gov

Yes. My brew partner and I have a peristaltic pump. We use it for  
moving the hot wort from the brew pot through a copper coil immersed  
in ice water to the primary fermenter.

Here are some of the big advantages:

- 1) the pump is self-priming - no need to prime the pump with water via  
gravity
- 2) no contact with pump - the wort only passes through tubing
- 3) infinite speed control - you can adjust the speed of the flow to get  
the  
    correct temperature out of the wort chiller
- 4) clean up is easy - just run boiling water through the tubing when you  
are  
    done

The only problem we had was trying to find the correct type of tubing for  
the  
pump. The most common type of food grade plastic tubing is too stiff to  
take  
the constant flexing of the pump armature. We found peristaltic tubing  
that  
can take high temperatures (autoclavable).

This morning's Boston Globe reports that the government is FINALLY going to require all fruit juice to list the types of fruit juice used AND the percentages. Oh, Happy Day!

This regulation has been fought vigorously by our friendly neighborhood farmer's co-op and toxic dumper Ocean Spray. Noone would want to drink 100% cranberry juice (at least noone I know), so Ocean Spray feels that having to list the amount of corn sugar in juice will cause people to avoid cranberry based products, since they are (generally) mostly corn sugar. But the feds have finally prevailed, and soon we'll really be able to know what's in those bottles.

From: David J. Sylvester <sylveste@wsfasb.crd.ge.com>  
Subject: Fast Ferment -- Conclusion and More Wheat Beer

Hi

First, I would like to thank everyone who responded to my last post about a fast ferment on an attempt at a wheat beer. Sad tosay, I think the batch may have to go. Its been in the bottle for almost three weeks. I opened one after about two weeks. The carbonation was good, nice head but nasty smell and aftertaste. I'm going to wait and see what the effect of longer ageing will be before dumping.

Now for my next question. I have 6lbs of Williams Weizenmalt extract and 2lbs of wheat malt. I would like to try a wheat beer with this. What I would like are some suggestions for hops and yeast. I plan on making a five-gallon batch. Is the entire 6lbs of extract too much for a wheat beer? My understanding is that wheat beers should be somewhat light-bodied. Since I plan on using some of the wheat malt (2-4 cups) I'm wondering if 6lbs of extract would make the beer to rich.

As a related question, concerning yeast, does anyone care to comment on Whitbread's yeasts, ale and lager.

Thanx in advance  
Dave Sylvester

this?

Pure ethanol has a specific gravity of 0.79... which is close enough to  
say .8 or 4/5. Therefore, it is true, that the Canadian 5% v/v beers  
have just the same amount of alcohol as the American 4% w/w beers.  
(Sorry to shatter that myth).

> hypothetically, assume that you have 1.040 S.G unfermented wort,

000  
> A hydrometer calculation would indicate that that you have lost  
> .048 S.G, and have an alcohol content of 6%, not 5%!

Another way to look at this is that the \*Plato scale measures % sugar  
in solution. (This is a table that was originally cooked up by Dr.  
Balling, and then improved by Dr. Plato.) As a reasonable  
approximation, each 4 specific gravity points represent one \*Plato, or  
1% sugar in solution by weight. Of course, with a beer wort, not all  
of that is sugar; 10% or so is going to be protein. And even of the  
sugars, some are still too complex to ferment (dextrins). This is why  
beer fermentations don't get down to (or below) 1.000, while mead and  
wine do.

A rough approximation is that the yeast will ferment each 2 sugar  
molecules into 1 CO2 and 1 Ethanol. So each 2\* (8 points of specific  
gravity) drop--with the alcohol removed--results in a 1% w/w alcohol  
addition.

Consider now, that we have

$$d = x + y$$

where d is the drop in gravity noted

x is the drop resulting from loss of sugar

y is the drop resulting from the increase in alcohol

For y, each drop of 1\* in the x column results in the increase of  
alcohol by 0.5%. But that 0.5% registers as only 80% on the hydrometer  
because the alcohol is lighter than water. So, when we gain 0.5%  
alcohol, we lose 1 - 4/5 or 1/5 of a degreee. Therefore,

$$y = (x/2) * 1/5 = x/10$$

Now we have

$$d = x + x/10 = 11/10 x$$

which can be turned around to

$$x = 10/11 d$$

But we aren't really interested in the drop from loss of sugar,  
we want to know the drop from the increase in alcohol. Substituting  
from above

$$y = 1/10 x = 1/10 * 10/11 d = 1/11 d$$

Finally, the drop from the increase in alcohol is 1/5 the actual quantity  
of alcohol present.

$\% \text{ alcohol w/w} = 5 * y = 5/11 d$

Remember that this is all back of the envelope figuring, based on some approximations. In particular, this assumes an "ideal" fermentation. Yeast are not ideal fermenters, as they go through a respiratory phase (while oxygen is present) that doesn't produce ethanol, and also some of the carbohydrates are used to make more yeast and to keep as energy reserves. And some of the ethanol is transformed into esters.

For backup, however, I see that Fred Eckhardt, in his The Essentials of Beer Style, cites that each \*Plato drop results in the increase of % alcohol w/w by 0.4167. Greg Noonan in Brewing Lager Beer also cites 0.42 \*Plato as an approximation. 5/11 (0.45) is a 4% difference from above.

Because hydrometers have been sold to winemakers in the past, they are calibrated for % alcohol v/v. Since, as you point out, there is a linear relationship between % v/v and % w/w, they could easily do it either way.

From: MIKE LIGAS <LIGAS@SSCvax.CIS.McMaster.CA>  
Subject: RE: Wort Aeration Notes...

In HBD 672 Kurt Swanson <kswanson@casbah.acns.nwu.edu> posted a most interesting suggestion. He described a tap system (remembered from High School Chemistry class) in which an extra vent hole on a faucet provided a means of perfusing the running water with air. He reasoned that this may be the basis for an effective wort aeration system.

Well Kurt...you got me to thinkin' again! I am an all-grain brewer most of the time and that calls for a full 5 gallon boil followed by wort cooling via a counterflow wort chiller. It seems reasonable to suggest that a T-fitting could be placed at the end of the copper coil where the cooled wort is exiting. As the wort passes by the open side of the T-fitting it would be aerated in the same manner as water in the forementioned faucet. One could add an added level of security by placing a filter disc on air intake part of the T-fitting to provide sterile air. The filter disc would be the same as the one used in the 'Happy Yeast Infusion System' advertised in Zymurgy Magazine. These discs are available from lab supply companies and can provide filtration down to 2 microns.

The one potential problem I can see with this hypothtical design is that the flow rate of the cooling wort may not be sufficient to pull air through the microscopic pores of the filter disc but it should work without the disc in place. I'll give it a shot next time I brew and report my findings to the forum.

Mike Ligas  
ligas@sscvox.cis.mcmaster.ca

PS. I hope my verbal description is clear...I was considering an attempt at ASCII graphics but chickened out. Let me know if you have any problems envisaging my suggestions.

Subject: Oregon Micro-breweries beer fest

A friend of mine just sent me a message from Boulder. He just got back from a trip in Oregon and noticed that there is some kind of micro-brewery beer festival coming up in a few weeks.

Does anyone know if this is an annual event? I've already got my vacation plans booked for England and Germany in September. But this would be a great thing to plan for next year if it's an annual event.

BTW -- Anyone know of a special XB recipie? I love Theakston XB for its smoothness, but I can't seem to reproduce it's texture or the head retention for that matter. I suppose I should exercise less and drink more so that I may brew more!

Thanks

Subject: Mackison's after taste.

My experience with imported beers is very limited. A friend gave me a bottle of Mackison triple x stout yesterday. I tried it and was, well, not happy with the result.

I thought Mackison was supposed to be a "sweet" stout. It was sort of sweet, and that was just fine. My problem was with the aftertaste, one that was reminiscent of fermented raisins ... or was it prunes ... Needless to say, I found the aftertaste unpleasant. Did I get a bad bottle, or is that a correct taste. What contributes to that strong after taste? How do I keep from duplicating it?

More importantly, is Mackison considered a fine beer and my palate just uneducated?

From: gozer!klm@uunet.UU.NET (Kevin L. McBride)  
Subject: Brewing by the seat of your pants

Just some random notes from my kitchen...

My latest batch is ready to rack into secondary. I brewed it last Saturday almost entirely on a whim. I had almost no homebrew left in the house and needed to do something. I'm going to call it:

"Clean out the closet Porter"

Well, I *\*think\** it's going to be a Porter. :-)

Due to a combination of being overwhelmed with technical information at the conference, and discovering some supplies I didn't know I had languishing in the back of my pantry, I took a "screw it!" attitude, relaxed, didn't worry, and tossed it into the brewpot.

Ingredients that I found lying around:

- 1 can Ironmaster Scottish Mild Ale extract
- 1 can Bierkeller light lager extract
- 1 lb. crushed crystal malt
- 1 lb. Munton & Fison Light DME
- 1/2 cup Lactose

Ingredients that I bought for the occasion at the last minute:

- 1 oz. Brewer's Gold hop pellets
- 1 oz. Cascade hop pellets
- 1 pkg. Whitbread dry ale yeast

Standard procedure - put crystal malt in cold water, heat to just shy of boil and sparge into brewpot, add malt extracts and water, bring to boil, add Brewer's Gold hops, boil a little over 1 hr., stop boil, add Cascade hops and chill on the way into fermenter. I tossed the dry yeast directly into the fermenter atop the cooled wort at about 10:00 pm.

Original Gravity: Beats me, I didn't even check.

The yeast started flocculating within an hour and by the next morning the air lock was burping continuously. Today, 4 days later, it is completely fermented out and I'm going to transfer it into secondary probably before I go to bed.

While I still do mostly extract brews with some adjunct grains, I haven't brewed with canned extracts in quite some time. I was at a homebrew shop a while back and they had a great deal where if you bought 6 cans you got an extra discount and I said, "Yeah, sure, why not?" Actually made a couple or three pretty good brews from them too. I do prefer to use DME now though because you do get more bang for the buck or fermentables per pound.

I can't wait to taste it and see if it's anywhere near decent or even what style it's close to (I think my original intent was to do a pale ale, but this is much too dark for that. :-) If it's good it will reaffirm my position that you don't need to get so scientific to brew good beer. You only need to get scientific to brew good beer consistently. I rather enjoy my own creations and have only tried on

a couple of occasions to get really methodical about recreating some commercial brew.

Some commercial brews are fairly easy to approximate if you're willing to overlook some of the minor rough edges. Others are difficult. Sam Adams Lager, for example, is pretty easy to approximate; start with enough light malt to make a moderately full bodied golden lager, add some crystal malt to give it that amber reddish color and more body, and go nuts with the Hallertau hops. A couple of my beer illiterate friends could hardly tell the difference. Of course, they also probably couldn't tell the difference between Bud and Pilsener Urquell. Why do we keep these people around? :-) I guess we need somebody who's willing to keep A-B in business. :-)

I wish that this new beer was going to be ready in time to take to the next Brew Free or Die meeting. (Hmmm, maybe if I siphon a couple of bottles full while I'm racking and slightly overprime them they'll be ready in a week. They certainly wouldn't last much beyond that, but then again, I don't intend to let them stay around that long.)

BTW, for any of you New Hampshire net.lurkers who don't already know, the next meeting of BFD is on Sat. July 13 at 3:00 p.m. Dan Hall can give you details. You listening Dan? :-)

Subject: ACK! It won't stop!

Hi all! I've got a batch of ginger beer in that I'm beginning to be concerned about. I pitch on the 15th of June and it's still bubbling through the fermentation lock! I did try rehydrating the yeast in some water (I think I added some sugar as well) then pitching. The stuff never did take off as it has in the past and the activity in the carboy has been pretty slow (compared to my past batches). What is going on? Is there something in ginger which contributes to slow fermentations? Any tips?

From: mcnally@Pa.dec.com  
Subject: decoction mashing

I picked up Greg Noonan's "Brewing Lager Beer" over the weekend, primarily to get more information on water treatment. The most interesting thing so far about the book is the staunch stand he takes on the benefits of decoction mashing vis-a-vis infusion mashing. As an infusion masher, I'm seriously intrigued. I'd like to hear something from people who've done both.

One thing I don't quite understand (I haven't read the whole book yet) is the exact procedure for boiling the decoctions. It seems to me that the thick part of the mash won't really boil, but will sort of splutter and spurt wads of wet grain all over the place. What sort of consistency should the boiled portions have?

The book is extremely informative. It seems to me to stand in relationship to TCHOHB as TCHOHB stands to Papazian; it's pretty heavy stuff. Excellent description of the chemical properties of cleaners, by the way.

From: smithey@esosun.css.gov (Brian Smithey)  
Subject: brewing English bitter

For those of you who have tried "brewing beers like those you can't buy in North Anerica", and have been put off by Dave Line's use of funny sugars, or confused/discouraged trying to substitute lactose (or anything else) for the saccharine, I think a friend and I have stumbled across the secret: use REAL English Crystal Malt. Rick (rolson@sea.com) and I recently brewed up a batch of bitter based on the recipe for Tetley's Bitter in Line's BBLTYB for Rick's wedding reception, and it came out with a nice residual sweetness that reminded us both very much of the Double Diamond that we've had on tap at a local pub. We've both used lots of domestic crystal in the past, up to 2 pounds in a 5 gal batch, and I've messed around with lactose, and never had results like we got in this batch with only .5# English crystal.

The recipe for this low-gravity bitter was very simple: English Pale Ale malt, English Crystal, a little wheat malt for head retention (this beer had a beautiful creamy-white head), Fuggles for bittering and a late addition of Bramling Cross for flavor/aroma. Maybe Rick will provide the quantities when he gets back from his honeymoon in a couple of weeks, he kept the records on this one.

For those who can't find real English crystal malt, all of the ingredients for this batch were purchased mail-order from Great Fermentations of Santa Rosa. They're listed in the "Cat's Meow" supplier index, and advertise in Zymurgy, etc.

From: eisen@kopf.HQ.Ileaf.COM (Carl West x4449)  
Subject: `T' aeration

It seems that if you're going to try to introduce filtered air into your cooled wort through a `T' fitting you would do well to \*pump\* the air in. Which calls out a problem with the idea. If you put the `T' fitting too far up the siphon hose, the air leaking in will tend to break the siphon. The `T' should be lower than the bottom of the source vessel. Then, if you want enough suction to draw alot of air through a filter and into the wort you'll need a fair drop in the hose after the `T', I suspect that 10 or 12 feet will not be enough. This is becoming a two-story operation. Pumping the air will solve the suction and height problem, but it makes the siphoning problem somewhat worse, the `T' will have to be put even lower in the hose to keep the added air pressure from backing the siphon up. Pumping the wort would fix the siphoning problem, but if you pump the wort, you \* must\* pump the air. How much equipment do you want to have?

It could be underhopped, or possibly too much crystal malt, or both.

I now add 1/4 to 1/2 oz. finishing hops (hallertauer, or cascade in a  
pinch)  
to my stouts to make a nice "hmm - I think I'll take another drink"  
finish.

To me, this is especially important when making a sweet stout, where  
the sweetness remains on the palate - it won't fade without the  
finishing hops.

bb

P.S. Isn't it spelled "Mackeson", or is that a different company  
that makes the scottish ale? (not that it isn't practically a stout)

Date: Mon, 8 Jul 91 12:11:03 MDT  
From: mike@chtm.unm.edu (Mike Lang)  
Subject: wheat beer (extract)

In HBD #674 David Sylvester asks:  
>> Is the entire 6lbs of extract too much for a wheat beer?  
I would say no, the wheat beer I had in germany was pretty thick.

These are my last two attempts at wheat beer, they may not be traditional but I liked them.

6#'s Wheat/Malt extract  
1# honey  
3 cups crystal  
1# DME  
2oz Haulertau Boil 1 hr  
1/2 oz Haulertau finish 2 mins  
cooled overnight outside  
rack to new carboy next day and pitch wyeast Bavarian Wheat

This one turned out good. Light amber color, a bit on the sweet side and I can taste a hint of clove. The next one I tried to make a little lighter with more hops

6# Wheat/Malt extract  
1# honey  
3 cups crystal  
20z Tetanger (alpha 3.6) boil 1 hr  
1/2 oz tet to finish 2 mis  
cooled overnight outside, rack and repitch slurry from previous batch

This ones a little lighter, I was expecting a big difference in the hop taste and aroma but the difference was very slight. Maybe there were too many fermentables to let the hop taste through. Both brews have a good kick (sorry about the lack of gravities but I brewed during finals week.)

The wheat malt extract was 60/40 mix from Alternative Beverage, the bulk stuff that comes in a jug.

Hope that helps,

From: wolfe@zeus.WEC.COM (braumeister)  
Subject: faucet aspirators

Regarding the devices you have all seen in chemistry labs in high school and college. They are faucet aspirators. They are designed to draw a vacuum on the side port when water flows through them. The limit of the vacuum is determined by the vapor pressure of the cold water stream. [about 24-26 inches of Hg]. A water pressure of @17psi gauge is required to start aspiration. They will act as aerators if the side port is not constrained.

I moonlight as chemist/analyst for a micro brewery and have access to lab supply houses. A nylon version (no temperature rating) model is available for \$12.50US, lab grade stainless for \$37 and chrome plated brass at 19.50.

Shipping time is about 2 weeks. (Most chemical supply houses will not sell to individuals, only to schools and labs because of previous law suits.)

Subject: Power Brew?

I read an article in the San Jose Mercury News this weekend that discussed a new product from Heilman's (sp?). The reason it was getting attention was because 1), it is allegedly being marketed at lower income minorities, and 2), it's name breaks some US regulation against allowing beer to have names that imply extra strength (Power, Super, etc.). I dont recall what this particular new brew is called, but was curious to note that the article stated that it's actually against the law to label the alcohol content on beer in the US. This is apparently to protect us from ourselves, as we would squander our dollars on the most powerful stuff without considering flavor :-). Incidentally, Heilman's is dropping the product.

Subject: off flavors

I've got a question about off flavors, but first a clarification on my mashing technique. I put all the contents of my picnic cooler into the boiler to raise the temperature, not just the liquid.

Now on to questions:

I made a dry stout (Miller's recipe) and have been getting a very strange off flavor. I have two suspected culprits. First is Chlorine contamination from not enough rinsing, the second is too warm a fermentation temperature. At first I suspected chlorine, because I classified the flavor as "medicine-like" but now I don't know. After bottling (the flavor was there at the end of the ferment) the flavor seems to be stronger. I didn't use any bleach in the bottles, so the chance for this flavor to develop more strongly isn't there.

High temperature fermentation is suspected because it was very hot when the beer fermented.

My question is, I want to taste a chlorine problem and a high temperature ferment. Can I add a drop (or less) of chlorox to a bottle of beer and then taste? Can anyone recommend a medicine I can buy at the drug store that has that classic "medicine-like" flavor? To taste warm fermentation, do I need to ferment a hopped wort, or can I ferment a corn sugar and water solution to isolate the yeast flavors? Are the higher order fermentables needed to get all the yeast produced flavors? Has anyone tried this? If I don't get any response, I'll try it and post the results.

Parting shot: I've really enjoyed reading the exploits of the conference attendees, particularly about the "Cornell contingent". Being an alumnus from the old times (before the drinking age was raised to 21 in NY), I was afraid that the party had gone out of the school.

From: Rob <C08926RC@WUVM.D.Wustl.Edu>  
Subject: St. Louis Info

Can't say much about brewpubs except that I hear that three may be opening soon. As for bars, Aunt Heidi's Corner has a wide selection, and Kent's Deli, while not a bar, is pretty good, although a bit high. Just picked up some Samischlaus from them...

Two liquor stores also come to mind as having a good selection - Bevco on Delmar, and Hobnob Liquors (formerly Life of the Party) in South County.

Hope this helps...

Rob

From: smennitt@oasys.dt.navy.mil (stuart mennitt)  
Subject: Re: Power Brew

The Washington Post ran an anonymous editorial yesterday (7/8) that sounded identical to the one mentioned. It slammed malt liquors in general and Power Brew in particular. One of the beefs was the advertising strategy of targeting minorities. The artical mentioned Power Brew's closest malt liquor competitors both had alcohol strengths of 4.5% by weight. Power Brew had 5.9% alcohol.

The editorial suggested not banning or regulating the advertising, but limiting the alcoholic content of malt liquor in general (to 4%). This showed the ignorance of the author to the legal definition of malt liquor in this country. The idea of listing strengths and ingredients on beer was not addressed. The artical stated that it was preferable to limit the strength of beer than to "limit the freedom of expression" by restricting advertising.

It also seems that the top selling malt liquors are just after the malt liquor label for marketing. Their strengths are barely over the "malt liquor threshold".

Basically, this artical scares me. I wouldn't notice if Colt 45 or Old English 800 were altered, but this trend would definitely outlaw beers like Anchor's Old Foghorn and Sierra's Bigfoot Ale. Not to mention EQU 28 and many other fine brews over 4% alcohol.

From: Chris Shenton <chris@endgame.gsfc.nasa.gov>  
Subject: yet another (and another...) request for brew pub locations

Hey, you know, the AHA has a list of brewpubs and micros that they'll send you for \*free\* (at least they used to). They may not be as \_au courant\_ as the HBD, but it is an awfully good starting point. Of course, they do not rate, praise, or criticize them.

Perhaps we could get the AHA to send the HBD its list and archive it? Or are they just not hooked up enough. Does anyone here read their compuserv forum? if so, what's there, and could we ship it here?

Also, the best guide I've found is Jackson's new and improved and updated and revised guide. It's very accurate for the places in DC, Baltimore, and Seattle which I know, and it got me around the Munich area and Prague quite well; amazingly thorough. Highly recommended.

>  
> Is there, or has any one given thought to compiling a list  
> of brew pubs from old homebrew-digests?

Since brew pub and similar requests constitute 5-10% of the postings here, I thought I would let folks know about a publication that may help out. The editor/publisher of the World Beer Review, Steve Johnson, has compiled 'the only current, comprehensive guide to U.S. brewpubs and microbreweries'. It's called the 1991 Guide To U.S. Brewpubs and is available for \$14.95 + \$2.00(.50 each addt'l copy) P&H from:

ON TAP ABA--WBR Publications  
P.O. Box 71  
Clemson, SC 29633

Some quotes from the flyer I have about the book:

- 212 brewpubs and microbreweries
- Organized in easy-to-use, state-by-state arrangement
- State maps and other illustrations
- History of the American beer renaissance
- Description of the brewing process
- Beer vocabulary
- 314 pages
- Fully indexed
- Sturdy paperback binding with cover in color

I don't have my copy yet, but plan on ordering it soon...

I caught a blurb on this while watching CNN last week. The beer was called 'Power Master' and had a black bird on silver background with a shield motif. The way it was advertised certainly made me feel as if it was a strong beer. When I first saw an ad. for it I thought 'Oh no, not another Heffenrefer (sp?) style beer'.

I didn't see a response copied to HBD, so I don't know if you ever got an answer. I have a Golden Gate keg, which I use when I keg homebrew - I like it better than the Hoff-Stevens style, because the Golden Gate fittings can be removed for better cleaning (I had a special tool made to do this).

Anyway, I got my Golden Gate taps from Superior Products near St. Paul, MN. This was a number of years ago, and I don't have a current catalog here at work, so I'll just give their address and phone number, and let you do the research.

Subject: Oregon Brew Fest

Dates: July 19, 20 and 21.

Starts friday, July 19 around 4 or 5. Starts around 11 or so on Saturday and Sunday. There will be 40 to 50 microbreweries represented, last year most had more than 1 beer. It's down on the waterfront, (Front Street), south of the Burnside bridge a ways. Front Street is on the west side of the river.

This is all from memory, if anyone wants more detailed info, send E-Mail and I'll get my flyer out and post.

One thing, in prior years they have ran out of the popular brews early. This year, they are splitting the beer into 3 lots so all brews will be available each day. You may want to go early in the day for the best selection.

Subject: Wort Aeration

All this talk of faucet aspirators, in-line tees with air pumps, etc.!  
What do you folks use to hang a picture -- a pile driver?

Take a 1-foot length of flexible tubing. Make a small hole (maybe a sixteenth or an eighth of an inch in diameter) in the wall of the tubing, a couple of inches from one end. (An electric drill at low speed works fine for this.) Attach the end with the hole in it to the output side of your in-line wort chiller. Put the other end of the tubing into your destination vessel and siphon away. A fine stream of bubbles will be sucked into the tube through the hole and your wort will end up nice and foamy in the fermenter. Simple, reliable, works great.

If you don't use an in-line chiller, just make a special siphon tube with such a hole a foot from the downhill end.

To make it work extra well, attach a fancy label that says "In-line Wort Aeration Venturi Aspiration Implement".

From: hplabs!ames!rutgers!alliant.com!obrien (Bob Obrien)  
Subject: Double Bock

I recently had the opportunity to relax with a few glasses of Sam Adams Double Bock beer. I found it to have a nice malt flavor with plenty of hops

aroma and taste. However I found it to be very sweet tasting.

I find that my own homebrew is very similar in style and taste, but not nearly as sweet. Now here comes the question..

Is double bock supposed to be a sweet tasting beer or was the fermentation

of the Sam Adams stopped early for some reason?

Your comments would be welcome.

Bob.

Date: Tue, 9 Jul 91 10:42:47 PDT  
From: polstra!norm@uunet.UU.NET (Norm Hardy)  
Subject: Decoction mashing

Mike McNally brought up the issue of decoction mashing, an excellent question indeed, as I just finished doing one last weekend. The questions

to be answered or discussed might be:

- (1) for what malts is it necessary?
- (2) for what malts/beer styles is it helpful?
- (3) how thick is the "thickest" third?
- (4) does decoction mashing (with boiled grains) give better maltiness?
- (5) is the extraction better with decoctions?

More come to mind, but here are a few comments from what I did:

I used the scheme as mentioned by D Richman in the latest (yuppified?) zymurgy magazine when he talked of P Urquell's mashing method. It went well and took 4 hours just for that.

I took the "thickER" third to bring slowly (with rests) to a boil. The mash must have some liquid or else bad news on the brew pot bottom.

The mash does get darker because of the grains being boiled.

Noonan says that after sparging and starting the boil, that one need not boil the wort for 15-30 minutes before adding hops. I did notice much fewer protein flakes in the boil after 30 minutes of boil.

Maybe the real question is: is the extra time worth it? We'll see....

From: lcarter@claven.idbsu.edu

Subject: Oregon Brewers Fest.

There were several questions about the Oregon Brewers Festival that takes place this summer. This is an annual festival(three years so far) put on by Widmer, Bridgport, and Portland Breweries. This year it takes place on July 19, 20, and 21 at Waterfront Park. Micro brews from all over the country and Canada are featured. Last year there were thirty some odd beers and this year they are projecting 40 +. It is a great way to try many different micro brews and it is always a great party, with a large tent(Octoberfest style), food, music and of course beer. So far the festival has always been held on the weekend closest to the 20 th of July.

Let me know if you need more information.

Subject: ACK! It won't stop!

Hi all! I've got a batch of ginger beer in that I'm beginning to be concerned about. I pitch on the 15th of June and it's still bubbling through the fermentation lock! I did try rehydrating the yeast in some water (I think I added some sugar as well) then pitching. The stuff never did take off as it has in the past and the activity in the carboy has been pretty slow (compared to my past batches). What is going on? Is there something in ginger which contributes to slow fermentations? Any tips?

Date: Tue, 9 Jul 91 17:54:09 EDT  
From: srussell@snoopy.msc.cornell.edu (Stephen Russell)  
Subject: ramblings on wheat beer, and more

Howdy, folks.

On those wheat beer recipes of Mike Lang from Digest #675...

The wheat beers I've made using crystal malt (from 1/4 to 1 pound in a 10 pound mash that's 50% wheat, 50% Klages) are smoother, darker, and sweeter than ones without; this sweetness is somewhat balanced by adding about 33-50% more hops in the boil. However, I find that the refreshing, tart, fruitiness of a lighter wheat beer is more true to style, if this is what you are after.

What I would change in the recipes that Mike Lang gave would be to cut the crystal malt to zero and reduce the boiling hops to ~ 3/4 ounce. Tettnanger seems to be more true to style than Hallertauer although both are good; 1/2 ounce for finishing is fine. Too much hop flavor, aroma, and/or bitterness would be out of style for what is meant to be a delicate, slightly fruity and spicy, yet somewhat malty beer.

Wyeast #3056 Bavarian Wheat is a fine yeast. I've heard it's a blend of 2 or 3 species, one of which is *S. Delbruckii*, one of which is a strain of *S. Cerevisiae* (ale yeast), and perhaps one more that's a flavor-neutral flocculant. It seems, IMHO, that if you ferment above 75F that too much banana ester gets produced, and that if you ferment under 65-70F that you don't get enough clove. Either extreme puts you out of style for Bavarian Weizenbier. Anyone else with experience in the area of systematic temperature variation for this yeast?

Want clove? Go with the MeV Weizen, which is pure *S. Delbruckii*, and produces a really sharp, clove taste, with little or no ester to balance. It's too strong for my taste, but you might like it. Kind of on the other extreme from Mike Lang's beers.

On a related topic, when I toured the Boston Beer Co. (Samuel Adams) at the AHA conference pub crawl, Jim Koch said that the yeast employed for their new Wheat Beer was a wild yeast (*Brettanomyces*). After drinking it, the only thing I noticed strange was a smoky note in the finish; this to me seemed really

just a continuation of normal clove taste. I've tasted it in wheat beers made with 3056 (yes, your club champ, Dr. Beebe!) Nothing that seemed "wild"; that is, no taste of horse or curdled milk or Darryl Richman's electric blanket. I'm wondering if old Jim was just b.s.'ing us, if he was mistaken, or if there are some yeast of this genus that are, uh, relatively, well, uh, "tame".

DEXTRINS REVISITED.....

You know, I just realized that the debate on dextrins 'n body was somewhat abbreviated (for this digest, that is). I keep seeing contradictory information in different sources...TCHoHB says "it's been proven that dextrins don't add body to beer", other sources imply the opposite, such as Jackson's and Eckhardt's books. What do YOU think? DO DEXTRINS ADD BODY TO BEER?

Also, since any polysaccharide over 4 sugar units long is considered to be a dextrin, perhaps there are differences in flavor from shorter versus longer ones. Maybe big ones add to body but short ones don't? (Kind of like how longer polymers have more impact on solvent viscosity than shorter ones.) Maybe longer ones can't fit into your taste buds and therefore don't impart much, if any, sweetness? Maybe I should read up on my high school biology and stop drinking so many homebrews?

'Nuff said.

Yours in the Suds,

STEVE

From: larryba@microsoft.com  
Subject: Re: Aspirators

I wonder, do people worry too much about aeration of their wort?

Anyway, a surplus house has little (.75" sq) sintered stainless steel diffusers for cheap (2 for \$2.25). Being steel they would be easy to sterilize - just boil for 10 minutes. The other thing I have noticed is that hardware stores have bottled oxygen for home propane/oxygen torches. The bottles look just like a propane bottle.

So, skip the unfiltered air/pumps and inject raw O2 with a sintered diffuser. Hmm, maybe the sucker can be attached to the out tube on my keg to filter out yeast and hops? Maybe it can be used in reverse as a carbonation stone when I initially carbonate my beer?

If you wish to pursue these ideas, the surplus house is:

Jerryco inc.  
601 linden place  
Evanston, Illinois. 60202  
(708) 475-8440

I have never purchased anything from them (yet). Apparently they have retail outlets (American Science & Surplus Centers) in Chicago and Milwaukee.

Subject: Re: Possible Aphid cure.

Dan suggests:

>1/2 gallon white vinegar  
>1 bulb garlic, all cloves peeled and crushed  
>1 bottle cayenne pepper

And someone else said it would wash off because it was all water soluble. I would have to disagree about the water solubility. The garlic and pepper have oils in them. (Eat a Jalapeno -- yes, seeds and all -- and then drink all the water you want... the heat will not simply wash away.)

Back to Aphids. My hops are literally getting eaten alive by some kind(s) of bugs. I tried "Safer" but it didn't work and since then I have seen several aphids. (I don't know if it's only aphids that are my problem: holes eaten through the hop leaves -- some so eaten there's only 5% of the leaf left!!!) Another problem with the "Safer:" the liquid would cover the leaves and then run to the edges of the leaves. The lower edges of all the older leaves turned brown. I used premixed "Safer" (which, if you missed the previous discussion, is supposed to be some kind of soap-based insecticide), so I don't think it was a overconcentration problem.

Enter the heavy artillery: Malathion 50. I also have some Diazanone, but the Malathion label mentions fruits and veggies more, so I figured that I'll try that first. It's been about a week and three sprayings, but this morning, I found an aphid. I think I'll give the Malathion another week and then go to the Diazanone.

I've been reading an Ortho book on garden pests along with "Homegrown Hops" (which is a pretty good book, but contradicts the guy at Freshops in a few places) and the Ortho book mentions checking at night -- some of my little enemies may be night-feeders. If aphids are my only problem, it's off to the lady bug store for me.

I would have preferred to go all-natural, but at the rate I was losing leaves, I would have lost all above-ground growth in a week, so I went with chemistry.

I'm still open to natural gardening, but will probably wait till next year. I planted the rhizomes late this spring and probably would worry a lot less if my plants weren't so young. Hopefully, next year my plants will be 15 feet at this time (instead of 6 feet) and the leaves will be so big that I won't have to worry.

Al.

Subject: Oregon Brewers Festival

Last year I had the pleasure of attending the Oregon Brewer's Festival. I have one word of advice, GO!! It is a great opportunity to taste beers from all over the Northwest and beyond. This year they are expecting something like 46 breweries present. The festival is very well run, you pay for each sample as you go which tends to get people away from the "I paid my \$25 and now I'm going to get my money's worth" attitude. It's held in a pleasant park along the Willamette River. There is food and live music too.

Last year, I spent part of an afternoon tasting beers with Fred Eckhardt. During that time, I was mistaken for Charlie Papazian three times!!

Needless to say, it was a good time.

From: IOCONNOR@SUNRISE.ACS.SYR.EDU  
Subject: Brewery Tours

Just a few thoughts on some breweries I visited yesterday. I took a trip to the local Anheuser-Busch plant in Baldwinsville, N.Y., and the F.X. Matts Brewery in Utica New York. Tomorrow, weather willing (I want to ride my motorcycle) I'm going to go to the Genesee Brewery in Rochester, N.Y.

Anheuser-Busch--A totally boring brewery. They don't get you in to the guts of the place, you basically see the periphery. They show you a five minute film about how they brew and how good they are doing it. They showed the top of a fermenter, and that's about it. The receptionist was pretty good looking tho'; she had a wonderful phone voice.

The tour guide was pretty uninformed, she didn't even know what type of hops they used! I spied Saaz in the hops room they showed us, anyway. They just kept stressing about how their "product" was quality controlled to provide consistency.

The tour guide's boss also told someone who asked, that bock beer was made by cleaning out the bottom of fermenters! The boss claimed to know more than her worker. I couldn't believe it!

I tried all their beers, and concluded that Bud \*still\* sucks. Their non-alcohol beer is pretty lame, O'Doul's.

F.X. Matts--I like this place because when you walk in, it is like the parlor of someone's turn of the century house. Nice sitting chairs, elaborate woodwork and nice displays of old Matt's stuff. I was a little pissed because they charged 2\$ for admission and a tour. Pretty lame as far as I'm concerned. A tour promotes drinking the product, and I don't think Matt's is in that bad shape that they need 2\$ from people. Anyway....

The tour starts with a history of the founders and then moves in to a room with grains, adjuncts and hops. All there for people to touch. Nice. Then it moved to a room with a brew kettle. The guide showed how stuff went into the kettle from each of the areas and where the mash tun was.

We then went to the primary fermenters and the lagering room. Man the lagering room was cold, 32 f'ing degrees! They then showed us the bottling and labeling aspect.

The tour ends in their bar, where you could get two cold ones-- either Matt's beer or root beer. They also had a gift shop with all the stuff they brew, and with a nice 8 pack of all the contract brews they do: Samuel Adams \*Ale\*, Dock Street Ale, Albany Amber, Brooklyn Lager, Newman's and I can't remember the last one, so don't get mad. Saranac 1888 is in there, but they don't contract brew it, they just brew it.

Matt's felt much more like a family deal, Bud was so damn corporate. They even had Eagle snacks at Bud!

One interesting thing. I met an Assistant Brewer from Miller. We BS'ed about beer and he told me a few things.

One is that he claims the reason that Miller RGenueineS Draft doesn't skunk, tho' it's in clear bottles is the hops that they use. I can't remember what hops it was, but it was something I hadn't heard of.

Two is that he claims that there is very little difference between "Dry" beers and "Lite" beers. He said they are both inundated with a lot of yeast when pitched, to get rid of the fermentables. That gets rid of the calories in the sugar, then they dilute the beer with water so it's not high in alcohol. The "Dry" and "Lite" beers he said were just degrees of fermentables.

He also said that they had tried a wheat beer in the midwest, hoping to appeal to farmers. It was called "Dakota"but he said it failed miserably.

The thing I didnt like about him was the way he referred to beer as "product". I guess thats the way that Miller, Bud and the like see beer, but I dont. I like messing with it and seeing what happens. I haven't brewed a hell of a lot, but I do it for a hobby, not a job. I don't see it as a prduct but something I made. He just kept calling every damn thing a "product."

Anyway, thats about it. Sorry I rambled on for so long.

Keep on Brewin'!

Subject: aeration

Regarding pumping air into wort: there is a local outfit, named Spirit Brewing Systems sells a beermaking "machine" that is basically aplastic carboy, and a setup for pumping air into the wort.

Their major sales pitch is to new brewers, or people who aren't brewers. The major point is that the problem with most hombrews is lack of oxygen in the wort, and their "system" solves this. The system is an aquarium pump, a small (1" dia.) filter holder, that holds a small filter disk, and a "special" airstone that goes on the end of a tube that sticks into the wort. All of the equipment is "special, exclusive, designer,

.....", but to me it looked like your basic aquarium pump, lab type disc filter holder with 2um paper filters, and your basic aquairum pumice airstone. They recomend several hours of aeration after you do the basic open the can, pour and stir trick with the extract.

The aeration system described should work well for those of you who want to aerate your wort.

Oh, by the way, their extracts are special, better, exclusive.....  
ONe interesting thing is that the extract contained whole leaf hops. The beer they served was reasonable for a non boiled, corn sugar kit brew, but regardless of the name or style, they all tasted, and felt like an extra light draft style American or Canadian lager.

From: mike@ranger.bison.mb.ca (Mike Charlton)  
Subject: Mackeson Stout

We get Mackeson stout on tap at a local bar around here and I've had quite a bit of it. I've never had the bottled stuff, so what I have to say may or may not be relevant. Anyway, here is my impression of the beer. It is extremely dark (it seems even darker than Guinness, but I can't be sure as I've only had Guinness a few times). I've seen some stats about Mackeson (in Fred Eckhart's book and various other places) and I just don't believe the typical colour ratings given to it. Anyway, the beer is fairly bitter, but has a cloying sweetness that balances the bitterness nicely. The beer is quite mouth-coating which tends to hide the graininess. It is also fairly estery (I detect some cherry in it). Unlike many stouts, I don't detect any diacetyl.

My brewing partner is quite enraptured with this brew and has devised a recipe that comes quite close. He doesn't want the recipe spread around just yet, though, so I'll give some hints without actually giving away his recipe. Lots of crystal malt (a pound or more). This gives the beer a nice smooth flavour and increases the colour without adding astringency (he used 60 Lovibond crystal, but if you can get 90 Lovibond, it might be even better). Most of the colour should come from black malt (perhaps a little chocolate malt as well), but no roast barley. Adding blackstrap molasses gives it a bit of a zing which I find necessary. Finally, the secret ingredient: lots of brewer's licorice (1 or 2 5 inch sticks). Ferment with an unattenuative ale yeast (a german alt bier yeast actually works quite well). For hops, northern brewer or something similar to the tune of 70+ IBUs (mostly bittering). Since Mackeson is brewed by Whitbread, he used a water treatment that comes close to the typical values given for London water. It seemed to work all right.

I believe that the flavour the original poster was commenting on was probably a mixture of licorice and the flavour that occurs from adding molasses. The interesting thing about my above comments is that most of them fly directly in the face of the many recipes I've seen for Mackeson clones. All I can say is that my brewing partner's beer is extremely good and reasonably close to Mackeson.

One other interesting note. My brewing partner and I have been trying to make a Guinness clone for some time and have tried the recipes from both Line and Miller. Neither of these seemed to have the "creaminess" that I associate with Guinness. Taking a cue from the experiments with the Mackeson clone, we added large amounts of crystal malt to our latest Guinness effort. In combination with the astringency of the barley, this produced that elusive feeling (I call it a feeling because it really isn't a flavour) of creaminess.

Hope somebody finds this interesting,  
Mike

From: Ken Schriner <KS06054@UAFSYSB.UARK.EDU>  
Subject: Hops.

All of this talk about hops has raised a question in my mind. When will Freshops have their 91 crop harvested and ready for sale? Every time I call them, all I get is a phone answering machine asking me for my order. Is there a "good" time to call? Does anyone have any information about the hops harvest in oregon? When is it? Will this year's be a good one?

One note on aphids. I cure this in my garden by starting a fungus (or a mold or disease) to kill the aphids. Collect a bunch of aphids (no small task) in a container. Mash them up, let it sit for a while, add some water, spray it on the infected plants. These mashed up aphids end up creating some kind of plague for the still living aphids. They are usually gone in a couple of days, repeat as necessary. Of course, you have to use exactly a bunch of aphids, and if you use more than some water, no way this will work. :-)

Bob> tasting. Is double bock supposed to be a sweet tasting beer ...

I enjoy bockbier *\*very\** much, but I found SADB annoyingly sweet and  
unbalanced; I won't drink it again -- too cloying.

Yes, bocks in general and dopplebocks in particular tend to be sweet, but  
it's a maltiness, not a pure sweetness that you're after. And it should  
be  
balanced by a healthy dose of hops.

Excellent samples of bock I've found include: Eggenberger Ur-Bock (pale)  
,  
Ayinger [Mail]bock (amberish), or Celebrator (dark dopplebock). If you  
need  
a kick-in-the-head-dopplebock, try EKU-28 or Samiclaus.

Bis spaeter!

**Subject: Ninkasi beer**  
Full-Name: Rick Myers

If Anchor brewery's recreation of the ancient Mesopotamian beer, Ninkasi, has piqued anybody's interest, well, they should check out the latest issue of Archaeology (July/August 1991)! It has an excellent article written by the great(!) Fritz Maytag, along with Solomon H. Katz. They talk about some of the reasons why Anchor decided to brew the beer in the first place, such as answering the question, 'what did man make first, beer or bread?'. Anchor didn't just brew this beer to see how it tasted, but also to help answer this and other scientific questions about ancient history. The article has the most current translation of the 'Hymn to Ninkasi' which is found on a nineteenth-century B.C. clay tablet, which contains a recipe for Sumerian beer. The article also has some pictures of the Anchor brewing the ancient nectar. Check it out!

"You are the one who soaks the malt in a jar,  
The waves rise, the waves fall.  
Ninkasi, you are the one who soaks the malt in a jar,  
The waves rise, the waves fall."

From: hersh@expo.lcs.mit.edu  
Subject: Power Brews, Brew Pub Guides, Aeration

As a point of info, the Supreme Court has upheld that it is OK to limit commercial advertising (why cigarettes can't be advertised on TV & Radio), since advertising is not considered free speech (after all 45% of the price of a Budweiser goes to advertising & promotions, that's not free). Free speech is limited only to Political Speech essentially (artistic & religious also lumped in there).

I agree that we must fight this insipid attempt to limit brew strengths. Perhaps we can convince George Bush (King George??) that this movement amounts to restraint of trade?? Unfortunately many states do already limit alcohol content in beers.

>The editor/publisher of the World Beer Review,  
>Steve Johnson, has compiled 'the only current, comprehensive guide  
>to U.S. brewpubs and microbreweries'

Oh contraire, Monsueir, Pat Baker's Beer Bar Atlas, also lists beer bars, brewpubs, etc.. for North America. It's cheaper, though perhaps less comprehensive. I had to get a plug in for this as I was a contributor.

I too found this year's batch to be unacceptably sweet, however I  
wouldn't write SADB off entirely - last year's batch was very good,  
with a wonderful roasted flavor and just the right level of  
sweetness (that was on tap). I have very fond memories of a number  
of pints of SADB, the UCONN Huskies, and less than a second on the  
game clock... at any rate, I'd give it a shot again next year,  
maybe it'll be another good batch.

Subject: Re: Aphids & Hearbs

In HBD #677, Peter Karp writes:

"Most aromatic herbs, including catnip, chives, coriander, eucalyptus, fennel, garlic, larkspur, marigold, mustard, nasturtium, peppermint and

Well, I have an extensive garden with some fennel and nasturtium growing in

it. Both have been \*covered\* aphids. Early attack with Diazinon seems most effective. Blasting the critters off with water also works pretty well.

I bought one of those pump squirt guns at Toys-r-us, the water hose is too rough.

Now that we are in the heat of summer (as much as that is in Seattle) the aphids seem to have mostly disappeared. I think early spot nuking

(April, in Seattle) with chemicals keeps the total population down. You don't want to

continue nuking for two reasons: diazinon is not an approved beer additive

and b: other bugs (ladybugs, etc) come in later and start cleaning up. Spot

nuking of big colonies is still in my program. If it is small enough I simply grind the suckers under my thumb. Hmm, hmm tasty!

The Seattle area was a big hops growing region around the turn of the century.

Aphid infestation decimated the industry around 1919 - it might be a losing battle if you are interested in organic/pesticide free hops.

**Subject: Re: Aphids & Hearbs**

A friend of mine to whom I forward HBD's asked me to submit the following:

I recently sampled a bottle of a ginger/lemongrass mead that a friend and I brewed last December. The results were so impressive that I'm quite anxious to brew another mead. A couple of weeks ago, while hiking, I noticed blackberry plants that had immature berries on them. So now I have the idea of blackberry mead stuck in my head.

I would like to hear from people who've had experience using blackberries, either to flavor beer or mead. Here is a virtual plethora of questions:

Do blackberries have a strong flavor?  
How much would you use in a 5 gallon batch?  
Do blackberries have a lot of pectin?  
Should I boil them or add them to the cooled brew?

An aside: I enjoy highly spiced and strongly flavored foods and was slightly disapointed that the ginger/lemongrass flavors were not stronger in our mead, we used about 8oz of each.

From: polstra!jdp@uunet.UU.NET (John Polstra)  
Subject: American Brewmaster Digital Thermometers

In HBD #677, "N. Zentena" <zen@utcs.utoronto.ca> asks:  
> ... there is a company called American Brewmaster that advertises in  
> Zymurgy which sells digital thermometers and ph meters has anybody  
> dealt with them? If so what do you think? Is it a good deal?

I just recently bought one of the digital thermometers from American Brewmaster. The person who took my phone order was friendly, courteous, and efficient. The thermometer arrived promptly (it was shipped the same day I ordered it), and was everything the advertisement had claimed it was. The packing list contained a hand-written note from the owner thanking me for my order. So here's one vote of confidence in American Brewmaster. I'd certainly do business with them again.

I haven't actually brewed yet with the thermometer, but it looks like it will be OK. It's about the size of a ball-point pen, and in fact it comes with a little pen-body holder that you can use to keep the thing in your pocket. The probe is made out of stainless steel and is about 4-5" long. A 1" diameter body at the top of the probe contains the digital readout, the electronics, and a 1.5-volt silver oxide battery. (A battery comes with the unit). The readout is in degrees F and includes one digit after the decimal point, although I believe the accuracy is only specified as +/- 2 degrees F. (BTW, I have worked with a manufacturer of electronic thermometers on a consulting job, and +/- 2 degrees F [or +/- 1 degree C] is about good as you can get for under a few hundred dollars.)

Normally, the reading is updated about every 15 seconds to preserve the battery (there is no on/off switch). There's a tiny button you can press to bump up the reading rate to once per second.

So far, there are really only two things I don't like about the thermometer. First, it's so small that it would be easy to drop it into the mash. It would probably sink and get ruined. I'll probably stick mine through a chunk of styrofoam so that I can float it on the surface of the mash. Second, the button to increase the reading rate is so small that it's hard for me to make it work all the time.

Larry Barello <larryba@microsoft>, another HBD reader, recently told me that he'd found a similar thermometer with an 8" stem in a local restaurant supply store for around \$23. The longer stem sounds better to me, and that's a good price. So you might want to check restaurant supply stores in your area for something similar.

> enough that  
> they seem to be reluctant to get anywhere near hops, but are they now  
> trying  
> to tell us that they don't use water when they brew?

Dry brewing was originated in Japan by the Kirin brewing co (I think it  
was  
Kirin, either them or Asahi) it involves fermenting past the point when  
most yeasts stop working. According to Eckhardts' book they engineered  
some new yeast strains to get the job done. Fred also says that some  
brewers add some chemical additives to keep the yeast going...what this  
is supposed to produce is a drier beer (think in terms of dry wine).

P.S. I had a posting a while ago that talked about prices for grain  
mills,  
I picked up a corona at a local mexican market for \$29.99...it's your  
standard corona, the only difference is that the instructions are in  
spanish.

Subject: What Miller's up to

Steve Russell asks what has happened to Dave Miller

He couldn't make the conference as he has been too busy trying to get his brewpub underway. He has found a sponsor, and they are at present trying to finalise details on the location. He is involved with Dan Kopman (I think that's the spelling) who used to work with Young's in London. They hope to be in business by year end. It took him two years of hard work to get brewpubs legalised in Missouri. He is hoping to have an even more complete handbook out next year which will also cover all extract recipes, kegging, counter pressure fillers and the like.

Subject: Beer in Boulder

I will be in Boulder Sunday evening through Thursday evening of next week and I would like to solicit your recommendations of stores with good beer selection. Also, I intend to visit Old Chicago and The Walnut Street Brewery there. Any other watering holes worthy of note? Places to avoid? Denver is not out of the question since I'll be flying in and out of Stapleton airport. I seem to recall an excellent report someone did a while back about a beer run they made from Texas to Colorado. I though I had saved it but, alas, I cannot find it. Feel free to e-mail your suggestions if you prefer not to post to the digest. I would like to pick up a few samples of good beer since Alabama's selection is very limited. Hopefully, it will tide me over until my Belgian brews arrive in mid September. Thanks very much!

Subject: Dextrins & Body

From: srussell@snoopy.msc.cornell.edu (Stephen Russell)

DEXTRINS REVISITED.....

>You know, I just realized that the debate on dextrins 'n body was somewhat abbreviated (for this digest, that is). I keep seeing contradictory information in different sources...TCHoHB says "it's been proven that dextrins don't add body to beer", other sources imply the opposite, such as Jackson's and Eckhardt's books. What do YOU think? DO DEXTRINS ADD BODY TO BEER?

This topic is the subject of considerable debate. There seems to be no simple answer. The "traditional" wisdom seems to be that dextrins \*do\* add body to beer. The theory being that high mash temperatures favor alpha amylase over beta and that alpha tends to produce more dextrins whereas beta produces fermentable maltose. Beers mashed at higher temperatures generally have more body than those mashed at lower temps. Therefore.....

(Hmmmmm, people who carry matches in their pocket tend to have a higher incidence of lung cancer than those who don't. Therefore.....)

I believe that Miller is referring to the work of Jean DeClerk (sp?) when he says "it's been proven etc.". DeClerk's text is long out of print and I have been unable to get my hands on a copy. If anyone out there has access to a copy, it would be interesting to know what DeClerk did to prove this.

Dr.Lewis@UCDavis.fermentation.edu describes an experiment he was involved in that was directed at proving or disproving this. They began with some nondescript industrial beer (maybe Coors Light). They added dextrins to the finished product (there's that word again) in controlled amounts. They then did blind tastings with a panel of professional tasters. The panel was unable to detect any differences until the dextrin levels got ridiculously high - much higher than you could ever get using any "standard" mashing technique. Their conclusion was that dextrins \*alone\* do add body to beer.

I don't believe that anyone is doubting that high temperature mashes produce beers of greater body than low temp mashes, but the alpha amylase/dextrin theory doesn't accurately describe the process. I've seen in my own brews

that higher mash temps yield fuller bodied beers. I brewed two "identical" batches, the only difference being that one had a strike temp of 158F and the other 155F. The difference between the two beers was much greater than I expected.

Dr. Lewis believes that protein fractions (peptides, polypeptides etc.) are involved in the perception of body. He hinted that there may be some complex interaction between dextrans, protein fractions and our sensory perception. However, he admitted that he just didn't really know what was going on.

For now I've decided to not worry about exactly what is responsible for the sensation of body. The guys with PhD's in brewing science will figure it out someday, and then we'll know. From a practical standpoint, I know I can vary the body in my brews by adjusting the mash temp, and that works well.

Cheers,  
CR

**Subject: Dextrins & Body**

A few issues ago Randy Tidd asked about a tapper system for AB "Golden Gate Kegs". He also wanted information on "a place in Kansas called Foxx".

They are at:

Foxx Equipment Company  
421 Southwest Blvd  
Kansas City, MO 64083 (that's MO, as in Missouri, NOT Kansas)  
816-421-3600

A quick phone call to them this morning revealed:

- they are still in business
- they have a mail order catalog
- they stock a product called "Golden Gate Tapper"
- among the items included in the above are:  
(sorry, I couldn't take notes)  
a couple of devices with "air vent" in their names &  
a spigot
- they can probably order what you need if they don't stock it.

From: Nick.Thomas@Eng.Sun.COM (Nick Thomas)  
Subject: Blind beer tasting results

A friend of mine organized a blind beer tasting of 10 commercial beers and one homebrew. The results are kind of interesting, and I thought the brewers on this alias might enjoy reading them. The judges ranged from "very frequent" to "extremely infrequent" beer drinkers. The judge's comments aren't quite what you would find at a competition. They are more, ah... "informal." In fact, if mild obscenity offends you, don't read further.

-nick

By the way the "clarity test" refers to the fact that one judge won't drink any beer she can't see through.

1. Holstein (Tied for Worst of Show by one Judge)

Tastes like beer  
Thin. Gussed it was Rolling Rock. Thought Richard Gere might enjoy it.  
Weak, gross, watery  
Not Very Good  
Like Budweiser - plywood aged  
Gnarly  
(Did not pass clarity test for one Judge)

2. Franz(something) Weisbier (Wheatbeer) (Tied worst of show for 1 judge)

Injured Leather  
Bleh  
Yuck  
Worse than #1, but not gross  
Fascist Beer From Hell  
High School memories  
(did not pass clarity test again)

3. Rolling Rock

Clear, Sweet, Cool - just take the dead mouse out  
Light, fruity, rotten. Much like embalming fluid  
Cheap, like bud, tinny.  
Worse than #1  
Pabst Blue Ribbon  
got a kick like 2. but it has bite  
Tastes good with 11.

4. Due to a serious budget crunch in Winsconson, they've had to cut some necessary programs in the school system. One of those programs was everything related to the number 4. The host, being born in Wisconson, was one victim. Consequently,

there was no Number 4 at the tasting.

5. St. Pauli Girl

Not bad - what's wrong with me?  
A spatens? malty, I like it  
Yuck!  
Better  
Like making love in a canoe - Fucking close to water  
(we begin to lose some judges at this point)

6. Dead Cat Lager (Worst of Show for 5 Judges)

Lemonade - but spoiled  
Sweet & bitter & rancid  
What Kennan Said  
Piss Pour  
Lemonade and Chablis in equal parts (Kennan)  
Wow  
(Did not pass clarity test)

7. Boont Amber

Fuck you Asshole  
Sweet Spaten? Pretty good  
OK  
Pretty Good  
Good shit, but doesn't wear well

8. Corona (Worst of Show for one Judge)

Where was I?  
Light style American  
Yuck  
Marginally Good  
Steinlager or something like that  
Olympia's Little sister  
Tastes Like plastic

9. Samuel Smiths Old Pale Ale

Goodwith popcorn  
Malty, not bad  
OK. Foamy  
Good  
Sweet stuff dude. Might be Spaten

10. Red Tail Ale (Best of Show for 2 judges;  
tied best of show for 3 judges)

Makes me regret the theroatectomy  
Pretty Dam Good  
Foamy, lighter, good.  
The best  
This could be Spaten too  
very, very, very good  
Smells good; can't see through it

11. Homebrew Barleywine (Best of Show for 2 judges;  
Tied for Best of Show for 2 judges)

Nick - Marry me and have my baby  
Really Nice

Mold, sweet, better than good  
Very sweet  
Havenabamcnablededehaneha  
What a Kick!  
Sweet (Brandy)

12. Miller

I'm halucenating that I know what I'm doing  
Light, almost nonexistent  
Really Foamy, not much smell, weak taste, pale. Nope.  
Mostly water  
Making Love in Canoe II  
Bud's little brother  
Tastes like preservatives

Subject: Impressed by Anchor Steam Beer

Gooday,

Our Special Broadcasting Service has been showing Michael Jackson's 'Beerhunter' series, the most recent was the episode on the Anchor Steam Brewery at San Francisco. Wonderful stuff. I liked Fritz Maytag's philosophical approach to his chosen business. In particular his idea that people like to buy beer that has come from a good place, ie: a craft brewery where the workers care for the product they produce. He swaps a days production for a trip to the country to select a field of barley to make the Christmas Ale. Compare that to the union regimented workforce at the large mass market breweries, with bean counters ordering the quantity of malt in each brew.

Fritz compared beer to water painting and wine to oil painting. Beer can show style and sublety, is ready to drink fairly quickly and is not expensive. Wine takes months to make, is expensive to buy, then you are expected to lay it down for years before drinking it.

The copper vessels in the brewhouse are classically beautiful and are visible from the offices so the admin. people don't lose touch with the product.

I've tried Anchor Steam Beer and liked it very much. I'm wondering if Fritz is still in control of the Brewery and if conditions have changed since the show was made (1990)? Has Anchor Steam Beer altered over the years? Have the bean counters moved in? :-)

It all looked too good to last. Cheers everyone... David

I'd make a mead. If the yield was really high (if its a big tree)  
I might even consider apricot wine.

Last summer I made 6 cases (pints!) of apricot mead, took it to a  
really big bash (500-600), and it disappeared \*really\* quick.  
Everyone really enjoyed it. FWIW, this was a quick mead -- very  
sweet, highly carbonated, definately dangerous if allowed to warm.

and then on Thrusday, 11 Jul 91, chris@endgame.gsfc.nasa.gov said:

From: Greg Kushmerek <GKUSHMER@RUBY.TUFTS.EDU>  
Subject: Boulder Watering holes

Having spent some time in Boulder, I thought I'd throw in my two cents on what and where.

Concerning the Walnut Brewery: they had just opened it as I was graduating.  
My impression is that it is an inferior brewery when compared to the Wyncoop Brewery at Union and Wyncoop in Denver. The guys who made the Wyncoop helped construct the Walnut brewery, but they seemed to have kept the better batches down in Denver.

Old Chicago's is fun - I say go there on a Friday starting at 4:00 when Happy hour opens. You get a discount on beer and dollar mini-pizas. Once you're down that way, you'll find that a crawl on the Pearl Street Mall is a must. There are a number of bars there. Some, such as Pearl's, have some OK beers on tap.

Names are not my specialty, but if you want directions to the Pearl Street Mall bars that have Guinness, Sam Adams, Boulder Beer, and other decent beers on tap, e-mail me at GKUSHMER@RUBY.TUFTS.EDU. I'll fumble through directions and landmarks.

In summary, the whole outdoor mall is fun and all the spots are very close. Hit it on Thursday and Saturday for the really active crowds.

From: Alex\_M.\_Stein.osbu\_south@xerox.com  
Subject: Re: Impressed by Anchor Steam Beer

David Taylor (DAVID@phillip.edu.au) writes in #678 that he's impressed with Anchor Steam and Anchor Brewery in general. Me too.

I am pleased to report that the "largest of the micros" (or is it the "smallest of the majors" or just a damn good craft brewery) is still operating in the same way as when Jackson profiled it (hey, that was only a year ago). In addition to their Steam Beer, they make Liberty Ale (a hoppy Pale Ale), Anchor Porter (which is really a stout), Anchor Wheat (a fine example of American Wheat beer, which I had heard would be available sometime this year in bottles, but I think is still only available to their draft accounts), Old Foghorn (a sturdy barleywine), and their annual Christmas Beer (which everyone I know calls "Anchor Christmas" even though the labels say "Our Special Ale"). In addition, they have done several small runs of specialty beers (the Sumarian beer that was discussed here in HBD and another beer that they told us about when I took the tour but can't remember much about except that it was available only in the neighborhood for a couple of weeks and that the proceeds went to some children's charity).

By the way, Anchor has been around for decades. Legend has it that Fritz (who is, of course, an heir to the Maytag appliance fortune) used to quaff a few Steam Beers at a neighborhood tavern in the 1960s. One day his beertender told him to have an extra one, the bar was down to its last keg and the brewery was closing its doors forever at the end of the week. Fritz stepped in and bought the brewery, keeping it open. At the time, Anchor had quality control problems and a shaky reputation due to the hit-or-miss nature of the beer they sold. Over the course of the next dozen or so years, Fritz instituted more standardization, instilled a sense of pride in the workforce, and drastically raised the quality of the beer Anchor produced. At some point, the brewery even stopped losing money! The reputation of Anchor soared.

Oops, I'm gushing. Others will, no doubt, chime in with a lot more details than I can muster this early in the morning. Suffice to say, Anchor is alive and well.

Would it be possible to introduce the ladybugs earlier? I have heard that  
one can purchase ladybugs mail-order for this purpose. Anyone tried it?

"Nuking" is sometimes called for, no doubt, but a few weeks ago my small  
bush bean patch was suddenly swarming with bean beetles, chewing holes in  
all the leaves; I spent 20 minutes or so picking them off by hand and  
des-  
troying them, and voila, no more beetles ever since! Surprised the heck  
out  
of me, didn't think they could be "defeated" so simply.

**Subject: Blackberry Mead**  
Full-Name: Ted Manahan

Dan (c/o Shannon) asks about blackberry mead. I too have been planning to try a blackberry mead, as well as a blackberry ale, this summer. I just moved to Oregon last fall; there are an amazing number of wild blackberry plants here!

For the mead I plan to use 10 lbs. clover honey, 7 lbs. blackberries, and maybe a little tea to give it some astringency. I'll probably use 7 lbs. of blackberries for the ale too. I plan to pasteurize the berries at about 170 degrees, but not to boil them for fear of causing pectin haze.

Any comments on the above plan?

Ted Manahan

>It all looked too good to last. Cheers everyone... David

Well, lemme tell ya about the Anchor brewery tour I got back in 1977 or  
78... A couple of friends and I decided to drive up to San Francisco for  
the weekend. We arrived in the early afternoon, I think on December 30 or  
31. Being a brewery kind of guy, I suggested we hunt down the Anchor  
brewery and take the tour. All breweryps have tours every hour on the  
hour,  
right?

I looked up Anchor's address in the phone book, and we drove over. They  
were located in a small warehouse near the docks. The front door was  
locked, so we rang the bell. A guy answered the door and asked what we  
wanted. I explained that I liked Anchor Steam, and wanted to tour the  
brewery. He said, "Well, we're just starting our year end meeting, and my  
secretary isn't here today... But what the hell, come on in. I'm Fritz  
Maytag, the owner."

Fritz proceeded to introduce us to every employee of the Anchor Brewing  
Company (all 4 of them, except the absent secretary, of course), sat us  
down in a room full of beer memorabilia and pointed at the taps  
projecting  
from the large tanks whose ends formed one wall of the room. "That one's  
Steam, and the other one's Porter," he said. "We have to get our meeting  
started now, but you can stay and sample some beer if you want." He then  
shook hands all around, and went off to attend to business.

The brewery has moved to larger quarters, but I suspect the attitude  
hasn't  
changed in the 12 or 13 years since I was there, and won't as long as  
Fritz  
Maytag remains in charge. He loves what he does, makes money at it, and  
doesn't need to make money anyway. I can't really picture him selling out  
to Megabrew, Inc.

Corona makes more than one grain mill. I remember a flyer that  
came from William's Brewing a while back, they had a deal on  
some Corona mills that they accidentally got that were the  
"wrong" ones. They said that it would be ok for grinding  
flour, but probably not strong enough for cracking malt. I  
think the heavy-duty one common for brew duty is the Corn Mill.

From: Chris Shenton <chris@endgame.gsfc.nasa.gov>  
Subject: MeV yeast: :-(

In response to my request for info on where to buy MeV yeast, I got the following responses:

On Thu, 11 Jul 91, srussell@snoopy.msc.cornell.edu (Stephen Russell) said:

Stephen> The U.S. distributor is Mayer's Cider Mill, 800-543-0043, or  
Stephen> 716-671-1955. Or you can call the company yourself....MeV  
Stephen> Research, Waterloo, ONT, 519-579-0628.

On Thu, 11 Jul 91 10:10:06 PDT, grumpy!cr@uunet.UU.NET (C.R. Saikley) said:

CRS> Sorry to hear that Brewhaus has stopped carrying MeV's S. Delbruckii  
CRS> strain. They were my source also. I'd suggest contacting MeV  
directly.  
CRS> Here's their address : MeV: Po Box 123; Waterloo, Ontario; N2J 3Z9;  
CRS> 519-742-7227

On Thu, 11 Jul 91 06:09:18 -0700, darryl@ism.isc.com (Darryl Richman) said:

Darryl> There are persistent rumors circulating on CompuServe that MeV  
has gone  
Darryl> under. Apparently they had a bad batch of cultures that went out  
a few  
Darryl> months ago, and the repercussions have finished them. So says  
CI\$.

So I called up the US distributor. Not good news. She said:

1. We have no MeV yeast in stock
2. MeV is reorganizing [didn't say why, but her tone was downbeat]
3. Mayer doesn't ship/sell it in the summer due to problems with heat
4. They'll sell it in the fall, \*if\* MeV is still around

Yow! so stock up now on their strains -- especially their exceptional weissbier yeast -- and put 'em on slants for posterity.

Or perhaps MeV fan mail might help?

Subject: More industrial beer bashing.

Greetings,

As long as we've been bashing industrial beers, I thought I'd mention something I noticed on tv the other day. Has anyone seen the Coors Extra Gold commercials where they gloat about how Bud drinkers prefer it to Bud (some accomplishment, eh?)? At the end they mention that the "beer" is SLOW brewed. Do you think that they just sit around and casually take their time, or is it brewed by mentally deficient (i.e. slow) people?

G'Day,

Joe

order.  
> Is there a "good" time to call? Does anyone have any information about  
> the hops harvest in oregon? When is it? Will this year's be a good  
one?

From what I understand, the hop harvest occurs more-or-less  
simultaneously throughout the Northwest--it begins about the middle of  
August and lasts some 6-8 weeks after that. New crop hops will  
therefore be available around Sept. 1, although it would be naive of us  
to think that all purveyors of hops are going to immediately dump their  
remaining stock of 1990 hops out into the yards to rot.

The Freshops folks (I forget their names) do this as a part-time thing,  
I believe; that's why the answering machine. I think if you put a  
"please call me" message on the machine, with an idea of when they can  
best reach you, you'll hear back from them.

From an earlier HBD, a poster complained of having aphids eating his  
hops until only 5% of the leaf mass remained. Sorry, but that damage  
ain't aphids--they don't have mouths. Aphids have little sucking  
probosci like hypodermic syringes, and they live on plant juices that  
they tap like subdermal rivers. So if you're leaves are being eaten,  
there's another culprit.

Subject: Question from a virgin home brewer

Howdy!

Well, I finally went to the local beer and winemaking supply store and started picking up equipment. I realized that I had a question. This could probably be answered in either Miller's or Papazian's books, but they're still on order. The question: If I'm going to be doing a one step fermentation, do I need to have a carboy that is a gallon or three bigger than the amount of beer I'm brewing to account for the foam, or is this where I would be able to get away with a five gallon carboy for a five gallon batch using a blowoff tube? Thanks!

Yow! This is practically a religious question. Trying to be  
more-or-less dispassionate you have two choices:

- 1) Use a 5-gallon carboy and use the blow-off method. This means wedging a very large (1", 1.5"?) diameter tube in the top of the carboy with the other end in a large bucket of water. All the kraeusen and such will be sent out the tube into the bucket during the primary fermentation.
- 2) Use a 7-gallon carboy and just attach an air-lock.

Which is better I will leave to those who wish to argue about relative merits. Suffice to say that I use 2 because I can.

> Rory

For single stage fermentation you'll need a 7 gallon carboy with a fermentation lock or a 5 gallon carboy with a blow-off tube. You'll lose about a quart of potential beer using the blow-off tube, along with some hop resins and other stuff that some folks feel doesn't belong in your beer.

Because I often leave beer sitting in the carboy for ridiculous periods of time, waiting for an opportunity to go to the basement and bottle it, I do two-stage fermentations. I have a 7 gallon carboy for a primary, and 5 gallon carboys for secondaries.

Subject: Anchor Steam

I have to say, I'm a firm believer in Anchor Steam (unfortunately, it's rather difficult to get here in northern Alabama). I first had it on tap at the Sun Club in Tempe, AZ and was hooked from the first glass. I have since had both Anchor Porter and Liberty Ale and enjoy them very much. Those are, however, the only Anchor products I've had the pleasure to enjoy. Hmmm, I think I'll take a trip to Nashville and see if I can get any up there....

Curiously enough, I first learned of Anchor Steam in Robert Parker's Spenser novels, back before I knew that there were any American beers worth drinking. Anchor Steam turned me around.

**Subject: Peristaltic pumps.**

After doing a bit of digging, I found out what a peristaltic pump is. It does not touch the fluid, it acts on the very flexible tubing and gently moves the fluid along. Perfect for sort of sterile wort. I rushed home and dug out the Carolina Bio catalog and found the peristaltic pump. Oh, it's \$330. Ah well, maybe Cole Parmer will have more and cheaper ones, so

I broke my arm lifting that tome of a catalog.

Sure enough, they had pages and pages of peristaltic pumps, ranging in price from about \$225 to over \$2,500. Still, \$225 is a bit much to move wort. Does anyone know of a inexpensive peristaltic pump, or those terms mutually exclusive?

oh well, back to the siphon. I have a miligram scale and a ph meter ahead of the pump, so it'll be awhile.

Dan

From: elmer@snoopy.msc.cornell.edu (Mark Zaleski)  
Subject: Transferring hot wort to chiller

Greetings!

Three of us (from the Cornell contingent) have put together a couple of counter-flow wort chillers, using 3/8" copper tubing and 3/4" garden hose.

Thanks to this Digest, we know how to clean the inside of the tubing... extended discussion on this point way back in March/April were most helpful.

What we \*don't\* know is how to get the near-boiling wort into the tubing.  
.....

One wants to avoid oxidizing the boiling wort, so we believe that dumping it into a large, spigoted container would probably not be the best plan. We are a bit hesitant to drill holes in our stainless steel brewpots (but may end up doing so yet). And siphoning a boiling liquid is probably unreasonable.

So, how do YOU effect this transfer? And how do you achieve hop removal?

Thanks for your assistance,

I made a spigoted container out of a 5 gallon bucket and a spigot  
using electrical conduit nuts to hold the spigot to the bucket  
(the guy at the hardware store thought of this, not me). Anyway,  
the wort chiller had a threaded brass fitting which fit the threads  
on the spigot. I didn't worry about oxidizing boiling wort - I'd  
never even heard of it then, I just dumped it into the bucket  
and cooled it. I controlled the chiller by the spigot, the  
slower the flow, the more the cooling.

I abandoned the counterflow wort chiller a few years ago in favor of  
an immersion chiller.

Subject: RE: Homebrew Digest #680 (July 16, 1991)

re: Subject: Peristaltic pumps

These pumps don't need to be expensive, except when a) you need to maintain sterile conditions (as in using it for blood) or extremely precise flow rates. Since neither of these really apply to wort, all you really need is a length of durable tubing and some mechanism to routinely squeeze it along the direction of flow. This is usually done by bending the tubing into a horseshoe shape in a chase and then using a rotary squeezer (sorry for the technical terms here 8^).) to push the liquid through. Picture a clock face with tubing wrapped around it from 9 oclock till three oclock. The sweep hand would act as the squeegee, contacting the tube at 9 and pushing a volume of liquid along until 3, then repeating when it reaches 9 again.

This is a poor description, but look at the pictures in the catalogue and you will get the idea.

Should be easy engh to make. (well, about as easy as an all grain recipe anyway 8^)>).

/greg

From: "Justin A. Aborn" <jaborn@BBN.COM>  
Subject: Sparging, What's best/easiest?

I recently transitioned to all grain brewing, and I'm very glad I did. The beer is cheaper, smoother, more delicious and special tasting. My all grain clarity is not as good as my extract brews though.

I want to try to improve the filtering characteristics of my sparging technology, plus sparging is a pain in the butt and I think it could be easier. What I currently do is put a sparge bag inside a plastic bucket equipped with a spigot at the bottom. I run off some wort into a sauce-pan and carefully pour it back on top of the grain; recirculating for as long as I can stand it. I then run it all off into the boil pot, and do the same thing over again using new sparge water. During the recirculations the wort gets progressively clearer, but I have never gotten it to be "bright and clear," as Miller suggests is possible. Sparging takes a long time.

My favorite fantasy filtering answer is to put a peristaltic pump in the loop that would constantly, gently, and exhaustively recirculate while I am carefully evaluating the results of last month's brewing. I have done a little looking for a pump, but I have had the same results as Dan Graham. They're too expensive from the sources I found.

I suppose one could also add another filter to the process. I ran some wort through a coffee filter, and sure enough, it comes out bright and clear. The filter clogs quickly however. Perhaps some mondo coffee filter might be able to do a whole batch without clogging to a dead stop, but it seems messy and unlikely.

Does anyone have any sparging advice or anecdotes that might help negate the pump?

Does anyone know of a used medical equipment warehouse?

Subject: Cool refinement of John Polstra's aspirator

In HBD #676, John Polstra wrote:

Take a 1-foot length of flexible tubing. Make a small hole (maybe a sixteenth or an eighth of an inch in diameter) in the wall of the tubing, a couple of inches from one end. (An electric drill at low speed works fine for this.) Attach the end with the hole in it to the output side of your in-line wort chiller. Put the other end of the tubing into your destination vessel and siphon away. A fine stream of bubbles will be sucked into the tube through the hole and your wort will end up nice and foamy in the fermenter. Simple, reliable, works great.

Last weekend, I brewed a stout. I couldn't remember the details of John's article, just the fact he had holes in the racking tube somewhere. So I made mine from a 5" chunk of copper pipe left over from my chiller and racking tube. I drilled four 1/16" holes about 1" from one end. I started the siphon and stuffed the short end into my out tube. It was amazing how well it worked! The beer came out the far end just like the water from the kitchen faucet. I thought I wouldn't be able to get all 5.5 gals of wort into my 7.5 gal carboy because there was so much foam! The copper pipe is great since I didn't end up permanently modifying one of my racking hoses.

I repitched 1 cup of whitbread from the previous weeks brew and I had glugging start within two hours. Four hours later I had a two inch head of foam. Great stuff!

Subject: boulder brewpubs

With regard to the Walnut Brewery in Boulder.....

I was in Boulder last month for a conference, and needing to unwind a bit after giving my paper, I headed toward the Pearl Street Mall. In Boulder, there is a free trolley that makes a loop past several hotels, some dorms, and around the Pearl Street Mall. It let me off right in front of the Walnut Brewery where I went in for lunch. They have a beautiful atmosphere and the grilled chicken sandwich I had was delicious. I tried their sample set of six beers (about 4 oz. each) and enjoyed all of them. They had just premiered their Jazzberry Ale (a wheat-type beer with some raspberries included in the recipe) and really wanted to try one, but they were out. The hostess was quite charming, and stopped by my booth several times to ask what I thought of the beers and to tease me about getting sloshed by my lonesome. The staff was very efficient and courteous. Prices were quite reasonable. I would highly recommend a visit.

Just wanted to post an alternate opinion to the guy from a couple days ago that said he wasn't too impressed. Could be that the place has changed since he was there, or maybe the dirth of neat places to eat/drink around Lafayette just makes me easily impressed! Still, my palate does get around, and while none of the beers at Walnut were "jump up and down" spectacular, I thought they were all well done.

Not much to actually post about homebrew.....this Indiana heat has pretty much stopped all brewing activity at our house. And our stash of homebrew is getting dangerously low!!! Come on, Autumn!

From: keng@ic.MENTORG.COM (Ken Giles)  
Subject: Proteins vs. Dextrins and Re: Peristaltic pumps

I'm not yet ready to open the debate on whether body comes from proteins or from dextrins, but would like to get my facts straight. I remember that someone said that Miller had cited Jean de Clerk? (sp?) I tried to find the citation in TCHoHB and could only come up with the statement without the reference. Could someone possibly email me the page number of the citation?

In HBD #680 graham@drcv06.decnet@drcvax.af.mil says:

> Does anyone know of a inexpensive peristaltic pump, or [are] those terms mutually exclusive?

Since "inexpensive" is relative, I'll just throw this in. I have one of those electric painting machines which uses a peristaltic pump to push the paint to the roller. I think it was \$75 new. It uses a fairly large hose, maybe 3/4 inch OD. I can't say whether it's suitable, but if you found one sufficiently cheap at a garage sale, maybe it would be worth a try.

From: sxs32@po.CWRU.Edu (Subbakrishna Shankar)  
Subject: Request: General info on wheat beers

Now that summer is in full swing I've seen a number of specialty wheat beers (such as Sam Adams' Wheat Beer) and made one of my own (w/ Northwestern's Wiezen malt extract). I'm uncertain, though, of the proper nomenclature and origin of the various styles. Perhaps someone can answer these questions for me:

- 1) Are all wheat beers fermented w/ an ale yeast (e.g. Wyeast's Wiezenbier Liquid Ale #3056), or is there a lager style as well?
- 2) What are the differences among Wiesse, Wiezen, and plain old Wheat beers? I've heard of "Berliner Wiesse" which is supposedly drunk w/ fruit syrup added. Is the beer different or just the style of drinking it?
- 3) I bought some Hefe-Wiezen beers from Germany recently to test my own concoction against. The "Hefe", I was told, indicated the presence of a yeast pack from bottle conditioning. Both were delicious, though not quite as satisfying as my homebrew. Is it true that a different yeast strain is added at bottling time because the fermenting yeast flocculate poorly? Obviously, this would make culturing the fermenting yeast from the bottle impossible.
- 4) Should I go ahead and drink my wheat beer with a twist of lemon, risking being mistaken for Yuppie scum sucking on a Corona?

For answers to these questions my thanks in advance.

Subject: MeV,American Brewmaster and Thanks

Hi,

I called around here today and came up with the following on MeV. They supposedly moved 2-3 months ago. Since then they seem to have gone off the end of the world. My local retailer got a shipment about 1.5 months ago. But right now there phone number has been disconnected. Supposedly when they moved they intended to get back into bussiness but has of yet nothing. Having said the above this supposedly isn't the first time MeV has "disappeared" for a period of time so they may be back.

On American Brewmaster EVERYBODY was very happy with them. They are supposedly good people to deal with. I've called about a catalog and hopefully will be ordering a couple of things.

I would also like to thank everybody who sent me infomation. I've tried to get replies to everyone but some of the messages bounced. So thanks to everyone.

Nick

From: Tom Dimock <RGG@CORNELLC.cit.cornell.edu>  
Subject: Pump for Immersion Coolers

I just stumbled across a fairly cheap pump that looks like just what the doctor ordered for recirculating cold water through an immersion heater (Ref. thread of some months ago on immersion heaters and water conservation). My Grainger catalog (not quite current, but close) lists their stock numbers 2P370, 1P618 and 1P928 as coolant pumps - "For evaporative coolers, coolants, laboratories, decorative fountains etc.". They look like miniature versions of your standard basement sump pumps, and pump 4-6 gallons per minute. The first two are plastic, the third is all brass. The best thing are the prices - \$25.02, \$25.17, or \$32.78 for the brass one.

Grainger's are a ubiquitous industrial supply place with a couple of hundred outlets nationwide, plus many contractors supply stores can order from them. Check your Yellow Pages.

I almost got excited about their peristaltic pump for \$126, until I noticed it's maximum flow of 60 gallons per DAY... Sigh...

From: Darryl Okahata <darrylo@hpnmxx.sr.hp.com>  
Subject: Mead contamination and Brewing software

[ There are two wildly different topics in this message. ]

I have a fruit/ginger mead that's been aging for a couple of weeks in a 5-gal. carboy, and I've noticed that a yellow ring seems to be developing at the surface. It always seems to have been there (from the end of fermentation), but it seems to be getting thicker. I asked a question about this on CI\$, and it's been suggested that I have a wild yeast contamination.

Assuming that this is true, can I make a sparkling mead even if there is a wild yeast contamination, or should I dump in some campden tablets? I was hoping to make a sparkling mead, but I'll settle for a sulfite mead. ;-)

Going on to another topic ...

In the 1990 special issue of *Zymurgy*, Jackie Rager presented some equations for calculating IBUs, given weight, alpha %, time, volume, etc.. If anyone's interested, I've programmed the HP 48SX calculator with these equations, and you can now calculate any one of the following five parameters, given any four of them:

IBUs  
% alpha  
weight  
boiling time  
boiling volume

I've also added a couple of "enhancements":

- \* The hop utilization table is entered as a matrix (meaning that you can edit and change it). It's also interpolated, and not used as a simple staircase table (the way that it's used in the article). This also means that the answers from this program will not be exactly the same as the ones in the article, because of the interpolation.
- \* You can also calculate IBUs from AAUs, or vice-versa. I added a hack assuming  $AAU = \% \text{ alpha} * \text{weight}$ , and boiling time = 1 hour.

While the program is not fast (it can take 15-30 seconds to solve for an answer), it provides for:

- \* "Computing on the go". You can carry the calculator to a friend's house, to the local brewing supply store, etc., and you don't have to remember the equations.
- \* Automatic unit conversion. You can enter weight in ounces, grams, pounds, slugs, etc.. You can enter time in seconds, minutes, hours, days, years, etc. (;-). You can enter volume in gallons, liters, teaspoons, etc.. The answers will still come out right.

If anyone wants a copy of the program, send email (it uses up about 1700 bytes).

From: Martin A. Lodahl <pbmoss!malodah@PacBell.COM>  
Subject: Another Lambic Update

In HOMEBREW Digest #671, my unindicted co-conspirator Mike Sharp said:

> I heard from Martin Lodhal that some of you have been wondering about  
the  
> lambic experiments. So here goes...

Yep. I was asked to report just as I was edging toward the door,  
so I passed the buck to Mike, who ably reported on his own batches,  
then:

> Martin's batch --  
> ummm, I'm not sure what he did... probably something simmilar.  
> He'll have to tell you when he gets back from vacation.

I'm ba-a-a-ack! And here's my report.

Toward the end of April, I made up a batch using this recipe:

Ingredients -

7 lbs 2-row Pale Malted Barley  
3.5 lbs brewers' flaked wheat  
0.5 lb crystal malt  
1 oz equal parts Chinook, Willamette, and Northern  
Brewer leaf hops, baked 1 hour at 300F and  
left 3 days in the open air  
Wyeast 1007 (German Ale) yeast  
Pediococcus damnosus culture  
Brettanomyces bruxellensis culture  
A teaspoon of yeast nutrient  
0.75 cup dextrose (priming)

Process -

Mash water: 14 quarts @ 130F, w/ 1 tsp gypsum  
Mash-in: 5 minutes  
Protein rest: 20 minutes @ 140F  
Conversion: 60 minutes @ 158-155F  
Mash-out: 10 minutes @ 170F  
Sparge: 5 gallons @ 170F rising to 190F, pH 5.7  
Boil: 2 hours, with hops added near the beginning

The first surprise was when the iodine starch test came out negative  
after only 30 minutes of mashing. Quick! The mash itself looked  
different: I began to understand what was meant by a "turbid" mash.  
The sparge wasn't nearly as crystalline as I'm accustomed to seeing  
it, despite an excellent "set" to the filter bed, and the boil  
produced a hot break virtually outside the realm of credibility!  
Fermentation with the ale yeast took off like the proverbial shot.

After 12 days I pitched the *Pediococcus*. I have to admit, I didn't  
much care for the taste of either the beer or the starter solution.  
It only took about 10 days (and some premature hot weather) to  
produce decided ropiness, so I pitched the *Brettanomyces*. By that  
time the beer was starting to taste good, with a definitely Belgian  
cast to it. The *Brettanomyces* starter solution had a tang to its  
aroma that reminded me of the gutters of Brussels. I don't know if  
I should find that encouraging ...

I tasted it about a month later, and it had become very astringent, but with little apparent Brett character or lactic sourness. I'd been warned to expect this, so I'm not concerned. That was about a month ago, so I'll be tasting again soon.

I followed that batch up with a very light and delicate wheat beer, brewed in the same space and using much of the same equipment. After nearly 2 months, there is no sign of infection, which I find encouraging ...

Well they were selling the grain mill for the very purpose of grinding  
corn, I opened the box and looked at it before I bought it and it was  
just like every other corona grain mill I've seen homebrewers using,  
the only thing is that the hopper isn't as big as the ones usually sold  
for homebrewers, but this can be fixed with a plastic milk bottle and  
some duct tape.

From: Art Medlar <hman@violet.berkeley.edu>  
Subject: Cheap 10-Gallon Steel Brew Kettles

So, after three months of reading this digest and getting my nerve up, I've finally Made the First Batch. Five gallons of Bite Outta the Sun Brown Ale, brewed near enough to the eclipse to warrant the name, are now sitting around waiting to be drunk. And so am I.

While I was collecting the necessary equipment, I decided to get the biggest brew pot I could find, under the assumption that the bigger the pot, the more beer that can fit into it. If you don't live in the general San Francisco area, the rest of this note won't be immediately relevant, but it might give you a clue toward finding similar pots in your own area. The clue is "Chinatown".

Here in SF, Chinatown is the epicenter of Big Pots. There are at least half a dozen shops selling a vast variety of humongo cookware. Price, quality, and material bear no linear relation to each other. I spent a Saturday shopping around, and found the best deal at Ying's on the south-east corner of Stockton and Pacific streets, on Stockton (there's actually some sort of housing project \*at\* the intersection, but it's first shop past it).

Ten gallons, stainless(?) steel, with a lid, for \$42. Of course, this isn't weapons grade material, but it's not real flimsy either. In fact, just this morning I used it to stand on to get the parakeet down off the chandelier, with no ill effects to bird or kettle. It straddles two gas burners on the stove; five gallons of cold water heat to boiling in a little under half an hour.

I've seen what appears to be the same pot (it's way up on a shelf, can't tell for sure) for \$48 at a fruit and vegetable market near my house. Evergreen Market, east side of Mission street between 21st and 22nd, directly across the street from the New Mission Theatre. So maybe "the Latin-American part of town" is another clue.

Now if someone could tell me where to get some cheap carboys....

From: RJS153%SYSU@ISS1.AF.MIL  
Subject: Wanted: Weisse beer recipe/hints

Hi All!

Well, I guess I'm officially a homebrewer now. Me and a buddy started my first batch of bree this weekend. We used the Mutton & Fison English Ale extract kit. It came lightly hopped, but we added a little fresh hops for more bitterness and a little more near the end of the wort boiling for aroma.

I'm using a 5 gal carboy with a blowoff tube for the initial fermentation.

Those little ale yeast suckers were working like mad the first 20-24 hours.

Things slowed down a bit now, so I'm going to put on the air lock. Next time

I'd like to go all malt, but this time I used about 1lb of corn sugar to the

3.3lbs of extract. Is there a safely consistent cup per pound ratio for corn sugar? That was our only confusion. We had a food scale, but I wouldn't

swear to its accuracy.

Anyway, on to the real subject. My buddy has decided to join in also, and we

would like to try a wheat/weisse beer. Does anyone have a good recipe for such

a brew? We're still beginners so we can only handle extracts for our malt

ingredients, no actual grains yet. Thanks and I'll tell you how things turn

out!

From: R\_GELINAS@UNHH.UNH.EDU (Russ Gelinias)  
Subject: microbrew/brewpub

I had the chance to go to the Portsmouth Brewery (NH) over my (much-too-short) vacation. It's owned and run by the same person who does the Northampton Brewery (MA), Peter something, according to the waitress, who also knew very little about any of the beer. The beer was 2 lagers, light and brown, and 2 ales, wheat and brown. I had the browns. Both were good, but not "Wow this is great!". But the place is very new (and yuppie-styled, to be expected in downtown Portsmouth), so the beer is pretty commendable for such a new place. And serving lagers is a nice change from the standard brewpub-ale syndrome. Beer was affordable, but food was a little pricey (again, that's Portsmouth). I'm looking forward to checking it out again in a couple of months. Should be much-needed addition to the area.

On the other hand, I've heard mixed to bad reviews of Three-Dollar-Dewey's own beer. They're new at it though, so it might improve.....

On the subject of brewpubs/microbreweries, does anyone have any ballpark dollar figures on what it takes to start up a brewpub? A microbrewery?

Russ (no new kid yet....)

by

>>my lonesome. The staff was very efficient and courteous. Prices were  
>>quite reasonable. I would highly recommend a visit.

>>Still, my palate does get around, and while  
>>none of the beers at Walnut were "jump up and down" spectacular, I  
thought  
>>they were all well done.

What I had posted essentially said that the Wyncoop brewery in Denver is  
a  
better microbrewery to visit should one want to drink beer. Now if one  
would  
like to have a pleasant atmosphere and a pint of something besides the  
regular  
mass-produced beer, then the Walnut Brewery is fine. Then again, there  
are  
several other places on the Pearl Street Mall with a pleasant atmosphere,  
good  
food, and decent beer - Boulder Beer, Anchor Steam, Sam Adams, and the  
Very  
Large International Selection at Old Chicagos.

I stand by my comments that the Wyncoop has better tasting beer. I do  
agree  
that the Walnut Brewery is a nice place to visit, but so are a number of  
other places on the Mall and in Boulder. When I visited the Walnut  
Brewery, I  
was impressed with the crowd, the service, and the setting (never ate the  
food) but found the beer a disappointment compared to what else is  
available  
locally.

I'm not saying "avoid the place like the plague." I am saying "don't set  
your beer hopes too high."

From: bliss@csrd.uiuc.edu (Brian Bliss)  
Subject: sparging

Well, on monday I tried to make my second all-grain batch, and indeed, sparging is my low point. I recirculated for a half hour, and it never ran clear. I finally gave up and when I started pouring hot water over the top of the grains, it started to run clear, so I recirculated some of the muddy stuff again, and the runoff got muddy again. I consequently didn't use enough water after this, and probably left too much goodies in the grain. got an efficiency of .016 or .017 pts/lb of grain for 10 lb pale ale malt, 3 lb munich, 2 lb wheat. The gains were ground as coarse as I could get them.

What I finally did was just let the runoff sit for 3 hours in a fermenter, and all the husks settled to the bottom 3/4". This worked great! I then racked off the clear wort. I have (had) never seen wort of such clarity. Not only that, but I found the "purer" wort to be much less volitaile during the boil, and got an excellent cold break.

Next time I'll try 6-row lager malt (I think the 2-row malt, with the finer husks is the culprit), and stick a grain bag in the sparge bucket. If I still have to resort to letting the runoff settle, It will become part of my standard technique.

I just thought I'd mention to those that may not have thought of this:

Check your local scap yards and salvage companies!

I stopped into "Davis Salvage" here in Phoenix and they have A LOT of 5  
gallon Cornelius and Firestone tanks (ball lock). I poked around and  
found  
a few \_10\_ gallon tanks too! The 10 gallon tanks go for around \$198 in  
Fox  
and I picked up one (used of course, but in great shape) for.... \$20!  
The 5 gallon tanks go for \$8! (I grabbed a couple of them too). It's a  
filthy task, scrounging around in the mountains of scrap, but it was  
worth  
it!

Hi Brewfreaks!

Well after cooking up my first 2 batches. Both of which were great. I think I may have screwed up the batch I cooked up last night. It was my first try using liquid yeast. Anywho. I read the label on the yeast package about breaking the seal and neadinn the package. I went ahead and combined the ingrediants cooked em. but about two thirds of the way through I noticed on the yeast package that it said it would need a day or two to incubate. Woops! I went ahead chilled the wort and tossed it into the carboy. (I know now i should have sat the pot in the fridge and re boiled) but I went ahead and pitched the yeast anyway put the stopper on the carboy and let it sit. Ok my question is what are the chances that this batch will turn out alright? Should I go ahead and toss it out or should I wait and see what happens. BTW its a pale ale. I payed close attention at maintaining a clean environment. Your thoughts would be appreciated. Thanks!

From: GARY MASON 16-Jul-1991 1413 <mason@habs11.ENET.DEC.COM>  
**Subject: Irish Ale**

Does anyone have a recipe (or two, or three, or...) for an Irish Ale? If so, would you be good enough to post it? Also, other than the AHA definition, does anyone have a good description of what one of these is?

Thanks...Gary

From: darryl@ism.isc.com (Darryl Richman)  
Subject: re: Water, water everywhere...

I've never had to deal with either sulfur or iron in my water. But you ought to get a copy of the transcripts from this year's AHA conference; they should be out by the end of the year. Greg Noonan gave a very informative demonstration on testing water, including using a set of inexpensive test kits to determine the make up of your water. I'm sure that all the details will be included in the transcripts.

Subject: What light spectrum effects beer?

I've been wondering, what part of the light spectrum effects the hops in beer. Does fluorescent or indirect sunlight contain this part of the light spectrum.

Also for the NYC area HBD folks the "Zip City Brewpub" will be opening around the end of August (their estimate). The address is 3 West 18th Street (NYC) and phone # is 212-366-6333.

> planning on getting around to writing it someday, but hopefully  
> someone has beaten me to it. Thanks.

The Brewer's Worksheet is available from the various archives and is an Excel spreadsheet I wrote to do recipe formulation work. It will assist in devising water treatment, beer color and original gravity, and hop bitterness. It has a lookup table for malts and adjuncts that can be expanded if I forgot something that you want to use. The water treatment calculator takes entries of water salts and determines total ppm from a base water you supply (from a water report). If you also supply the ion concentrations of a target water, it will give you the differences and a % difference to assist in getting the overall profile correct. It also lets you select what units you want to work with throughout the process (e.g., you can work in pounds or kgs, ounces or grams, gallons or liters, and so on). A brewer over on CompuServe, Art Steinmetz, uploaded a version that had been translated to 1-2-3 on the PC (sorry, I don't have a copy--would someone be willing to download it and send it over to aem?).

The manual you get with The Brewer's Worksheet implies that this is a commercial product. I had thought about selling it, but decided that polishing a spreadsheet template was more work than it was worth, so it really is free.

I am working on a for-sale formulator/batch logger called The Brewer's Planner. This is written in C and the first version will be for the Mac. It should be available in the September time frame (look for an ad in the Fall Zymurgy). I demoed a prototype of it at the NH Conference, and a lot of people seemed pretty interested. I anticipate that I'll sell it for \$50, to keep it affordable. I hope to release one for the PC early next year. (If this is too commercial, somebody tell me and I'll shut up. ;-)

Other folks are doing similar things. I know that larryba up in Seattle is working on a formulator written in Visual Basic, and Doug Henderson has a HyperCard stack with some interesting heuristics for automatically determining water treatment.

From: rak@mayo.EDU (Ron Karwoski)  
Subject: Watermelon Beer

I was reading the newspaper last night and I read a trivia piece that said the Russians make a beer from watermelon juice. This sounded timely and interesting though I can't imagine a Watermelon Stout. Is there anyone out there who has ever used watermelon juice in making beer and could provide some details?

Thanks,  
Ron Karwoski    rak@bru.mayo.edu

From: Patrick\_Waara.WBST129@xerox.com  
Subject: Teleford's DME

Has anyone noticed a difference in the Teleford's dry malt extract lately? I used to use it exclusively, because it's good malt and was significantly cheaper than the syrup, but for a time I was unable to get it from my local supplier. He now has it again, but it looks very different than it used to. Teleford's used to have a crystalline quality to it; i.e., light used to shine off the facets in the malt. Now it is a very fine, dull powder much like American Eagle dry. Have they changed the way they malt their grains? Are they still using two-row malt or have they started using the 6-row stuff? I haven't had an opportunity to try the new Teleford's, so I can't tell whether it tastes the same or not. Anyone?

~Pat

>I have some water questions for y'all. I live in the country, and have  
... (paraphrasing) ... "bad water"

I too live in the country, and my water is not that great, particularly in the summer when the well is a little low, or in the spring, when the well is a little high. I solved this problem by buying my water at the store. I buy the cheapest water I can find, usually about \$2.50 for five gallons of water. It usually states on the label that it is water from the Little Rock municipal water supply. (I think that means they treat the water from the Arkansas River.) It has made a big improvement in my beer. In fact, the large improvement for \$2.50 convinced me to spend another couple of bucks per batch on liquid yeast. Easily the two biggest improvements to my beer.

are  
> well a, well B straight, or well B softened by a water softener. What  
> should I do? I have heard that iron is toxic to yeast - is that true,  
> and if so is there a reasonable way to remove it?

I have been using well water with a high iron content for over a year  
with no ill effects to my beer, that I can notice. My water has a  
distinctive odor to it, and I don't care to drink it straight out of the  
tap. I had often wondered what it was doing to my beer, if anything, so  
I tried an experiment. I hauled Colorado Springs city water (quite good,  
actually) home in 6 gallon jugs and used it to make my beer. I made 3  
batches with city water, and discovered that it made absolutely no  
discernable difference in taste whether I used my well water or city  
water.

Note that some styles of beer need softer or harder water than other  
styles,  
but I haven't been able to notice any difference when I make the same  
beer  
with my hard well water or the soft city water.

Why don't you make a batch from each well using the same recipe for  
comparison purposes and then let us know how they turn out?

Subject: Muddy runoffs

>From: bliss@csrd.uiuc.edu (Brian Bliss)

>Well, on monday I tried to make my second all-grain batch,  
>and indeed, sparging is my low point. I recirculated for  
>a half hour, and it never ran clear.

>What I finally did was just let the runoff sit for  
>3 hours in a fermenter, and all the husks settled to  
>the bottom 3/4". This worked great!

It probably did but all-grain brewing is long enough without  
adding an extra three hours to it.

-Stuff Deleted-

>Next time I'll try 6-row lager malt (I think the 2-row  
>malt, with the finer husks is the culprit), and stick a  
>grain bag in the sparge bucket.

AH HA!! If (and I'm not sure from your posting) you were just  
letting the sparge water run free through the spigot on your  
lauter tun, it's no wonder it never ran clear. By all means  
use a sparging bag or some other type of straining mechanism  
to strain out the husks.

Don't give up on the 2 row just yet. 6-row requires a step  
mash, is more complicated and difficult to work with, and  
as far as I can tell, doesn't taste any better, anyway.

(Is that the sound of rushing flames coming up behind me?) :-)

>If I still have to resort  
>to letting the runoff settle, It will become part of  
>my standard technique.

Let's hope not. Bear down on the straining of the husks from  
the sparge water. It really sounds like this is the source  
of your problem.

Cheers,

Kinney Baughman | Beer is my business and  
baughmankr@conrad.appstate.edu | I'm late for work.

P.S.

Just who is Darryl Richman, anyway ? :-)

Two items for my first posting:

1.) Water Analysis. When I moved into my latest house I requested a water analysis from the local water agency. The documentation they sent me was skimpy and lacked detail. It just didn't have the information I wanted in order to understand my brewmaking water. Then, one day while wandering through the local Sears I came upon their water-filter/softener department, and found that they offer a FREE water analysis service. It works like this:

You think you may want to purchase a water filter or softener. You pick up from Sears a little plastic sample bottle and postage-prepaid envelope. You take it home, fill it with water from your preferred brewmaking water faucet, close it, bag it and mail it off. A couple weeks later you get a nice, big fat report - your free water analysis! (The first step in the above process is optional. :)

2.) Calculating the temperature to cool the wort to. In making an extract beer, my brewpot usually boils about 3 gallons. Therefore I need to top off my primary fermenter with 2-2.5 gallons of water before pitching the yeast.

Since the temperature of my top-off water is usually not proper pitching temperature and my goal is to cool the 3 gallons of hot wort down to the point where I can add the top-off water and pitch the yeast immediately, I want to be able to calculate the proper temperature to cool the wort to (using my immersion chiller) such that the resulting mix ends up being a good pitching temperature.

If one assumes that all the liquids involved have the properties of plain water (the properties involved are density and specific heat) then the formula for the temperature to cool the wort to is:

$$\text{Temp.wort} = \frac{\text{Temp.pitching} + \frac{\text{Top-off Volume}}{\text{Hot Wort Volume}} (\text{Temp.pitching} - \text{Temp.top-off})}{1 + \frac{\text{Top-off Volume}}{\text{Hot Wort Volume}}}$$

But as we all know, the density of wort is somewhat higher than water, and the specific heat is probably somewhat different as well.

Right now I'm trying to work through some numbers to see if the likely dif-

ferences are going to make more than a few degrees' difference in the  
outcome,  
but I'm curious as to whether others have attempted to do this.

Of course, the other option is to make sure my top-off water is heated to  
a good pitching temperature to begin with; then I just cool the hot wort  
to  
match and not worry.

hmm. they seem to be getting cheapert by the minute.  
Maybe if I wait until next week, I can REALLY get a bargain :-)

.....

> I read the label on the yeast package  
> about breaking the seal and neadinn the package. I went ahead and  
combined  
> the ingreadients cooked em. but about two thirds of the way through I  
noticed  
> on the yeast package that it said it would need a day or two to  
incubate.

I did the same thing when I tasted my Wyeast british ale starter and  
found it to be infected. I used Wyeast german ale instead. It was  
a little slow to start, but worked fine. The damn thing took an entire  
month to ferment, but I talked to a friend who (presumably) let his  
package incubate, and hada long fermentation, too.

I re-cultured the dregs for the next batch, and with a ready starter  
bottle, it still took 24 hrs to start to krausen. I aereated this  
batch fully - we'll see if it still takes a month.

Back on the subject of infected Wyeast British ale yeast. I thought  
I was at fault when I made the starter bottle, so I ordered another  
package. When I arrived, the package has already started to swell,  
and the bubble had not been burst yet! Could Wyeast have released  
an infected batch? This has only happened on British Ale packets  
dated April 10 for me. I cut open the foil, and tasted the solution,  
and it was slightly sour, but certainly not "vinegary". I then  
cultured what was in the bubble, but I'll probably never use it.

cheers!

Subject: ginger, aphids

Regarding using ginger in beer slowing down yeast: I make ginger beer that has 1/2lb of fresh ginger in 2 gallons of water, and it certainly' doesn't slow down the fermentation in any way.

My mother's recipe to get rid of aphids:

Mix 2 cups of vegetable oil, and three tablespoons of dishwashing liquid together.

Taks two tablespoons of this liquid, and mix with 1 quart of water. Thouroughly spray plants with this liquid once a week. It apparently controls several types of bugs.

Subject: Troubleshooting a failing batch

I'm currently fermenting my 6th batch of beer - A Canadian Ale (The "traditional" package from Alternative Beverage; scoff if you must). I have never had a problem in my first 5 batches, but this batch doesn't seem to be going quite right. I cooked up everything on (last) Thursday night, added the yeast and let it go. By Friday afternoon, there was definite fermentation going on. But, Friday night, my A/C broke down, and ever since then my apartment has been above 85 degrees (it's been a real joy, let me tell you). Anyway, when I went to check it this morning to see if I could bottle this weekend, I noticed that it had not only not clarified, but that there were still hunks of "stuff" floating around in it (the normal stuff you see swirling around during active fermentation). So, I'm wondering if the heat might have killed off the yeast before it had a chance to finish fermenting. Assuming that this is true (and I'll be able to take a S.G. reading to verify this), is there anything I can do to salvage this batch? I'm going to be out of town all next week, so I also would like to know if it is ok to let it sit like this for another week. I sure would hate to pour all this work down the drain!

I still have some of this yeast in the bottom of my  
secondary. It's on its second batch of beer, so I know it's  
viable 8<:^), so if anybody in the SoCal area would like to  
come over and pull some slants off it, they're welcome.

I'm going to miss MeV; Wyeast wants a fortune for  
their pure S. Delbrückii strain, and I'll want to make wheat

Subject: New Jersey brewery tour

I know I posted this before, and several people expressed an interest, but just in case there are any more of you who didn't see it or had forgotten.....

The Ithaca Brewers' Union is planning a trip to Vernon Valley, NJ, Action Park, and the Clement Brewing Company this weekend (July 27-28). We have arranged to receive an owner-guided tour of the brewery, thanks to James Clement, who also owns a brewpub here in Ithaca. The tour will take place Saturday at 2:00pm, and will be followed by a tasting of Clement beer (including the Blond Double Bock), a homebrew tasting (all who come are encouraged to bring some, with a drinking glass), and then all the homebrewers will go to dinner. Many of us are staying overnight in the area, then going to Action Park the next day to participate in the German Festival and go on all the water rides. If you would like more information, please send e-mail to me directly or call me.

About 10 of us from Ithaca are planning on making the trip, and we expect a carload each from Philadelphia and the four New Jersey homebrew clubs, plus 5-10 from the New York City Homebrewers Guild. Plus, at least 4 people from this Digest are coming from around NJ and southern NY. This is a good opportunity for all the clubs to get to know one another, not to mention a chance for those of you who think you might like to become active in a brewclub to see what several Mid-Atlantic clubs are all about.

For more information, please contact me at:

607-273-7306 (home)  
607-255-4648 (work)  
srussell@snoopy.msc.cornell.edu

Sure hope you will be able to join us!

From: gozer!klm@uunet.UU.NET (Kevin L. McBride)  
Subject: Juniper Beer?

Well, the Junipers are all covered with berries. Blowing off the cobwebs from the back of my brain brings forth a memory of someone writing about Juniper beer many digests ago.

Is it worth trying? Just for a lark? Yes, I like gin, so I wouldn't find the Juniper taste to be offensive.

How much of the berry harvest should I use for a 5 gallon batch?

Do they go into the boil? Or is it better to "dry hop" the berries? Should they be crushed first?

Would Juniper go better with a "lawnmower" beer or with something heavier?

If you've done this before, please do tell!

From: korz@ihlpl.att.com  
Subject: Re: Yeasts

Alec asks:

> What is the difference between an attenuative yeast and an  
unattenuative  
>one?

An attenuative yeast eats more of the sugars in your wort leaving a less sweet beer and making more alcohol (see Dry Beer). A less attenuative yeast leaves more sugars behind in the final beer. Wyeast provides a sheet that describes its yeasts including "apparent attenuation."

I'm not sure what this means. The attenuations range from (I believe) 67% to (I believe) 78%. I once posted a copy of this sheet, but I seem to have deleted it. Maybe some kind soul can send you a copy or you can call or write to Wyeast (I don't have their number or address here) for the sheet. Here's some useful info from Pete Soper on Wyeast, however

I believe that Wyeast is a U.S. company in either Oregon or Washington state (just for the record, I don't use a starter and get activity in about 12 hours):

>Date: Fri, 26 Jan 90 13:00:04 EST  
>From: Pete Soper <soper@maxzilla.encore.com>  
>Subject: Wyeast

>

>In HBD #345, Mike Charlton asks about liquid yeasts.

>

>I highly recommend Wyeast #1056 for pale ales. This is a very neutral yeast that will let the character of your malt and hops come through. I love it. This is also called "Chico Ale yeast" and "American ale yeast" and is rumored to be the same strain as that used by Sierra Nevada (i.e. the brewery at Chico, California).

>

>If you don't mind or perhaps desire an estery character (fruity aroma) and less attenuation (i.e. higher final gravity, more residual sweetness) try Wyeast #1098 (aka English Ale yeast, rumored to be Whitbread's strain). For any given brew, this yeast gives me a final gravity perhaps 1/3 higher than a "regular" yeast (just for example, I recently got 1.018 instead of the usual 1.014 for an ale that started at 1.056) To compensate for the higher terminal gravity I boost my bittering hops a bit when using this yeast. This one is also very well behaved and reliable.

>

>I've only used #1084 a few times. This is "Irish ale yeast" and is rumored to be the strain used by Guinness. I can't say much about it except that it is well behaved and certainly hasn't added any flavor or aroma that could rise above the massive roasted barley character of my stouts. (I've got a long way to go with duplicating the smoothness of Guinness :-)

>

>I got nailed a couple times by #1028 (don't remember its "name"). I found it unreliable and in one case it was clearly defective.

>

Date: Fri Jul 19 23:57:18 1991  
From: semantic!bob@uunet.UU.NET  
Subject: All Natural Soda Recipes

Enclosed are some 'All Natural' soda recipes. There were some requests a few months ago for some such recipes. I felt inclined to send them to the digest for that reason and due to the fact that they seemed so homebrew like. To date I have not tried the recipes, but plan to run up a test batch of the Ginger Ale.

Recipes from Early American Life, August 1975, Pg 12, titled Making Your Own Soda Pop, by Caroline Kitchen Riddle.

I was presented this magazine while helping to clean old books and magazines from an elderly woman's porch. After a short explanation as to what specific article was contained in the magazine she said: "Oh Bob, make some ginger beer, I do \*like\* that stuff."

So here they are:

Root Beer  
=====

3 tablespoons ground sarsaparilla  
1 tablespoon sassafras  
1 heaping tablespoon hops  
1/4 teaspoon ground coriander  
2 gallons of water  
1 1/2 cups honey  
1/4 teaspoon wintergreen extract (Almost all natural)  
1/4 teaspoon yeast

Place the sarsaparilla, sassafras, hops, and coriander into an enameled or stainless steel pan. Cover them with water and bring to a boil. Reduce the heat and allow them to just barely simmer for 12 hours, making sure the water does not all evaporate. Strain out the solids and add the liquid to 2 gallons of water that has been boiled and cooled to lukewarm. Stir in the honey, wintergreen extract, and the yeast dissolved in 2/3 cup warm water. Stir the mixture thoroughly and allow it to mellow for several hours. You can then siphon off the root beer into a clean container before bottling, or fill the bottles immediately. Makes about two dozen 12-ounce bottles.

Ginger Ale  
=====

2 5/8 cups honey or 5 cups sugar  
2 gallons water  
3 beaten egg whites  
1 tablespoon ginger, moistened with a little water  
Juice of 4 lemons  
1/4 teaspoon yeast  
1 whole lemon

Dissolve the honey or sugar in 2 gallons water. Add the beaten egg whites and ginger. Bring to a boil and skim. Most of the flavor of the ginger will have been given out, so don't worry that you

loose much of it in the skimming. Add the whole lemon and set the mixture aside to cool. When it is lukewarm, add the lemon juice and the yeast dissolved in 1/4 cup warm water. Stir well and let stand for a while for the sediment to settle to the bottom. Strain through a cloth into a clean container. Give it a few more minutes to settle and you are ready to bottle.

The rest of the article goes into equipment, bottles, cleaning, siphoning, capping, fermentation, conditioning, ingredients, and exploding bottles. I won't repeat these points because they are all the same points brought out when learning to brew. I hope these recipes serve you well, and please do post any results to the digest.

Subject: Darryl who?? Hop Harvest

>Just who is Darryl Richman, anyway ? :-)

Never heard of the guy :-) !!

Well since I am going away for a bit (SIGGRAPH and a Grand Canyon hike) and a lot of my hops looked ready (as per Pete Sopers description of what that means), and I had to return the ladder I borrowed I decided ready or not to harvest my hops. Most of them seemed ready, some were just starting to brown out a little, Many were a little dry and papery, and when squeezed didn't spring back, so from what I understand they were probably ready.

Anyway while I was up there trying not to fall off the ladder I noticed that a few leaves had been munched on, but lo and behold the cavalry was there.

I spotted at least 2 lady bugs, a few spiders and a cricket (these eat other bugs right??), so it looks like the balance o nature was working for me here to keep nasties in check and protect my lovely hops.

With a little luck I may get another harvest off these plants.

Anyone ever use any manure, fertilizers, or other growth inducing agent on their hops?? If so what is good for the plants & good for the environment??

Subject: DeClerck on dextrin body

I found a reference in DeClerck's Textbook of Brewing to the 'Dextrin Body' controversy. After reading it (text follows) I was surprised to discover that contrary to David Line's citing of DeClerck as a supporter of dextrin as the source of body (DeClerck uses the term 'mellow'), DeClerck has come to his own conclusions.

From DeClerck (pg 262):

Beers rich in dextrin are generally considered to have a more mellow palate and this is usually attributed to the greater viscosity of such beers compared with beers with a higher alcoholic content. This view, however is quite erroneous. The author has made a series of mashes so as to obtain worts of differing dextrin content (12-15% difference in attenuation limit) and found that the beers brewed from these high dextrin worts lacked palate fulness. This result is probably due to the fact that raising the mashing temperature suddenly from 50 degC to 70 degC to suppress partially sugar formation, at the same time leads to a failure to form intermediate protein degradation products, as will be seen in the next paragraph.

These intermediate protein degradation undoubtedly make a major contribution to palate fulness, nor must it be forgotten that the higher the dextrin content, the lower will be the concentration of alcohol, which is also a contributory factor to mellowness and palate.

Subject: T-shirt trick

Sunday last week I started a batch. Since then we've been in the sweltering grippe of a heat wave (90-100). I don't have air conditioning or a Hunter Air-Stat for one of the extra fridges, so... I figured I'd try the T-shirt trick.

I put three T-shirts one inside the other, wet them down, put them over the carboy (5 gal) and put the dressed carboy into a dish-washing pan. I then filled the pan near brim-full and propped a gallon jug, full of water, mouth down bubbler-style in the corner of the dishpan and strapped it to the carboy. This `system' went for three days on the gallon of water, all the while the T-shirts were wet or damp all the way to the top.

CAVEAT: If a corner of the T-shirt (like a sleeve) hangs out over the side of the pan it will drip on the floor and make a fair size puddle. Tuck the sleeves in.

Subject: aluminum v stainless

If a magnet will stick to a pot it is not aluminum, but if it won't stick, you can't safely conclude that it is made of aluminum. There are (at least) two families of stainless steel, one of which is non-magnetic. If memory serves, the non-magnetic family is often used for cookware because of it's greater ductility. The surer way to test the pot's mettle\* is to have at an inconspicuous corner with a pocket knife, if you can actually remove a small curl of metal, it is not stainless steel.

**Subject: Culturing Yeast**

With all of the discussion going on about yeast I decided it was time to try culturing some myself. I bought the Ironmaster cider kit in my (what now appears to be) life-quest for perfect cider (i.e. Strongbow). If this yeast works better than the M&F ale yeast that I have been using I'll want to keep some around. So question is, how do I do this? I would really appreciate a nice step-by-step (hopefully easy) way to allow me to keep this strain going. This is of course assuming that the cider is drinkable.

From: zentner@ecn.purdue.edu (Michael Zentner)  
Subject: "stainless" pots...

I thought I found quite a deal a while back on a "stainless" 10 gallon pot for about \$70...very heavy duty, made by Wearever. I got the thing home, after being assured by several people at the store (even the buyer) that it was indeed SS, and decided to test how long it would take to boil 5 gallons on my stovetop. The pot discolored horribly, arousing suspicion.

What I did first was, as many of you suggested, take a magnet to it... didn't stick. Not being sure about the alloy, I dug out my materials books and found that not all alloys known as SS have magnetic properties. This was confirmed by the fact that the magnet did not stick to my kitchen sink, which was labelled SS.

I rigged up a measuring device to gage the width of the pot material. Measuring the dimensions of the closed cylinder and calculating the volume of metal involved vs the weight of the thing, it weighed about 1/3 of what the same volume of SS should weigh, which corresponded almost exactly to the density of Aluminum. I verified with a call to the manufacturer and got my money back.

Since then, I bought the Polarware 10 gallon SS pot for \$90 from Rapids Inc. This is a very nicely constructed pot. I had it out on my 165000 BTU burner last night for some moonlight brewing and have no doubts as to it's durability (iron grate was glowing red, but the pot transferred the heat nicely). I'd highly recommend this pot to anyone considering spending more than \$50.

Another use for such a big pot...our group decided to make a strawberry mead one day and went out in the morning to pick fresh berries. We came out of there with 70 lbs in about an hour. Brews were popping, and we got a little carried away pureeing strawberries, ended up using about 30 lbs of berries and 16 lb of honey, having quite a large volume of material which undoubtedly would plug up an airlock on even a 7 gal carboy.

So, we just let it cool down from the 170 F steeping temperature in the pot and carried out the primary in stainless. The thing wiped clean with no effort. Now, as to what we're going to do with such an outrageously high gravity mead, we haven't figured out yet....either a very sweet dessert wine or dilute it (or both).

Subject: Request: recipes for Bridge Port Ale and Pilsner Urquell

My wife has decided that her two favorite beers are Bridge Port Ale and Pilsner Urquell. Since my wifes total beer consumption last year was about 12 - 15 bottles, this new found interest in these beers is quite interesting. She's already bought about 2 or 3, 6 packs of Pilsn Urquell.

Given the motivation, I need to find recipes for both of these beers, I'll be looking in Miller and Papazian, but I wanted to ask the rest of you on alt.beer.guru to send me any recipes that you might have for these scrumptious brewskies. Full mash is fine, I can mash about 9 pounds of grain at a time.

|Well, don't all of you get your airplane tickets to S.F. too quickly. I  
drove  
|up to SF Chinatown yesterday to check out this \$42/\$39 stainless steel  
pot.  
|Well folks it isn't stainless, it's aluminum! I talked at length with  
the owner  
|and he verified that the pot was aluminum. Not to waste the trip, I  
scouted  
|several other places and found a 8 gallon pot that really looked like  
Stainless, but didn't have a magnet to check it. I'll probably go back  
up  
|next week to re-check since this pot was nothing short of beautiful.

A magnet is not a reliable indicator of SS. Some varieties are magnetic,  
some not. No aluminum pot is magnetic. I am not a metallurgist but I  
suspect the following will reliably identify your metal:

- if it rusts, it is regular steel
- if it corrodes under lye (easy off) it is aluminum (i used to make  
hydrogen ballons using this technique)
- if none of the above it is probably SS.

If it is thin (like formed sheet metal) and has a rolled or folded edge,  
it  
ain't aluminum. Aluminum is too soft and all aluminum pots I have seen  
are  
pretty thick. Also, aluminum, unless surface treated, is easily  
scratched -  
it is much softer than SS. Take one of your kitchen forks and do a  
simple  
hardness test.

The brewers warehouse in Seattle has 5 gal korean ss pots for \$40. They  
are  
thin bottomed vessels. I could imagine a 10gal pot for the same \$ from a  
super discounter buying direct from Korea or Taiwan.

Although I brew in SS, I have heard from reliable brewers that aluminum  
has  
no detectable affects on their beers. If I had known that before  
dropping  
centa-bucks on SS I would have opted for aluminum...

From: Rob Malouf <RMALOUF@SBMS01.MSRC.SUNYSB.EDU>  
Subject: Flat beer

A while ago, I made my first attempt at a partial mash. It was an all-around failure, but I decided to let it ferment out anyway, just to see what would happen. It's been in the bottle now for about three weeks now, and it tastes a little weird but not all bad. Unfortunately, it's almost completely flat! I used the same priming (1/2 cup corn sugar), bottling, and capping procedure I have always used, and I've always gotten good carbonation within 2-3 weeks. The starches in the mash didn't convert, but I added enough DME to get an OG of 1.033. I pitched about a cup of Wyeast Chico Ale slurry, and had strong fermentation within eight hours, and fermentation was complete in a week. The gravity at bottling time was 1.006. The beer was still very cloudy when I bottled it (I assume the unconverted starch had something to do with that). The bottles have a good yeasty sediment. The temperature has averaged 75 to 80 degrees for most of the time, but this week it's been more like 95 (I live in an attic). I also chill each bottle for a couple of days before I taste it. Does anyone have any idea what might have caused this? By the way, I've brewed a small all-grain raspberry beer since then, and the mash went very well, so I guess I've solved that problem.

Sorry Russ, but a magnet won't help you. Neither SS nor aluminum are ferromagnetic, so the magnet test will not distinguish between the two. Besides checking the specific gravity of the metal, which would be difficult given the size (remember the "EUREKA!" story?), I can only think of testing the electrical potential of the metal (I think that's what it's called). Anyone care to comment if the following will work:

1. look up the electrical potential of aluminum and of copper
2. soak a piece of filter paper in an electrolyte (say, lemon juice & water)
3. sandwich the wet filter paper between the pot and a piece of copper
4. measure the voltage potential between the pot and the copper
5. if the voltage is equal to the difference between the AL and CU electrical potentials, then you know you've got AL.

If the voltage is different, then I don't know what you've got. I don't have my old Chem book anymore (these potentials were in an appendix) so I can't look them up for you, and I'm pretty sure that you won't find an electrical potential for SS. Try the CRC Chem & Physics Reference Manual.

Subject: Sam Adams Wheat Brew.

I got my first six-pack of the new Wheat Brew from Sam Adams (The Boston Beer Co.), this weekend. Now, I am new to experiencing many different types of beer. Two years ago, I hated beer because all I had ever tasted was the usual American barley sodapop. When I finally discovered beer in all it's glories, I missed wheat beer. This new brew from Sam Adams is the first wheat I have ever tasted. (I intend to brew some, but too many stouts to try first!)

Does anyone know what the wheat percentage is in this beer? Do they brew it on premises, or is it contract brewed. Most importantly of all, how does it compare with other great wheat beers of Europe. (I intend to get around to trying all of them, too ... it just takes time, a lot of time.)

Oh yes, how did I like the new Wheat Brew? Since I haven't heard any other opinions yet, I'll go out on a limb and say it is delicious. There is a good solid taste that starts with a lot of flavor and lingers longer than any other beer I have tasted. The far end of the aftertaste is not unlike that you get if you chew raw wheat berries. Now, if the consensus is that it's a bad beer, I'm proven to have no taste ... but I think it will hold up to be pretty good in all quarters.

From: Mike Fertsch <FERTSCH@adc1.adc.ray.com>  
Subject: Dry brew, cold filtered

Last week, Dave Barrett had a few questions about Bud Dry, cold filtering, and dry brewing.

I always assumed that Bud Dry is "dry brewed", meaning fermented with a very attenuative yeast. Attenuative yeasts will ferment all the sugars out of solution, resulting in a low final gravity and a dry (not sweet) taste.

I assumed that "Cold filtered" meant that the beer was not heat pasteurized. Typically beers is heat treated to kill any living thing such as yeast or bacteria. Cold filtering means that the final beer is passed through a fine filter to remove these organisms. This is reportedly better to the taste of the beer.

Listening to the adverts, I think it is intesesting to note the order of the process. A-B always says "cold filtered, then dry brewed" to describe their process. This seems backwards to me. My bother to filter, if afterwards you are going to brew the stuff?!

Subject: sterilizing water?

Hello! I bought a starter kit and cooked up my first batch of homebrew last night. I checked on it this morning, at it was bubbling right along.  
It looks to be off to a good start---I can hardly wait.

Anyway, I'm writing for some opinions. In addition to reading Papazian's "The complete joy of homebrewing", I got some tips from the fellow at the homebrew store (The Wine & Hop Shop in Denver). He strongly recommended  
Boiling all of the water for 20 minutes to sterilize it, then letting it cool overnight in the fermenter. Then boil and cool the wort and add it to the fermenter. Do the rest of you go to such extreme measures as boiling  
3-4 gallons of water for making your beer? It was pain, but the shopkeeper  
said that using fresh tap water could result in unwanted bacterial contamination. Next time I will be inclined to skip that step and relax, don't worry, and have a homebrew. Opinions?

I also cooled the wort by placing the brewpot in a sink of cold water, which worked rather well. I observed a lot of the protein sediment (trub) settling out in the fermenter, so I guess that means I got a good "cold-break", right? This fellow also recommended using two packets of yeast and rehydrating it in a bit of warm, sterilized water before pitching. Are these also good ideas?

From: teroach!fse@phx.mcd.mot.com  
Subject: Conditioning in tanks

I've asked this before and did get a number of helpful responses...  
Thanks to those that replied...

But I'm still having trouble and thought I'd cry out once again:

I "keg" my homebrew in 5 and 10 gallon ball lock style Cornelius and  
Spartenburg tanks, I've followed the majority of the sound advice I've  
had

for conditioning in the tanks and I still come up with nearly flat beer.  
My local brew supply proprietor and local expert in these matters has  
been

kegging his brews in standard half kegs (15.5 gal) from his normal 65  
gallon batches he does in a single mashing session. He has no problems  
with in keg (i.e. large volumes relative to bottles) conditioning.  
I've made sure that there's no residual sanitizer in the tanks, that the  
seals are 'set' with 8-10 lbs of CO2 after priming with about 1/2 cup of  
corn sugar boiled in a pint of water (and let cool of course). After the  
lids on I purge the Air with CO2 for several seconds via the presure  
relief

valve and then let the pressure build and set the seals... I make sure  
the

sugar/water mixture is well mixed with the beer. I've measured the  
gravity

after conditioning and it's exactly the same as before I primed,  
indicating

that the sugar has indeed been consumed during conditioning. I even, as  
one person suggested, rechecked the pressure each day for about 5 days to  
make sure the CO2 didn't all get absorbed into the beer before it had a  
chance to build up it's own presure and therefore lose the seal. The  
second and third day it took on a little CO2, the next day, it didn't  
take

on any and the forth and fifth day it tried to pump beer up my CO2 line!  
But by God, after two weeks of conditioning, I've got very little fzzzz!  
If you slosh the beer, stir it or agitate it, it produces head pretty  
well.

So I'm back to artificially carbonating this tank again.

>From the responses last time, I know that some people have given up on  
natural

conditioning of Cornelius tanked beer, but maybe those of you that have  
good

luck with this can give me an idea of what I need to do.. Am I cutting  
back

on priming sugar (as sugested by C.Papazian) too much for this volume? Do  
I

need to use a full cup to get a 5 gallon tank carbonated? Two cups for a  
10  
gallon tank?

Geeezzz! I gotta relax! Good thing I'm sippin' on a homebrew. 8^[]  
(burping smiley)

Subject: Isolating *S. delbrueckii*

>I'm going to miss MeV; Wyeast wants a fortune for their pure *S. Delbrueckii*  
My way around this was to purchase Wyeast's Weizenbier yeast (No. 3056 - a blend of *S. cerevisiae* and *S. delbrueckii*) and to plate it out on a Petri dish containing malt agar. The individual *S. cerevisiae* and *S. delbrueckii* colonies that formed displayed radically different colony morphologies. The *S. cerevisiae* colonies were smooth, small and round domes, typical of the majority of *S. cerevisiae* colonies on malt agar. The *S. delbrueckii* colonies grew more rapidly and spread out flatter, with jagged edges around the colony perimeter. They looked exactly like the colonies I had obtained many moons ago after plating the pure M.eV *S. delbrueckii* strain.

I then picked a well isolated *S. delbrueckii* colony from the plate and used it to inoculate a small volume (50 ml) of sterile wort. This was scaled up to a 500 ml culture which I used to make a batch of Weizenbier. The result was a nice tangy Weizen with plenty of clovelike phenols. :-D

If you culture yeasts on agar plates I recommend this procedure. If not I recommend looking into home culturing. It's not as complicated as it first seems. I'd be willing to send pure *S. delbrueckii* to brewers within reasonable mailing range (I live in Hamilton, Ontario, Canada). Maybe there are other HD subscribers/yeast culturers willing to do the same in their local areas.

From: Tom Bower <bower@hprnlme1.rose.hp.com>  
**Subject: Bottling from kegged beer?**  
Full-Name: Tom Bower

I got my Cornelius keg mostly to bypass the onerous chores associated with bottling my homebrews, but sometimes I'd like to bottle some of a batch anyway -- for transportability.

So, what's the best way to bottle some when you're also kegging?

1.) Pull off some of the flat brew before kegging. Prime it with corn sugar based on the volume, and bottle. Assuming I'm only going to do a half-dozen bottles or so, what's the best way? Some sugar per bottle, or make up a syrup to add to the whole bunch? What's the best proportion on a per-ounce basis?

2.) Bottle some of the already-carbonated beer straight out of the keg.

Are there any tricks/gotchas with this? Does naturally-carbonated work as well as CO2-tank-carbonated for bottling?

3.) Other methods?

Tom Bower, HP RND R&D

Yup, good ideas. Liquid yeast pitched into a starter is probably an even  
better idea.

Subject: SS vs Al revisited

OK, my vote. The winner for best method is...

Weight, well actually density. If you have some container big enough to determine the displacement of the pot, and a scale to weigh it, then you can determine it's density, and thus easily know whether it's Al or SS.

As for Craig Artley:

In all the places I've lived in the last five years I've gotten city water specs. All of them had bacteria ranges in the level of 1 per 10,000 parts water (ie real low). Boiling to sterilize is a waste of time. Boiling to remove volatile chlorines however is worthwhile.

If you have a big enough brewpot (see SS vs Al debates... :-) then you don't need to pre-boil your water, just boil all your wort and use a wort chiller. If you don't well pre-boiling is good, but I'd say far from a mantra.

Hello,  
I started my first batch of beer (a brown ale) Sunday July 13. I think I pitched the yeast a bit early (the wort was not 78 degrees), but it seemed to be doing just fine. July 18 or 19 I racked it into a second carboy to get it off the trub (a friend who homebrews says it's too hot to leave it there). It has not been bubbling much at all since then. The temperature has been over 85 each day since before I racked, and got up to 102 last Saturday. Have my yeast all died? Will taking a SG reading let me know anything? (I forgot to do an original SG reading, but the kit had predicted final gravity readings). It also gave off banana smells. Is this really bad? I thought brown ales were supposed to be fruity, and I do like bananas... When I racked it it tasted like it had fermented.

>Maybe I'm just slow on the uptake, but what's "rope"? I've seen the >term in a number of places, but I've never been able to figure out what >it means...

Sorry I missed this question the first time I read this Digest issue. "Rope" is a really weird effect of certain bacterial contaminants, where gelatinous filaments are formed, often accompanied by a sort of oily texture and a lactic acid sourness. By almost any standard it's revolting, but it's one of the stages lambics usually go through. Some lambics never get beyond it. In my present batch, it appeared as if the top 1" or so was utterly crammed with clear-to-whitish tubifex worms. Within a couple of weeks of pitching the Brettanomyces culture, it had cleared up.

From: eisen@kopf.HQ.Ileaf.COM (Carl West)  
Subject: reCulturing Yeast

Mark Castleman asked about saving a successful yeast.

I recently cultured the yeast from a SNPA bottle and have since pitched a batch with it (the batch in the T-shirts). Everything smells and looks good. When I rack the beer off, I figure on swirling-up and bottling some of the yeast-cake itself and sticking it, unprimed, directly into the fridge. I figure that if the yeast survived that sort of treatment before it got to me, it can take some more of it. So long as it's already dormant it seems it should work.

That's how I plan to go about it unless someone here can show me that it won't work.

-Carl `This is all conjecture, I've never done it either' West

P.S. The yeast was cultured *in* the SNPA bottle (after pouring out the beer) by adding progressively larger amounts of weak wort, then allowing it to ferment out and go dormant. At which point I tasted, flamed and capped it and stuck it in the fridge for a couple of weeks. That part seems to have worked.

Subject: brewery tour

Date: 23-Jul-91 Time: 04:11 PM Msg: EXT01588

Hello again,

We went on a tour of New Haven Brewing Company, a local micro. They make Elm City, Connecticut Ale, Blackwell Stout and Mr. Mike's light (made light by replacing some barley with wheat and fermenting to only 2.3%). They use local water and boil it 3-4 hours but add nothing to treat it. (New Haven water has lots of bacterial problems and they use lots of Chlorine to combat it in the water supply) They mash, sparge, ferment (at very cold temps) and then filter (cold filtered). They carbonate in a "bright beer" tank with a stone that lets them put CO2 back in, then bottle.

One can't taste the beer there, they are afraid of suits. They used to let people have up to 2 beers, but got sued twice and lost insurance once (in only 2 years of operation). Suit one was by a City Alderman who hurt his gums on the crab dip at the opening party. Chris (who gave the tour) couldn't remember the second suit. The insurance loss was strange. They had a homebrew club coming in, and were having a small party for the club (a keg and some munchies) . A couple came and wanted a tour (they were not with the club) they were given a short tour, told about the club coming in, and the couple asked could they stay for the long tour? They were allowed to stay, and no one kept a real close watch on them. When the party started, the homebrew club acted responsibly, talked, ate, drank some beer. The guy with the couple drank himself sick. Turns out that the woman was a secretary with an insurance company and when NHB applied for insurance she told her boss "don't give them insurance they got my boyfriend drunk." Now the brewery is applying for a license as a brewpub as well as a micro so they can serve beer after their tours.

Now they are having to fight Molsen. Molsen and Volvo are sponsoring a Tennis tournament in New Haven and have paid all the local merchants to run Molsen specials (normally few bars have it, it doesn't sell locally). They are sponsoring a beer garden and concerts on the Green, etc. NHB has just begun to

advertise more, and are getting drowned out by the big corporation.  
Support the  
little guys, buy local beer!

From: R\_GELINAS@UNHH.UNH.EDU (Russ Gelinias)  
Subject: SS/Al covers

I have been contemplating the purchase of a stainless brewpot from Rapids, Inc. Expensive at some \$90, but I think it may be worth it. On the other hand, a s.s. cover for the pot goes for a good chunk of \$ too, somewhere around \$20-30, whereas an aluminum cover goes for less than half of that. Anyone know if there's any reason \*not\* to put an Al cover on a stainless pot?

Re. boiling all your brew water: I use municipal water that comes from a lake. The water quality is better in the winter than it is in the summer. That's a subjective statement, (it tastes better in the winter), but it also makes some qualitative sense. Summer lake water has a higher and more active bacteria level, and treatment requires balancing between chlorine and bacteria levels. I haven't boiled all my water in the past, and I've produced some fine beer, but the beer I've made in the summer sometimes "soured" after a while (months, usually), whereas winter-made beer hasn't soured. There's a zillion possible reasons for this other than the water, but it seems to me that if you've got a way to cool and store the top-off water, it would eliminate a possible major source of contaminants, especially in the warmer months if your water supply is like mine.

Still no response on my question of how much it costs to start up a brewpub or microbrewery. Anybody know?

**Subject: Stainless Steel Fermenter**  
Full-Name: "John Cotterill"

Does anyone know where I can obtain a stainless steel fermenter with a conical bottom on it (just like the pros!) that holds about 6 gallons?? I had this great idea that if I cut the bottom off of a Cornelius Keg, and welded a stainless funnel on the bottom, I would have just what I need. The trouble was that I could not find a funnel large enough. A custom funnel costs about \$250. Anyhow, you get the idea of what I'm looking for. Any suggestions where to find it??

Try the lid from a wok. You should be able to get away with a small lip  
around the inside of the keg. One of my fellow Maltose Falcons (NOT  
Darryl  
Richman!) made a fluid level indicator for his keg out of a toilet bowl  
float  
so that he didn't have to stand on a ladder to check it. I haven't  
started  
building my 15 gal. setup yet.

I haven't made the index of HB digests for June yet since I am missing  
some.  
Did anyone get a whole no. 667? I saw references about Europe. I am  
going to  
beer heaven (Germany, Belgium, Netherlands, and Denmark) next month.

I was able to get a 10 deg. F. drop in temperature using the wet T-shirt  
method. The upside-down jug is a good idea for refilling the tub with  
water.  
I used a fan several feet away to help the effect. Putting the fan too  
close  
causes the shirt to dry up faster than it can wick.

**Subject: Beer tasting in Boston**

While listening to the radio this weekend, I heard an advertisement for a beer tasting, sponsored by WBUR (Boston). The date is Thursday August 15, and the cost is 30 bucks. It will run from 6 to 10, and is supposed to be the largest beer tasting on the East Coast this year. Brewers from every New England state except Rhode Island will be present. (I wonder why Hope is not involved...) Also, several restaurants and snack food companies will be offering their wares. The location is 808 Commonwealth Ave. Boston.

You can order tickets in advance by calling WBUR at (617)353-3800 and using your MC / Visa card. They recommend buying tickets in advance.

E-Mail me if you're interested; maybe we can get a whole gang of homebrewers together.

From: mason@enuxha.eas.asu.edu (Frank W. Mason)  
Subject: Re: brewing software

Greetings!

I am about to attempt my first batch and would like to trouble the experts

for a little advice before I forge blindly ahead. I have been reading the Digest (and anything else I can find) for about two months now and have poured over so much info that it is becoming a bit muddled! Any advice

would be greatly appreciated.

I purchased a "starter kit" from the best-known local supplier (read only local supplier) and got everything but a glass carboy (I know...the Digest's

Beginner file recommends one. I guess I just got so caught up in the excitement

of it all I forgot). Anyway, the supplier suggests I forgo secondary fermentation

in the carboy by priming the bottles. I know I have read opinions regarding this here before, but forget what the consensus was. Should I take the slightly more complicated route and procure a carboy first, or is simplicity worth the cost in flavor for the first batch? I have a

hopped malt extract (IRONMASTER Brown Ale) to keep it simple, but should I also add some finishing hops or is that getting a bit too esoteric for a first batch? Another concern is that I live in the desert. The days are about 105 degrees right now and keeping the house at 65 degrees for aging the bottled brew would raise the per bottle cost beyond reason. Is 78 - 80 degrees

OK or will it ruin the quality of the beer?

Thanks in advance for any help. This Digest has been the single greatest inducement for my interest in homebrewing...thanks to all involved!

Frank

From: Dr. Tanner Andrews <tanner@ki4pv.compu.com>  
Subject: Re: making malt

I suspect that it's not practical to make barley malt in the home, but there are people who would disagree. One home soda/wine/beer book advises doing just that thing.

I have made wheat malt, but just a couple of pounds to flavor some beer. Buy whole wheat at the health food store, cover it with water and let it sit in the sun for a couple of days to start sprouting. Dry in the oven at low temperature, stirring regularly. Grind and use in the mash.

Lots of trouble. Add in oven and labor and it's cheaper to buy it.

From: nolan@lhevax.DNET.NASA.GOV (Tom Nolan)  
Subject: Pre-boiling water

There were several replies to the guy who's brew-shop-owner advised him to pre-boil all his water, the replies all having to do with the low bacterial count in tap water making this step unnecessary. I think they missed one of the main points - boiling the water and \*letting it cool in open-top containers\* drives off chlorine and other dissolved junk in the water. Miller (the author, not the dry beer) devotes some space to this concept in TCHoHB. The same things the water company does to keep bacteria counts low are going to work against your yeast, too. By pre-boiling you are likely to make the water more habitable for your little pals. I think pre-boiling has some effect on mashing also, by softening the water (you want to add minerals to compensate). BTW, I notice that Colonel John always uses preboiled water in his beer kit reviews in Zymurgy.

> suggestions where  
> to find it??

Any competent sheet metal shop should be able to make  
up a stainless cone for maybe fifty bucks, including the  
welding. \$250 is outrageous. The hardest part will be finding  
the valve or fitting for the bottom.

Call the manufacturer to get the alloy! You'll want to  
match what they used to make the keg, to make welding easier.  
I think both Cornelius and Firestone use 303, but if your  
fermenter turns into a pressure vessel accidentally and blows  
up because this tidbit of data is wrong I will NOT be liable.

Some observations on welding with kegs:

In a desperate attempt to get 2.5 gal kegs, a fellow  
brewer, whose name I will not divulge (after all, he has a  
family, and if word of this got out...) and I tried to make  
one. He found a cheap source of 5 gal kegs, and I sawed the  
middle out of one and got the top welded to the bottom. Since  
you can't weld from the inside, it got welded from the  
outside, and this left the inside of the bead pretty ugly.  
Lots of rough, jagged surfaces to hold microbes.

I used up several grinding stones in my die grinder,  
and damn near buzzed a Dremel tool to death trying to get the  
bead ground smooth. The tools proved near impossible to hold  
thru the opening of the keg, and grinding the weld (rather  
than the keg) proved difficult. I still have the keg, but  
haven't used it.

If somebody comes up with a great idea, I'd like to  
hear about it.

That's what I did a few months ago.

>  
>That's how I plan to go about it unless someone here can show me that it  
won't  
>work.

It worked fine for me. I am on the third batch from the original yeast.  
The  
first batch was from the Wyeast #1056 American Ale yeast. I then took  
the  
stuff off the bottom of the primary and put it in a 48 oz. juice jar. A  
couple of months later I pitched half of it into the carboy of the next  
batch. I let it warm up to room temperature first. The third batch's  
yeast  
came from the bottom of the primary of the second batch after being  
stored in  
the 'fridge for a month. A starter was used for this batch. I spoke to  
Dr.  
Fix at the Southern California Homebrewer's Conference and he said that  
as  
long as there is a layer of beer over the yeast it would be OK in the  
refrigerator for a while. Make sure the yeast is a clean white color and  
the  
beer tastes good. Also, don't forget to sterilize the jar, lid, and the  
funnel used to transfer the yeast sludge. I got a good enough yeast pack  
on  
the second batch and had to add a little sterile water to have some  
liquid  
covering the yeast.

Another hint from Dr. Fix: if you don't have boiling water to rinse the  
carboy, use a can of cheap beer. It's sterile and will readily absorb  
the  
chlorine.

Subject: Re: Homebrew Digest #686 (July

A Dietz wants to know where to get great glassware. Well two recommendations I can give are the following:

1. If your area has a store called 'Crate & Barrel', you're in luck. They have an \*INCREDIBLE\* selection of glass/barware. I know this retailer isn't just a California phenomenon. They're also reasonably priced. Glassware is sold by the piece rather than sets. This gives you the flexibility of constructing a set sized to your needs, as well as a way to replace broken glasses without buying a whole set!

2. I live in the San Francisco Bay area. Any phone book lists restaurant/bar supplies stores that are open to the public. They are listed under 'Restaurant supply' in the yellow pages. These folks tend to sell glassware in large sets, like 36 per! This can work in your favor. Buy a set and keep out only the number you need. Pull from the remainder you pack away as needed. My brew partner purchased his wine glasses this way -- we're winos too ;-) I think he said the glasses cost about \$3.00/per. Not a bad deal at all. I would imagine beer glasses and the like could be had for a reasonable price as well.

Bottom line is you \*CAN\* get nice glassware for a decent price AND not feel awful when a glass is broken.

Hope this helps!!!

I can't verify the chemical that causes the banana flavor/aroma, but  
it isn't always an undesirable trait. It is my understanding that  
additional oxygenation of the wort will reduce the effect.

Sam Adams Wheat Beer has a very distinct banana aroma/flavor and I  
personally find it to be a wonderful part of the character of this  
beer.

The new Sam Adams Wheat Beer is certainly *\*different\** from most of the other wheat beers that I have had. I had a chance to taste it at the brewery during the AHA Conference brewery/pub crawl and immediately fell in love with it. This was before it was available in stores. As soon as it became available, I went out and bought a whole case. It's that good.

)

No, I don't know. Jim Koch told us during the tour, but I wasn't taking notes. It is brewed both in their Boston brewery and by contract in Pittsburgh. How does it compare? Well, it's different, but it is definitely up there on my list as one of the "great ones."

>Oh yes, how did I like the new Wheat Brew? Since I haven't heard any

I agree. It IS delicious. It has a wonderfully complex flavor and aroma, but at the same time, it is light, dry and crisp. A definite replacement for your old lawnmower beer. I can drink a LOT of this stuff. (I HAVE drunk a lot of this stuff. :-)

Phil <can'trememberhislastnamerightnow> of the Cambridge Brewing Co. has this cute little sign on the wall inside his brewery. It reads like a David Letterman "Top Ten" list describing beer advertising gimmicks, etc., ad nauseum.

At the very bottom of the list (No. 1 reason) is:

"Cold Filtered, because you don't know what that means."

IMHO, "Dry Brewing" and "Cold Filtering" don't mean squat to the Big Beer Co.'s target audience. They just sound like revolutionary techniques designed to deliver a beer with even less flavor than before. Pure Marketing Bullshit. I personally don't want anything to do with a beer that has "absolutely no aftertaste." A-B tries to make it sound like there is no such thing as a "good aftertaste."

Blech.

>of it all I forgot). Anyway, the supplier suggests I forgo secondary fermentation in the carboy by priming the bottles. I know I have read opinions

It's not the secondary fermentor that's what's important here, rather, a second, large food-grade container for priming.

I suggest you get the carboy (give up the deposit from the bottled water company and keep the carboy) and use the plastic bucket you got with the kit for mixing-in the priming sugar.

In any event, be very careful to not scratch the plastic bucket -- scratches harbor bacteria.

>regarding this here before, but forget what the concensus was. Should I  
>take the slightly more complicated route and procure a carboy first, or  
>is simplicity worth the cost in flavor for the first batch?

It's not the flavor -- you may get inconsistent carbonation and you should boil your priming sugar to kill any nasties.

Wolfgang Puck said it took him \$1 million to get Eureka off the ground. He hadn't realized it would be so much more expensive to do a brewery vs. a regular restaurant. The guys at New Haven Brewing Co. spent \$100,000 just on legal fees to get the Connecticut laws changed, and they are spending a great deal of money on licenses, permits, etc. The equipment alone must be terrifically expensive. As I understand it, it's all made by this place in Oregon. There is also a magazine/trade paper for micros you could subscribe to. Call micros and ask them what it cost them, running costs, etc. Also you have to factor in the physical plant. Height is important.

Subject: re: Fermenters, bottling from kegs

>From: Tom Bower <bower@hprnlme1.rose.hp.com>

So, what's the best way to bottle some when you're also kegging?

I simply bleed off the pressure and fill bottles from my tap. My beers are in a refer @48f + I freeze the bottles before filling. They seem to keep their carbonation just fine. Before I had a refer for my beer, I would drop the kegs into my chest freezer for a couple of hours.

>From: "John Cotterill" <johnc@hprpcd.rose.hp.com>

Does anyone know where I can obtain a stainless steel fermenter with a conical bottom on it (just like the pros!) that holds about 6 gallons??

I had a similar "great idea", but quickly dropped it when the fabrication costs started running \$500 or more! New kegs run about \$90 and they are mass produced. I might be willing to part with \$200 to get an equivalent conical fermenter for 6-7 gallons that has the same form factor as a keg. Then I can get a fermenter + several kegs into my refer. As it is now I can only stuff one carboy + 3 kegs into it. To ferment/lager/store more beer would require a second fridge + a remodel of the house. Hence my willingness to blow money on a fermenter. I doubt even the massive homebrew market wouldn't allow the kind of efficiencies needed to get down to \$200. :=(

> of the berry harvest should I use for a 5 gallon batch? Do they go into the  
> boil? Or is it better to "dry hop" the berries? Should they be crushed  
> first? Would Juniper go better with a "lawnmower" beer or with something  
> heavier?

I have no experiences either, but I am going through the same questions as Kevin. My wife bought some "freezed dried" juniper berries for cooking. They smell wonderful - just like good gin. I recall reading that the Belgians used juniper berries in beer before the world discovered hops. Michael Jackson says that one or two Belgian breweries STILL make juniper beer. Some info must be available! Any Belgianophiles out there?

I was planning on making a strong spiced beer (Belgian triple strength = 1.080) I plan on using coriander and orange peel at the end of the boil, hoping for a Hoegarden Gran Cru-type beer. As an experiment, I'll add some crushed juniper berries to the secondary fermenter (split batch). I'll go pretty light on the berries as each berry has tremendous flavor and aroma. 1 tablespoon of the crushed berries will be my starting point. My limited experience tells me that spices should not be boiled for long periods of time. I'm brewing this weekend, and I'll let everyone know how it turns out! I hope it works, because I just "discovered" a big juniper tree in my yard!

From: kevin vang <MN033302@VM1.NoDak.EDU>  
Subject: 2 questions

1. I made a batch a few weeks ago using yeast cultured from a Chimay bottle. This weekend I dumped it out into the flower bed. It had an extremely sour taste; not a pleasant, fruity or lambic-like sourness, but a nasty, somebody-puked-in-the-primary sourness. It smelled great, strangely enough. I assume this is the work of some sort of bacterial infection, right? Anybody had any thing like this happen? I've been brewing for 8 yrs now (my, how time flies..) and I've had some batches go bad, but this is the first that was so bad that I couldn't stand to have even a drop in my mouth for one second...

2. Having sterilized my equipment extra thoroughly, I was making a new batch Sunday. Just before the wort came to a boil, a thick layer of ugly scum floated to the surface, as usual. I was about to skim it off like I usually do, when I asked myself, "Are these the degraded protein molecules so necessary for body and head retention? Is this the reason I've always had problems with head retention?" So, in the name of science, I stirred the scum back into the wort. I'll report on the results later on if anybody's interested. Anybody know for sure (or have a blowhard opinion) if the scum should be removed or left in?

Subject: Re: Bottling from kegged beer?

Tom Bower asks about bottling and kegging from the same batch:  
> 2.) Bottle some of the already-carbonated beer straight out of the  
> keg.  
> Are there any tricks/gotchas with this? Does naturally-carbonated  
> work as well as CO2-tank-carbonated for bottling?

I haven't tried bottling already-kegged beer, but I can confidently say that bottling carbonated beer (or any carbonated liquid for that matter) requires a counter-pressure filler. The way this works is that, first, you equalize the pressures in the bottle and the keg and then, transfer the beer into the bottle. If you don't equalize the pressures, a lot of the CO2 you have in the beer will come out of solution and you'll get less-carbonated beer out of the bottles. Foxx Equipment Co., KC, MO, 1-800-821-2254, makes an apparatus, which I have not yet bought, but I have had excellent service from Foxx. Ask for the "Homebrew Expert" when you call -- the other salespeople may not be familiar with the homebrew equipment.

Subject: Re: Kegging Question

Warren Kiefer asks:

> I now have obtained a root beer keg from the local pepsi distributor,  
> what I'm wondering is what I'll have to do to get this baby in action ?  
?

You will need to replace all the rubber gaskets/seals on the tank if you don't want your beer to taste like root beer. New seals are also a good idea to minimize leaks. No, your hardware store will probably not have the connectors you need -- I suggest Foxx Equipment Co. (see above). I also suggest metal connectors (they are significantly sturdier than the plastic ones). If you get the "Homebrew Kegging Kit" you will, by default, get plastic connectors. If you can, substitute metal ones -- you'll pay an extra buck or two, but you won't regret it. The only in-line faucet (one that does not mount onto anything -- just sits on the end of a hose) they used to have at Foxx was plastic. Unless they've gotten something new, you won't be able to trade up to metal at this point in the setup, however, I have not had any problems with any of the faucets I got from them. I also recommend a two-gauge regulator (one tells you the pressure going into the keg, the other, the pressure in the tank). With a two-gauge, you will have less chance of running out of CO2 unexpectedly. Finally, (I'm sure that the person at Foxx will ask you, but just in case) what you've got is a "pin-lock" keg (as opposed to "ball-lock").

Full-Name: "John Cotterill"

> Tom Bower asks how to fill bottles from kegs...  
<<I tried to E-mail this to you Tom but it got bounced back>>

Tom,

I know just what you need! Its called a counter pressure bottle filler. It allows you to fill the bottle with carbonated beer straight from the keg. Basically, you hook the unit up to the keg, connect your CO2 up to both the keg and the filler. The beer line from the keg also connects to the filler. You put the filler into your bottle which forms a tight seal on the bottle. Then, flip a valve on the filler, and pressurize the bottle to the same pressure as the keg. Close the valve and open the beer valve from the keg. Guess what? Nothing happens! Remember, the keg and bottle are at the same pressure. Now, bleed off some of the pressure from the bottle, using another valve. The beer slowly flows from the keg to the bottle at the keg pressure. No fuss, no muss. I got mine from DeFalco's in Houston (713-523-8154) for about \$50.00. The thing is entirely stainless steel, and is a good value. If you want to see mine, call me and I'll bring it in.

From: darryl@ism.isc.com (Darryl Richman)  
Subject: re: Brewpub/micro startup costs

On the far ends of the spectrum: I think the guys at Lakefront spent a few \$K putting theirs together. But they did all their own work. On the other hand, Los Angeles Brewing (Wolfgang Puck's operation) spent about \$4M building a brewery that has the potential to grow larger than Anchor. Frankly, I enjoy Lakefront's product quite a bit more; I got to taste it again at the Oregon Brewer's Festival. It's too bad that Puck apparently has no taste for beer (I'll not comment on the food he creates ;-). Although LA Brewing makes a high quality beer, it is only one notch up from Michelob in interest level. If you're in the LA area and want a good microbrewed lager, drink Alpine Village instead (I think their micro was about \$500K).

Subject: Startup Costs

From: R\_GELINAS@UNHH.UNH.EDU (Russ Gelinias)

> Still no response on my question of how much it costs to start up a  
brewpub  
>or microbrewery. Anybody know?

OK, here's one data point.....

A friend has a brewery in the SF Bay Area. It's a microbrewery and not a  
brewpub. His mash tun & brewkettle are designed for 14 barrel batches.  
He told me that he spent about \$220K getting started. I believe that he  
is leasing the building (not sure about that).

And here's some fuzzier data.....

After a recent competition, I was having lunch with a couple of brewers.  
One of them claimed that his backers had lots of \$\$ & spent \$180K on  
the brewery alone, not counting the cost of the kitchen, property, pub  
etc., etc. The other brewer pointed out that things could be done much  
cheaper, and that his brewery was built for a mere \$85K (again, not  
including kitchen, etc.).

The Sudwerks brewery in Davis, CA is a very big, beautiful and lavish  
brewpub. I've heard various people state that it cost anywhere from  
\$2M - \$5M to build. The figure quoted seems to be proportional to the  
number of beers that the person doing the quoting has had!!!

Real estate costs are a big consideration. Obviously it will cost alot  
more to build a brewpub in Manhattan than in Coeur D'Alene. The costs  
will also vary alot depending on the equipment. Brand new stainless  
(not aluminum!) tanks from a turn-key supplier like JV Northwest or  
Western Brewing Systems run into five figures each. On the other hand,  
the Indianapolis Brewing Company purchased used 64 barrel stainless  
dairy tanks for only \$3500 each. Your mileage will vary.

So Russ, should we keep our eyes open for the Gelinias Brewing Company???

BTW, could someone mail me a copy of HBD #685, it seems to have gone  
the way of #646 and I'd hate to miss a single blow in the exciting  
Al vs SS debate.

Thanks,  
CR

Subject: Keg/Kettle Lids

Subject: Keg/Kettle Lids Time:2:13 PMDate:7/24/91  
Find a restaurant supply place and they should be able to provide 11" or so aluminum lids for about \$10 a piece. These will work fine if you cut a hole in the top of the keg and retain the handles. If you cut the whole top of the keg off you'll need about a 16" lid. Buy a lid prior to cutting the keg to be sure you cut the right size hole. Rapids' prices for the aluminum lids are as good as any I have found locally.

Subject: All grain mistakes

Howdy,

I have a couple procedural questions about all-grain brewing as my first all grain beer was a partial failure. I followed all the instructions in Miller except that I didn't do any pH testing, and had difficulty removing all the bicarbonate from my water. The yield from the mash was supposed to be around 40-45, but it ended up at only 25. (I added dry malt extract to raise the OG sufficiently and the beer turned out) So without going into all the details of my mash and sparge, can anyone answer these questions:

- 1: Does pH make all that big of a difference as Miller seems to think? Would pH have enough of an effect that it could reduce my yield to 50% of what it should be?.
- 2: How would one eliminate 500-700 ppm of bicarbonate in my brew water? (Yep, believe it or not, that's how much I've got!) I used a fair amount of gypsum in combination with a 15 minute boil, but I was uncertain of the amount of gypsum necessary to remove the bicarbonate., and was concerned about other affects. Is there a simple formula or something?
- 3: What is the best way to manipulate pH, assuming it does make a difference?
- 4: If pH is important, but I can't adjust it, can one compensate for an improper pH by increasing the rest times?

Thanks in advance for any advice on my problem. My next beer will hopefully be a true all-grain effort. Adios.

Subject: Re: Bottling from kegged beer?

In HBD #686, Tom Bower <bower@hprnlmel.rose.hp.com> asked:  
> So, what's the best way to bottle some when you're also kegging?

It is possible to bottle beer from a keg without any special equipment, and with excellent results. I didn't invent this method, but I'm happy to pass along the following tips:

1. Go ahead and carbonate the beer in the keg, using whatever technique you choose.
2. The kegged beer must be in the refrigerator and cold. It must have been stable at around 15 PSI for an extended period of time (weeks, ideally). In other words, the beer should be well-conditioned and not still absorbing CO2.
3. This works best if the bottles are also cold.
4. Lay out a towel on the floor, because you are going to spill a little bit of beer.
5. Use a sanitized length of siphon hose an inch or two longer than the height of the bottles as the filling hose. Standard siphon hose (3/8") will fit snugly over the spigot of a Cobra tap.
6. Crank your CO2 pressure regulator all the way down to 0 PSI. Use the pressure relief valve on the keg to vent out all of the pressure. Now slowly increase the setting of your regulator until you get a pressure of about 2-3 PSI. This should be just enough pressure to move the beer gently out of the keg when you open the tap.
7. Stick the length of siphon hose (attached to the Cobra tap) into the bottle all the way to the bottom. Open the tap all the way. The bottle will fill with beer. There will be some foaming, but surprisingly little.
8. Keep the tap all the way open until the bottle is completely full. Even let it overflow just a little. Don't try starting and stopping the flow or regulating it by partially closing the tap. That will only cause foaming to occur. If the flow is too fast, try reducing the CO2 pressure. If foaming occurs \*inside\* the filling hose, your flow rate is too slow; increase the CO2 pressure slightly.
9. After the bottle has filled to overflowing, close the tap and gently pull the hose out of the bottle. Hold the hose at an angle so it will drain into the bottle. This will end up leaving just the right amount of head space in the bottle.
10. Set a cap loosely on the mouth of the bottle, set the bottle to one side, and fill the remaining bottles. The agitation from bottling the beer will cause some CO2 to be released, forcing much of the air out of the head space.
11. When you are done filling, crimp the caps with your capper.
12. Crank the keg pressure back up to your desired level.

Subject: brewpub/micro startup costs

> Still no response on my question of how much it costs to start up a  
> brewpub or microbrewery. Anybody know?

William Mares' MAKING BEER has a whole chapter ("A Savage Commitment") on this. Estimates ranged from \$100,000 (if you're willing to do a \*lot\* of work building your equipment from scrap or from scratch) to \$200,000-\$250,000. Michael Lewis, who teaches fermentation science at UC-Davis, said, "You can't plan to work sixty hours a week and take Sunday off." (You have to work harder than that.) There weren't any figures on brewpubs; the brewing end should be cheaper than for a microbrewery, but you've still got to build the kitchen, and the restaurant, and the clientel.

The most common de-mystifying points were that you have to run a business that just happens to sell beer instead of laundry detergent, and that getting beer into bottles (or even kegs) is only half the battle if you want your product distributed and sold. You'll spend a lot more time balancing books and marketing your beer than you will sparging and siphoning.

William Newman (who started the first Ringwood "brewery kit"-based brewery in the U.S.) has taught a two day course on this. I have no idea where or when it's offered, if he still teaches it.

Subject: Re: Homebrew Digest #687 (July 25, 1991)

we have a question concerning racking after having dry hopped. when we rack to the bottling bucket, the hops plug the syphon and it takes about three times of restarting the syphon to get all the beer out, and we end up with stirring up more sediment than we like. we have tried tying screen over the syphon but the hops just end up clogging the screen. the problem is compounded by the secondary being one of those glass carboys that has a fairly narrow neck, so the solution to our problem has to be under an inch in diameter... any ideas?

From: James Myles <myles@biostat.washington.edu>  
Subject: Juniper Porter

There have been a couple of request for information on beer brewed with Juniper berries. My partner and I have twice brewed Papazian's everything-but-the-kitchen-sink porter (a.k.a. Goat Scrotum Ale) using 1/4 cup juniper berries harvested clandestinely from the neighbor's bush. We crush the berries and include them in the boil. Otherwise we followed the recipe in the book exactly (including the liberal admonishments to relax etc).

This was our favourite brew until we discovered Wyeast and dry-hopping. It had a very pleasant hint of juniper, not overpowering at all. The flavor tended to decrease as the beer aged (> 5 weeks), so it provides a good excuse to drink it up quick.

I could mail the recipe, but it is in the partner's basement right now. Mail me if you want it and I'll try to get it into the system.

Just talking about it makes me want to try it again with the liquid yeast and some Cascade hops added to the secondary...

Speaking (well, typing, anyway) as a  
generally-satisfied Foxx customer and owner of one of their  
counter pressure fillers...

DON'T BUY ONE!

You could make one in your garage for less money that  
would probably work better. This product is junk, a pain in  
the butt to use. The valves take too many turns to open or  
close (which leads to foaming and painting your kitchen with  
homebrew) and the handles will cut your fingers to ribbons.  
Most of the parts are brass, except for the ones that rust  
solid the first time you use it.

However...

I am going to give these people a call. If it doesn't  
look good, I'll probably make my own, built into the mechanism  
of an old portable drill press I've got. Just pop the bottle  
in, pull the handle, and pass the jug to the capper.

Well, I'll probably intercept one or two...

I find bottling to be pretty boring, and am thinking of buying one of those Edme plastic dispensers. The way I understand it, you go through primary and secondary fermentation as usual, but prime in this dispenser.

What kind of experience have you folks had with this device? In particular, does it reliably maintain carbonation if you drink your beer over a fairly long (one or two months) period of time?

Thanks,

Stuart

From: keng@ic.MENTORG.COM (Ken Giles)  
Subject: Re: All grain mistakes

Howdy ez005142, whoever you are.

I find that measuring and adjusting the pH is easy, so I recommend doing it. Is it causing your low extract efficiency? Maybe, but I think it would have to be extremely out of line (and high) for a 50% reduction. Let me tell you about the evolution of my extract efficiency.

When I first started all-grain, I didn't have a mill, so I had the grains ground at the homebrew supply store. The lautering system I use is a picnic cooler with a false bottom constructed of 1/2 inch slotted copper tubing. In my first few batches I was getting maybe 70% of Miller's extraction rate. While searching for a way to increase it, I read that during the sparge, the sparge water can have a tendency to flow down the sides of the lauter tun, and that the problem can be avoided by making a shallow depression in the grain. This keeps the sparge water directed away from the sides. Doing this got me an extra 5%. I thought I was doing OK. Then, I got a grain mill as a gift (thanks Mom). When I ground my own grain, I got pretty close to 100% extraction on the first time. Granted, I'd learned a lot about all-grain brewing by then, but the finer grind made the biggest difference.

So what I'm saying is that you should experiment with the coarseness of the grind if you have the means. Next, make sure your sparging/lautering system is working for you. Is the grain bed deep enough? It needs to be at least 8 inches from what I've read. Is the sparge water really rinsing the grain and not running down the sides? And go ahead and at least check the pH with pH papers. You don't want to be above 6.0. Miller recommends 5.3.

As for adjusting pH, gypsum (calcium sulphate) will lower it, and calcium carbonate will raise it. I typically add these in 1 teaspoon increments for ten gallons, with each teaspoon bumping the pH by a few tenths. I think! I'm doing this from memory. Miller can help you with the amounts.

Sorry, I can't answer your bicarbonate question. You should be able to do some compensation for pH by adjusting rest times, assuming the pH is within reason. I can't give you any guidelines, though. The problem is that the

enzymes that break the starch down rely on a particular pH range in order to carry out their mechanics.

Hope this helps.

> Does pH make all that big of a difference as Miller seems to think?  
> Would pH have enough of an effect that it could reduce my yield to  
> 50% of what it should be?  
>  
> How would one eliminate 500-700 ppm of bicarbonate in my brew water?  
> (Yep, believe it or not, that's how much I've got!)

I would normally say that pH wouldn't likely have so strong an effect on your mash extract, but that is a tremendous amount of bicarbonate, which is a good alkaline buffer. The starch converting enzymes like an acid environment, but your mash will never overcome that buffer to get down to 5.5-5.0.

You can boil your water and let it cool over night, then ladle it off of the precipitate.

You can leave the carbonate in the water and force the pH down with lactic acid (some inorganic acids like hydrochloric or sulphuric have been used too, but I understand that they can be more noticable in the final flavor). However, carbonates can emphasize the harsh bitterness of hops.

Also, even though Miller advises against it, using iodine can give you a good idea about how your mash is proceeding. If the iodine never stops reacting (turning blue-black), you have a problem with conversion that will result in a low yield. Calibrate your thermometer in ice water and boiling water so that you know you're in the right temp. range.

Good luck,

Subject: GRG brews

Well thanks all, for the somewhat depressing dollar numbers concerning starting up a brewpub/microbrewery. I passed the info along to my brew-buddy, and he wasn't thrilled either, but he was still interested. He's a metal-bender, so we could save money by building our own stuff. There's also been some negotiating with local microbrewers to open a branch office, so to speak, in the unused space of his metal shop. So there's still some possibilities. And no, don't go looking for Gelinias Beer. It will be called GRG beer, for Gary Rice and Russ Gelinias, but actually it will stand for "Good, Real Good" beer. ]:-) Look for it at fine restaraunts and sleazy bars near you.....

I was gonna let it slide by, but since there's been all this Wolfie  
bashing, I guess I'll chime in with my reaction to Eureka.

My mother-in-law lives about two blocks from the place, making it a  
convenient crawl back to bed when we visit LA... I'd agree with Darryl's  
evaluation -- the beers just didn't have much character. I tried the  
lager,  
dark lager, and ale. None had significant malt character. The ale was  
best  
of the lot.

No fooling about the potential capacity of that brewery. They have three  
(I  
think 15 barrel) vessels in series, so they can mash, sparge, and boil in  
a  
continuous process. Fully geared up, they can probably produce 3 batches  
per day. The bartender said they were only using about 1/4 of their  
potential fermentation and lagering capacity right now.

One thing Darryl didn't mention is the noise level in the restaurant.  
It's  
at rock concert pitch. My ears were literally ringing when we left. Bar  
none, the noisiest place I've ever eaten. And that includes Dodger  
Stadium.

From: darryl@ism.isc.com (Darryl Richman)  
Subject: Review of the Oregon Brewers Festival

The Oregon Brewer's Festival

by Darryl Richman

Well, I've been to the Great American Beer Festival, I've been to the Munich Oktoberfest, and I've tried the regional specialties at the last three AHA Conferences--I guess it was just a matter of time before I went to the Oregon Brewer's Festival. But I should have done it sooner--and so should you!

First of all, Portland is a lovely town, with many beautiful attractions. There's the Oregon Museum of Science and Industry (OMSI) which rivals similar attractions in LA and SF for hands on fun. The Japanese Gardens, overlooking the city and the Willamette River are peaceful and meditative. Powell's Books, a whole city block of a bookstore, has whatever reading material you might be interested in. There's the Columbia Gorge for windsurfing, and the Saturday Market under the bridge for bazaar shopping.

Of course, Portland may be the gravitational center for West Coast brewing, what with the Yakima Valley and Seattle tugging northward and California pulling south. One could easily spend a week investigating all of the pubs, brewpubs, and breweries. Fortunately for those of us with limited vacation time, you can take in a lot of this while standing in the shade of a big tent watching the boats go by on the Willamette on the third weekend of July each year.

To assist you in keeping the 46 different breweries straight, "The Cascade Beer News" included a special supplement in their July/August issue with a glossary of terms, a list of the breweries and their selected beer (many of which were brewed especially for the festival), and a guide to beer styles. These were available at the entrance.

The OBF works on a pay-per-taste arrangement. You buy wooden nickels, which are redeemable for half a mug (6 oz.) at any booth. The beer is served by volunteers, and kept cold in refrigerated trailers. The brewers hang out and are happy to talk to you about their products. There are food booths at one end of the area, away from the main tent, and a bandstand with live music playing late in the afternoon and into the evening. Admission is free and the event is quite family oriented.

Those volunteers are recruited out of the local homebrew club, the Oregon Brew Crew. Not only did they organize all of the serving duties, but they had a booth and made homebrew all day long, including some all-grain beer. Other booths included hops (Hop Union and Freshops were there) and malt (Briess Malting and Great Western Malting). I met Jack Erickson, author of "Great Cooking With Beer" (an excellent book I use often) who was pitching his latest offering "Brewery Adventures in the Wild West." It worked, too--I bought a copy and a quick read indicates that it is up-to-date and full of information for the touring beer enthusiast.

So what was good? Well, I didn't have a bad beer. But some of the standouts were CooperSmith's (Fort Collins, CO) Green Chile Beer--crisp and clean and refreshing with a spicy nose, and then as I finished swallowing, a glowing warmth that made me want another sip. The Bombay Bomber IPA from the Steelhead in Eugene (there are two, unrelated,

brewpubs--the other is in Cave Junction, OR, and a third pub in California serving a steelhead beer) was big and incredibly hoppy. The Cave Junction Steelhead had a Kolsch that was quite true to style. Rogue Red (Newport, OR) was big and caramelly. Baderbrau (Pavechivich Brewing, Chicago) was a beautiful German Pils. Bridgeport, one of Portland's finest brewpubs, produced a special Pintail Pale Ale for the festival that was more rounded than their hoppy Blue Heron. Tiny Lakefront from Milwaukie had a doppelbock that was a Salvatore knockoff.

I never did get to try Wynkoop's Irish Cream Stout--it ran out early on both days, so I guess it must have been really good. I spoke with the brewmaster at Roslyn Brewing, a small resort town over the Cascades from Seattle. He was making "Just Beer" which turned out to be a very nice dark lager with a dry finish. We decided that it ought to be called Roslyner.

Outside of the festival, I only got to try out a few pubs. The Horse Brass Pub, in the south east suburbs, has a great English Public House atmosphere. Except that you don't have to breathe cigarette smoke, this really feels like it was plucked up from across the Atlantic.

Portland Brewing is a masterwork of space conservation, putting a brewery, pub, and live entertainment into a very small square-footage room. This started a trend I noticed in other Oregon pubs: they tend to be well lit and include warm finished woods in their decor, without the tendency to overdo brass and chrome.

Perhaps the ultimate was Teri Fahrendorf's new location (she was previously the brewmaster at Triple Rock in Berkeley)--one of the Steelheads--in Eugene, where the mahogany panelling and the tables with high backed wing chairs made one think of an English country manor's library. The brewhouse is just as pretty, behind a huge picture window and well lit.

I also paid a visit to the schizophrenic Bayfront Brewing/Rogue Brewery in Newport, OR, where homebrewer of the year (1988) John Maier is making more smoke. John has been perfecting smoke beers since he worked for Chinook (now Alaskan) Brewing and smoked grain in a fish smoker. The Rogue smoked ale has a delicate touch and beautiful color and balance. Watch out for his Old Crustacian barleywine if you're planning on attending the GABF this year!

From: rich@progress.COM (Rich Lenihan)  
Subject: Glassware answer and water questions

Hi,

When I was looking for Pub glasses (as seen at my favorite tavern), the only place I could find them was at a restaurant supply store. The advantage to using them is three-fold: 1) They've got a great selection. If they don't have it in stock they can order it. 2) The stuff they sell to restaurants and bars has to be high-quality (but not fancy) and durable. 3) The prices should be lower than department or specialty stores. Also, don't believe you have to buy in bulk. In these recessionary times, any sale should be appreciated. I picked up a dozen glasses (I could have bought less, but the price was right) for \$14 and change. Check your y\*ll\*w p\*g\*s for a supplier in your area.

Now my water questions: Like all good homebrewers, I called my municipal water dept. for a water analysis report. They very nicely mailed me a report detailing levels for about 20 different elements in the water supply. However, the water guy there told me that at the apartment complex where I live and brew the management adds a softener to the water to protect the pipes. So I called the apartment management and asked about what they were putting in my water. Once I told him why I wanted to know this, he was pretty helpful, too. They have some water treatment company come in once a month and check the water and treat it, if necessary. They do a chemical analysis as well, although not as thorough as the town. Anyway, the softener they add is called MP204. The apartment manager wasn't sure what it was (some calcium compound) but there's 3.0 mg/litre in my tap water. I'm told that adding softener to water supplies is fairly common (if the towns don't do it, many apartment complexes do). And \*now\* my questions:

1. What is MP204?
2. Both the town and apartment water analysis report substances in terms of milligrams per litre but all of the brewing guides I've read talk about ppm (parts per million). Is there any way to convert mg/l into ppm?

Thanks in advance. I've really learned a lot in the few months I've been reading the Digest and I'd like to thank all of you and especially Rob Gardner (and my mother and my wife and my eighth-grade science teacher) for all you've done.

From: Richard.Stueven@Corp.Sun.COM (Richard Stueven)  
Subject: "Dry Malting"?

Last winter, I discovered a beer that I think qualifies as my All Time Favorite. It's North Coast Brewing Company's 1990 Christmas Ale, from Fort Bragg CA. Like any good holiday beer, it's heavy and very malty, but what sets it apart is its exceptional malt flavor. It tastes \*exactly\* like raw crystal malt! You know that wonderful smell you get when you first open a bag of crystal...that's what this beer tastes like.

How did they do it? The only thing I can think of is something I've been calling "dry malting": putting raw malt in the fermenter along with the wort. (Like "dry hopping", get it?)

Is that possible? Is it feasible? I think I'll try it at home, unless someone can show me it's a Bad Idea...

have fun

AT the risk of boring some of the professionals on HBD, I thought the beginners might be interested in this article I posted on usenet.

Article 341 (19 more) in alt.beer:  
From: berkley@kuhub.cc.ukans.edu  
Subject: Stuff you always wanted to hear.

>On another note, what do you homebrewers like to store your stock in?  
(Yeah, bottles, but what kind? .

ARF says: (That's me, Schmidling)

Since reducing my consumption to one beer every other day and discovering a slick and cheap bottle filler, I have found 16 oz pop bottles convenient and easy on the arithmetic. I was unsplesantly surprised with the difficulty of finding empties these days.

I also admit there ain't much class in pouring a beloved home-brew from a bottle that says Coca Cola on it.

>. .or do some of you actually use kegs?)

ARF says:

When I was drinking it faster that I could brew it, I developed a system using "pony" kegs (1/4 barrel) and the old Falstaff 2 gal "Tapper".

Both systems require an external CO2 tank. The pony is the easiest because all the hardware for hook-up and tapping is readliy available from most liquor stores. The main problem is getting out the bung and replacing it with a removable stopper. I used a plexiglas plate and o-ring which screwed into holes that I drilled and tapped into the keg. I also mounted a pressure gage on the plate to monitor pressure during fermentation.

After primary fermentation, the whole batch is racked into the keg, sealed, up-ended and moved to a location where it can remain till consumed. Co2 must be hooked up when the pressure of fermentation falls below what is needed to push it through the tap. The system works very well and has the main advantage of only one container to clean up instead of dozens of bottles.

Its main disadvantage is the difficulty of putting it in a refrigerator,  
so  
it is at its best for winter brewing in the basement.

The "Tapper" provides a useful compromise. You either use two of them  
or one  
and bottle the rest. Furthermore it fits easily into the fridge.

However,  
hooking up CO2 in the fridge presents problems of its own. The original  
tapper has a cartridge built into it but is too complicated to deal with  
and

I have no idea where one would get the odd sized cartridge. The big  
problem  
is that they are as scarce as hen's teeth these days and some drilling  
and  
customizing must be done. I still have a few if anyone is interested.

I also found on my last visit to "Brewin-Beer", that there is an  
imported  
contraption that does about what my keg system does. However, it costs  
about  
\$80 and uses tiny soda syphon CO2 cartridges for pressure. My guess is  
that  
you would spend more on CO2 cartridges than on the raw materials for the  
beer.

Subject: Bicarbonate and pH

> 1: Does pH make all that big of a difference as Miller seems to think?  
> Would pH have enough of an effect that it could reduce my yield to  
> 50% of what it should be?.

I doubt it unless it's miles out (under 4 or over 6.5). Temperature is far more critical. pH should be between 5.0 and 5.6 (so the books say). Lower pH favours alpha-amylase so more dextrins at the expense of fermentable sugars which means a sweeter beer. Higher pH favours beta-amylase so a drier beer but not necessarily a stronger one. Frankly this is theory, I cannot honestly put variations in flavour of the beers I've produced down to pH rather than anything else, but I have had a better mash extract when I've taken care over the pH, though never more than 10% better.

>  
> 2: How would one eliminate 500-700 ppm of bicarbonate in my brew water?  
>(Yep, believe it or not, that's how much I've got!)

Boil it! This will precipitate bicarbonate as carbonate. Boil for 10-15 mins and then allow another 10-15mins for it to settle, then rack. Bicarbonate is a damn nuisance as it buffers malt acids and prevents you getting the pH down. I always boil mine and always get both chalky scum and sediment. The scum floats until you drain the water, when it gets drawn to the sides and sticks there. With care very little comes out. I have heard that sulphuric acid will get rid of the bicarbonate but have never tried it and am unsure why it should work. Perhaps someone who knows a bit more chemistry than I (not hard!) could explain.

>I used a fair amount of gypsum in combination with a 15 minute boil,  
>but I was uncertain of the amount of gypsum necessary to remove the  
>bicarbonate., and was concerned about other affects. Is there a  
>simple formula or something?

I don't think gypsum can remove bicarbonate can it? I thought it only offset the effects of keeping pH high.

>  
> 3: What is the best way to manipulate pH, assuming it does make a  
>difference?

more gypsum -> more acidic  
less gypsum -> less acidic  
If you can't raise the pH even with no gypsum, add precipitate of chalk (calcium carbonate) during the mash.

>  
> 4: If pH is important, but I can't adjust it, can one compensate for  
>an improper pH by increasing the rest times?

I don't know about this one. improper pH slows down one or more of the enzymes working to produce fermentable sugar, so maybe a longer rest will

give them more time to finish the job.

From: Mark Nickel <hplabs!kpc!uunet!canrem!mark.nickel>  
Subject: lager question

As a relatively new homebrewer(working on my sixth batch), I was hoping that the digest can give me some advice.

My latest effort has seen me attempt to make Papazian's honey lager. After making, cooling, and then shaking the hell out of my wort, I added a package of liquid lager yeast which I had started several days earlier. I then placed my wort in the fridge. It has been 32 hours and so far nothing. Should I have waited for active fermentation before placing the wort in the fridge? Any suggestion on how to remedy this situation would be appreciated.

Thanks in advance,

From: hplabs!bnr-vpa!bnr-rsc!crick (Bill Crick)  
Subject: fruit in beer

Regarding the request on berries (beeries;') in beer, or for than matter any fruits. I would think that somewhere between 5 - 10lbs. of fruit would be a good starting point, keeping in mind the strength of the fruit flavor, and the beer flavor.

For example, Cherries in the Snow, has 10lbs of sour cherries, but their flavor is not that strong.

I believe that boiling most fruits would be bad, because this would set the pectin in it, and cause haze problems (or jelly). At the end of the boil, turn off the heat, wait a few minutes, and add the crushed fruit, and steep for 15-30minutes, leave the fruit in the primary.

NOTE: I also believe most larger fruits ike peaches, plums should be peeled because the skins have some pretty bitter stuff in them. This is easily done if you scald them in boiling water for a few minutes.

What do I know? Bill Crick Brewius, Ergo StrawberryStout.

From: R\_GELINAS@UNHH.UNH.EDU (Russ Gelinass)  
Subject: \$\$ for micro/brewpub

Well, someone asked me to post the results of my survey of startup costs for a microbrewery/brewpub. So here they are: Costs range from "A few thousand" well into the millions. The general consensus was that it would take between \$200 to 300K. Big bucks. It seems that it is possible to save \$\$

by manufacturing your own equipment and/or buying it used. Renovating a building is a major cost. Making a super-yuppie fern bar with mahogany et al. is a major cost. Wanting to compete with the bigger micros. will cost you more in equipment. It is very easy to spend alot of money very quickly. It is not very easy to get people (ie. banks) to give you the money.

Brewpubs/micros are still often considered fads, and restaraunts and bars are not the most secure investment anyway. The most important piece of advice I received is to plan well, then plan well again, and always plan on

being a businessman first and a brewer second. That takes alot of the fun out of it, but that's the way it is. It's very similar to playing music for a living; it's supposed to be fun, but in fact you spend alot of effort

being a businessman, in support of the fun of actually playing. Keeping the business in line allows you the freedom to enjoy your art/science.

Hey Darryl, speaking of used equipment, what's the chance of me picking up some used oak casks from the Pilsner Urquell brewery?

Russ

Put the hops in a hop bag. They're pretty cheap, and you can get  
disposable  
cheesecloth-like ones, or reusable nylon ones.

I use the nylon ones for all my hopping and they keep things neat.

(You could always just use cheesecloth, or probably nylon)

>tried tying screen over the syphon but the hops just end up clogging the  
>screen.

Try tying a copper (or stainless) wound pot scrubber around the pick-up  
tube  
before tying the screen on. It will increase the surface area making it  
more  
difficult to clog.

>the problem is compounded by the secondary being one of those glass

>I find bottling to be pretty boring, and am thinking of buying one of  
>those Edme plastic dispensers. The way I understand it, you go  
>through primary and secondary fermentation as usual, but prime in  
>this dispenser.

>What kind of experience have you folks had with this device?

No personal experience but the consensus is thumbs down. Old soda  
kegs are the way to go. They cost more to begin with because you need  
a CO2 keg but in the end you will be much more pleased with them.

>In particular, does it reliably maintain carbonation if you drink your  
>beer over a fairly long (one or two months) period of time?

Holding and regulating the pressure are the most common complaints  
with these things. Moreover, they're plastic...

>From: eisen@kopf.HQ.Ileaf.COM (Carl West)

>OK, so how much yeast is too much yeast?

Greg Noonan recommends 1/4 c. slurry per 5 gallon batch.

>What are the flavor repercussions?

I'm not sure about this one but I think excessive esters will be  
produced in a too rapid fermentation.

>Are there any warning signs?

Yeah, beer foaming all over the place. Fermentation over in a couple of days.

>If I pitch a whole lot-o-yeast, should I not aerate so much?

You can't aerate too much unless you're shooting straight O2 into the cooled wort. The beautifully simple suggestion of drilling an 1/8" (or two?) hole towards the end of the siphon hose sounds like the way to go. It wouldn't hurt to slosh the beer around in the fermenter as well.

Do this to cool wort, though. As Martin Lodahl pointed out a couple of months ago, one should not try aerating warm or hot wort.

>Does overpitching cause `yeast bite'?

I don't know. I've never tasted anything like 'yeast bite'. My dog bites. Snakes bite. But frankly, my yeast don't bite!! Can't speak for anyone else's though. :-)

>If not, what does cause it?

Who knows. Methinks it's a myth.

>What does it taste like?

Don't know what it tastes like but it hurts like hell.

>Does it go away with age?

No. I think the scars are there for life.

Mal Card asks:

There is a 20 quart stainless steel pot (light guage) on sale at Lechmere's for \$27.00. Usually only \$35.00.

Would this this be an adequate size for an all-grain brew? Or is all-grain boiling as subject to boilovers as extract boiling?

20 quarts (5 gallons) just isn't big enough. You'll boil away a gallon of liquid and have a gallon of trub left in the bottom of the kettle when you make an all-grain beer. 7 gallons is a minimum as far as convenience goes. You can get away with 6 gallons by topping up at the end of the boil.

>From: Mark Nickel <hplabs!kpc!uunet!canrem!mark.nickel>

>My latest effort has seen me attempt to make Papazian's honey lager.

>earlier. I then placed my wort in the fridge. It has been 32 hours  
>and so far nothing. Should I have waited for active fermentation before  
>placing the wort in the fridge?

Much ink has been spilled and many terminal keys tapped on this one. Some say you should cool the wort down as far as you can to increase the cold break as much as possible and pitch. This will definitely increase the lag time, though, as you are finding out. IF you have been your usual scrupulously clean and sterile self, a long lag phase won't hurt the beer.

The other camp (and the one I subscribe to) is cool the wort to 70 degrees and pitch. Yeast propogates quite rapidly at 70 degrees and fermentation is likely to get off to a quick and rapid start. After pitching, wait a few hours, and put the fermenter in the fridge. By the time the wort cools to fermenting temperature, the yeast will be up and running.

And as for the continuing running commentary of late: Yes, I think Darryl Richman (Did someone say Darryl Richman again?) IS an alias -- for Poor Darryl Man. Poor fellow sure has been taking our abuse well. But, hey, in real life (if he has a real life) they (they prefer to remain anonymous) say he's a swell guy (yeah, sure!). I've even heard he's a closet Southerner living in California.

By Gawd, theah's hope fuh the boy yet!!

No clue, see if you can find the container it came in and check the ingredient list.

> 2. Both the town and apartment water analysis report substances in terms of milligrams per litre but all of the brewing guides I've read talk about ppm (parts per million). Is there any way to convert mg/l into ppm?

I think this is correct if I remember my chemistry correctly. I'll double check tonight just to make sure.

OK, for a solid dissolved in some liquid:

$$\text{ppm} = (10^6 * \text{wsolid} * \text{awliquid} * m) / (\text{awsolid} * \text{wliquid})$$

where

$10^6 = 1,000,000$

wsolid = weight of solid in grams

awliquid = atomic weight of the liquid. This is 18 for water if I remember correctly.

m = number of atoms or molecules of the thing you are interested in that a given solid

contributes to solution per molecule of the solid (this is important for salts, which is mainly what we are interested in in checking the chemistry of the brew water. For instance if you are adding CaCl<sub>2</sub> to water m would be 1 when calculating

ppm for Ca but would be 2 when calculating ppm for Cl. (This has an official term

but I can't remember it, molality maybe?)

awsolid = atomic weight of solid (your on your own with this one, get a periodic chart).

wliquid = weight of liquid in grams (1 cc of water weighs 1 gram at 4 degrees C).

If any of the above is incorrect, please let me know. If anyone wants the derivation of the above equation let me know, I'll send it to them.

> which allows you to refill and pressurize the balls. Has anyone used  
> this system?

Yes, I just started brewing this year, and since I am lazy I knew from the start that I wasn't willing to bottle. I borrowed a friend's copy of Zymurgy, and saw the advertisement for the beer sphere. Mark Fritz was the name of the company, in Potsdam, NY...although they answered the phone by a different name the last time I called. I called up and ordered the home draft system for \$180 because it sounded like a good price to me. That consisted of a batch latch (which mounts on the top of a party ball making it reusable), a 5.2gal ball, a 5lb CO2 tank (filled), regulator, plus all the necessary hoses, etc. Additional batch latches are overpriced at \$19.95 each, but I got one a few weeks later in order to have multiple batches going. You also need disposable seals for each batch of beer, at a cost of about \$1 each. These are punctured when you tap the ball. I bought a ball of Coors (yech, I gave the beer to a friend for his birthday) and the system works well that reclaimed ball.

I have no complaints about the system; it works well. However, I think now that for the same money I could have gotten more sturdy kegs than the party balls.

> How do the beer balls compare to soda kegs?

Since I haven't used soda kegs, I can't answer this, except to say that it seems to me that the soda kegs are a more convenient shape, plus they have the handles on top.

1) Use the shift key on your keyboard. Capitalized, mixed-case prose is easier to read. Capital letters act like fining agents - they attract the hops, allowing cleaner siphoning ;-)

2) Put your dry hops in a mesh bag. No hops will get into the siphon. The problem with this is that you might have problems removing the bag from the carboy. I solve this problem by doing my dry hopping in a Cornelluis keg.

Subject: various answers

Bill asks about pin- vs. ball-lock kegs:

>Is one somehow better than the other? Or is the ball-lock and pin-lock just  
>so Pepsi stuff won't work with Coke stuff?

As far as I know, neither is better than the other. The main reason to choose one over the other is availability of used kegs in your area (if you plan to buy used kegs). I bought all of mine new from Foxx, so availability was not an issue (not that I think it would have been here in the Chicago metro area).

tamar & steve ask about hops clogging up the racking tube:

>we have a question concerning racking after having dry hopped. when we rack  
>to the bottling bucket, the hops plug the syphon and it takes about three  
>times of restarting the syphon to get all the beer out, and we end up with  
>stirring up more sediment than we like.

Are you using hop pellets? Since I started dryhopping (last brewing season) I would never do without. My beers finally have the bouquet that a SNPA or Sam Adams have. I love it!!! Anyway, I have always used whole (leaf) hops instead of pellets for dryhopping and they simply float on top (even up to 6 weeks -- that's the longest I've dryhopped). I still use pellets for the boil -- they stay fresh longer. I use a hop bag in the boil and just throw the hop leaves into the fermentor after the krausen falls. I've yet to have a clog or to break the siphon since I've started to dryhop.

I agree 100% with Marty's assessment of the Foxx filler. I spent \$30 for ball valves and built a pop-off pressure regulator and now after overhauling my Foxx filler I get decent results without turning the air blue or needing any bandaids. But for the total investment I could have bought a different filler in the first place and missed out on all the fun.

> There is a 20 quart stainless steel pot (light guage) on

> Would this this be an adequate size for an all-grain brew?  
> Or is all-grain boiling as subject to boilovers as extract  
> boiling?

Sure, for a 3-3.5 gallon batch size. All-grain brewing is subject to initial boil volumes larger than the eventual batch size. For a 5 gallon batch size you will be happier with an 8 gallon pot.

korz@ihlp.att.com quoted an old message from me that had this:

>>  
>>I got nailed a couple times by #1028 (don't remember its "name"). I  
>>found it unreliable and in one case it was clearly defective.  
>>

This is now called "London Ale" yeast by Wyeast. The problems I referred to happened quite some time ago and Wyeast was honest about the situation and withdrew the strain for several months. It was reintroduced and in the 18 months or so since I made the comments quoted above I've used this strain a lot, from Wyeast packets, after plating it out on dishes and from slants. I've had no new problems and have found this yeast to make wonderful ales with complex flavor profiles.

BEER YEAST

Every book I have ever read and every person I have asked, says bread yeast makes yucky beer but I have never heard it from anyone who has ever actually tried it.

I would like to hear from someone who has made good beer with beer yeast that has tried bread yeast.

In light of the fact that all beer and ale yeast are the same species as bread yeast, I find it hard to believe that any residual taste could be significantly different.

I am even having a hard time believing there is a difference between top and bottom fermenting yeasts. They look and act pretty much the same, as far as I can tell.

Fed up with bottles? USE A KEG!!  
There has been a bit of chat about this already (apologies for lack of acknowledgments):

- -----  
> >I find bottling to be pretty boring, and am thinking of buying one of  
> >those Edme plastic dispensers. The way I understand it, ....  
- -----  
> Oh, one more silly thing...any opinions on those british-style plastic  
> mini-keg things? ...  
- -----  
> > I am interested in keggung my homebrew and am thinking about using a  
> > beer sphere (party ball)....

I have been keggung in those British-style plastic things for several years now and am most satisfied. They are far easier and quicker to clean. They impart no taste to the beer. They give the beer a finer, creamier head. The beer is smoother and less fizzy as less CO2 get forced in. (Tho' if you like gassy beer this is a big minus). The beer keeps for weeks; months if you keep the air space to a minimum. It's somehow more satisfying having beer on-tap than in bottles.

The only problem I had was with the CO2 injector. I was induced to buy a fancy constant-pressure regulator/injector (Brits only - from Boots). It gave me nothing but trouble. It leaked, lost pressure, cracked, ate CO2 cylinders. In the end I junked it and replaced it with a simple injector consisting of little more than a nut and bolt with a hole down the centre and a rubber non-return sleeve over the end. Since then nothing but simple pleasure.

The only other thing I'd add is that the tall drum-style kegs take longer to clear than the horizontal keg on legs (piggy). I like my pig best.

- -----  
On another matter entirely, I got the effect of pH on mash enzymes the wrong way round. It should be:  
higher pH favours alpha-amylase -> more dextrin, sweeter  
lower pH favours beta-amylase -> more maltose, dryer

I said I couldn't actually taste the difference, but after my last batch when I deliberately raised the pH I'm beginning to wonder...

This gives the implication the author dry hops with pellets...

> I still use pellets for the boil --

> I use a hop bag in the boil and just throw the hop leaves  
> into the fermentor after the krauesen falls.

Why use a hop bag with pellets? Anyway, here it's plainly stated that leaf hops are used for dry hopping. I can't rationalize that against the first statement. Do you use leaf hops or pellets for your dry hopping ?

From: Daniel S Robins <dsrobins@magnus.acs.ohio-state.edu>  
Subject: mg/L to ppm

As a chemist, I thought I could be of some assistance with your questions concerning conversion of mg/L to ppm. Parts per million/billion (depending on which you would like) are used to express concentrations of solutes (stuff of interest) that are quite dilute. Below is the conversion:

$\text{ppm} = (\text{weight of solute} / \text{weight of solution}) \times 10^6$

Some points to remember:

1. Doesn't matter what weigh unit you use as long as it is consistent. By that I mean, if your solute weight is expressed in mg then your solution weight must be in mg as well.
2. Since your solution I assume to be water, the simple conversion is 1L = 1000 mg.

If the explanation has been clouded, let me know. Hope I could be of some further assistance.

Subject: wet-hopping

This talk of dryhopping and clogged siphons got me thinking (don't worry I'll be careful). Why not heat up some hops, strain it, and put the "tea" into the fermenter, in effect, wet-hopping? I seem to remember a "Hop-head" beer at the AHA conference made by a Maine club that did just that, and it worked very well. You might even try adding some alcohol to the tea as you're heating it up; that might help with the oil extraction.

Aha, I knew it. Darryl Richman/Poorman is actually Steve Russell! That's why you never see them posting messages at the same time! Good one, Steve.

TO BOIL OR NOT TO BOIL

The following excerpt is from "BREW IT YOURSELF" by Leigh P Beadle. I would be interested in comments. His position is very clear and stimulates my conspiracy hot button.

On p.42 he is discussing the brewing process with canned extract.....

"You simply pour the malt extract into you container and dissolve them in water.

There is one very important point I should make concerning the mixing of the malt, which I will again emphasize in the section on porcedures. Do NOT bring the water to a boil. .... stuff on enzymes.... If you allow the water temperature to approach the boiling point, you will upset this sugar conversion and cause it to refix at a stage that will not allow the yeast to convert all the malt sugar to alcohol and carbon dioxide. The temperature of the mixing water must not exceed 153 degs F. Every other book on home-brewing has incorrectly given instructions to boil the malt in the water to dissolve it. This will only guarantee that some of the malt sugar will not be converted. This single bit of misinformation from those who should know better has caused many beginners to become unnecessarily discouraged in their attempts at brewing."

.....

Wow!

From: "Anton E. Skaugset" <skaugset@aries.scs.uiuc.edu>  
Subject: Boulder Stout

Greetings.

Has anyone out there tried Boulder Stout (Boulder Brewing Company, Boulder Colo.)?

I got a six-pack this last week, and notwithstanding M. Jackson's rating of three stars, I think it's almost undrinkable.

It's got a very light stout flavor, and it's quite sweet, but what really turns me off is an overwhelming flavor of chicory. The label says they only use water, malted barley, hops, and yeast. But the flavor of chicory is very intense. It's like drinking iced coffee.

Do they actually use chicory in their beer? If not, does anyone know what kind of malt gives this flavor? And what are other beer-drinkers' opinions of the beer?

Thanks.

Subject: A yeast cluturing experiment.

I sure hope the experiment goes better than the spelling on the "subject" line.

It seems to me that slants are nice, but more trouble than necessary for saving yeast to reuse. I'm going to try this little, semi-scientific experiment.

1. Make a regular batch of beer.
2. Save several ounces of the yeast slurry.
3. Divide the slurry among two dozen sterile culture tubes.
4. Top off each tube with the beer just made.
5. Cap and store in refrigerator.
6. Each month for two years, make a starter from a tube.

If the yeast is viable, I should have an active starter within a day or so.

I have been told that yeast stored under beer will remain viable for over a year. I'll let y'all know as the experiment progresses.

If this works, it will sure make storing a large variety of yeast an easy task.

From: strasser@raj2.tn.cornell.edu (Tom Strasser)  
Subject: ppm vs. mg/L

With the conflicting information yesterday I thought I would add my two cents worth on the conversion issue. ppm are NOT equal to mg/L unless the atomic species being measured has the same atomic weight as that of the liquid (e.g. water, e.g. 18 g/mol). Two cheers for Rich who realized this in his entry. To be a little more specific, as Rich didn't deal with units, the equation to convert mg/L of atom x to ppm is:

$$\text{ppm} = [\text{mg/L}] * m * (\text{Aw}/\text{Ax})$$

Where: Aw=atomic weight of water, 18 g/mol  
Ax=atomic weight of x, the mg/L species reported initially  
m=the same m as listed in Rich's formula, a factor to correct the concentration of species x if more than one atom of interest is present in the molecule report in [mg/L] (e.g if mg/L of CaCl<sub>2</sub> is reported, then Ax=40+2\*35.5=111, and m=1 if you calculate Ca ppm, while m=2 if you calculate Cl ppm).

For those of you who doubt this, a simple way to think of it is ppm measures the number of atoms in the water, while mg/L measures the weight of the atoms in the water. The number relating the weight to the number of atoms is the atomic weight of the species involved, and this is why the atomic weight must be a part of formula relating these two measures.

I'd be happy to give a more thorough analysis to people interested, but I doubt this would be of interest to the digest subscribers in general.

Tom Strasser.....strasser@raj5.tn.cornell.edu.....Long live the IBU's!

P.S.- Does this sound right to you Darryl??? or should I say Steve???

Subject: Malt Aromatics

In HBD 660 srussell@snoopy (Darryl?) asks of ways to impart malt aroma to a beer. I have watched with interest, as no replys were forthcoming. I have done an informal poll among Ithaca brewers who I know have more malt aroma in their beer, and it seems they may cover during the boil (many because they have to).

I was wondering if those of you in digest land think, as I do, that this is a plausible way to increase malt aroma in beer. We all know that during the boil there are a tremendous amount of volatiles driven off which we can smell anywhere near the boiler. If this is the case, then perhaps if you cover during the boil you will prevent the malt volatiles from being driven off, leaving them to be enjoyed by the drinkers of our homebrew. So what do you think???

Tom Strasser.....strasser@raj5.tn.cornell.edu

P.S.- Did anyone see Steve Russell and Darryl Richman at the convention at the same time???

From: srussell@snoopy.msc.cornell.edu (Stephen Russell)  
Subject: Brewery Tour wrap-up, future Mid-Atlantic conference

Summer is here and the time is right for drinking beers in New Jersey, of all places. Some sixty homebrewers and friends converged upon the Clement Brewing Company in Vernon Valley this past weekend. The brewery, with its open, wooden cask fermenters, and wooden cask lagering tanks was a bit of an ana-chronism, but great to see nonetheless. Clement Pilsener and Blonde Double Bock flowed freely, as did homebrew from 10 clubs in 4 states (NY, NJ, PA, CT). Hopefully, we will be able to go again next year, drink more beer, dance more polkas, drink more beer, eat more ham hocks and honey chicken, and drink more beer. Thanks to all who came and made it such a worthwhile time.

It is hoped by many of us that at some point in the not-too-distant future (maybe by 1993?) we can set up a Mid-Atlantic Regional Homebrew Conference and Competition. The first stage is to get homebrewers from the area together just to get to know each other. I hope that others around our region that hold events will publicize them (and this goes for other regions as well) and encourage multi-club and independent participation. Hats off to those seven clubs in Southern California who put on their first regional this past spring; I would enjoy hearing how you all organized this and what went on. Perhaps one of those Maltose Falcons (maybe even Darryl himself, or should I just write myself? :-)) or Barley Bandits or someone else could e-mail info to me.

IBU ERGO SUM,

STEVE

ps Despite rumors circulating to the contrary, I am \*not\* Darryl Richman, but I do believe that a certain tall, lanky North Carolinian just might be.

From: srussell@snoopy.msc.cornell.edu (Stephen Russell)  
Subject: The Great, Unabashed, ppm vs. mg/L Debate

Ok, I couldn't resist.....

As for the ppm vs. mg/L debate (n.b. don't you all just LOVE how we can flame on about such stupid, nitpicky things like this for days on end.....), Tom (strasser@raj5.tn.cornell.edu) Strasser is \*NOT\*, generally speaking, correct that ppm measures the NUMBER of atoms of a given species dissolved in solution. Actually, ppm is most often the WEIGHT of these atoms, although from the sound of "parts", it seems like it SHOULD be by number. It's just a convenience thing...people have easier access to scales than they do to periodic tables and calculators, I suppose. My feeling is that ppm is anachronistic.

Let's suppose you add 5 grams (5000 mg) CaCO<sub>3</sub> into 1 liter of water. This gives 5000mg/L (obviously!). It also gives 5000 ppm. How? You have, by weight, 1,000,000 mg water in 1 liter, since the density of water is 1 g/cc.  $5000\text{mg}/1,000,000\text{mg} = 5000 \text{ ppm}$ . Of course, you have  $.4 \times 5000 = 2000 \text{ ppm Ca}$  and  $.6 \times 5000 = 3000 \text{ ppm CO}_3$ . This is just illustrative: I wouldn't add these concentrations for brewing unless I was after a \*real\* chalky product (wouldn't dissolve under normal conditions, anyway, I'd bet).

But, hey, let's let Tom and John Polstra fight it out, and since the whole thing is contingent on whether or not one defines a priori whether you have ppm by weight or by number, both are right and both are wrong.

And now, back to your regularly scheduled program...

IBU ERGO SUM,

STEVE

Hmmmmmm....will the REAL Darryl Richman PLEASE stand up?!?

> c. from a and b we have - 1 litre = 1,000,000 mg  
> d. from c - mg/L and ppm are the same

>  
> Please correct me if this is wrong. If everything about making

It's wrong. 1 liter does indeed equal 1000 grams -- of pure water at 4  
Centigrade. You wouldn't expect a liter of Mercury to weigh the same as  
a liter of alcohol, would you? Since you're trying to discover the amount  
of stuff in your water that isn't water, it seems reasonable to assume  
that

it will not have a density of 1.0, right? So, I'm afraid you're going to  
have to go back to the calculating board and figger it out.

Now if I was really smart, I'd tell you how, but I missed that day in  
Chem.

Steve

Date: Mon, 29 Jul 91 15:07:51 CDT  
From: Mark Sandrock <sandrock@aries.scs.uiuc.edu>  
Subject: stuck (top) fermentation

Tried my first batch of homebrew in about 6 years Friday night, and seem to have a stuck fermentation on my hands. The details are: 3kg (6.6lb) light malt extract, plus 1lb crystal and 0.5lb toasted pale ale malt, boiled for 1 hour with 2oz Bullion and Cascade hops, and a starter made from Edme dry Ale Yeast. Cooled wort in sink and added to cooled preboiled water in 5 gal glass carboy to make 4 gals of wort. Initial SG and temp not measured, but temp estimated to be about 70F (based upon room temp). Used blow-by method with 1"ID tubing leading to bucket of (strong) bleach solution.

Fermentation was strong through first 16 hours or so, but then slackened until finally ceasing by 24 hour after pitching. Repitching additional (M&F) Ale Yeast and placing carboy in 90-100F bathwater produced steady bubbling, which ceased again overnight as water cooled to room temp (70F)

Haven't taken SG yet, but surely a high gravity ale like this (Palilia recipe from p.155 in Papazian's book) has a long way to go still. In trying to figure out what might have gone wrong, I come up with 2 possibilities:

(1) wort not adequately aerated. After pouring the 2.5 gals preboiled water into the carboy, I swirled it around a bit hoping this would help. Wort was both poured and siphoned (filter kept clogging), but I have no idea if this constitutes adequate aeration. It's pretty hard to stir wort in a carboy and not easy to shake it up either, considering the weight. Any hints about this?

(2) It turned out that I had misread the instructions in Papaizan for making a sterilizing solution. Instead of the one teaspoon or so he recommends for this purpose, I was using the 2oz (per 5 gals) he recommends for a "cleaning" solution. On top of that, I always rinsed using \*cold\* tap water, rather than the warm or hot tap water recommended by Papazian. Is it possible that some small amount of chlorine made it into the wort and caused the problem?

Any email responses will be summarized, or reply via the Digest.

Thank you.

Subject: A Judge's Lament

At a tasting last night, someone said something we all "know", and a little light went on: "Homebrew can't make you sick!"

\*BZZT!\* Wrong! True, an infected beer is not likely to pass its infection on to you. That would be like catching the Dutch Elm Disease. But the more acquainted I become with infected beer, the more I'm convinced it's not harmless.

For the last few days I've been judging the first round of the California State Fair's homebrew contest, and there have been a shocking number of infected beers, with unusually serious infections. Saturday, for example, we had two "self-emptiers" out of a flight of eight. That's a pretty scary percentage! Another beer caused all the judges in the panel to develop violent (though brief) headaches within seconds of tasting it. I've developed even less pleasant physical complications after my last two contests, and I'm beginning to suspect it isn't just a coincidence. Have other judges experienced anything like this? I've noticed that some with much more experience than I have simply refuse to taste anything that smells especially bad, and I think I'm beginning to see the wisdom in this.

The advantage to this attack of the Creeping Green Horribles is that it helps convince me that I'm not just another virtual homebrewer, dreamed up by Kinney Baughman and Darryl Richman (who?) ...

Subject: Water, Conical Fermentor, Brewpub Costs

First, hats off to Tom Bower for his pointer to Sears as a source for a reasonably-priced (like, free) water analysis, and hats off to Sears for offering it. The cost of buying a filter setup from them is less than the prices I'd been quoted for an analysis. I'll send my sample off right away ...

Was anyone else (other than Kinney Baughman) as surprised as I that no one mentioned the Brewcap in answer to John Cotterill's question concerning a conical fermentor? Functionally, I would think that would fill the bill nicely, but I haven't tried one yet.

And another word on the discussion of the cost of starting up a brewpub or microbrewery: if you're seriously considering such a move, I urge you to attend a session of Dr. Michael Lewis' course, "Brewpubs and Microbreweries: Brewing & Business", offered a couple of times a year through the U. C. Davis Extension at a cost of about \$275. Yeah, that seems like a lot, but it's cheap compared to the risk you'll be taking in starting such an enterprise. Dr. Lewis was deeply involved in the Back Alley Brewery debacle, as well as having served as a consultant to many successful micros & brewpubs, and offers unique insight into what you can expect to meet. You can get an advance taste of reality the next time your brother-in-law Harry says you should go pro, by asking how much he's willing to invest, without guarantee, in your brewpub ...

Subject: Re: YEAST

Jack Schmidling writes:

>Every book I have ever read and every person I have asked, says bread yeast makes yucky beer but I have never heard it from anyone who has ever actually tried it.

Someone on the digest (a long time ago - maybe digest #50 or #100) wrote of a comparison test that they did using a couple of dry beer yeasts and bread yeast and the beer from the bread yeast (to them) tasted the best. But that was a long, long time ago in a land far, far away and I've probably killed most of the brain cells that held that info.

>In light of the fact that all beer and ale yeast are the same species as bread yeast, I find it hard to believe that any residual taste could be significantly different.

Different strains of yeast produce beer with significantly different flavors.

I brewed two batches of beer, back-to-back using all the same ingredients and technique except for the yeast. One was made with Muntona dry yeast (from a Munton and Fison kit) and the other with Wyeast London Ale. Both tasted quite good, but the Muntona batch had quite a strong clove taste. The clove taste faded to where it was tolerable after about two months, but never quite went away.

>I am even having a hard time believing there is a difference between top and bottom fermenting yeasts. They look and act pretty much the same, as far as I can tell.

I have only brewed ales (because I LOVE ales and like lagers) but have read quite a bit on the subject. Besides *actually* flocculating to the top or bottom, the main difference (or at least the main difference that is important from a mechanical perspective) is that lager yeasts are tolerant of colder fermentation temperatures whereas ale yeasts either go dormant or die at colder temps. Just to make the picture complete, at colder fermentation temperatures, yeast produce less esters and other by-products, hence lagers don't have the fruity flavors that ales do.

From: David Taylor <DAVID@phillip.edu.au>  
Subject: Controlling fermenter temperature

Gooday, I am brewing through winter here while most HBD readers are enjoying warm beer drinking weather! I am about to brew some batches with ale yeast and need to control the fermenter temperature. To date I've used a flat, flexible waterbed heater (300W) wrapped around a plastic fermenter with the sensor poked between the heater and fermenter. I'm not really sure what temperature the brew is sitting at, (the plastic is a poor conductor) and can't use the heater on a glass carboy.

I'm thinking of building a cabinet large enough for three fermenters, heating it with light bulbs, stirring the air with a computer cooling fan and controlling the temp. with the water bed thermostat.

Does anyone have any comments on using heated-air cabinets as opposed to water baths, or any other clever ideas?

Thanks all... David

Subject: For Sale: Yeast Bite Ointment

OK. There's nothing like talking about what you don't know what you're talking about to send you to the reference books.

Quoting from Malting and Brewing Science, page 539. (I hope you're ready for this. Parenthetical comments come directly from Webster's and are for the benefit of those who are as ignorant of biochemistry as I am. OK, Cornell. Quit laughing!!! Some of us went to a liberal arts college. So there!)

"Yeast cells in stationary phase of growth often contain a single large vacuole. Within this organelle there are usually several dense 'granules' (volutin granules) of polyphosphate. During exponential growth (this is primary fermentation, I assume) there may be one or several vacuoles in the cell and they often lack granular inclusions (that's the polyphosphate stuff, I think), possibly indicating the mobilization of a phosphate reserve during active growth. Vacuoles are bounded by a single membrane and contain hydrolytic enzymes (these guys react with water producing a weak acid OR base) whose function is to recycle ('turn-over') the macromolecular components of the cell e.g. protein, nucleic acids. The vacuolar membrane isolates these lytic enzymes (that is, the hydroLYTIC enzymes whose action is destructive) from the cytoplasm. It is of interest that these enzymes have no substantial carbohydrate moiety (funny what those chemists find interesting, ain't it?), in contrast to extracellular enzymes of yeast. Disintegration of the membrane, which is encouraged by high temperature, alkaline pH, the absence of nutrients and certain organic solvents, results in the autolysis of the cell. Leaving yeast for long periods in contact with beer may also induce autolysis and the products released IMPART A BITTER TASTE (YEAST-BITE) TO THE BEVERAGE." (emphasis mine)

On page 637, during a discussion of how to make yeast concentrates: "The autolytic procedure involves the disintegration of the vacuole and the release of lytic enzymes."

And on page 819: "Yeast should not be allowed to autolyse in contact with beer as the fatty acids liberated will destroy the foam stability."

Now. Here's where I need help from you chemistry types. I read the above as saying: As a result of high temperature, alkaline pH, the absence of nutrients and certain organic solvents, or just plain old age, a yeast cell will autolyse. Autolysis is the distintegration of the vacuolar membrane within which we have these granules of polyphosphate (sounds bitter to me) and hydrolytic enzymes (I guess these could be bitter, too). Once the membrane distintegrates, these polyphosphates and lytic enzymes are released (along with some fatty acids) producing a bitter taste in the beer, commonly known as "yeast bite".

Whew!! That's the best I could come up with. No matter what the particulars are, it sounds like "yeast bite" is a product of autolysis.

I stand corrected.

Yeast does bite.

Ouch! Stop that!!

From: "Dr. John" <JELJ@CORNELLA.cit.cornell.edu>  
Subject: whatever

In today's (7-30) HBD Russ Gelinas suggests "wet-hopping" in lieu of "dry hopping. I think, and this is really only an opinion unsupported by hard scientific evidence, that any boiling of the hops will drive off some of the volatiles. And I think that the retention of these volatiles is a critical factor in dry hopping. However, Noonan, as I recall, does recommend using some sort of hop tea to increase the hop nose in a lager at bottling time (it's in his "Brewing Lager Beer" though I don't have the exact page number).

Jack Schmidling quotes Leigh P. Beadle to the effect that extract-based beers should never be boiled. I'm not convinced. How does Beadle propose that one extract the alpha acids from hops used in conjunction with an unhopped extract. It looks to me like Beadle is the one who should know better.

Boulder Stout (as I recall this is really a misnomer) is almost undrinkable according to Anton E. Skaugset. While I wouldn't go quite that far, I agree that this isn't one of the finest examples of the style. We (the infamous IBU) held a dark ale tasting back in February, and included in the tasting were two of Boulder's products (there is that nasty term again, but in this case it seems very appropriate). Neither the Boulder Stout nor the Boulder Porter were terribly impressive, both seemed rather thin, and borderline insipid; and neither was really very exemplary of the style one would expect when reading the labels. Perhaps they have changed the product specifications since Jackson rated them.

Water, water, everywhere. But the problem is what, or how much of it, is in it. I'm basking in the glow of this flame (too bad you can't can it or something David, it would solve your cold weather ale fermentation problems).

Now, if Darryl is really Steve, my question is "why aren't we getting some prize winning bock to drink at the IBU meetings?" IB ergo U?

And, lastly, a question. I've been wondering for a while, after reading it in Noonan's book and more recently in "The Practical Brewer" about the formula for calculating the pounds of extract in a barrel of wort of a particular density. The formulae, with minor transformations of the denominator, that

are given for this purpose in these two references add the degrees  
Balling  
to the weight of a barrel of water, then multiply this result by the  
degrees  
Balling. After the appropriate division, either by 100 or 3100, the  
result is  
presented as the pounds of extract, in either a barrel or a gallon. So,  
what  
gives here? Why is the density measure added to the weight and then also  
used  
to multiply the result? If my muddled description is inadequate I  
apologize.  
I'll consult the aforementioned references and give the full details of  
the  
formulae tomorrow.

From: ralph@ecn.purdue.edu (Ralph L McCallister)  
Subject: Hops, bags, yeast, & malt....

Dry Hopping:

There should not be any difference in the out come of your beer using pellets, leaf, or plug hops. I don't think that I would ever use pellets, but to each their own. I have always used plugs and just put them into the secondary and rack the beer right on top. I feel that one advantage is that leaf/plug hops float thus adding another barrier to infection. I also feel that leaf/plug hops impart a much better aroma and bitterness than pellets. Sure, it is a little harder when you go to bottle and yes you do leave a little more brew in the carboy but, it's the effect of dry hopping that I am looking for and not just the ease of the operation. It is well worth the effort and really only adds another 15 min. or so to the bottling procedure. As far as using hop bags in the boil and then reusing them for dry hop is like saving your boiling hops for your next batch. If you use fresh hops for bittering then I use fresh hop for dry hopping. Really, it does not cost that much more to use fresh hops, it makes a better homebrew.

Hop Bags:

I have tried hopping in hop bags and without and the brews without have had a better bitterness and aroma without. You all realize that this is purely subjective. After reading Dave Lines' 'The Big Book of Brewing' it seems to me that more flavor of the hops is released when they are allowed to bubble freely in your wort rather than just roll around in a bag. I always wondered how you get the hop flavor from those hops stuck in the middle of the bag? Any way, I strain off as much as I can when I transfer the wort to a siphon bucket I use with my wort chiller. Again, I use plug hops so I do not have the grit problem with pellets. What leaf/plug hops the strainer does not get stays in my siphon bucket. Just one more of the many different ways in the world of brewing a better beer.

Bread Yeast:

Yeuck!!!!!! I tried this in a pinch one time and will NEVER make that mistake again. A most terrible yeast after taste.

Malt Aroma:

This is a very interesting question and one that I thought would bring out all the master brews comments. Not being a master brewer, yet, and only just finished my fourth all grain batch, all grain is the way to go and it's more fun too, I will put my two dollars, inflation is such a bother, in on what little has been written for homebrewers. I seems that the German beers seem to impart that malt aroma and taste. There seems to be a correlation between this and the type of barley they use. I have a batch going now based on Papazians' Honey lager where I substituted 5 lbs. of Munich malt for the extract. I also toasted 2 of the 5 lbs. based on Papazian. I am hoping that this gives a more malt aroma and taste, alas I am still three weeks away from bottling. The only other solution is to experiment with all grain batches. I cannot see how an extract brewer could get more malt into their brew without using grain that made up more than 50% of the O.S.G. Just a thought. Has anyone asked Papazian or Miller or Burch?

Last A Question:

Please define what constitutes a CREAM ALE. Another mystery of brewing.

...Ralph... ("What's going to happen.....Something wonderful!!!")

Since the wood stove causes large temperature variations upstairs in the (New England) winter, I started fermenting in the basement. This worked fine until the basement temp dropped to around 50 (too cold for ales, not cold enough for lagers). So I built a carboy sized cabinet out of 3/4" plywood. It has a false bottom (with holes drilled through it) into which I placed a doorless toaster oven. The oven is controlled by a regular room thermostat (through a relay) placed in the upper part near the carboy. The oven control is turned way down (about 100 degrees) so the whole thing doesn't over-heat. It works great, keeping the carboy at a constant 65 degrees (or whatever the thermostat is set to).

From: dyer@marble.rtsg.mot.com (Bill Dyer)  
Subject: ppm -> mg/l

OK one last word and I'll shut up about this thing. As far as all the brewing books I've read, ppm is indeed equal to mg/l, no matter what I said the first time. However, as was mentioned, ppm is not a very useful measurement if you are concerned about the actual ionic concentration of a solution (number of ions in solution). For instance 1 ppm of Ca does NOT have the same ionic concentration as 1 ppm of Na. Also, strictly speaking, 1 ppm = 1 mg/l only at 4 degrees C where 1 cc of water weighs (has a mass of, actually) 1 gram. If you are interested in the actual number of ions in solution, you will have to use the formula I posted a couple days ago (similar to the one Tom Strasser posted). As far as I am concerned, the total ions in solution should be more important than their weight in solution (chemically speaking), but as was stated, it is much more convenient to state measurements in mass/volume since most people can handle this easier, even though there is a simple conversion from weight to number of molecules in a substance if you have a periodic chart handy. OH well, enough said, back to brewing!

-Bill Dyer

P.S. Someone stated that 1 liter of water = 1000 mg, it actually = 1000 grams = 1000000 mg.

Thats very interesting, because just yesterday I was trying to think what to brew for my next batch and while I was thinking "Oranges" came to me in a fit of insanity. OK everybody, will throwing some oranges in the brew make good beer or will it just screw everything up. I have heard of lemon beer and people put lemons and limes in their beer all the time at imbibing time, but I've never heard of oranges until just now. What do you think, should I go for it? What other fruits have people put in beer besides the standard berry and cherry kind of things?

So, is more than this too much?

>>What are the flavor repercussions?  
>I'm not sure about this one but I think excessive esters will be  
>produced in a too rapid fermentation.

Yes, but the question of initial yeast population is a different one (IMHO) than speed of fermentation. The "lag time" is the amount of time it takes for the yeast to reproduce and build up a sufficient population to start the fermentation. More initial yeast, less "lag time". Too much initial yeast? I don't know.

>>Are there any warning signs?  
>Yeah, beer foaming all over the place. Fermentation over in a  
>couple of days.

I don't know as I agree with that. My fermentations haven't seemed to \*end\* any faster, they just \*begin\* faster with more yeast.

>>If I pitch a whole lot-o-yeast, should I not aerate so much?  
>You can't aerate too much unless you're shooting straight O2

>drilling an 1/8" (or two?) hole towards the end of the siphon  
>hose sounds like the way to go. It wouldn't hurt to slosh the  
>beer around in the fermenter as well.

Again, I have the same question as the original questioner. My understanding is that you aerate the wort to allow the yeast to be fruitful (not fruity) and multiply. Yeast don't need any oxygen to \*ferment\*, just to reproduce. So, if you put in enough yeast, they won't need to reproduce (can start fermenting right away) and won't need any oxygen at all. (At least this is what logic tells me, but is it right?)

MALTING BARLEY

I am trying to malt my own barley and have come to recall why I gave up on the idea the first time I tried it about 15 years ago.

The germination rate is only about 30% which results in mashing about 70% rotten mush.

My first reaction is that it is just old barley but the 15 time interval (and new barley of course) with the same results makes me suspicious.

It now occurs to me that there may be a trick to breaking the dormancy of barley.

Does anyone have any advice?

Has anyone out there malted barley?  
.....

Am I correct to assume that when rice or other grains are use in beer that they are malted like barley?

From: ... the seasons change ... <strahs@murex.bioc.aecom.yu.edu>  
Subject: yet another stuck (top) fermentation; also, Vermont beers

My third batch of homebrew has been stuck now for about 3 weeks.

Started off with 1 can M+F light unhopped, boiled with 1 lb. crushed crystal malt, 1 lb. corn sugar, 2 oz. Cluster hops and 1 tsp. non-iodized table salt (I couldn't resist). Final volume was ~3.5 gal. I cooled the wort in about 40 minutes in the covered brew kettle in the sink, strained out the hops and spent grain while pouring into the primary fermenter and pitched Red Star Ale Yeast straight from the packets into the fermenter. The wort was brought up to five gallons by the addition of 1.5 gal. sterile (boiled) water.

The wort bubbled for a few hours the next day and stopped. I waited a week, siphoned off some of the wort, re-boiled, placed in a sterile beer bottle fitted with an airlock and added another packet of Red Star Ale Yeast to that. The next day that was going strongly, so I pitched it back into the primary. The primary fermented longer this time (about a day) before slacking and dying. The ferment has now been stationary for more than 2 weeks.

This ferment is nowhere near complete... Any ideas?

I thought the wort would be aerated enough by the straining. Even if it wasn't, I have picked up the primary and shaken it in an effort to aerate the beer.

All help greatly appreciated.

Dan Strahs  
strahs@murex.bioc.aecom.yu.edu

BTW: Was in Vermont 2 weeks ago... picked up several local brews from the Catamount and Long Trail breweries... The Long Trail brews are very hoppy, but the Catamount brews are very good... Highly recommended are the Catamount Gold and the Catamount Porter... The Catamount Amber was also good, but they added Galena hops which I felt really overwhelmed the malt.

Subject: Lager question

Hi

Here's a question for all the lager experts out there. I bottled a lager yesterday that had been fermenting for four weeks at 45-50F. The recipe used 4lb of a John Bull hopped lager extract and about 1-1/2 cups of crystal malt. When I prepared the wort I didn't realize that the extract was hopped, so I may have used too much hops. I used 1oz of Cluster pellets in the boil and 1-1/4 oz Hallataur pellets as a finishing hop. The yeast was Whitbread lager yeast. Here's what happened:

It appeared as if fermenting was done. I was noticing no signs of activity in the air lock. When I started bottling, I found the beer was very gassy. For example, when I siphoned from the fermenter to a carboy, the beer foamed up in the carboy, almost like a head. When I put the beer in bottles (160z Grolsch with good gaskets) I saw bubbles rising in the beer after I sealed the bottles.

Did I bottle too soon? Is this bubbling continued fermentation? It was very hot when I bottled, so the temperature change in the wort was great. Once I got the bottles back in the 'fridge at about 40F, the bubbles stopped rising.

Comments. Thanx in advance.

E-mail is OK too.

Dave Sylvester

In HBD #684, Art Medlar asks:

>Speaking of Chinatown, has anyone tried brewing with ginseng ?  
>A beer than not only cures its own hangover, but is an  
>aphrodisiac to boot.... Sounds too good to be legal.

Brown Street Brewery in Napa CA has both a light and a dark ginseng ale. The brewer claims that he "invented" the recipe a couple of years ago, but in any case, it's quite a tasty brew. He also does a GREAT chili beer (brewed with jalapenos), a very nice brown ale, and four other excellent brews. How he maintains eight fresh beers with only two tanks is beyond me...

Subject: Yeast Question

Hi there, this is my first posting to htis forum after lurking in the  
woodwork  
for several months. I really enjoy this forum!

I have a question about culturing yeast. So far I have poured agar  
slants and  
innoculated the slant with the yeast. My question is about how to store  
the  
slant after the yeast have grown on it. DO you store it in the  
refrigerator as  
- --you would for bacteria or in a dark cool place or else where? I am  
doing  
this on the fly without any kind of references. I am applying the  
microbiology  
techniques that i know for E. coli and am using materials that are our  
lab to  
grow the yeast. Thanks in advance for your help.

Subject: Hop teas vs dry hopping

From: R_GELINAS@UNHH.UNH.EDU (Russ Gelinias)

> This talk of dryhopping and clogged siphons got me thinking (don't
worry
>I'll be careful). Why not heat up some hops, strain it, and put the
"tea"
>into the fermenter, in effect, wet-hopping?

Well of course you could do this, but the effect would not be the same as
dry hopping. The reason we dry hop is that dry hopping imparts volatile
hop aromatics (things with funny names like geraniol) into the beer.

Because

they are volatile, they are driven off easily during the boil. By making
a
hop tea, you will drive off the aromatics just as you would during the
boil.

In short, hop teas are no substitute for dry hopping.

After careful research and experimentation, I have determined that :

ppm = 42;
mg/l = 6 X 8;

Further evidence suggests that these two quantities may in fact be equal,
but the program is still running.

Finally concluding :

>Whew!! That's the best I could come up with. No matter what the
>particulars are, it sounds like "yeast bite" is a product of
>autolysis.

Yeast autolysis can definitely wreck havoc upon your beer. Miller
suggests
leaving the dregs from your fermenter out in the open to give a sense for
unforgettable stench given off by autolysis. However, my understanding is
that yeast bite and autolysis are different phenomena. Yeast bite is
allegedly caused by pitching too much yeast, thereby largely
circumventing
the reactions that normally occur during the yeast's respiratory/growth
phase.

I read somewhere (maybe Noonan?) that yeast bite is more of a concern of
commercial breweries, and that homebrewers weren't likely to encounter it
unless they pitched the entire dregs from one batch into another.

In any case, it sounds like yeast bite is nothing to *worry* about.

From: RJS153%SYSU@ISS1.AF.MIL
Subject: Missing Fermentation?

I know the key is to relax and not worry, but I am concerned. Me and a buddy bottled last Fri night, and now 4 days later the bottles do not show any sign of activity. Should we be able to see something going on in there? There is some sediment that could be new yeast that's settled, but I don't see any bubbles from CO2. Is my concern warranted? If the yeast has croaked, should we open the bottles and pop some new yeast in each one? We did the original fermentation in a 5 gal carboy with a blow off tube and then later put on an airlock when things calmed down. The entire time in the carboy was 13 days.

Thanks,

- --Randy--

From: polstra!jdp@uunet.UU.NET (John Polstra)
Subject: Lies, Damn Lies, and PPM

Amidst all the rampant confusion and misinformation regarding PPM vs. mg/l,
srussell@snoopy.msc.cornell.edu (Stephen Russell) says in HBD #690:

> But, hey, let's let Tom [Strasser] and John Polstra fight it out ...

Fine, I'm game.

First, let's review the original question that was asked, in HBD #688,
by rich@progress.COM (Rich Lenihan):

> Both the town and apartment water analysis report substances in terms
> of milligrams per litre but all of the brewing guides I've read talk
> about ppm (parts per million). Is there any way to convert mg/l into
> ppm?

So that's the question: how do we convert from mg/l into ppm? My
response in HBD #689 was:

> ... for all practical purposes, the two units of measure are the same.

Let's take a look at the "Conversion Factors" table in the back of the
CRC Handbook of Chemistry and Physics. Lo and behold, we find the
following (this is a direct quote, and the footnote appears in the
original):

To convert from	to	multiply by
-----	--	-----
...
milligrams/liter	parts/million*	1
...

*Density of 1 gram per milliliter of solvent.

In homebrewing the solvent is water, and *for all practical purposes*
(that's what I wrote), the density of water is 1 gram per milliliter.
We'll come back to that in a moment.

In case further evidence is needed, I cite the following direct quote
from the Seattle Water Department's 1989 water analysis report:

Results given in Milligrams per liter, i.e., parts per million (ppm)

Now, also in HBD #689, dyer@marble.rtsg.mot.com (Bill Dyer) came up
with a complicated answer involving atomic weights:

> ppm = (10^6 * wsolid * awliquid * m)/(awsolid * wliquid)

which was hailed in HBD #690 by strasser@raj2.tn.cornell.edu (Tom
Strasser)

as the one true answer. While there probably exists a question to
which the above equation is the correct answer, that question is not
the one that was asked. Both Bill Dyer and Tom Strasser seem to think
that PPM means atoms per million atoms, but it simply does not mean
that. In water analysis, PPM is in terms of mass, not atoms and not
volume. Always. Period. Don't take my word for it -- get on the

phone and talk to the chemist at your local water department.

Now back to the density issue. In HBD #690, Steve Thornton <NETWRK@HARVARDA.HARVARD.EDU> writes:

> 1 liter does indeed equal 1000 grams -- of pure water at 4 Centigrade.

Actually, it's at 3.98 degrees Centigrade, if you want to get picky about it. And at 20 degrees C (roughly room temperature) it is 998.23 grams, which again **for practical purposes** is 1000 grams. Do you think your scale has an accuracy of 0.2%?

> You wouldn't expect a liter of Mercury to weigh the same as a liter of
> alcohol, would you?

In water analysis, which is what we are discussing, the solvent is water. Not mercury. Not alcohol.

> Since you're trying to discover the amount of stuff in your water that
> isn't water, it seems reasonable to assume that it will not have a
> density of 1.0, right? So, I'm afraid you're going to have to go back
> to the calculating board and figger it out.

What matters is the density of the solvent (water), not of the solute. However, this comment does bring up an interesting (but **for practical purposes** insignificant) point. The CRC Handbook seems to imply (but does not directly state) that PPM is the ratio of solute to solvent. In that case, the density of the solute would not matter at all. However, sometimes the concentrations of solutions are expressed as the ratio of solute to **solution**, i.e., $\text{solute}/(\text{solute}+\text{solvent})$. In that case, the density of the solute would enter into the equation. But again, for the concentrations involved in brewing and in water analysis, there would be no **practical** difference. Remember, at 100 PPM (a typical value) we are talking about a solute concentration of 0.01%. In a liter of water, that's 0.1 grams out of 1000 grams. You couldn't even measure the difference at home.

Sorry for the strident tone of this posting, but when I am "corrected" with unsubstantiated misinformation, it makes me grumpy.

Last winter, I bought some apparently not new enough Wyeast yeast, and
was
wailing and gnashing my teeth as brew day approached and the foil pouch
was
showing little interest in inflating. I begged my wife to shoot me, but
instead, she suggested I do what she does with balky bread dough. Which
is,
set it on a heating pad set to a low temperature and cover it with a
towel.

This worked so well that I went berserk and wrapped the starter bottle in
the
pad with a towel around it. And did the same thing with the carboy. (The
heating pad isn't really big enough to "wrap" around the carboy. I just
rubber-banded it to the side, set the carboy on a few thicknesses of
towel,
and wrapped more towels around it.) Surprisingly, the "low" setting was
enough
to keep the beer several degrees above room temperature.

When winter returns to the Northern Hemisphere, I'm sure we'll be
fighting over
our one ancient heating pad. Gives me a warm feeling just thinking about
it.

Subject: Re: Dryhopping

Sorry Bill and everyone else.

I use pellets for the boil in a hop bag so I don't have to strain them out later, and whole-leaf hops (without a hop bag) for dryhopping. The pellets disperse throughout the whole kettle and I would rather pull them out with the bag, cool the wort with my immersion chiller, and then pour the wort carefully into the carboy through a large, funnel. The funnel has a sieve in the bottom, which periodically clogs with trub anyway (at which time I stop pouring, let it drain, and dump the sieve). It would clog instantly if I didn't use a hop bag. By the way, I think hop bags (and grain bags, for that matter) are not nylon but polyester (however, I may be wrong).

I'm not 100% sure, but I think that as soon as you begin heating the hops, you begin losing aromatics, which is the main reason for dryhopping anyway: HOP BOUQUET. I used to put up to an ounce of Hallertauer pellets into the kettle after turning off the heat, and let them sit there for two hours with the cover on the kettle, but never got the hop nose I get when dryhopping with an ounce of Hallertauer leaf hops.

Does anyone have any suggestions as to what kind of yeast to use for
making homebrewed root beer? This is for the kids, of course:-). The
recipe with the extract says to use bread yeast...

Root beer is/should be somewhat sweet, so there will still be
fermentables in the pop unless I use some "fake" sugar. I may just try
a beer yeast when I make the root beer. Better still, if I'm
motivated, I may divide the batch in two portions and try a controlled
experiment between bread yeast versus beer yeast!

> infection on to you.

Maybe not, but it can give you a few ideas. My brewing partner and I got ahold of a bottle of San Andreas' Earthquake Porter during an afternoon of comparison tasting - an excuse to avoid all responsibilities. Anyway, the taste was so sour that it was hard to believe that it was beer at all. When we asked others about the brand, several commented that it was a bit sweet for their liking, and have since discovered that we got a bad bottle. Bad - but actually *great* once our palettes adjusted to it.

Does anyone know of controlled methods of souring a beer without letting the bacteria run rampant? The owner of our neighborhood supply store warned against the growth of *fecal* bacteria with one method - so we're reluctant to even try.

> Every book I have ever read and every person I have asked, says bread yeast

Subject: re Yeast Bite Ointment

> During exponential
> growth (this is primary fermentation, I assume)

My recollection is that Papazian and Miller actually agree (!) that growth (yeast -> YEAST!!) and fermentation (sugar -> ethanol & CO2) are two separate phases. When you pitch the yeast starts doubling every N minutes (N controlled mostly by temperature and aeration?); by the time you see krausen the yeast has reproduced about as much as it's going to and is using sugar for energy instead of construction.

> are bounded by a single membrane and contain hydrolytic enzymes
> (these guys react with water producing a weak acid OR base)

True in a close sense but leaves out the hydrolyzed party. Hydrolysis is the reversal of a reaction in which two substances (frequently an ester and an organic acid) were merged into one by squeezing out water, e.g.:

(acetic acid + ethanol, catalyzed by acid, yields ethyl acetate + water)

The most familiar reversal of this is called saponification:

fat catalyzed by alkali yields soap plus glycerine.

(Hydrolysis will produce weak acids or weak bases depending on the catalyst and the ingredients. In this case the fatty acid will immediately react with the catalyst (as shown), but the fatty acid is weak enough that its salt, in the absence of strong alkali, will absorb H+ from (increase pH of, alkalify) the water it's dissolved in.)

What is produced in the presence of hydrolytic enzymes in the chemical stew that is beer? Your guess is as good as mine, but it certainly won't be what you started with. Since beer is already slightly acidic, you could convert some of your flavor/odor esters to, e.g., acetic or butyric acids, which smell/taste like vinegar and rancid butter respectively.

Subject: Beer & Bread

Larry Gerstley <ldgerstl@uci.edu> writes in HBD #691:

> You can make bread with beer, though. Use malt extract instead of
> honey in any recipe that calls for it. I am going to try to bake
> bread with beer yeast and use homebrew in the recipe.

I frequently do this. I have never tried re-pitching the yeast from the primary for my next batch but I frequently use it to make bread. My favorite recipe is George Lang's recipe for Potato Bread with Caraway Seeds (follows) in his book "The Cuisine of Hungary". I am told it is also in

James Beard's book, "Beard on Bread" as 'George Lang's Potato Bread'. The bread is very moist and flavorful and has some weight to it. The dough is a lot stickier than most other breads I have made to having a heavy duty mixer to do a lot of the kneading helps.

Anyhow, when I make it using homebrew, I get a slurry of the lees & left over beer from the primary to make about 2 c. and add a little water to come up to 2.5 - 3 c. of liquid. This has a fair bit more body than is in water so sometimes it takes a little more liquid.

Here's the recipe as it appears in "The Cuisine of Hungary":

Potato Bread With Caraway Seeds

3 medium-sized Potatoes
2 pounds Bread Flour
1 envelope of dry granular yeast, or
1 cake of compressed fresh yeast
1.5 tablespoons Salt
0.5 tablespoons Caraway Seeds

1. Boil the potatoes in their skins. Peel them, and mash through a sieve or potato ricer while warm. You should have one cup mashed potatoes. Let cool. (He seems to have smaller potatoes than I have found here. I use 1 c. of potatoes)
2. Place yeast in 1/2 cup warm (not hot) water, and mix well with 3 tablespoons flour in a 4-quart bowl. Let the starter rise for 30 minutes. (Omit this step if making it with the lees from the primary)
3. Add 2 cups lukewarm water, the salt and the caraway seeds. Add the rest of the flour and the mashed potatoes. (Substitute the lees etc. described above for the 2 c. water)
4. Knead the dough until it separates from hands and sides of the pot. This will take from 10 to 12 minutes.
5. Let the dough rise until it doubles in bulk. Depending on the temperature, the nature of the flour and the yeast, it will take anywhere from 1 to 2 hours.
6. Preheat the oven to 400F. Place the dough on a floured board and rework it for a few minutes. Shape it into a loaf, and let it rise for about 30 minutes.
7. Dip a brush into water and brush it on the center of the bread. Then make an incision in the loaf. Bake it in the preheated oven for 45 minutes, or until it is done.

I usually bake it on a "Pizza Stone" (available from lots of kitchen shop) and do the second rising on a pizza peel (usually available wherever you find pizza stones). The pizza stone goes in your oven and is supposed to simulate a brick oven as well as possible on a small budget. I spread corn meal on the peel before I rise the bread on it and also on the pizza stone before I slide the loaf onto it. The stone must be pre-heated in the oven in step 6.

It takes a while to make but most of the time is spent waiting so you can do other things and it is well worth the wait!

Subject: Stuck Fermentations

Mark Sandrock writes in #690:

> Tried my first batch of homebrew in about 6 years Friday night, and seem
> to have a stuck fermentation on my hands. The details are: 3kg (6.6lb)
> light malt extract, plus 1lb crystal and 0.5lb toasted pale ale malt, .
..

and Dan Strahs writes in #691:

> My third batch of homebrew has been stuck now for about 3 weeks.

> Started off with 1 can M+F light unhopped, boiled with 1 lb. crushed
> crystal malt, 1 lb. corn sugar, 2 oz. Cluster hops and 1 tsp. non-
iodized
> table ...

Well, alas, I discovered yesterday morning that I, too, have a stuck batch on my hands. I was trying to make a lighter beer (in alcohol content) so I used 3.3# M+F light malt extract (unhopped), 2# dried malt extract, 8 oz. crystal malt, 11 AAU Cascade Hops and 1 oz Cascade finishing hops. The original gravity was 1.032 (a little lower than I hoped - my previous batch was in the 40s with 4# Mountmelleck Amber extract & 1# dried malt extract) and after 2 weeks the fermentation had stopped. (It didn't take that long, I just didn't check it until then.) I did not have time to bottle it so I wanted to rack it off the lees. When I did this, I took another S.G. and found it was only down to 1.020. It does not have any off-flavors that I can detect (not that my palate is particularly discerning) but it is still sweeter than what I wanted. I have 4 books I can check so that's what I did next & here is what I found:

1. Papazian, TCJoHB: (pg. 305) said I was probably worrying and that many all malt beers will start as high as 1.038 and end as high as 1.013. Some will start as high as 1.055 and end at 1.028. Says to roll with the punch and bottle when fermentation has stopped. -- Not very helpful but may be what I will do. With all those hops, the sweetness isn't too objectionable.
2. Miller, TCHoHB: (pg. 189) says the problem is an unattenuative yeast and that I should change yeast. I am using M+F dried yeast - the same as for my previous batch that started in the 40s and ended about 1.010.
3. Reese, "Better Beer & How to Brew It" (c) 1978 said usually caused by weak yeast or fermentation temperature too low.
4. Eckhardt, "A Treatise on Lager Beers" (c) 1981 said that stuck fermentation is relatively common and can be caused by poor yeast, too low temp OR too high temp. I am starting to suspect the latter because nothing else seems to fit and we did have a bit of a heat wave here in the past 2 wks. I was fermenting in the basement & don't know what the temperature actually got to but it was in the 90s & up to 100 for several days straight. Eckhardt suggests the following remedies:

"It is best cured by making up a strong healthy yeast starter, and adding by stages a little of the stuck beer, until about a gallon of healthy young beer is going strongly. This is then added to the stuck beer, along with enough sugar or malt extract to raise the specifig gravity by 5 points.

Even better than the above procedure is to Kraeusen the stuck beer from a newly started batch at about 1.035, to raise the old beer's gravity by about 5 points. Remove an equal amount of the old and add it to the new beer. If your beer is in the last stages of secondary fermentation add more finings."

That is what I have found. I am planning on trying Fred Eckhardt's first method (starter) and if that doesn't work, I'll relax and bottle it and see if it comes out potable. Does anyone else have any suggestions?

(I'm also planning on waiting until autumn to start my next batch!!)

Subject: Reculturing Yeast

For a few months now, I have been enjoying my greatest homebrew success. Unfortunately, I am down to my last few bottles. I have been planning to try and recreate this batch. Recently, it dawned on me that reculturing the yeast from these last bottles might be a way to reduce at least one variable. Enough background here are my questions:

- 1) Is the easiest way to reculture this yeast to combine the dregs (sp?) into one bottle, add a bit of wort, and put a fermentation lock on the bottle?
- 2) In general, is it best to reculture yeast from the bottle, the primary, or the secondary?
- 3) Assuming that I want to make a third batch of this recipe should I save some of the yeast from this first reculturing effort (i.e. don't add it all to the second batch), or take it from one of the three sources in question 2?

Thanks in advance for all your words of wisdom.

Subject: Yeast and oranges.

Oranges in a brew:

Be careful how much of the orange you use, rather what parts you use. The orange part of the peel has a lot of oils and will impart a Grand Marnier like flavor. The white part of the peel has a nasty bitter taste, not the kind of bittering we love in beer, but one that will gag you. The fruit has the usual orange juice flavor. I would suggest using either the fruit sans peel or the zest sans the rest of the fruit. Maybe I'll try a "Florida Porter" next batch myself.

Yeast:

The question of how much yeast to pitch is one which will always be with us, and that's all right because we need things to argue about. Whether you pitch one yeast cell or a billion, the final yeast concentration will be in the neighborhood of one to ten billion cells per milliliter, depending on temperature and fermentable concentration.

The more cells (up to a point) you pitch, the shorter the respiration phase and the sooner primary fermentation will ensue. Back in issue 600, Father Barleywine discussed his "yeast kicking" method of using the yeast mat from a batch as the entire pitch for the next batch. I and a few others have tried this and had great success. There is virtually no respiration phase at all. If you use the same, or a little greater volume of wort, there is no overpitching because the yeast present was that needed (minus what remained in solution at bottling) for primary fermentation to begin in the first place. I have seen active fermentation in less than two hours with this method, and the results are a great beer.

As I described yesterday, I'm conducting an experiment to see how long yeast under beer in the refrigerator will last. I still have questions about autolysis. The information is rather contradictory; maybe one of our august bio types will comment.

Gee, listen to me already, been brewing for seven months and I think I'm an expert ... must be too many homebrews ... and not even ten in the morning yet ... oh well, take it with a shaker or two of salt.

From: "Todd Enders -- WD0BCI" <cos.hp.com!plains!bolshoi!root@hp-bsd>
Subject: Mashing, Dextrins, and American Lager Stats.

After the recent discussion about dextrins, mashing, etc. I went and did a little research into just how much the mash temperature effects the fermentability of the wort. I found the following in Industrial Microbiology by Prescott and Dunn, 3rd ed. (used without permission)

Effect of the Temperature of Conversion on the Ratio of Sugars to Dextrins

Conversion Ratio of Sugar
Temp.to Dextrins

Conversion Temp.to	Ratio of Sugar Dextrins
147.2F	1:0.37
150.8F	1:0.40
154.4F	1:0.48
158.0F	1:0.52
161.6F	1:0.57

Hopefully, this info will be of some use in calculating the change in final gravity vs. mash temperature.

Another interesting exerpt is the ratio of malt to adjuncts in American lager over the years.

193719461956			
%malt per barrel	72.41	57.38	65.53
% adjuncts " "	27.59	42.62	34.47
% " (hops) " "	1.21	0.98	0.804

This data was extracted by the authors from Annual Reports to the Commisioner US Treasury Dept., Internal Revenue Service, Alcohol and Tobacco Tax division, for the fiscal years noted above. I'm going to have to see if I can find the relavent BATF reports for a more current year to see how much more commercial beer has been diluted in this country.

The most popular adjunct was corn (1956 - 21.293%), followed by rice (10.377%), Sugar and syrups (2.671%), wheat (0.091%), soybeans and byproducts (0.021%), sorghum (0.0009%), and barley (unmalted) (0.0002%)

The hopping rate fell from 10 oz. per barrel (31 US gal.) to 5.8 oz. per barrel over the period. Assuming 5% alpha Cluster or Cascade hops, that works out to a high of about 8 AAU down to about 4.7 AAU. Pretty sad, IMHO.

Hope you all find this interesting/useful.

Subject: A Short Note on pH

Here's what an old brewing volume has to say on the issue of pH:

According to Hopkins & Krause, the yeild of extract in a mash is maximum at a pH of 5.0 - 5.2. Beta amylase is very active at this pH as well as protease. Maltose formation and attenuation are best at a pH of approx. 5.5.

This value is excellent for filtration (sparging) also. At pH values below 5.0, amino nitrogen (sic) is formed at a maximum rate.

Tannin and bitter resins are dissolved from the husk more readily at higher pH values, since they are weakly acidic in nature. Color, likewise is extracted better at higher pH values.

Industrial Microbiology 3rd. ed. Prescott & Dunn, 1959

The Hopkins and Krause citation was extracted from:

Hopkins, R. H. and C. B. Krause: "Biochemistry Applied to Malting and Brewing", 2nd. ed., D Van Nostrand Co., Inc. 1947.

Subject: Re: Bread Yeast

I've been extremely fortunate in my short life; I have only made one batch of beer that was undrinkable. While there are many opportunities for a batch to go awry and it is frequently difficult to pinpoint exactly what went wrong when a beer doesn't quite meet your expectations, I'm pretty sure I've nailed down the cause of my one brewing disaster.

I was making dinner for my fiance and her parents last summer. A big pot of my world famous chili (made with my less than world famous homebrew) had been on the back burner for the better part of the day. I had a loaf of bread in the oven and a bubbling brew-cauldron on the front burner. My roommate (and usual brewpartner) was unexpectedly called in to work, so my fiance was pressed into service. Just before dinner was served, she and I strained the schmod (see the definition at the bottom) and set the hot wort aside to cool.

Several hours later, her parents had (thankfully) left and she and I went back to the evening's true work: the beer. I opened the fridge and reached for the yeast. The shelf was empty (shades of Mother Hubbard...). Refusing to panic I carefully searched the entire refrigerator from top to bottom, hoping that my dastardly roommate had moved it (for what had better be a damn good reason...). I was finally forced to accept the fact that my mind had snapped and I had used the last of the brewers yeast in the bread and that all I had left for the beer was the bread yeast.

Well, to cut a long story short, it was the worst beer I've ever tasted. To this day, it is still the only beer I've ever poured on the garden. Of course, it may not have been due to the bread yeast, but I can't imagine what else could have gone that for wrong. I don't know who asked about bread yeast making yucky beer, but I hope this answers your question.

Now, I have a question of my own. What is the difference between bread yeast and brewers yeast?

-Nils

schmod: 1. The grains left in the wort at the end of the boil that must be strained off.

2. The yeast sediment (also called gunk) that accumulates in the bottom of the fermenter.

3. The sediment in the bottle. ("Wow, there's a lot of schmod in that beer!")

4. Anything useless or unwanted. ("Get that schmod off my desk!" "Don't listen to him, he's just talking schmod.")

Here is another myth I need to get sorted out.....

I have always skimmed the foam off the primary ferment just prior to its falling back in because most books say you will get yeast bite if you don't.

The guy who runs the local brew shop says it is not necessary.

One book I read said it is only necessary with ale yeast.

And then we come to another gem from:

"BREW IT YOURSELF"
by Leigh P Beadle

"If you look into the fermenter, you will see a rich foamy head bubbling on top. This head is composed mainly of resins from the hops, which are forced up by the carbon dioxide bubbles. Some books advocate skimming off the head, but this should never be done because it contains all the oils and resins that will give the beer its body, aroma, and characteristic beer taste."
"

I was going to plagiarize his title for the "how to" video we are producing but I am having serious second thoughts. Anybody have an idea for a title?
A free copy to anyone whose title is selected.

We are covering root beer, ginger ale and simple beer. Lots of micro and timelapse stuff.

I have been looking at getting a pressure cooker for vegetable canning
and thought about using it for beer. Since a pressure cooker raises
the boiling temperature, could that in fact hurt the beer. Also, one
couldn't add any thing to the wort once the pressure was on. (without
serious consequences 8-)

In HBD #691, ralph@ecn.purdue.edu (Ralph L McCallister) speculated about malt aroma:

> I seems that the German beers seem to impart that malt aroma and
> taste. There seems to be a corrilation between this and the type of
> barley they use.

I agree with that. One of our local homebrew supply shops (Liberty Malt Supply) somehow secured a connection for true German malts (i.e., imported) about 9 months ago. Several of us lager brewers (Norm Hardy is another name you'll recognize) have been making a lot of beers from these malts. I've been amazed at how different the results have been. There is much more of a malty nose, with the honey-like aroma that the good German lagers have. The body seems to be much better, too.

Subject: Boulder Beers

Last autumn, the perpetually-financially-ailing Boulder Brewery was bought by the highly successful Walnut Brewery, a really good brew-pub just off the Pearl St. Mall in Downtown Boulder. Apparently Walnut did not have sufficient capacity to serve everyone who walked in the front door, and also they wanted to bottle some of their beer. Therefore, the deal was a natural - Boulder Beers would still be made at Boulder Brewery, Walnut would make its Buffalo Gold Beer at Boulder as well, both for consumption at the brewpub and to be bottled, and there was finally enough money in the operation to keep it afloat. (Boulder Brewery is about four miles away from Walnut Brew-pub.)

I always thought Boulder Stout suffered from inconsistency, but that their Porter was good to the point of being one of the best Porters anywhere in the US. The Porter remains good (when fresh, as it was a week ago when I got it in Boulder) even while they don't quite have it together on Stout. Their realignment of the sundry shades of Amber Ale has simplified things somewhat, with the very nice darker amber ale for us beer-geeks and the lighter amber ale positioned for the Lite beer crowd.

The Boulder Brewery remains one of the best photo-opportunities in the area. The scene of the brewery in front of the Flatirons (those rock formations pictured on the Boulder Beer label) is breathtaking. Inspirational, even. (The light is best for photos in the morning.)

From: R_GELINAS@UNHH.UNH.EDU (Russ Gelinias)
Subject: wet-hop

Hey, easy now, I never said to *boil* the hops to make a hops tea. I said to *heat* them. Boiling will release the volatiles that you are trying to get. Steeping hops with the heat off after the boil will probably release a lot of the volatiles too; the temp. is still pretty hot. Maybe "tea" was the wrong word. I was suggesting heating the hops/water/(alcohol?) mix just up to the point where the hops oils will be released from the hops, *into the water*, not into the air. An alternate approach would be to steep the hops in room temp. sterile beer (or vodka, etc.) for a few weeks, then strain and add that to the secondary.

Bad news: My very first harvest of hops went bad. I guess I didn't dry them out enough. Bummer.....

Subject: RE: YEAST

Regarding the question about using bread yeast for beer:

I made a batch where I used both Red Star Ale Yeast and Red Star Active Dry Yeast because after having just had my first batch after moving fail on me and because the supplies for the second batch came from the same place I didn't really trust the yeast they gave me. I had intended to get some fresh yeast from a different place but had forgotten till it came time to pitch. I pitched the Ale Yeast and then, since it was late on a Sunday the two stores in the area are closed on Monday, went to the grocery and bought and pitched two packets of Active Dry Yeast.

I *thought* I could detect a slightly bread-like smell when I opened the fermenter to rack to the secondary but the beer turned out real good.

For my last several batches I used a brand of dry yeast, I beleive it was called Whitbread, I boughth from Beer Makers of America on 4th Street in San Jose. It comes in a silver foil packet. It is faster acting than other brands I have used. The active portion in the primary takes 1-1/2 rather than 3-4 days. I haven't tried any of the finished product yet as it is conditioning but the yeast seems to work well.

Subject: lager question

As a relatively new homebrewer(working on my sixth batch), I was hoping that the digest can give me some advice.

My latest effort has seen me attempt to make Papazian's honey lager. After making, cooling, and then shaking the hell out of my wort, I added a package of liquid lager yeast which I had started several days earlier. I then placed my wort in the fridge. It has been 32 hours and so far nothing. Should I have waited for active fermentation before placing the wort in the fridge? Any suggestion on how to remedy this situation would be appreciated.

Thanks in advance,

Mark

No, no, and no. Relax. Try a bottle every week till you think the
beer has the proper level of carbonation. Then, begin consuming it.

From: Conn Copas <C.V.Copas%loughborough.ac.uk@hplb.hpl.hp.com>
Subject: Re : kegging

Regarding the virtues of British plastic kegs, beware of your brand ! The cheap and nastiest ones often possess no pressure relief valve, and consequently are liable to distortion. Another critical design feature is the pressure rating of the tap, with 'drum' taps (round handles) being superior. I am afraid that Boots' reputation is mud amongst most serious brewers here. Hambleton Bard's Supercask (ie, 6 galls) is one I can personally endorse. Assuming conditioning requires about 3 weeks at room temperature, the cask will hold condition for approximately another 3 weeks before a CO2 boost is required. Of course, if you consume the contents rapidly, you may require earlier boosts just to equalise the pressure and make the beer flow.

Other features to look for : an intake valve which permits slide-on rather than screw-on gas cylinders, plastic valves (resistant to steriliser corrosion), wide necks for internal cleaning, translucent body which shows the beer level (therefore, do not store in strong light).

Judging from some comments on the net, some of you in the US do not seem familiar with draught brewing techniques. One of the aims, surprisingly enough, is to consume the beer fresh, before the aromatic content has degraded. The standard practice is to employ a 5-7 day primary ferment, after which the beer is fined, primed and possibly dry hopped simultaneously in the cask. The character of a draught beer is totally unlike the same bottle-conditioned beer, possessing a much creamier head and less 'tingle' on the tongue. Some of the more extreme members of CAMRA object to top conditioning (ie, CO2 boosting) on the grounds that this practice over-carbonates the beer, but I personally can't taste the difference and think the claim is scientifically dubious anyway.

Cask lager is also a possibility, although obviously a typical lager carbonation will not be obtained. Chilling could also be a problem.

David Taylor writes :

>I'm thinking of building a cabinet large enough for three fermenters,
>heating >it
>with light bulbs, stirring the air with a computer cooling fan and
>controlling
>the temp. with the water bed thermostat.

The easiest solution to your problem is to build an insulated cupboard with an electric towel-rail(s) as the heat source (much safer to leave unattended than anything with a motor or an exposed element in it; also, the brew may not benefit from too much light exposure). I have never found a circulation fan to be necessary. The wattage of the rail will determine the maximum heat output. If you just want the thing for Winter, you may find that a fixed, low wattage heater left on constantly will maintain the brew within acceptable limits. The next more sophisticated solution is to fit a rheostat to the heater, which will allow you to control the heat output manually, similar to operating an electric stove. Lastly, you could fit the thermostat, which will maintain a constant temperature by switching the heater on and off automatically. Water is admittedly a more stable medium than air, but think of all the construction problems !

Despite what manufacturers such as Coopers claim, warm ferments are a disadvantage for any brew which has pretensions of taste cleanness, such as lagers or standard gravity bitters. The 'homebrew flavour' is just too noticeable (in fact, I would avoid Coopers yeast entirely). I would recommend fermenting at 15-16 degrees, although this does not stop you pitching the yeast at up to 25 degrees, or conducting the first couple of days of bottle conditioning at 25 degrees for quicker maturation. I have found my brews to stabilise at around 11-12 degrees inside during a NSW Winter (regardless of time of day), so you may not need too much extra heating. The bigger problem can be Summer cooling, because that definitely requires water as a medium !

Subject: Query about Beer/Ale brewing reference

Has anyone a brewing reference work similar to the way Michael Jackson's "New World Guide..." is a masterwork for Beers of the World? I have a C. J. J. Berry book on brewing, but it sticks too much to recipes (most of which employ malt liquid extract of some kind). It's a pretty good book for technique (sparging is covered very well, for instance). I'm interested in learning about the various malts, adjuncts (MJ's book well covers which beer styles use what, but since it's not a brewer's text, it rarely goes into proportions, &c), and even the all the different characteristic of the various hops. Essentially, I'm looking for some book (or books) which will not only well ground in the brewer's craft, but also provide a comprehensive body of reference data.

Incidentally, the brewers' magazines are valuable for locating the various ingredients (such as some particular Saaz hops or type of malt).

Thank you,
Robert M. Seretny

Please email any responses, and I'll summarise them back as a service to other neos out there.

>siphon off it after the boil is finished.

>So, can anyone come up with a reason to skim?

I've been skimming the creamy head that forms on wort as it comes to a boil for several years. I first started doing it because I noticed that it eliminated boil-over. I tasted the stuff once while I was skimming. Astringent would describe it well. So I continued skimming to help eliminate that taste as well. I've had no problem with head retention in my beers as a result.

> Started off with 1 can M+F light unhopped, boiled with 1 lb. crushed
>crystal malt, 1 lb. corn sugar, 2 oz. Cluster hops and 1 tsp. non-
iodized table

I'm not sure about the answer to your original question. Just wanted to point out that you shouldn't boil the crystal malt with the extract. Steep it in a bag as your water comes to a boil. Remove the bag when the temperature hits the neighborhood of 170 degrees F. Boiling grains will extract tannins, giving the beer an unwanted astringency.

Subject: Pitching Rates (Re: Overpitching?)

In Homebrew Digest #688, eisen@kopf.HQ.Ileaf.COM (Carl West) writes:

> OK, so how much yeast is too much yeast?

The question of pitching rates was thrown around the HBD many moons ago but I don't remember that anyone came up with a definitive answer (i.e. Biblical, as in from the works of Miller or Fix). I recently came across a value for commercial "standard" pitching rates that I thought I'd share with the rest of you.

My wife's aunt knows of my interest in brewing and often sends me newspaper clippings and whatnot from the Portland area. She worked for many years in a microbiology lab and I assume that that is the source of a publication she recently sent my way. It's titled "Microbiological Control in the Brewery", Application Report AR-71 from the Millipore Company. Millipore supplies filtration equipment and culture media to the brewing industry (and others). This report was kind of interesting in its discussion of controlling and monitoring the wee critters in a commercial brewery.

One section on Critical Control Areas talked about testing the pitching yeast for Lactobacillus and Pediococcus contamination. As part of this test a "pitching rate equivalent" dilution is made and cultured on the proper medium. Here are the directions. Parts 1, 2 and 5 are the interesting ones.

1. Obtain a sample yeast cream from the brink.
2. Place 2 ml of the sample into 50 ml of sterile saline solution.
3. Shake the dilution bottle and plate (i.e. spread in thin coating) a 0.1 ml sample on Wallerstein Laboratories Differential Medium (WLD medium).
4. Incubate anaerobically for ten days (refer to section on "Anaerobic Culturing").
5. If the count is under 50 bacterial colonies per ml, the yeast is considered to be in sound biological condition.
If the yeast is diluted as described, the number of organisms that appear on the plate will be identical to the number per ml that would appear in the wort if the yeast were to be used in pitching. Or, to put it another way, a "pitching-rate-equivalent" dilution is the same as the dilution that results when the brewer pitches the standard one pound of yeast to one barrel of wort.

Following this formula, a homebrewer would need to pitch 0.8 quarts of "yeast cream" for a 5 gallon batch. Now I generally pitch about 3 pints of starter solution but you can bet that that is a small fraction of the "standard one pound of yeast to one barrel of wort."

Worried about overpitching? Don't. Have a homebrew :-)

Subject: stuck ferment

Somewhere in Miller (look for Crabtree effect in the index), he discusses why "beginner recipes" are bad, and I believe he says something to the effect that because these recipes are very light on malt, like 3 lbs., there is a lack of the proteins and amino acids that the yeast need to multiply. So the yeast only grow to a certain point, then they start fermenting. He says something about maltotriose not being able to be taken in by the cells, so the result is a high-final gravity beer. I suppose even if you make a 1.040 OG brew, if the malt does not have enough of the required yeast nutrients, then you could get the same result. Unfortunately, I don't think you could just add yeast nutrients to the stuck batch; the yeast are already "damaged". Yeast experts, wanna comment?

Looking back, 2 of the people with stuck ferments used M&F malt. Mark S., did you also use M&F? Maybe M&F made a nutrient-poor batch.

Russ (I don't claim to understand any of this. If in doubt, boil the book, no wait, don't boil it, just simmer it, like tea, no, not like tea, like...)

Subject: Saving Malt Aromatics

It occured to me -- now why on earth would you want to do a thing like that? The greatest value of those malt aromatics "lost" during the boil is what they do to my house while I am brewing. It is a truly heavenly aroma, and one of the definite rewards of brewing at home, despite the upstairs neighbor who periodically drops by for a homebrew when he smells it.

Subject: Christmas Ale Recipe

>From: Curt Ames <7872P%NAVPGS.BITNET@CORNELLC.cit.cornell.edu>

Hmm. Another one of those renegades from Cornell.

>Subject: Christmas Brew

>I'm looking for that special holiday brew made with any Christmas-type herbs
>and spices. Anyone have a favorite mix out there for a dark, high alcohol
>winter brew.

Following is Phil Fleming's recipe for Christmas Ale that I posted last fall in these electronic pages. The recipe is in the latest special issue of Zymurgy. I judged this beer in Oakland at the AHA competition. All I can say is that after the first sip I was singing "Jingle Bells"! It finished runner-up in Best of Show.

Ingredients for 5 gallons

3 1/2 pounds Munton and Fison Stout Kit
3 1/2 pounds Munton and Fison amber dry malt extract
3pounds Munton and Fison amber dry malt extract] ?? Typo ??
1/2 ounce Hallertauer hops (60 minutes)
1/2 ounce Hallertauer hops (5 minutes)
3/4 pound honey
53-inch cinnamon sticks
2teaspoons allspice
1teaspoon cloves
6ounces ginger root
6grinds from medium size oranges (scrape the white insides of the
rind away)
Wyeast No. 1007 German ale liquid yeast
7ounces corn sugar for priming

*O.G.: 1.069

*T.G.: 1.030

*Primary fermentation: 14 days @ 61 degrees F.

*Age when judged: six months

BREWER'S SPECIFICS

Simmer spices and honey (45 minutes). Boil malt and hops (50 minutes). Add finishing hops and boil (5 minutes). Cool, strain and pitch yeast.

MY COMMENTS:

The second call for 3 pounds of M & F amber dry malt extract is probably a typo in the magazine. 7 pounds of extract and 3/4 pound of honey would give you an O.G. of around 1.069. 10 pounds of extract would give you an O.G. much higher than that.

I never did decide if the second call for the M & F was a typo or not. It was discussed but I'm not sure I was convinced. So please take my comments with a "shaker or two of salt". Anybody close to Phil care to ask him? This was one of the best -- no, I take that back -- this was THE best Xmas ale I've ever tasted. I'd like to

set the public record straight especially since I might be the one screwing it up.

Though he doesn't say so, it sounds like Phil did not brew the honey and spices together with the extract but mixed them together in the fermenter.

I will say that, unlike other Xmas beers I've tasted, this beer had the freshest, most aromatic spicy smell and taste. Oftentimes, spices will add a bitterness to the beer if boiled too long. This beer was not bitter at all.

Merry Christmas.

Subject: Fear and Loathing in the Great PPM vs. mG/L Debate...

I couldn't resist holding off until the fiery debate subsided...

About 2 months ago I received a city water analysis in terms of mg/l, and discovered that my reference (Miller), described the variants in terms of ppm.

Thus I, too, was wondering the conversion rate. So I posted a Usenet msg to sci.chem saying that I had measurements of certain ions dissolved in H₂O in terms of mg/l and needed ppm. I stated how chemically ignorant I was, but that I believed some equation must exist that uses Avogadro's number.

I received about 15 replies. They all said that "ppm" is a misnomer, outdated term, shouldn't be used, etc.... And they assured me that any reference to ppm for dissolved ions in water is in fact equivalent to mg/l... But, unfortunately, about half told me that I should multiply mg/l by 1 to get ppm, while the others said I should divide... thus the great debate continues.

This is probably not so relevant to tasting and judging, but different beers of the same strength certainly can have different hangover potential.

The culprit seems to be higher alcohols (often referred to collectively as fusel oil), although I must admit that the whole subject of the effect of congeners in alcoholic drinks is somewhat contentious, scientifically. Fusel oil is promoted by the use of certain (typically amateur) yeasts, warm ferments, and nutrient deficiencies. Having said all this, some ale brewers intentionally encourage fusel oil production for the sake of additional complexity, in the same way that high gravity brews are regarded for their fruity ester content. I've had many a homebrewer tell me that their brew treats them more lightly than commercial brews, due to the natural methods employed, presence of yeast, etc. By and large, my investigations have revealed this to be wishful thinking, and that anybody who uses 'yeast anonymous' and no temperature control is asking for a headache.

Subject: Yeast

Hi,

With all this talk about yeast I've been thinking (Always a bad sign)

.
What if, rather than take the slurry out of the primary, I put new wort into the primary. I figure I could brew up a new batch on the day I'm tranfering to the secondary. After siphoning the firth batch of, I could siphon in the new wort. Of course, the new wort would have to be the right temp. when it was siphoned. I think I'd only want to do this once or twice before giving the fermenter a good cleaning.

Anybody tried this? I can't see that there'd be more chance of infection than transferring the yeast from place to place several times.

Comments?

Date: Thu, 1 Aug 91 13:22:32 CDT
From: kswanson@casbah.acns.nwu.edu (Kurt Swanson)
Subject: Musings on a first mash

For my first all-grain recipe, I chose Miller's All-Malt I.P.A., (pg. 224), using 6 lbs 2-row lager, 1 lb crystal, .5 ounce chocolate, and 14 AAU's of Fuggles (is this pronounced like goggles or bugles?), which worked to be 3.2 ounces. I placed the grains into my corona's hopper, and proceeded to set the grind as per Miller pgs 111-112. With the 2nd plate assembly firmly screwed to the rest of the mill (with the 2 wing nut on the sides), I found that even with the adjusting screw completely loosened (or taken off), the grain was just ground much too fine - flour. Thus I loosened the two wing nuts which gave the grinding plates a bit more room. Now the grain came out still very fine, but the husks were not ground, so I said "intact husks - no problems sparging" (mistake #1). Then I mashed-in as the stated temp, adjusted pH correctly, and proceeded to starch conversion temperature (150F). With my 33 quart pot covering 2 burners, this did not take long. When it got to 147F, I turned off the burners, and watched the temp settle at 150F - so I thought (mistake #2). So I placed the pot into my insulated box, and waited one hour. Then I checked the temp, and found it to be 153F! I had no idea how high it went. So I decided let it cool, and at 148F I closed it up again. After another hour I took the temp and found it at 147F - the box is a pretty good insulator. So I proceeded to sparge. I used a grain bag slightly suspended over the bottom of one of those Canadian 6.7 gallon food pails (which I believe come straight through Crosby & Baker), to which I had added a spigot. The first runnings were opaque. So were the third, fifth, and twelfth. So I just decided I had obviously ground the grains too much, and proceeded to rinse that which was not flour.

Now, because of mistakes 1 & 2, I decided I just might not have enough sugar in the wort to make anything stronger than Miller Lite. Thus, lacking any extract, I added (get ready to cringe), one pound of corn sugar. Then I completed the boil and hop additions to complete the recipe, chilled the wort, racked off the flour into the fermenter, and took an O.G. reading of 1.047 in 4.5 gallons. (For some reason I decided not to top this up to five). Miller obtains an OG of 1.045 with this recipe, so assuming a complete 40 pts/gallon

of gravity for the pound of corn sugar, and discounting the lost fermentables in there with the dead flour in the boiler, bearing any miscalculations, I believe I obtained an efficiency of 85+% of Miller's. How good is this?

To complete the story I pitched with 7 month old Wyeast (British Ale), which only took 1 day to explode to near bursting levels in the foil. (My last Wyeast was 1 month old and took one hour to get to pitchable size.) Anyone else encounter this?

Another comment: I have a 33-quart pot & a 9-quart pot. Thus I mashed in the 33-quart, and had to try to get 5 gallons of sparge water into a 9-quart pot, immediately rinse out the 33-quart to collect the runnings & then boil. I suspect the purchase of a 20-quart pot for sparge water would be a good idea, or even two, with one to mash in - and thus only use the 33-quart for boiling since 33-quart is a bit large for mashing (I would like my floating thermometer to actually float....). So what sort of setup do y'all use?

From: Dale Veeneman <devl@gte.com>
Subject: Re: Liberia's own Club beer

I have very fond memories of Club beer. I served as a Peace Corps volunteer in Liberia for nearly 4 years in the early 70's. Since water was generally not safe to drink without boiling, I drank a great deal of beer. A few European imports were available in bigger towns (and at special embassy functions), but cost more than I could afford on my meager salary so I drank Club. (Palm wine, a naturally fermented beverage collected from specially prepared tree tops and immediately consumed was also available, but you had to know someone who had a tree and besides that's a whole 'nother story -- as is "cane juice.") Rumor had it the brewery was started by a German, but when I was there the company motto could have been "Relax, don't worry, have a Club."

Once there was a period of extended drought (unusual for a rain forest climate) which caused the level of Monrovia's St. Paul river to drop. The level dropped far enough that brine from the ocean started backing upstream. This wasn't too bad, except that the city's water supply was taken from the river. So for a period of 3-4 months the city's water was so salty, you couldn't drink it. Not to worry, just drink Club! Unfortunately, the brewery got its water from the city supply. Did this bother them? Not in the least, they just continued brewing, producing case after case of salty, undrinkable beer (talk about water conditioning - I hate to think of the ppm). For a year or two afterwards, I would occasionally order a beer in some out-of-the-way up-country dive, take a sip, pucker up, spit it out, and dump the bottle.

On another occasion (the night before my wedding, in fact), a group of friends and I were out bending a few elbows. Now, Club beer bottles came in two sizes, 750 ml (the usual), and something around 300 or 350 ml (nobody bothered with these). Because the bottles could be found all over the country, they became a standard for measuring volume by the market ladies. Palm oil, palm wine, kerosine, etc., all could be found in Club bottles lining stalls at the markets. Anyway, this night, I noticed something terribly wrong with the beer I was drinking. Everybody tasted it but nobody could tell what it was. We finally called the proprietor over to taste it - he took a swig, spit it on the floor and said he thought it was kerosine. So we all tasted it again and agreed that yes, although it probably wasn't 100% kerosine, it had alot in it.

Beginning in December of 1989, a tragic civil war has decimated the country (Nimba county, in which I lived for two years, is virtually deserted). A tenuous cease-fire appears to be holding, but things are still in a very bad way.

Subject: Dry-hopping
Full-Name: Tom Bower

Questions for the hop-heads!

The major problem I've heard of with dry-hopping is the risk of contamination. Over the last months, there have been discussions of microwaving, tea-brewing and various other techniques, but I haven't been able to get a clear idea of what the best method is.

- 1.) How do you keep your brew from becoming infected when dry-hopping?
- 2.) Does dry-hopping in a (refrigerated) keg work well? I'm thinking of trying this on my next beer. I would hope that the cold temperatures might reduce the risk of any nasties becoming a problem.

Any advice would be appreciated!

From: aimla!ruby!ken@uunet.UU.NET (Ken Ellinwood)
Subject: Re: Stuck Fermentation

Last year I too suffered from a long string of stuck fermentations. Here was my situation: I brewed all ales, almost all of which had original gravities of 1.044 and stuck at 1.016 or 1.020. I fermented in a refrigerator and used a lamp timer and some personal attention to control the temperature inside the refrigerator. Believing that higher temperatures of ferment were worse than lower ones and that since the weather affected the temperature inside the refrigerator, I kept the temperature of fermentation down in the low 60's (this way, I thought, I could keep the weather from ruining my beer when I was unable to attend to it for a while). After trying to solve the problem with different malt extracts, better wort aeration, stronger pitches and yeast nutrient, (none of which had any noticeable effect - leading me to believe that they were not the problem), I fermented with the fermenter mostly submerged in large water bath and kept the temperature of the bath at a somewhat stable 67-69 degrees. Problem solved - the two batches that were fermented in this manner both fermented down to about 1.010. Apparently, ale yeasts prefer this kind of temperature.

I have since purchased the hunter energy monitor for my fermenting fridge. Although I haven't had time to brew with it yet, I hope that it will allow for many successful brews in the high 60's (unattended, of course)

> 1.) How do you keep your brew from becoming infected when dry-hopping?

I've been wondering this too. I assume it is the hops themselves. After all, one of the reasons hops are added (or why they were added originally)

is because of their qualities as a preservative. Is this right?

From: "Justin A. Aborn" <jaborn@BBN.COM>
Subject: Sparging Success and Mashing Advice

I saw the posting about Kurt Swanson's all grain experience and the sparging part sounded familiar.

A while ago I posted a message complaining about murky sparge runnings and I mused about adding a peristaltic pump to the process. Don't bother. I think my problem was the sparge bag. It did not tightly contact the sides of my lauter tun and I think that the wort was leaking out the sides of the bag rather than running through the full eight inches of grain husks.

I bought another plastic pail that fit into my first pail. The first pail has the spigot. I drilled a bizillion 1/16" holes into the new pail, and installed the new holy pail inside the spigoted pail. This makes one great lauter tun. The first time I used it I got bright and clear wort after just three sauce pans worth of recycling. Sparging still takes an hour though.

I have used the new lauter tun three times. Once I had a bad grain crush that caused foggy runnings. The grain was not crushed enough. There were many even uncracked grains. This batch did not run bright and clear. The wort ran very quickly through the grain bed and stayed foggy. Watch your crushes.

I am drinking my original sparge bag beer these days and it is quite delicious despite the lack of perfect clarity. Don't toss those foggy runnings!

Subject: Re : Mashing, Dextrins, and American Lager Stats.

Don't care what the textbooks say, I have always found the effects of both temperature and pH to have relatively little influence on dextrin content.

A prolonged, dilute mash is a much more effective way of achieving a dry beer, if you like that sort of thing.

>Anybody tried this?

Yup I tried it in a gallon batch. This is how I found out what yeast-bite tastes like. When I try it again, I'm going to dump out about half of the yeast. Note that I was doing single-stage fermentations, so **all** the yeast from the first batch was 'pitched' into the second and third, just 'pitching' from a primary might solve the problem.

From: card@apollo.hp.com
Subject: CHRISTMAS ALE

MODIFIED FILMORE ALE - 10 gallons

- * 1 # crystal / remove when boiling starts
- * 5 oz black patent /

BOIL (40 MIN)

- * 12# M+f dried light extract
- * 5 tsp yeast nutrient
- * 2# light clover honey
- * 5 oz. cascade @ 4.9 ph (pellets, in hop bag)

LAST 10 MINUTES

Add fruit/spices, to a hop bag - squeeze every few minutes with tongs

- * 2 Orange rinds
- * 1 6" x 3/4" root of ginger (pre-heat in microwave ~ 20 sec
- squeeze juice into wort)
- * 1 tsp whole cloves (crunched up a bit)
- * 5 3-inch cinnamon sticks (ditto)

- * 1 tsp irish moss

LAST 2 MINUTES

- * 4oz leaf tettnager (added loose in wort - stir thouroughly)
- * newish cuttings from Blue Spruce sapling (~ 1.5quart jar filled
loosely with cuttings)
- * Strain the hops
- * Leave the blue spruce during cool down

COOL WORT 20 MINUTES - remove spuce cuttings

Primary - 6.5 gallon glass carboy - filled to ~ 4.5 gallons
(blow hose necessary)

SG = 1092 (IN 5 GALLON carboy - I diluted into (2) 5 gallon carboys
when I racked to secondaries in ~ 1 week)

Yeast: I tried Wyeast 1007 German ale liquid yeast BUT
saw little activity in primer and no activity
in primary fermenter after 30 hrs

SO

I panicked - whitbread dried ale yeast into krausen
(i was saving for priming) very active after
2 hrs. -- pitch into secondary >> very active
within several hours).

SG = 1032 (before dilution)
SECONDARY FERMENTATION ~ 2 WEEKS >>> FG 1010 (diluted)

Bottle - PRIME (.5 cups corn sugar x 2)

RESULTS: - after only 3 weeks I sampled and it tasted great. Orange and spruce flavor very evident. Even my wife liked it until I told her about the spruce cuttings.

Note: This tasted great even during a 100 degree day with the humidity seemingly almost as high. As Kinney Baughman said: "after the first sip I was singing "Jingle Bells"! and thinking about a cold snowy night in December.

> what the best method is.

I never boil my finishing hops, and have never had an
infection. Pitch lots of healthy yeast and RDWHAH.

> 2.) Does dry-hopping in a (refrigerated) keg work well? I'm thinking
of
> trying this on my next beer. I would hope that the cold temperatures
> might reduce the risk of any nasties becoming a problem.

Works great. Use a hop bag to keep the hops from
plugging the pickup tube, and boil the bag for a few minutes
before dropping the hops in and tossing down the hatch. Expect
to wait a week or two before the flavor/aroma changes much, but
this is (so far, in my experience) the best way to get hop
aromatics into your beer.

Methinks you doth worry too much. Cold temperatures
may slow down an infection, but won't stop one. Alcohol and
healthy yeast will.

From: korz@ihlpl.att.com
Subject: In defense of M&F

Among the many brands of extract that I've used, four of my best batches have been made with M&F Old Ale Extract. Generally speaking, for 5 gallons, 1 can of Old Ale Extract, 0 to .5 lbs of Crystal Malt, 2 to 3 lbs of Light Dried Malt Extract (M&F or Laaglander, if it makes a difference) 1 to 2 oz of Hallertauer Pellets (boil), 0 to 1 oz Hallertauer Pellets (finishing), 0 to 2 oz Cascade Leaf Hops (dryhopping), and Muntona or Wyeast Ale yeasts. (Warning: As I have mentioned before, Muntona Yeast produces quite a bit of clove taste and aroma -- I'm not very fond of cloves so I will avoid Muntona in the future, but that's no reason you should.)

I have not used any of the other M&F products, so I cannot comment on them, but just for the record, I wanted to add a positive data point for the Old Ale Extract. Notice: I had no stuck ferments (I never have, nor have any of my brews ended up in the garden -- all at least pleasantly drinkable).

Al.
korz@ihlpl.att.com

P.S. Oops! I forgot about the one beer that ended up on the ceiling due to a clogged blowoff and one beer that I dumped because I literally forgot about it and it sat there *all* summer between 80 and 100F. :^(

Subject: Re: Dry-hopping

Tom Bower asks about dryhopping and sanitation.

I thought about this for a long time and then finally, stopped worrying, took 2 oz of leaf hops out of the fridge and dumped them in the primary (the day after the krausen fell). I read somewhere that, if the hops are dry, there is nothing for bacteria to live on (dry leaves and lupulin oils -- that's it). The beer turned out the best I've ever made and now I would rather not brew than not dryhop (well, maybe that too extreme). I have not had any infections from the dryhopping (almost 1 year of brewing since starting to dryhop). Relax.

> I never did decide if the second call for the M & F was a typo or
> not. It was discussed but I'm not sure I was convinced. So please
> take my comments with a "shaker or two of salt". Anybody close to
> Phil care to ask him? This was one of the best -- no, I take that
> back -- this was THE best Xmas ale I've ever tasted. I'd like to
> set the public record straight especially since I might be the one
> screwing it up.

I brewed this Christmas Ale las year, and I followed the first comment above, leaving out the extra 3 lbs of dry malt. I followed the rest of the recipe exactly. However, when I measured a sample of the final wort solution (WITH spices and honey) it was nowhere near 1.069. I don't remember exactly what it was, but I think it was under 1.050. I was worried that the brew would turn out weak, so I boiled up another couple of lbs of dry malt that I had lying around in as little water as I could get away with, and added it to the fermenter. Then I let it ferment.

Even with the last minute change to the recipe, this beer was great. I only waited about a month after bottling to drink it, and it was fine then and just got better as the year went by.

I want to brew this beer again, now, so it will be just right for the holiday season, but the extra 3 lb question is nagging at me. Anyone else have an opinion? Does anyone want to do the math?

Thanks, Chris

Subject: Pressure Boiling

From: sja@grog.cray.com (Sheridan Adams)

>I have been looking at getting a pressure cooker for vegetable canning
>and thought about using it for beer. Since a pressure cooker raises
>the boiling temperature, could that in fact hurt the beer. Also, one
>couldn't add any thing to the wort once the pressure was on. (without
>serious consequences 8-)

I've never tried pressure cooking wort, so I have no practical experience with this, but I can offer a little theory.....

According to The Practical Brewer (compiled by the Master Brewer's Association of America), pressure cooking wort has been tried by the big guys. It has its advantages and disadvantages.

The advantages are that some of the things that we want to happen during the boil happen much more quickly. Alpha acids isomerize at an accelerated pace, and protein flocculation rates double for every 4 degrees C that the temp is increased. Thus if you could get the temp up to 112 C, you could achieve some of the results of a one hour boil in only 7 1/2 minutes. Furthermore, the shorter boil causes less caramelization of wort sugars and destruction of yeast nutrients.

On the down side, there are volatile compounds in wort that are generally considered undesirable. Certain amino acids, if not destroyed, provide a source of sulphur which the yeast will turn into things like H₂S and DMS. During an open boil, the sulphur is driven off as H₂S, but it will stay in your wort if pressure boiled.

Another disadvantage is that the accelerated trub formation causes increased coprecipitation of protein and hop resins, which results in a decrease in hop utilization. This is a big deal for major league brewers who are guided by economic considerations. As homebrewers, we can laugh with glee and add more hops.

The Practical Brewer goes on to recommend that brewers who boil under pressure follow this with an open boil at atmospheric pressure, or flash the wort in a vapor separator at reduced pressure. Starting to sound like alot of trouble. (Honey, where do we keep the vapor separator??)

Having said all that, pressure cooking your wort would still be an interesting experiment. After all, the people who wrote The Practical Brewer have titles like "Supervisory Brewmaster, Moosehead Breweries Ltd.", and "Director of Brewing Research and Development, Adolph Coors Company"; people who seem to think that any flavor compound is an undesirable one.

Who knows, this technique may produce just that malt character you've been seeking. If you decide to give it a go, let us know how it comes out.

Cheers,
CR

From: jmaessen@ATHENA.MIT.EDU
Subject: Plastic fermentation vessels

Greetings to fellow homebrewers and netters all!

I have in the past heard various stern warnings against using plastic 2-liter soda bottles and similar beasts in any stage of brewing (well, they make rather silly fermentation vessels anyhow...) because ethanol will dissolve the solvent used to produce the plastic. I'm not especially keen on using these bottles anyhow. Since then, I've discovered that I can get 6-gallon plastic water carboys at work, however, and it occurs to me that they could be extraordinarily useful for home brewing. I'd like to know if anyone out there has knows if these are safe for brewing (certainly home brewers do use some kinds of plastic), and if so whether anyone has experience with them and can offer helpful hints, caveats, etc. (e.g., are the molding lines big enough inside to trap bacteria, what's the best way to clean one out...). I'm actually mostly a mead brewer, but am interested in just about anything that'll ferment--I'd like to branch out. Thanks!

Subject: homebrewing and drinking in the third world

from DevelopNet News, vol 1, no. 5:
[DevelopNet News is published by Volunteers in Technical Assistance
(VITA) in Arlington, Virginia, USA.]

ALCOHOL ABUSE IN THE THIRD WORLD

Widespread "problem drinking" is relatively new to the Third World. But the health and social damage caused by excessive alcohol consumption is already becoming extremely serious in most developing countries. So far, governments seldom recognize drinking as a problem even though it now drastically affects agricultural output, worker productivity, and child health. Indeed, governments often promote alcohol production by overstating its economic benefits to the nation.

Many people see alcohol use as a symbol of elevated social status and this belief is encouraged in advertising by multinational alcohol producers. Where significant fractions of men drink, the whole burden of farm work often shifts to women. Since commercial brew is expensive, home brewing thrives as small, unregulated industry. Home-brews often are made from the same grains used locally for food, thus competing with the local food supply. In some countries, a third to a half of average per capita income (excluding the informal economy) is spent on beer, and more than half of all patients admitted to medical centers are alcoholics or problem drinkers.

According to Lori Heise (recently of San Pedro de Laguna, Guatemala), a few developing countries have decided that the social costs of unbridled alcohol use are no longer acceptable. But home brewing is an important source of income to some families. So instead of enforcing prohibitions, some governments try to provide credit and job training to help the people assume new roles in the informal economy. Swaziland is having some success in school programs that help young people under 15 years of age toward responsible individual development, which includes resisting peer pressures to drink. According to Heise, the greatest successes are reported where individual communities, with effective group or individual leadership, have "exercised this power to restrict alcohol availability or challenge public drunkenness."

Source: "Trouble Brewing; Alcohol in the Third World," by Lori Heise. World Watch (Worldwatch Institute, Washington, D.C.), vol. 4, no. 4, pages 11-18, 1991.

Subject: Re: pressure cooker for aromatics

>Since a pressure cooker raises
>the boiling temperature, could that in fact hurt the beer.

Sorry if this old news, but a higher boiling temperature will hasten both hop bitterness extraction and the hot break, so this is a plus if your cooker is big enough. Beware of pressure cooking high gravity worts, because this will produce a caramel character (could actually be interesting I suppose).

Another use of the cooker is to extract hop aroma. Alexander's "Brewing Lager Beer" recommends raising the temperature just to working pressure, then switching it off and resting for 15 minutes. I have always found these sort of infusion techniques to produce a more harsh flavour than cold aroma extraction, probably because some extra bitterness is extracted as well. Another variation is to boil under reflux (ie, collect and return the vapour) by fitting a vertical water-cooled condensing column to the outlet of the cooker. Even this method seems to lack something, suggesting that heat disintegrates as well as dissipates hop fragrance. The imaginative amongst you could probably think of other uses for the aforementioned equipment, but far be it from me to encourage illegal activities in a public forum ...

From: darryl@ism.isc.com (Darryl Richman)
Subject: re: Malt Aromatics

When you cover the pot while boiling you do hold in a number of elements that would otherwise boil off, including large quantities of DMS. DMS will be scrubbed out during a vigorous primary fermentation also, but not as efficiently. I would wonder if the malt aroma you're noticing isn't at

least partly due to this DMS character, which in lower concentrations can add sweet notes. As the concentration increases, these change into sweet corn and then take a more vegetative character into turnips and cabbage. In fact, a quick look through "Principles of Brewing Science" by Dr. George Fix indicates that DMS at 1 to 2x the flavor threshold (30ug/L) produce "malty lagerlike notes", and at this secondary flavor characteristic level, DMS is a key taste discriminator between ales and lagers.

Subject: CABA Contest

From the CABA Newsletter, Vol. 1, No. 4, June '91:

ALL ABOUT ALES CONTEST, OCTOBER 26TH, 1991.

Once again this year there will be a fall contest for Ales. This year we have a few twists!

First: We are going to have an Awards Dinner.
Second: The categories have been refined and expanded; the entry rules have been changed to hopefully reduce the expense of shipping entries to the contest.

AWARDS DINNER:
This year we will celebrate your best with a dinner. Saturday, October 26, 1991, we will all get together following the General Membership meeting and award the winners of the All About Ales Contest. Registration forms and details will follow in the mail.

- CATEGORIES:
1. Canadian Ale
 2. India Pale Ale (OG > 1.050)
 3. English Bitter (OG < 1.050)
 4. Brown Ale
 5. Trappist Ale
 6. Porter
 7. Dry Stout

ENTRY DEADLINE:
A) One bottle required by:
5 pm, Friday, October 4th, 1991 at 'To Your Taste' in Toronto.

To Your Taste
317 Jane Street
Toronto, Ontario
M6S 3Z3

Those passing to second round will be notified by telephone between 7&10 pm Thursday & Friday October 10th & 11th.

B) A further two bottles will then be required by 5 pm, October 22nd at 'To Your Taste'.

Second round and best of show judging will be done on the morning of the Annual

General Meeting. Prizes and Medals will be presented after the Dinner following the General Meeting and election of the CABA Board of Directors.

Further details and entry forms will appear in the next newsletter.

....so start brewin' and stay tuned to HBD.

Subject: hbd no. 694

Greetings,

Did anyone receive a complete copy of today's HBD (#694)? I did not and when I requested a replacement from netlib I got another truncated version. So, what gives?

In the truncated version I received, there was a letter from Justin regarding his sparging setup. Now, my question is "Are those 'bizillion' holes measured on a parts per gazillion basis, or are they bizillion holes per litre? : -)
Seriously though, I have used the two bucket system for all of my full mashes, to good effect. With the exception of wheat beers, I always get quite clear runoffs after recycling a gallon or so.

I want my HBD.

Ooogy wawa,
Dr. John

Subject: refrigerator questions

What types of refrigerators do people use for fermentation and lagering? Are regular kitchen fridges built strongly enough so that the shelves support a full carboy (I doubt it!)? It seems to me that the ideal configuration for a beer fridge would be some sort of horizontally oriented box with a good solid floor, a shape totally useless for all other refrigerator purposes. A freezer would be OK, but it would be better if the door were on the side.

I guess I could just wait until I win the lottery and then build a custom insulated chamber with a custom-made refrigeration unit. I'd probably set it up with a couple of different zones so's I could ferment and lager at the same time.

Has anyone ever seen any plans for some sort of water-jacket heat exchanger for a fermentation setup? A friend suggested that thermo-electric modules could be employed, but methinks this would be a little bizarre and a lot expensive. Right now, I've got a hokey swamp cooler evaporative heat exchanger that lets me do ale fermentation, but it's useless for lagers.

Oh well, I can't really fit a refrigerator in my apartment anyway, unless I got rid of my wife (hmm...). I am curious though.

Subject: rampant infections

I have a severe problem that I hope somebody can help me with.

I have had to toss my last two batches of beer due to really horrible, awful, slimy, foul smelling infections. Well, probably not that bad, but bad enough.

I used to produce some really good beer, but lately I can't seem to keep the "undesirable elements" out of my fermenter.

I am not aware that I have been doing anything different from my traditional procedures. Most of my brews are extract and I usually do a boil of only about 3 gallons, adding 2 gallons or so of chilled bottled spring water to the fermenter.

I do the primary ferment in a 7 gallon carboy, and I do secondary in a 5 gallon carboy. I recently replaced all carboy stoppers and siphon hoses. I sanitize everything in a chlorine bleach solution and rinse with hot tap water. I am very careful with my siphoning procedures, probably to excess. i.e. I do things like wipe around the mouth of the carboy with a piece of gauze soaked in ethanol before putting in a stopper or a siphon hose. I'm getting absolutely anal with my process and nothing seems to help.

Now the "Clean out the Closet Porter" that I brewed a while back is growing some ugly looking scum on the surface. I hadn't had a chance to bottle it, but I didn't worry since, of course, I felt that I had done everything properly and that I could leave it in secondary for another week or two. The temp. where I stored the fermenter has not gotten above 70 degrees F. and typically stays at about 65.

Could I have a nasty infection in my kitchen that permeates everything? Could my bottled water supply (Poland Springs) have gone bad? Could my cat be spitting in the fermenter when I'm not looking? Will I have to hose down my kitchen with sanitizing solution? Would an ionizing air filter help?

Help! I'm starting to worry! And I'm all out of homebrew. I sure hope that a fellow BFD or two bring some good beer to the next meeting... How are the Lambics coming Mike?

From: lg562@koshland.pnl.gov
Subject: German beers

I had the good fortune to attend a conference in Berlin, Germany. While I didn't take very good notes on the particular beers that were served, I never came across a poor example of brewing science. All beers were excellent pilsners. Either at the conference dinners or the sidewalk cafes. One of the interesting features of the way they server beers: Apparently the length of time it takes to pour a beer is a measure of the quality of the beer and the bartender. It takes anywhere from 5 to 10 minutes to pour a good beer. (You have to wait for the head to die down before you can continue to fill the glass!) So my question to this list is: How long does it take you to pour a beer?

On the way through Frankfurt am Main, I was able to sample an interesting "brew" called apfelwein. This apple wine was interesting with a sharp aftertaste, but not of hops. I had to sample another just to be sure and realize that this too was a good taste of Germany.

From: card@apollo.hp.com
Subject: more brewpot queries

Hi:

At the risk of beating a subject to death, I would much appreciate further clarification re: 5 gallon boiler for all grain brewing.

I do realize you can't squeeze 6.5 gallons of wort into a 5 gallon boiler (too messy) BUT, rather than make a sizable investment for an 8 gallon brewpot, my thought was to only boil ~ 4 gallons and dilute it in either the primary or secondary vessel with boiled and chilled water, bringing it up to 5 gallons - very similar to my extract method.

Am I missing something?

/Mal Card

p.s. I've read them all re: sparging and everyone seems to have different opinions (papazian loves the double plastic pail tun, while Miller claims the false bottom is too far off the real bottom yielding inefficiencies). Well anyways, I like the simple method described of Byron Burch, of the mesh bag into a plastic container with a spigot.

But what keeps the water from channeling through to the sides leaving the sweet wort trapped in the middle? He calls for an all mesh bag but wouldn't it make more sense to have a bag with solid sides and mesh only at the bottom?

> \$13.59 to try it before I have an idea of it's quality. Anyone tried
> Bitberger? Is it a decent beer?

IMHO these keglets are the closest thing to "real German beer" that you
can get in the states, aside from some wursthaus type place where they
have
fresh Spaten or something on tap. Been drinking them for years now,
and Bitburger ranks as a B+, with A being the best. As far as I know
the
brew is not pastuerized (Warsteiner isn't and Reichelbrau isn't).

If the place you saw the Bitburger has Warsteiner Pils, go for the
Warsteiner.
It's much better IMO, but if they just have Bitburger and you want to try
some good German brew, go for it. It's worth the \$ if you have it. It's
a nice Pilsener.

Reichelbrau Kulmbacher is also excellent. Forget Dinkel Acker. DAB is
also
good in kegs.

Look for expiration date(s) on the can, if any, to make sure what you buy
is
fresh. I had a bad keg once but got a replacement.

And don't bother with buying a tap. The gravity taps that sometimes
accompany
these kegs work great. You might want to save the tap for future kegs
bought
with no tap. Also plan on finishing it in 1 night (watch out if you
drink
it alone!) because it loses a lot of carbonation overnight.

Enjoy!

Ken ("Bitter is Better But Bavarian is Best") -> Someday I hope to have a
comment on Belgium, if we have any customers over there it could happen
some day ;-)

> for the head to die down before you can continue to fill the glass!)

Coincidentally, a friend of mine, in a telephone call Sunday night,
mentioned discovering a bar in Chicago which served Guinness on tap.
He marvelled that it took several minutes to pour the beer, because of
the
foaming, and asked me what that meant.

Several possibilities dawned on me, including the "new keg" foaminess
mentioned here, but he assured me that he'd investigated for a
sufficiently
long time to see the keg well on its way toward emptiness. 8-)

Also, his description of the flavor didn't match with my own very well,
giving me to wonder if this bar might be serving the *real* draught
Guinness
as found in Ireland (it *is* an Irish pub).

All this makes me curious. I can imagine ways that the type of pouring
might affect the beer; a good frothy pour would release more aroma to
tickle the nose, and perhaps the entrainment of air somehow emphasizes
the flavor and/or body. So how is beer poured for competition judging ?

From: polstra!norm@uunet.UU.NET (Norm Hardy)
Subject: Bitburger Pils and Germany in General

A question was raised about Bitburger Pils and it's quality....

BUY IT! A 5-liter keg would be a wonderful way to closely experience a German beer on tap. Bitburger is one of the top selling German beers, somewhere close to Warsteiner. It is considered to be a well made pilsner by those who know. The Bitburger man is prevalent on placards outside drinking establishments throughout Germany.

While you're at it, e-mail me a keg.

Secondly, to recommend good beer establishments in Germany is moot. Go anywhere that beer is served on tap (vom fass). Relax while it is slowly poured (actually while the foam subsides for the next blast from the keg) and ponder how you can make the stuff at home.

>
>I don't know, but you're not the first to ask. I bet the shipping is
>fairly high, however inexpensive the casks themselves. Are you, or do
>you know a good cooper?

Consider that you don't want the barrels to spend any significant time
empty once they have been used, or they go sour. I think winemakers
leave an SO2 solution in if one batch of wine is used before the next
is ready. That would add about 400 pounds to the shipping for a ~50
gallon barrel, but then you might as well get it shipped full of beer
:-).

RE cider:

>I have recently come into a mess o' apples, and would like to make some
cider.
>Problem is, I don't have a cider press. If anyone can tell me where I

>buy (cheap), rent or borrow one in the SF Bay area I'd appreciate it.

I don't know if they come cheap. The one I bought in 1982 was a
couple hundred bucks. They have to be a lot sturdier than wine
presses.

Just so you can figure how much you have if you DO find some place to
press them, I need about 25 pounds of apples for a gallon of cider,
but some apples are juicier than mine.

>out about half of the yeast. Note that I was doing single-stage
>fermentations, so *all* the yeast from the first batch was 'pitched'
>into the second and third, just 'pitching' from a primary
>might solve the problem.

When you take half the yeast, I suggest the top half: it has been
dormant or dead a shorter time than the bottom half. Another
poster (I believe it was Father Barleywine) who said he just dumped
new wort on the old yeast cake in the fermentor (I don't recall if
it was the primary or the secondary) and said that the beer turned
out great for a number of batches. I make single-stage ales and
dryhop, so after I siphon off the beer, I have a real mess in my
fermentor, so I can't realistically reuse the slurry, by the simple
means described here.

Secondly, I think that the yeast in the secondary might be better
to use than that in the primary. Any yeast that falls out of
solution in the primary (while fermentation is still going on)
is probably dead. Yeast that falls out of solution because all the
fermentables are gone is still alive, "it's just resting." I'm
not a microbiologist, but I suspect that the yeast that is "just
resting" is what you want to use.

Subject: Re: refridgerator questions

In HBD #695, mcnally questions those of us with spare 'fridges about our setups, and states that a freezer would be good, but wants something with an upright door - like a 'fridge.

So, don't buy a floor freezer, buy an upright one. I just picked one up used here in Chicago for \$100 delivered. Be sure to pick one up that has *MOVABLE* shelves, as many have fixed shelves (coolant tubing runs within them). I can fit 2 carboys and still have room for 2 shelves and a door full of bottles. Don't forget you'll need a Hunter Energy Monitor, model Airstat II, to go with it. (In order to get the right temperature range.)

By the way, as soon as I got my freezer, I popped on over to Builder's Square, and lo and behold, the Air Stat was on sale again... This makes 7 purcashes of this same product, same outlet, same year for me... My offer still stands: Send me a check for \$25, and I'll send you a HEM, post-paid, anywhere in the U.S.A. Act quick, sale ends 8/13, so I'd need to receive your check by next tuesday...

Subject: re plastics

A chemist acquaintance of mine opines that the 2-liter plastic bottles containing Watney's and Ramrod are the same as the bottles holding soda; the plasticizers (if any) are probably //not// soluble in ethanol (if there were any solvent remaining, it would leach no matter what was in the bottle, as it's volatile enough to evaporate).

I was vigorously discouraged from using the plastic bottles that cooler water now comes in by a prizewinner who was doing the homebrew demo at Common Ground (organic fair in Maine). These bottles may not be approved for anything more corrosive than water. More important, they scratch more easily than the PET (polyethylene terephthalate) used for soda and beer; scratched plastic is very hard to sanitize. (This is why you should replace racking tubes and plastic fermenters every so often.)

Subject: Efficiency of Dry-Hopping

Ever wondered about the efficiency of dry-hopping? Late last night, my brewing partner and I surely did. We had one batch ready to rack to secondary and were about to dry hop the s**t out of it with 2 ounces of Cascades. We had another boiling down on the stove, our intent being to dump the new wort onto the old yeast cake. As we had to boil down an especially large volume (> 7.5 gal), we had plenty of time to hit the bar scene in town and tip a few.

We came back, added the 1st hop addition to the stove-top wort, and attempted to add dry hops to a clean, empty, 5 gallon glass carboy. However, despite our best efforts, much of the hops ended up on our kitchen floor. Rather than immediately query the readers of this esteemed Digest (one or more of whom may in all reality be Darryl Richman) as to the proper technique for adding dry hops through the neck of a carboy, we thought we would instead formulate the efficiency of dryhopping ourselves and post it so everyone could study it.

Let:

a = area of the carboy neck
A = area over which the hops are actually added; this is roughly, say, the size of your kitchen
(in general, $a < A$)
n = number of beers consumed prior to dry-hopping
O = amount of hops being added, in ounces
o = amount of hops that actually make it to the carboy, in ounces
F = efficiency of dry-hopping under sober conditions, a constant
E = o/O = actual efficiency of dry-hopping, a function of n

One would intuitively expect that as n goes to zero, E approaches 1; meaning that essentially *all* of the hops you are adding make it into the carboy.

However, this is not quite true in practice due to uncontrollable muscle spasms, unexpected crosswinds, large, mutated hop-eating cockroaches that often appear in a brewer's kitchen, and the fact that the \$%!&?&@%# hops clump and unclump of their own accord, usually at exactly the wrong time. Nevertheless, these factors are more-or-less independent of the number of beers consumed. We'll just say that under conditions approaching sobriety that the

limiting efficiency for dry-hopping is a number F, and typically $.9 < F < 1$.

Conversely, as n approaches infinity, E approaches a/A; that is, hops are added more or less randomly over your entire kitchen, with some just happening to fall into the neck of your carboy.

After much calculation involving the partial differential equations for fluid-type flow in a kitchen-type environment under brewing-type conditions, we were able to derive the following formula for the efficiency of dry-hopping:

$$E = [F - (a/A)] * \exp(-n) + (a/A)$$

This is more easily seen in the plot below:

Units have been left off for the purposes of obfuscation.

Does this sound about right to you folks? Sure hope this helps in some small way to the general improvement of brewing as we know it.

Long live the IBUs,

STEVE

Subject: Toxic Homebrew

Re: Martin Lodahl's concerns

The statement "Homebrew can't make you sick!", isn't true. The statement that beer yeasts don't produce toxic substances is true. The difference being that there are bacteria that can spoil not only beer that is fermenting, but even beer that has fermented already (ie these bacteria are resistant to the growth deterring effect of alcohol, in fact some thrive by reducing alcohol such as acetic acid bacteria).

Fortunately for the judge these same bacteria produce nasally and often visually (gushing, rings) apparent signs of their presence.

My question is why as a judge would you taste anything that was such obvious symptoms of contamination. As a rule I will not score a beer that has obvious contamination. I simply note the contamination, try to identify it from its aroma then move on. Being a beer judge may have its responsibilities, but the "taste at all cost" philosophy doesn't do anybody any good. Sick judges don't judge well and risk their health, and drinking contaminated beer put contest organizers at risk of liability.

Have you gotten sick from beers without obvious signs of contamination??

I would strongly advise any judges out there to let their nose be their guide. If a beer smells (or with gushers looks) obviously contaminated, approach with caution!!

Subject: stuck fermentation / hot break question

> The next day no bubbles or CO2 smell/bite. I was afraid
> the yeast was bad so I added more. Still no luck. After 5 days now
> it still smells OK (gingery) but does not seem to be fermenting.

...
>Can I save this batch or does it go on the garden?

A long as it doesn't smell bad now, try re-boiling it,
add more finishing hops & irish moss, and pick using
a healthy starter. Don't forget to aerate!

and a question:

On my last batch of Ale, I got a beautiful 2" hot break in
the fermenter after about 3 hours, and was going to siphon
it off after I got a few more hours shuteye. Alas, the whitbread
ale yeast I used took off so rapidly that the vigorous fermentation
stirred up the sediment, and was producing so much CO2 that
my siphon didn't hold a vacuum long anyway.

That was Saturday night/sunday morning. The fermentation
is almost over, but I am planning to krausen with a more
attenuative yeast. I added a tbsp of gelatin directly
to the fermenter and stirred, and tried dissolving another
is 1/2 cup of lukewarm water, and adding.
nothing spectacular happened.

Should I try a shitload of gelatin, a different fining agent,
Or just let it sit?

On the subject of whitbread ale yeast, has anyone noticed a
similarity in behavior between it and M & F ale yeast?

I sent the following to Todd Fisher regarding German beers but noticing more talk I thought I'd post it to the digest.

Subject: Beer in Germany

Date: 06 August 1991, 09:55:07 CET
From: SWELTON at ESOC
Subject: German Beer

Todd,

I saw your request about beers in Germany, so just happening to live here I thought I'd pass on some information. In the pubs here you will more than likely find 4 different types of beer. Probably the most common is Pils (Pilsner), this is what you will get if you just ask for a bier. This is probably closest to an American beer, but stronger. The next most popular is Export which is similiar to Pils but stronger and tends to be served in tankards (and is my favourite). Also on draught is a dark beer called Alt, this is reasonbly close to an English beer, but where you're going is not likely to be very common, but if you do see it, try it.

German

pubs don't tend to stock bottled beer's but the one that you are most likely

to find is a Weizen beer which comes in two types. Kristal Weizen which is

clear and Hever Weizen which is dark and cloudy. These beers are usually served with either a slice of lemon or a few grains of rice (have'nt got a clue why). I personally don't like them as they have a slight banana taste.

Every area has it's different breweries so I can't recommend any but one's

to look out for - IMHO - are Pfungstadter, Schmuker, Bitburger and Eder.

They also have some variations that they they drink here which some people

find weird. A good one is Diesel which is 1/2 Export, 1/2 Coke which isn't

as bad as it sounds. Then there is Grafelder (or muddy water) which is 1/2 Alt, 1/2 Coke and is quite nice. Then there are such things as 1/2 Export and 1/2 Fanta orange and Berliner Weizenbier which is a Weiz beer with a rasberry cordial.

German pubs tend to be very good with the amjority serving good food but as with all pubs check first as it might not be the right type.

re. Bitburger Pils by us Brits living over here is not considered a particularly good beer, but compared to a lot of other beers that are available it's okay.

There is a kind of rule in Germany that a Bier (only Pils) should take 7 minutes to pour. If your beer comes quicker than that you complain. But you can always ask for a schnell Pils.

Hope some of this helps.

Subject: RE: Time to Pour and Guinness

In response to Michael Bass and Bill Thacker concerning time to pour and Guinness:

I've lived in Germany, Ireland and now the U.K. The way a beer is poured *does* matter.

In Germany, a Ma_ is generally poured quickly (this however causes a lot of complaints at bierfests such as Oktoberfest that you get 3/4 liter beer and 1/4 foam).

However, a Pils is poured slowly down the side and builds a very large head. This is allowed to rest and then refilled (can take 5+ minutes)

A Wei_bier is poured from the bottle into the tall glass by inverting the bottle into the beer as it fills the glass just under the surface; if done correctly, this causes the foam to be sucked back up into the bottle, which is placed on its side and allowed to rest and then poured into the glass. If done incorrectly, you get a real mess.

In Ireland, pouring a pint is ritual. However, after sampling an uncounted number of Guinness (and Murphy's) I do believe it does make a difference. To properly pour the pint you place the glass at an angle and place it against the tap and pull the handle towards yourself. This causes the Guinness to pour slowly into the glass. As it reaches the top, the glass is straightened; this starts creating the foamy head. When the glass is nearly full, it is placed on the counter to rest. The "bubbles" are diffused throughout the drink and slowly rise to the top, turning the pint from brown to black. When this is complete (about 2-3 minutes), it is topped up again by pulling the handle towards yourself. Then, the handle is pushed away. This causes an injection which really builds a head. This again is allowed to settle (about 1-2 minutes). Then it is offered to the customer. The secret is in the tap.

Why does this actually make a difference? The head of a Guinness is very creamy and bitter (the creamyness comes from nitrogen). A good Guinness should have a head that lasts until the drink is finished. When you drink it you get a little bit of the head with each sip. This blends the bitterness properly.

Singha is Thai, and when it is fresh it's pretty good. Fairly rich malty
flavor and amazing head characteristics reminiscent of a Belgian
Trappiste
(thick, creamy, and perpetual).

Another pretty good Indian beer is Golden Eagle (or some close
permutation
thereof), which is an ok lager. Always interests me to think about
'colonial' brews and the influence they show from their European
progenitors (eg. San Miguel, Mexican brews, Carribbean, etc.)

> Su Misra (t13329@Calvin.EDU (Percy)) writes:
> I'm looking for a recipe for mead.

Here's my "standby" -

2 pounds of honey per gallon of water
one thumb-sized piece of ginger per gallon of water
grated skin of orange peel (two tablespoons/gal and avoid
the white pith of the peel as much as possible)

bring the honey and water to a boil skimming off the white
and brown foam as you heat it

simmer/skim for about 5 minutes per gallon (5gal == 20 min)

when the boiling is almost done, add the ginger and orange peel

cool (I usually let it cool "naturally").

work with yeast (Werka Mead Yeast is good, champagne or
general purpose wine yeast will do)

bottle after two weeks (while it's still sweet and still
quite active)

refrigerate the bottles after another two weeks (to avoid
the glass grenade syndrome and to make the yeast settle out
of the mead)

To quote the original source: "It will be quick and pleasant
from the very start and will keep for a month or more."

Variants:

Add lots more honey and let it ferment till it stops. Bottle
and wait a month or more, you get champagne.

Use some other citris fruit peel, such as lemon or grapefruit.

Add some other fruit flavoring (crushed berries of some sort).

Load up on the ginger (my friend makes "death by ginger" by
using pounds of ginger per gallon!)

Have fun, and may the yeasty-beasties be kind to you!

>It's bloody expensive though.

Singha is from Thailand. I've never seen UB (available in England only?)
But
Kingfisher, in 12 oz. and 25? oz. bottles is widely available in the US,
particularly in Indian restaurants. Another I've seen is Golden Eagle.
The
Kingfisher is an Indian brand and an Indian recipe but the US bottles say
"brewed under contract in England" or some such on them, which is wierd.
Golden Eagle appears to be really from India. I'm not real crazy about
any of them, but then I'm a dedicated ale drinker. Keep your lager.

>

As for Guinness, the foamy pour results from the special tap system they
employ. There are two inlets for compressed gas in a Guinness tap. One
introduces more or less 25% nitrogen. The rest is CO2. I've always been
told that it's the nitrogen that gives draft Guinness its extraordinary
head.

My question is: do they do they same in Germany for their beers? If they
do, I've never heard of it. The one time I was in Germany, I didn't
notice the bartenders taking any longer to pour a brew than they do over
here. Then again, I wasn't in Bavaria where I understand long pours are
common.

So are the long pours in Germany a function of the tap system or the
style of beer? Expiring minds want to know.

> water, bringing it up to 5 gallons - very similar to my extract
> method.
>
> Am I missing something?

Yes. The problem with large wort volumes when making all-grain beer is a result of the sparging process. Unfortunately, the sparging process won't allow the production of a concentrated wort, unless you are willing to leave a considerable amount of extract behind in the grain. Extracting the maximum amount of sugars in the sparge will require you to sparge until the runnings reach a specific gravity of 6 or lower. This requires a certain amount of sparge water, and when you add this to the volume of water used in the mash, you'll always come out with a volume greater than the target beer volume. Mashing and sparging for five gallons of beer will give you a preboil wort volume of greater than 5 gallons (typically 6.5).

British brewers would sometimes split their mash in half, collecting the first runnings for a strong beer and collecting the final runnings for a mild. I suppose you could go that route. Before I got a kettle suitable for 10 gallon batches, I would collect all the runnings in my 48 quart picnic cooler (yes, to the brim) and then divide it and the hops among three kettles (two on my double propane burner system and one on the stove). After the boil, I would chill each pot, put the chilled wort back into the cooler, mix in the yeast, and divide into two carboys for fermentation. Needless to say, it wasn't long before I invested in the proper size kettle. A 33 quart ceramic-on-steel pot can be had for \$25 at restaurant supply stores.

>

It seems to me that this formula does not lend itself to real life dry hopping. I agree with the limits you have established, however the rate of decay, me thinks, might vary considerably in real life situations. For this reason, I suggest that the exponential term in the equation be changed to a product of n and a new variable, Tau, which a measure of a brewers tolerance (e.g. including body weight, drinking experience, sex, and altitude above sea level). Tau would be directly proportional to the brewers tolerance, and as a guess, it would be equal to the 0.36788 times the number of beers it takes to get the brewer so twisted he/she will randomly dry hop the entire kitchen.

I think this addition would be of great help in using this equation to correctly predict hopping efficiencies in real life situations.

> Units have been left off for the purposes of obfuscation.

Subject: Reusing yeast

Two professional brewers in Seattle have mentioned that using the yeast off the secondary is the way to go for getting good healthy yeast cells. But, you might have to build up the amount before reusing.

I have a system that works well with ale yeasts, and in particular, with Wyeast 1056: Primary ferment for 5 days at a controlled 65-72f. Rack and condition in the fridge at 45f to 40f for 8 days. Bottle. Carefully pour the yeast into a starter bottle (32 oz) with some starter wort to make about 20-26 oz of fluid. Set at room temperature. It should be ready for a new batch by the next day (or 2 at the most).

Temperature shock? Not really a problem so far.

It's not the real Guinness (as I had in Ireland). Ironically, there's
more
alcohol in the U.S. version (not by much). The Irish version is pure
velvet -
it was all I drank in Eire. (not that Smithwicks is a bad ale, but
Guinness is
SOOOOO good over there -- forget Harp Lager). To my knowledge, there are
no
Guinness breweries in America, which makes getting an unpasteurized
product
very difficult (impossible). Too bad... Irish Guinness is to die for -
- I
can't drink the U.S. product at all (draught or bottled).

> .
> On the subject of whitbread ale yeast, has anyone noticed a
> similarity in behavior between it and M & F ale yeast?

I brewed a cherry ale ~10 days ago, into which I pitched rehydrated Whitbred Ale Yeast. Within three hours, I had active fermentation, and within 12 hours, I had explosive fermentation. It was fermenting so vigorously that the lid was actually lifted off of my plastic bucket; that's a lid that I have some difficulty removing by hand. (I know, I shouldn't use a plastic bucket- I usually use a glass carboy, but had no way to get the cherries through such a narrow neck.) Good God, what a mess- cherries pieces all over the kitchen!! Anyway, I was able to salvage the beer, and transferred it to a (glass) secondary 36 hours after pitching. The gravity had gone from 1.065 to 1.017 in 36 hours!! Five days later, I bottled it; the gravity was still 1.017.

I thought that this experience was probably due to the cherries, but now, I'm beginning to wonder. Is Whitbred selling a new, mutant, over-achieving, quick-starting yeast? I saved some of the yeast (from the secondary) and will probably use it again in a more traditional ale. I'll definitely brew it in a glass carboy equipped with a what-cha-ma-call-it hose off the top into a waiting receptacle.

What do y'all think?

Subject: Toxic Homebrew

Re: Martin Lodahl's concerns

The statement "Homebrew can't make you sick!", isn't true.
The statement that beer yeasts don't produce toxic substances is true.
The difference being that there are bacteria that can spoil not only beer
that
is fermenting, but even beer that has fermented already (ie these
bacteria are
resistant to the growth deterring effect of alcohol, in fact some thrive
by
reducing alcohol such as acetic acid bacteria).

Fortunately for the judge these same bacteria produce nasally and often
visually
(gushing, rings) apparent signs of their presence.

My question is why as a judge would you taste anything that was such
obvious
symptoms of contamination. As a rule I will not score a beer that has
obvious
contamination. I simply note the contamination, try to identify it fro
mit's
aroma then move on. Being a beer judge may have it's responsibilities,
but the
"taste at all cost" philosophy doesn't do anybody any good. Sick judges
don't
judge welland risk their health, and drinking contaminated beer put
contest
organizers at risk of liability.

Have you gotten sick from beers without obvious signs of contamination??

I would strongly advise any judges out there to let their nose be their
guide.
If a beer smells (or with gushers looks) obviously contaminated, approach
with
caution!!

Subject: Sparging Bags

Mel asks if it wouldn't be better to have a sparging bag with solid sides and a mesh bottom. Indeed it would. Miller (the author, not the alleged beer) recommends a bag with muslin sides and mesh bottom. I thought I might make such a thing, but then found one at me local brew supply store. It has a drawstring top which secures it to the bucket and is sized for a five-gallon food pail. I added one of those little spring-loaded cord locks you can buy in backpacking stores to the drawstring. The bag cost \$7.95 I think. That beats making your own. If you can't find suck a bag at your local store, call The Grape Arbor in Albuquerque and ask for Victor. I'm sure he'd be glad to mail you one. 505/883-0000.

Subject: Help Wanted at Homebrew Store (Boston Area)

Sorry to suck up bandwidth, but this is about the only way to get at the proper audience. My friend, Jeff Pzena, owner of The Modern Brewer (Massachusetts Ave., near Porter Square, Cambridge, Mass.) has found himself in the unenviable position of losing his primary employee. He is seeking someone knowledgeable in homebrewing to replace him. Actually I think he is looking for 2 people, one full time, another part time, but a knowledge of at least the basics of homebrewing is a pre-requisite for the job. I don't know what the pay is, but the hours are approximately (they vary based on the day) Noon-7PM. The store is open 6 days a week, but I think the full time slot is only for 5 of those, the part time provides coverage for the full timers day off, and busy days (ie weekends I think).

If you want more info call 1-800-SEND-ALE, or locally 868-5580.

Please call the above number, no e-mail inquiries. Thanks for your indulgence.

Subject: Re: Malt aromas and DMS

In #695, Darryl Richman, referencing George Fixx, indicates that DMS is a primary distinction between Ales and Lagers w/re to secondary flavor components.

My question is, why? What is different that causes the DMS to hang around the lagers much more than Ales? I have done 8 ales and 4 lagers (the last is still fermenting so make that 3 data points) and the lagers have always had dms smell (creamed corn) that dissapates quickly one the head has formed. My Ales have **never** had this smell.

Is it the high temperature vigorous ferment that causes the difference (blowing more DMS off)? Or is it a function of the metabolism of the yeast used? Lager yeast sure smell different when fermenting! I have made a lager using English Pale Ale and single step infusion mashes - that one (this is from memory because my notes are not in front of me) had the strongest DMS aroma, so it doesn't seem to be a related to using "lager" malts...

Subject: Re: Suitable refrigerators

In HBD #695, Mike McNally inquires about refers for fermenting.

I am successfully using an old 18cf Sears frost free refer (with freezer on top). The price was right: free if I hauled it away. I have a hunter energy monitor, but fiddling with the thermostat was easy enough to do. The only advantage with the hunter is easy setting of temp and less cycling of the compressor (less electricity and longer life). To fudge the built in thermostat, disassemble it. There are a couple of adjustment screws that can be used to set the proper range.

I don't use the freezer section other than to store glasses/bottles before filling with beer. To make it more efficient I used plastic boxing tape to modify the ducting to direct more cold air into the main refer portion. I store filled bottles on the door.

I have three cobra taps set in the side. I can have three firestone kegs in it + a 7.5 gal carboy. I ferment, lager, store and delivery at 48f with reasonable results. Also a week at 48f for newly kegged ales really cleans/clears them up nicely.

Since the floor isn't flat, I cobbled up a false bottom (short shelf - plywood board with another board on one side as a leg) to set the carboy on. The kegs fit just fine without the false bottom. There is no room for shelves.

In other words, just about anything will do. Skip those dorm friges. they are too small (my brew buddy has one and the carboy + airlock doesn't fit) and are suitable only for delivery of one keg.

If I had more room, I would get a second refer to handle lagering of multiple beers. Having room for only one carboy is my critical path in making lagers!

card> leaving the sweet wort trapped in the middle? He calls for
card> an all mesh bag but wouldn't it make more sense to have a bag
card> with solid sides and mesh only at the bottom?

You're right about the mesh bag -- the water does tend to run out of the
sides and avoid the middle. I haven't seen (tho I haven't looked too
hard)
sparge bags with non-porous sides.

Here are two things that work for me:

One of my mash/lauter tuns is a cylindrical 5-gallon cooler made by Gott.
I
found at an Asian store a large plastic collander just big enough to fit
snugly
down in the bottom of the cooler. This is great for 5-gallon batches of
not-too-heavy beer; a heavy bock would probably not fit.

The second is a 54 quart rectangular cooler, Igloo or something. I've
made
a 4-pipe drainage thingy out of 1/2" copper pipe which I slotted half way
through every 1/2" inch or so, and soldered them up with 2 elbows and
three
Ts; it is coupled to the tap with a couple inches of plastic hose. I use
this for my double batch mashes and it gives me a sufficient grain bed
depth. It's not hard to build one -- certainly easier than drilling a
zillion 16th inch holes -- but make sure you use silver solder to avoid
the
lead.

On both, I replaced the push button valve with a drum tap thing.

PS: Through the miracle of ASCII graphics, a diagram of the plumbing:

```
/=====      [] drum tap
| | = T
|=====      /= elbow
| ]---|== slotted pipe
|=====      -- plastic hose
|
/=====
```

PPS: re your real question about 5 gallon boils: you could use 2 5-
gallon
pots, or do like I did and cut a hole in the top of a keg (LOUD!)

Subject: Yeast Lifetime Expectancy

One discussion I have not seen during the last eight months since I began receiving this digest is about yeast lifetime expectancy. To frame my questions, I'll describe my current situation. Let me preface this with the fact that my brewing opportunities have been limited in recent months, so I've had yeast laying around unused much longer than I had expected.

A few months back I brewed what was easily my finest batch. At the recommendation of several HBD readers I used a liquid yeast for the first time, and was pleased enough with the results to culture another starter from a bottle to use in my next batch, which also turned out fine. The other night, I tried again to get a starter going from a bottle from that first liquid yeast batch, boiling up a small amount of wort and being as sanitary as possible. After several days it became obvious that this starter was going nowhere (there was absolutely no activity). I made up another wort, poured in the yeast dregs from another bottle, and waited again, with the same non-results.

Could the yeast in the beer have been too old to make a starter from? That batch had been in the bottle about four months. Is it possible that some storage conditions could have affected the yeast - we had a lot of hot weather around here earlier in the summer. I realize that my technique of starting the culture could also be at fault, but I'm interested in learning how long yeast remain alive but dormant in a beer.

Also, I have a few packets of dried yeast I had bought before my conversion to liquid yeast. These are over four months old, and I wonder how they are affected by age. On those dried yeasts that are marked with dates, how meaningful are they? Can these be stored for long periods of time (> 6 months)? Are there optimal storage conditions for dried yeast?

Thanks in advance for any advice.

Tom

Subject: RE: Oatmeal Stout Recipe

I don't know how this recipe is, as I haven't started brewing yet, but it was posted a few months ago. (I save all recipes in the hopes that one day I'll be able to try them all. :-)

I hope it's a good one. Let me know. And, to whoever originally posted this, thanks!

8lb British Amber Malt Extract
0.5lb Plack Patent grain (cracked)
0.5lb roasted barley (cracked)
0.5lb Chocolate Malt grain (cracked)
1lb Steel Cut Oats
2oz Eroica (boil)
1oz Fuggles (finishing)
Whitbread ale yeast

Procedure:

Crack all grains (except the oats), add to about 2 gal cold water (incl oats), bring to a boil (my table top range takes almost an hour to do this). Remove the grains with a strainer when boiling and add the malt extract and boiling hops. Boil for an hour. Add the finishing hops and continue boil for a minute or two. Turn off heat and let steep for 15min. Put about 4-6" of ice into a plastic bin and strain the wort into it. Sparge. Bring up to volume (5.25 gal) with cold water and mix well. I find that the temp by now is down enough to pitch (i.e. <80F). Rack into 6gal glass carboy and pitch the yeast (I just throw in the dry stuff). Use a blow off tube for the first couple of days! I.e. A plastic tube from the carboy into a jar of water. Bottle when the fermentation is done (usually 2-3 weeks).

NOTE: Quaker Oats can be substituted for steel cut oats.

Subject: thumbrules (sort of)

Greetings fellow brewers,

We seem to be recycling on some topics lately. In the interest of advancing the discussion, I thought that a few thumbrules might be useful. So here goes:

1. If you buy liquid yeast cultures, make a starter.
2. If you are going to be travelling buy Michael Jackson's "Pocket Guide to Beer."
3. Homebrew can't make you sick; but drinking it can.
4. Don't mess with John Polstra.
5. There is more than one way to dry hop a beer, your mileage may vary.
6. Don't touch Rodney's beer.
7. Singha is a Thai beer.
8. Optimal storage of dried yeast is at someone else's house; that way you won't be tempted to use any.
9. Send those @\$%^&! "subscribe me" and "unsubscribe me" messages to
homebrew-request@hpfcmi.fc.hp.com
and be patient.
10. Aren't you Darryl Richman?

Ooogy wawa,

Here in Davis there's a brewpub called Sudwerks, which serves traditional German style beers. A pilsner takes forever to pour, simply because of the

thick, long lasting head. The beer is allowed to drop straight to the bottom of a tall pilsner glass, generating lots of foam. The foam is allowed to subside, and more beer is added until only about 1" of head remains. No special tap, just the proper glass and good beer. The process takes time, but results in an incredibly dense and creamy head. I've been accused of having a dense head, but never a creamy one...

From: strasser@raj2.tn.cornell.edu (Tom Strasser)
Subject: Pouring Times

A comment or two on beer pouring time. I studied as an undergrad for eight months in Bavaria (which is, of course, where my beer love comes from) and had a few German beers myself.

In HBD697 Kinney Baughman writes

> Whatever the case with the bartender, I certainly don't see a
> one-to-one correspondence between quality of brew and length of
> pour.

There has been some confusion here, actually the case in Germany is that the length of pour is a gauge of how good a *Pilsner* is, not other beers. The Bavarians are adamant about this, and have a rule of thumb that it takes 7 minutes to pour a good Pilsner. They take this rule so seriously that many of them will actually look at their watch when they order to ascertain that the beer is not delivered in less than 7 minutes! It should be noted that, if another type of beer is ordered when the pilsner is, this beer will probably be delivered in a minute or two, while the pilsner will come later, after at least 7 minutes.

> My question is: do they do they same in Germany for their beers?
> If they do, I've never heard of it. The one time I was in
> Germany, I didn't notice the bartenders taking any longer to pour
> a brew than they do over here. Then again, I wasn't in Bavaria
> where I understand long pours are common.

I seriously doubt they do this in Bavaria for their beers, to my knowledge, Guinness alone in employing nitrogen dispensing. I didn't spend enough time outside of Bavaria to recall whether pilsners in other parts of the country are poured in this manner, but I suspect in many places they are, Bavarian beer standards have a way of turning up throughout Germany. One place this also seems to be common is in Pilsn, Czech. When I was there, the server would start your next glass of *fresh* Urquell at the correct time before you finished your previous one (say, about 7 minutes before you were done). The next beer would then be delivered to your table at the moment you finished your beer. I found this quite enjoyable as the (1986) black market exchange rate made the cost of each glass about a nickel! Needless to say, we kept our server busy.

> So are the long pours in Germany a function of the tap system or
> the style of beer? Expiring minds want to know.

Well, I was curious of this myself when I was there because the pour is almost exclusively foam when it exits the tap. It comes out very slowly, however, so it is not a function of overpressure or carbonation. As a homebrewer of continental pilsners myself I thought perhaps my head retention was inferior which was why I could not get this head. Alas, while I have made pilsners with excellent head retention (Kinney has tasted them), they did not approximate what I saw in Bavaria.

I found an explanation I believe from the Braukunst (?) kegging supply store in Minnesota. The owner claims that the Germans use a different tap which aerates the beer on pouring. He described a taste test at a Chicago Brewery where they use a tap that can pour in the standard manner, or aerate. He claims this aeration adds significantly to the taste of the poured beer. This test so impressed him that he imported this tap from Germany, and now sells it (for \$47). I have considered getting it, but don't have the bucks. I am curious, does anyone have, or know of someone who has one?

Bis Spater,
Tom

P.S. - How about you Darryl, did you get a look at the taps in Pilsn?

Subject: comments on US Guinness

I too love Guinness, and have had the opportunity to have it on tap and in the bottle in a number of different countries. While it was generally good in Europe, the quality in the US (at least on tap) ranges from quite poor to almost excellent. There are a number of establishments in my local area which serve it on tap, and my experiences here as well as in Irish pubs in Boston lead me to believe that Guinness must be fresh to have that incredible flavor on tap. Unfortunately, most of the places which serve it on tap serve so little that the kegs become miserable in no time.

By far and away the best I've had in the states was in a pub in Boston, where it appeared that they consumed at least a keg every day. This was only slightly off the quality I found in Ireland. Locally there is a pub run by some Brits which has a nice range of UK brews on tap, and the nationality of the owners brings in enough other UK folk that the Guinness is consumed fast enough to keep it reasonably fresh. On the far end, another bar in the area keeps a fair number of imported beers on tap, however 90% of the customers drink MassiveUSCorporationBackwash(TM), and about 5% of the remaining folk drink Guinness, so their kegs are usually worse than the bottled product.

Also, someone commented on the foamy head/CO2/nitrogen setup. I've been lead to understand that the creaminess of the head is a product of the high pressure at which it is pumped (60 psi?) and the aerating effect of the specialized spigot. The nitrogen is used (I believe as the majority (75%?) of the gases) because it doesn't go into solution very easily, therefore it can be used for the high pressure work.

Subject: Dudes...

Hey, thanks you all for the mead recipes. I'm going grocery shopping today and I'm going to get me the stuff I need and make some mead.

I think it's going to be a very satisfying experience. I don't know what mead looks like, or smells like, or tastes like, so just as long as the end product gets me f'd up, I guess I'll call it a success.

(I know there are many people out there who have water analyses done for their brew supplies, and grow their own hybrid hops, and have gadzillions of dollars of beer-making equipment, and sacrifice their children to the beer gods to ensure a good brew - to you all, I apologize for my utter unprofessionalism. May I rot in a land where fermentation never occurs)

BTW, you can't get poisoned and like die from homebrew, can you? Right?

On other things - the slow pouring beer story is fascinating. 7 minutes is a looong time to wait for a beer, though. I'd probably be sticking an Uzi in the guys face going "HURRY UUUUP, Dickhead!!!!!"

I tried an English brew called John Courage the other day. It was pretty good (I don't know the tech. words so I'm not going to use them). Anybody ever drink it? English dudes? BTW, this may sound like a stupid question but why do you all over in England drink your beer warm? No offense but I think warm beer tastes like shit. Anyway, the Courage stuff set me back like \$8 for a sixpack. Man, for my money the best beer is still Miller Genuine Draft Light. (No flames please ;]

From: Martin A. Lodahl <pbmoss!malodah@PacBell.COM>
Subject: Sugared Extracts

A discussion of the adulteration of malt extracts with corn sugars has been going on over in the newsgroup rec.food.drink, and Paul Chisholm of Bell Labs asked me to let HBD in on the secret. I started the whole fracas by making a cryptic reference to recent research that cast the purity of extracts in doubt, and Doug DeMers of Amdahl immediately asked for sources, and more information. So the following day I posted this:

The flap all began in Zymurgy, Vol. 13 #5, Winter 1990. On page 15, in Dan Fink's "Brew News" column, was an item describing a report presented by Professor Michael Ingledew of the University of Saskatchewan to the 1990 meeting of the American Society of Brewing Chemists, on research he and his colleagues were doing on the composition of malt extracts. This research, a combination of High Performance Liquid Chromatography and fermentation studies, disclosed the substantial unlabeled presence of glucose syrup, invert syrup/liquid sucrose, and high fructose corn syrup in the extracts tested. They also discovered poor fermentation from some extracts, due to a deficiency in the free amino nitrogen content normally provided by barley malt (had any stuck fermentations lately?). In the presentation, they did not identify the extracts tested.

I don't have to tell you what a storm that raised! The AHA followed up on it, and in Dan Fink's column (page 14) in the Summer 1991 issue of Zymurgy (Vol. 14 #2) they published a letter from Professor Ingledew in which he said that they indeed were NOT planning to release the names of the extracts tested. They felt they couldn't be sure whether the adulteration was done by the manufacturers, or by the distributors. They also felt their sample might not be representative, as they had only tested 44 "lager" extracts, and no "ale" extracts (their terms). They didn't feel they had the time or money to handle either additional testing or possible legal action. They also felt that the burden of following up on the problem they'd identified rested with the brewing industry, through the marketplace. Then Professor Ingledew closed with this paragraph:

In spite of my comments above, I have complete confidence in the results obtained in my lab by my colleagues. There is no doubt that some manufacturers are profiting from the addition of lower cost corn sugars to malt extract.

Well! Where does that leave us? Neither of the articles made it clear what percentage of the extracts tested had been "juiced", or to what degree. And, of course, we have no idea what they were testing.

I hope you're not too terribly depressed.

Subject: RE: Time to Pour and Guinness

>In Ireland, pouring a pint is ritual. However, after sampling an
>uncounted number of Guinness (and Murphy's) I do believe it does make
>a difference.

Since I am a *big* guinness fan, I must agree that how a guinness is
pulled
makes a noticable difference in the taste. Some places (in the states)
turn the tap pressure way down. This keeps the brew from foaming and
reduces
the amount of time spent waiting for the head to settle. But it makes
the
beer taste thin and bitter, and of course, Guinness looks much nicer with
a
thick creamy head.

We have an Irish Pub a few block from my house that is run by an
expatriate
Irishman. He says another problem with getting *good* Guinness is
storing it
properly. They have the same problem in Ireland. Ask the locals where
the
best pubs are, because not all of them pour a good Guinness.
Interestingly
enough, one place to avoid Guinness is at the brewery itself.

cheers

Guinness is a wonderful brew,
but does it have just one 'n' or two?

From: Tom Bower <bower@hprnlme1.rose.hp.com>
Subject: Ale AND Lager Yeast Together?
Full-Name: Tom Bower

A friend of mine at work claims he makes a homebrew, affectionately known as "moose-heiny" for its resemblance to Moosehead and Heineken, the brewing of which he accomplishes with BOTH lager and ale yeasts pitched together at the same time. The initial fermentation is done at warmer temperatures, and the latter portion in a fridge. He says he can detect some of the characteristics of each in the final beer (which I have not tasted). And the process sounds like a mix, as well.

My question is: has anyone else out there in HBD-land done this? Is it reasonable to expect that the ale yeast will take off during the first (warm) fermentation, and the lager yeast will clean up afterwards in the fridge?

What think ye?

In HOMEBREW Digest #697, my ol' Bud (no offense?) Ken Weiss sez:

>The Sacramento Bee ran a front-page-of-the-Metro section article on the
>recent homebrew festival run by the Gold Country Brewers Assn. The
>publicity was substantially more positive than the last GCBA event, the
>infamous "Smoker you drink the driver you get" display reported by
Martin

>Lodahl. Yo, Martin, were you a judge at this thing? How about a report?
The

>Bee says it was the third largest homebrew contest in the US of A...

Thanks for the plug, Ken! Yep, it was our club, the Gold Country
Brewers Assn., that ran the show, in conjunction with the California
State Fair. And it was a BIG one. Ken Buswell, Brook Ostrom, and
Jim Long played crucial roles in making this a superbly organized
event (I can say that, not having contributed to its success at
all). And yes, I was a judge. For about 10 days before the finals,
panels of judges narrowed down the field. No panel had fewer than
three judges, nor more than 14 beers, and all had at least one BJCP
participant. The finals received a surprising amount of coverage,
and the journalists were treated to all the (ahem!) hospitality we
could offer, which seems to have borne fruit. It's been a
long-standing practice to bring in BJCP judges from other clubs for
the finals, and the cast of characters looked surprisingly like the
group that did the Left Coast First Round of the Nationals ...

Best of Show was won by Ray Call of Stockton, for a pale ale --
considering the number of these entered, it must have been SOME pale
ale! Congratulations, Ray!

Subject: Judging Sick Beer

In HOMEBREW Digest #697, Jay Hersh offered:

> The statement "Homebrew can't make you sick!", isn't true.
> The statement that beer yeasts don't produce toxic substances is true.

I agree with that.

> The difference being that there are bacteria ...

And I would definitely include fungi, and am tempted to include wild yeast as well.

> Fortunately for the judge these same bacteria produce nasally and
> often visually (gushing, rings) apparent signs of their presence.
>
> My question is why as a judge would you taste anything that was
> such obvious symptoms of contamination.

Well, if it's THAT obvious, I for one, usually won't. But it usually isn't that obvious. Gushers, for example, can also be a result of (damn severe) overcarbonation, of otherwise harmless wild yeast, or of mishandling. I'd hate to dump a beer untasted because it had been mishandled by contest personnel.

> I simply note the contamination, try to identify it from its
> aroma then move on.

Good rule, if the contamination is that clear-cut.

> Being a beer judge may have it's responsibilities, but the
> "taste at all cost" philosophy doesn't do anybody any good.

In light of my recent experiences, I'm coming around to your point of view on this, Jay. I've been trying to give every beer the best shot I could, but as my experience grows, so does my caution.

> Have you gotten sick from beers without obvious signs of contamination?
?

Yes. The one that gave the whole panel headaches and slight vertigo had no other sign of trouble, except a strange moldy note in the aftertaste.

> I would strongly advise any judges out there to let their nose be
> their guide. If a beer smells (or with gushers looks) obviously
> contaminated, approach with caution!!

'Nuff said.

Subject: Guinness & Nitrogen

Kinney writes:

>As for Guinness, the foamy pour results from the special tap system they
>employ. There are two inlets for compressed gas in a Guinness tap. One
>introduces more or less 25% nitrogen. The rest is CO2. I've always
been
>told that it's the nitrogen that gives draft Guinness its extraordinary
>head.

I have read that the incredible head is due to the fact that the beer is
dispensed at very high pressure. It is also well known that nitrogen is
not very soluble in beer (the Rotterdam (I believe that's the name)
brewpub
in Toronto uses a nitrogen/CO2 mix to dispense their beer because when
they
used pure CO2, it caused too much carbonation). Putting those two facts
together, the following is simply my speculation, but: I suspect that the
reason Guinness uses their special tap system and nitrogen is to allow
them
to dispense at the high pressure without causing carbonation like Coca-
cola.

I have not heard the 25% nitrogen, but for my above theory to work, it
should probably be mostly nitrogen and only a small amount of CO2.

Al the Speculator.

Subject: MALTING BARLEY, AGAIN

I note, with some cynicism, Darryl Richman's comment in Zymurgy, that the brewmaster of Pilsner Urguell seemed totally ignorant of the malting process.

From the responses I received to a very basic question on malting, that particular form of ignorance seems to apply equally to home brewers.

The diagram in the article came tantalizingly close to answering my question but left out details that could be used in action.

As I suspected, in order to get acceptable germination, dormancy must be broken. He talks about three steeping periods and a temperature range but leaves out what separates one "period" from another.

What happens after 21 hours at 15-17 degs that separates this period from the next 21 hour period or from the final 17 hour period?

I have been experimenting with freezing, friging and steeping but surely someone out there can save me from re-inventing the wheel.

Darryl.... where are you? Finish your article.

Subject: Singha

Singha is indeed Thai and has more in common with a German Pils than any other style of beer. (German technical help was used in 1934 to set the brewery up).

With all of the comments in the last couple of HBD's, I'm amazed that most people called it "malty". The key word here is "hoppy, hoppy, hoppy", (although it does have enough malt sweetness to not be way out of balance). Singha is brewed with an OG of 1055, alc. is 6% by volume, and it has , according to Jackson, "a hearty 40 units of bitterness." When fresh, it is a world class beer (IMHO). It's the hoppiness that helps it cut through spicy foods so well.

Subject: Good Guinness depends on Freshness, Tap, Pouring Style

First, a comment on Bavarian Pils and pouring:

strasser@raj2.tn.cornell.edu (Tom Strasser) writes:

> The Bavarians are adamant about this, and have a
> rule of thumb that it takes 7 minutes to pour a good Pilsner.
> ...
> The owner claims that the
> Germans use a different tap which aerates the beer on pouring.
> ...
> aeration adds significantly to the taste of the poured beer. This

I was in Bavaria for almost 2 weeks on a business/pleasure *-) trip and agree with the above after careful observation and analysis ;-). After asking the barmaid "where's my bier" on the first day she said she was working on it. The tap seemed to "spit" the beer out into the tall thin pilsener glasses, and it foamed up a lot, then settled, then some more pouring, and so on. Some of the head would get scooped out during this process until a nice full glass with an over-the-top-head remained.

Great stuff.

Now onto Guinness:

I've been supping Guinness for at least 12-14 years and where you get it, the type of tap, and how it's poured makes a HUGE difference! Probably #1 is the tap type. It's got to be the patented Guinness tap that uses nitrogen. Fresh Guinness out of a regular tap produces a bubbly dark brew, nothing like the real thing or the way Guinness should be. The nitrogen tap produces the creamy head with "micro-bubbles" and a much smoother product.

The Guinness must be fresh for the brew to be a *good* Guinness. A couple of bars in Dorchester (Boston) would have great Guinness on Sunday afternoons after a new keg would be tapped from the previous nights.

The best place for Guinness in the Boston area is in Cambridge at the Plough & Stars. It's the prevalent brew drunk there and is always fresh (particularly on weekends). They know how to pour it: nice and slow, though it depends on the bartender. They typically have a few lined up and settling at the bar, about 1/3 to 1/2 full. When you order one, the bartender fills the remainder of the glass (in two or more steps if you're lucky ;-). I'd usually ask the 'tender to start another before I'm finished with the current one so there'd be no rush.

A slowly poured Guinness, where a bit is poured at a time, then settled, then

more pouring/settling, makes a huge difference IMO.

Even in the UK they poured it too fast sometimes.

From: "Harold A. Rosenberg" <rosen@rockies.eecs.umich.edu>
Subject: Brewpubs/bars in NYC?

I was in NY a couple of weeks ago, and a friend took me to McSorleys. It is billed as the oldest bar in NY City. They have two choices of beer, light and dark, and you usually order two at a time because they are in such a rush that they only fill the glasses half way (they are priced accordingly.) The beer was pretty good, and the atmosphere was interesting. It seemed more the run down type of place that you would find in a college town than a NY bar. It was a definite relief from all of the overpriced trendy places that I had seen in NY.

Have Fun,

Hal

I would classify such a higher gravity beer as a "weizenbock".
A "dunkelweizen" should have some roasted grain flavor/aroma.

Weizenbocks have the characteristic of bock sweetness but with
wheat flavor (duh!) and the phenolic nose of weizen yeasts.

I am pleased to announce the creation of a Hard Cider Mailing List, with me as it's humble organizer.

To get on the list please do the following:

- 1) Send Mail to cider-request@expo.lcs.mit.edu
- 2) Put the word Subscribe on the subject line
- 3) Include your preferred e-mail address in the body of the message, I don't want to rely on the included reply address

To get off the list or stop multiple copies:

- 1) Send mail to cider-request@expo.lcs.mit.edu
- 2) Put the word unsubscribe on the subject line
- 3) Include the e-mail address to which the cider list has been getting sent in the body of the message (again I don't want to rely on reply addresses)

To submit to the list:

- 1) Send mail to cider@expo.lcs.mit.edu

Thnigs to remember:

- 1) This is an echo'ed list not a daily digest
- 2) There is a human processing subscribe/unsubscribe requests
- 3) Please no flaming!! Let's try to keep this on a par with the HBDS quality

A lot of people sent for my cider write-up a few months back. I think I have saved all or most of your addresses. I am considering automatically subscribing those people, except for the few who specifically asked not to be subscribed. So if you don't want to be on it and you'd received the cider write-up please write me soon and I'll take you off. Otherwise I will start this list up early next week.

Enjoy.

JaH

PS Presently this offer is only being made available to HBD Subscribers and not the newsgroups. This is in order to try to keep the discussion level high, and the traffic volume manageable.

Subject: NYC, dry malt extracts

I'm no expert on NYC beer (since I live in California), but on my last visit to Brooklyn my friend introduced me to a local beer called (appropriately enough) Brooklyn Lager. Don't have any idea where it is brewed exactly, but it is worth a shot. Seemed a bit heavy and dark to me, but it was much better than the other yellow-watery stuff most bars serve.

I remember hearing somewhere that dry malt extracts are actually made for the bread-making business, not the homebrewing business (if you'd call homebrewing a business!). I had heard that this is the reason you can never be sure about the color a dry malt extract will impart to your brew--because bread makers couldn't care less about Lovibonds! Perhaps this is why the dry malt extracts tested and reported in Zymergy had so much other stuff in them. Please that (a spelling error) take the above information with a grain of salt--I can't remember where I heard it. If anyone out there knows the truth, I'd be interested to hear it. I have abandoned dry extracts for that reason.

Where does one get Calcium Chloride? I've been egetting most of my supplies from Great Fermentations of Santa Rosa, but CaCl doesn't seem to be one of the brewing salts that they sell. I want it to eliminate the 500-770 ppm of bicarbonate. Boiling the water after/ addition of enough CaCl ought to remove most of the carbonate, and the Chlorine should evaporate upon boiling. Anyhow, any info on where you all get the stuff would be helpful. It seems like a chemical distributor would be the best bet because you could buy a ton for really cheap, but I'm unsure of the purity of something from a chemical company--no offense to those in that industry, but. . . .

Thanks, adios.

Subject: Re: Oatmeal Stout

In HBD #698 a recipe for oatmeal stout showed up. It listed Steel cut oats as the source of oats. Speaking from ignorance (about the beer, not oats) I would think that it would be better to use rolled oats. Rolled anything (oats, wheat, barley) has been pre cooked by the hot rollers. The cooking gelatinizes the starch and breaks down the structures to make the starch more available. Steel cut oats would have to be cooked some amount of time before adding to the mash. Another word for "rolled" would be "flaked" and flaked barley/wheat is often called for in brewing as they can be added directly to the grist w/o cooking.

From: microsoft!larryba@cs.washington.edu
Subject: Re: Aluminum clad pots

Spend the extra \$'s. The cladding lessens the carmelization of sugars on the bottom of the pot. With my old enameled pot I *never* got off some of the carmel/carbon after a few brews. With the new clad pot what is down there is a small quantity of light colored, easily removed stuff.

Some unsolicited hints: I use a wimpy electric stove, so I wrap my pot with a layer of insulite to speed the time to boil and create a more vigorous boil. I find that putting a couple of chop sticks between the lid and the pot (i.e. lift the lid up 1/4") allows me to have the heat cranked on full and never boil over - yet I get a vigorous boil that fills the 4 gallons of head space with foam/hot break.

Subject: Filter canister sale at Builder's Square

Builder's Square, friend of the gadget-crazed homebrewer, has another pretty good deal until August 13th (in my area). They are offering the Teledyne Water Pik Water Filter Canister model K-50 for \$9.97, normally \$17.97. Combine that with a polypropelene filter cartridge (see below) and some sundry plumbing bits and pieces, and you can be filtering beer (or water destined to become beer) for less than \$20. I intend to filter beer between two soda kegs, a la Rodney Morris' article in Zymurgy several issues back (just after the Kentucky AHA conference).

Filter cartridges: Morris' lists several suppliers. Builder's Square has all types for the Teledyne, but I think they were cheaper directly from Teledyne (\$12.99 including shipping for a Teledyne IR-20W Twin 2-pack, polypropelene wound-string style). Morris reuses them by soaking in a lye solution and then a bleach solution.

Subject: How do I pour my Homebrew???

After reading about the length of time required to "properly" pour Guinness, I was wondering how should I pour my homebrew?

Anybody care to email/post a list of how to pour the different styles, or should I JRaHaHB (just relax....)?

Also any info you want to send about how you repitch your yeast would be appreciated...

peace,
greg

Subject: Unwarranted Beginner's Worries aka "It's Alive!"

I want to thank everyone who replied in the digest and directly to me for relieving me of my worries concerning the lack of bubbles in my bottled beer. As you all pointed out, the action was too slow to see visibly. I popped open the first bottle and was met by a beautiful sound "fsst". Sounded good, tasted good, it's homebrew! For my first try, I'm pretty satisfied. Next time I'm gonna use all malt during the primary instead of cheating with a little corn sugar. That should give me a fuller body taste, correct? Can you use DME or something along those lines for priming?

Again, thanks for your help.

Subject: It's the yeast I could do...

I live on the coast of Maine (hee hee hee :->) where homebrew supply shops are few and far between. It is rare that any of the three stores that I am aware of have anything other than your standard Red Star dry yeast :-(. Certainly there is nothing like the selection I've heard of on the net (German ale yeast #1007 !?! what!?!). Is there another store in Maine (other than the Whip&Spoon, the Purple Foot, and the Grainery) or is there a reliable mail order house? Any addresses or phone numbers would be much appreciated.

Oh yeah, any idea why a beer would gush when opened warm but not when it's been chilled?

From: rdm5g@hemlock.cs.Virginia.EDU
Subject: Bottles and Storage

With regard to beer bottles and storage, the domestic brands come in the very convenient, heavily waxed cardboard boxes. They are great for aging and storage.

What do you folks do when these boxes wear out. I haven't run into this problem yet, but I expect to in the near future. What I would really love to get my hands on are some of the old wooden crates that the returnable Coca-Cola bottles were shipped in. Guess it is time to start hitting rummage sales....

Sooner or later I will have to begin using kegs and leave the troublesome bottles behind.

any input?

Subject: Vapor bubbles in thermometer

OK, heres an interesting situation. Recently I set out to make a batch of all-grain something-or-other, and thought things couldn't get any worse than the time I tested out my home-made counter-flow wort chiller two weeks ago.

As usual, Murphy found me and slapped me over the head with his law. While checking my equipment, I found that my thermometer had developed a case of the bends. It had several distinct vapor bubbles in the mercury column, making it offset by an unknown amount.

A simple solution would have been to calibrate it in ice water and boiling water, and hope that the vapor bubbles didn't vary with temperature. The other solution I thought of was to somehow force the mercury back together again. Shaking it didn't help; I couldn't develop enough force. Then I tried centrifugal force. I put the thermometer in its case, plugged it up, and duct-taped a long piece of cord to one end. I know, you can see it coming already, but let me finish. I proceeded to swing the contraption about my head, gradually letting out string. Occasionally I stopped, and not seeing any results in the mercury column, I proceeded to swing it faster and getting madder.

If your thermometer ever gets the bends, don't use this procedure. Forcing the bubbles back together had as much effect as forcing the Yugoslav's back together. While letting out more string and swinging it faster, I heard a distinct(you guessed it) crash. The end of the case made contact with a palm frond, and the resulting shock reduced the thermometer to a mass of glass shards and liquid metal. Perhaps I should have tried the calibration method first.

Anyway, if someone has had this happen before, and managed to solve it, could you let me know? It will give me the satisfaction of knowing what I could have done instead.

By the way, is there anybody out there in the San Diego area that knows where I could pick up a thermometer cheap...and quick?

Subject: cooling wort with ice (from rec.food.drink)

When one of the posters on the Netnews rec.food.drink group posted about boiling and then cooling (but not freezing) his water, I was moved to ask the following:

What would happen if I tried to cool the wort in the pot by adding ice? If I was concerned about water quality, I could freeze boiled or spring water. This would cool the wort faster than adding cold water. The wort would give up heat equal to the ice's heat of fusion (ice absorbs a *lot* of heat when it melts). Would the cold break not work?

There were some very nice followup postings (with two people saying they'd done this to good effect). I thought the information should be shared with the Homebrew Digest. I've done some minor editing, mostly of header lines and margins.

compares to full-volume boil and wort-chiller.)

The only caveat I have heard of is that your freezer is a source of bacteria and such. So I always boil the water, pour into wide-mouthed containers (so the ice can get out), cover tightly, then chill and freeze. Thus I am reasonably assured of getting sanitized ice for chilling.

Subject: cooling wort with ice (from rec.food.drink)

Assume you have five gallons of 100C wort (just boiled). How much ice will it take to get the temp to pitchable temp? Well, you need to drop five gallons by 80 degrees C. If I am correct in remembering that water's heat of fusion is 80, then an equal amount of 0C ice will be needed to lower the temp of some amount of 100C water. Thus, you would need equal volumes, which is quite a dilution of the original wort. Note that this is pseudo-scientific:

a) wort is not equivalent to H2O (I believe wort takes more than 1 calorie to raise 1 gram, 1 degree C). Thus more ice is needed.

b) the original ice is now liquid, but still at 0C, and would thus mix with the wort cooling it further. Thus less ice is needed.

While I would be surprised if a & b cancelled each other out, they have opposing effects. I believe b would have more of an effect. The key here, is that is going to take a lot of ice probably somewhere in the range of 25-50% of original boiling wort volume. Most brewers (even extract) like to boil the entire quantity of wort, (for reasons more than simple infection possibilities, but I won't get into that), not diluting it at all - this is why we have wort chillers. Mind you this is just a pet diagnosis obtained without full consideration of the entire data. Would ice affect cold break? I don't know. My inclination is yes, but to a minor extent.

Newsgroups: rec.food.drink

Subject: Re: cool wort with ice???

Date: 30 Jul 91 20:10:22 GMT

Organization: Pacific * Bell, San Ramon, CA

Subject: cooling wort with ice (from rec.food.drink)

In fact, if you're not boiling the entire wort volume, this method works wonderfully well. You'll get a great cold break. Until I went all-grain, I used this method with considerable success.

The principal advantage of adding ice to the kettle rather than pouring boiling wort over the ice is that agitating hot wort in the presence of air will oxidize the melanoidins in the wort. Over time, these will then serve as a catalyst for the oxidation of alcohols into aldehydes, producing stale, papery, and cardboard-like flavors. Oddly, if the melanoidins remain reduced (as they usually are at the end of the boil), they can retard this same reaction (see Fix, George: "Principles of Brewing Science").

Subject: Book: Under the Influence

Well, I just finished Under the Influence - The unauthorized story of the Anheuser Busch Dynasty. I must say I enjoyed the book. Lots of scandal and such. Two things I did find disturbing, though.

1. The authors make very little mention of the taste of A-B's "product" over time. The only real mention it got was in the last chapter. After dumping on them for 400+ pages, they praise A-B for the ability to make ~ "arguably the finest mass produced beer in the world."
2. Throughout the book, all the Busch's are praised for their unerring battle to maintain quality in the beer. August Sr. was praised for not changing the recipe to make it sweeter after the repeal of prohibition. Gussie was praised for not shortening the lagering process to match Schlitz in the early 70's. There were other things mentioned, but all pointed to A-B not modifying their "process" to make the "product". Now, is this true? Has Bud not changed in 100+ years? I doubt it.

A good read. I recommend it. I wish August III would use that drive of his to make a style of beer that I like.

Subject: Malts & Carboys

First off, thanks to the MANY people who responded to my first query: all of the information I got was helpful and informative. Sorry I couldn't respond, but it's been a busy week.

Okay, I'm a rank novice homebrewer. I have a few specific questions:

1) What advantages are gotten out of a carboy rather than bucket? Will it make a difference for my first few batches which will undoubtedly be made with "commercial" hopped malt syrup? How much should I expect to spend on one? Can I get one anywhere but a homebrew shop?

2) Could anyone describe the differences between
a) Various brands of hopped malt extract.
b) UNHOPPED malt extract, and the hopped kind.

I think I have a handle on the from-scratch method (although I'm not ready to try it, yet). Basically, what are these prepared "syrups" really going to produce? For info, my "starter kit" came with John Bull hopped amber.

Yes, I know these are probably amazingly naive questions, and I am going to find out someday through experimentation, but I'd like to hear others' experiences.

Subject: mead questions

I've been making homebrew for about 6 months now, 6 batches and have been happily consuming/sharing the results. This past weekend I brewed a Barkshack Gingermead, based on Papazian's recipe, which is now fermenting away in the closet at about 70-75 degrees F. Neither Miller nor Papazian (to my recollection) discuss mead very much, and my trip to the library produced very little more. At what temperature should this mead be fermented? At what temperature should it be aged after bottling? Do you have any helpful tips about this recipe, or mead in general? Thanks much for any info.

Subject: re: Pouring Times in Pilsen

strasser@raj2.tn.cornell.edu (Tom Strasser) asks:
> How about you Darryl, did you get a look at the taps in
> Pilsn?

Nope, I didn't. I drank at the brewery's restaurant, and didn't see the taps themselves. It did take a while for the beer to show, but I was busy pumping Jaroslav for more information. At the various pivnices I drank at, there were no legendary pours; watching the barman working was akin to watching a barman at the Oktoberfest or in the Englisher Gartens, which are renowned tourist traps where you pay outlandish sums for a liter that apparently doesn't have to come close to the mark on the glass. (But it's fun anyways. I hear that this year it's going to cost over 8DM for a "liter" of beer at the O'fest.) Of course, even at official exchange rates, a half liter in Czechoslovakia was only about 30c, and their glasses were made with a lot of room at the top for foam.

It is true that ordering a Pils in Germany does take a long time to pour. The altbier in Koeln is also very slow. I have always been informed to order another one just as soon as the first arrives, and the same for Guinness.

You can almost do this even with Bud (well, maybe not for 7 minutes, but you can stretch it out quite a bit) by pouring down the middle. The European theory is that the CO2 is harsh and unpleasant, and the way to get rid of it is to have strong turbulence to degas the beer as much as possible. The English are ahead in this score, since they bleed it off before serving.

From: "Jean B. Hunter" <MS3Y@CORNELLA.cit.cornell.edu>
Subject: Gushes, Boxes, and Thermometers

Nils Nieuwejaar asks why a beer gushes when warm, not when cold. Carbon dioxide, like any other gas, is more soluble in cold liquid than in hot liquid. Gushing occurs when two conditions are present: nucleation sites for submicroscopic bubbles to form, and supersaturation of the gas, so there is a driving force for the bubbles to grow. When your beer is warm, the supersaturation is greater, so it is more prone to gushing.

The heavy duty cardboard boxes that we all know and love are called carry cases, and are sometimes available at bars or bottle/can redemption centers. Evidently the boxes are deposit/redemption items (like bottles) for the bars that use them. They are lighter than wood and totally enclose the beer, preventing photochemical damage. The only drawback vs. wood is that they will get soggy if your basement floods :-).

Re thermometers : If your thermometer develops gas bubbles in the stem, put it in a beaker of crushed dry ice (plus acetone if you have any). The mercury will contract until all of it is down in the bulb. Then when it warms up it will refill the stem from the bottom, with no bubbles. This works about 75% of the time. P.S. I hope you don't have any little kids around, since the small particles of mercury from a busted thermometer will gradually evaporate, releasing mercury vapor (a mild but chronic toxin) for weeks or months. What's more, ingestion of even small amounts of liquid mercury can cause mercury poisoning. If the mercury didn't all stay in the case, find a chemical safety expert (probably @ the chem department of your local college) to advise you on cleanup.

Cheers -- Jean

From: bliss@csrd.uiuc.edu (Brian Bliss)
Subject: Oatmeal / enzymes / sugar extract / Chimay / thermometers

On Oatmeal Stout:

You HAVE to mash the oatmeal with some malt, preferably lager malt, in order to convert the starches to sugars. It just don't work if you don't - believe me, I tried it. You'll wind up with a thick, syrupy wort, but the specific gravity will not reflect this. Much of the starch will settle out into the fermenter. The resultant beer will have no head retention. My batch got infected shortly after bottling, and good riddance.

- - - - -

What is relationship between the type of malt, degree of modification, and enzyme content? Pale ale malt is low in enzymes; is this due to thin husks, undermodification, or the kilning process?

- - - - -

On corn sugar in malt extract:

If you buy it dry, it is easy enough to look for the shiny crystalline corn sugar. If I'm not completely off base, pure spray-dried barley malt is much duller, and slightly more compact than that adulterated with corn sugar.

- - - - -

Has anybody tried culturing chimay ale yeast lately? My recent attempts have turned out much more sour than they were just a few months ago. Is it the change in seasons over in Belgium, or perhaps related to the temperature in my kitchen?

- - - - -

> I found that my thermometer had developed a case of the
> bends. It had several distinct vapor bubbles in the mercury column,
> making it offset by an unknown amount.

Get it cold enough to where the all of the mercury contracts back into its little bubble. Try dry ice, or a liquid nitrogen freezer.

From: lutzen@phys1.physics.umr.edu (lutzen)
Subject: John Bull Extract

I have used John Bull light and dark, hopped and unopped, very successfully.
I have very little choice when buying extract locally, ie. a choice of two.
John Bull was always a bit cheaper than the other brand, and that was my deciding factor. I have had no problems with it, but don't follow their instructions and add the 6 cups of corn sugar! I tried it once, and after about three weeks in the bottle, the cidery taste finally went away and wasn't too bad after that.

Here is my favorite recipe that I use John Bull in:

Lutzen's Pleasing Porter

1 - 3.3 lb can John Bull unopped Dark
1 - 3.3 lb bag Northwestern Amber Malt extract
1.5 oz Clusters (boil)
1 oz Cascades (finish)

Bring 2 gal water and malt to a boil. Add .5 oz Clusters at beginning of boil, 20 minutes, and 40 minutes. After 60 min. turn off heat, and add Cascades. At this point it was late in the evening, I poured the wort into my sanitized bottling bucket and brought the quantity up to 5 gals. and stuck the whole thing in the beverage refrigerator. Next morning I siphoned off the wort into the fermentor, leaving all those hop particles behind, pitched the yeast (Red Star Lager. Please! NO COMMENTS. It's hard enough getting supplies here.) Put on the blow tube, and put the fermenter back in the refrigerator. I had the Temp. set at 45 degrees. After a week, I replaced the blow tube with an airlock, and bottled after a month of fermenting.

S.G 1.052
F.G 1.016

Very smooth, nice hop balance, but a bit heavy for a summer drink. Will try to save the rest for this fall.

Karl "who knows what's next" Lutzen

From: cjh@diaspar.HQ.Ileaf.COM (Chip Hitchcock)
Subject: re Vapor bubbles in thermometer

Many thermometers have a relief reservoir at the high end. This may be useful to prevent explosions if the thermometer is heated above its range, but I have also been told in the labs I used to work in that you can sometimes drive the mercury up into this reservoir and get the mercury back in one piece. Try concentrated salt water (at least 12 ounces (weight) of salt per quart of water), probably in a stainless-steel pot (aluminum could corrode in boiling salt water).

The opposite approach, using rubbing alcohol or glycerine in a freezer, might also work, but it's unlikely your freezer will go low enough (and I'm not sure what the freezing point of mercury is...).

Subject: new york places/glass versus plastic

Hello from a Chicago-area homebrewer. I've been reading the digests from #697 on and have enjoyed the discussion.

re New York places to visit: I suppose McSorley's is a must visit, but just east of it on the same side of the street, you'll find Brewski's. The neighborhood is part-Ukrainian, and you're liable to find a mix of beer lovers and USSR expatriates--thus the name. I recall roughly 7-10 beers on tap, including Old Foghorn (!) and a brown ale from the Brooklyn Brewing Co. There also is a list of easily a couple hundred bottled beers from around the world and U.S., and the prices weren't bad (for New York). Brewski's is a tiny place, with a short bar and a handful of tables, but well worth the visit.

Within walking distance, just south of Washington Square and the NYU campus, is the Peculier Pub, at Bleecker and LaGuardia. Again, you'll find a draft selection of choice German and English beers, including Fuller's ESB (!) the last time I was there, along with a large bottled list.

Finally, at the south end of SoHo, on Thompson Street, is the Manhattan Brewing Company, a brewpub featuring a number of draft products.

All over Midtown, you'll find Guinness, Bass, and New Amsterdam. I usually try to stop at Rosie O'Grady's (the bar, not the restaurant) for a Guinness. It's typically drawn slowly for the creamy head. Have you ever seen those bartenders who leave a signature shamrock in the head? They say you should be able to float a coin in it! Rosie's is on 7th Avenue at about 50th (north end of Theater District).

re Mr. Berger's question on carboys versus buckets: the usual reason given for using a glass carboy rather than plastic is a good one, namely, the glass is less likely to scratch when being cleaned than plastic. The small scratches in plastic might harbor bacteria that will contaminate your wort in primary. The real reason to use glass is so that you can watch your beer! Seriously, with plastic buckets you know something's going on in there, but you can't really see it, and there is a temptation to lift the lid, thereby risking contamination. With glass, in addition to seeing how far along your fermentation is, you get to see the yeast clumps roll around in the wort! I've brewed about 25 batches now, and I still find this to be amongst the most fun parts of the process (next to sipping the beer and crafting a recipe).

Subject: Re: Vapor bubbles in thermometer

As to where you can buy a thermometer cheap and quick: I use a darkroom thermometer, available at any photo store for \$10-\$20; ok, maybe that's not cheap enough, *but* they are fast acting bimetal devices (harder to break), with an easy to read dial. Oh yeah, they glow in the dark, if that helps :-). Mine is `recalibratable', which means that I can rotate the dial w.r.t the needle if it ever gets out of whack.

Carboys are easier to keep clean than buckets -- they don't scratch like plastic -- so there will be less chance of infection. I wouldn't worry about getting one until you've got the technique of brewing, cooling, fermenting down; it's easier to pour stuff into a bucket, and if yours has a spigot on it, easier to hook up the bottling hose. You can pick up a 5 gallon carboy for about \$8-12; I got a 7 gallon one from Colonel John for about \$15-20 including shipping. Homebrew shops should have them, and I picked a couple up from a housewares (dried flowers and stuff) shop.

John
Peter> Bull hopped amber.

The hopped versus unhopped extract is pretty simple: the manufacturer has put hops (of *his/her* choosing) into the syrup; same with `stout', `amber' or whatever-style syrups. You can produce good beer with them, but you give up some control and freedom. I like using the unhopped, light (un-dark, not `lite'!) extracts, then adding my own hops, and coloring/flavoring with specialty grains. The AHA has a nice, free pamphlet which describes how much of what grain to use to achieve various styles; I think they call it something like ``Using specialty Grains''.

By ``from-scratch'' are you talking about all-grain? Stay with the syrups for a while -- get the techniques down before talking the all-grain plunge. You'll learn very rapidly, but it's easier if you learn one or two things at once!

Good luck.

Subject: John Bull extract

Greetings,

Dave Sylvester asked about John Bull extract and I've recently been wondering about it also. I have made a few good beers with JB amber and dark (both unhopped), and I'm thinking about using it a lot more. So I was thinking about this brewhaha with adjuncts in extract. According to Zymurgy's special issue on malt extracts (V9,No4,1986) the "AHA Definitive Guide/The Lowdown on Malt Extracts" (pp20-23) lists the ingredients for JB's light and amber as just "malted barley extract"--the dark has caramel as an additional ingredient. My question is how reliable is this? In the table did they just write down what the label said? Or were they sneakier than that? After all they do list the Bittering Units per can; that is certainly not listed on the label. Does anyone know anything about this? By the way, some of JB's other extracts are listed as having more than just malt and caramel. Some, like the American Light (why bother any way-- pardon my snobbery) have corn syrup, and their Master Class kits have stuff like iso-hop extract, coloring, Irish moss, and sodium bicarbonate! I guess they try to do it all for you. One thing that seems to be found in a few M&F extracts that I can't figure out is d-glucitol. Anyone out there know what this is (I'm a physicist, I don't do chemicals)?

G'Day,

Joe

Subject: John Bull extract

When visiting New York, and looking for a great place to taste some truly exotic brews, one cannot afford to miss one of my old time favorites:

B R E W S K Y ' S B E E R B A R

With over four HUNDRED (400) brews and ales to choose from, it effectively manages to blow away any competition, including the famed McSoreley's. The place is small, sawdust on the floor, NO commercial beers (no Bud, Coors, or any other brands who have the tenacity to call themselves beer makers), rock-and-roll on the radio, Harley Davidsons rumbling on the street outside (and sometimes inside too|), all of it in the Village on E. 7th St.

Rating: ***** Five Stars, by yours truly.

Enjoy, and No, I'm not getting paid for this.

Thanks,

Pete

Subject: NYC pubs -- a brief trip report

Thanks to all who responded to my query. I guess I went to all the pubs which were mentioned except The White Horse. Here are excerpts from some of the respondents and my comments:

From: "Harold A. Rosenberg" <rosen@rockies.eecs.umich.edu>

> I was in NY a couple of weeks ago, and a friend took me to McSorleys.
> It is billed as the oldest bar in NY City. They have two choices of
> beer, light and dark, and you usually order two at a time because they
> are in such a rush that they only fill the glasses half way (they are
> priced accordingly.) The beer was pretty good, and the atmosphere
> was interesting. It seemed more the run down type of place that you
> would find in a college town than a NY bar. It was a definite relief
> from all of the overpriced trendy places that I had seen in NY.

I found the light a bit thin, but quite respectably hopped. The dark was a bit too sweet for my taste, but decent; my companions preferred the opposite of me. We stopped in about 5pm on Saturday, and the place was crowded, so I would avoid it at night.

From: mittle@watson.ibm.com (Josh Mittleman)

> The Manhattan Brewing Company, which is in lower Soho. I think it's on
> MacDougal at Spring St., but don't quote me. They brew five or six
kinds
> of beer, and serve a decent southern-style barbeque to go with it.
Decent
> food, great beer.

If I recall, they're on Broome just west of Broadway. Didn't try the food, but they had a *very* good Bavarian style weizenbier. Their amber was OK and their stout too sweet, but I had these after the weizen so my opinion may have been biased. The place? We got attacked by a cockroach, the music was more suitable to a dance club, and the interior looked like a mutant hybrid between techno-industrial and wood-brass fernbar. Service was good and prices were decent.

> The Slaughtered Lamb Pub, on 4th St., west of 6th Ave. If you knew the
> Peculier before it moved, this is in the same place. They have a brew
> called Full Moon Ale, which is their own. Very nice. They also have
ESB
> on tap.

I enjoyed the Full Moon, but thought it was a bit thin -- I preferred the ESB which seemed more balanced. Their beers are made for them at ``by a small brewer in upstate New York'' (any guesses? :-). Good selection of other beers, too. The interior looked inviting, but we sat outside and watched the crowds go by. Pleasant experience, but their prices were rather high -- about \$4.50 for a pint of Full Moon or ESB.

> I've heard of a place called the White Horse, on Hudson St., but I haven't been there yet.

Neither did I -- no comment.

> McSorley's is a tourist trap. Not worth the trouble, in my mind.

Seemed that way -- we were walking down the street and got accosted by a carful of Virginians demanding that we tell them where Mecca -- er, McSorley's -- was.

From: GERMANI%NSLVAX@Venus.YCC.Yale.Edu

> I highly recomend McSorleys, although go early in the day so as to avoid the line. I don't think that it is worth waiting hours in line for.
> They only serve their own beer (and coke). The dark is better than the light. They sell it in small mugs and you must buy two at a time, but that's no problem because you'll probably want to drink more than that.
> When McSorleys gets crowded,

[probably about lunch time! :-]

> stagger down the street a block or two to Brewskis. The last time I was there they had every beer from Anchor Brewery on tap, as well as a good selection of bottled beer. If you haven't had Liberty Ale on tap you must, its heavenly.

I really liked Brewski's -- large selection (100-150?) of interesting beers (eg: a bunch of Belgians), but no homebrew. Also, if you're heading to NYC, Brewskis has got a Christmas in August special: all beers at half price, which brings an \$9 krieg down to less than I can buy it in the store. The deal runs through the end of August.

Prost!

Subject: Wort chilling

Hi

Recently there has been a discussion of using ice to cool the wort, and this included a comment on using ice that was colder than 0 degrees. What about using something even colder. Liquid nitrogen. @-177 C (if I remember correctly) A couple of liters should cool the wort right down, and talk about cold break... Further, I can't believe anything could live it it (and if it could, I doubt chlorine would do anything to it anyway) and instead of forming water, you get nitrogen, which as perviously stated will just bubble back out.

Most people here are at a research lab or university, and thus the stuff should not be to hard to get (if you can't find it, what about dry ice).
It's cheap (<1.00 a liter usually).

Has anyone tried this? With what results?

David

Subject: thermometer breakage

Chad Epifanio writes:

>The end of the case made contact with a palm frond, and the resulting shock
> reduced the thermometer to a mass of glass shards and liquid metal.

First of all, I hope that you are mistaken and that the liquid in the thermometer was either toluene or alcohol based (i.e., it was red).

If it was silvery, it was mercury. In that case I hope that you broke it outside, because if you broke it inside your home and the mercury bulb shattered, you have a serious problem on your hands. Although it may not look like much, that mercury is a health hazard. If dispersed on the floor in a room, the vapors from it can reach a dangerous levels. You should consider getting a mercury absorption kit (available from lab suppliers like Aldrich Chemical Co. or Fisher Scientific) and get that stuff out of there.

The proper way to get rid of the bubbles in a thermometer column is to immerse the bulb in a solution cold enough to contract all of the liquid back down into the bulb. Depending on exactly what kind of thermometer you are using, a salt/ice bath may be enough (Calcium chloride/ice gets colder than sodium chloride/ice). For low temperature thermometers, one may be forced to go to a dry ice/acetone bath).

This should be a warning to all of you homebrewers out there. DO NOT use a mercury thermometer in your brewing. It is dangererous and will cause you problems if it breaks (which it will eventually). At the very least you will be forced to dump a mash or wort if it breaks in them. Get yourself a toluene or alcohol thermometer. Even better, get a digital thermometer. They are more accurate, are easier to read, and won't break when you drop them. Cole-Palmer (1-800-323-4340) sells a very nice one for \$29.50. It is a solid-state electronic thermometer that reads temperatures from -58 to 338 degrees F. It has a detachable general-purpose stainless steel probe that is 5-3/16" long. It comes with a 1.4V battery that lasts for 1000 hours. Accuracy is +/- 2 degrees up to 290 degrees. They take Visa or MC and there is no minimum order (there is also a shipping charge). I have one that I've been using for three years and the only problem I've had with it is that I had to clean the battery contacts once. I highly recommend it. Other lab suppliers offer similar digital thermometers.

Subject: Hard Cider Mailing List Re-Post

Thought I'd re-post this in case anyone missed it the first time. Some of the people who I said I'd add automatically (people who requested cider info directly from me a few months back) your addresses bounced. Rather than post those names here, just look for mailings from cider@expo.lcs.mit.edu. If you don't get anything inside the next 2 weeks or so (it will take time for traffic to pick up on the list) then please send a subscribe message. Sorry about that, but I haven't kept all the bounce messages and I'd rather not take up too much more HBD space with administrivia.

So here it is again....

I am pleased to announce the creation of a Hard Cider Mailing List, with me as it's humble organizer.

To get on the list please do the following:

- 1) Send Mail to cider-request@expo.lcs.mit.edu
- 2) Put the word Subscribe on the subject line
- 3) Include your preferred e-mail address in the body of the message, I don't want to rely on the included reply address

To get off the list or stop multiple copies:

- 1) Send mail to cider-request@expo.lcs.mit.edu
- 2) Put the word unsubscribe on the subject line
- 3) Include the e-mail address to which the cider list has been getting sent in the body of the message (again I don't want to rely on reply addresses)

To submit to the list:

- 1) Send mail to cider@expo.lcs.mit.edu

Thnigs to remember:

- 1) This is an echo'ed list not a daily digest
- 2) There is a human processing subscribe/unsubscribe requests
- 3) Please no flaming!! Let's try to keep this on a par with the HBDS quality

Enjoy.

JaH

PS Presently this offer is only being made available to HBD Subscribers and not the newsgroups. This is in order to try to keep the discussion level high, and the traffic volume manageable.

Subject: Corn Syrup in Extracts, Brooklyn Lager

Well this ain't about John Bull, but a few years back there was a real inexpensive extract that used Corn Syrup in it. I think it was called American Eagle and came out of one of the Carolinas. I used it a few times, but didn't like it that much, then I looked at the label and discovered why, it had Corn Syrup in it. I found it OK to use as a fortifier for building up the gravity of other recipes without modifying the taste too much, but I stopped using it as a base for recipes.

Won't swear to this but I think as with many other Northeast beers, Brooklyn Lager is brewed under contract by you guessed it.... F.X. Matt's in Utica, the brewery that has made a quite a killing on this contract brewing scheme.

Dry Malt extracts & Bread. Well yes & no. Dry malt extracts were at one time made exclusively for the Bread making industry (pre-prohibition). During prohibition the way a lot of breweries remained in business was to make Extract Syrups for "breadmaking." Of course records show that during prohibition extract production went up to 10X what the Bread making industry actually used. You guess where the rest went. In recent years many extract makers have cropped up that produce their product exclusively for the homebrewing market. In particular Alexanders is one of these, though I suppose many of the British & German brands are as well. I think Blue Ribbon was probably an example of extract brewed for bakers interests, not brewers, but things have changed a lot since the days of Blue Ribbon.

Subject: Re : Calcium Chloride

Chris Swingley writes

>Where does one get Calcium Chloride? I want it to
>eliminate the 500-770 ppm of bicarbonate. Boiling
>the water after addition of enough CaCl₂ ought to
>remove most of the carbonate, and the
>Chlorine should evaporate upon boiling.

Pardon me if my chemistry is mistaken, but I can't see the above being effective. Your water contains alkaline buffers, namely, calcium bicarbonate and calcium carbonate. The latter is largely insoluble, but will still react with acidic mashes and worts. One can convert the bicarbonate to the carbonate by boiling, and then eliminate most of the carbonate by cooling and racking. IMHO, this method is tedious and not completely effective anyway. So chemical removal is required.

In theory, the bicarbonate could be precipitated by adding some soluble salt, XY, such that X-bicarbonate is insoluble. I can't think of a good example offhand, but the salt would probably involve a medium-heavy metal, which could be dangerous. The best method is to add just enough of a weak acid (eg, citric or lactic) so that all the buffer is consumed in the reaction. I have found that a quarter teaspoon of citric acid per gallon will remove about 160 ppm carbonate. I don't completely trust water authority figures, because these are often averaged over wide areas. To be sure, you really need to titrate your tap water using some acid-base indicator such as methyl orange. In other words, add small amounts of acid incrementally to a measured volume of water until the colour change indicates that the solution has just become acidic. You could use pH papers instead of the indicator, but the results will not be as precise.

Adding calcium chloride will precipitate nothing, because the metal 'X' is the same as that already present. This method will increase the chloride ion content, which is not the same as the chlorine content. Chloride ions are said to improve the smoothness of sweet, dark beers, and the most common source is table salt (sodium chloride). Salt substitutes such as potassium, calcium and magnesium chlorides are often available from health-food shops or pharmacists. Watch out for additives !

Subject: Re : Oatmeal stout

I can only agree that rolled oats are better than steel cut, on the grounds that the whole oats will contain oat germ, which is a source of oil and could affect head retention. Some writers also claim the oil can give a rancid/bitter taste, although I haven't tested this personally.

After observing my porridge as it was cooking one morning, it did occur to me that all that lovely viscosity might do wonders for a beer's head retention. So I used rolled oats as an adjunct in the next lager mash. Flavour was good; a sort of smooth graininess. Clarity was terrible, even after employing a half-hour protein digestion rest and testing for starch end-point. I concluded that I had encountered a protein haze of fairly large proportions, which probably explains why oatmeal is traditionally reserved for stouts. Incidentally, the haze was responsive to isinglass finings.

Some questions for any biochemists out there : would a longer protein rest, or the addition of extra digestion enzymes, cure the haze problem ? Or might it defeat the original purpose of introducing more gum-like substances into the mash ?

>From: Chris Swinglet (ez005142@pollux.ucdavis.edu)

>Where does one get Calcium Chloride?

Calcium Chloride is the prime ingredient in salt which is marketed as "lite". You can find some brand or other in your local grocery store.

My purely volative random access memory says that ice cream salt (rock salt) is another kind of salt as well. But it's taken too many voltage surges and that info is even beyond Norton's at the moment.

Subject: SG question

Ok, here's an odd question: Which would have a higher specific gravity, wort that was mashed at low temp (ie. highly fermentable), or wort mashed at a high temp (ie. less fermentable)? Both were converted to completion.

Your first thought is probably that they are the same. But try thinking of specific gravity in terms of thickness of the fluid, rather than the amount of dissolved solids. The high temp. mash will have larger molecules (on the whole) than the low temp. mash. Will these larger molecules make the solution "thicker", ie. have a higher SG? Just what is specific gravity measuring, anyway?

Subject: Carry a Spare

From: chad@mpl.UCSD.EDU (Chad Epifanio)

>While
>checking my equipment, I found that my thermometer had developed a case
of the
>bends. It had several distinct vapor bubbles in the mercury column,
making it
>offset by an unknown amount.

(Stuff about swinging the thermometer overhead deleted....)

>I heard
>a distinct(you guessed it) crash. The end of the case made contact with
a
>palm frond, and the resulting shock reduced the thermometer to a mass of
>glass shards and liquid metal.

Sooner or later, most brewers experience the distinct (you guessed it)
crash
of a thermometer or hydrometer biting the dust. This usually happens when
you
need it most, i.e. while brewing. One thing you can do to minimize the
impact
of the distinct (you guessed it) crash is to simply carry a spare. If an
instrument breaks when you need it, you retaliate by whipping out the
backup
copy and proceeding undauntedly. Then you have until the next time you
brew to
replace the spare. Since you'll probably be visiting your supplier before
brewing again anyway, there's no additional hassle.

I've kept an extra hydrometer and thermometer handy for about four years
now
and in that time I've broken one thermometer. That one experience
convinced
me that I'd always carry a spare.

Now if they'd just make them with flat sides instead of round, you could
place them flat on a table and they wouldn't roll off!

This is correct, but as Kurt noted, there is more to the equation.
We can make a pretty accurate prediction, in fact, with just a bit of
guesswork.

I'm not going to go through all the math here; suffice that the heat
needed
to change the temperature of a substance (Ice, water, or wort in this
case)
is the material's mass times its specific heat times the change in
temperature. Water has a specific heat of 1 cal/g-C as a liquid, about
half that as a solid. For ice to melt, it must undergo a phase change,
requiring energy amounting to its latent heat of fusion times its mass.
The latent heat is 80 cal/g.

The specific heat for the wort is the tough part. I found one
reference which states that a 4% solution of cane sugar in water has a
specific heat of .756 cal/g-C, but I find that a suspiciously large
change;
caveat emptor. Don't forget that the specific heat will be slightly
different depending on the type of wort you have; a barley wine wort will
have a different value than a light pilsener. However, as the numbers
will
later show, the sensitivity to specific heat is not *that* great...

OK, assume a spherical football... no, wait, that's another story. Ah..
assume you just pulled the boiler off the burner, so you have hot wort at
100C. You want to dilute this with ice to get 5 gallons of 72F (22C)
wort,
cold-broken and ready for the yeast. Also assume ice at 0 F, which is
typical for American freezers. Then:

If the specific heat (C_p , my poor attempt at $c_{\text{sub-p}}$) of the wort
concentrate is 1 cal/g-C (like pure water), a 5-gallon solution at 72F
would be obtained by mixing 7.7 kg (8.5 liters) of ice with 11.3 kg (3
gallons) of boiling wort. So instead of the original estimate of
50/50, we've got something more like 60% wort / 40% ice.

For a wort-concentrate C_p of 0.9, that becomes 11.7kg (3.1 gallons) of
wort and 7.3kg (8.4 liters) of ice.

For $C_p = 0.8$, it's 12.3kg (3.2 gallon) of wort and 6.7 kg (7.4 liters)
of ice.

For $C_p = 0.7$, it's 12.8kg (3.3 gal) of wort and 6.2kg (6.9 liters) of

ice.

I'd guess the specific heat at something around .9 to 1.0, so I'd say that about 8 liters of ice would do the job, and you want to have 3 to 3.2 gallons in the boil. The initial gravity of the full 5-gal wort should be about 60% of that of what was in the boiler; e.g., if your boiler gravity (mind you, corrected to 60 F!) is 1.080, the 5-gal wort gravity will be 1.048 ($0.6 * 1.080 = 1.048$).

Oh, if anyone's wondering "Why does this dweeb keep mentioning gallons of wort and liters of ice?", it's because I figure everyone can picture 2 liters; it's the size of a plastic pop bottle. It takes four blocks of ice that size to cool three gallons of boiling wort.

From: Steve Anthony <steveo@Think.COM>
Subject: Wort Chilling

Seems to me that the price of extract keeps going up and up. To counter the trend, I'm thinking of going to all-grain. I do partial grain brewing now (3-5 lbs grain with 5 lbs extract, for example), so it won't be that great a step. I know I need to get a 8g brew pot, I have a nice mash tun (4g SS stock pot), a lautering system will be easy to devise (based on Papazian's Zappap (sp?) system). The one thing that has me stumped is the wort chiller.

I had thought that getting a length of copper pipe and having a friendly local plumber coil it for me would be a start. I could then sweat solder (using non-lead solder, of course) some elbows and straight runs of pipe on to the coil; perhaps using some flexible hosing and hose clamps for areas where one might need to be able to bend the tube. I thought I might even put a valve and perhaps a thermometer on the output side.

I had then thought that putting the coil of the chiller in my kitchen sink and surrounding it with crushed ice water would cool the boiling wort appropriately. But will it? Is there a way to figure out what the resultant temp of the wort would be? I'd hate to end up with wort that was at 120F and risk possible infection waiting for it to cool in the carboy prior to pitching.

Any comments, answers, etc are welcome!

Prost!

Subject: Re: Specific gravity and fermentables

Russ Gelinas asks if a high-temp mash full of dextrins or a low-temp mash full of fermentables will have a higher specific gravity. I'm not expert enough as a masher to give you an answer in terms of yields. However, I claim that original gravity and % fermentables are independent of each other.

If you add enough corn sugar to a batch, you can get the O.G. up very high and still have a very light-bodied beer (like malt liquor, yuck) because all the sugar is fermentable. Conversely, if you add corn syrup or boiled oatmeal to the wort, you will again increase the gravity, but without adding much in terms of fermentables. After all, the yeast can't assimilate the dextrins in Karo or the glucans in oatmeal. Adding these adjuncts (which I don't recommend) will produce a syrupy heavy-bodied beer.

Specific gravity is the mass of one cubic centimeter of wort, measured in grams. Any carbohydrate that dissolves in water will increase the initial gravity, whether or not it is fermentable. Body in beer is related to the viscosity of the beer, which depends on the presence and the length of non-fermentables (whether these are dextrins and glucans or peptides has been a matter of intense debate in earlier HBD's)

So, Russ, whether you mash hot or cold, if your yield is the same, your OG will be the same whether it is due to dextrins or fermentables.

Did I answer the right question?

Cheers -- Jean

Subject: Liquid nitrogen in wort.

Greetings,

David Klein suggests using liquid nitrogen or dry ice for chilling wort. I believe, as David suggests, that nothing will probably be living in either, however the thing that I would be concerned about is what chemicals (or other debris) is mixed in. One never knows what was in a nitrogen dewer in the past. I know lots of people that have broken off pieces of tubing into dewars, and I've often seen bugs and dirt in them also. Then there are always people (like me) who dip everything they can find in the room into liquid nitrogen just for fun.

All of this is just something to consider before actually adding liquid nitrogen directly to wort. But of course, against my own advice, I have put it directly into things that I have consumed and I'm still alive. So I guess what I am saying is you might want to think about where something has been before putting it in your wort, and that microbes are not the only thing to worry about.

G'Day,

Joe

Subject: PLEASE READ THIS!! (Was: rampant infections)

This is a re-post of an earlier submission. The response was underwhelming. Respond via e-mail if you don't want to clutter the digest, but PLEASE RESPOND!

* PLEASE PLEASE PLEASE PLEASE PLEASE PLEASE HELP ME! *

I have a severe problem that I hope somebody can help me with.

I have had to toss my last two batches of beer due to really horrible, awful, slimy, foul smelling infections. Well, probably not that bad, but bad enough.

I used to produce some really good beer, but lately I can't seem to keep the "undesirable elements" out of my fermenter.

I am not aware that I have been doing anything different from my traditional procedures. Most of my brews are extract and I usually do a boil of only about 3 gallons, adding 2 gallons or so of chilled bottled spring water to the fermenter. This procedure has, historically, worked quite well for my extract brews. I occasionally do a full boil when a partial mash has been involved, but these are a pain since I don't have a wort chiller (yet.)

I do the primary ferment in a 7 gallon carboy, and I do secondary in a 5 gallon carboy. I recently replaced all carboy stoppers and siphon hoses. I sanitize everything in a chlorine bleach solution and rinse with hot tap water. I am very careful with my siphoning procedures, probably to excess. i.e. I do things like wipe around the mouth of the carboy with a piece of gauze soaked in ethanol before putting in a stopper or a siphon hose. I'm getting absolutely anal with my process and nothing seems to help.

Now the "Clean out the Closet Porter" (one of the few full boil batches that I do) that I brewed a while back is growing some ugly looking scum on the surface. I hadn't had a chance to bottle it, but I didn't worry since, of course, I felt that I had done everything properly and that I could leave it in secondary for another week or two. The temp. where I stored the fermenter has not gotten above 70 degrees F. and typically stays at about 65.

Could I have a nasty infection in my kitchen that permeates everything? Could my bottled water supply (Poland Springs) have gone bad? Could my cat be spitting in the fermenter when I'm not looking? Will I have to hose down my kitchen with sanitizing solution? Would an ionizing air filter help?

Help! I'm starting to worry! And I'm all out of homebrew.

Subject: Quantity of beer in Germany

I've seen some really disturbing allegations that the beers poured in some Munich beer gardens and at Oktoberfest are routinely shy of a liter. While there may be some rogue pourers who commit this crime, it should be noted that at Oktoberfest several inspectors patrol the tents with a notched stick used to randomly inspected just-poured glasses of beer. If a short glass is found, the customer gets it free and the perp is fined.

From: DAVID KLEIN <PAKLEIN@ccit.arizona.edu>
Subject: Re: Liquid Nitro.

Whoops...

After yesterdays submission about liquid nitrogen, I checked the good old CRC, and checked some numbers. First (for what it matters) the T of LN2 is -195 C (not -177 C) But, unfortunately, the specific heat is only about 0.2 kcal/(l*degree C). The heat of vaporization buys a 2 degree reduction in the water temp for 5 gallons water, and 1 liter of LN2. So, the calculations show that one needs 15-20 l of LN2 (4 - 5 gallons). this is quite a bit of liquid to carry home. (or buy at 3-4 \$ per gallon.)

I also did the calc for dry ice, and found that about 25 Kg (>50 lbs) would do the trick. I don't remember how much that costs though...

Well, it was for for a while...

Subject: oatmeal

Steel cut oatmeal needs to be mashed. Because off the heat and pressure used to make rolled oats, however, they (rolled) do not need to be mashed. I made a stout using 1 lb. steel cut oats mashed with 3.5 lbs of pale malt (and then added to 6 lbs of dry malt), and it turned out delicious. But it has no head. It's well carbonated, but the head disappears almost immediately. My guess is that it's because of something in the oatmeal (proteins? oils?). What could I use the next time to increase the head retention? Wheat flakes? Barley flakes?

And, could someone please send me the address of the infamous Colonel John?
It's time for one of those 7 gallon carboys. Thanks.

Russ G.

From: cjh@vallance.HQ.Ileaf.COM (Chip Hitchcock)
Subject: re SG qq

Don't confuse SG and viscosity. SG is density; dissolving sugar in water doesn't increase the volume proportionately, so the density goes up. Viscosity is a much touchier subject, but I would guess that green wort with more unfermentables would have a higher viscosity---not sure whether it would be measurable, but many thickeners are naturally-occurring sugar polymers (cf cornstarch).

I would assume that converting the same weight of starch to solubles would produce the same SG regardless of the mix of fermentables and unfermentables (dimers vs oligomers?). It's possible there's some effect from hydrolysis of the sugar bonds, but I'm not sure which effect

will have on density (e.g., do the smaller molecules hydrate more or less effectively?, does absorbing h₂o reduce the volume by more or less than it's expanded by increasing the mass of the solute?); in either case it's likely to be very small.

Subject: Redhook ESB Recipe

Hello all,

Just recently I had the pleasure of touring around Washington state. As part of the "vacation" my wife and I went through a number of brewpubs in the Seattle area (thanks to the people who emailed lists to me telling me where they were and describing them -- that information was invaluable!). One place that I missed, though, was the Red Hook millibrewery. One reason I call them a millibrewery is that they seem to have a larger capacity and distribution than a microbrewery would. I find their ESB beer excellent (we had this beer numerous times during our travels throughout the state). Has anyone taken the tour (apparently they discuss their recipe and methods extensively) and more specifically does anyone have a recipe they feel approximates this beer? I would be very interested in attempting to make this beer.

Thanks for the information

Subject: Whitbread Lager Yeast

Howdy all!

I was wondering how many out there have ever used Whitbread's lager yeast. I've used it a couple of times, and have been pretty well satisfied with it. However, I've never done a test comparing it with any other lager yeasts on the market, so I haven't been able to judge whether the final product leans towards malty, clean, complex, hoppy, etc. Note, while this is a dry yeast, it was favorably reviewed in Zymurgy's special yeast issue a couple years back. The main reason I have used it, as opposed to any of the fine liquid cultures, is that it seems to be a fairly potent strain (even at temperatures below 45 F), while some of the liquid strains I have used can really dddrrraaaaggg the fermentation along slowly.

Anyhow, any feedback would certainly be appreciated,
Mike

>my trip to the library produced very little more. At what temperature
>should this mead be fermented? At what temperature should it be
>aged after bottling? Do you have any helpful tips about this recipe,
>or mead in general? Thanks much for any info.

My first batch of mead was also Barkshack Gingermead and I loved it. I
have
made 12 batches of mead so far and my technique has changed quite
drastically
since that first batch a la Papazian.

To start with, I only make still (non-carbonated) mead now because I find
mead
to be more of a wine-like beverage, high in alcohol and splendid when
given
time to age. I found that carbonated mead resembles Champale too much
(anyone
out there remember Champale?) but this is of course an "IMHO" so put your
blow
torches away!

I ferment my mead at 18C (65F) for 6 days in primary, 3 weeks in
secondary and
3 months in tertiary. Needless to say that my O.G.'s average 1.090-1.
100. I
use standard wine yeasts (Pasteur or Epernay) although I am interested in
getting my hands on a culture of mead yeast. I age my bottled mead in
corked
wine bottles for 1 year (minimum) in a wine cellar which can be anywhere
between 10-15C (50-60F) depending on the season.

In terms of processing, I boil the honey/water mixture for 30 minutes and
chill
it by using a counter-flow wort chiller. After this I usually add various
fruits to the cooled solution along with some yeast nutrients and tannin.
When
adding fruit(s) I always add 1/4 tsp. potassium metabisulfite per gallon
to
sterilize the mixture and let it stand (covered) for 24 hours before
pitching
the yeast. This is how wine musts are sterilized since boiling fruit will
set
the pectins and cause chill haze problems, as well as ruin the delicate
fruit
flavours one wishes to enjoy later.

I will post a recipe in HD soon to clear up some of the above
generalizations
since I am preparing this posting without having access to my recipe
book.

Mike

PS- mead IS an aphrodisiac!!!

Subject: Chimay Yeast Experiences

bliss@csrd.uiuc.edu (Brian Bliss) writes:
>...Has anybody tried culturing chimay ale yeast lately?
>My recent attempts have turned out much more sour than
>they were just a few months ago. It it the change in
>seasons over in belgium, or perhaps related to the
>temperature in my kitchen?

Your problems are more likely due to microbial contamination from bacteria or wild yeast, either a result of a less-than-sterile culturing environment or from the source of yeast itself. One cannot be sure though without knowing more about how you culture yeast and what temperature your kitchen is.

I had problems culturing Chimay yeast from the bottle until I got into agar plate culturing to isolate single colonies from a potential background of nasty beasties. I finally achieved success (2nd place in the Canadian Amateur Brewers Association 'All About Ales' contest) with the following method:

- inoculate 50 mls of sterile (pressure cooked) unhopped wort with 2 mls of yeast slurry from a bottle of Chimay. Apply an airlock and wait for signs of activity (3-4 days).
- streak out a loopful of this culture onto an agar plate (do a few plates) and let colonies develop (3-5 days).
- pick a single colony and inoculate 10-50 mls of sterile wort. I did this for ten colonies in ten separate tubes.
- after 3-5 days remove 1-2 mls of each fermented sample and taste. At this point I was shocked at how raunchy some of the fermented wort samples were with flavours ranging from burnt rubber to eggs to a beautiful Chimay-like fruitiness. Needless to say I saved the later culture and scaled it up to 500 mls to pitch into a batch of Trappist Ale.

Now I am aware that this may draw some fire from those of you who know that Chimay is fermented using a blend of five different yeast strains. I have obviously only purified one strain using the above method. Unfortunately all of the colonies on my agar plates appeared morphologically the same but my flavour analysis indicated that different yeasts were present, and certainly more than five strains I assure you! Obviously there were some unwelcome

intruders along with the proper strains and a more detailed analysis (genetic and/or molecular) would be required to come up with the proper combination of strains...but to no avail, the ale was fairly authentic and dream inducing.

For those of you who responded directly to my posting a few HD's ago about purifying *S. delbrueckii* and who suggested I prepare a letter describing agar plate culturing, stay tuned. It's in the works but is taking a backseat to *less important* ;-) commitments.

Just to amplify a bit, the English "Real Ale" people, CAMRA, who have pretty much finished off the enemy in the most successful consumer revolt in history, violently object to the presence of any CO2 not produced by the beer itself, preferring natural cask pressure to what they call "blanket" pressure (forcing the good stuff out by the top pressure of an externally applied gas. That's what those quaint hand pumps are for, and why the beer is relatively flat to an American. A seven-minute wait sounds intolerable to me. Well, maybe if the result is Guinness.....

From: doc@brewing.cts.com (Mitchell M. Evans)
Subject: A First Time for Everything

Howdy fellow brewmaniacs!

I had a first...my first BAAAAD batch. I've been brewing for about 3 1/2 years now, and was getting a little cocky, so I figure it was bound to happen. Went something like this:

After about 6 days (which I thought was a short fermentation at the time), the fermentation stopped. S.G. looked pretty good...not as good as hoped, but still acceptable. Wrong Answer! I was making some mighty fine glass grenades. The time came to open the first one of the batch...

Glass and beer shot 20 feet across my house, peppering the walls in my living room, dining room, and kitchen. On the way to the walls, the glass opened my thumb to the bone. Yee-hah. The mess was horrible, as you might imagine. I bled like a stuck pig.

The moral of the story? If you're in the least bit wary about how your fermentation has progressed...be careful opening the first one of the batch! I just (very cautiously) opened one of my new batch, an oatmeal stout, last night. Perfecto. My hands were shaking. I am very glad that I open bottles out (away from my body), and not up toward my face.

How can I be sure that the bottle I am about to open is not a bomb? Any hints would make opening the first bottle of a batch much less traumatic for me, from now on.

Mitch

> pitching.

I use 10M of 8mm copper tubing (easy to coil by hand and lots of
surface area for the volume) placed in the kitchen sink under running
water at 15C. I syphon the almost boiling wort through and it comes
out at approx. 18C. It takes about 20 mins to do 5 gallons.

I've not done the sums, but I suspect your crushed ice water would
warm up too quickly - there's a lot of heat to be transfered!

Ifor.

Ken:

I'd bet on the water. Try boiling ~ 3-4 gallons a day or 2 ahead. Cool it overnite in the pot and the pour it into the 7 gallon carboy and cool to ~40F in a fridge. Also as a precaution, never add unboiled water (finings, primer, etc.). When racking to the secondary, add boiled and cooled to room temp water to top off.

Subject: Re : Beer Infections

To Kevin McBride : Sorry for the lack of response, but I suspect that public discussion of beer infections is almost as taboo as discussion of personal infections, ie, it is something we have all encountered at one time or another, but are reluctant to admit.

When in doubt, suspect your yeast! Just because it is commercially produced doesn't mean it is good. So my first move would be to change strains. Alternatively, if you are really attached to that strain, you might like to try purifying it. The simplest method is to acidify your starter culture overnight at a pH of 4. That should take care of most bacterial nasties. It is a standard routine for those who save and propagate yeast cultures. You could use more advanced lab techniques as described in HD 701. There is a discussion there of the problems of culturing from Chimay. I have also found the same with Guinness.

Lastly, an obvious suggestion. Why not try pre-boiling your spring water, or at least giving it a dash of sodium met the day before brewing ? Also, if you have the misfortune to encounter again the beginnings of more spoilage, sodium met treatment at an early enough stage could salvage something drinkable. In that case, you would need to re-pitch with yeast the following day.

Subject: Centennial Hops

Has anyone had any experience with Centennial hops? I picked some up the other day because I had never tried them. When I got home and checked my references on hops (including the Zymurgy Hop issue), I couldn't find anything on Centennial. I assume that it is a fairly new variety? So what's it like? Thanks.

I am somewhat allergic to potassium metabisulfite, as are a number of
asthmatics, I hear. Some champagnes, labelled ``Contains Sulfites'' have
really set me off, so I would like to avoid using them in my recipes for
mead.

Wouldn't you get the same effect if you boiled/simmered the honey,
allowed
fermentation to begin until a high alcohol level was achieved, *then*
added
fruit?

To be honest, I did use the sulfite trick for my first batch of mead, and
it hasn't bothered me. Of course, subsequent batches without haven't
either!

Am I missing something? [Where's Cher Feinstein, by the way?]

Subject: RE>Homebrew Digest #701 (Au

Reply to: RE>Homebrew Digest #701 (August
In HBD #701 Russ Gelinas says:

> Steel cut oatmeal needs to be mashed. Because of the heat and
> pressure used to make rolled oats, however, they (rolled) do not need
> to be mashed.

Sorry Russ but this goes against my understanding of the use of oats,
etc. ALL
forms of oats must be mashed. Any form other than oatmeal must be
"cooked"
prior to mashing (just like rice and whole barley) in order to get the
starch
into the proper condition. The action of "rolling" oats (or other
grains) to
get "meal" or "flaked" versions does the same work as cooking and they
may be
added directly to the mash. Adding non-mashed oatmeal to a brew only
increases
the starch content of the wort which does not ferment out as it never
becomes
sugar. I believe Miller covers this in TCHoHB.

I doubt I have to make this request in this Digest, as I know I hear if
I'm off
base, however, Please correct me if I am in error here.

Thanks, RW...

Subject: help

Kevin's got a problem with infection. Here's my suggestions: boil *all* of your water, including the Poland Spring water. It can't hurt. Cool your wort as fast as possible, and keep it covered. Use all new tubing. Buy a new bottle filler. Use only squeaky-clean bottles. Soak them overnight in a bleach solution. Boil your bottlecaps. Wash down your whole kitchen. Keep drafts away when brewing. Wear clean clothes when brewing. Don't weed the garden while you're waiting for the wort to cool. An open window on a windy summer day is an invitation for *things* to come into your clean kitchen. I guess most of all, think of any and all ways for those *things* to get into your wort, and eliminate them.

The worst case would be to just wait until the summer *thing* activity calms down with the cooler fall weather. But that would mean months without homebrew....hmmmm, I wouldn't want to risk that. Good luck.

Subject: Boulder Creek Brewing/Cafe

Dearest fellow homebrewers,

In case you haven't heard (and believe me I *CHECKED* past issues before posting this for fear of being shot down in flames ;-))

While traveling through the Santa Cruz mountains here in California, Slug and I passed through the quite little town of Boulder Creek. Lo and behold there on the main drag (Highway 9) was the 'Boulder Creek Brewing Co. & Cafe'. Much to our pleasure it was open for business (last time we went through Boulder Creek they were under construction, approx. 9/90).

The beertender, Stacey (great name, huh?), assured us they'd been doing a booming business since their opening in 10/90. This was backed up completely by the fine beers we tasted. The first, a marzen, was INCREDIBLE! The second was a bock and equally incredible. The final offering was a Red Ale. We didn't try this one. The first two were so incredible that we each had a second pint of the same beer.

As for the food, what a menu. After reading it over it was easy to tell that the proprietor knows what goes with good beer. All I can say is GARLIC FRIES TO DIE FOR!!! Incredible burgers, we tried the cheese, bacon and mushrooms and the cheese and avacado (*VERY* Santa Cruz-ish ;-).

Anyway, I heartily recommend the Boulder Creek Brewing Co. and Cafe to anyone passing through Boulder Creek. We enjoyed it so much that we decided it would be a delightful drive from our home in Mountain View on a lazy Sunday afternoon. It could also be paired with a trip to the Bonny Doon Winery in Bonny Doon! Anyway, for what its worth, there ya have it...

Subject: Cider list has gone Digest (I think, hope....)

To all of you who felt themselves inundated with e-mail from the Cider list
(be glad you don't subscribe to xpert@expo.lcs.mit.edu)

I have received some scripts from Rob G (your humble HBD coordinator) and seem to have successfully got them working (and blew 1/2 a day, but what the heck it's that or write PEX documentation Ugh...).

So now the Cider list is a 2 times a day (11AM & 6PM EWT....Eastern Whatchamacallit Time) in a digest format.

It won't send you empty digests (I hope :-)

After Cider Season is over I can drop it down to once a day, or leave it as is.

Personally I prefer the fast turnaround (and frequent distractions) provided by the mailing list, but a few people voted with their feet, and I figured that no one else would mind a digest format since they are used to the HBD.

So once more (Sorry to eat your bandwidth...)

To get on the list please do the following:
1) Send Mail to cider-request@expo.lcs.mit.edu
2) Put the word Subscribe on the subject line

To submit to the list:
1) Send mail to cider@expo.lcs.mit.edu

etc, etc, etc....

From: ez005142@pollux.ucdavis.edu
Subject: Brewing salts (CaCl)

Howdy,

My terminal has no editor functions so please excuse the typo's.

I wrote in last week asking about obtaining CaCl. Thanks to all out there to told me where I could get the stuff. Since no one responded to the article yesterday about the ineffectiveness of CaCl for removing carbonate and bicarbonate, I thought I'd demonstrate my limited knowledge of chemistry, and perhaps embarrass the hell out of my self in the process.

In any case, here's my perception of how CaCl would remove carbonate and bicarbonate without any ill effects. I've got clost (close) to 700 ppm of carbonate in my water, and only about 75 ppm of Calcium. In order to remove all that carbonate my idea was to first boil the water. This would convert the carbonate (I mean bicarbonate) into carbonate. While boiling I would add a sufficient amount of CaCl. The Calcium would go into solution as an ion, in the presence of carbonate /would precipitate out calcium carbonate. Meanwhile, the chlorine ion that is also dissolved in the water would become volatile and evaporate into Cl₂ in the air. So I would have precipitated out all the bicarbonate in my water with the calcium, and the chlorine ions would evaporate harmlessly into the air. Problem solved, and not bad (no bad) taste imparted on my water.

Please correct me if I am wrong about the above chemistry (but don't correct my typo's please!). Miller talks about similar reactions using Calcium sulfate, but I don't want to add all that sulfate to my water which already has too much to begin with (begin with).

The final alternative is to buy bottled water. What a drag!

Thanks to all you who have a better knowledge of the chemical world than I do--I'm just a simple biologist. Hey, better living through chemistry right?

Adios.

>anybody tried culturing these yeast?

Well, yes the sediment is yeast, but there's a great deal more to making a Lambic than simply culturing the dregs of a bottle of Lambic. There are no less than three types of bacteria and three types of yeast that conspire to make Lambic. If you simply cultured the dregs, you would get part of the flavor, but not all of it. Get Jean-Xavier Guinard's book "Lambic" from the AHA Classic Beer Series, if you are really serious about making a pseudo-Lambic. Call the AHA at (303)447-0816 to order.

Subject: Thomas Jefferson, Fellow Homebrewer

Gary Varner, an old graduate school buddy, sent me this the other day. Thought I'd share it with the Digest.

Today as I looked (for wholly unrelated reasons) through a copy of Thomas Jefferson's Farmbook (a facsimile of Jefferson's records plus excerpts from many letters) I ran across some letters he wrote regarding homebrewing. They illustrate some of the eternal verities of the malted beverage.

1) You can never have too many good bottles on hand.

"I am now engaged in brewing a year's supply of malt strong beer, which however I have no chance of saving but by a supply of quart jugs from you. I recieved [sic] (I think) 10 1/2 dozen and must ask the favor of 4 gross more [=576] for which Mr. Gibson will pay your bill." (letter to Richard Randolph, written at Monticello, March 20, 1814)

2) Not everybody's a hophead.

"Our brewing of the last autumn is generally good, altho' not as much as that of the preceding year, the batch we are now using is excellent. That which Peter Hemings did for Mr. Bankhead was good, and the brewing of corn which he did here after your departure would have been good, but that he spoiled it by over-hopping. A little more experience however will make him a good brewer. My absence in Bedford in the spring prevented our preparing some malt then, which I now regret." (letter to Joseph Miller, written at Monticello, June 26, 1815)

3) Some people disagree with the German beer purity law.

"During the revolutionary war, the brewers on James river used Indian corn almost exclusively of all other. In my family brewing I have used wheat also as we do not raise barley." (letter to Joseph Coppinger, written at Monticello, April 25, 1815)

With all due respect to Bill's calculations, I brew empirically. Before I built my immersion chiller, I used to make 2 gallon boils and add 1 gallon of partially frozen pre-boiled water and two gallons of pre-boiled water from the fridge at about 40F. After all that, my wort was at about 75F, at which time I could safely splash it into the carboy and pitch.

From: "Spencer W. Thomas" <Spencer.W.Thomas@med.umich.edu>
Subject: Sulfites

Unfortunately for those sensitive to sulfites, a certain amount can be produced during fermentation. This is why almost all (in fact all that I've seen) wines are labelled "contains sulfites". I don't know if this is also true of beer (I haven't seen such labels on beers), maybe it's something in grapes that does it. There's a fellow in Michigan that makes "organic wine". Some years, he can leave off the sulfites warning, others, he has to put it on (I assume he's testing the wine after it's done).

Subject: centennial hops

Centennial hops used to be known as CFJ90. I've used them under both names, the harvests of 1989 and 1990. The 1989 version was better, but I understand that the 1989 harvest was much better in general than the 1990 one. Anyway, Centennial are a high alpha hop, and I believe they are a somewhat new strain.

Well, you can never be sure, but a very good indication of a "bomb" is when the cap takes on a convex shape due to the excess pressure in the bottle.

While I don't have any experience using them, I believe that Centennial is a relatively new "super-Cascade" variety, i.e., it has a lot of the Cascade characteristics for hop flavor and aroma, but is substantially higher in alpha acid content. I believe that during development it was referred to as "CFJ-90" which may be how it is listed in the special hop issue of Zymurgy. I'm not sure of the alpha acid content (don't have any info with me here at work), but if memory serves me (it often doesn't) they would be in the 10-12 percent alpha acid range, so discession is advised if they are to be used for bittering.

From: Dave Barrett <DAVE.BARRETT@OFFICE.WANG.COM>
Subject: beer frige & infection?

I have a friend that is trying to get a tap system together for his home. He wants to have 1/2 barrels of Catamount port on tap. The problem is to find an appropriate refrigerator. All the 5 cubic foot one's he has been able to find appear to be made by Japan Inc. and come in one of two versions: one has the cooling coils built into the shelves and the other has a built in freezer. Since he would prefer not to get a full size frige, does anyone know of a source of domestic 5 cu ft friges? Something in the Massachusetts/New Hampshire area would be nice. Direct replies are fine.

On another note. Last May I made a honey ginger beer that was a take off on Rocky Raccoon Lager. The wort that went into the primary was an opaque mustard/honey color and tasted pretty good. After about 4 days I transferred it to the secondary. Everything looked fine, but still opaque. Four weeks later the beer had cleared a bit and there was a great deal of trub. I could also see a 'hazy' layer in the middle of the carboy. Since it smelt and tasted ok I bottled it anyways. After 4 weeks in the bottle (the beer, not me) I began to suspect that something was wrong. The haze was still there. So I brought a bottle into work to show to another brewer to get his opinion on what was happening. Naturally transporting the bottle shook all the dregs back up into the beer. We left the bottle on my desk for the weekend to give the dregs a chance to settle out. A surprise was waiting for me when I came to work on Monday. (Nope this isn't another glass hand grenade sob story). The bottle has cleared. Totally. Not only had the dregs settled back out, but the haze was gone as well. This caused me to do something completely unnatural. I ran home and violently shook 5 gallons of homebrew. Every bottle cleared after 2 to 3 days. The beer still smells great and tastes pretty good but a little too sweet for my taste. The \$64,000 question is what was that haze? Where did it come from and how do I keep it from coming back? This batch was the first time I ever brewed with honey. Does that have something to do with it or did the dog sneak some dirty diapers into the carboy?

Thanks in advance,

db

From: dinsdale@chtm.eece.unm.edu (Don McDaniel)
Subject: Re: Centennial Hops

Regarding the use of Centennial hops:

I got four ounces from Freshhops this spring as they were out of all high-alpha varieties that I was familiar with. I have since used some in a couple of batches of ale (I believe a brown ale kit and an all grain pale, although my brewsheets are not here at work). They have given perfectly satisfactory results when used for bittering (60 min. boil). I am in the habit of using Cascade or Willamette for aroma and a high-alpha variety for bittering. Used in this way, I don't think the variety of bittering hop is really important, assuming of course you account for the alpha acid content in determining the appropriate quantities.

The theory behind this disregard for variety is that in a 60 min boil, the aromatics which distinguish hop varieties are boiled away. Consequently, you might as well save some money and use the highest alpha variety you can find.

From: tony@spss.com (Tony Babinec)
Subject: prevent infections/lager&ale malts/centennial hops

Here are some comments on recent discussions in HBD.

Regarding preventing infections: there were many good suggestions in recent installments of the digest, but I thought I'd mention or reinforce a few.

- After acquiring carboys for fermentation, I've used my original plastic fermenter as a sterilizer bucket. EVERYTHING that will touch the boiled wort gets an immersion in the plastic fermenter. That includes spoons, funnels, siphon tubes. Immediately after siphoning wort, I siphon some of the chlorine water into the tube and immerse it. Glass carboys should be visually inspected, scrubbed with a brush, and also treated with a mild chlorine solution. Occasional use of a caustic such as lye (Drano, Red Devil) will clean and sterilize, but be careful with it! Lye treatment followed by scouring pads will usually remove stubborn burnt malt from your brewpot. On the other hand, I haven't used it on siphoning tubes, of course!

- Boil all water prior to use.

- Get a quick cold break. When I began by making extract beers, I'd add water at the end to bring the volume up to 5 gallons. When I moved to partial mash/all mash brews, and had a greater volume of wort, I bought a wort chiller. Slowly-cooling wort goes through temperature danger zones where bacteria might take hold. A rapid cooling is good insurance against them taking hold.

- Build up the yeast prior to pitching. If you have no special equipment, boil some dry malt extract to make a wort starter, pour it into a sanitized 16 oz beer bottle, and cover either with sterile cotton gauze or even a bit of aluminum foil. Or, a local science supply store had some 1000 ml flasks, and these were easily fitted with stoppers and fermentation locks. There are few things worse than a long lag period between the time the yeast is pitched and visible signs of fermentation appear. As pointed out many times, a quick start of your yeast is reasonable insurance that the yeast will dominate the fermenter environment and suppress bacteria. As pointed out in the Yeast issue of Zymurgy, commercial packaged yeasts, especially the otherwise wonderful WyYeasts, are of insufficient volume for a 5-gallon wort.

The point about these and other suggestions is that it's unlikely that the average homebrewer can work in a truly sterile environment, however, some of these practices at least stack the odds in your favor.

Regarding lager/ale malts: There are several things going on. I'm neither a physicist or chemist, and I don't have my references handy (they're at home, I'm at work), but here's what I recall.

Our local supply store has the following pale malts: 6-row American, 2-row American, 2-row German, and British (2-row) pale ale malt. Of these malts, only the pale ale malt should be used for making pale ales. Malts vary in the degree to which they are modified and the degree to which they are kilned. Modification refers to how much the acrospire (embryonic barley plant) is allowed to germinate. Kilning

refers to length and temperature of drying of the sprouted barley.

British pale ale malt is a well-modified malt that is kilned a bit more than the pale lager malts. Because it is well-modified, you can use a single infusion mash, although I always do step infusion. The degree of kilning of British pale ale malt accounts for the wonderful color of pale ales. Another effect of kilning is to destroy enzymes. This is why highly-kilned malts (chocolate, black) are used as specialty malt add-ons to a pale malt or extract base. This is also why if you want to use flaked maize, wheat malt, or other specialty grains in small amounts in a pale ale, you might consider adding a bit of 6-row American for its enzyme content.

6-row American has high-enzyme, high-protein content. Because of high-protein content, it needs a protein rest. Because of high-enzyme content, it is particularly suited to American-style adjunct brewing, where corn and rice become routine ingredients in the recipe. Discussions of American 6-row always caution that since it is somewhat husky, too-hot sparge water can contribute to husky, tannic flavors in the wort.

German 2-row malt is suited for pilsners. It tends to be less-modified. If it were especially undermodified, you might have to use a decoction mash. If it isn't too undermodified, you could use a step-infusion mash. I've had success with step-infusion. See Noonan's books and articles for all the reasons why you'd want to do a decoction mash. See Miller's "Continental Pilsner" for more on this topic.

American 2-row tends to be fully-modified and not so high in protein or enzyme content as American 6-row.

In sum: use only pale ale malt when making British pale ales; use other pale malts when making lagers or Continental ales. If you use pale ale malt to make a lager, you'd have a difficult time making a truly pale beer. If you use other malts to make a pale ale, you'd have difficulty getting the right color. Plus, these other malts give rise to DMS flavors which at appropriate levels are okay for lagers but wrong for pale ales. Of course, the above are disclaimers, and it would help to have more information on any particular malt from the supplier!

Centennial hops: Aren't these the same as CFJ-90? I think I used some CJF-90s with an alpha of 7 or so. They're suitable for brewing West-Coast-style ales. I'm not certain, but aren't they descended from Cascades?

[Stuff about carbonate and bicarbonate removed]

>
> Please correct me if I am wrong about the above chemistry (but don't
> correct my typo's please!). Miller talks about similar reactions using
> Calcium sulfate, but I don't want to add all that sulfate to my water
> which already has too much to being with (begin with).

A couple things here seem questionable, first, I'm not sure that boiling will convert bicarbonate to carbonate, in fact I'm not even sure what carbonate and bicarbonate are, I'll look this one up tonight.

Second, you are assuming and calcium carbonate will precipitate, is this a good assumption? I don't know.

Thirdly, and this one I am pretty sure about, chloride ions will not simply become 'volatile' and evaporate. I don't think you would want that anyway since chlorine gas is not pleasant. The reason is that chloride ions have an extra electron given to them by the calcium atom when the ionic bond was formed. In order to convert chloride ions into chlorine, they have to give up their electron to some other positive ion, which in turn will become a non charged molecule. This is not likely to happen on your water since there is nothing to accept the electron (positive metal ions will not do this since they gave up their electrons in the first place, besides you do not want calcium or sodium metal floating around in your brew). You may be able to get the chlorine out of the water by applying a current to the water, for instance this is how electro-plating works. A metal is deposited on the surface of some other metal and a gas is released.

Subject: Pumpkin Ale

Greetings,

The season for making pumpkin pie approaches, and what better time to brew a Pumpkin Ale? I hear there is a recipe for "Punkin Ale" in this summer's Zymurgy, but my supply store is out of that issue. Could someone mail me, or post, a copy of that recipe? Or does anyone have a favorite extract-based recipe for pumpkin beer?

Thanks,
Jim Buchman

Subject: need some east coast homebrew shops

Hey now- I'm new to this digest and to homebrewing in general and I could use a little help from you guys. I'm starting to look for starter kits etc, and I got a catalog from Great Fermentations of Santa Rosa (CA). The stuff in the catalog is great, but the problem is that ordering from the left coast will cost me a small fortune in shipping.

Can anyone recommend a supply house in the central NJ area? I think there's a place on Staten Island, but I'm not sure. Any info would be appreciated...

Here is some questions:

1. What is Corn Sugar ?
(Sorry for this stupid question but I have never seen this type
of sugar in Sweden or the U.K.)

This is glucose, aka dextrose, aka D-glucoopyranose. Sorry I can't
answer the other question.

>appropriately. But will it? ...
>
>Any comments, answers, etc are welcome!

Sounds like the Ultimate Chiller. But you can achieve the same effect much more simply with an immersion chiller. I made mine by taking a 50' coil of 3/8" soft copper tubing (readily available at hardware stores, plumbing supply stores, etc.), added a compression fitting to each end, along with a 3/8"-male-pipe-to-1/4"-female-pipe bushing and 1/4" hose barb. To each hose barb I attached flexible plastic tubing. I used food grade because that's what I had; as the wort won't touch it, lesser grades are fine. To one of those hoses I attached a "Gilmore" (1/4" hose barb to 3/4" female garden hose) fitting. I re-coiled the copper tubing (easily done) to fit inside my boiler. I fill the thing with hot water, and place it in the boiling wort to sterilize for at least 20 minutes. After turning off the heat, I attach the Gilmore fitting to a water tap, and slowly run cold water through it, capturing the VERY hot water coming out of the exhaust hose for use in cleanup. In a half-hour, this will get it down into the 80's(F). I usually don't let it go that long, shifting over instead to icewater recirculation after the wort temperature drops below 100F. Simple, works great.

After I'm done with it, part of the cleanup of it is always to blow as much water as I can out of the coils. I used to be more relaxed about this, but a hard freeze last winter destroyed my previous chiller ...

In HOMEBREW Digest #701, Russ Gelinas asked:

> I'm confused (what's new?). What's the difference between lager malt
and
>ale malt? I always thought lager was 6-row, and ale was 2-row, and you
>could really use either for either. But I've seen references to pale
ale
>malt. Is that just 2-row lager?

My understanding of the differences is that lager malt is usually
6-row in North America and 2-row everywhere else, the exception
being the 2-row Klages barley malted to the moderate degree of
modification lager malts usually use, and frequently sold as "pale
malted barley". This is versatile stuff, very akin to Continental
lager malts but with nearly the diastatic power of 6-row. Pale ale
malt is a 2-row malt with a very complete degree of modification,
slightly more highly kilned than most pale malts. It has relatively
little diastatic power, but will produce good yeild when mashed in
the British single-temperature infusion menthod.

Subject: Ka-BOOM

In HOMEBREW Digest #702, Mitchell M. Evans described the most traumatic experience a brewer can have:

> After about 6 days (which I thought was a short fermentation at the
> time), the fermentation stopped. S.G. looked pretty good...not as
> good as hoped, but still acceptable. Wrong Answer! I was making
> some mighty fine glass grenades. The time came to open the first
> one of the batch...
>
> Glass and beer shot 20 feet across my house, peppering the walls in
> my living room, dining room, and kitchen. On the way to the walls,
> the glass opened my thumb to the bone. Yee-hah. The mess was hor-
> rible, as you might imagine. I bled like a stuck pig.

No fun. It's interesting, though, that the "S. G. looked pretty good". You may not have done anything wrong! This may be a form of contamination noted in these pages before, where after a pause of several days fermentation resumes, sometimes continuing all the way down to 1.000! Obviously not a normal and healthy fermentation. Wild yeast seem the most likely cause.

> How can I be sure that the bottle I am about to open is not a bomb?
> Any hints would make opening the first bottle of a batch much less
> traumatic for me, from now on.

Mike Sharp has reported running across very high-pressure bottles, and has taken to lifting just a tiny bit of the cap to get a sense for how rapidly the gas "wants" to come out of solution. If it seems too vigorous, he can clamp the cap down again before it really gets going. I usually take a slightly different approach with a new batch, opening a bottle every few days after bottling. The first few aren't likely to taste that good, but if there's a developing overcarbonation problem I'd know about it before it reached the danger point. Good luck!

From: STROUD%GAIA@sdi.polaroid.com
Subject: CaCl

Chris Swingley writes, suggesting adding CaCl₂ to a high carbonate water supply to precipitate the carbonate, then boiling to remove the chlorine.

Bad news, Chris. You can boil until doomsday and you'd **never** get rid of the chloride. All you'd do is boil off the water. Chlorine and chloride are two different chemical species. Chlorine is a volatile gas. Chloride (an anion) ain't and it will just stay there when you boil. Chloride WILL NOT become chlorine just by heating it up in boiling water. What you are suggesting won't work.

It is like saying that you can get salt (sodium chloride) out of water by boiling it. We all know that that isn't true. All you get is a more concentrated salt solution.

If you try what you have suggested, you'll end up with some mighty salty tasting brew.

Steve

From: rush@xanadu.llnl.gov (Alan Edwards)
Subject: Calculating Alcohol Percentage

Hello everyone.

I would like to know the REAL formula for calculating alcohol content from starting and ending specific gravity readings. Somewhere I picked up this formula:

```
Alcohol_by_weight = (Final_Gravity - Starting_Gravity) * 105  
and  
Alcohol_by_volume = Alcohol_by_weight * 1.25
```

I KNOW that at least the second part cannot be correct, because Alcohol_by_volume and Alcohol_by_weight do not have this linear relationship--otherwise 100% alcohol by weight implies 125% alcohol by volume (powerful stuff)! That makes me suspect the first equation also. Somehow, I don't think that either equation could be linear. These must be approximations. (They were probably inferred from those potential alcohol marks on a hygrometer.)

Does anyone know the definitive, correct set of equations--or at least something more accurate? Miller's book does not mention this calculation (at least I couldn't find it).

If you don't know the correct equations, what do you use in practice?

Thanks,
-Al

From: Martin A. Lodahl <pbmoss!malodah@PacBell.COM>
Subject: The Malt Extract Report (LONG!)

After my previous posting on the abstract(s) in Zymurgy of a report on adulteration of malt extracts, Russ Wigglesworth of the San Andreas Malts provided me with a copy of the original report. Entitled "Malt Extract: Relationship of Chemical Composition to Fermentability", by J. Paik, N. H. Low, and W. M. Ingledew of the Department of Applied Microbiology and Food Science, University of Saskatchewan, Saskatoon, Canada S7N 0W0, it was received May 15 1990 by the American Society of Brewing Chemists, and accepted September 5 1990. It's my understanding that it was published in the February 1991 issue of their Journal. This is a very long posting, but I think the subject warrants it.

The report makes fascinating reading, and clears up some points raised by the Zymurgy articles. It begins with an abstract:

Forty-four commercial malt extracts used in microbreweries, brewpubs, and/or homebrewing were adjusted to 12 degrees Plato and fermented at 14 degrees C. Results were compared with those of an all-malt wort from a large Canadian brewery fermented under the same conditions. In general, the worts made from malt extracts contained lower utilizable free amino nitrogen (FAN) values, showed slower fermentation rates, and had darker colors than the brewery wort. The extracts with higher FAN fermented better than those with low FAN levels. The slow fermentation rates of some malt extracts that contained low initial levels of utilizable FAN could be improved by supplementation with assimilable nitrogen from yeast extract or the nitrogen (but not the carbon skeleton) from glutamic acid. The carbohydrate profiles of the malt extracts as determined by high-performance liquid chromatography showed considerable variation. It was possible to detect in the malt extracts the addition of, or adulteration by, lower cost adjuncts such as glucose syrup, invert syrup, liquid sugar, or high-fructose corn syrup.

Significantly, one of the search keywords is "Stuck fermentation". The early part of the report describes the methods used with a level of detail one would expect of a paper of this nature. What would interest us is that "Forty-one malt extracts (all of light lager type) were purchased from a local brewing supply store. These malt extracts were called beer kits, home brew kits, concentrated brewing worts, or malt extracts for home brewing ... In addition, one bulk malt extract sample from a malting company and two bulk malt extract samples from a local brewpub were obtained". Red Star Lager yeast was used for all the fermentation studies.

The first sign of real trouble apparently came when they noticed that the time the extract brews required to drop from 12P to 6P varied from a low of 45 hours to a high of 173, compared to the baseline of 51 hours for the Molsen wort. In fact, "93% of the malt extracts had demonstrably slower fermentation rates than the standard wort", with a "correlation between initial FAN level and fermentation time (to 6P) yielded an r value of 0.75 -- a correlation significant at the 0.01 probability level" for all you statisticians out there. To summarize the conclusions of the fermentation part of the study, yeast nutrients appear to be much

more helpful than we've previously been led to believe, in dealing with extract worts. That fact is rather surprising: I, for one, wouldn't have expected there to be that much difference between the performance of an all-malt extract wort and an all-malt, all-grain wort.

The sugar profiles provided the real bombshell. They divided the extracts into 3 groups, according to the contents listed on the labels. Groups 2 and 3 both had various supplements listed, and the analyses tracked pretty well with the labeling. Group 1 extracts, however, "were labeled at the source as pure malt extracts". Of the 21 extracts in that group, a commendable 14 had carbohydrate profiles "similar to the standard all-malt wort", which placed them in class 1. From here I quote: "Group 1 class 2 extracts had a D-glucose concentration 2.7 times that of the standard, with concomitantly less maltose and maltotriose. The two possible explanations for this sugar profile are that wort production was carried out using a longer saccharification period during the mashing process (considered unlikely as the final ethanol concentration of the beer would then be >5%), or that a glucose syrup was added to the malt extract. A single Group 1 class 3 extract was found to have 88% of its total sugar content as D-glucose. Because this sample did not contain any D-fructose, sucrose, maltose, or maltotriose, this product was highly adulterated with a high-glucose syrup". WOW! A malt extract, without a trace of malt extract! They continue: "Carbohydrate analyses of all Group 1 extracts indicated that seven of the 21 samples labeled as pure malt extracts were adulterated with glucose syrup."

So there you have it. We all know that it's quite possible to make very good beer using malt extracts, but most of us have at some time had some problem extract batches. The degree of variation this study identifies suggests we may not always have been at fault. The study suggests to me a few considerations:

- + If you're not at least partial mashing, add yeast nutrient. It can't hurt, and might help.
- + Don't add sugar to an extract wort. It may already have all it can stand.
- + All extracts are not alike. if you're using a good one, stick with it.

Happy brewing ...

From: rich@progress.COM (Rich Lenihan)
Subject: astringent beer, partial mash? and Guinness

Thanks to all who responded to my recent question re: ppm vs. mg/l. I feel a little guilty because I haven't done anything with the information I've received. I don't treat my water yet (but I am pre-boiling all my water now).

Now some new questions:

A few weeks ago I made a batch of red ale using 6 lbs. light DME, 11 g. Edme dried yeast, 3.5 oz. Goldings leaf hops, 1 cup crystal and pre-boiled water for 5 gallon volume. Two problems: 1. The brew fermented fine for about 3-4 days, then stopped. Initial SG @ 1.044, subsequent readings stuck at about 1.032. I attributed this to a heat wave that killed my yeast (this is the first time I've brewed in the summer). I took another 11 g. packet of Edme dried yeast, started it in sterile wort and re-pitched into the carboy. From the taste, smell and look of the starter, the second packet of yeast seemed healthy enough (both packets purchased together). A month later fermentation is steady but sloooow. SG last Saturday was @ 1.021. Is this typical of Edme or is it just the heat? The AC in my apt. stays set at about 75 F. 2. When I tasted my SG samples, there was a definite astringency caused by (I guess) boiling the crystal for too long. Can this be fixed? What I'd like to know is if there is a way to sweeten or mellow the beer at this point without adding any more fermentables (I'd like to bottle it this year) and without raising its gravity.

Also, while I'm still extract brewing, I've been giving some thought lately to mashing my own. Now most "experts" recommend starting with a partial mash to get the hang of it for a while. Why? What are the advantages to this? It seems to me that if I'm going to go through the trouble of milling, decocting/infusing, spargeing and all of the rest of it, why not mill a little more malt and do a full mash?

Finally, I've read with interest the discussion re. Guinness on draft. Good Guinness is a wonderful drink (I've never been to Ireland, but I assume when saints die, they ascend to heaven on the foamy head of Guinness stout). However, noone so far has mentioned the #1 problem with getting Guinness draft in the States. Temperature. In most bars, all the kegs are kept in one room at one temperature - *cold*. So even if the Guinness is fresh and they use official Guinness tap systems, if they serve you a pint of Guinness at Budweiser temperature, it won't taste velvety smooth with complex undertones. It will taste harsh and bitter. The best you can do is to hold the glass in your hands until it warms up...if you can stand it :-)

End of HOMEBREW Digest #703, 08/16/91

Date: Fri, 16 Aug 91 09:53:06 EDT
From: "Spencer W. Thomas" <Spencer.W.Thomas@med.umich.edu>
Subject: alcohol by weight and volume

Clearly, these formulas are approximations, valid at low concentration. I'll address the second, as it is subject to fewer guesses.

$$\begin{aligned}\%V(\text{alc}) &= 100 * V(\text{alc}) / V(\text{alc}+\text{water}) \\ \%W(\text{alc}) &= 100 * W(\text{alc}) / W(\text{alc}+\text{water}) \\ 1/\text{SG}(\text{alc}) &= 1.25 = V(\text{alc}) / W(\text{alc}) \\ \%V(\text{alc}) / \%W(\text{alc}) &= V(\text{alc}) / W(\text{alc}) * W(\text{alc}+\text{water}) / V(\text{alc}+\text{water}) \\ &= 1.25 * W(\text{alc}+\text{water}) / V(\text{alc}+\text{water})\end{aligned}$$

Now, if the amount of alcohol is small compared to the amount of water, the second fraction is approximately 1. Assume the total weight is 1, the weight of the alcohol is w_a , and therefore, the weight of the water is $1 - w_a$.

$$\begin{aligned}W(\text{alc}+\text{water}) / V(\text{alc}+\text{water}) &= 1 / (1.25 * w_a + (1 - w_a)) = \\ 1 / (1 + .25*w_a) &= 1 / (1 + .25 * \%W(\text{alc}) / 100)\end{aligned}$$

For a 4% by weight brew, this amounts to

$$1 / 1.01 = .99$$

so the true percentage of alcohol by volume, instead of being 5% is 4.95%. Not really a measurable difference, at least with HB equipment.

From: PEPKE@SCRI1.SCRI.FSU.EDU (Eric Pepke)
Subject: Kegging in mini kegs

I "kegged" a batch of bitter in a couple of mini kegs a few weeks ago. (By mini kegs, I mean those 5 liter cans that are roughly shaped like kegs and have a stopper with a 1 cm hole in the top.) It worked fine. I just santitized the can, poured the beer in, and plugged it up with one of the minimalist taps. They hissed and bubbled a bit through the imperfect seal over the next couple of weeks. Last night, I tried drinking the first results. I used a CO2 tap designed for the kegs inserted not quite to the bottom to avoid picking up sludge. The beer was not carbonated much at all, which was desirable, as this was supposed to be a bitter. In contrast, the same beer bottled (with bulk priming) was a borderline gusher.

The total annoyance factor, though, was not much less than bottling.

I was under the impression that the sulfites were added to the wine must
before fermentation and during racking. Sulfites are added in the form of SO2
gas, or as sodium metabisulfite or potassium metabisulfite. Sulfites are added
to kill stray bacteria and yeasts in the must.

I've never heard that SO2 can be produced by fermentation and I'm quite
suspect of this claim. The reason that most wine bottles are labelled as
"contains sulfites" is that most wine makers use sulfites to control the quality of
the product; the practice is near universal.

Subject: Re: Cleaning Glass Carboys

>From GC Woods:

> If there is some gadget I'm missing to clean carboys, please e-mail me!

I clean my carboys as follows. It never fails to get them 100% clean.

- 1) Fill the carboy with hot water to within 2 inches of the top.
- 2) Top off with chlorine bleach
- 3) Let stand for several hours. You should see the scum bubble off the sides!
- 4) Brush the carboy thoroughly with an appropriately sized carboy brush.
(Carboy brushes of various sizes are available from your local homebrew supply store).
- 5) Rinse the carboy thoroughly with a jet-stream type bottle washer
(also available at your homebrew supply store).

Subject: what is high gravity/weizen style definitions

A few digests ago, someone posed the question of what's a high-gravity beer. I think of a starting gravity of about 1050 or so as the cutoff. Why?

If you think of the common styles, here are some gravity ranges and styles.

1030s berliner weisse, mild, ordinary bitter
1040s brown ale, kolsch, alt, standard pale ale, standard pilsner
1045-1055 munich helles, munich dark, vienna, flanders brown,
california common beer
1050-1060 dortmund, maerzen
1060+ trappist, old ale, bock, doppelbock, imperial stout, etc.

Beers in the 1030s are truly session beers. You can have 2 or 3 pints for lunch (food optional) and go back to work and still expect to function. Beers in the 1040s and 1050s are progressively heftier. By the time you get to the 1060s, alcohol is pronounced and even becomes part of the expected flavor and aroma profile.

A related reason for considering 1050 the cutoff is that high-gravity worts, with 1050 or so being the cutoff, require progressively greater hops due to inefficient hop utilization. See Ramsey's article in the special hop issue of Zymurgy for the formula including the adjustment.

An interesting related point is this. When I brewed extract beers, I'd add the malt to a couple of gallons of water, and top off to 5 gallons in the fermenter. I assume this is how many homebrewers do it, given the expense of large brewpots. In this situation, the couple of gallons of wort are a high-gravity wort. For example, if the wort when topped off with 2.5 gallons of water becomes 5 gallons of 1050-gravity wort, then the original 2.5 gallons of wort before topping off must have been 1100-gravity wort. By all rights, hop additions should take this into account! Needless to say, when I thought of hop additions in the 1/4-1/2 ounce increments the book recipe called for, this point was not known or appreciated.

Regarding Weizens, here are style attributes taken from a recent Zymurgy which presented definitions of the styles.

	weizendunkelw	weizenbock		
starting gravity	1040-1050	1045-1055	1066-1080	
alcohol volume	4.5-5.0%	4.5-6.0%	6.5-7.5%	
IBUs	8- 14	10- 15		
SRM range	3- 8	17- 22	7- 30	

So, according to these style definitions, a dunkel weizen is a dark weizen with perhaps a slightly higher starting gravity, while a weizenbock is definitely a bock in starting gravity while affording the brewer much leeway in color.

From: keng@ic.MENTORG.COM (Ken Giles)
Subject: Water treatment with CaCl2

George fix states (in Principles of Brewing Science, p.20) that bicarbonate (HCO3) combines with calcium ions to form calcium carbonate (CaCO3), water, and carbon dioxide when heat is applied and aeration is performed. Calcium carbonate is precipitated. Here's the formula:

He further states that the calcium content must be above ~10 mg/l to facilitate this reaction.

As for the resulting chloride ions, I can't find a place where he mentions their effect. Clorine is a problem because it causes formation of clorophenol compounds, which adversely affect flavor. Chloride ions will not cause this problem. Since NaCl (and hence, chloride ions) is a common additive in pale ales, it seems like low risk to have some extra chloride hanging around. Someone was concerned about the resulting saltiness. Doesn't this require presence of sodium as well?

George also says on p.13 that "Calcium chloride is finding increasing favor in water treatment programs because it does not have sulfur ions." Its useful to keep in mind that the intended audience for Principles of Brewing Science is the microbrewery industry as well as the homebrew crowd.

P.S. If you're trying to achieve a target concentration of calcuim ions, note that calcium chloride is really (according to George, p.12) CaCl2 + 2H2O. This will affect your molecular weight calculations.

kg.

Guinness

>as found in Ireland (it *is* an Irish pub).

I worked for a restaurant in Munich about 10 years ago. We had 3 kinds of beer, a normal helles, a Pilsner, and Guinness. The helles poured in a few seconds. The Guinness took about 10-12 minutes to pour, and the Pilsner took almost 15!!! That was not unusual either as when we would drink Pilsner at other places, we would generally order the next round just as the last round we ordered was being served.

From: "Dr. John" <JELJ@CORNELLA.cit.cornell.edu>
Subject: Wort chilling, etc.

In HBD #701 Steve Anthony asked about a wort chilling system based on ice water

This is the sort of system I have employed since I started doing all-grain, full-mash beers. I opted for a somewhat simpler design though. I use a coil (20 or 25', I can't remember which) of 1/4" copper tubing immersed in a 5 gallon bucket of ice water. I won't bore you with the details now, anyone who is interested can get in touch for a more in-depth description. This system chills 5 gallons of wort in about 20 or 25 minutes, and gives me a very good cold break; the wort goes in boiling hot and very clear and emerges cool (somewhere in the 60's (F)) and looking as muddy as the Mississippi. By incorporating both parts of my Zapap lauter tun into the chilling system, I kept the expense to a minimum. In addition to the coil of copper tubing the only extras I needed to put this together were an extra 5 gallon bucket (food grade of course, and thick enough so that it doesn't distort when filled with boiling wort), a couple short lengths of racking tubing, and a couple little metal hose clamps. I'm not sure, but I suspect that this method uses less water than either a counterflow or an immersion chiller.

On another topic, Geoff Woods, in HBD #703, says that he thinks carboys are more difficult to clean than plastic fermenters.

Carboys aren't really all that difficult to clean, if you have patience and a carboy brush. I usually rinse mine several times to loosen as much of the gunk as I can, then fill them completely with a bleach solution and let them soak for several days. This usually loosens most of the rest of the gunk and the carboy brush will get whatever is left. Of course you can omit the soak and have at it with the carboy brush immediately after the carboy is emptied. One indispensable item, at least for me since I haven't come up with the bucks for a keg system yet, is one of those jet bottle washers. They really speed up the rinsing of bleach-soaked bottles, and put out a forceful enough spray to do a nice job on carboys too.

Mitch Evans, in HBD #702, related the sad tale of an exploding bottle and its nasty effect on his thumb.

I hope things are on the mend Mitch. You might consider getting a kit to do a reducing sugar test. I have some of the Clinitest tablets that are sold by drug stores to diabetics. There was an article in Zymurgy, a couple years ago, by Nancy Vineyard on using this kit to test beer for reducing sugars. I'm not sure about her suggested procedure, seems that she doesn't use enough beer to get a good test, but I haven't gotten around to calibrating the thing myself yet, haven't felt a pressing need as I haven't had any explosions. This sort of test, if properly calibrated, should be more reliable than the hydrometer and a prayer method that seems to be so commonly used.

Al Edwards, in #703, raises a question about formulae for approximating alcohol content based on attenuation.

These formulae, or something very much like them, come from Papazian, and probably elsewhere. Now, while they obviously break down for extreme values on the high end they are probably accurate enough for approximating alcohol contents in the ranges we normally achieve with our beers. If you want something more technical try Noonan's "Brewing Lager Beer" in which you will find a description of how to go about determining real attenuation, as opposed to apparent attenuation, and a bunch of related stuff. As for me, I'll stick to the approximation I can get using my hydrometer and calculator. Even though the relationships may not be linear the approximation seems good enough, we are probably talking about some pretty small approximation errors here.

From: neptune!pryzby@uunet.UU.NET (Greg Pryzby)
Subject: liquid yeast question(s)

I have made the jump from dry to liquid yeast with my latest batch. I have a few questions concerning liquid yeast though.

I started the liquid yeast about 26 hours before I needed it. The package was HUGE (I don't think it could have gotten bigger.) I pitched the yeast at 70F and waited for the fermentation to start. Well, about 48 hours later the fermentation started. But it has been VERY slow. With dry yeast, the fermentation started within a few hours and was vigorous for a few days and done between 3-5 days. This batch looks like it is going to take a little (or a lot) longer.

Is this typical for liquid yeast? A slow start (about 48 hours to start)?

Slow fermentation (some bubbling)?

Temp should not be a problem, it is the same as for my last batches, between 70-76F.

I would appreciate any feedback from someone who can tell me about the difference between liquid and dry yeast. And why liquid yeast is preferred?

Or will I know that when the batch is tasted?

peace,
greg

From: ez005142@pollux.ucdavis.edu
Subject: Bicarbonate

Thanks to all who responded to my somewhat foolish questions regarding chlorine and chloride. After several people beat me over the head, I think

I am finally beginning to understand why my idea won't work. But if my idea is that bad, how the hell does one get rid of 700 ppm of bicarbonate?

One answer given awhile back was to use acid to shift the buffering potential

(or something like that) to a level where the bicarbonate would precipitate out. But what would it precipitate out as, and where would it

get positively charged ions to bind with. According to Miller you need a certain ratio of Ca⁺ ions to each carbonate ion in order to precipitate anything. In my water I've only got 70 ppm of Ca⁺. Where would all the precipitate come from? I can't add more Ca⁺ because all the compounds

containing Ca⁺ also contain things I don't want in my water (like Cl⁻ and sulfates) Doesn't anyone else have this problem or is Davis water really THAT bad? Or am I worrying about something that really doesn't matter anyhow.

In any case, I appreciate all the answers on my last stab in the dark. Thanks to everyone who can help me with my current questions.

Pretty soon I'll say screw it and buy bottled water!

Subject: Chill Haze

I have recently moved up from kit brewing to brewing with extracts, adjunct grains, and hops. While I have been very pleased with the taste of these beers, they have a chill haze that I never encountered with the kits. I suspect that it is due to the proteins dissolved in the wort from the adjunct grains (crystal malt and toasted barley malt) that I've been using. I put the adjuncts into the cold water and remove them when it comes to a boil, then add the extract.

Does anybody have any suggestions on the use of finings, or better still, how to avoid a chill haze without the use of finings? Is it alright to add finings to a secondary or will this precipitate out too much of the yeast needed for bottle carbonation? Should I close my eyes, not worry, and just enjoy the taste of the beer?

Subject: Harvesting and storing hops

Someone recently asked how to tell when hops are ready to harvest and I don't remember seeing an answer. Mine are getting to that point and, while I can make a pretty good guess, some advice would be helpful. The buds seem a little small right now, but in past years I think I've let them go a little too long.

Once the hops have been picked, what's the proper way of processing and storing them? I had one shop tell me to just put them in plastic bags in my freezer, but it seems like they get a little too damp this way.

One final question. Is there any way to tell what I've got? The hops were just growing there when I bought the house (no, that wasn't a consideration -- I didn't notice them until the first time I mowed the yard -- they're growing semi-wild along the edge of the property) and I've got now idea what variety they are. I'm pretty sure the previous owner didn't use them & he had the place for 15 years before me. The house was built in 1823, so who knows how old they really are.

Thanks for any help.

>
>Also, I believe that there is one brewpub there, called L'Inox??? Anyone
ever
>been there?
>

I've been trying to catch up on mail after having been gone for almost 2
weeks,
and haven't seen any response to this request.

I was in New England & Quebec in June of this year, and stopped in at
L'Inox.
L'Inox is in old town (vieux ville, if I remember my spelling); in fact
its in
the lower part of old town (along the river) at the 'downstream' end of
town
(northeast I think). I probably have the address at home; let me know if
you
want the address....

When I was there they had 2 "blonde" biers (light color); one filtered
and one
unfiltered (and slightly cloudy). The bartender gave us a sample of each
of
the biers, and I decided that the unfiltered was better (more hops taste
as
I recall). The only food that they serve is steamed sausages in a
steamed
bagette (french roll) -- not fancy, but still good.

For a 1 or 2 block stretch along the "main drag" (something boulevard, as
I
recall) just outside of vieux ville, the street is lined with restaurants
and sidewalk cafes. We ate dinner one nite at a place serving excellent
"homemade" sausages and good bier, and at another restaurant serving
great
dinner and dessert crepes (and reasonably good bier).

Hope this helps,

Subject: German 2-row

Tony Babinec writes that
>German 2-row malt is suited for pilsners. It tends to be
>less-modified. If it were especially undermodified, you might have to
>use a decoction mash. If it isn't too undermodified, you could use a
>step-infusion mash.

Apparently many commercial German brewers now use a single step
infusion (to save on energy costs), so I assume that you don't
necessarily "have" to use a step infusion with German 2-row.

On an unrelated topic I recall reading several weeks ago that
someone recommended only using British crystal for making bitters
and pale ales. I have had good successes with Briesse crystal malts
and don't think that the secret to making good bitters lies with the
nationality of the crystal used. What does help is to let the cooled
wort sit overnight in the fridge, and racking it off of the trub
before pitching the yeast. I only use British pale ale malt for
pale ales, and this may help. (A 55lb sack costs me \$45).

From: MIKE LIGAS <LIGAS@SSCvax.CIS.McMaster.CA>
Subject: Sulfite Discussion

It seems that I've touched a sensitive point with some HBD'ers with my mention of sulfites in mead making. First of all, if one is making straight mead (no additional fruits) then a boil is all that is needed to provide sufficient killing of unwanted microbes. As I mentioned a few issues ago, I use a low level of potassium metabisulfite when fresh fruit is added to the preboiled and cooled honey/water mixture, and that sulfiting is a standard practice in winemaking. One can make wine without sulfiting and let the resident yeasts in the must carry out the fermentation. This would of course be true to historical methods but can be a hit or miss proposition depending on the yeasts present.

The advent of pure strains with particular fermentative characteristics allowed zymurgists more control over the final outcome of their fermented nectars. It followed that to ensure that the yeast strain of choice would dominate the fermentation one would need to kill or reduce the population of 'wild' yeast and other microbes prior to pitching the chosen strain. Hence the use of sulfites when using fresh fruit since boiling fruit would set the pectin and destroy some of the finer aromatic and flavour components of the fruit.

One objection to sulfiting is that some people are 'allergic' to sulfites. This is partially true. The real problem is that sulfites hypersensitize you to what you are already allergic to, like airborne dust and mould. Many wine makers add a small amount of sulfite to their wine at bottling time in order to ensure a long shelf life and to actually enhance bouquet development in the bottle. The problem here is that SO₂ cannot escape and the wine can pose a threat to those who suffer from allergies. I have experienced quite an attack of sneezing and watery eyes once after consuming a heavily sulfited Italian red wine.

The trick is to use minimal sulfite to ensure that most wild beasts are killed or weakened and to add sulfite 24 hours prior to pitching your yeast, thus allowing sufficient time for SO₂ dissipation. Do not sulfite prior to bottling.

The use of sulfites is not restricted to wine and mead making. Read the

contents of a bottle of Mackeson's XXX Stout. Sucrose is added at bottling time to make this Sweet Stout style of beer but if the yeast fermented the additional sucrose a Stout bomb would be the result. Therefore the beer is pasteurized and sulfited to stabilize it from bottle fermentation.

IMHO, judicial use of sulfite is warranted in certain circumstances and should pose no real health problem unless you constantly exhibit allergic reactions to various allergens.

Subject: MALTING BARLEY, AGAIN

I note, with some cynicism, Darryl Richman's comment in Zymurgy, that the brewmaster of Pilsner Uguell seemed totally ignorant of the malting process.

From the responses I received to a very basic question on malting, that particular form of ignorance seems to apply equally to home brewers.

The diagram in the article came tantalizingly close to answering my question but left out details that could be used in action.

As I suspected, in order to get acceptable germination, dormancy must be broken. He talks about three steeping periods and a temperature range but leaves out what separates one "period" from another.

What happens after 21 hours at 15-17 degs that separates this period from the next 21 hour period or from the final 17 hour period?

I have been experimenting with freezing, friging and steeping but surely someone out there can save me from re-inventing the wheel.

Darryl.... where are you? Finish your article.

Subject: Re : Boots yeast

Regarding the difference between Boots' 'standard' and 'genuine brewers' dried yeasts, I have only tried the latter and can vouch for it (surprisingly enough, given the supplier !). It is a good general-purpose yeast, producing a very clean flavour even at fermentation temperatures up to 25 C; possibly a bit too neutral for ale fanatics. Its other main characteristic is its sedimenting ability, which allows glasses to be poured repeatedly from the bottle without disturbing the deposit. Keeps fermenting down to at least 15 C. For reasons that escape me, it seems to produce a better head on the finished beer than some other strains I have used. Looks like a mainly bottom fermenter.

Come to think of it, where are all these top fermenting yeasts we keep reading about ? You know the ones I mean, that are supposed to send up rocky pancake heads of yeast which threaten to engulf the house, and which require daily skimming and rousing management. I have tried most of the commercial dried yeasts available in both Australia and England, and am yet to see anything which resembles this description. Ditto culturing from Guinness, although I suppose they could be using a supplementary bottle-conditioning strain. The only thing I haven't tried is begging the dregs from a cask at the local pub. We have very few liquid cultures available here in the UK.

Which brings me to another set of questions : is it possible that top fermenting yeasts do not like closed fermentation ? In the absence of oxygen, might they possibly dive to the bottom ? Consequently, are we robbing our ales of some complexity by using airlocks during primary fermentation ?

Just to complicate matters further, I recently tried Geordie's Extra Pils kit. The kit is touted as producing a genuine continental lager (and does, full of sulphide). Strangely enough, there are also instructions to rouse the yeast daily. Why do this with a lager yeast ?

Lastly (I know, I'm full of questions today), what about the advice not to stir yeast with metal spoons. Myth or not ?

I used cultured Guinness yeast and an open fermenter for my last batch of all-grain Stout. Sure enough, I got beautifully large cauliflower heads which often brought up lots of brown muck. The pancake heads did try and take over the whole house, but fortunately didn't manage to crawl out of the kitchen.

Traditionally, ale has been fermented in open vats. I presume that the vigorous fermentation and abundant head cover must protect the beer. Even if it doesn't contribute to the complexity of the beer, it's fun to watch!

Subject: Re: Sam Adams Wheat beer

Sometime in the last week or two there was a discussion, initiated by Dan Graham I believe, about Sam Adams wheat beer. I finally had a chance to try it this weekend and, while it's great to see attempts at this happening in the US, was disappointed.

Comparing it to a substantial amount of other wheat beer tasted from German brewers, it was very one-dimensional (to me). It matched most closely to a wheat beer brewed by Tu:cher, also a filtered brew. In both cases, the characteristic clovey taste/odor was there, but it seemed like both brews were made to specifically emphasize that flavour only and not the other aspects of beer. I'd say it's similar to wanting the taste of chocolate and eating bakers chocolate instead of eating the sweetened stuff. I'm convinced, now, after comparing an amount of Kristal vs Hefe weizen, that wheat beer should not be filtered.

Some places (in Munich) I had to ask for lemon, but I'd say the lemon ritual is more particular to the tangy Northern German Weissbier rather than Bavarian Weizenbier.

A local restaurant, Cafe Berlin (run by three Germans) serves Spaten Club Weiss with the lemon wedge on the edge of the glass so you can choose.

I just plop it in -- squeezing gives *too* much lemony flavor/aroma, overpowering the delicacy of the beer; it also reminds me of the Corona/Sol/Tecate crowd, adding flavor to their `beer' by adding lemon :

Subject: a little help for a right-coaster (no homebrew suppliers in New Jersey)

(Originally posted to rec.crafts.brewing, in reply to a message from rec.food.drink.)

In article <49@pyuxe.UUCP> dab@pyuxe.UUCP (D Ballard) writes:
>Can anyone recommend a supply house in the central NJ area?

There are no brewing supply stores (or even brewpubs) anywhere in New Jersey. In fact, the legal status of home brewing in the state is uncertain. A Federal law was passed in 1979, "giving home brewing the same legal status as winemaking." [Mares, MAKING BEER, p. 21, which also quotes some of the bill.] This presumably loosened the bounds set by a previous law. However, a similar NJ law allowing winemaking doesn't mention brewing. Some Jersey prosecutors have occasionally promised that they won't enforce the "law against home brewing", but no merchant is willing to take the chance. (I've heard, third hand or so, from someone who predicts that New Jersey will be the *last* state in the U.S.A. with a legal brewpub.)

A gentleman named Bush (no relation to the President or to A-B) has been pushing for a specific law that *permits* limited home brewing. (One of the details was the question of requiring a license to make wine or beer. The compromise position is that a household could make 100 gallons/year without a license, and 200 gallons/year (the federal limit) with a license that costs about \$100/year, as compared to the \$20/year license New Jersey currently expects for making wine. This in a state that may soon require a license to design software, as described in the comp.software-eng newsgroup.)

That's not to say there are no home brewers, or no home brew clubs, in the state. There are supply shops in Staten Island and Greenwich Village. I've heard that they charge more than a lot of mail order places. I've gotten a recommendation for one of the latter: Semplex of U.S.A. (612-522-0500, 4159 Thomas Ave. North, Minneapolis, MN 55412), which doesn't charge extra for shipping most items. (They charge UPS rates for carboys and corn sugar; the prices for extract, grain, whole beginner kits (plastic bucket, no carboy, two cans of extract, and five pounds of sugar) and even Rotokegs "include shipping to anywhere in the U.S.A. and also to APO and FPO addresses.")

Subject: carboy cleaning

What exactly do you people put in your carboys that requires a long soak with a strong bleach solution to get out?!? When I wash my carboys, I just put in about 1/2 gallon of warm water and about a tablespoon of chlorinated TSP, then violently slosh the stuff around a few times. The only "gunk" ever stuck in the carboy is in the fermentor, around the top; that's kindof a pain to remove, but not much. Carboys used for intermediate settling and clarifying never get very scummy at all. Hmm.

I'll take this opportunity to re-endorse the cheap-beer-rinse technique of removing chlorine residue. After I wash with chlorinated TSP and rinse with the jet thing, I pour in a couple cans of Blatz (\$3.49 a twelve pack!) and slosh. Chlorine residues go down the drain!

Subject: Message from Kieran O'Connor

I went to high school in NYC, and one of the places we used to go to drink beer was McSorley's. We didn't go there because the beer was great (although the sandwiches are); we went because they never "proofed" us.

One interesting note. I was told by a regular that McSorley's used to be a men-only bar until recently (late 70's perhaps?). Therefore, they had no ladies bathroom. NYC sued the bar for discrimination, and McSorley's had to open its doors to women. However they did not put in a ladies room. The bathroom became co-ed. I haven't been there for 6 or 7 years, but I assume they have both bathrooms now, but I don't know.

Email addresses. I just moved to a bitnet only site. I have absolutely no access to internet. Therefore, if you have a bitnet address in addition to your internet address, could you please put *both* in your signature at the end of your post? I know it'll help me and I'm sure a few others who want to email folks, but who don't have the proper address.

I had to mail this to a friend on internet--I could not send this post to the HBD via bitnet (the listserv process) Could someone tell me how to do it? I sent it to BEER-L@UA1VM and it bounced, saying I had no authorization.
I successfully subscribed to the list via listserv, but can't post.

P.S. I'm a history teacher, and I was reviewing the 1988 elction campaign, espeically the Lloyd Bentsen-Dan Quayle debate. I happened to have headphones on, and I thought I heard Bentsen say (correct me if I'm wrong) "Senator, you're no Steve Russell." Although it might have been "Richman." Any one hear this too?

The way I have usually had it served is with one slice of lemon floating on top, and a couple of grains of uncooked rice at the bottom. Weizen is traditionally drunk more in summer, since it has more carbonation than other beer and is more refreshing. The rice will give the CO2 a place to form more bubbles, similar to the little scratches sometimes put into the bottom of champagne glasses. Lemon and rice are usually left in the glass.

> Darryl.... where are you? Finish your article.

Well, I've been out of town for a bit. I'm including below the
original text of the malting section of the Pilsner Urquell article.
Since the article was quite long, Zymurgy had to edit it down
somewhere, and the malting section took the biggest hit. (In fact, the
complete story was published, with more figures and photos, as a four
part series in the Maltose Falcons newsletter "The Brews & News".
Since the Falcons exchange newsletters with about 50 clubs out there,
you might check around and see if you can find the Feb. through May
issues.) I appologize for the length of this posting, but I'm not
really sure just where the cuts were made, and I feel it's better
read as a whole.

--Darryl Richman

The Maltster's Tale

To homebrewers, malt may seem like a pretty dull sidelight, an
ingredient that is just assumed. And yet, how can one hope to make the
finest of beers without understanding the materials required? Being the
largest ingredient after water and the arbiter of mashing conditions and
the source of food and nutrition for the yeast, its characteristics are
extremely important to the final product. The process of malting has
results that appear in the product as many subtle and not so subtle
effects on the flavor and appearance: grainy, toasty and malty flavors

and aromas, head retention, beer color, body, and so on.

Malting is the process that takes raw, harvested barley grains and readies them for the conversion of starch into sugars in the mash. Raw barley is very hard, or steely, because the starch is locked together with a lattice work of protein, called a matrix. If raw barley were crushed and enzymes added, very little starch would be converted to sugars because most of it would still be locked up in the matrix, unavailable to the enzymes. Even the germinating plant cannot reach the starch in this form, so it makes protease enzymes that slowly cut away at the matrix. As the plant grows, more and more of the matrix is destroyed; brewers call this process modification. As modification proceeds, the plantlet is also producing its own amylase enzymes to reduce the starches to digestible sugars. It is both of these processes that the maltster wants to encourage. However, as it grows, the plant uses its enzymes to make sugars which are then used as fuel for its growth. Overmodification means reduced extract.

The same grounds that contain the brewery include 2 malting works. In former days, most breweries did their own malting, but over the last century specialized companies have come to take over the malting process instead. Pilsner Urquell has adopted a hybrid approach: the maltings are run as a separate company, but the close proximity of their largest customer, and under the former communist system, the fact that they were both arms of the same "holding company," means that the maltings are dedicated to producing the malt that Pilsner Urquell specifies. They also supply malt to many of the other breweries, including Budvar. Jaroslav insists that Pilsner Urquell gets their best product, however. There is a new, larger maltings 2 kilometers down the road as well, which was built in 1988 and opened in '89.

We walked over to the nearest malt house to see how they work. Curiously, Jaroslav did not know a great deal about the maltings--he had to get a guide for both of us. He explained that he is in charge of the brewing activities (and previously had run the fermentation cellars), but the brewmasters and the maltsters don't get together much.

The maltings produce 50,000 tons of malt each year. If you are an all-grain brewer, and you get a pretty reasonable extract, that means you could make over 2 million barrels of beer at Pilsner Urquell strength. The grounds include storage space for 70,000 tons of barley and 15,000 of finished malt. The compound has a rail line passing through it, which not only facilitates delivery of the finished product, but malt as well, and there are also facilities for loading trucks.

The Process

The Pilsner Urquell maltings are based on a gravity system, not unlike that used in brew houses. The dry barley comes into the plant and goes into a storage silo. From there it is cleaned of dirt and foreign seeds, and brought to the top of the 6 story building, where it goes into the first of a series of steep tanks.

The steep tanks provide the environment for the barley seeds to wake up and begin to grow. Barley has a natural dormancy that must be overcome before it will germinate. It has evolved this mechanism to preserve the seed through the harsh winter and into the next spring. The steeping process is repeated 3 times in order to stimulate the seed to germinate. Each steeping takes about 21 hours.

The steeping process begins by filling the tank with cool water and pumping oxygen through. Although green plants get by employing photosynthesis, which breaks sugars and CO₂ into O₂ via sunlight, the germinating plant falls back onto respiration (sugars and O₂ to CO₂) as

a means of developing energy, so the water must be highly oxygenated to keep the germinating seeds from starving. (Fermentation, with which we are familiar, breaks sugars into alcohol and CO₂, without employing O₂; however, the yeast must go through a respiration phase to reproduce quickly.)

Each steep holds the barley under water for between 4 and 6 hours and then drains the water away for most of a day. This simulates rainfall, and is how the maltster fools Mother Nature into thinking that spring has arrived.

As germination begins, with each seed respiring, a lot of CO₂ is given off. Every 2 hours a huge fan pulls the heavy CO₂ out of the tank from underneath; it is naturally replaced with fresh air. This goes on for about 15 minutes. At the end of each steep cycle, the grain is released into a new tank waiting below it, and the process begins again.

Finally, after 4 days (and four stories' drop), the now-germinating barley ends up in a germination bed. This is a long, shallow, rectangular frame that holds the barley as it grows. It is here that the barley will grow to its final stage before kilning.

There is a cross-member that runs over the short dimension and is motorized so that it can proceed from one end of the frame to the other. On this member are a series of screws that slowly turn, lifting and separating the germinating grain so that the roots will not grow together and form an impenetrable mass. This also aids in the air flow through the bed, which is held at 60* F and 47% moisture.

The barley is carefully watched, until the acrospire, or growing tip of the barley plant, reaches 2/3 to 3/4 of the way around the long dimension of the seed. It is at this point, after about 7 days, that the barley is sufficiently modified, and the germinated plantlets are moved off to the kilns. For comparison, in English malt the acrospire is usually allowed to grow all the way to the top of the seed; most 2 row malt is allowed to reach the 3/4 point before germination is stopped.

The kilns are special closed boxes with hot, dry air blowing through them. The service entrances have airlocks to prevent losing heat if someone must inspect or repair them while they are in operation. The maltings has three of these boxes, and they can dry 50 tons of malt at a time.

The wet malt is dropped (once again) into a kiln to a depth of 85-90 cm (just under a yard). The hot air is held at 80-81* C (176-178* F) until the malt reaches a moisture content of just 3.5-4%. The process takes about 20 hours. After drying, the malt is cleaned again--this time to remove the rootlets from the malt.

The malt produced has a color of 3.8-4.0 EBC (about 1.9-2.0* Lovibond), which is pale indeed, but not as pale as most 6 row malts, or even 2 row malts in this country. In fact, this is very near the figure often quoted for English Pale malt. This is one reason that Pilsner Urquell is not as light in color as American or even many continental lagers.

The malt ends up with 11.5% protein, on average. (Barley protein figures vary with each crop, and can have substantial swings.) This is a relatively low figure when compared with American crop figures, which tend more towards 12.5-14%. The protein number is a figure of merit with respect to the amount of adjuncts that can be added to the mash without affecting yeast health. Since Pilsner Urquell is an all malt beer, this is not, of course, a concern. It can also indicate potential haze and heading problems.

Subject: Re: Harvesting and storing hops

-> From: cj@wisny.att.com
->
->Someone recently asked how to tell when hops are ready to harvest
-> and I don't remember seeing an answer. Mine are getting to that
point
-> and, while I can make a pretty good guess, some advice would be
helpful.
-> The buds seem a little small right now, but in past years I think
I've
-> let them go a little too long.

I usually pick when the little tips of the buds just start turning brown.
The inside of the hops should have lotsa pretty little yellow sacks that
smell absolutely wonderful when you crush them in your hand.

Mine are much smaller and later this year than the last two. I think the
size may be due to my letting too many vines grow from one root, and the
lateness may be due to the unusually cool summer we've had in San Jose,
Ca.

->Once the hops have been picked, what's the proper way of processing
-> and storing them?

Dry them. This will improve your control of amounts when adding them to
your brew, as the wet hops will lose about 2/3 of their weight when
dried.

(I have a not-exactly greenhouse, which gets way hot, and I just let 'em
sit in there for a day. You could use your oven on low.) Then I seal
them
with as little air as possible in your normal kinds of sandwich bags.

->One final question. Is there any way to tell what I've got?

I don't have a clue. This also raises the question of how to measure
the alpha of homegrown. I don't - I use 'em for aromatics, only. As
a matter of fact, I'm going to pick some tonight and use them to dry hop
a batch I am racking from primary to secondary (and not bother drying
them first!).

Two Questions:

- 1) A while back someone posted a reference to a company which markets small submersible pumps which could be used to pump ice water through a immersion chiller. The company name was Grainger and I need to find out the model numbers which were referenced and approx. cost.
- 2) I may be leaving my current position for another opportunity. What are my options of still having access to Homebrew Digest?

Please email responses to link@rsi.prc.com

Thanks,

John S. Link

Subject: Re : The great CaCl₂ debate

Seeing I provoked some of the current debate, I'd better set the record straight.

Hard water contains lots of dissolved mineral salts. Salts contain both a positively and a negatively charged ion, eg, calcium (++) and chloride (-).

Depending on the type of beer being made, some of those ions are more or less desirable. Calcium (++) ions are universally regarded as being good for pale ale and bitter production, for a whole host of reasons, including the fact that they increase the acidity of the mash by an indirect process.

Ditto magnesium (++) ions. Chloride (-) ions in small amounts are good for bringing out the sweetness in beers. Most salts which contain chloride ions taste 'salty'; this is not a function of sodium (+) content.

Carbonate (--) and bicarbonate (-) ions are alkaline, that is, they react with anything which is acidic and thus reduce the total level of acidity. For various reasons, these ions are dreaded by all brewers except those who make very acid beers using roasted grains. Let's forget about stouts for the moment.

Hard water which has flowed through gypsum contains calcium++ sulphate-- , both good news. Hard water which has flowed through limestone usually contains calcium++ and/or magnesium++ (good news) bicarbonate- (bad news) .

How can the beneficial half of the salt be retained whilst disposing of its undesirable negatively charged partner ? Simple, react the salt with a controlled amount of acid, at room temperature. The products are water and carbon dioxide, not a precipitate. Less simply, heat the untreated water. The bicarbonates- will be transformed into carbonates-- and will precipitate (good news), along with an equal molecular amount of calcium+ + and/or magnesium++ (bad news). Therefore, you might wish to supplement the calcium++ content by adding some calcium++ chloride-. But the treatment is starting to get complicated.

Most of the time, adding calcium chloride will precipitate nothing, unless there is a soluble carbonate salt present, such as that of sodium+ or potassium+ (most unusual). Calcium chloride could be a better choice than table salt for bringing out the sweetness in a beer. Notice that most water authorities quote the total alkalinity as the 'equivalent' of ppm calcium carbonate, even though this salt is never present in large amounts.

It would be very unusual to have both a high bicarbonate ion content and a low calcium ion content, unless (a) the alkalinity is mainly due to

magnesium salts, or (b) some drastic treatment has already been performed.

Can't say that I have read Miller, but ... Even the late, great Dave Line had his moments. For example, recommending gelatine as a fining agent (has anyone ever found this to work) ? Or the occasional 'any yeast will do' philosophy.

Clear as mud ?

Subject: Mash questions, cleaning carboys

I'm gearing up soon for an all-grain. I have a couple of questions.

- 1) Is it better to acidify the mash water with gypsum or lactic acid?
What about the sparge water?
- 2) Can one make a good pale ale with Klages 2-row? Or should I save
the Klages for lagers and use British pale ale malt?

For cleaning my carboys, I simply add a few tablespoons of TSP, available at your nearest hardware store, and fill with water. I let it set overnight, then spin the carboy 90 degrees quickly. I also use a carboy brush to get the stuff I might not see. Works great.

Subject: sc homebrew worksheet

There was some mention earlier of a brewer's worksheet for Lotus or Excel or something like that. Since I don't have either of these, I've put together a little brewer's worksheet for SC (spreadsheet calculator). I've tried it with version 6.16, but it might work with others. It's pretty simple, it calculates the O.G., color, and IBUs (among other things) based on the grains and hops. It's kind of fun to play with, and helps to zero in on the right quantities to get desired results.

I've ftp'ed it to ftp.uu.net in /tmp/bw.sc.shar. I believe it will live there for a while. I'd like to send it to the homebrew archives at mthvax, but I don't know how. If somebody knows how to do this, would they please send me some mail? If you can't find it in either place, please mail me and I will send it in shar form via email.

Subject: Old Peculier

Has anybody successfully brewed a beer that closely resembles Theakstons Old Peculier? This is one of my favourite beers and I wish I knew the secret.

I know about Dave Line's extract recipe, but it doesn't come close to the Real Thing. I've formulated and tried several all-grain recipes, but none matched Old Pec. The brews were either too stout-like, too dry or had the wrong kind of sweetness. None had the distinctive Old Peculier taste.

Does anybody know how Theakstons do it?

Thanks in anticipation,

Ifor.

Subject: Re: Malting and enzyme destruction...

One thing that has bothered me for a long time: Miller, et.al. cautions against mashing at too high a temperature as that will destroy the enzymes and give poor yeild (or high dextrines, or what ever you happen to believe in)

The thing that bugs me is information like what Darryl said about the kilning process at Pilsner Urquell: they kiln at 178f for 20 hours!!!. Even Miller, after talking about enzyme activity vs temp, then goes on to recommend "kilning" lager malt in an oven at 212f for 2 hours before using it to make Vienna Lager. Jeeze, if Miller and Papazian believe that enzymes are killed in Mash-Out at 168f, then someone is on drugs.

Can anyone explain? Is it the availability of H2O? The acidified Mash? Could it be that Mash-out is an achronistic step in mashing?

From: microsoft!larryba@cs.washington.edu
Subject: Gelatine Finings; Calcium & Klages

Conn V Copas asks about Gelatine finings:

My beers never satisfactorily cleared (kegged and usually drunk within 6-8 weeks after conditioning) until I started adding gelatine. I dissolve 1/4 tsp of gelatine in 1 cup of boiling water and just dump it into the open keg after racking the beer. I have also done this directly into the secondary when lagering. Usually within a week the beer is fairly clear. Two to three weeks later it is bright.

I use Knox unflavored gelatin, about \$.80/oz at local supermarkets. It appears to be a lifetime supply...

Darren Evans-Young asks about Calcium and Klages:

a. use calcium sulphate or chloride. The calcium is needed for certain enzymatic reactions that causes the acidification/buffering of the mash. If you have soft water, 8 gm of Gypsum will add ~75ppm calcium to 7 gallons. Miller has a good discussion of water treatment/solutions.

John Polstra had a good summary in HBD #671 and #672

b. I have used klages and obtained good results. If you are making a pale ale (vs an brown or IPA), you might need some color (10% munich malt, perhaps) since the klages is much lighter than English Pale Ale, Mash the same.

Subject: Re : Malt extracts

Thanks also from me for the post on extract analysis. Explains lots of things, like why mashed brews ferment so much faster than extract brews, and why an extract brew of SG 50 can have a similar amount of malt flavour

to a mashed brew of SG 30. Re nutrients, as well as ammonium salts as a source of nitrogen, brewers might also wish to consider vitamin B energisers, which can also be deficient. Combination nutrient/energiser mixtures are available here commercially, and they have cured any of my stuck fermentations. Bear in mind that the brew may attenuate further than

what you are used to. Most of the commercial extracts here give about one-seventh unfermentables, which is not enough for me.

Another interesting aspect of extracts is their speed of clarification. Edme's diastatic liquid extract (DMS), for example, yields an almost perfectly clear liquid after boiling and cooling. The end result is that, with a good flocculating yeast, it is possible to have clear beer 2 days after primary fermentation, without using finings. Something to do with the

protein content maybe ? Alternatively, diastatic extracts are manufactured

by condensing at relatively low temperatures under vacuum. Could this method have advantages for clarity ?

Lastly, another part-mythical creature : the malt extract 'tang'. Fact or fiction ?

From: "Jack D. Hill" <jdhill@BBN.COM>
Subject: Lagering problem

My first attempt at a lager seemed ready to bottle this weekend, but in a short time it became apparent I was wrong. On June 10th I brewed the honey lager from CJHB. I pitched with Wyeast Pilsner. Advice I had received from a local homebrew supply house said he had good success by waiting for initial fermentation to begin at room temperature before refrigerating at 55 degrees. After the bulk of the initial fermentation is complete, transfer to a carboy and lager at 45 degrees. This I did, two weeks in the primary at 55 degrees and two months in the secondary at 45 degrees. The primary had all the activity you would expect from an ale. After I had transferred to the secondary, I could see a healthy rate of tiny bubbles running up the side of the carboy, the fermentation cap riding high and occasional burps from the fermentation lock. The krausen was thick.

Last week I noticed the fermentation cap riding low and a marked decrease of bubbles. The krausen was thin. Bottling seemed to be in order. Yesterday, I brought up the carboy and let it settle while I prepared and cleaned the bottles. After an hour I was getting an incredible amount of fermentation activity. Obviously it wasn't ready to bottle. I put the carboy in the basement (where it is cool) to wait out this second spat of activity.

What should I do? Should I put it back in the fridge in a few days, immediately or should I let it finish its fermentation at room temperature?

Thanks,
Jack Hill

Hello,
I must correct Paul Chisolm who states there are no home brew stores in NJ.
There is at least one. It is called Wine Hobby (908-874-4141) and is on Route 206 in S. Somerville/Hillsborough. They are open from 10-5 and stay open until 8 on Thursdays. Call to check weekend hours. They have both wine and beer supplies, and while not the biggest store on earth, they have or can get what you need. There is also a home brew only (virtually no wine specific supplies) store at 20th and Sansom in Philadelphia (forget the name) and a place in NY City called Milan Home Wine and Beer (212-226-4780) at 57 Spring St. in Manhattan.

Also, since the USA made it legal to brew beer (in 1976?) wouldn't it then be legal in NJ to brew beer? Or has it been given to each state to make its own laws? Is Utah a dry state? If so, can one brew beer there at home?

From: Frank Tutzauer <COMFRANK@ubvmc.cc.buffalo.edu>
Subject: Why is my beer so sweet?

Ok, it's time to help the novice. I'm getting ready to brew my third batch, but before I do I want to correct the problems of the first two batches. To wit: The beer is too sweet. In fact, the first batch was so sweet as to be undrinkable. (It's not a total waste. I've been mixing it with store bought, which cuts the sweetness of the homebrew and improves the body and taste of the store bought.) Here's what I did. For the first batch, I followed the beginner's chapter in TCJoHB, namely, hopped extract, yeast, and water. Not knowing one extract from another, I chose American Eagle Amber (hopped), mainly because Alternative Beverages said something to the effect of, "A good extract, unaffected by the price increases of the English extracts." I boiled two cans of the extract in 2 gallons of water for 15 minutes, put it in the carboy with enough water to make 5 gallons, cooled to 78 degrees, and pitched 14 grams of dry Whitbread ale yeast. O.G was 1.033. I then attached a 1" blow off hose, and moved the carboy to the basement. Wouldn't you know it, but Buffalo experienced a heat wave right when I was ready to brew, so fermentation temps were between 75 and 78 degrees throughout (it was the coolest place in the house). Anyway, within a few hours, the fermentation was going great guns (which, incidentally, is a cool thing to watch). In two days, the krausen had fallen back into the beer and I attached an air lock. Two days later, the glubs had ceased and the gravity had fallen to 1.012. I checked the next day and the next and got 1.012 both times. This seemed like a short fermentation to me, but I figured it was the heat, decided to not worry, and bottled. Two weeks later, I opened a bottle. It wasn't carbonated enough, although it was coming along, but geez louise was it sweet. Almost as sweet as the wort. Charlie said I could expect a beer with a "sweet palate," but this was ridiculous. The second batch, an English pale ale, went like this: 1 can Edme English bitter extract (hopped), 2 lb. light DME, 1/2 oz Kent hop pellets (alpha = 4.7) for finishing, 14 g Edme ale yeast pitched at about 80 degrees. O.G. 1.031. Fermented for 8 days at 72 to 76 degrees. F.G. 1.011, constant for the final three days of fermentation. This beer is at least drinkable, but it's still a little sweet for my tastes. I know some people like a little residual sweetness in their beers, but I like mine downright bitter. In fact,

underneath the sweetness you can tell there is a good beer lurking here, but

like I said, I prefer more bitterness.

My next batch is going to be an Irish dry stout. The kit came with a can of Munton's hopped export stout extract, 3 lbs. dark DME, 1 cup black patent,

1 cup flaked barley, 1 lb. of roasted barley, 7 g. of M&F ale yeast, and 1 oz.

of Bullions hops, half for bittering and half for finishing. What can I do to

make sure that this batch doesn't turn out too sweet? My novice-like hypotheses for what went wrong the last times are:

1. Crummy extract.

2. Not hopped enough.

3. Too high a fermentation temperature, producing these famous "esters" I've been reading so much about. (I suppose the nose and taste might be described as "fruity" but I think "sweet" is a better adjective. There certainly are no identifiable fruit scents/tastes--no raspberry, banana, pear, smells or anything like that.)

4. I screwed up the yeast somehow, so not everything fermented. (The yeast was not dead, given the gravity drop and the fact that the beer is carbonating, although SLOWLY. Charlie says it takes 7 to 14 days. Mine's taking about three weeks. Also, I think fermentation was complete, given the

constant gravity readings and the fact that I don't have any gushers, at least as of yet.)

5. An infection. I don't think so. I was pretty careful about sanitation. I've had practice helping my wife with her canning. (Unless the

food is acidic, there's nothing to prevent bacterial growth, so the canning

people are far more paranoid about sanitation than homebrewers. I found the

level of sanitation Charlie asked for to be an easy thing to carry out.)

Is the remedy something as easy as adding more hops? What should I do?

(Sorry for the length of this post, but since I'm not sure what in my technique is responsible, I wanted to include all the details.)

Thanks.

In HBD # 703, GC Woods <gcw@garage.att.com> writes:

>Does anyone have an extract recipe for making a "lager style" beer
>with ale yeast. I've been in brewpubs which do not have the
>facilities/capacity to brew lagers, but will make a similar brew using
>ale yeast.

Although I haven't tried the recipe below, it should give you an
idea of where to start:

Lageresque Ale

4# (1 can) Alexander's light unhopped malt extract (syrup)
1.5# Light dried malt extract (DME)
5 AAU's of your favourite bittering hops (ex.: 1/2 oz. of 10% alpha
chinook)
1.5 oz. Hallertauer or Tetnanger hops for finishing
Ale yeast (Wyeast American Ale #1056, aka Sierra Nevada *strongly*
recomended)

Production:

Dissolve the extracts in 5 gal. of brewing water. Bring to boil,
After 15 mins, add bittering hops. Boil 60 mins total. Turn off heat
and add finishing hops. Cool as rapidly as possible to 60-70F. Rack to
fermenter, top up to 5 gal., pitch yeast, relax, etc.

Hints; Conduct the fermentation at as cool a temp as you can muster, to
keep the esters down. If you can, rack the wort off the trub before the
fermentation really gets started (i.e. let it settle out for 4-6 hours,
then
rack, but pitch the yeast *first* to avoid nasty surprises). Use an ale
yeast
that is "clean" (i.e. produces few esters). Reportedly, Wyeast #1056
(American
Ale) is supposed to be the best yeast in this regard. You can also
culture
this strain (or one with a *very* similar flavour profile) from Sierra
Nevada
ales. Boil the full volume of your wort. The more dilute wort gives
better
hop utilization, and helps avoid caramelization of the wort. After
bottling
or kegging and subsequent carbonation, let the brew "lager" in the
refrigerator
for 4-6 weeks. Hope this helps!

Todd

Subject: Liquid Yeast Behavior

To my surprise, no one has yet answered the questions Greg Pryzby asked in HOMEBREW Digest #704:

>I started the liquid yeast about 26 hours before I needed it. The package
>was HUGE (I don't think it could have gotten bigger.)

The amount of time required to swell the packet can vary widely, running from just a few hours (for a very fresh packet in a warm environment) to several days. A couple of years ago Wyeast experimented with a new packet design, and for several months (before Pete Soper's valuable work in collecting anecdotal data over HBD pinpointed the problem) people all over the country experienced little explosions ... They went back to the original design which is somewhat stronger.

> ... I pitched the
>yeast at 70F and waited for the fermentation to start. Well, about 48
>hours later the fermentation started. But it has been VERY slow. With dry
>yeast, the fermentation started within a few hours and was vigorous for a
>few days and done between 3-5 days. This batch looks like it is going to
>take a little (or alot) longer.
>
>Is this typical for liquid yeast? A slow start (about 48 hours to start)
>?
>Slow fermentation (some bubbling)?

Given the circumstances you name, it's to be expected. You can pitch directly from the packet, and I've done so successfully, but that's underpitching to a significant degree. It's much safer to culture the yeast cells up to a much larger number before pitching. I usually start the packet on the Wednesday or Thursday before I brew, anticipating pitching on Sunday. After the packet swells, I boil 4 Tbsp. DME (dry malt extract) in 2 cups of water for 20 minutes, adding a pinch of yeast energizer. After cooling in a water bath down to the 70's or so, I sanitize the swelled packet, carefully open it, and pour into the starter solution I've just made. Usually it's at high kraeusen by the next day, and if it looks like the kraeusen will fall before it's time to pitch, I make another batch of starter that's twice as large, and pitch the first one into it. I always get a fast start from that method. However, in the temperature range you mention, I've usually gotten a pretty fast start even just pitching the packet contents, without reculturing.

Another reason for its apparently slower action is that dry yeast have hardships to overcome that liquid colonies never meet. Many yeast cells die from the rigor of being kiln-dried, and rehydration (especially in a sugar solution) subjects the yeast to severe osmotic stress. For these reasons, compromises must be made in selecting the yeast strains, with an emphasis on "survivability" and vigor, often to the detriment of the qualities of the finished beer. That's why dry yeast seem to "hit the deck running", while liquid cultures (usually) seem more relaxed in their action.

> And why liquid yeast is preferred?
>Or will I know that when the batch is tasted?

You'll know. As an experiment, I tried dry yeast (Lallemand, which is seeing wide application in brewpubs just now) in my last batch. My next batch will use either a liquid culture or a strain from my own lab cultures.

Subject: Lauter Tun Set Up

To those of you using the bucket within a bucket lauter tun (w/the hundreds of drilled holes), what kind of buckets do you use? I have 2 of the ubiquitous 6.7 gallon plastic food pails. They sit about 6 inches apart, no need to cut off the flanges. So I thought I'd pick up an even more common 5 gallon, of the same design. I cut the flanges off, but even then the bottoms fit about 3 inches apart. I have since become an expert at spotting these pails - they are everywhere, and have noted that *ALL* have exactly the same diameter - only differing in height. So what's the story? Keep looking? Deal with the inefficiency & increased sparge time of the 3 inch difference? Some other idea? (no picnic cooler stories please)

Subject: Cheap(er) SS Stock Pots

If anyone has been thinking about buying a stainless steel stock pot, the best deal I have seen is available from Superior Products Mfg. Co. of St. Paul, Minnesota until October 11, 1991. Superior Products is a restaurant supply place that also has a lot of great beer dispensing equipment. Get their catalog.

The right thing to get is a Vollrath Stainless Steel Stock Pot with cover. I have the the 24 quart model, and it is everything anyone could want in a stock pot. It's built. I will be passing this thing down to my great grand children after it has happily brought thousands of gallons of beer into the world.

The special sale catalog I received says the following (I will only list the part number, volume, and sales price (the list price is a lot more)):

Made of 18.8 stainless for greater resistance to pitting and corrosion, plus heat conductive base to save energy. Flat covers allow stacking to save space.

7-L-105	16 qt.	6 lbs	\$59
7-L-107	20 qt.	8.5 lbs	65
7-L-129	24 qt.	9 lbs	70
7-L-130	38.5 qt.	13 lbs	90
7-L-492	60 qt.	15 lbs	130

Covers

7-L-127	For 16, 20, 24 qt.	\$18.40
7-L-136	For 38.5 qt.	22.00
7-L-494	For 60 qt.	23.00

You can use your credit card and the phone number:

Subject: Re: Why is my beer so sweet?

Acting as an armchair expert;-), my guess is that the beers that you are making are underhopped. When there's not enough hops to balance the malt flavor, the beer is going to taste *alot* sweeter. Your best bet is to stop using hopped extract (the reason alot of people advise mashing is to have more control over the beer than using extracts, by using hopped extracts, you are giving up one more thing under your control) and use real hops. You should also probably try to boil more than 2 gallons of wort, if you can.

The temperature factor is perhaps valid as well, but I don't think that it is the major contributor.

Good luck,
Jason

Yes and yes. The enzymes can stand higher temperatures when they are dry.
That's why the malt must be dried at lower temperatures before it can be kilned.

They're not totally invincible, though. Roasting will destroy them.

Subject: Re: Lauter Tun Set Up

I use a pseudo-double-bucket lauter tun. I started with two 5 gallon buckets. I not only drilled the proverbial million holes, but to beat the problem you described, I cut the bottom off the 'holy' bucket and it fits all the way down to the tap in the other bucket. I also cut a couple of tabs into the sides of the false bottom so I can pull it out when I'm done (it's a very tight fit).

Subject: Detonation imminent?

Hi,

I need a quick expert opinion to avoid redecorating my basement in broken glass and Toad Spit Stout. I brewed this using the recipe in Papazian; fermentation was very vigorous for three days, then slowed to almost nothing. Gravity went from 1.050 to 1.020 and held there for five days, so I assumed fermenting was done and bottled with 3/4 cup corn sugar.

Because of the high ending gravity, and keeping the recent discussion on bottle bombs in mind, I carefully opened a bottle last night. After only three days in the bottle the stout had about the pressure that one would expect from a mature bottle, or more: even though I opened it in stages, it gushed over a little bit. When poured, it had a lot of head on it, which dissipated within two minutes. The brew itself did not taste overly carbonated.

About half the batch is in resealable Fischer (Grolch-style) bottles, so I took the precaution of opening and closing all of them to relieve the pressure. None of them gushed, but I didn't leave the bottles unsealed long enough for them to do so. The other half, though, are in capped bottles. What I would like to know is:

- should I uncap and recap all of these bottles to avoid a problem with excess pressure? It might result in flat beer (though I can always open and reprime the bottles), and then again it might prevent bottle bombs.
- Will it be sufficient to just put the bottles in the refrigerator, on the theory that cold beer holds more carbonation and so is less likely to blow up? I hate to chill good stout but will do so if necessary.
- Am I worrying too much? After all, the final fermentation could have finished quickly because of the warm weather in summer. The basement stays in the 75 range this time of year, but might reach 80 during the day when it's hot.
- If I want to take another SG to see if there were excess fermentables which are now being "processed", will the carbonation in a bottled beer skew the results? I could leave a bottle opened but airlocked overnight to let it go flat. And of course I would have to adjust for the sugar added for bottling.

You can respond directly to me at buchman@marval.enet.dec.com, or post the response. I'll summarize any interesting responses.

(btw, I never heard back about the recipe for Pumpkin Ale from this summer's Zymurgy. Does anyone have it?)

Thanks,
Jim Buchman

Subject: The great yeast hunt

I'm relatively new to the digest, but I've been brewing for some time. I've been slowly working my way through the past year of archived digests but (surprisingly) haven't found an answer to one question I've had for a long time. While there are many accounts of culturing the yeast from a bottle of commercial beer, most (if not all) of these involve Sierra Nevada.

I'm sure everyone has heard apocryphal stories of an individual purchasing

10+ cases of some exotic beer, hoping that there will be just a single stray yeast cell that can be nurtured and cared for and encouraged to reproduce.

Rather than spend a small fortune on commercial beer, I thought I would turn

to the experts. From what brands of beer has yeast successfully been cultured?

-Nils

From: R_GELINAS@UNHH.UNH.EDU (Russ Gelinias)
Subject: ss pots

Sorry Justin, but Rapids Inc. still has the best prices. I just bought a 40 qt. ss pot (made by Polar, I think) with lid. The pot was \$90, and the lid was \$18. I also got a ss spoon for \$2.25. UPS shipping to NH cost about \$11, so the whole package cost me \$121. I believe Rapids is located in Iowa, which would lead to lower shipping costs to most of the US than from Minnesota.

I just getting caught up with my digests and read your article:

> I live on the coast of Maine (hee hee hee :->) where homebrew supply
> shops are few and far between. It is rare that any of the three
> stores that I am aware of have anything other than your standard
> Red Star dry yeast :-(. Certainly there is nothing like the selection
> I've heard of on the net (German ale yeast #1007 !?!? what!?!). Is
^

This is a liquid yeast. Wyeast (as well as others) sell liquid yeast cultures designed for different types of beer. This is not to say that you couldn't use the german ale yeast in making a stout or other type of beer. The different strains of yeast will impart different flavors to the finished product.

> there another store in Maine (other than the Whip&Spoon, the Purple Foot,
> and the Grainery) or is there a reliable mail order house? Any addresses
> or phone numbers would be much appreciated.

I'm not sure where else in Maine you could try, but some mail order places are:

The Home Brewery 1-800-321-BREW
Alternative Beverages 1-800-365-BREW
Brewhaus 1-800-265-BIER

I've only ordered from Alterative Beverages (located in Charlotte, NC) and had no problem.

> Oh yeah, any idea why a beer would gush when opened warm but not when
> it's been chilled?

Simple physics: A colder liquid can hold more compressed gas than a warmer one. However, if you're getting gushers in non-infected brews, you're probably putting in too much priming sugar or bottling too soon.

> -Nils 'my cup runneth over' Nieuwejaar

BTW, I'll be in Brunswick for a friend's wedding the weekend of October 12th and probably for a hockey weekend sometime. If you want to, we could get together and exchange experiences and homebrew.

Subject: Reply to Homebrew Digest #706 (August 21, 1991)

In Homebrew Digest #706 Dean Cookson asks:

> I've been wondering, is kegging really worth the starting expense??
> The Cat's Meow lists a couple of places with complete Cornelius
> systems in the \$150-\$175 range. Is that a good price??

I am in the process of setting up a kegging system. I had been watching the "business equipment" section of the local want ads for several weeks. I finally saw an ad for a restaurant that had gone out of business and was liquidating its equipment.

I showed up at the restaurant at the appointed hour. I was able to buy two 10# CO2 tanks, two 2 guage regulators and a half full coke canister (Firestone) for \$60.00. I also met a fellow who owns and runs a used restaurant equipment company. He said that he had a supply of used kegs that he could part with for \$5.00 each.

For comparison, I had been quoted prices of \$32 for a new regulator, \$50 and \$70 (two quotes) for CO2 tanks. (empty, \$5.32 to fill.) and \$49.95 (used) \$89.95 (new) for Cornelilus kegs. My impression is that \$32 is a good price for a new regulator, \$50-\$70 is a reasonable range for new 5# CO2 cylinders and that \$50 is a little high for used Cornelilus kegs.

I don't have any handle at all on what one should expect to pay for hoses, fittings etc...

The moral of this story is that it is pretty easy to spend \$150 to get set up to keg your brew, but that with patience and a little research you can do much better.

Subject: Boston brew locations

> Daniel S Robins asks:

> I am going to be heading to New England in the near future and will
> be interested to visit some places of interest with beer as a
> theme. Specifically, I will be spending a day in Framingham, MA
> and a weekend plus in Conway, NH. Be they brewpubs,
> microbreweries, or homebrew supply shops, I would appreciate any
> suggestions.

There is a beer and wine supply in Framingham:

New England Wine Making Supply
501 Worcester Road
Framingham, Ma.
(508)875-1414

I went there once perhaps 10 years ago and thought it was rather
expensive,
but things can change a lot in that amount of time.

In Woburn:

Beer & Wine Hobby
180 New Boston Street
Woburn, Ma.
(617)665-8442

This is a very well stocked store.

From Framingham, go east on Rt 9 to Rt 128, then North on Rt 128 to the
Washington Street Exit. Take a left to the lights, then another left
and

follow this road about 1 mile. They are located in the rear of a
warehouse.

And in Cambridge:

The Modern Brewer
Massachusetts Avenue
Cambridge, Ma.
(617)868-5580

This is my favorite store. They are relatively new, but are extremely
helpful. They tend to carry some of the harder to find hopps and yeasts.
I
highly recommend this store.

Although I don't know of any 'Great' drinking locations in Framingham,
for
price of a short drive into Boston (about 20 miles), or take the commuter
train into North Station. from here, you could try the
following locations:

The Commonwealth Brewing Company
138 Portland Street
Boston, Ma.
(617)523-8383

Exit North Station onto Causeway Street. Take a right then your third left.

This is Portland Street, and the Brewpub is a few hundred feet down.

This is a brewpub and restaurant. It has been here for 7 years and has several brews on tap. They also bottle two or three of their beers. I am not too familiar with the styles, but do know that they have a stout and I believe a pale ale, and a few others.

After you finish here, go back to the 'T' station across from North Station.

Take any train to Park Street Station. Go down stairs and take the Red Line train outbound to Kendall(MIT) Station. When you come out of the station, walk through the lobby of the Marriott Hotel, turn left and walk about 1/4 mile. The brewpub is on the right.

The Cambridge Brewing Company
1 Kendal Square
Cambridge, Ma.
(617)494-1994

This is also a Brewpub and Restaurant. They have Amber Ale, Golden Ale, Pale Ale, and Porter plus one special beer which currently is Scotch Ale. I like the Pale Ale and Porter the best. All of the food that I have had here has been excellent.

If you haven't had enough yet, get back on the Red Line outbound to Harvard station. Right smack in the center of the square at Mass. Ave. and JFK street is:

The Wursthhaus
4 John F Kennedy
Cambridge, Ma.
(617)491-7110

They have several beers on tap (including Spaten), about 150 beers in bottles, and excellent German style food.

Now, get back on the Red Line (if you can see the entrance) and head inbound to Park Street. Go upstairs and take the Commonwealth Ave Green line train, stay on this until you come to Comm Ave and Harvard Street. Get off, take a right onto Harvard Street and follow to Brighton Ave. Take a right and just around the corner is:

The Sunset Grill & Tap
130 Brighton Ave.
Alston, Ma.
(617)254-1331

Food is great, there are 14 Taps of which at least one is cider. They also have many, many beers in bottles (enough to fill a four page menu). Highly recommended.

In Jamaca Plain there is:

The Boston Brewing Company
St Germaine ST ???
Jamacia Plain, Ma.

This is where some of the Sam Adams beer is made. They have tours and beer tastings on Mondays, Thursdays, and Saturdays at 2 PM.

We have one other brewery near Northern Ave which makes Harpoon Ale. I don't have any info on their tour hours, or even the name of the brewery, but someone should be able to fill you in. The ale is quite nice.

Hope this helps you out a bit. I don't know the area you are going to in New Hampshire that well so can't help you there. There is a new Brewpub in Portsmouth (which is on the coast and quite a distance from Conway) which I went to last Sunday. Unfortunately I didn't get to try the beer because the power was out and they couldn't accept a Visa Card which was my only method of payment at the time.

Dean> is kegging really worth the starting expense?? The Cat's Meow lists
Dean> a couple of places with complete Cornelius systems in the \$150-\$175
Dean> range. Is that a good price?? How long will homebrew (ale) keep in
Dean> a keg?

I like kegs -- less work and tho I've never had the problem, no glass grenades (if you make sure your kegs have overpressure reliefs).

The prices you mention *are* good. I went with Foxx but used my own kegs; they're a good company to deal with and are very competitive. I got a double guage regulator so I can see the keg and CO2 pressure.

My only complaint about kegs is that when my friends hear I've 'tapped' one, it doesn't tend to last too long! I've now switched to doing double batches :-). I've had a couple batches hanging out for quite some time -- months. I think it should be as good as bottles because of the CO2 blanket and so on.

Cheers.

I have taken to sparging the grains to get more from them. After I strain them, I put them back in a pot, cover with warm water, then strain the water into the brewpot--it is often very dark, too. I'll also put the grains in my strainer/funnel and pour hot water over them while the result is still dark.

Subject: Re: Lagering problem

In HBD #706, "Jack D. Hill" <jdhill@BBN.COM> asked about an apparent resurgence of fermentation in a lager he was brewing:

> Last week I noticed the fermentation cap riding low and a marked
> decrease of bubbles. The krausen was thin. Bottling seemed to be in
> order. Yesterday, I brought up the carboy and let it settle while I
> prepared and cleaned the bottles. After an hour I was getting and
> incredible amount of fermentation activity. Obviously it wasn't ready
> to bottle.

It probably wasn't a renewed fermentation you were seeing. This is a normal phenomenon when brewing lager beers. CO2 is more soluble at lower temperatures. During fermentation, a lot of the CO2 that was produced went straight into solution in the cold wort. As the wort warmed up while you were cleaning your bottles, the dissolved CO2 began to come out of solution, producing the activity that you saw.

Beers that I have lagered at very low temperatures (just above freezing) have exhibited this effect to the extent that, when warmed up to serving temperature, they are already rather nicely (if lightly) carbonated.

I'd say go ahead and bottle your beer.

From: chad@mpl.UCSD.EDU (Chad Epifanio)
Subject: Stuff From my Head(semi-long)

Dean asked about "Single vs. 2 stage fermentation":

I've been told that ales generally do not benefit from extended aging in the fermenters, and should be bottled within two weeks(ideally right after fermentation ends). I've usually found this to be true, except with the *extremenly* high gravity beers(like Russian Imperial Stout) or flavored beers(like Raspberry Ale), which seemed to benefit from a bit longer aging.

I racked off the trub before fermentation twice, and both times came up with rather insipid brews; pale and tasteless. I am now into all-grain brews, and I get a big cold-break in the kettle. I've taken to pouring about half the sediment(thru a strainer) into the fermenter, and it seems to work OK.

When my beers are in the primary for more than a week, I usually rack off the sediment. Yeast will begin autolysis after about two weeks or so, so I'm told; I've never let it hang around that long. Usually I'm more concerned with giving the beer a chance to clear. After I rack, I get about an inch of precipitation immediatly. Perhaps the agitation of siphoning shakes some things out of suspension?

I've used 5-gal and 6.5-gal carboys as primary fermenters, but now I use a 7-gal plastic bucket with lid. I like the bucket for many reasons. One is that I "recycle" my yeast, and grabbing a cup of slurry is easy with the bucket. Another is that it makes very little mess pouring the wort into the bucket, as opposed to thru the narrow neck of a carboy. Still another is the handle, which makes carrying 5.5 gal of beer easy. Plus its cheaper than the carboys, which I save for secondary fermentation, and a bit easier to clean. I know, the bucket does seem a bit unsanitary compared to a clean glass carboy, but during active fermentation the yeast should put up a good head and a blanket of carbon dioxide which protects the beer quite well. Disadvantages of the bucket are that it scratches easier, and you can't see when the yeast begins to sediment.

Jack Hill writes about "Lagering Problems":

Lets assume that you were very carefull, and no contamination problems occurred. I see no reason whatsoever why you should see active fermentation after that long(I've made that same recipe). You realize that CO2 is more soluble at cold temps than at warm, and the yeast would have produced a lot of CO2 by now. Perhaps what you saw was the saturated CO2 coming out of solution when the liquid warmed up??? Five gallons can hold a lot of gas.

Frank has sweet beer:

Well, I have tried variations of those recipes, but have found that hopped extracts are not hopped for shit, or at least don't taste like it. Try an unhopped extract, and add a good bit of hops to counter the sweetness. By the way, 1/2 oz. Bullions may not be enough for a stout bitterness, but that's just my hophead opinion. I have had complete fermentations in two days before, so I don't think that's

the problem. My beers usually take longer to carbonate than Charlie says, as well. They may "dry out" with age.

JaH has repeating articles:

Just curious. The last couple seem to be twins.

Kurt asks about "Lauter Tun Set Up":

I'm unsure of your exact question, but I'll throw this in instead. What I've been using successfully is the old sparge bag method with a twist. I took a piece of 1/4"od copper tubing(which, by the way, was left over from my counter-flow wort chiller fiasco), and bent it around the bottom of the bucket, connecting the two ends with a piece of 1/4" id plastic tubing. Put this circle into the bag, and wedge it as far down as it will go. This forces the edges of the bag tight against the sides, preventing sparge water from running prematurely down the sides. I also float the grains with the `ol "loop the output hose to the level of the grains" trick. It keeps the grains from compacting too tightly.

From: joshua.grosse@amail.amdahl.com
Subject: Low temp. fermentation procedures

In HBD 706, Martin Lodahl wrote about starting liquid yeasts at room temperature and fermenting at 55 degrees, including a discussion of underpitching and reculturing. He said that he usually recultures but has had successes with pitching directly from the started package.

I just used Wyeast for the first time also, and want to discuss my first attempt at cold fermentation. I pitched from the package.

My latest batch is an extremely light wheat beer (SG 1.025) that has been in the primary for 6 days. I pitched Wyeast Pilsner when the wort was just about 86 degrees, and it slowly dropped down into the 40's while in the 'fridge. There is about a 1/3 inch kreusen on top of the wort, though I think it contains mostly coagulates from the Irish Moss, as its thick and not foamy. There has been some outgassing, but not enough to blow the kreusen out the blowout tube. I replaced the blowout tube (which went into a jar partly filled with water, so it had a lock) with a standard fermentation lock yesterday. Based on this slow start, I needn't have bothered with a blowout tube.

When I replaced the blowout and bung with a lock and bung, I sniffed at the old bung. NICE ODOR. So, I'm assured I don't have an infection, and my only concern is for procedures and temperatures for refridgerated fermentation.

My wife, who doesn't drink, looked into my fridge and said, "It looks like someone threw up in there." She may have meant the thick kreusen, but she may also have meant the very pale clouds of flocculations that I can see layered in the carboy. There are cumulous clouds at the top, and stratus clouds about two or three inches above the trub. I believe these must be yeast. At first, I thought I might have had the fridge turned down to low and that ice was forming. Then, I looked a little more closely. Definitely not ice, though I do have vodka in my fermentation lock, as the top of the carboy is closest to the refridgeration unit.

The CO2 activity is very slow. Have I underpitched? Is it my low SG? My temp too low? My temp too high? Did I pitch too early? Is there anything I should do? shouldn't do? A thermometer in the fridge is showing 42 degrees.

Should I be concerned, or should I RDWHAHB?

From: neptune!pryzby@uunet.UU.NET (Greg Pryzby)
Subject: can i save the yeast cake?

I was wondering if I could save the yeast at the bottom of the primary fermenter? After I transfer the wort to a secondary fermenter I was wondering if I could store the yeast cake for future use.

Thanks on the "solutions" to my slow start fermentation using liquid yeast. I now know how to "properly" use liquid yeast.

peace,
greg

From: cjh@vallance.HQ.Ileaf.COM (Chip Hitchcock)
Subject: re brewing legalities

Congress did not pass a law saying that anyone can brew beer; they canceled a previous law that said nobody can brew at home. cf after the 18th amendment (prohibition) was canceled by the 21st, many counties and municipalities remained dry (e.g., Arlington MA), even those where alcohol was an industry (Jack Daniels' ads say you can't buy it where it's made as the whole county is dry). If somebody wanted to make an issue about it, the right-to-privacy elucidated by the Supreme Court in /Griswold/ (ruling out CT law against contraceptives) could be argued to apply to home brewing, but it's unlikely anyone wants to take the time and money to fight and the current Court is mostly opposed to the right-to-privacy.

I don't think Utah is a dry state; Tim Powers (SF writer) mentioned picking up a suitcase of Coors on his way from downtown to BYU for a speech (as a leadin to the fuss when someone noticed the case cooling on the outside of his windowsill).

Subject: Re : Malt extracts

I'm a (barely) beginning homebrewer, and have been reading with some concern about nutrient problems in malt extracts. Does anyone have any advice on how to alleviate the problem? As in, what to add to the extract before fermentation? Bear in mind that I'm a rank novice at this, so I'll probably need brand names. I don't plan to start mashing (even as an adjunct to the extract) for a good while yet.

I know, "relax, don't worry, and have a homebrew." I do the first two fine, it's the third one that I want to get to.

From: man@kato.att.com

Subject: Same recipe, same conditions, different ferment times plus NJ store

On August 11, I made a batch of bitter doing a partial mash plus extract (Miller's Ordinary Bitter). I've made this before with good results. Anyway, I used WYeast's Chico Ale yeast that I used to start a 1 pint wort mixture. When the large wort was cool, the starter was at high krausen and I pitched. The visible ferment was underway in about 12 hours, but the krausen stayed high. OG 1.055 TEMP during ferment was 72-74 F in my basement.

On August 17, I made another starter of 1 pint and inoculated it with about 3 oz of the batch made on August 11. The starter took off immediately.

On August 18, I made the same beer again. All ingredients came from the same place. The yeast was from the starter made the previous day. It smelled fine.

Conditions were the same. OG was the same. TEMP was the same for ferment.

On August 20, the beer made on the 11th was finally nearing completion. Gravity was 1.010, but the batch still had a slight pancake on it. The beer made on the 18th was also at 1.010 and had no such pancake.

Both samples taken for the gravity check tasted similar. Any ideas as to what would cause a faster ferment? Both batches were aerated the same way (shaking and sloshing) and both had visible signs of fermentation after about 12 hours. My 2 guesses are:

1. The first batch did ferment fast and the excessive bubbling was not a sign of fermentation per say, but only a sign of excess CO2 or O2 being released.
2. The second batch was in reality better aerated and the extra healthy starter got the ferment going fast (for all I know it started at midnight).

Supply stores in NJ:

In addition to Wine Hobby in Hillsborough (not recommended at all), there is Jersey Brewing in Lebanon, NJ. It is run by Mark Bernick mostly as a service to the members of MASH. He does do mail order and his prices are competitive. I don't have the number, but he is listed under his last name (as opposed to Jersey Brewing). The area code is 908.

> 2. Not hopped enough.

Hey Frank, good job on the description. I, too, like hoppy bitterness to balance malt sweetness, and as long as you use the (under-)hopped extracts, you'll end up short on those infernal bittering units. We tend to use 2 oz of high-alpha (>10%) hops for an hour in over 2.5 gallons of boiling wort, and another 2 oz of medium-high-alpha (4.5-8%) hops for 5 minutes finish. Bitters it right up. I'd switch extracts to unhopped varieties posthaste, but don't worry about your fermentation temps, yeasts, or infections yet; those aren't your problem.

Excerpts from internet.homebrew-beer: 20-Aug-91 Re : Malt extracts Conn
Copas@loughborough. (1732)

> Lastly, another part-mythical creature : the malt extract 'tang'. Fact
or
> fiction ?

Fact, of course. I don't think Tang is exactly a malt extract.

A friend of mine (over a pitcher of Sam Adams and some truly fattening
Polish dinners) suggested that Tang might be a good source of
fermentable sugar. I gave it a try, using one of those 8-in high
bottles of Tang and water to make 1 gallon of liquid (added a tsp. of
yeast nutrient). Pitched Montrachet wine yeast (dry). Fermented in a
plastic bucket for 4 days, then in a glass vessel for 4 weeks. Racked,
and 4 months later, I've a fairly strong wine, just a bit bitter (due to
the high citric acid count -- maybe diluting the original must would fix
that).

A great party favor!

Subject: KEGGING, BAD NEWS

RE:: cookson@mbunix.mitre.org
Subject: Kegging

>I've been wondering, is kegging really worth the starting expense?? The Cat's Meow lists a couple of places with complete Cornelius systems in the \$150-\$175 range.

The good news is that you can make your own for just about nothing. Just take home a keg of stuff from your local liquor store and water the garden with it. Remove the bung and replace it with a removable hatch (a few tapped holes and a piece of plexiglas) and you have a keg for the cost of the deposit.

The BAD NEWS is, the system works so well that it is probably the shortest distance between social drinking and alcoholism, not to mention a belly that looks like the keg.

I attribute my escalation to "over-indulging", to a very large extent, to kegging. I even had a tap on the outside wall near the swimming pool. When you don't have to wash bottles and no one is able to count them, it gets real easy to just slosh around in the stuff.

I quit drinking for ten years and have started brewing again but only allow myself one 16 oz bottle every other day. That may not seem to be worth the trouble but first of all, it's not much trouble to meet my current demand but more importantly, it's infinitely better than NO BEER.

> What's the collective HBD wisdom on these questions?

I can only speak for myself and I say, wash bottles.

In HBD #702, Mitchell M. Evans writes:

>How can I be sure that the bottle I am about to open is not a bomb?
>Any hints would make opening the first bottle of a batch much less
>traumatic for me, from now on.

Yikes! Hope the thumb's better now. Well, I just had a similar (but not so dramatic) experience with a batch of Ginger Ale (more on *that* in a moment). I found one hint that I had bottle-bombs from the cap: My capper puts dimples in the caps when it seals. I lost only two bottles (:-(, but at least I weeded out the weak ones...Darwinism in a most peculiar way.. .), and I noticed that the dimple in the surviving bottles had popped up. Needless to say, I bled it open (the bottle, not my thumb), letting the pressure leak out more slowly, before popping the cap off. I also did this wearing safety glasses (will these become standard issue for making soda?)

Speaking of sodas, the Ginger Ale recipe was the one posted by Bob Gorman, HBD #685. I brewed up a batch about 3 weeks ago, using Champagne Yeast. I cooled it to 78 F and pitched the yeast, then let it sit for about 9 hours, in the SS pot, covered, to let it settle out a bit. Bottled it and put it aside. After one week, the carbonation was already phenomenal...pour it in a glass, and you saw 90% bubbles and 10% liquid. The aroma was that of a cheap champagne, and it had very undeveloped flavors of honey and slight lemon. After two weeks, not much different. After 2.5 weeks, I came down one morning to find bits of glass all over the dining room (fortunately, I had the bottles in a box. Glass shards were driven right through the cardboard, tho.) I bled the pressure out of the rest of the bottles and stored them in a box in my ice chest (sans ice.) The taste was better, getting somewhat closer to Ginger Ale.

Now for the questions:

1. How long should I expect the Ginger Ale to sit in the bottle until it tastes like Ginger ale (a time estimate rather than "until it's done" would be helpful :-)
2. Is honey the best thing for this recipe? What about sugar? What kind?
Corn? Cane? Nutrasweet??
3. What can I do to prevent future batches from blowing up? (This is assuming I'm still interesting in using up precious bottles that would rather be harboring beer.) Any hints/tips would be appreciated.

btw, Bob, how did your batch turn out (assuming it's still intact?)

I apologize if this isn't the most appropriate forum for soda-questions, but it's the best I got. If you don't want to send it to the HBD, send it directly to me.

- -- Steve Kirkish, sun.com!kla!kirkish

PS: I did brew a batch of dark ale [porter? How do *you* define it?] that same day [my first batch in about 5 years!]...it's starting to turn out wonderful, but inspires me to tweak the recipe some and start another batch.
This must be how the rest of you guys and gals got hooked!

End of HOMEBREW Digest #707, 08/22/91

From: David J. Sylvester <sylveste@wsfasb.crd.ge.com>
Subject: Corn sugar in malt extracts

Hi

I will be leaving my position here after tomorrow and will no longer be able to read this digest. I just want to say that I have learned an amazing amount about homebrewing from the experts who have contributed so much so well. My thanks to you all!

As a final \$0.02 worth, I just opened the first bottle of an amber lager I made using a John Bull hopped ****lager**** extract. This actually came as part of a lager "kit" that included an unmarked package of yeast and an unmarked package of "wort finings" which I later found out was Irish Moss. I used Whitbread dry lager yeast instead and I added some pellet hops, just to be sure.

Overall, the beer had some good qualities. Very crisp and clean, not too sweet. But I noticed a distinct odor and taste that I couldn't quite put my finger on. I gave the glass to my wife, whois NOT a beer drinker, and asked her what it smelled like. Her unbiased reply was "fruity, like cider". !!!!!!!

I added no other malt (dry or otherwise) and I certainly added no sugar (except for the 3/4 cup for priming).

As I recall from the discussion here about sugar in extracts, the group that did the research would not name the extracts except to say they were lager extracts. My experience with John Bull (I believe it is called the Master Lager Kit) would certainly verify this.

Keep up the good work folks!

Dave

Subject: Re: Kegging and other things...

[Richard Dale talks about buying used stuff from a deceased restaurant]

This seems like the best idea I've heard in a while. Maybe the failed Mass. miracle can help me find some cheap kegging supplies. It looks like I'll still have to go through some place like Foxx for the hoses and tap and stuff, but so what... Maybe the batch of bitter that's bubbling away in my basement is keg bound. I sure wouldn't miss washing out bottles...

[Chris Shenton says]

>My only complaint about kegs is that when my friends hear I've 'tapped' one,
>it doesn't tend to last too long!

That may not be such a tragedy. I already keep pretty warm in the winter. Generally the same way whales do... :-)

[Chad Epifanio says]

> I've been told that ales generally do not benefit from
>extended aging in the fermenters, and should be bottled within two
>weeks(ideally right after fermentation ends). I've usually found this
>to be true, except with the *extremely* high gravity beers(like
>Russian Imperial Stout) or flavored beers(like Raspberry Ale), which
>seemed to benefit from a bit longer aging.

I wasn't really thinking of aging the beer, just getting in away from the trub, once it settles out. Also, I'm planning on dry hopping this batch. Do I just shove the hops down the neck of the carboy, or what??

[Jack Schmidling says]

>The BAD NEWS is, the system works so well that it is
>probably the shortest distance between social drinking and
>alcoholism, not to mention a belly that looks like the keg.

I doubt if the former is likely to become much of a problem. As far as I've been able to tell, the only thing I'm compulsive about is breathing, and then only bearly... :-) As far as the latter goes, that's what my health club membership is for.

Thanks for all the suggestions folks. It looks like it's time to start checking out the forsale ads.

Subject: In defense of Arlington, MA

In HBD 707, Chip Hancock writes that after prohobition, many counties remained dry "(e.g. Arlington, MA)".

Well, Arlington is not quite "dry". There are two restaraunts which have liquor licenses and another which is applying for one. It is true that there are no bars or "packies", but I can attest to much homebrewing (hic).

In Arlington, it is more important that you are well connected to councilman Charlie Lyons, than anything else. If he likes you, you can get a license for anything. If not, take a hike. Arlington would be a much nicer town without his garbage.

Isn't small town politics wonderful?

/greg

As far as I can tell (I am not a lawyer), the federal law sponsored by Alan Cranston made the homebrewer and home winemaker exempt from paying any federal taxes on the alcohol produced. This makes homebrewing legal without the necessity to procure federal licenses and pay federal taxes. The law spells out that it is illegal to brew without paying the federal taxes *unless* you qualify for the exemption by being an adult and brewing fewer than 100 gallons (or 200 for multi-adult household).

Of course, as you point out, states may also have applicable laws.

In fact, on a return trip from California, my wife got off the plane at a stop in Utah, and picked me up some Park City beer. Pretty good. I also saw a story on the area that implied that the ski resort areas (such as Park City) were influential in repealing some of the anti-alcohol laws in Utah, so they could sell beer and liquor to tourists.

In HBD #707 larry@evi.com (Larry McCaig) writes:

>[Lotsa nice Boston pub crawl sites]
>

>We have one other brewery near Northern Ave which makes Harpoon Ale. I
>don't have any info on their tour hours, or even the name of the
>brewery, but someone should be able to fill you in. The ale is quite
>nice.

The Mass. Bay Brewing Company. The brewery is located in a warehouse and looks more like a working brewery (because it is) than the Boston Beer Company's brewery. We went there on our brewery crawl during the AHA conference.

Nothing much to see unless you are a real micro-brewery freak and get off on seeing stainless steel tanks, plumbing, concrete floors, and stacks and stacks of empty F.X. Matt kegs. This brewery is where they produce their kegged "products." Their bottled varieties of Harpoon are brewed and bottled under contract by Matt.

At the Boston location they also brew a custom contract light beer for a chain of pizza joints called Bertucci's. (The pizza is better than the beer.)

The guy who runs the brewery was very hospitable to us during our tour but made it pretty clear that they don't normally do tours and that they were making an exception for us. He seemed really paranoid about having a bunch of people poking around his brewery and asked people several times to not touch anything. He was probably reviewing his liability policy in his head as Fred Eckhardt walked around behind the fermenters.

It was also dreadfully hot inside. Perfect excuse for him to whip out a couple of pitchers and a stack of cups and offer us some free beer. (Free Beer!) The Harpoon Ale is (IMHO) better when drawn straight off the bright beer tank than when poured from a bottle, but then most beers are. They're usually free at that point and you KNOW they're fresh. :-)

>Hope this helps you out a bit. I don't know the area you are going to in New
>Hampshire that well so can't help you there.

Conway, NH ain't what it used to be. It used to be a quaint sleepy little New England town. My family has a place in Conway and I spent my summers there when I was a kid. Now it's Factory Outlet Hell and there are no really good places to go drinking. There are some really good restaurants in the area and they all have pretty reasonable wine lists, but they don't serve any really interesting beers. The pubs cater mostly to the Bud swilling general public. I'm sure that there is a place in town where you can get a pint of Bass, but I haven't seen it. There are a LOT of places and I haven't been to all of them recently. Your best bet would be to check out the lounge at the Eastern Slopes Inn. After that, you're on your own.

Outside of the downtown area is some excellent nature sight seeing,

and there are a couple of really awesome fishing holes, but I'm not telling. Conway also has its slummy section which you'll get to see if you take a ride on the Conway Scenic Railroad.

From: Timothy Mavor <tmavor@pandora.cms.udel.edu>
Subject: Oatmeal Stout/hops/new home

Concerning Oatmeal Stout recipes, my recent batch of Bachelor Stout (made the night before my wedding!) used Steel Cut Oats (24oz) for 6 gallons. I found the head retention to be very good. I would think that with Rolled Oats that clarity would be a problem. I got the recipe off of the digest, but if anyone wants it I will post it/ email it. Of the several recipes that I have seen, this seemed to have the most success for others. I thought it was good, but am willing to test others! ;)

This year I attempted to grow my own hops, but didn't get the rhizomes in the ground til mid May, so no harvest is likely for me this year :(However, how should I "winterize" them? Should the bases be covered with some mulch-like material? Would fertilizing be helpful? Should I trim the vines back? When?? The plants are growing at my parents in Mass., so there is frost. Is this a major concern?

I have recently moved down to the U. of Del. and am looking for brewpubs and homebrew supply stores in the area. Any suggestions in the area from about Philadelphia down to Balt? I looked at a recent HBD with the listings of all micro's and brewpubs but found there to be none in Delaware! Any help would be greatly appreciated.

It's not just homebrewing.....
It's Chemical Engineering, Fluids and Sorcery!

From: Frank Tutzauer <COMFRANK@ubvmc.cc.buffalo.edu>
Subject: Say what?

Everything I've learned about brewing (so far) has been from reading. Other than netfriends, I don't know a single soul who brews (yet). I've never even SPOKEN about brewing to anyone except my wife, and she knows less than I do, although she is responsible for getting me started. (She bought a bunch of books and gave them to me because she thought brewing would be a cool thing to do--she was right.) As you've undoubtedly noticed, brewing has a quite colorful vocabulary. Unfortunately, my reliance on the printed, rather than spoken, word means there are many terms about which I am absolutely clue-free concerning how to pronounce them. I learned how to say "kraeusen" from Old Style beer commercials, and "wort" and "trub" are no problem because EVERYBODY tells you how to pronounce those. But what about:

gyle -- hard g or soft?
lauter tun-- is it ton? toon? tuhn?
Papazian -- Puh PAY zee uhn? Pap a ZEE un?
Saaz -- saz? soz? sa-oz?
Wyeast -- Why yeast? Why NOT yeast?
Fuggles -- one of those words that's probably pronounced like it's spelled, but looks as though it shouldn't be pronounced like it's spelled.
Reinheitsgebot -- gimme a break.... (Actually, with a nice German name like Tutzauer you'd figure I'd be able to say this one. What can I tell you? I'm very far removed from my heritage.)

While we're on the subject of words, I would like to comment that brew jargon is, IMHO, very strange. About half of it is scientific/technical sounding stuff (counter-flow wort chiller, diastatic enzymes, autolysis) but the other half is downright goofy (carboy? bung? barm? sparge??). Cheesh!

Subject: poland brewery

Has anyone ever heard of any breweries in Poland? My brother-in-law has been in contact with some brewery in Poland, and they've been discussing using some of his machine shop space to open a US branch. (!) I guess the brewery VP is sending over a case or 2 for us, I mean him :-), to check out. Supposedly they use quality materials and make good beer, but I'm suspicious. The VP said that no Polish beer is currently exported, so they're trying to be the first, in a way.

Any of you world travelers been to Poland?

On a different note, is it possible for tap water to have a pH of 4.5? That's what the papers say. My wife, who worked for the water company, said that the water they pump out is 7.0. I've got a friend who thinks she can get me a digital pH meter, so I'd know for sure then, but in the mean time, what gives? The papers do show alkalinity when I add baking soda to the water, so they at least work somewhat.

Subject: Haste appears to have made waste (help!)

Hello! Well, as I am having a party on Saturday, I wanted to have homebrew to serve my guests. As I only had one brew ready to go, about 2 weeks ago my SO and I did a brew. We used an unhopped amber extract, 1 C cracked crystal malt, 1/2 oz of bullion hops, and reused Wyeast #1098, British Ale yeast. We had been planning a stout for our next beer, but since we were in a hurry, we tried to do a beer that would ferment and age quickly, while still using up ingredients we had on hand.

All went well until it came time to "bottle". We decided to keg the beer, a first for us. We purchased the equipment, including a keg that had been mostly full of root beer. This was the end of my involvement in the process, btw. When we got home, eric rinsed the keg several times with water, but did not bleach or use any detergent because the keg was clearly sterile (nothing had been growing in the root beer syrup, after all). He used *no* priming sugar and just racked the beer from the fermenter into the keg. The plan was to use the CO2 from the canister to carbonate the beer.

Last night I tried some of it, which has been kegged since Sunday night. There was a huge head which dissipated quickly and the beer was flat, to my taste. The beer was warmish, and is clearly meant to be served cold, but the big problem was that it had a root flavor. I am reluctant at this point to serve this to my guests, but am wondering if the net has any suggestions to a) improve it in time for the party (tomorrow, by the time you get this) or b) salvage it in an arbitrary length of time.

I only have about 3 six packs of other homebrew, an amber which I am especially fond of!

Please email your suggestions as I am clearly in a time crunch,

- --kt

From: Conn Copas <C.V.Copas@loughborough.ac.uk>
Subject: SOME RANDOM HERETICAL THOUGHTS (longish)

For the sake of a discussion, thought I would stick my neck out and invite public decapitation ! The gist of my argument is that I sometimes wonder whether, in our efforts to imitate professional brewers, we occasionally miss the point.

1) Sparging

To a chemical engineer, sparging is a solvent extraction problem. Theory says that a series of small extractions are more efficient than one big extraction, with sparging being the ultimate extension of this approach. So, for example, if one wishes to pass 6 gallons of water through a mash, a series of 2 gallon rinses is better than one 6 gallon rinse, and sparging is better still. On the other hand, sparging causes lots of problems (for some), as witnessed by all the discussion of set mashes and home lauter tun design. We have all read about the dire consequences of washing sediment into the boiler, but maybe this is an illusory problem. What about simply leaving the wort to settle, then racking into the boiler ? On the occasions when I have had to leach the grains because of a set mash, I can't say that either efficiency or beer quality has suffered noticeably.

More heretically still, we've seen recent recommendations to add boiler trub to the fermenter in order to ensure depth of flavour. Food for thought, huh ?

2) Boiling Times

We see recommendations for EXTRACT boiling times ranging from nil up to 2 hours. Given that the extract has previously been condensed (probably under vacuum, at a temperature less than 100 C), it is reasonable to presume that at least a partial hot break has already occurred. I've personally found no advantages in boiling extracts longer than 10 minutes, although obviously hop bitterness extraction takes longer than that. Even regarding full mashed brews, Alexander cautions against over-boiling on the grounds that excess protein precipitation can reduce the beer's head retention. Does anybody have any experience in this area ?

3) Wort Chilling

A commercial-size brew will take days to cool at room temperature, so the professionals inevitably resort to using heat-exchangers. Most homebrews will cool overnight. Once again, we have been warned of the consequences of defective cold breaks, but my limited experiments have shown this not to be a particularly significant problem. Granted, you may be anxious to pitch the yeast and prevent infection, but isn't this also a criticism of the

environment that you are brewing in ?

4) Unmalted Adjuncts

Unmalted adjuncts are cheaper than malt and, in days gone by, were even cheaper than sugar. So they found favour in brewery practice. Admittedly, some adjuncts convey desirable properties on the beer, eg, wheat for head retention, rice for lightness of flavour without sacrificing body (yes, some people like this), and even (yechh!) the flavour of maize has come to be appreciated by some misguided individuals :-)

But consider this. You are making a stout and the recipe calls for flaked barley. Why not simply add more malt ? Does the flaked barley possess anything that the malt does not (like different proteins maybe) ?

5) Hop Drying

Commercial hops are fast-dried at high temperatures, then often dusted with sulphur as a preservative. We don't need to imitate the second step, and I'm not so sure that we need to imitate the first. The standard method of home-drying most herbs is to place them in a dark, ventilated position at room temperature for about 3 weeks. This method certainly has advantages as far as retaining volatiles goes. Secondly, the method encourages a limited type of curing, in which the green chlorophyll in the plant becomes degraded. Great if you're planning to smoke hops, but probably also does have flavour advantages for the brew !

Yours in alchemy

Subject: kegging startup

In Homebrew Digest #706 Dean Cookson asks:

> I've been wondering, is kegging really worth the starting expense??
> The Cat's Meow lists a couple of places with complete Cornelius
> systems in the \$150-\$175 range. Is that a good price??

And rsd@silk.udev.cdc.com replies. May I add:

I got started in kegging by asking my wife to buy me a basic setup from Steinbart's (CO2 tank, valve, fittings, and one keg), then obtaining other parts elsewhere. Both Rapids and Foxx have all kinds of fittings and parts at good prices. The biggest issue for me was where to get used kegs. Finally, after messing around with older kegs (like Firestone, which is discontinued), I asked the manager of the local Pepsi bottling company to sell me kegs. Now, I can purchase their regular, used, excellent kegs for a farthing (wish I could say how much, but I will say it is at their cost!).

There is something to be said for starting with a new, clean setup like I did. It's nice to be able to keg right away with new equipment minus all the hassles of used junk that doesn't seal, etc.

From: Chuck Coronella <CORONELLRJDS@CHE.UTAH.EDU>
Subject: Brewing in Utah and New Jersey

My eye was caught by Lee Katman's questions/comments. I moved from New Jersey to Utah about four years ago, and I have really felt the difference in attitudes to alcohol. Utah is not actually a dry state, contrary to popular belief; it just seems that way. In Utah, I can buy more BudMilloorselob than I could possibly want (at 3.2% v/v alcohol). In fact, I can buy these beers at convenience stores, making them MORE accesible in Utah than in NJ. However, I cannot get the more interesting beers, like Sierra Nevada, anywhere in this state. To continue the comparison between my two home states, hard liquor is FAR more easily accesible in NJ than in Utah. There are a limited number of state owned and operated liquor stores here, with really bizarre hours. Who the hell can tell, before 9 p.m., that they're gonna want a bottle of vodka tonight, anyway? In Utah, the laws involving drinking in bars and restaurants are far too numerous to go into here. Just trust me that the division between church and state is nearly invisible. (An interesting sidenote- a good friend of mine from Iran tells me that, in Iran, all non-Moslems would be allowed to brew there own beer!!! ;-)

Surprisingly enough, Utah and NJ are alike in the fact that homebrewing is illegal in both; the difference is that action is under way in NJ to change this. Anyway, it's not much of a problem for me, since there are two homebrew supply shops in town (supporting an illegal industry!) But perhaps the most interesting contrast between the two states is that I know of at least an order of magnitude more homebrewers in Utah than in NJ. Wild, eh? There must be some kind of antiestablishmentaryism (?) at work here.

From behind the Zion curtain,
Chuck

Subject: Brewing Down Under

G'day!

I'm new to this group so 'scuse my ignorance....

Anyway, I was wondering whether there are any brewers around NZ who would be interested in swapping some recipes, ideas, hints, etc... E-mail me at the address below if interested.

One question I do have.... I have a few books on home-brewing, some American, some English. The names of the hops in the recipes (such as Fuggles, etc. ..) aren't readily available here (not that I know of) but we have types such as Sticklebract, Super Alpha, Green Bullet, etc... Could someone perhaps give me some sort of direction as to which ones are interchangeable?

Cheers (hic!)

From: Chuck Coronella <CORONELLRJDS@CHE.UTAH.EDU>
Subject: Unequal Budweiser

Greetings,

Here in Utah, the beer sold in most stores (except in state operated liquor stores and some private clubs) is by law limited to 3.2% (by volume) alcohol. I understand the same is true with a few other states. I guess this must create a significant hardship for the smaller breweries, since I am unable to find beers from any microbreweries and most imports. Let's be generous and assume that the smaller breweries have dedicated brewmasters who are unwilling to compromise. Anyway, we have available all your favorite brands- Bud, Old Milwaukee, Coors, Miller, Keystone, etc. as well as some imports- Heineken and Molsen are two that come to mind.

My question is this- what is the percent of alcohol in most of these beers otherwise? This is perhaps too broad of a question. How about telling me simply, what is the strength of Budweiser, the all-American classic, (for good or bad, let's not get into that now) outside of Utah. I have heard both that 1) These MegaBreweries brew special low alcohol beers for the 3.2 market, and that 2) The beer is the same everywhere. Of course, the federal law prohibiting the listing of strength serves to obfuscate the issue.

Let's hear it- how unequal are all Budweisers created?

Cheers,

Chuck

P.S. I'll take a homebrew over a Bud anyday.

Subject: Norm Hardy's Germany series of last fall

As I needed the typing practice, and since there has been some interest, I re-entered the series of six articles that Norm Hardy wrote about his trip to Germany last July. Still very good (the articles, not my typing).

If anyone would like a copy of this re-electrified series, I will email it to you. I typed it into Word on a Mac, but it will convert to Ascii very easily.

I know what you're thinking..."Why did he do this?" Well, I thought it might be useful and I didn't want to mess around retrieving the old digests from the library server. Also it served an interesting exercise to hone my newfound typing skills.

Norm, you give a recipe (including procedures) at the end of the last article. Would you care to comment on the outcome of that batch? It sounds pretty tasty.

Since I am now interested in brewing established styles of beer, I found the series more interesting than the first time around.

Subject: Porter vs. Stout

A number of days ago, I wrote about a stout I brewed that ended up tasting like a porter. I got mail from someone (sorry, I forgot who) saying I had it all wrong... that stout is associated with a roasted barley flavor and porter is not. I sent email back continuing to argue my position. Yesterday, I checked Papazian and sure enough, according to Charlie, I'm wrong.

Now, I plan to investigate this more to find out where I got mixed-up. I plan to compare my beer with my benchmarks for sweet stout (Tooth's Sheaf Stout & Mackeson's Triple Stout) and porter (Anchor Porter). Maybe I just haven't had my benchmark beers for too long a time.

Subject: Metallic taste

I've been plagued by a slight metallic taste in some of my brews, not all.

It couldn't be sterilant. I overrinse, if that's possible.

I think I've discovered the source. The copper scrubbers that I use over the end of my siphon pickup. They are NOT pure copper, just copper coated..a thin one at that. I've been reusing them instead of using a new one each time. For those that use them, use a new one each time. It's not worth sacrificing 5 gals of homebrew to save 59 cents.

Also, I boil my new ones in a vinegar/water solution to remove any tarnish and/or manufacturing oils/gunk.

likely
> to blow up? I hate to chill good stout but will do so if necessary.

My last batch was a stout that started gushing only one day after
bottling. Luckily, I usually sample a bottle a day right after bottling
to see how they're coming along (i.e., I can't resist). Finding two
gushers, I put all the bottles in the refrigerator, which arrested the
process pretty well. They came out a tad undercarbonated and a bit
sweeter than I'd planned on, but quite drinkable and no bombs.

Subject: Re: Why is my beer so sweet?

Speaking of underhopped, sweet, and extract in the same breath:

> best bet is to stop using hopped extract (the reason alot of people
> advise mashing is to have more control over the beer than using

My first batch of Hopped Malt Extract brew tasted a lot like apple cider at the end of two-three weeks. After 4 it was good. After 6 it was very good, but it was gone.

15 years later, I still brew hopped malt extracts because I like it. I have brewed only two all malt batches. I didn't like them. I have tried unhopped, adding hops. I didn't like that either.

I have had brew made by a lot of folks that are serious about their brewing (try an SCA chapter). I like mine. I do not like heavy hops, in fact the 'Beer Maker's Australia' Pilsener is a hopped malt extract kit that borders on too hoppy for my tastes.

That does bring on another thought though. I read in Zymurgy that some extract manufacturers were providing an all-malt recipe, without the corn sugar additions. Is this just an "alternate" recipe, or is it a different malt? If all you do is make three gallons with no sugar, as opposed to 5 gallons with sugar, with the same malt and hops, it sounds like one or the other of the recipes is faulty.

Subject: Undercarbonation in Corneleous Kegs.

Gentlemen, I have unsuccessfully tried to naturally carbonate my homebrew in 3 and 5 gallon Corneleous kegs. I followed Papazian's recommendation of adding 1/3 to 1/2 cup of cornsugar to a 5 gallon batch. Next I pressurized and bled the keg 3 or 4 times to release the O2 and replace with CO2. Finally I left the keg at 5 psi at room temperature for 1 to 2 weeks. The result: no carbonation. I'd prefer to naturally carbonate but am forced to artificially carbonate to get any carbonation. Am I doing something wrong here? I have never had a problem naturally carbonating in the bottle. Should I try 3/4 cup cornsugar? By bleeding off the O2 am I making it impossible for the yeast to get going again? On another note: Has anyone tried making a Mild with a hint of Ginger (1/2 oz grated)?

From: cjh@vallance.HQ.Ileaf.COM (Chip Hitchcock)
Subject: re heresies

A lot of what you call "unmalted adjuncts" aren't. Rice and corn are used because they have less effect on the flavor, in proportion to the fermentables they yield, than barley. (or at least a different effect/balance; all-rice beer, aka saki, is an acquired taste.) Certainly you don't want to use roast malt in place of roasted barley in a stout; the flavors are observably different. I expect this would be true of other additives as well, but you should feel free to try changing an additive and report on the results. :-)

sparging: I've done only extract-plus-additives brews, so I can't give practical answers. But as a former chemist I would expect that making up the mash to full volume (6 gallons plus net bulk of grains) and racking would be wasteful, since:
- you'll certainly leave some wort around the grain (and on top--- racking doesn't get everything)
- you'll probably get less net efficiency than you'd get from rinsing the grain. This may or may not worry you---I haven't seen any estimates of whether a low-efficiency mash produces a different flavor.

hot-break in extract---don't bet on it! If the extract was condensed under reduced pressure, it will never have gotten near boiling (that's why the reduced pressure). I have only had one batch of extract, a can of M&F Old Ale, in which any trub was visible when I opened the can, although several batches showed some break in the kettle even before boiling. Also, most hopped extracts are notoriously under-hopped (see recent comments on sweet beer) so a 1-hour boil with added hops is likely to be a good idea.

wort chilling and infection: yes, your kitchen is unlikely to be as sanitary as a brewery; for one thing, you don't cook in a brewery, and for another it's unlikely that your kitchen is made entirely of tile, plaster, and metal (wood may be charming but it's virtually impossible to sanitize). This doesn't indicate some moral defect in homebrewing....

adding trub: one man's deep flavor is another man's sewage. I tend to like full-flavored beers but didn't like any of the deliberate defects shown in a recent Dr. Beer session.

From: jlf@poplar.cray.com (John Freeman)
Subject: nested buckets for sparging

After reading about other people using the nested bucket trick for sparging, I thought I'd describe mine.

For my first sparge bucket, I drilled a bunch of 1/8" holes, but never found that to be adequate for drainage. When it thankfully broke, I made another one using a propane torch, and an old butter knife, and a bucket of course. I heated the butter knife to about red hot and pierced slots in the bottom of the bucket. This was faster, cleaner, and better than holes, because drilled holes always had those annoying wisps of plastic that required deburring, where the slots had clean edges. And the slots don't plug up during sparging like the holes did. I could pierce four or five slots before I had to reheat the butter knife.

As for nesting them, I didn't worry about finding buckets of exactly the right size, I cut the lid of a bucket into a ring, and slipped this ring onto the grain bucket. This keeps the grain high above the wort level. Another ring on the sparge water bucket keeps that bucket above the grain bed. I then have a stack of three buckets, sparge water on top, grain in the middle, and wort on the bottom. I call it the Tower of Power. Actually, I now sparge directly into my boiling kettle.

Date: Fri, 23 Aug 91 14:06:07 EDT
From: hersh@expo.lcs.mit.edu
Subject: Boiling Times, Wort-Chilling

Conn Copas sez:

I've made batches with Alexanders (my favorite for Ales) with boils of 90 minutes typically, and occasionally up to or over 2 hours (for Kolsch styles) with no bad effects.

My personal before and after experience is that Wort chilling is the single best thing I have done for my brewing, substantially reducing occurrences of infection, and leading to better cleaner tasting beers. I will adamantly take a stand against anyone that claims that there is no difference.

As for criticism of the environment you are brewing in, that's ridiculous. Every house everywhere, no matter how clean has literally thousands of bacteria and yeasts. They are in the air, everywhere, all the time. While they may not take off in your beer, that doesn't mean that some amount hasn't made it in there. Short of owning bacterial air filters and a clean room there will always be bacteria in your beer. The way to defeat them is to give the yeast (who are much more vigorous consumers of sugar) a leg up in the competition.

From: Andrew Lawson <lawson@ra.nrl.navy.mil>
Subject: Ester vs Cider

I have a question for those with beer judge vocabularies. I have heard much discussion of the various fruity esters produced by ales and that these can impart a fruit flavor hint to the brew. I have also read the lengthy and repeated discussions of "cidery" flavors, usually blamed on excess sugar.

I am consuming my current batch which has a slight apple hint to it (which I do not find objectionable) and am trying to tell what to call it.

So the question is:
What is the difference between apple ester and cidery taste?

-> From: Timothy Mavor <tmavor@pandora.cms.udel.edu>
-> This year I attempted to grow my own hops, but didn't get the
rhizomes in
-> the ground til mid May, so no harvest is likely for me this year :(
-> However, how should I "winterize" them? Should the bases be covered
with some
-> mulch-like material? Would fertilizing be helpful? Should I trim
the vines
-> back? When?? The plants are growing at my parents in Mass., so
there is
-> frost. Is this a major concern?

I can't speak for frozen wastelands, but here in San Jose, CA, I just
cut the shoots off at ground level at the end of the season. It becomes
clear that nothing more is going to happen, so you can tell by looking
when to do it. I half-heartedly cover with mulch; I would guess that
you would be better served by seriously mulching. I would also guess
that fertilizer would not be a good idea; the plant needs to go dormant
and not have another round of growth.

Then, in springtime, I watch carefully, waiting for the first sprouts
(if you don't watch, they won't sprout :-).

When I bought my pot from Rapids I said I wasn't a business, and they sold it to me any way, they might ask for a tax id number if your a business, which of course you won't have as an individual.

>

> Russ
Rapids is indeed in Iowa, Cedar Rapids Iowa to be a little more specific, and if look at a map Iowa is right under Minnesota, and I would bet that there is a much larger UPS shipping depot in the Twin Cities than in Cedar Rapids....shipping might even be cheaper.

From: robertn@folsm3.intel.com (RUBICON READY)
Subject: split keg/tap

Hi all,

Is it a big deal to set up both a homebrew cornelious keg and a regular brewery keg together?

Why I ask, is my roommate wants to convert a old refridgerator to a tapper setup. He likes stuff like Henry's and Mikelobe. I'd like to try my hombrew in kegs. So, would it be difficult to set it up to do both?

More than likely, there'd be two taps. In that case, I imagine I'd need all the stuff for a homebrew keg, but share CO2 from a manifold. But, what if we just wanted one tap? Is this scenario worth pursuing?

Thanx,

RobertN

Subject: Re: TEXAS Beer

Howdy from Houston -

Unfortunately in The Lone Star state brewpubs are currently illegal. However, there are a few good pubs to grab a pint at. Some that come to mind are The Gingerman, The Ale House, Crown & Serpant, and Mucky Duck's. All of these can be found in or near the Village, an area near the Rice University campus.

DeFalco's is THE place for homebrew supplies. It too is located in the Village. Scott Birdwell, the owner of DeFalco's, and John are quite knowledgeable and helpful when it comes to homebrew. Scott is hoping to get The Magnolia Brewery in Houston off the ground this fall/winter.

Pecan Street Lager is a contract beer which is brewed by August Schell in New Ulm, MN for a company in Austin. Quite a respectable beer IMHO. There is also a microbrewery in Dallas, but I haven't tried any of their beers. Hope this helps.

Jeff

P.S.
These are my own opinions, damnit!

> 1. How long should I expect the Ginger Ale to sit in the bottle until it tastes like Ginger ale (a time estimate rather than "until it's done" would be helpful :-)

>3. What can I do to prevent future batches from blowing up?

JS says:

I can't speak for your recipe but the one I have developed and demonstrate in (soon to be released) "BREW IT AT HOME", takes 48 hrs and will never blow up.

Here's the relevant part of the script.....

BREW IT AT HOME

ACT 2 GINGER ALE

Scene 1 GINGER ALE GRAPHIC

OUR NEXT PROJECT IS TO MAKE GINGER ALE. THE PROCESS IS EXACTLY THE SAME AS ROOT BEER EXCEPT THAT WE ARE GOING TO MAKE OUR OWN GINGER ROOT EXTRACT.

SCENE 2 GINGER ROOT

PICK OUT A NICE FRESH LOOKING PIECE OF GINGER ROOT AT THE SUPER MARKET. IF YOUR NEIGHBORHOOD STORE DOESN'T CARRY IT, TRY AN ORIENTAL NEIGHBORHOOD.

OUR ONE GALLON RECIPE CALLS FOR TWO OUNCES. THAT IS A PIECE ABOUT THE SIZE OF AN EGG. THE QUANTITY IS NOT CRITICAL AND YOU WILL NO DOUBT WANT TO EXPERIMENT WITH THE INGREDIENTS AS YOU GAIN MORE EXPERIENCE.

SLICE THE TWO OUNCE PIECE INTO THIN SECTIONS AND ADD THEM TO, TWO CUPS OF BOILING WATER. SIMMER THIS ON VERY LOW HEAT FOR 20 MINUTES.

SCENE 3 BLENDER

WE THEN POUR THIS INTO A BLENDER AND BLEND ON HIGH FOR ABOUT

ONE MINUTE.

SCENE 4 STRAIN INTO BOILING WATER

AT THIS POINT, WE SHOULD HAVE OUR GALLON OF WATER WITH TWO CUPS OF SUGAR THAT WAS BOILED FOR ONE MINUTE. IN THIS CASE, WE CAN ADD OUR EXTRACT WHILE THE WATER IS STILL HOT. POUR THE BLENDED GINGER EXTRACT THROUGH A STRAINER INTO THE SUGAR WATER.

WITH A SOUP LADLE, POUR A FEW CUPS OF THE HOT BREW THROUGH THE PULP TO EXTRACT A BIT MORE OF THE GINGER FLAVOR. THEN LET IT COOL TO ROOM TEMPERATURE.

SCENE 5 VANILLA

WHEN COOL, ADD ONE TABLESPOON OF VANILLA EXTRACT AND AT THIS POINT YOU CAN TASTE YOUR GINGER ALE BUT I RECOMMEND THAT YOU DO NOT ALTER THE RECIPE ON THE FIRST BATCH. BUT THE AMOUNT OF GINGER, SUGAR AND VANILLA ARE VARIABLES THAT CAN BE ADJUSTED TO SUIT YOUR OWN TASTE.

SCENE 6 ADD YEAST

AT THIS POINT, ADD THE YEAST AND AGAIN 1/8 TEASPOON MAXIMUM. STIR AND LET SIT FOR ABOUT 30 MINUTES. THEN BOTTLE AND AGE IT JUST LIKE THE ROOT BEER.

And from ACT 1 on bottling.....

SCENE 9 BOTTLES

THE SIMPLEST AND LEAST EXPENSIVE BOTTLING PROCEDURE IS TO USE EMPTY, ONE LITRE PLASTIC SOFT DRINK BOTTLES. THE ONES WITH PLASTIC, SCREW CAPS ARE THE MOST RELIABLE. THERE ARE NUMEROUS OTHER POSSIBILITIES AND WE WILL TALK ABOUT SOME OF THEM WHEN WE GET TO BEER MAKING.

THE NUMBER ONE RULE IN BOTTLING IS CLEANLINESS. THE BOTTLES AND ALL EQUIPMENT THAT COMES IN CONTACT WITH OUR BREW MUST BE STERILIZED TO PREVENT ANYTHING OTHER THAN, THE YEAST WE ADD, FROM TAKING OVER.

ACT 1, P3

SCENE 10 BLEACH AND WATER, STERILIZING AND RINSING BOTTLES

THE BEST WAY TO STERILIZE PLASTIC BOTTLES IS TO RINSE THEM IN A SOLUTION OF HOUSEHOLD BLEACH AND WATER. A TABLESPOON OF BLEACH IN A QUART OF WATER IS POURED INTO AN EMPTY BOTTLE. THE SOLUTION IS THEN POURED FROM THIS BOTTLE INTO THE NEXT AND THEN RINCED THOROUGHLY WITH CLEAN WATER TO REMOVE ALL TRACES OF THE BLEACH.

THE CAPS CAN BE STERILIZED IN THE SAME SOLUTION. BE SURE TO RINSE THEM THOROUGHLY.

SCENE 11 FILLING

WHEN THE BOTTLES ARE READY, FILL THEM WITHIN ONE INCH OF THE TOP AND SCREW THE CAPS ON TIGHTLY.

SCENE 12 CARBONATING, SQUEEZE BOTTLE

SET THE BOTTLES ASIDE TO CARBONATE. THE NICE THING ABOUT USING PLASTIC BOTTLES IS THAT YOU CAN CHECK THE CARBONATION SIMPLY BY SQUEEZING THEM.

AT NORMAL ROOM TEMPERATURE, THEY WILL BE HARD AND FIRM IN ABOUT 48 HOURS. YOU CAN THEN REFRIGERATE THEM TO FINISH THE AGING PROCESS. THE LONGER THEY AGE, IN THE REFRIGERATOR, THE BETTER THE ROOT BEER TASTES BUT YOU CAN DRINK AT ANYTIME.

A DAY ONE WAY OR THE OTHER BEFORE REFRIGERATING, MAKES A SIGNIFICANT DIFFERENCE IN THE AMOUNT OF CARBONATION. UNLIKE ORDINARY BEVERAGES THAT GO FLAT AFTER OPENING, IF YOU RE-CAP A HOMEBREW AND LEAVE IT OUT OF THE FRIDGE OVERNIGHT, IT WILL RE-CARBONATE.

IF THE BOTTLES DO NOT GET FIRM AND HARD, SOMETHING WENT WRONG AND THE YEAST DIED OR WAS TOO OLD. THROW IT OUT AND TRY AGAIN WITH NEW YEAST.

.....

I left a bottle out for 30 days just see what happens and although the bottle survived, the amount of carbonation was beyond usefulness. I had to lower the temp it to almost freezing to even get it open and I still lost about half to gushing.

The key to control of carbonation is to refrigerate when adequate and three days is more than adequate for both my rootbeer and gingerale process. Making one gallon batches minimizes the strain on refer space.

I actually bottle in pop bottles but always include one plastic bottle to monitor carbonation. This of course, also applies to beer but it usually takes much longer to carbonate and the plastic bottle is fun to squeeze when you get bored.

Subject: Conn-troversy ...

In HOMEBREW Digest #708, Conn Copas offered some intriguing opinions, including:

>... We have all read about the dire consequences of washing sediment
>into the boiler, but maybe this is an illusory problem. What about
simply
>leaving the wort to settle, then racking into the boiler ?

Ah, but why? The sediment can usually be eliminated by cycling the cloudy wort back through the filter bed. In all but one batch I've done this until the wort runs clear. That one batch was a lambic, made with large quantities of unmalted wheat, and both mash and wort were so turbid that I gave up hope of its ever clarifying. I would think that husk material in the boil would be asking for astringency in the finished beer.

>More heretically still, we've seen recent recommendations to add boiler
>trub to the fermenter in order to ensure depth of flavour. Food for
>thought, huh ?

Yes, someone here (Bill Crick?) said several years ago that any "flaw", if it's just above the taste threshold and too mild to be obnoxious, adds interest. I remembered that when my beer became more bland as I gained control of the process, and dialed back on my efforts to remove trub before pitching. I now remove most of it, but leave just a trace. It works.

>But consider this. You are making a stout and the recipe calls for flaked
>barley. Why not simply add more malt ? Does the flaked barley possess
>anything that the malt does not (like different proteins maybe) ?

Like beta glucans, which will dramatically change viscosity and mouthfeel, making stout really stout. Add more malt instead and you'll end up with something more like a Trappist "dubbel": dark, malty, raisiny, with a high alcohol content, and without the thick and heavy mouthfeel of a stout.

>Yours in alchemy

Always! Brewing processes are as close to magic as most of us will ever get! Thanks for the interesting thoughts, Conn.

In HOMEBREW Digest #708, Timothy Mavor asked:

>This year I attempted to grow my own hops, but didn't get the rhizomes
in
>the ground til mid May, so no harvest is likely for me this year :(

Mine wasn't worth beans either. But we had a cool, dry summer.

>However, how should I "winterize" them? Should the bases be covered
>with some mulch-like material? Would fertilizing be helpful? Should
>I trim the vines back? When?? ... there is frost. Is this a major
>concern?

I've been told by the hop mavens in my club that frost gives a very good clue to when it's time to cut the vines back. When the vines appear to be dying, cut them right back to the ground. Cover the stumps (and, in fact, the entire hill) with manure (I use a mixture of horse & chicken, with straw mixed in). Some people add a pinch of a boron salt, but that depends largely on the amount of boron occurring naturally in your soil and should in any case be used very sparingly. The manure serves both as fertilizer and mulch.

On the subject of hops, my daughter brought home yesterday some enormous hop cones she got from some wild vines nearby. They smell disgusting, but apparently I could get tons of the stuff for the effort of picking it. My hops, on the contrary, smell divine, but there isn't enough for even one batch. Surely there is a moral here, but it eludes me.

Subject: Low Temp Lager Behavior

I posted a letter in HBD 705, and another in rec.crafts.brewing, with questions I had about the behavior of the wort in my fermenter. This was my first attempt at low temperature brewing and I had some concerns. I recieved several replies; but I thought that Chad Epifanio's reply to my post in r.c.b. was the most complete in answering the questions I'd raised. He has given me permission to publish his letter, as I wanted to share his comments with others who are either doing or are thinking about cold fermentation. Lines that begin with ">>" were from my article in r.c.b, and lines that begin with ">" were in his e-mail to me.

>>I used Wyeast Pilsner, and according to the package directions and the >>date stamp, activating the culture in the package the day before I brewed.
>>I pitched it directly from the package into the wort when my fermenter >>was still above 80 degrees, then began refridgeration. My fridge is at >>42 degrees.
>
>Well, you may have activated it a bit too close to pitching. The package >should have a chance to get EXTREMELY swollen. Don't worry, there >should >be enough to finish the job, and the low temps will inhibit >contamination.
>
>>There was never enough activity to justify a blow-by tube in the fermenter.
>>There was some CO2 production, but not much, and after 5 days I >replaced >>the blow-by with a standard fermentation lock.
>>This fermentation looks strange. The kreusen is fairly solid, not at all >>foamy, and is about 1/3 inch thick. There are clouds of what must be >yeast >>in the wort. A large cumulous cloud just underneath the kreusen, and several >>cirrus clouds a few inches above the trub. CO2 production is minimal.
>
>When I ferment at cold temps, there is never enough activity to warrent a blow- >off tube, either. The fermentation will be slower at that cold a temp, and >the kreusen will be thinner and harder..
>
>>The wort's original gravity was 1.025. After 6 days, the gravity is at >>1.021. The wort tastes flat and sweet. Both gravities were measured >>at 60 degrees.
>
>Patience, my brewing friend. One reason for the cold temp is so that >fermentation is slower, resulting in a smoother finished product. Good >lagers >are not made in a week, nor in a month. Yeast is a living organism, and >if you rush it, it will likely get pissed at you.
>
>>Is this normal behavior for a refridgerated fermentation? Did I >underpitch

>>by not creating a 1 or 2 quart starter from the Wyeast package? The package
>>didn't suggest a starter would be necessary, and I assumed that their built-in
>>starting system would be enough. Is my wierd kreusen due to Irish Moss?
>>Are these yeast clouds normal? Is there anything I should do, other than
>>rack on the 14th day as I was planning to do?
>
>Chill, Josh. I'm not going to repeat the homebrewers oath that you know so
>well. There is a great deal of magic and mysticism involved in homebrewing,

Subject: Chill Haze in Extract Brews

In HBD #704, Graham Leith writes:

>I have recently moved up from kit brewing to brewing with extracts,
adjunct
>grains, and hops. While I have been very pleased with the taste of
these
>beers, they have a chill haze that I never encountered with the kits. I
>suspect that it is due to the proteins dissolved in the wort from the
adjunct
>grains (crystal malt and toasted barley malt) that I've been using. I
put the
>adjuncts into the cold water and remove them when it comes to a boil,
then add
>the extract.

>Does anybody have any suggestions on the use of finings, or better
still, how
>to avoid a chill haze without the use of finings? Is it alright to add
finings
>to a secondary or will this precipitate out too much of the yeast needed
for
>bottle carbonation? Should I close my eyes, not worry, and just enjoy
the
>taste of the beer?

I also brew using the same method you do, and have encountered chill haze
in every single batch. The only fining agent I have used is Irish moss;
it doesn't seem to have much effect on *chill* haze - but I don't think
it is supposed to. After some e-mail discussions with HBD and brewing
veteran Martin Lodahl, I began altering my methods somewhat.

Normally, I would brew using the single-stage blowoff method. Martin
suggested that I get another carboy, and after fermentation was complete,
rack the beer into it for a week of clarification before bottling. This
improved the clarity of the beer when not yet chilled, and it cut down
some
on chill haze but did not eliminate it.

The other thing I began doing was trub separation. With some batches,
I've poured the reasonably cooled (80 F) concentrated wort onto sanitized
ice, let it sit overnight, racked off the trub, and then pitched. With
others, I let the brewpot holding the concentrated wort sit in ice
water until it got down below 60 F (about 40-45 minutes), put it into
the carboy with cool water (again below 60 F), let it sit for about an
hour, racked off the trub, and then pitched. Both methods work
OK for me, but chill haze again does not seem to be much affected (flavor
definitely is - the trub separated beer tastes "cleaner").

Just yesterday I had an interesting experience vis-a-vis chill haze. I
opened a bottle of light pale ale that had been in my refrigerator for
at least 6 weeks, perhaps 8 weeks. All the previous bottles of this
ale had chill haze after only a week or two of refrigeration, but this
bottle was *crystal clear*. I guess the stuff that precipitates out at
cold temperatures eventually settles to the bottom of the bottle.

When all is said and done, I think your last sentence sums up my attitude
about chill haze - ignore it and enjoy your brew.

Subject: Re: TEXAS Beer

Eric Simmon asked about Houston bars, brewpubs, etc.
As a two-time summer (damn it's humid there) resident of Houston,
I can recommend the Richmond Arms on Richmond Ave, on the
west side. I can't remember the precise cross street, but I think it
is a bit west of Chimney Rock. This is a great British style pub with
a good selection of ales (et al.) on tap.

The same folks operate the Ale House, which I believe is also on
Richmond, but much closer to downtown. I've never been there,
but heard many good things about it.

Other good bars include Dirty's (sports bar) and Sherlock's.
Sherlock's is a pub wannabe. They put a lot of work into the
Holmes-style atmosphere. Many beers available, but I'm more
comfortable at the Richmond Arms.

And just about any place with Shiner Bock on tap. Shiner is made
in Shiner, Texas, of course. It is my all-time favorite supermarket
beer. Good stuff. Probably the main thing I miss about Texas.
I was able to buy some here two years ago, but haven't seen it since.
I always bring some back when visiting the in-laws.

I don't think there are any brewpubs in the entire State of Texas,
nor any microbreweries in Houston, though they seem to be
popping up all over these days.

From: Peter Glen Berger <pblp+@andrew.cmu.edu>
Subject: Worried parent blues

Okay, I have two maybe problems, and I'd like to know if they really ARE problems.

This is my first batch of beer. I'm following the probably-inferior-but-simple hopped malt-extract and corn sugar path. I used less corn sugar than was recommended (3 1/4 cups instead of 4).

1) The wort never had a hot-break. My girlfriend and I theorize that this was because we are boiling around 2 gallons of wort in a huge (5 gallon) vessel. Are we right, or was this indicative of a problem with our procedure?

2) NONE of the various references we have seen tell us exactly how much fermentation should be going on. Lots of phrases like "fermenting madly," but no indication of what this means. We pitched the yeast about 28 hours ago, in a 7-gallon plastic bucket (5 gallons of wort), and are getting "bubbles" in our fermentation lock about every 13 seconds, with variations from 8 to 16 seconds. There seems to be about half an inch of kreusen. Are we OK, and just fretting over nothing, or is this a substandard fermentation?

Thanks in advance,

Subject: Utah Beers

Just to add a bit to the noise, one of my favourite stouts is brewed in Utah. `Irish Stout', apparently by the Wasatch Brewing Company, in Wasatch, Utah, is really nice stuff.

Note, however, that I prefer sweeter brews. My previous bottled favourite was Watney's Cream Stout. This preference seems to fly in the face of the general opinion of the HBD group, so please take the recommendation with a grain of salt (which seems to help cut the bitterness of the Watney's, interestingly enough).

Subject: Settle & Rack you spargings!

>... We have all read about the dire consequences of washing sediment
>into the boiler, but maybe this is an illusory problem. What about
simply
>leaving the wort to settle, then racking into the boiler ?

works great. The only drawback is the time it takes to settle,
but when I get done with the sparging I'm already 4 hours into
the brewing process, and need to take a break for a few hours,
anyway. Even if the spargins finally run clear, let them
sit a few hours, and you'll be suprised at how many husks
settle out. I now recycle only the first quart or two of
runoff, let the spargins settle and rack. My spargings never
seem to run clear until I add the sparge water. The husks take
up a very small volume (O.K. I guess there is another drawback);
expect to lose a quart of wort, tops.

Has anybody noticed:
the fewer husks in the boil, the better hot break?

Subject: Beer proof plug information request

I saw a most unusual glass carboy this weekend. It is a 5 gallon carboy, solid glass, with a nipple molded onto the side about an inch up. The nipple tappers to about a 3/8" O.D. opening. Immediatly, I thought "wow, this thing is just the right height that I could brew in here and drain it, leaving the yeast cake/trub behind." Then unpleasant reality hit. What would I use to plug the hole while I am brewing? I not only have to find a beer proof material to plug the hole to a few weeks, I also have to find something to allow me to drain this without spewing beer all over basement while I connect a hose to the nipple (unless I just want it to shoot out and I'll catch it in a bucket, kind of a bad idea for several reasons). About the only reasonable thing I could think of is to put a length of food grade hose on the nipple with a length longer than height of the carboy and loop it up so the end is above the top of the wort. I am concerned about this too. I suppose I could sanitize the inside of the hose and rig up something to keep it closed and clean inside. What about the wort/beer in the hose? Would enough yeast sneak in there for complete fermentation, or would I have spoiling wort mingling with my beer? That stuff would be washed out first and I could dump it as I flush out my hose, but still, there it sits next to my beer ... Not even to mention my concern over getting a slow enough flow rate that I don't wash a lot of yeast off the top of the cake.

Has anyone ever used something like this? Does it sound like a lot of trouble and expense (\$29) and possible contamination because I hate sponing so much? Should I just get a pump instead? Any ideas, jokes, puns, flames, personal slanders, spelling or gramatical corrections? I'll be offline for the next week, but I look forward to any responses.

>in Utah. `Irish Stout', apparently by the Wasatch Brewing Company, in
>Wasatch, Utah, is really nice stuff.

I have read that Utah has a 3.2% law that covers *all* types of beer.
Even
malt liquors have to be less than 3.2% alcohol. Seems to me that would
make
for some pretty weak stouts. Anyone in Utah buying Schlitz Malt Liquor
for
the extra *kick* is just fooling themselves.

This was based on information compiled by the Beer Institute (formerly
the
United States Brewers Association) but is 5 or 6 years old (maybe more).

Subject: carbonation in soda pop

In HBD-709 Jack Schmidling <arf@ddswl.mcs.com>, talking about homebrewed root beer, says:

> UNLIKE ORDINARY BEVERAGES THAT GO FLAT AFTER OPENING, IF YOU RE-CAP
> A HOMEBREW AND LEAVE IT OUT OF THE FRIDGE OVERNIGHT, IT WILL
> RE-CARBONATE.

Is this because the yeasties in commercial beverages have been killed by pasturization? Or are commercial root beers carbonated by CO2 injection?

> I left a bottle out for 30 days just see what happens and
> although the bottle survived, the amount of carbonation was
> beyond usefulness. I had to lower the temp it to almost
> freezing to even get it open and I still lost about half to
> gushing.

Perhaps someone can explain what happened here: Long ago, I left a couple bottles of soda (probably Pepsi, but that was too long ago to remember) in the back of my pickup when I went skiing and came back to find them nearly frozen. Since we were miles from nowhere and that was all we had left to drink, we popped off the tops. Nothing happened - not even the normal *ffffpppttt* - the soda in the neck was frozen solid. As it began to melt, however, the soda started frothing and eventually got to gushing out of the bottle quite a bit.

I didn't question why back then because this was the first experience I'd had with soda that was that cold. But Jack's scenario suggests that the colder the soda is, the less it should gush. Or was my soda's reaction because it was changing from a solid to liquid?

Subject: Homebrew Digest #708 (August 26, 1991)

Well, thought i would let everyone know what happened:

we served the beer and a fair amount of it got drunk, so it couldn't have been *all* bad...

but, it is still bvery young and the root beer taste is there to stay. i am going to let it sit for a couple of weeks and see if the tastes have mellowed more.

the biggest thing that i learned is that there is more to making a lightly flavored beer than just going easy on the hops. this beer could definitely have used more hops!

thanks for all the helpful advice!

From: mcnally@Pa.dec.com
Subject: decoction mashing, lauter tun temp.

I tried a decoction mash over the weekend, and was satisfied with the technique and the effects. Overall, I'd say it's a more involving and more satisfying process than step-infusion mashing. There's something about boiling the thick porridge of grain that convinces me that *something* is going on. Temperature control is more precise, as well; I don't have to put up with my stove.

My setup consists of an Igloo 36 qt. mash tun and a 33 qt. ceramic-on-steel boiler. The Igloo works extremely well at keeping the temperature constant.

I learned that it's a big pain to undershoot, and that as much grain as possible should be boiled for the acid rest--->saccharification rest decoction. It's easier to let the excess hot grain cool if there's too much than to cope with the mash being too cool.

One question: what techniques do people use to keep the mash in the lauter tun warm while sparging? Mine is insulated, and when I recirculate I drain into a saucepan directly on a portable electric stove element. It stills cools off too much.

>Lager Kit) would certainly verify this.

The implication here (that John Bull adds corn sugar) may be undeserved.
Just because a beer is fruity or because someone attributes some quality
of "cider" to it, does not mean that there is corn (or other) sugar added
to the extract. Dave failed to mention the fermentation temperature. The
fact that the can says "lager" does not mean it will automatically be a
lager.

What makes it a lager is the fermentation temperature. A "lager extract"
fermented with a bottom fermenting (lager) yeast at 70F will taste like
an
ale. No doubt about it. ^^^

Let's not be too quick to "cry sugar."

From: FATHER BARLEYWINE <rransom@bchml1.aclcb.purdue.edu>
Subject: Flat Cornelius, Gingane, and Magic

Heydie Brewmeisters!

Wow, this newsletter is really getting huge! I've been just filing them away recently, and I was very pleasantly suprised at how very large this has become.

First a bit about flat beer in Cornelius (sp?) kegs. I consistantly turn out well carbonated, and sometimes very well carbonated, beers from Cornelius kegs. The secret to assuring carbonation and preventing gushers is to prime with low amounts of sugar or krausen (1/3 cup sugar, 1-2 cups malt extract at fermentation strength) and to put on a significant quantity of carbon dioxide (20 psi or more). I've heard some complaints about 'artificially carbonating' beers by putting on high CO2, but to artificially carbonate requires lots of gas (add 50 psi, shake, repeat indefinitely)

The reason you're ending up with flat beer is that the seals around the central fill port require at least 15 psi to seal properly (the working pressures for syryp are around 80 - 100 psi) and much below this value will allow all pressure to escape. It is essential to maintain pressure early, since this is when the beer is still fermenting and building up a good level of CO2 in solution; later when the beer is saturated with CO2 losing pressure is not as much of a problem. If you end up with overcarbonated beer, don't be afraid of letting off some steam with the pressure release and letting the beer reach a new (less gushy) equilibrium.

Schmidt productions listed a long recipe for ginger ale, and so I thought I'd slap together a short recipe for ginger champagne (gingane). There are a couple of considerations....first, this stuff is high octane brew (10% alcohol and up) and it is very similar to champagne (high gas pressure) so I would ask you to be very careful with your bottles (use only champagne bottles) or avoid the danger of explosion and use a Cornelius keg. Don't let this stuff ferment out completely so it has a bit of residual sweetness to mask any slight off flavours...being made of sugar and ginger, it has no body to mask imperfections. Fruit is also a nice addition, either with the pre-fermented mass or in the Dutch style as a final addition a few hours (1 day tops) before bottling.

GINGANE ala RANSOMNIA

1 - 2 lbs. ginger (yes, pounds!)

5 - 7 lbs. corn sugar

1 - 2 lbs. sucrose (table sugar)

juice of several (3) citroids (lemon, lime, grapefruit, or combination of high citric fruits like lime with oranges)

various additives (fruitoids, spice thangs, herbs, hops, or whatever floats yer boat)

2 packages champagne yeast

Chop ginger (leave that skin on!) in discs and blend with hot water. Use plenty of water, then filter homogenized ginger through several layers of cheesecloth. Squeeze dry, then add more water and squeeze again. Add water to make about 2 gallons, heat, and dissolve in sugars. Bring to boil, add citroid juices, and boil stirring frequently (to avoid excessive sugar carmelization) for about 30 minutes.

Pour into fermenter containing 2 + gallons cold water carefully (to avoid hot stuff on cold glass) and add more water to make about 5 gallons. Pitch. Ferment. Bottle. Drink.

If adding fruit, do so 5 minutes after you stop boil and give it 10 minutes to pastuerize a bit. Dump the whole bleeding thing into the fermenter, and strain off the fruit when passing into secondary (or just fergit the secondary and strain when bottling). I personally prefer to make a fruit extract (blend fruit and strain off juice) and add the juice to the finished product. Remember to bottle before fermentation stops, and be careful about the priming (1/2 to a maximum of 3/4 cup).

Gosh, this was supposed to be a short recipe....ah well, my mouth gushes over.

A last blurb about magic.... We've all humorously jibed about what the phase of the moon, or astological sign of the brew party, or even bad and evil

influences does to your brew; I personally find astrology offensive, and I

think the phase of the moon primarily affects tides, but your attitude and

emanations (for lack of a word that hasn't been New Aged into uselessness) are

seriously all important to brewing. Brewing has only recently been made into

a science, and like all sciences (I'm a scientist, and so I can at least talk

out my ass with assurance) discounts the effects of subjective (i.e. personal and non-reproducible) reality. Beer is a mystery, and being able to

describe what happens chemically or dissect the constituents of a fine brew

does nothing for understanding the 'whats' of a beer. Science is inherently

descriptive, and cannot say much about just what something is; we can precisely describe the behavior of something, but what exactly that something

is is still a matter for the philosopher. I can say that I know the way I

feel influences the beer I make (to the extent that I never sanitize and don't bother with secondaries) by making the living organisms that produce it

happy (for lack of a better word).

However, I cannot put down in black and white how I do it. This is the essence of magic, and unfortunately the above diatribe has mainly tried to

communicate to you the uncommunicatable. I will end this lame monologue with

the thought that you really should think of your beer as an expression and

extension of your self, not as a cooking project or experiment.

From: KENYON%MOE%erevax.bitnet@pucc.PRINCETON.EDU
Subject: ???Aluminum Kegs/Mead/Chemistry???

Howdy All,

I've got a few questions for the HBD peanut gallery:

1) On two occasions I have kegged a batch of beer in Aluminum Anheuser-Busch kegs. They're pretty easy to get open, you've just got to remove a coil spring on top (after carefully depressurizing, of course!!) and the ball valve/outlet tube assembly comes out all in one piece. The problem is, on both occasions the kegged beer came out substantially darker (more amberer??) than I had anticipated. Darker in fact, than some of the same batch that I had bottled alongside the keg brew. I've been brewing for a couple'o'years so I realize light malts won't give me 'Bud-colored' brews. The brew tasted fine, but it was difficult to get some less adventurously friends to try it simply because of the color (Rascist Bastards!). My questions are these:

- a) Is the yeast reacting with the Aluminum to cause this effect?
- b) Can I get Alzheimer's from drinking it?
- c) Am I simply losing my mind?
- d) Has the yeast's reacting with the Aluminum given me Alzheimer's from drinking it and I'm losing my mind?

2) I recently tried my hand at brewing a fruit flavored Mead. I used the following recipe (approximately) for 6.5 Gallons:

- 12 # Goldenrod Honey
- 2 Qts. Cherry Wine Kit (Whole cherries - pits, stems, the works)
- 2.5 Gal. Grapefruit Juice
- .5 Oz. Hallertauer Hops (The beer brewer in me - what can I say)
- 1.5 Oz. Acid Blend
- Some Pectic Enzyme
- 6 Campden Tablets
- 1 Pkt. Mead Yeast

I mixed all of the above (except for 1 gallon of G.J.) in warm water (not boiled) filling the fermentor up to 5 - 5.5 gallons. A day later I pitched the yeast from a 1 Quart starter. Primary fermentation seemed to go pretty well and after about two weeks I racked into a 6.5 gallon secondary. I topped the secondary off with another gallon of G.J. which I had sterilized (maybe?) by mixing in a couple more Campden tablets the day before. Well, it's about 6 weeks later and I'm still getting a fairly heavy Sulphery nose from the neck of the Carboy when I chance to sniff in. Well, here they come:

- a) Will the sulphery smell go away if I ignore it?
- b) Will it go away if I don't ignore it - i.e. anything I can or oughtta be doing??
- c) Did I just plain dump too much Sulphur in, in the form of Campden Tablets?
- d) Can anybody tell me if there was any method to my madness (no Alzheimer's jokes, please)?
- e) Any recommendations whether this Mead will turn out better if I carbonate it (which at this point, I intend to do), or would it best be treated like a wine??

Any comments as to the positives/negatives of the steps I've taken would be greatly appreciated. Looking forward to your responses ...

-Chuck-

P.S. - Tim, was that 3 parts sorcery to 1 part fluids, with a pinch of Chem. Eng.???

Subject: stuff

Ok, if you go north from Iowa, you end up in Minnesota. I was right the first time. That's enough of that.

Martin L., you may be right, I might be confusing Rapids with Carolina Bio.
Supply re. individuals vs. businesses.

I'm definitely confused this week. Lack of sleep I guess.

I've got a half-batch that's been fermenting 16 days now, with Wyeast Chico Ale yeast. It's still in the primary, and it's about done. It's also about time for another batch, and I'd like to reuse the yeast. F. Barleywine's mysticism aside, I don't want to just pour the wort onto the yeast cake in the carboy; there's a solid line of crud about halfway up that I'd rather avoid. So I was thinking of bottling the half-batch, and setting aside the first and last bottles (to be sure I get the one with the most yeast, if you follow my logic), and pitch those into the next batch. Isn't that the way it was done (more or less) for centuries, before yeast cultures were made available? Having the yeast in bottles would also loosen up the timetable (somewhat) for the new batch. And it does add a nice touch of that mysticism, sacrificing some current brew for the future (hmmm, vaguely pagan mysticism at that, how appropriate).

Subject: An interesting epitaph...

A friend here at work showed me a picture he took when he was in the UK a while back. I thought it might be of interest to the digest folks. I'm not sure I understand some of the phrasing and terminology, but I think by 'small' they mean 'weak'. I wonder if weak beer had a tendency to become infected on hot days during that time period (?). Anyway, here it is:

In Memory of
Thomas Thetcher
a Greadier in the North Reg.
of Hants Militia, who died of a
violent Fever contracted by drinking
Small Beer when hot the 12th of May
1764. Aged 26 Years.

In grateful remembrance of whose universal
good will towards his Comrades, this Stone
is placed here at their expence, as a small
testimony of their regard and concern.
Here sleeps in pease a Hamphshire Grenadier,
Who caught his death by drinking cold small beer.
Soldiers be wise from his untimely fall
And when ye're hot dring Strong or none at all.

This memorial being decay'd was restored
by the Officers of the Garrison A.D. 1781.
An honest Soldier never is forgot
Whether he die by Musket or by Pot.

In digest #708, Chuck Coronella wrote:

>Here in Utah, the beer sold in most stores (except in state operated
liquor
>stores and some private clubs) is by law limited to 3.2% (by volume)
>alcohol. I understand the same is true with a few other states.

In Colorado, grocery stores are limited to selling 3.2% alcohol *BY
WEIGHT*
beer. I can't swear to it, but I'm pretty sure the other states that
deal with 3.2 beer measure in % by weight also.

>I guess
>this must create a significant hardship for the smaller breweries, since
I
>am unable to find beers from any microbreweries and most imports. Let's
be
>generous and assume that the smaller breweries have dedicated
brewmasters
>who are unwilling to compromise. Anyway, we have available all your
>favorite brands- Bud, Old Milwaukee, Coors, Miller, Keystone, etc. as
well
>as some imports- Heineken and Molsen are two that come to mind.

These are the only ones available in our grocery stores as well. Liquor
stores
can sell more potent stuff, but not on Sundays. (Funny though, I can't
seem to find anything in the State constitution which would validate
Sunday being treated differently from any other day of the week!)

>My question is this- what is the percent of alcohol in most of these
beers
>otherwise?

Well, first of all, 3.2% by weight is about 3.9% by volume. This is
pretty
close to the figures I've heard for the Standard American Lager, and
actually
higher than the Standard American Lite. Now this is pure speculation on
my part, but I'd wager that the 3.2 Bud carried at 7-11 is identical to
the
"high-point" Bud carried at Liquor stores; I'd bet the family farm (if
there
was one) that Bud Lite is the same at both localities. From personal
experience,
I got just as drunk in college drinking 3.2 beer as I did drinking the
stuff
from Liquor stores.

Luckily, since I started homebrewing I haven't had to deal with any of
it!

Subject: The magic of brewing.

I couldn't resist commenting on the latest "brewing is magic" thread.

Thank you Father Barleywine, you inject just the right amount of insanity whenever it's needed. [grin]

I love the science of brewing. I love learning of the many chemical reactions and the exotic sugars and proteins that go to make up a delicious brew. However, when I put kettle on stove and open up some ingredients, I forget the science and enter into the magic world of the 11th century alchemist. If I had a cone hat with stars and moons on it, a la Merlin, I'd wear it when I brew. I use the science to plan things, but the execution is strictly under the control of the netherworld.

Although I cannot prove it scientifically, I am convinced that the universe responds to attitudes. I am in total agreement that my attitude towards my beer will influence its outcome. (This is going to convince you that I'm a certified loon.) I can command away the microbes that could damage my brew, and command to action those that make it what it should be. (Do I really mean that ... well ... I'm not discounting it completely.)

Although I'm not nuts on the most popular of the homebrew books, the advice to "relax" is the best that could be given. Oh yes, be sure you talk nicely to the yeast. (In fact, they really like Bach and Vivaldi, especially the concerti grossi.)

See, I told you that I was crazy ... but that is all right because I make good beer.

Dan Graham,
Beer made with the Derry air.

Subject:

In HBD 710, Thomas Manteufel described a special glass carboy he found with a spigot near the bottom, and wondered what he could plug it with.

I am a crumugeon about some things. Sanitation is a tough enough struggle (I've made quite a bit of contaminated beer myself) for homebrewers without adding all sorts of gee-gaws to collect crud in. I'd just be nervous about it - one of the beauties of the glass carboy is its perfectly smooth interior finish, which cannot hide anything if you follow relatively simple cleaning and sanitizing procedures. This gizmo would complicate all that. What do you have against siphoning?

Date: Tue Aug 27 09:56:12 1991
From: larryba@ingate.microsoft.COM
Subject: Root Beer

I recently had some delicious root beer made by a local microbrewer, Thomas Kemper. The ingredients listed Sassafras extract and vanillia as the only flavors. There was other stuff as well: carmel color, corn sugar, maltodextrin, phosporic acid and carbonated water.

Several months ago I talked with the Kemper head brewer) and he said that the sassafras extract comes from only a few licenced processors since the raw stuff is apparently quite carcinogenic. I presume the maltodextrin is responsible for the lush creamy mouth feel and head. The rest is standard pop ingredients.

The point is, do y'all have any recommendations for the flavor essence for root beer? I looked in my local supermarket for some "hires extract" that my dad used way back when and all they had was some totally artificial and loaded with odd chemical components stuff from Shilling (i.e. no sassafras in it at all!)

This stuff from Kemper was *GREAT* and I would love to have a keg of it next to my ales in the fridge (there is always room for one more tap!)

Thanks, in advance.

From: Conn Copas <C.V.Copas@loughborough.ac.uk>
Subject: Re : cidery tastes

There are at least three different classes of substances which can give beer a fruity flavour : esters, aldehydes and fusel oil (higher alcohols)

Esters are generally well-received in ales and are encouraged by the use of certain yeasts and also by high gravity ferments. In fact, some brews are fermented at double strength, then later diluted, for this reason. Esters can also be a product of maturation, according to the principle that alcohol + organic acid gives ester (slowly). Some acids esterify more effectively than others, with some winemakers advocating additions of succinic acid for this purpose. Could be an interesting experiment in beer : you might possibly wind up with some appealing fruit flavours, or you might wind up with a vinous tasting beer.

Just to contradict myself a little, I have noticed that hop aroma degrades with maturation. I have always been under the impression that this aroma was primarily due to esters. Possibly not ?

Aldehydes are a precursor to alcohol (ethanol) during yeast metabolism. In other words, they are present in green beer, but should vanish with maturation. They taste a fraction sickly and are poisonous. Fusel oil is encouraged by certain yeasts, warm ferments, and nutrient deficiencies. It too is sickly and reputedly toxic. Both aldehydes and fusel oil are thought to be implicated in hangovers. If you will pardon an anecdote, the last time I was in Munich, I had 1 litre of what looked and tasted like a very young draught hefe weizen with dinner. The dinner was not particularly exotic (after all, this WAS Germany) and I had no other intoxicants (honest to God) ! Next morning, my head felt like trolls had danced on it during the night (to steal a phrase).

Back to the point. When people complain about 'homebrew flavours', 'bubblegum flavours' and maybe 'cidery flavours', I suspect they are often referring to aldehydes and/or fusel oil. This suspicion is reinforced if the brew drinks cleaner with maturation.

Back onto toxicity. I now take the point that unhulled adjuncts have a place in brewing. But this has led me to question whether the rolling/flaking process has any effect on cellulose content in the cereal. If not, one is introducing one of the precursors to methanol into the brew; yet another nasty substance.

Just when you thought it was safe to ... RDWHAHB ?

From: FATHER BARLEYWINE <rransom@bchml1.aclcb.purdue.edu>
Subject: That Satanic Mead

Geez Looueez, what a recipe for mead!

As you might have gathered, I'm replying to Chuck's recipe for cherry mead and the resultant nasty sulphur odor. Chuck, try:

- 1) Cutting the addition of grapefruit juice to naught, and using lemons or limes (3 - 5) instead.
- 2) Boil the stuff...I've had no problem with boiling up the mead constituents (honey, water, and citrus juices) and then adding the fruit after it has cooled a bit.
- 3) Ack! Dispense with the Campden tablets. What an idea, sterilizing components for a brew that tasted great before Pastuer was a sparkle in his father's eye. Honey has all sorts of nasty antibiotics in it (when was the last time you found mold on your honey?) including, of course, high sugar content, and if your yeast isn't kicking ass on all competitors very soon after hitting the meniscus, you need to get some different yeast.
- 4) Dispense with the acid and pectic enzyme. Unnecessary and probably expensive.
- 5) On the yeast note, try using champagne yeast. If you prime it a bit, the mead has a delightful small-bubble sparkle that will tickle away your troubles (and champagne yeast will ferment out enough alcohol to savage any remaining ones).

Personally, I like both wine (flat) and sparkling meads. Frankly, I could drink mead continually, sing off key, and bathe in it too. Mead is truly the drink of the gods, while beer is the soothing nectar of their resulting well-wishes for the prosperity of mankind. Besides, mead is really easy to make (especially after killing yourself to produce a fine all-malt extravaganza).

Hope I helped a bit...

Father B.

hiya

this may sound dorky but what about putting some hose on the 'nipple'
(ooooooooeerrrrr!) and then blocking it with a couple of bulldog clips?

i s'pose you would need hose that would be a bit more flexible than the
average food-grade stuff (thinner perhaps?).

in our lab (molecular bio) we use these things like thumbscrews for
closing
off hoses (and for torture...) maybe a vice or something may work the
same.

if you know someone who works in a lab they may be able to get some glass
taps which slot in to bits of hose, this may also work but i'm not too
sure
what the pressure would be like inside the hose.

good luck

Andy

If you are talking about the newer style of kegs (from your description, it looks like it), they are stainless steel. *If* you could purchase them, you could cut the top off (except for the handles) and have one heck of a brewpot. There was an article in Zymurgy a coupla years ago on disassembly of the top, careful about that spring! The older Hoff-Stevens stainless kegs can be repurchased. They can be cut (with caution) with a steel cutting blade on a circular saw, grind or file the edges when done.

Subject: Warm (hot) weather brewing

OK. I should have asked this in June, but here goes. Aside from the various cooling strategies discussed in this forum, is there a yeast that behaves better in the summer. Since they brew Guinness in Nigeria and brew a lot in the American tropics (as well as SE asia and 'Strylia), do they use a different yeast or do they AC the entire brewery?

I brewed 3 batches over the entire summer. None in August. They were drinkable but not up to my usual cooler weather standard. All were pale ales (mjas o menos) done with London Wyeast. Is (are) there better yeast for the hot times of the year?

Subject: Re: Homebrew Digest #711 (August 28, 1991)

regarding repitching your yeast Russ, I haven't actually tried bottling the previous batch and then later using one or more bottles of beer. I wonder whether or not the pressure and carbon dioxide buildup might not inhibit the yeast too much. What I have done with regular success is dump a couple of quarts of the slurry at the bottom of the secondary into a half-gallon jar, cap it and put it in the 'fridge until I was ready to pitch. In my experience you don't end up with quite so much extra trub at the outset or quite as many dead yeast cells, there's no "crud" left over in the carboy since I always clean and sterilize it before re-use, and I can still wait a couple days or more before brewing the next batch.

Subject: Re : heresies

Apologies if I gave anyone the impression that I posted my heretical thoughts for the sake of being frivolously controversial. My intentions were more noble than that and, if you can stand a philosophical ramble, read on.

a) Most homebrewing textbooks contain umpteen variations on the same basic handful of recipes, yet have very little discussion of alternative techniques. IMHO, mastery of homebrewing technique is the route to progress. In most fields of endeavour, one of the things which distinguishes novices from more advanced practitioners is knowledge of what the most significant factors are, and knowledge of when the 'rules' of that field should and should not be applied. A good example in brewing is the making of ales using bottom fermenting yeasts. It can be done successfully, provided that you know what you are doing.

b) I still maintain that large-scale production techniques are not necessarily the most appropriate for the home. For example, we can probably afford to employ a greater number of distinct stages in the brewing process.

c) Somewhat paradoxically, simplicity of technique is probably also a desirable goal. Especially if one wishes to be more than an occasional hobbyist and wishes to incorporate brewing into his/her lifestyle (sort of like doing Yoga :-)

d) By implication, I was encouraging more experimentation in homebrewing. As someone said recently, they preferred to brew 'empirically'. In other words, if the technique can't stand up to the scrutiny of a double-blind tasting comparison, it is questionable. I received some enlightening mail on some quite subtle virtues of wort-chilling, thanks very much. But I'm still wondering whether it is the chilling itself or the subsequent racking into the fermenter which is more important for quality. It's bemusing to read posts in which people describe how they have conscientiously chilled the wort, then pitched the yeast straight in on top !

e) This list is forever receiving posts of the type : "I would like to join the arcane world of mashing but I don't possess a large enough boiler/lauter tun/wort chiller/etc". My advice is RDW, and improvise. Your resulting brews may not win competitions, but then you won't go back to extract brewing either. Remember that beer was brewed with limited equipment in most households prior to the 19th century. Mail me for more details, or I can post if there is enough interest. Incidentally, one can make a quite effective boiler or mash tun using a plastic bucket and a kettle element. Same offer applies.

Oh, and I have dreamt up another heresy, which is that mashing temperatures

are not as critical as we are often led to believe (once again, it helps to know what you are doing if you intend to mash cool). It's interesting to speculate on the reasons why mother nature invented an enzyme system which functions most efficiently at decidedly un-natural temperatures. About the only natural situation I can think of is when a heap of grain is composting on the ground. Any thoughts ?

An interesting note here is that "beer" is defined as a lager and that California does not have a limit on the alcohol content of Ale.

>Most nationally distributed beers are less than 4% as this
>is the level that most states use to define beer.

Based on the latest data compiled by the Beer Institute (formerly the United States Brewers Association), the maximum permissible alcoholic contents for beverages sold in the various states is as follows:

STATE MAXIMUM PERMISSIBLE
ALCOHOLIC CONTENT

Alabama 4% by weight, 5% by volume
Alaska No limit
Arizona No limit
Arkansas 5% by weight for most malt beverages
California 4% by weight for beer; no limit for ale, etc.
Colorado 3.2% by weight except for malt liquor
Connecticut No limit
Delaware No limit
District of Columbia No limit
Florida 3.2% in dry counties; no limit elsewhere
Georgia 6% by volume
Hawaii No limit
Idaho 4% by weight in nonstate stores
Illinois No limit in most areas
Indiana No limit
Iowa 5% by weight in nonstate stores
Kansas 3.2% by weight except for liquor store
package sales
Kentucky No limit in most areas
Louisiana 6% by volume in most areas; 3.2% by weight
in dry areas
Maine No limit
Maryland No limit
Massachusetts 12% by weight
Michigan No limit
Minnesota 3.2% by weight for most malt beverages
Mississippi 4% by weight
Missouri 3.2% by weight. Exception: 5% or "malt
liquor"
Montana 7% by weight
Nebraska No limit
Nevada No limit
New Hampshire 6% by volume in nonstate stores
New Jersey No limit

New Mexico No limit
New York No limit
North Carolina 6% by volume
North Dakota No limit
Ohio 6% by weight
Oklahoma 3.2% by weight except for liquor store
package sales
Oregon 4% by weight for beer; 8% by weight for
other malt beverages
Pennsylvania No limit
Rhode Island No limit
South Carolina 5% by weight
South Dakota 3.2% by weight for "low point beer"; 6% by
weight for "high point"
Tennessee 5% by weight for most malt beverages
Texas 4% by weight for "beer"; no limit for others
Utah 3.2% by weight in nonstate stores
Vermont 6% by volume in nonstate stores
Virginia No limit
Washington 8% by weight in nonstate stores and
unlicensed establishments
West Virginia 4.2% by weight; 6% by volume
Wisconsin 5% by weight for most malt beverages
Wyoming No limit

In order to accommodate the differences in state regulations, most
national
brands are brewed in two strengths, one at 3.2%, the other as high as 5.
0%
alcohol by weight.

>Bonus Question: How does 'light beer' differ from the 3.2%
>beer?

Light beers range from 2.4 to 3.2% by weight.

>constant.

I use an igloo mash tun also, mine is a little smaller though which makes
things a little sloppy sometime. Overall it worked really well. I was
surprised at how well these things hold heat.

>I learned that it's a big pain to undershoot, and that as much grain as
>possible should be boiled for the acid rest--->saccharification rest
>decoction. It's easier to let the excess hot grain cool if there's too
>much than to cope with the mash being too cool.

Yes, I had the same problem. I boiled my second decoction and put it
back
into the mash and took a temperature reading - 142 degrees. Not quite
enough, I was shooting for a strike temperature of about 153. Not know
what the hell to do next, I did another decoction, to try to raise the
temp. This time I got it up to about 148. By this time I was getting
a little frustrated. I finally gave in and added about a gallon of
boiling
water to bring the temperature to about 152, close enough. Who knows
what all this playing did to the final wort, but it fermented strongly for
about a week, so I must have done something right.

On a related matter, how long does starch conversion usually take? Mine
took
over an hour, but this may have something to do with all the messing
around
I did with the temperature.

>
>One question: what techniques do people use to keep the mash in the
>lauter tun warm while sparging? Mine is insulated, and when I
>recirculate I drain into a saucepan directly on a portable electric
>stove element. It stills cools off too much.

I use a simple bucket in bucket lauter tun, and the wort cools off
significantly
when recirculating. I figured that the amount I was recirculating was
fairly
small (maybe about 2 quarts??) that I didn't worry about it cooling too
much.

The sparge water cools off some by the time it exits the lauter tun, but it keeps it's temperature pretty well during the sparging process. I use sparge water at about 180 degrees and it cools to about 170 or so by the time it gets through the grains. Not a significant problem I hope.

Subject: Aluminum Wort chiller

Greetings!!

Although I have been reading the Digest for some time, this is my first posting.

A store near where I live sells all sorts of junk and overstocked items (electric motors, old computer and medical electronic equipment etc.). While browsing through the bins yesterday, I came upon a bunch of aluminum coils that appear to be used for air conditioning. They are about 3/8" in diameter and uncoiled would probably stretch about 20 feet. It seems as if they would make perfect wort chillers (they were unused of course, no nasty chemicals other than from the machining would be in them). They cost about \$9.50 each.

However, I was wondering if there would be any potential problems due to the fact that they are aluminum. I know it is not good to have an aluminum pot to boil the wort in (although I don't really know the chemical reactions that would happen), but would the same reasons apply to chilling the wort? The size of the coils would allow either chilling method (running the beer through the coil, or running cold water through the coil immersed in the beer), but the fact that there would be hot wort in contact with aluminum with either method has me wondering...

I don't do mashing yet, but I am looking for cheap equipment before I get into it, and a wort chiller for \$10 would be a nice thing to have.

Any suggestions would be appreciated (e-mail or through the digest).

Thanks,
John

From: srussell@snoopy.msc.cornell.edu (Stephen Russell)
Subject: Frozen and frothing Pepsi bottles

In HBD 710, Dave Kensiski (kensiski@nas.nasa.gov) wanted to know why his nearly-frozen Pepsi bottles, a) upon uncapping, froze solid in the neck, and b) upon subsequently melting, began frothing uncontrollably.

Two things that have been touched upon before are helpful to know: one, that as the temperature of a liquid is lowered, it can hold more dissolved gas, and two, that as the pressure over the liquid is raised, it can also hold more gas. However, neither of these are the dominant factors in this problem.

The problem here is of the transformation from solid to liquid and how it is affected by dissolved gas concentration. Dissolve anything in a liquid...salt, CO₂, alcohol, etc, and you will both *raise* its boiling point and *lower* its freezing point. We're talking 2-8 degrees or so. Thus Pepsi, which is carbonated, has a lower freezing point than pure water. Now take that Pepsi and put it in your freezer to the point at which it *just* begins to freeze. Now, uncap it. Suddenly, the overpressure maintaining the high concentration of dissolved CO₂ is removed, CO₂ comes out of the solution, leaving (near the top, at least) nearly-pure water. But the temperature cannot respond as rapidly as the pressure, so you've got (liquid) water below its freezing point. This is why it instantaneously freezes near the top.

Another factor is the change in the freezing point due to pressure. If you apply pressure to ice, it will melt (otherwise, how could we ice skate?) meaning that an increase in pressure leads to a decrease in the freezing temp. So, lowering the pressure over water will raise its freezing point, which works in the same direction for the given problem. However, this effect is small compared to the one due to dissolve gas concentration mentioned above.

Of course, this frozen cap prevents further CO₂ from escaping, but as the temperature is only a few degrees below 32F, it quickly warms up and melts. As it melts, some of the underlying CO₂ escapes, driven by the removal of the overpressure (the change-in-temperature effect is much less significant). The more forcefully the CO₂ leaves, the more thoroughly the slush gets broken up, and the more forcefully the CO₂ leaves...a runaway reaction until the slush is pretty much gone. The violence is just due to the slush being in the way.

Gee, I guess all that solution thermodynamics has paid off....

Ooogy wawa (that's Zulu for "we don't need no steenkin' Pepsi!),

Subject: Yeast autolysis / DMS and quick chilling

Ok, my turn to be the gadfly.

What keeps yeast autolysis from occurring in bottle-conditioned homebrew?
Is the presence of trub required to start this process?

On quick wort chilling...

DMS (dimethyl sulfide) is formed from its precursors at wort temperatures above 70F. At high enough temperatures, (sorry, I haven't been able to find the exact temp) the DMS is volatile and is expelled (i.e. from the kettle boil). An active ferment will scrub out some DMS via the release of CO2. So, I conclude that lagers are highly dependent on quick chilling in order to minimize formation of DMS. Ales may be less sensitive to this, because of a more vigorous ferment and the presence of other masking flavor compounds (i.e. esters).

This may actually be some basis for choosing between counterflow and immersion chillers. While the total throughput for both are generally considered the same, immersion chillers keep the entire wort volume in the DMS production-without-volatility range longer than counterflow chillers, which take the wort through the range in a matter of seconds.

Does anybody know the volatile temperature of DMS and what mechanisms cause it to be expelled? Any comments?

Subject: DMS

Following the recipe for Lambic Ale in Dave Miller's The Complete Handbook

of Home Brewing (fruit added peaches). I added a pound of pale malt. Used a water and ice bath to chill the wort.

I believed that while chilling the wort became infected with dimethyl sulfide (DMS) before pitching.

Mr. Miller states on page 157 that "DMS is eliminated during fermentation

as it is flushed out along with evolving carbon dioxide." Is this true in all cases? What happens if not all the DMS are not flushed out? Does it have an effect on the taste or smell on the final product?

Thank You,
Tom

Subject: bottling yeast?

Greetings,

I have never tried to recycle my yeast, but what Russ Gelinas said today about just pitching a particularly yeasty bottle of homebrew got me thinking. How about just stirring up the last few bottles worth and bottling

some of the slurry (without priming, of course). I would think that a couple

bottles of slurry would keep quite well in the fridge. Just don't mistake

it for a homebrew, wow what a surprise that would be!

Has anyone tried this? Any idea how long this could be stored? How would you prepare it for pitching?

G'Day,

Joe

Russ Gelinias writes :

>So I was thinking of bottling the half-batch, and setting aside the
>first and last bottles (to be sure I get the one with the most yeast, if
you
>follow my logic), and pitch those into the next batch.

While this will probably work (depending on yeast viability, age since
bottling, storage conditions etc.), you are likely to get a long lag
phase. Those dormant yeasties will have plenty to do before they can
begin
thinking about fermentation. A friend of mine tried this and it
eventually
worked, but his lag phase was a full 5 or 6 days. Your mileage may vary.

Although it's a little more work, you may want to consider making a
starter
from your previous batch. Simply make a quart of low gravity (1.020-1.
030)
wort, and pitch the dregs from 2 or 3 bottles into it. When fermentation
is
at its peak, pitch the starter into your regular batch. By pitching a
much
greater number of already active yeast cells, your fermentation will take
off much quicker. This technique has worked well for me many times.

Subject: all-grain wheat brewing

After two successful extract brews, i'd like to make a wheat beer. due to cost considerations, i would like this to be my first all-grain brew, but from reading, it seems that an 8-gal pot is needed to hold everything. also a wort chiller which i don't have. so maybe i'll just mash the wheat malt use add pale extract to the wort. i haven't sat down and worked out the details yet, but this may give me an introduction to mashing and save money.

Are there any special considerations i have missed? any suggestions?

i just realized that the enzymes supplied by the barley would be needed during the wheat mash, right? so i would have to add the extract at the beginning of the mash. how would this affect the amount of water needed during the mash?

One final question to anyone in the East Bay: what sort of water additives do you use with EBMUD water?

Thanks.

From: cjh@vallance.HQ.Ileaf.COM (Chip Hitchcock)
Subject: re an interesting epitaph

This sounds like the standard misbelief that alcohol is better than water if you're hot. "small beer" in that period was weak but unlikely to be infected, as it would generally be consumed as soon as it was finished (and the soldiers probably wouldn't have known if it were infected). It is

true that alcohol can make you sweat more, which can make you cooler /if the sweat evaporates/---not likely in the heavy uniforms of that period.

This belief shows up in interesting places, e.g. one of Kipling's "Barrack Room Ballads" telling of a British]politician[who visits India in

December and yaps about the "Asian Solar Myth"; he is "persuaded" to stay for a year and the rest of the poem is a listing of his various ailments, beginning

Imprimis, six weeks "liver"

(it came from drinking beer). [[instead of gin'n'tonics?]]

The odd thing about this remark is that Kipling generally defended the common soldier against the mistakes of officers and powerful civilians, but

he never quotes a soldier complaining about drinking India Pale Ale instead

of gin or rum. He also knew that hot work called for water instead of alcohol, hence "Gunga Din". Perhaps the epitaph was recommending water over

beer? (not bloody likely....)

From: Frank Tutzauer <COMFRANK@ubvmc.cc.buffalo.edu>
Subject: Too sweet? More hops!

Well, thanks to everyone who responded to my post about too-sweet beer. A couple people thought it MIGHT have been the yeast or the temperature or even the water, although a couple of people also said that these things definitely were NOT the problem. By far and away, the consensus was that hopped extracts are way underhopped, and the solution is to simply add more hops. I will do so on my next batch (an Irish dry stout) and will report back.

On a related note, I recently visited a local brewpub (Buffalo Brewpub) and ordered their Red Ale. It had a sweetness whose flavor was EXACTLY like mine. I, of course, had much more of the sweetness, rendering the beer undrinkable. Their's was certainly drinkable (very so), but the "quality" or "flavor" of the sweetness was identical to mine. Their description of the beer was "lightly hopped with a malty sweetness," making me think that my problem was indeed too much malt sweetness not offset by enough hop bitterness.

Thanks again,

Re: Fruit flavored ales

I recently visited the "Tied House" in San Jose that had a very refreshing summer sort of brew called "Passion Pale." The description said that it was their regular Pale Ale with Passion Fruit and a little Lemon added. I'd like to make something similar. I've made a few brews so the Pale part is no problem, but I have yet to venture off into the land of fruit. Papazian recommends adding the fruit when the wort has ceased boiling to achieve some level of pastuerization but avoid the pectin problem. OK, I can handle that. But, how much fruit do I add? I'll most likely wind up using juice, I haven't looked to see what's available yet, and lemons are no problem. I would like some recommendations so I don't overdo it the first time around. I have one remaining bottle of my "light American" brew that I plan to use as the base for this next brew, and I thought of adding a little fruit juice until I got something reasonable, but I'd still like to know what the boundaries are. Any help out there?

Subject: What's the scoop on the new NYC brewpub?

I was in New York City last weekend, and as I had heard that a new brewpub was supposed to be opening up in August, I thought to drop in and quaff a few. The new place, called Zip City, is at 3 W. 18th St. just off of 5th Avenue. Needless to say, every time I called (212-366-6333) I got their answering machine saying "we are in and out, blah blah", and upon driving by that address I failed to see a sign or anything else indicating that their opening is imminent.

Does anyone out there in HBD-land know what the scoop is, and if they are having licensing difficulty or something like that? Such is only too often the case with these establishments...damn narrow-minded city governments! I have also heard they have several beers (lagers, fortunately) sitting in tanks awaiting consumption (I volunteer).

My quest for beer was not totally in vain; I found the Manhattan Brewing Co. in Soho and tried their 4 available beers. The "Light" seemed a bit sweet and bland, the "Stout" more like a Munich Dunkel Ale, and the "Bitter" really weird-tasting, like a liqueur but not as alcoholic; certainly not bitter enough to warrant putting it in this style. I thought their "Wheat" was OK, though, smoother and less bitter than Sam Adams. The "Amber" was sold out that night. Does anyone have some knowledge of these beers that could tell me if I got typical or atypical batches (or if I have zero palate)?

Kampai,

STEVE

>thought it would take about a week to see desired critters. Can I just
let
>it hang out for a while and see if I get colonies along the streak line
I
>made, or will the plate get infected by these invaders?

>Anyone care to describe what a weizenbier yeast from Weihenstephen looks
>like? (furry, not green in the center, etc?)

Without a doubt you do not want any colonies that are coloured blue,
green or
anything other than white. It is unclear from your description if the
blue-green area is a separate entity from the surrounding white areas
which look
furry or if you are talking about one structure which has a blue-green
centre
and a surrounding white perimeter. If the first case is true then the
white
structures may be the yeast you desire (*S. delbrueckii*).

The blue-green monster is a contaminating mold. Just think what would
have
happened if you had simply scaled up the yeast slurry which you obtained
from
the pub and pitched it into fresh wort!! As far as timing is concerned, a
2-3
day incubation period may be sufficient to develop yeast colonies. This
would
be related to the temperature that the plates were kept at and the yeast
strain
itself. I have found *S. delbrueckii* to be a rapid grower.

The mold may also have been introduced during your culturing procedure.
All
wort & wort/agar must be pressure sterilized either in an autoclave or a
home
pressure cooker (minimum 15 psi for 20 mins). The petri dishes must be
obtained
sterile (irradiated plastic or baked glass). Once you are sure that all
equipment is sterile then the culturing environment is your next concern.
Wash
your hands with a deodorant soap and dry them with a fresh towel. Spray
the air
with a quick shot of Lysol and wait a few minutes. Do not talk, cough,
wheeze
etc. when lids are opened or when the petri dish lids are removed. Have a
flame

source in the culture area to quickly flame the necks of any glass containers holding sterile wort or a liquid yeast culture and to sterilize your innoculating looped needle. Essentially, be anal retentive.

S. delbrueckii colonies are white to cream coloured. They tend to be flatter than most *S. cerevisiae* colonies on malt agar in that they resemble pancakes more than domes. Furthermore the edges of *delbrueckii* colonies are uneven where *cerevisiae* colonies tend to be quite round (smooth, circular). They grow rapidly as mentioned above and have an uneven top surface (not smooth like *cerevisiae* domes). ...god I wish ascii graphics weren't so limited...

I'd recommend picking a well isolated colony which fits the given description and innoculating a 50 ml aliquot of sterile wort with it. After three days take a loop of this freshly grown batch of yeast and replat on malt agar. Reselect a healthy looking colony from this plate and innoculate sterile wort again. In a few days you can remove a small bit of this for a taste and you'll know then if you've purified *S. delbrueckii* by the presence (hopefully) of a nice clovelike essence. This of course can be done in duplicate or triplicate to increase your chances of getting what you want. It's not as difficult as it may sound.

Good luck and let us know how things pan out.

PS: I've tried many times to send you a letter directly but the letter was spooled back to me. Do you have another E-mail address I can try?

Subject: What does your club do?

Hi Bill,

In the last Homebrewer's Digest you asked about some club activities. Two interesting ones come to mind that our club (Ann Arbor Brewers Guild) has sponsored. One was called "bad brew." In this one, a series of additives was introduced into beer that approximated some brewing artifacts (large amount of esters, fusils, ethel alchohol, etc.) such that people can correspond tastes to these artifacts. This is an ongoing program and it has been very informative. Another activity that has been interesting is for the whole club to brew a specific recipe. We have done this with a number of recipes (an extract, partial mash, and full mash) such that everyone can get involved. We end up tasting the end product(s) and try to ascertain the differences in taste of the (presumably the same) beers. We then try to understand the differences in brewing techniques and see how they forment these differences. This has caused alot of good brewing technical interchange since one variable (the recipe) has now been fixed.

Hope this helps,

Nik

From: dbreiden@mentor.cc.purdue.edu
Subject: 2nd generation yeast & heresies

1. I made one of my finest beers using yeast I cultured from a friend's homebrew (thanks again, Ralph). Of course, he started with good yeast, but I am still amazed at how well the yeast stays in the bottom of the bottle even with a somewhat careless pouring.

The only thing about such an operation is that there are more chances for the stuff to get infected while you are culturing. But for me, culturing off finished brew (drink the beer, reculture the dregs), is far more efficient than trying to save slurry. No disrespect to Father Barleywine, but I can't imagine what effect the trub and spent gunk has on the next batch. It just doesn't sound natural.

2. Our local heretic posed the question of why the often benevolent (and equally often malevolent) Mother Nature would design a natural system that only occurs at unnatural temperatures. I suspect that our extracting sugars from the barley is UNnatural. That is, our Mother Earth intended for little baby plants to get the goodies inside the barley -- not a bunch of beer swilling humans. Thankfully, She is looking the other way while we work our own version of alchemy.

Subject: yeast slurry

I guess I was a little unclear in my wording about saving the slurry from the primary. I realize that you can always culture a starter from the conditioned bottles. I also realize that you can stir up the slurry and save that. I've done both of those. There are a couple of parameters in this case that make me want to handle it differently.

The yeast has not flocculated very well, and I believe there is quite a bit of trub. So stirring up the slurry may give me a low yeast-to-trub ratio. Also, the most recently active yeast is still in suspension, not in the slurry. It seems to me the way to get the cleanest and most active yeast is to save a couple of pints when I rack to a new carboy before bottling.

Now the real question is why doesn't this yeast, Wyeast Chico Ale, settle out very well? Certainly Sierra Nevada Ales have a solid pack on the bottom of the bottle. *Someone* published a test report on Wyeast yeast, and Chico ale was said to be a low-medium flocculator, which seems to be the case. How does Sierra Nevada do it?

Subject: re enzyme temperatures

> speculate on the reasons why mother nature invented an enzyme system
which
> functions most efficiently at decidedly un-natural temperatures.

Stephen Jay Gould has written extensively on various aspects of this fallacy, and given it at least one elaborate name; you should definitely read as much of his work as you can find if you are trying to figure out "why nature invented" anything.

His basic observation is that nothing in nature is deliberate, or maximally efficient. Among the reasons for this are:

- evolution is accidental. Natural selection culls some traits and strengthens others, but not very strongly unless there's a massive [dis]advantage---ordinary variations generally aren't strong enough to be subject to selection. Populations drift and mutate, and often we can't even

make a good guess at why selection pushed in a certain direction (we don't

/know/ that giraffes evolved long necks to eat high leaves; there could have been some other force, or even accident, that let them fill this niche).

- nature has to cover a wide variety of conditions. A machine shop can be precise because everything is controlled; biology has to survive extremes of temperature, food, and water. An organism that can survive extremes is more likely to be around after a few decades than one that is very good at filling a narrow niche.

Another factor is simple thermodynamics: most chemical reactions go faster when heated. The better the enzymes can survive serious heat, the more likely the grain is to reproduce (see above); that they will actually work faster at this temperature is incidental. In fact, high-temp activity could be unhelpful, breaking down the starch faster than the resulting sugar can be assembled into cellulose---have you every seen your mash sprout?

Subject: Re : heresies

Conn V. Copas enhances his heretical position by adding a new heresy to ones he's already espoused. However, I don't find anything heretical, nor even more than mildly controversial about what he says. I believe the key to profficient and successful brewing is an understanding of the processes involved and what parts the brewer wants to manipulate and why. The actual how of it isn't particularly important, and can employ whatever the brewer has available or can buy or fabricate.

Conn's newest heresy seems to revolve around the question of why would an enzyme system evolve that is most efficient at unnatural temperatures. The answer, to my mind, is that the definition of "most efficient" is different for us as brewers than for the barley plants that make those enzymes. Their concern (if plants have concern) for efficiency is with the enclosing system that provides energy for growth from starch without benefit of sunlight, which is a plant's primary energy pathway.

In this sense, "most efficient" is probably defined as that which provides the breakdown of starch at a pace that closely matches the rate of sugar consumption. The plant throttles this rate by generating the right level of enzyme concentration for about 60F to match this pace. That's why there's an ability for brewers to convert unmalted adjuncts at the higher temperature--the balance at 60F is a very high level for 150F. On the other hand, a plant can't make use of all that sugar in a matter of an hour, and it would be subject to rotting and vigorous consumption by animals.

> are. Any help out there?
>
> -phil duclos

If you're going to buy fruit to flavor your beer, I'd recommend you buy
fruit juice. What I did recently was to add one quart of blueberry
juice to one gallon of pale ale - the rest of the ale was bottled as
usual. I did this in the secondary fermenter, not the primary like you
would have to do to sterilize fruit. Specifically, I added the juice
when I racked off the rest of the ale for bottling. It then fermented
a couple more weeks.

The only deficiency is that the blueberry flavor does not come out
without a little sweetness. So, when I serve Bluebeerd, I add a
teaspoon of sugar to each glass in the form of syrup.

As far as proportions, with blueberry I think it's hard to overdo the
fruit. At 25% juice, it is barely noticeable as a blueberry flavor - I
taste something, but can't identify it as blueberry till I add the
sugar.

Subject: Re: HBD #712 Crown Caps on twist off bottles

>From: eisen@kopf.HQ.Ileaf.COM (Carl West)

I understand that it takes a certain kind of luck to get crown caps to work on twist-off bottles and ordinary mortals shouldn't even bother trying.

In my past life as an extract brewer, I always used recycled twist off bottles and capped them with regular crown caps. After the 4-5th bottling the edges of the threads started chipping and they became a bear to twist off (gee, i had to use a church key). So I would tossed them and get another batch. Big deal.

Nowdays I use soda kegs for regular consumption and shorty seltzer bottles (styrofoam wrapped, platic screw caps) for transporting beer to social functions. The bottles seem infinitely reusable and the styrofoam sides keep the beer at temp longer. Plus a pint bottle is soo compact! I have not conditioned beer in one of these, but I can't see any reason why it wouldn't work just fine. Be careful boiling polyethylene caps: they might warp. Cold sanitization (bleach) might be better.

Yes, the lights are off in my fridge as well when the door is shut.

Cheers.

Agreed. However, you can't blindly rely on the double-blinds of others. I
know
plenty of beer enthusiasts who just can't distinguish certain flavors. I
consider phenols in a pale ale to be a fault. Others will never notice
it.

> Oh, and I have dreamt up another heresy, which is that mashing

the
> only natural situation I can think of is when a heap of grain is
composting
> on the ground. Any thoughts ?

When brewers and brewing textbooks say 'enzyme efficiency', aren't they
really
saying 'enzyme efficiency during mashing'? The temperature of the mash is
partially intended to destroy (gelatinize) the kernal and dissolve its
carbohydrates. This is not the same goal as the life-processes for which
the
enzymes were intended, where less mechanical action is involved. So, I
don't
find it odd that the mash efficiency temperature of enzymes would be
different
from the life-process efficiency temperature of those same enzymes.

And I suspect that if you go ahead and sparge the contents of your
compost
heap, you will get a fermentable fluid. :-)

kg.

Chris:

I'd avoid anything furry. Sounds like the white stuff is also mold.

Another suggestion is to get more of the yeast slurry from the Weizenbier and add 2-5 mls of it to 50 mls of sterile wort. See if the yeast can get going in this environment and then streak out a few plates of this culture.

The one problem I foresee is that most authentic Weizens are naturally conditioned with a lager yeast which is added at the time of priming. You may be wasting your energy if that is the case with the beer from which you are getting the yeast.

Send me your snail-mail address and I'll mail you pure *S. delbrueckii* when the weather cools down a bit (to ensure viability when the vials arrive).

Take care,
Mike

PS: Incubate your plates upside-down from the beginning.

In Australia, most beer is in screw-top bottles. They have very few of our 'long necks'. Homebrewers use a thinner cap, labelled 'twist off' on the package, which is pressed on with a standard bench press capper.

I have tried some of these on American screw top bottles. It requires a lot of pressure to put them on, but they do work.

OK, I'll bite.
What's unusual about chilling wort and putting yeast on top??

>It's interesting to
>speculate on the reasons why mother nature invented an enzyme system
which
>functions most efficiently at decidedly un-natural temperatures.

Mother Nature would not have optimized the enzyme system for grain to
make
beer. She would optimize the system such that grain could best make more
grain. As far as the unsuspecting little barley kernels are concerned,
that
enzyme system is what will allow it to nourish itself during the early
days
of spring while it begins to sprout. The little bit of starch in the
grain
must sustain the fledgling plant until it is able to photosynthesize.
Thus
it must be doled out slowly - not converted all at once as we brewer's
strive
for. It follows that the strains best adapted to survive the germination
phase would prevail. (Until, of course, man steps in and mucks around
with
everything.) As brewers, we are very fortunate that our goals require
only
a small, easily achieved deviation from nature's course.

In fact, we should be grateful that some deviation is necessary. For if
the
conditions required for making beer were too "natural", then all the
grains
would be turning themselves into beer in the fields, and then where would
we
be??? :-)

Cheers,
CR

Subject: Conn's heresies

Regarding Conn's heresies part d)

>In other words, if the technique can't stand up to the scrutiny of a double-blind tasting comparison, it is questionable.

Conn it depends a lot on whose doing the tasting. If your palatte is untrained, or insensitive or both, then obviously off flavors deriving from brewing technique don't matter. Then again perhaps neither does recipe formulation (in the extreme, see my signature) so why not brew Miller clones??

We do Dr. Beer trinaing sessions (me & Steve Stroud) and find that some people just aren't sensitive to certain substances. Others just don't know what to look for or how to sort out and identify what it is they're tasting. My personal experience is that after trainign my palette some I began to detect off flavors in beers I was making that I hadn't recognized for what they were previously. Adjustment of my brewing technique eliminated these.

Also in d) you say
>It's bemusing to
>read posts in which people describe how they have conscientiously chilled
>the wort, then pitched the yeast straight in on top !

What do you mean by this?? I'm not sure what youre describing and/or criticizing here.

Nature never meant for the enzymes to change the starch to sugar as
quickly
as we do. It meant for the starch to be converted to sugar only at the
rate
at which the growing barley plant can use it. Nice try, but I'm just too
relaxed to get short-circuited at this point in time.

From: FATHER BARLEYWINE <rransom@bchml1.aclcb.purdue.edu>
Subject: Yeast Caking, Aluminum, and "Oh no not AGAIN!"

This one is for all of you who groan every time you see a Father B. posting...

It has been a while since I proclaimed again my heretical belief in the brew without sanity philosophy. There has been a lot of discussion of using yeast from the bottom of the fermenter, and to keep my dirty fingers in the discussion I'd like to raise a few points:

- 1) Try racking off your beer for bottling just as you finish the preparations for your next brew, and within 20 minutes of uncovering the yeast cake, pour in your next (cooled) batch of wort. Close your eyes if necessary so you won't see the brown ring of scuzze on the walls of your fermenter. Pray to your favorite deity or just stare at a spot on your wall. Stick on the fermentation lock and don't even look at that carbouy until tomorrow. I guarantee that a good yeast batch will produce a couple (I've tried 11) sequential batches of beer, and that the dried dead yeasties on the walls of your carbouy will not be (detectably) detrimental. Some final suggestions: ferment as cold as possible, and use a good yeast.
- 2) Be really careful when storing trub in your refrigerator unless you really enjoy cleaning dried malt substance/yeast off your refrigerator/vegetables/catsup bottles. Just a warning
- 3) Try keeping a culture (adding yeast cake to fresh wort) instead, using about 1/2 - 1 cup yeast of good texture to about 3/4 gallon wort. This will last a while, and you don't need to worry too much about catching the yeast in log phase (i.e. 2 - 3 days old).
- 4) Please don't sanitize everything (anything!). Keep your equipment clean, free of deposits, and above all dry in storage. I know you don't want to hear it from me again, but you really don't need to bleach/boil/Campden/irradiate items used in typical brewing. Culturing yeast is an entirely different ball game.

The "Oh no not AGAIN" was in reference to the Great Aluminum Debate. There have been many many MANY postings about whether aluminum will discolor wort/beer, cause Alzheimer's Disease, and everything else that our diverse collection of posters could blue-sky. Aluminum will dissolve into aqueous solutions, particularly acidic ones (like beer), but my personal philosophy is that aluminum exposed to beer (wort) before fermentation will dissolve in it and then be efficiently sucked up (chelated) by the hordes of yeasties which pass the total wort volume through themselves many times over during the course of a brew. Admittedly, you are drinking some of these yeasties too in

your final beer, but most sit languidly on the bottom. Relax, use
aluminum,
and worry about the carcinogenic compounds you run into at high
concentrations
at work every day.
Ah, another diatribe smoking out of the keyboard! Please, flame me!
I thrive on abuse.

>All wort & wort/agar must be pressure sterilized either in an autoclave or a home pressure cooker (minimum 15 psi for 20 mins). The petri dishes must be obtained sterile (irradiated plastic or baked glass).

Aside from the environmentally unfriendly use of throw-away petri dishes, I would like to point out that I have been sterilizing glass petri dishes in a microwave oven with good results.

A few drops of water in the bottom create steam and, I suppose, limit the temperature but I suspect the critters get "nuked" directly.

Has anybody done any research on this technique? My work is strictly amateur and I have not the equipment nor inclination to test it thoroughly.

[Just to clarify things, DMS is a chemical, and not a living organism.
However, a bacterial infection of the wort could cause "large" amounts
of DMS to be produced.]

> Does it have an effect on the taste or
> smell on the final product?

I've been told that, in high concentrations, DMS can give beer a
hint of "cooked vegetables" or "shellfish". Perhaps someone who knows
more can give a better description.

If you're interested in finding about what causes various
off-flavors, you may want to get a copy of the 1987 special issue of
Zymurgy, which is entirely dedicated to "troubleshooting" problems with
beer flavor. The special issues of Zymurgy seem to get periodically
reprinted, and should be available at your local beer supply store (if
not, mail-order places have it). However, note that they're not cheap,
being about \$8.00 for a 64-page magazine (in the case of the 1987
issue), but I think that they're worth it if you plan to do any serious
beer-brewing.

Subject: 33 quart brewpots in Mass

After looking "everywhere" for a 33 quart ceramic on steel brewpot, I finally decided yesterday to go mail-order and ordered it Great Fermentations for 32.95 plus ~ 7.00 postage/handling.

Well, while out shopping with my wife last evening at KITCHENS ETCETERA, they had the very same pot (with a canning insert) for \$34.95!

%^#@&^

Oh well, that's \$5 for the economy.

/Mal Card

p.s.

BTW, I wasn't that impressed with the handles. As I picked it up and exerted a little pressure the handles seemed to move a bit, and you could hear the ceramic crunching.

Moving 5 1/2 gallons of boiling wort from my stovetop to the sink for cooling might spell D-I-S-A-S-T-E-R.

Any experiences out there?

Subject: iodine test

I've been mashing for a while now and have got the process down from eight to six hours. Naturally, I'm looking for ways to further streamline the process. Right now, the largest chunk of time involved is in the actual starch conversion. I use Miller as my primary homebrewing reference. As you may know, he doesn't believe in iodine tests for starch conversion. Also, he often calls for two hour starch conversion rests.

I think Miller's two hours is often out of line. I've had one brew which fermented down to an OG of 1.005 and another that reached 1.002! There's a dry beer for you (but this one has flavor!). This suggests to me that I've overconverted the starch and may be able to get by with a shorter starch conversion rest. But I don't know how to conduct such a test.

Would someone please instruct me on the mechanics of performing such a test and how to interpret the results? Also any discussion of the limitations of the test would be appreciated.

From: Thomas Conner <SYSTCT%GSU.EDU@CUNYVM.CUNY.EDU>
Subject: Rotten-egg aroma

I'm using liquid yeast for the first time (Wyeast Bohemian 2124) to make Rocky Raccoon Lager. Thirty-six hours after pitching, an almost frantic glug rate was achieved, but unfortunately, it was accompanied by a sweet, rotten-egg smell. Papazian says this is not unusual and that it can be avoided by changing yeast, but he says nothing about the impact on the current batch. Is this merely a passing phase? Will the brew be drinkable, or should it be reserved for slug bait?

Any advice would be greatly appreciated. Thanks.

Now hold on just a minute here. Freedom, independence, security and
dignity
are fine, but what about the things that really matter? Before we go
jumping on
any political bandwagons, we need answers to a few questions.
To wit:

1. I have never tasted Lithuanian, Latvian or Estonian beer. How good
is it?
What styles do they produce?
2. Was their beer better before Soviet annexation, or has it improved?
3. Do their legislatures recognize the sanctity of Home Brewing?
4. Are any of their leaders actual Home Brewers (or Brewers of any sort)
?
5. Have they endorsed the proposal that Brewing become an Olympic event
(as
a replacement for synchronized turtle roping)?

The pro-wine American press has deliberately withheld this information.
Until
we get answers, I say we withhold our endorsement.

|>From: Darren Evans-Young <DARREN@UA1VM.UA.EDU>

|Has anyone tried mashing pot? ...just kidding...
|Seriously, what size pot is needed to mash, say, 10 lbs of grain?
|I already have a 10 gal SS pot to boil in. Is a 5 gal SS pot large
|enough
|for mashing a maximum of 10 lbs of grain?

I got a 20qt SS pot for holding sparge water, but started mashing in it.
It seems to hold 8lb of grain doing a papazian style step mash. It might
get
a little tight with 10-12lb of grain. However, it turns out to be pretty
easy to step mash Miller style (stir crazy, while applying heat in 2
minute
increments, etc) - and it should easily hold 10-12 lb of grain.

From: chad@mpl.UCSD.EDU (Chad Epifanio)
Subject: Simple yeast recycling

Just to throw my humble opinion onto the growing pile:

Due to the expense of liquid yeast and the difficiency of my salary, I am forced to reuse the previous yeast several times. My first step is to prepare several steril wort solutions for use in making starters for pitching. I take about 1.5 cups of dried malt extract, boil in about 2.5 pints of plain filtered tap water for about 45 min to an hour, with 0.25oz bitter hops(I used Bullions). Pour the boiling hot mixture through a strainer into sanitized 12oz beer bottles. It makes about 5 full bottles. If you fill it all the way to the top and cap immediatly, it will leave a 1.5in vacuum gap when it cools down. Make sure those bottles are preheated and are not on a cold countertop, or the sudden thermal gradient will crack them. Store the cooled bottles in the fridge until you need them. They shouldn't go bad if you fill them while the wort is still boiling hot.

To use, I crack open a steril wort bottle and pour it into a sanitized wine bottle, fitted with a fermentation lock. Add whatever yeast you like. I use this for Wyeast packets to increase the pitching volume. Within a day or two, it should be revin' up and ready to go. The last batch of beer I made began bubbling within hour, and was *violently* active within four. Fermentation was completed in two days.

I've also used a Yeast Bank in conjunction with the starter. I put a bit of the steril wort into a test tube, and added a bit of the yeast to it. It will ferment for a couple of days, and flocculate to the bottom. Pour off the top beer, add a bit of the included solution (glycerine?), shake to coat the yeast, and freeze. Bingo! You have yeast for your next starter without having to worry about slurries or trub. Notice that the yeast bank provides yeast for the starter, which provides more yeast for the yeast bank...

When I brew within a few days of the last batch, I just grab a cup of slurry from the previous batch and store it in the fridge. When this much yeast is added to the wort, I usually get violent ferments starting in an hour or two.

The whole point of this confession is that I am far too lazy to prepare a fresh starter for each batch. The prepared steril wort really makes thing easier.

Subject: Yeast reuse secrets

This is really annoying: Just how do I address a letter directly to Father Barleywine? The following and several permutations were all bounced back.

To: uunet!rransom@bchml.aclcb.prudue.edu
Subject: Yeast reuse secrets

Mr BarleyWine:

You alluded to phases of yeast growth. Can you fill me in with some more details? Is there a good reference?

I collect the yeast portion of my primary cake. Ususally I can keep the trub to a reasonable minimum by letting things settle naturally, leave in a pint of wort after racking and swirling to stir up the top layer of yeast. This doesn't always work since sometimes I rack too soon and things haven't settled in nice layers. When this works, however, I get a fat looking tan gloop that stores in the refer (35f) under a little wort (1:1) for a couple of weeks and almost explodes when dumped into the fresh batch o beer. It is most satisfying to be at high krausen in 4 hours and be fermented out in 2-5 days (ale vs lager).

Does this sound reasonable? Sometimes it takes 6-8 weeks till the next batch - yeast stored under these circumstances don't seem to survive as well. Would storing under a couple o quarts of wort be better? Would it be better to store under fresh unfermented wort - or is it better to replace the old wort with fresh stuff a couple of days prior to the brew to re-activate?

I want to do a series of lagers. I have a good secondary yeast cake in a 5 gal carboy, I am thinking of transferring it to my 7.5 gal one for the rest of the lagers and pitch ala your suggestion. One question: do you chill, let settle and rack off the trub before dumping the new wort onto your yeast cake to avoid trub accumulation?

Using your scheme, one would pretty much let the beer sit & condition/lager until ready to brew the next batch, regardless of how long the ferment took.

Right?

Thanks

Subject: Caps for pop bottles.

Alright already. I'm going to try to bottle some homebrew and some homemade soda in plastic pop bottles. I have a small collection of one and two liter bottles. What I need is caps. Most of those bottles came with the aluminum caps and they don't hold pressure so well as the plastic ones.

I have patiently clipped the rings left after unscrewing the cap for the first time from all the bottles. Now, where can I get some replacement caps. Does it take a special machine to install new twist off and leave a little ring caps, or do they just screw on and then break when screwed off.

Even the plastic caps won't last very long, and I have a raft of 16 ounce plastic bottles I'm intending on using for transportation of homebrew. Caps! I need caps! I don't want my "MTV," I want my CAPS.

Thanks to any or all who respond.

>little baby plants to get the goodies inside the barley -- not a bunch
>of beer swilling humans. Thankfully, She is looking the other way while
>we work our own version of alchemy.

Ah, but the enzymatic conversion of starches to sugars DOES occur at
"natural" temperatures-- just a heck of a lot more slowly. As you say,
Mother Nature's reason for the reactions in the first place is to
nurture that little baby barley plant. The plant only needs the sugars
a little at a time, over a period of days or weeks.

We homebrewers, on the other hand, are an impatient lot. We want it
all converted right now, not over the time period it takes the barley
sprout to grow leaves large enough for photosynthesis to support
it. What we're doing with those "unnatural" temperatures is simply
speeding up the natural process.

Subject: Summary of replies re: Stout Bombs

Hi,

Thanks to the many responses on my overcarbonating stout. If you remember, I had a version of Toad Spit Stout (called Empirical Stout) whose ending gravity seemed high (1.020). Three days after bottling, a bottle that I opened was a mild gusher, so I yelled for help, lest I end up brewing a small arsenal of stout bombs.

I got about five or six responses--thanks! Here's a summary:

a) Several folks said not to worry about it; that a final gravity of 1.020 is not too high for a stout; and that ales frequently finish carbon-

ating in just a few days, particularly when the weather has been warm.

b) Most added that there is no problem in taking a specific gravity from the bottled beer as long as bubbles are not forming on the large, moving part of the hydrometer; doesn't matter if there are bubbles around the scale. Chip Hitchcock recommended first pouring the beer straight

into a glass to kick up a big head, then letting the head subside to get rid of some of the carbonation.

Also, there should be no need to compensate for the priming sugar in taking the gravity because it should be consumed by the yeast within three days. I did take a gravity reading of the stout on day 10 from a bottle which gushed when opened; it was still 1.020, so there were probably no excess fermentables being eaten by reawakened yeast, as I feared.

c) Also, most advocated cooling the beer if I was worried about bottle bombs, since cool liquid can hold more dissolved CO2 than warm, and so be under less pressure.

d) A good way to check for an impending detonation is to check for everted bottlecaps. Many cappers put a circular dimple in the bottlecap; an overpressurized bottle will tend to push that out. My capper puts the dimple in for most bottles but not all of them, e.g., NOT for Bud Dry longneck bottles; those which had it were not everted.

e) Chuck Coronella recommended opening a bottle every few days to check for overcarbonation; if that is a problem, he has used this remedy with success:

```
> . . . do this- get a bottle
> opener and your bottle capper. One at a time, open each bottle
slightly,
> until the level of the foam reaches the cap. At this point, quickly
clamp
> that cap down, preventing any beer from leaving the bottle.
```

He suggested that the trouble and wait will pay off:

```
> . . . I made
> a batch of Cushlomachree (?) stout from CJoHB about 18 months ago, and
> ooooooh, it is so smooootth now. As I recall, (don't have my notes
here),
> this beer had a small overcarbonation problem about two months after
> bottling.
```

Florian had one dismaying, but very good, piece of advice:

> You should get rid of all your Fischer bottles. In all my years of
> brewing, I have only had two bottles break. Both were Fischer and
> in that batch, none of the others broke. The Fischer bottles are
> simply too thin and are not meant to be re-used. Use Grolsch bottles
> if you are lucky enough to get them, or order the Grolsch type
> bottles out of Canada.

Another source of resealable bottles are the more expensive Belgian ales, which often come in extra-thick ceramic bottles with Grolsch-style caps. A German beer which is simply called "Pils" also comes in such a bottle; but all of these are too expensive to buy more than very occasionally. I've accumulated about a case of the 22-oz Fischer bottles, and it would be a wrench to give them up. Perhaps they can be safely used for beers destined for the refrigerator, with monitoring.

Then again, Florian is a cautious fellow:

> ... If it were my beer, I would put the bottles inside
> of heavy plastic garbage bags, put the bags into boxes, and leave
> them alone for about three months. After that, take the whole box,
> put it into the fridge, and when it's cold, remove the bottles
> carefully, using goggles, and open them. If the beer is good,
> drink it with careless abandon. If it gushes, pitch it out and
> start over.
>
> And don't forget to relax.

I monitored by opening a bottle every two days; most of them foamed up at least to the top of the bottle upon opening, and some overflowed. Here's what I finally did on day 10:

- Put the batch (except for one "control" six-pack) into the refrigerator overnight.
- Carefully popped and resealed the tops of all the Fischer bottles.
- Opened all the other bottles and resealed with new caps. I didn't want to trust that the original caps would still seal well after being removed (even carefully) with a bottle opener. None of the cold bottles showed any tendency to gush.
- Warmed gradually back to cellar temperature.
- Put into cardboard boxes in the back of the basement closet; to be opened in November.

By cooling first, I hoped to prevent gushers/explosions, and also to force some carbonation back into solution; with luck this batch will therefore be neither over- or under-carbonated.

Thanks again for everyone's suggestions.

Jim Buchman
buchman@marval.enet.dec.com

p.s. -- I'm still avidly seeking the Pumpkin Ale recipe from this summer's Zymurgy, or an equivalent recipe.

From: Ken Buswell <kenb@hpsmeng1.rose.hp.com>
Subject: What our club does (fwd)
Full-Name: Ken Buswell

Bill,

As president of the Sacramento CA. area homebrew club, The Gold Country Brewers ASSN. I can tell you what our club has done over the past year.

Feb. Guest speaker; Marry Merinda from UC Davis yeast lab
Mar. Guest speaker; Jean Xavier Guinard, author of Lambic
Apr. Celebration; Annual social event/club party
May. Guest speaker; Dr. Larry Lapsley and a member of the CHP talked about alcohol effect on the body and drinking and driving. (Some of you may remember Martin Lodahl's commented about this meeting)
Jun. Organized tasting of commercial IPA's.
Jul. Speaker; Vern Wolf, club member who has been very successful in National comp.
Aug. Guest speaker was to be Karl Eaden, brew master at the Sudwerks in Davis. However Karl canceled at the last min. So we did a meeting on judging. Speaker was Brook Ostrom, West Coast AHA competition organizer.
Sept. Scheduled topic; "Cooking with Beer"
Oct. Scheduled topic; "Fest Beer" (Okterber fest ect.)
Nov. To be determined
Dec. Annual club Christmas party

I can offer some advice on how to prevent your meetings from turning into a

"home brew free for all" :

1. Have a speaker or topic planed in advance of each meeting.
2. Publish a club news letter.
3. Do not allow drinking before or during the speaker's presentation. Its real tuff to keep control of the meeting when everyone is "relaxed and having a homebrew".
4. Have a mix of meetings through out the year; ie. some technical, some purely social.
5. Have a fixed schedule for the meeting dates. For the G.C.B.A. its the second Tuesday of every month.
6. Elect responsible club officers.
7. Ask that everyone who attends the meeting bring some homebrew or a commercial beer to share.
8. Try to boost membership to a "critical mass" by advertising at the local homebrew store, articles about the club in newspaper, announce club in Zymurgy.

Hope this is of some help.
Best regards
Ken Buswell

From: FATHER BARLEYWINE <rransom@bchml1.aclcb.purdue.edu>
Subject: Screwy Tops, Fruity Beers.

Relax! This posting has nothing to do with yeast cakes or magic...

As a reply to the screw-top issue, I've been recapping screw-top bottles for quite some time. I like rebottling in beer bottles with pretty labels (like Boulder Beer, even though the beer that comes out of the bottles [at least in Indiana] is pretty average), and several of these pretty bottles have those nasty threaded tops. I've generally been of the snobbish 'if it's in a screw-top bottle, it's rubbish' philosophy (similar to the wine bottle without a cork in the top), but Sierra Nevada does it, so it can't be all bad.

I find that capping the bottles is more difficult, but I have no trouble with the seal and if you don't care about your hands (or use a towel) you can actually twist them off. Admittedly, I have an old, cast iron monster of a capper, which can crush glass bottles if you torque it enough, but I just blithely capped them, and never had any problems.

Adding fruit to beer yielded some mixed results in my brewery, since beautiful, juicy, fragrant fruits and berries when pastuerized and fermented in the presence of malt extract and hops can change character to the point of disaster. Peaches, one of my favorites, are particularly different after yeast gets through mucking with them. I (damn, inadvertant carriage return) ended up with 5 gallons of bitter, nasty brew. I have had triumphant success using fruit, fruit extracts (blended and strained fruit), and fruit juices added as described in the last HBD... added in the secondary (or in my case the primary) just before or with bottling.

Less fermentation occurs in the presence of the fruit, and more aroma is retained. I finally managed a tasty and beautifully aromatic peach pale ale using mashed peaches on an extremely starting gravity ale (> 1.090) and letting them sit in mutual harmony for about 6 hours before racking and bottling. I prudently primed with just a touch of honey (1/2 cup) and the resulting mead-like brew was very pungent and actually tasted like peaches. I would also recommend trying a Belgian peach (Pêche) beer by (I believe) Lindemann's. They use a similar process (but a decidedly different beer) and the taste of the final product is what I continually seek in my own fruit beers. Good luck

with it, and keep trying. I think of myself as a fairly competent brewer, but it took me many brews to get what I could drink, much less a really superior beer (and I'm still working on a honey ale).

This is probably an old old joke, but a German friend of mine drank a Bud light and remarked that 'this beer is so light that the head should be on the bottom'.

Father B.

Subject: Yeast Sprinkling

In HOMEBREW Digest #713, such worthies as C. R. Saikley and Jay Hersh seem baffled by Conn Copas' terminology:

Conn Copas writes :

>It's bemusing to
>read posts in which people describe how they have conscientiously
chilled
>the wort, then pitched the yeast straight in on top !

And CR retorts:

>OK, I'll bite.
>What's unusual about chilling wort and putting yeast on top??

So, to move the discussion from obscure to impenetrable, I'll attempt a clarification. What I think Conn was saying is that we'll often take great care in producing our wort, only to entrust it to dry yeast which we haven't so much as rehydrated. We've often read (here and elsewhere) about the problems associated with using dry yeast (chiefly contamination, and strain selection emphasizing yeast survival rather than brewing characteristics) at all, but since the massive swing to liquid cultures a couple of years ago, we've almost forgotten about gently reviving dry yeast in warm water. Pitching the dry granules upon the wort shocks the yeast, subjecting the cells to osmotic stress, and usually producing off-flavors, negating altogether all that care ...

Subject: Mashing Wheat

In HOMEBREW Digest #712, Bryan Gros was preparing to try wheat beer and all-grain brewing, simultaneously (points for courage!):

>After two successful extract brews, i'd like to make a wheat beer.
>due to cost considerations, i would like this to be my first all-
>grain brew, but from reading, it seems that an 8-gal pot is needed
>to hold everything. also a wort chiller which i don't have.

Well, you could survive without the wort chiller, but you will need a kettle large enough to hold all the first runnings, sparge, and froth formed during the boil. For a 5-gallon batch, 8 gallons seems about the minimum. And the wort chiller really is a very good idea, as a rapid chill reduces the likelihood of infection, produces the "cold break" that will remove compounds from the wort that you really don't want to keep, and will greatly reduce the production of dimethyl sulfide (DMS), a large-scale producer of off flavors.

>so maybe i'll just mash the wheat malt use addpale extract to
>the wort. i haven't sat down and worked out the details yet, but
>this may give me an introduction to mashing and save money.

This is known as a "partial mash", and is a very good idea. Bryan, I would suggest postponing your first all-grain batch until you have done several partial mashes and are comfortable with the procedure.

>Are there any special considerations i have missed? any suggestions?

Yes. Mashing the wheat malt by itself is a waste of time and grain.

>i just realized that the enzymes supplied by the barley would be
>needed during the wheat mash, right?

Right.

> ... so i would have to add the
>extract at the beginning of the mash. how would this affect the
>amount of water needed during the mash?

Wait! Most malt extracts are completely devoid of diastatic enzymes, so you can add all you want and it won't help the mash convert one bit. What you need is grain. Here, in general, is what you'll want to do:

1. Heat up 4 quarts of water to 135F. When it's there, add 1 pound of pale malted barley (or pale lager malt) and 2 pounds of wheat malt. Stir, stir, stir (with the heat off) until all the grain is thoroughly wet. A couple minutes at least.

2. Check the pH. It should be somewhere in the ballpark of 5.3 or so. Adjust downward by adding gypsum or upward by adding calcium carbonate. On no account add more than 2 tsp of either; if the pH is out of bounds, you're better off living with it than adding too much of the minerals.

3. Bring the temperature up to the range of 124-121F, stirring all the time, and keep it there 20 minutes (protein rest). It's okay if it fluctuates, as long as it stays in the range. You probably won't

need to boost it back up more than once.

4. Raise the temperature to the 150-141F range, stirring as before. Keep it in that range at least 60 minutes; with this much wheat, 90 may be better. Unless you have an insulated box to keep your kettle in, recheck the temperature at least every 15 minutes.

5. While you're at a rest, start 2.5 gallons of water heating to 168F. Adjust the pH to 5.7. You'll need to improvise some sort of lauter tun here -- I used to use a large colander lined with cheesecloth, others have used spaghetti cookers. If your boiling kettle isn't in use either as a mash kettle or heating the sparge water, you can sparge directly into it. Otherwise, you'll need a clean receptacle large enough to hold all the liquid you've heated so far.

6. Your starch conversion (step 4) complete and your sparge water (step 5) ready, heat the mash to 168F. Let it sit for 5 minutes.

7. With your strainer mounted over its receptacle, pour the mash into it. I used to strain into a bucket, then move the strainer to the mash kettle (which I also used as a boiler), pour some of the wort from the bucket back through the strainer and use it to rinse all the grains out of the kettle and back into the bucket, then pour gently all the wort from the bucket through the strainer & grains again. The wort in the kettle would then be crystal clear.

8. Use the water you heated (168-165F) in step 5 to gently rinse the residual sugars from the grains (sparging). When this is done, put the resulting wort on to boil, and add the extract & hops when the boil begins. proceed as usual from there.

This is by no means the only way to make a partial-mash wheat beer, but it will work. Some different times and temperatures would also work; the process is surprisingly resilient (and I'm accused of being uptight about it! ;-)) Let us know how it turns out!

Subject: Mashing Pot (any way you want to take it)

In HOMEBREW Digest #713, Darren Evans-Young asked the musical question:

>Has anyone tried mashing pot? ...just kidding...

Something over two decades ago (surely beyond the statute of limitations) a friend made an extract batch using a considerable quantity of said herb in place of hops. Don't know if it "worked"; the taste was too horrid for anyone to drink enough to find out.

By the way, this topic touched off one of the few ugly flame wars this Digest has seen, several years ago. I hope we're all calmer this time.

>Seriously, what size pot is needed to mash, say, 10 lbs of grain?
>I already have a 10 gal SS pot to boil in. Is a 5 gal SS pot large enough
>for mashing a maximum of 10 lbs of grain?

It might be tight. I feel you'd be better off using a larger kettle (like your boiler), so you can stir vigorously without fear of sloshing over the edges. My mash kettle is smaller than 5 gallons, so I end up mashing in my boiler more than half the time. The mash kettle (and the spaghetti kettle, and sometimes the autoclave as well) are then pressed into service heating sparge water ...

Subject: The latest rumor: new micro in Kingston, NY

Far be it from ME to spread the evil winds of gossip, but..... :-)

I heard from a reliable source who shall remain nameless (although he actually BREWED "Olde Cock Ale"!) that Nat Collins of the Hudson Valley Homebrewers is opening a microbrewery in Kingston, NY, in November. It will be called the Woodstock Brewing Company. Kegging will begin at that time, with bottling to follow in the spring. I have no further information at this time, but this is enough to whet MY whistle.

Anyone else with more information along these lines??

Yours in the Rumor Mill,

STEVE

Subject: Re: Homebrew Digest #711 (August 28, 1991)

Conn Copas asks (my paraphrase) if rolling or flaking has any effect on the cellulose content of adjuncts, as he believes cellulose to be a precursor to methanol in the final brew.

Rolling, flaking or heat treatment should have next to zero effect on the cellulose content of adjuncts. Moreover, the cellulose content shouldn't matter since neither the mashing enzymes nor the yeast is capable of breaking down cellulose into its monomer form, glucose (same as corn sugar). Further, there is no direct chemical pathway between cellulose (or glucose) and methanol via any organism normally found in beer.

Perhaps Conn is thinking of hemicellulose or lignins as a source of methanol. Hemicelluloses contain a few methyl esters and lignins are full of methyl ethers - but they should both be quite stable during the brewing process since specialized enzymes are needed to liberate the methanol. RDW - there is probably far more methanol in your child's glass of apple or orange juice than in your home brew. Cheers - Jean

Subject: Re : The great aluminium debate

I can verify Father Barleywine's lack of concern about aluminium. A while back, I was experimenting with mashing various flours in the presence of various enzymes. I left one of the mashes overnight in an aluminium boiler.

What had previously been a translucent liquid was now grey, ie, it was full of aluminium salts. Possessing a somewhat perverse nature (if you hadn't already guessed), I decided to ferment this mess and see what happened. The brew settled out crystal clear. This has led me at least to question the wisdom of draining the dregs from bottled brews in the name of health !

From: FATHER BARLEYWINE <rransom@bchml.aclcb.purdue.edu>
Subject: I asked for the abuse, didn't I?

Well to those of you who care, my address is:

rransom@aclcb.purdue.edu

My name is Richard Ransom, and I can only think that the nasty VMS system that

I must work through is the cause of this confusion. My address is probably properly expressed as 'rransom@bchml.aclcb.purdue.edu', since I must log into bchml to get online, but as far as a mailing address is concerned, don't include the bchml.

In reply to the bounced messages, I don't use a part of the yeast from the fermenter, but the whole stinking mess, trub and all. I feel that transferring the yeast is pushing my 'brewing without sanity' practices beyond their rational limits. The reasons: first, the yeast stays under the last

batch of beer (yes, lagering until I get up the gumption to make another batch) in safety, and then when the beer is sucked off, it stays under a cushion of CO2, and in fact farts out some more, so there is a continual drift

of CO2 coming out the top of the fermenter and gently wafting away the airborne spores. This lasts at least 20 minutes, so with this as a safety limit, I have

experienced no problems with hammering on a new batch of wort.

Transferring

the yeast adds some problems: you expose the yeast to the air, you assume

that the container it goes into is clean, and you assume that the transfer

implements are also clean. Too many assumptions for me.

There are several reasons why this works for me (and I hope it's not 'absolutely wrong').

1. I use Whitbread Ale yeast, dry from the package. Whitbread has several nice things about it that keep me buying it. It comes in 14 g packages, twice the normal dry yeast size. It makes a mean ale (speak to my friends). It ferments quickly but controllably (i.e. no huge head shooting out the top of the fermenter) through the primary and ferments out the fermentable sugars in the 'secondary' (I don't transfer to one, I just call the late stages of fermentation a secondary)...I've made a barley wine (my namesake!) with a starting gravity of 1.140 and it ended up at 1.030....needless to say a favorite. Finally, the yeast/trub cake is a nice, solid mass; no fluffy stuff, and in general so compact that I can recover all the beer I put on it (I even thought of pouring off my beer).
2. I reuse the cakes, so the yeast concentration is sooooo high that any other organisms just never have a chance. These puppies are fermenting within hours, and I've never had a bad batch from contamination while using this method. I have had bad batches resulting from: poor ingredients, poopy yeast (not Whitbread), and especially high temperature fermentations.

Let me stress the last reason. Keep Cool!

3. I ferment everything as cold as possible. I made a lager once using the ale yeast and a frankly ale recipe (it was even dark dark brown) by slapping the fermenter immediately after filling it (onto an old cake) into 40 degree farenheit temps and leaving it there for 4 months. It did ferment, and I hope I have access to that particular refrigerator again. Every (and I mean every) beer I've made that was of the Nectar of the Gods category was made either in the refrigerator all the way through or in a poorly insulated basement in the winter. Frankly, summer (and especially Indiana summer) sucks for brewing.
4. I don't sanitize anything. Yes guys, nothing. I won't beat it into the ground again (see HBD #600 (I think) and recent diatribes).
5. I think nice thoughts about my beer.

Sorry, just reading that last letter got me stirred up. I wish I could send you all a bottle of my last Scrofolous Red Ale, but we drank it savagely and my last batches got left while I PhD'd all summer in the sweltering heat (and they taste like it). Don't think that I never went through the 'bleach bleach sulfite bleach bleach' phase...I used to do sterile tissue culture, and being anally retentive is a byword in that sort of work. I personally think that temperature is the bane of most of those attacked by foreign organisms.. .yeasts don't mind near-refrigerator temperatures nearly as much as the typical mold or bacterium, and every degree closer to 98 degrees increases the chance of some nasty little thang adding that stamp of undrinkablity to your beers. So do as you feel you must, but try the insane sometime and raise a glass of the resulting beer to me (but don't send any to me if it goes off).

Love and kisses...

Father B [rransom@aclcb.purdue.edu]

Subject: Malt extract

Someone (ie, me) posted this recently :

>Lastly, another part-mythical creature : the malt extract 'tang'. Fact
or
>fiction ?

My reply is try putting your brain in gear before you post in future. If you look at the labels on tins of malt extract, you will notice that some contain caramel. This is used as a colouring, but the worse examples can impart an 'acidy' flavour as well. IMHO, the addition of caramel to extracts (or for that matter to beer) suggests that the manufacturer has something to hide. Apologies to Newcastle Brown Ale fans :-)

One of my standard tricks when using extracts is to boost the final gravity with partially fermentable malto-dextrin powder. I have tried either adding this to the boiler or adding a solution at bottling time. The boiled dextrin often seems to attenuate too far whereas the bottled dextrin seems to remain unfermented for months. So I am now entertaining two theories :

- a) Boiling the malto-dextrin causes some chemical change into more fermentable sugars, or
- b) Adding malto-dextrin to a voracious primary ferment causes more of it to be consumed.

Any ideas ?

>Honduras. I also like "fresh" SINGHA. Is it water? (;-[])

I doubt it. I've noticed that most tropical beers are lagers, which
require artificial refrigeration of the fermenting vessels virtually
everywhere. That being the case, the only difference between the
physical plant required to produce Belikan and that required to
produce Molsen's, is the size of the refrigeration system, as the
temperature differential between the air and the beer is greater
in Belize than in Canada. The temperature outside the vessels
is otherwise irrelevant, I would imagine.

- > cooling might spell D-I-S-A-S-T-E-R.
- >
- > Any experiences out there?

I think of this with every batch I brew. I use one of these kettles, and have recently begun thinking in terms of using it as a mash kettle full-time, and saving my pennies for a SS kettle as a boiler. Every time I lift that kettle from the stove to the sink it "talks" to me, but I don't yet see the little telltale cracks in the ceramic indicating flex damage. Those handles are the weak point, beyond a doubt. Rather than use the handles in the manner they were (apparently) intended, I now pick up the full kettle (using oven mitts) by the sides, looping my thumbs through the handles for slippage control. Not a perfect method, but it seems to strain them less. I also clear the kitchen of kids, dogs, cats, spouses, and other living things and obstacles. It still scares Hell out of me. In my opinion, that's the only problem with using one of these kettles.

```

Well, you're both wrong and you're both right, in my opinion. I'm sure Fr. B. would agree that it's possible for a homebrewer to make a beer with a bacterial infection. It can be achieved by simply cooling the boiled wort slowly, or even easier, by adding a teensy little bit of yeast at the beginning of the ferment so it will have to compete with lots of other beasts for the "sugar pie."

My experience has been similar to his. I think I worried far too much, and for too long, about cleanliness, when in reality the major problems I had with *my* process control were lack of sufficient yeast quantity for pitching (potentially solved by the fresh-wort-in-over-the-top technique he espouses) and inadequate oxygen in the cooled wort. The beers I've done since discovering those faults have been remarkable, and I'm brewing in an environment that is clean but in no way "sanitary."

Just another data point, as it were.

>

I can't comment specifically on the recipe I posted (haven't tried it yet)

I would suggest that anyone try making a normal soda with an extract
before you try one of those recipes. This would give you a little
insight
into the procedures used in making sodas. You could then apply these

procedures to the all_natural recipies. For example; the appropriate time to bottle so things don't explode.

I think cane sugar in place of the honey would be fine for soda. This might also help with the exploding bottle problems, the champagne yeast could continue to slowly ferment the honey for a few weeks, resulting in the increase of pressure. You could also try an ale yeast in place of the champagne. This would ferment less of the sugars and you would also lose the champagne flavors.

> btw, Bob, how did your batch turn out (assuming it's still intact?)

I got sidetracked into making a batch of sugar-free iced-tea. Pretty tasty, and oh what a caffeine jolt! It's funny you mention Nutrasweet. I was trying to find some bulk but couldn't, so I ended up using good old saccharin (sp?).

I think my next soda will be a sugar-free cola. (Once I find some bulk Nutrasweet).

Cheers,

Leading, we should note, to their ultimate downfall! I'll bet the Party
made them use Red Star yeast, too. It's a real pity... I'd love to have
the Red Square concession for "Lenin Lager, served in a commemorative
pewter tombstein." Sure, "Stalin Stout" would never sell, but I'd make a
killing with my dopplebock, "Dictator," and what about "Glorious
Workers'

Proletariat Socialist Soviet Revolutionary Red Ale" ? (Sold in 22-ounce
bottles, of course, to provide enough room for the label.)

In a related issue, it struck me yesterday that "Oprah" is "Harpo"
spelled
backwards. Well, actually "harp0," but you get my drift. She's probably
put a few sixpacks away, too, so it's even more relevant.

Hmm... it's no wonder the Russians stick to vodka. How do you make
12-year-old Scotch on a 5-year plan?

Subject: First All-Grain Batch

Hello, being a glutton for punishment, and a veteran of a whole whopping 4 extract brews, I would like to try an all-grain brew. What I would like is opinions on techniques for making a first all-grain wort. I guess simplicity is the key, I would rather buy extra grain than sweat getting optimal extraction efficiency. I've scanned Papasian and Burch and realize there are a variety of mash techniques available, I'm looking for suggestion on which I should use as a first timer.

I have a 33qt ceramic on steel pot, a 22qt al. pot, and the normal variety of kitchen pots and pans and utensils. I realize I'm missing something to hold the grain while I sparge, need suggestions here too. Over the past few months, I've heard of people use stacked 5 gal plastic buckets, "Igloo" type coolers, etc.

I will be re-using the cake from some Williams ale-yeast, which will conveniently become available while cooking the mash...

Receipts, techniques, and hardware suggestions are all welcome.

From: caa@com2serv.c2s.mn.org (Charles Anderson)
Subject: Reusing Yeast Cake & Soda Kegs

Well I decided to reuse my yeast cake from my previous batch of Xmas Ale for my current 'Get Rid of Old Extracts Ale'. Unlike Father Barleywine I am using Chico Ale Yeast, and have decided to dry hop this mess. After an hour or two on the yeast cake there was an occasional glub, this morning that sucker was bubbling almost continuously.

On another note I recently picked up a keggng system using soda kegs and bought some used kegs which still had product in them so I dumped them out and rinsed them thoroughly, and I was going to keg my beer into one of them but after I put some boiling water into it to rinse out the sterilizing solution (I imagine even Father Barleywine washes out used bottles well) it started smelling like Pepsi. Right now I have it soaking with a baking soda solution in it. I'm wondering if the smell is coming from the rubber seal, they're still good but should I replace them anyways??? Also I bought my setup from Foxx, but they just sent me a box with no instructions at all, I'm a reasonably intelligent guy and got everything hooked and running in no time at all but is there something I should know about putting beer in kegs. A friend of mine here at work says you only need 1/4 of priming sugar for priming in a keg and to keep the pressure at 5psi, I read on the HBD here that the seals don't seal unless subjected to 10-15 psi, so I initially pressurized it to 12psi to make sure that it sealed well then released some co2 to get it down to 5psi.

Also my friend at work here says that pepsi no longer uses kegs, and that they ship their syrup in boxes with a plastic bag inside, and that they have a large amount of empty kegs lying around. (his brother worked for the local bottling company, and now works at VFW (or something like that) that has all of these boxes of syrup laying around connected to their system so I trust he knows what he's talking about.) The point is, does anyone know if this is just our local bottling co, or is this nationwide?

Sorry to ramble so much...

Sodium metabisulphite when dissolved produces sulphur dioxide fumes which are good for sterilising but bad for breathing. This reaction is often speeded up by adding a little citric acid and the fumes can get very unpleasant. It won't do a lot of permanent harm to a healthy individual but

I suspect an asthma sufferer could be very badly affected.

Always use it in a well ventilated area. Don't sniff it or stick your head into a large container cleaned with it. Personally I don't like it and always use a proprietary chlorine cleaner. This makes no fumes at all and cleans as well as sterilising.

The simplest thing to do is peel the orange skin off the pith with a
potato peeler BEFORE cutting up and eating the orange. I've done this
many
times with lemons when making Elderflower champagne.

Subject: Steel wort chillers

Ok, Thanks for the advice on buying/not buying an aluminum cooling coil to make a wort chiller. After talking to a Dr. friend of mine, who told me that aluminum MAY be related to early stages of Alzheimer's disease, I decided I would forget the aluminum (better safe than sorry, at least until the final verdict is in).

So, I'm all set to go to the hardware/plumbing supply store to buy copper tubing, when my roommate notices a cooling coil ad in a catalog (picked up in the store where we saw the aluminum coil) that has three kinds of coils. Two are steel tubing with steel cooling fins and one is copper tubing with aluminum (again) fins. The prices range from \$10 to \$12.50, and all three types are unused merchandise.

Now, my question...
I do not imagine that the steel coils are actually stainless steel, but if I were to use regular steel tubing, would there be a chance of making the wort taste like steel also? Will the fins on the coils, be a plus or a minus on the actual use? If regular steel is ok, I could see using the coils as both immersion and syphon type coolers, although the copper coil could only be a syphon type.

If using one of these coils is a good idea, I can post the catalog #'s and the phone number of the mail-order place if anyone is interested.

Thanks in advance,
John

OK, here is **my** interpretation.

Rapid chilling of the boiling wort gives a good cold break.
Removing the wort from the cold break before starting the
fermentation makes the beer taste a lot better.

Therefore, if you chill the wort and pitch the yeast directly
on it, **without** racking to a new container and leaving the cold
break behind, you are losing much of the benefit of rapid cooling
of the wort in the first place.

From: darryl@ism.isc.com (Darryl Richman)
Subject: re: Lovibond

Dr. Lovibond was a brewery chemist in the last century, and he developed a scale for measuring beer color based on standard solutions in 1/2" vials. This scale has stood the test of time and proved itself quite useful, to the extent that even though this is quite obsolete with the advent of spectrophotometry equipment, the American Society of Brewing Chemists (ASBC) have developed a new scale, called the Standard Research Method (SRM) that closely mimics the Lovibond scale.

A rough, but workable way to predict beer color--for pale colored beers--is to multiply the Lovibond number by the number of pounds of grain and divide by the batch size in gallons. So a pale lager with 7 pounds of Klages 2-row malt and a pound of Munich might be $((1.8 * 7) + (10 * 1)) / 5 = 4.5$. Budweiser is about 3 Lov.

Subject: re: Soda Kegs

Charles Anderson asks about kegs and that Pepsi smell. My advice is to throw out all of the rubber parts, as I've never been able to remove the soda aroma (and flavor) from them. I also clean out the interior of the kegs and valves by cleaning them with lye--in fact, I use crystal Drano. This may sound pretty drastic, but if you can smell the soda pop aroma, you are going to get that in your beer. I've tasted a number of rooty-toot beers, and all were pretty disappointing to their owners. Once I have removed all of the soda pop character from the keg and valves, I then rinse several times, assemble, and fill with boiling water. I then use my CO2 tank to push the water out, leaving a sanitized, CO2 purged atmosphere in the keg, ready for filling with beer.

Subject: Carboys in England

I've just started Homebrew, guided partly by Papazian's book, the beginner's guide produced by this list, and instructions on the side of kits. Sad to say my first couple of batches were disastrous - both got seriously infected. I sanitised everything with all the loving care I could, but no. I used a plastic fermenting bin bought from a homebrew shop, but I had to leave the lid slightly ajar to let the CO2 out. (I least I presume I had to...) Unfortunately I think this is where the bad guys got in. Reading Papazian, and the beginners guide, they both recommend the use of carboys rather than open bins, and I can quite see why, it sounds pretty sensible to me. Only problem is, you can't seem to get them in this country. Does anyone know where I can get one, and how much it would cost? Alternatively, I could bore a cork-sized hole in the lid of the bin and fit a lock to it, but that seems decidedly second rate as a solution to me.

Comments?

Date: 04-Sep-91 Time: 10:06 AM Msg: EXT01814

Hi there,
To get nice orange peel without pith for putting into recipes it is
easier to
get the orange off the pith, rather than the other way round. Before you
eat
the orange use a paring knife or veggie peeler and peel all the orange
layer of
peel off (make sure to wash the fruit first). Then you have a layer of
pith
surrounding the orange flesh. If you save the peels and then try to
scrape off
the pith it will be more difficult and harder yet if you let the peels
dry.

What I do is I rub a whole, unpeeled orange on a cheese grater. That
scrapes
off the orange part of the peel and leaves the pith on the orange. It's
a
whole lot easier than trying to whittle chunks of orange peel. Also, the
oranges will last for quite awhile in this de-oranged state (though they
look
kind of funny), so there is no need to OD on oranges on brewing day.

I bottled my weizen last week (no oranges in that one). It was an all-
grain
brew that I fermented with Wyeast #3056. Someone on HBD said that a high
temperature fermentation would increase the clove esters in the finished
product, so I tried it despite the August heat. After three weeks in 85-
95
degree heat, the finished product is certainly estery. Unfortunately,
the
dominant aroma and flavor is banana. I haven't seen anything like this
since I
stopped using Red Star yeast! I just mention this as a warning to
others:
don't let your weizen get to hot.

Subject: Don't pith in your wort

Instead of trying to remove the pith from the zest, try removing the zest from the pith. A vegetable peeler will do a fine job, it'll be easiest if you do it before opening the orange. When I'm making mead and I want **just** the zest and **no** pith from a lemon, I use a fine grater, and grate off just the yellow. It's more work, but I get to avoid adding any of the bitter pith.

From: chad@mpl.UCSD.EDU (Chad Epifanio)
Subject: Mead help!

OK, so I'm worried...so sue me.
I'm seeking advice from veteran mead brewers. I've read up on the subject, but I need experienced advice. Infact, there may be no problem at all; I just don't know.

How fast(slow) does mead ferment? I made a 5.5 gal batch the other day, and so far I see NO signs of active fermentation(from a homebrewers point of view). Here is all the details:

8lb. Orange blossom honey
8lb. Clover honey
2oz. Tartaric acid
2oz. Malic acid
1/3oz Grape tannin
6tsp. Yeast Nutrients pH: ?
Montrachet dry wine yeastOG: ?

This was a variation on the traditional dry mead in "Making Mead", p.31. The yeast was rehydrated and thrown into a 12oz. starter solution of steril wort for pitching later. All ingredients except yeast were combined in my brew pot with enough water to bring it up to 6.25 gal. The water was held at 170F for half an hour, dumped into my plastic primary fermenter, and allowed to cool somewhat. Eight crushed up Campden tablets were stirred into the must and allowed to sit for 24 hrs. Approximatly 0.75 gal of must was siphoned off and saved for future topping off, leaving 5.5 gal in the fermenter. The active starter was pitched into the must, and the fermenter fitted with a fermentation lock.

All this was Sunday afternoon. So far, I haven't seen that damn fermentation lock bubble once! Whats the deal? If you tell me this is normal for meads, I'll go home a happy, non-worrying, homebrew-slugging man. Otherwise, advice would be much appreciated.

Subject: Re: HBD #716 Used soda kegs

Charles Anderson notes a Pepsi smell to his recycled soda keg...

I soaked my kegs for an hour or overnight with lye or washing soda (sodium carbonate - in the blue box at your local supermarket) and replace as many of the gaskets as I could (all, eventually). That removed the "coke" house flavor just fine. I also disassembled the quick disconnects; there are o-rings within that need replacing as well.

Automatic dish washing detergent would be a reasonable substitute for washing soda since that is the primary ingredient.

Subject: yeast

Re. yeast slurry: I got the Wyeast Chico ale yeast to settle out by putting the carboy in cold water for 24 hours. The water was only 5 degrees colder than the air (68 vs. 72), but it worked. I bottled, and saved about a pint of the slurry. Haven't used it yet, but it looks ok.

The beer is tremendous: clean, crisp, bread-like, malty, and hoppy. I "dry-hopped" it by making an infusion of hops, vodka, and water, gently heating it, letting it stand over night, and then straining into the carboy.

It really worked, and there were no hops to worry (er, be concerned) about in saving the slurry. Without a doubt, my best beer.

Subject: The Controversial Enzymatic Power of Wheat Malt

In TCJOHB, Papazian states that wheat malt is weak in diastatic enzymes and must be mashed in conjunction with barley malt of great diastatic power. I have seen this opinion stated elsewhere I think; Gary Bauer's article in the Zymurgy All-Grain Issue comes to mind.

I am aware of some dissenting opinions and (I think) some counter examples:

Miller, Fix and Foster in their books on Continental Pilsener, Brewing Science and Pale Ale respectively state that wheat malt has plenty of enzymes (Miller and Foster say this in text, Fix shows the DP of Wheat Malt in a table).

The Widmer Brewing Company of Portland Oregon mashes Briess wheat malt and Klages 2-row pale in a 50/50 ratio without any diastatic crutches that I am aware of. Anchor uses an even higher ratio of wheat/barley according to their outstanding tour-guide and only has problems with the runoff, not the mashing.

I have only mashed tiny amounts and ratios of wheat/barley up to now; and so am without direct experience.

Are Papazian and Bauer completely wrong? Do I understand the problem?

Subject: Keep it Cool

In HOMEBREW Digest #714, Ted Amsel repeated:

>> OK, I know that temperature is important during fermentation. Part of
my
>>question was HOW DO THEY BREW GOOD BEER IN THE TROPICS? I know they
don't
>>AC the whole plant, for I've been to several breweries in Mexico,
Belize and
>>Honduras. I also like "fresh" SINGHA. Is it water? (;-[])

To which Martin Lodahl responded :

>I doubt it. I've noticed that most tropical beers are lagers, which
>require artificial refrigeration of the fermenting vessels virtually
>everywhere. That being the case, the only difference between the
>physical plant required to produce Belikan and that required to
>produce Molsen's, is the size of the refrigeration system, as the
>temperature differential between the air and the beer is greater
>in Belize than in Canada. The temperature outside the vessels
>is otherwise irrelevant, I would imagine.

A conversation with Roger Bergen confirms Martin's reasoning. Roger is
the head brewer at the Anderson Valley Brewing Company who formerly
worked at a major brewery in the tropics (may have been Red Stripe,
not sure). Since he was considered an expert on the topic, he was asked
to give a talk on warm weather brewing at a meeting of the East Bay Fog
Society (a now defunct homebrew club). His response was that he had no
knowledge that would be practical for homebrewers, and that they had a
monster refrigeration system to cool their fermenters. Other than that,
nothing special was required to brew in the tropics.

On a related note, I recently had the pleasure of touring the Blitz-
Weinhard Brewery in Portland. (It was a great trip, we visited 13
breweries between SF and Seattle in 9 days!). They have these *enormous*
blue tanks outside which are actually fermentation vessels. Although
Portland's climate is moderate, it can reach the high 90's. Nonetheless,
Henry's is fermented in these outdoor tanks. All it takes is sufficient
cooling capacity.

Subject: Flaming makes the mainstream media (again, I guess)

FLAME THROWERS: Why the heated bursts on your computer network? by Doug Stewart (copied without permission from Omni magazine Sept 1991 issue)

"You are a thin-skinned reactionary jerk," begins the computer message sent from one highly educated professional to another. "I will tell you this, buster, if you were close enough and you called me that, you'd be picking up your teeth in a heartbeat." There follows an obscene three-word suggestion in screaming capital letters.

The writer of the above message, sent over the Byte Information Exchange, was apparently enraged after a sarcasm he'd sent earlier was misinterpreted as racist. In the argot of computers, his response was a "flame" -- a rabid, abusive, or otherwise overexuberant outburst sent via computer. In networking's early days, its advocates promised a wonderful world of pure mind-to-mind, speed-of-light, electronic conversation. What networks today often find instead are brusque putdowns, off-color puns and screenfuls of anonymous gripes. The computer seems to be acting as a collective Rorschach test. In the privacy of their cubicles, office workers are firing off spontaneous salvos of overheated prose.

Sara Keisler, a social psychologist at Carnegie Mellon University and Lee Sproull, a Boston University sociologist, have observed that networking can make otherwise reasonable people act brash. In studies originally designed to judge the efficiency of computerized decision-making, they gave small groups of students a deadline to solve a problem. Groups either talked together in a room or communicated via isolated computer terminals. The face-to-face groups reported no undue friction. The computerized sessions frequently broke down into bickering and name-calling. In one case, invective escalated into physical threats. "We had to stop the experiment and escort the students out of the building separately," Keisler recalls. Keisler and Sproull documented a tendency toward flaming on corporate electronic-mail systems as well. At one large company, employees cited an average of 33 flames a month over the email system; comparable outbursts in face-to-face meetings occurred about four times a month.

Keisler and Sproull attribute the phenomenon largely to the absence of cues

normally guiding a conversation -- a listeners's nod or raised eyebrows.
"With
a computer," Keisler says, "there's nothing to remind you there are real
humans
on the other end of the wire." Messages become overemphatic -- all caps
to
signify a shout; "(smile)" or ":-)", a sideways happy-face, to mean "I'm
kidding." Anonymity makes flaming worse, she says, by creating the
equivalent
of "a tribe of masked and robed individuals."

In real life, what we say is tempered by when and where we say it. A
remark
where lights are low and colleagues tipsy might not be phrased the same
under
fluorescent lights on Monday morning. But computerized messages may be
read
days later by hundreds or thousands of readers. Flaming's ornery side is
only
half the picture, says Sproull, who co-authored Connections: New Ways of
Working in the Networked Organization with Keisler. "People on networks
feel
freer to express more enthusiam and positive excitement as well as
socially
undesirable behavior," she says. Sproull finds it ironic that computers
are
viewed as symbols of cool, impersonal efficiency. "What is fascinating
is the
extent to which they elicit deeply emotional behaviors. We're not
talking
about zeroes and ones. People reveal their innermost souls or type
obscentities
about the the boss." What, she asks, could be more human?

Subject: Explosives and homebrewed soda

With all of the recent postings about homebrewed soda and detonating hand grenades, it seems that there are two obvious solutions:

1) Keg your soda and artificially carbonate. Don't use any yeast. Just sugar, water, and extract (or flavorings) into the keg (using normal sanitation procedures), then pressurize. After all, isn't this how real soda is made?

2) If you insist on bottling, follow the "Jack Schmidling Productions" instructions, the important thing being USE PLASTIC BOTTLES! The one-liter ones with the screw caps that Pepsi or Coke or whatever come in are perfect, are reuseable, and as Jack points out, you can tell when they're carbonated by squeezing them.

From: FATHER BARLEYWINE <rransom@bchml1.aclcb.purdue.edu>
Subject: Red Baiting, Address Hell, and Pressurization

Hey There Brewsters!

First, I must say that the posting by Bill Thacker about proposed names for hot new Socialist Brews (remember Bill, you can't use Communist anymore

'cause it's ILLEGAL) had me rolling. Your wit must be well aged, and properly carbonated. Seriously, they are looking for new 'free' enterprise over in

Confusion land and especially Western technological assistance....

Sorry Larry, I probably made a great point of giving you the proper address and misspelled the name of the university I've been going to for 6

years....it's P-U-R-D-U-E, not prудue, as in:

rransom@aclcb.purdue.edu

I hope this finally clears up the Great Address Mystery, and that your computer

can now talk to mine. Don't you just love literal-mindedness in your mail? I

think we put down the US mail system too much...I got several pieces of email

and would like to ask the senders (listed below) to send me a short bit to

confirm THEIR addresses since my mailer refuses to send to them:

Michael Bass-----lg562@pnl.gov

Stephen Russell----srussell@snoopy.msc.cornell.edu

Are these the right addresses? Are you on bitnet? Thanks...

On kegs...and pressure...and priming: I would recommend using _20_ psi of pressure to start, and priming with 1/3 - 1/2 cup corn sugar, especially if you are using a well-fermented beer with low residual sugar level. You can always bleed later (I usually leave all that initial

pressure on) unless your beer gets way way too carbonated, but if you miss the initial

carbonation through leakage or insufficient priming, the beer will never carbonate properly. Even if you like a more British style of carbonation, you

want to have a good concentration of dissolved CO2 which can be released later to inhibit over-heady brews. 20 psi insures that the seals are made;

you might also toss the seal in the boiling water you use to make the final

cleaning ('sanitization'? Oh no!) to get it softened up...makes a better seal.

Finally, when I make the beer to be wanked onto the old yeast cake, I run it right from the chiller into the carboy without letting the trub settle.

I let the stream fall the height of the carboy (my hose runs into a stopper

which fits loosely in the mouth of the carboy) which provides good aeration,

and give the first few quarts a swirl to break up the cake. The resulting

wort looks rather nasty, especially since a few of the pieces of dried yeast ringing the carbouy at the level of the old beer always fall into the new beer, giving the whole thing that "Oooooo, what _did_ you do to your beer?" look, but I put it in a dark place right away to keep people who might be bothered from looking at it. I use an immersion chiller and chill with my tap water, which leads me to believe that my cold break is not the best, but chill haze never bothered me much anyway.

Thanks for the support of my admittedly extreme postings, and keep up the snide and nasty comments. I'm not in love with my opinions, just extremely fond of them. There's room here for disagreement (and possibly for roasting your detractors over a roaring Cajun cooker and basting them with rock salt).

Kiss kiss, glub glub,

Father Barleywine

Subject: Good/Bad Mail Order Experiences

Sehr geehrte Bierfreunde,

I have yet to brew my first batch, but both my wife and I are Very Excited about trying it. There appears to be no Homebrew dealer in my area (correct me if I'm wrong), which is Raleigh NC, so we'll resort to Mail Order.

- 1) I have two catalogs -- Alternative Beverage and Hennessy Homebrew. Any comments? Any other suggestions? I promise I'll summarize.
- 2) How good are the True Brew Ingredient Kits? (or any other ingredient kits for that matter...) I suppose it wouldn't hurt for a FirstTimer to start out with a "just add water" kit, but not if the results don't justify the efforts. Again, any suggestions for The Rank Amateur?
- 3) How much space do these brewing activities take up? Should I get another (1/2 size) fridge?? Where the hell do I put it? We have no basement. Does my freshly minted HomeBrew need to be refridgerated?
- 4) Pick 2 books without which the FirstTimer should NOT attempt to even THINK about doing this mystical task.
- 5) Does Wyeast Yeast Come From Oregon? "Wyeast", or better "Wy'east" is the Indian name for Mt. Hood in Oregon. There is magic in the name..

Pleeeeeeeze reply by mail and I'll summarize.

Thanks,

Jeff

End of HOMEBREW Digest #717, 09/05/91

Date: Fri, 6 Sep 91 00:11:42 -0700
From: bgros@garnet.berkeley.edu

Someone asked about mail order grains. I just received a catalog (haven't ordered yet) from The Home Brewery, based in Ozark, MO with distribution centers in San Bernardino, CA and Las Vegas. They advertise Klages 2-row malt for 0.90/lb. Also, 10lbs is \$7.50 and 50lbs is \$32. sounds pretty cheap to me. all specialty grains are \$1.50/lb or \$6.50/5lbs.

to get a catalog, call 1-800-321-BREW. Does anyone have any experience with these people? Just for comparison, they sell most hop varieties for \$1.95 per 2oz pack. Wyeast is \$3.75 each. A wort chiller is \$29.95

Quick question: when priming a normal 5-gal batch with honey, how much should i add? and what kind of honey? i was considering trying it with my wheat beer.

From: scott@sps (Scott Benton)
Subject: Sassafras, Aluminum, and Lager

**** Sassafras ****

Safrole is the major component of sassafras oil (75 to 93%). It is carcinogenic in mice and rats. Administered orally, safrole is metabolized to a compound which produces liver tumors. However, such effects are only manifested at high dose levels (5 g/kg body weight). Safrole is present, in lower amounts, in cinnamon, nutmeg, and mace. So if you can get some, relax, and don't leave any out for Willard.

**** Aluminum ****

There is no hard evidence that Al causes Alzheimer's. However, if the prospect of Alzheimer's causes your stomach to become upset, you may (on your physician's advice, of course) take an antacid. Be sure to read the label, though, because aluminum hydroxide, or a similar Al compound, is the active ingredient in many antacids. If you do go with an Al containing antacid, be forewarned that Al inhibits intestinal contractions, causing constipation, a much more likely effect of Al than Alzheimer's. Relaxation is the best treatment here.

Incidentally, for those of you (or your friends) who drink commercial beer out of cans (ugh!), can companies test can interior coatings to ensure that Al does not migrate into the beer.

**** Brewing ****

On a more serious note, I have to date done higher temp. fermentations (65-75F), but with the acquisition of an old fridge, am considering a lager fermentation. I'm looking for a few tips on how to start out successfully (which commercial yeast to use, pitching temps, etc). Also, when racking to secondary fermenter, should the settled material (which I'm presuming contains a generous amount of the yeast) be transferred as well?

Thanks.....Scott

From: "Ihor W. Slabicky" <iws@sgfb.ssd.ray.com>
Subject: translate some German beer labels

I am wondering whether someone can translate some of this German language text that I found on two German beer labels:

(on the neck label):

Kulmbacher
Kapuziner Schwarze
Dunkles, Hefetrubes Weizenbier

(on the main label):

(on the left side of label):

Imported by Dieter Steinmann Inc.
Garden City, NY (this is overprinted in the label)

Gebraut nach dem deutschen Reinheitsgebot

alc. 5.3% / vol (this has overprinted with a black stripe,
but I could just make it out)

e 0,5 l

(on central area of label):

Kulmbacher
Kapuziner
Schwarze
Hefeweizen

Kulmbacher Premium-Weizen

1 Pint
1 fl. oz. (again, overprinted)

Imported beer
Product of W.-Germany (overprinted)

(on right side of label):

(list of refund states - overprinted)

Hersteller: Monchshofbrau Kulmbach

Mindestens
haltbar bis

22.11.89

and on the second bottle, it says:

(on the neck label):

Kulmbacher
Kapuziner Weizen

Kristallklares Weizenbier

(on the main label):

(on the left side of label):

Imported by Dieter Steinmann Inc.
Garden City, NY (this is overprinted in the label)

Gebraut nach dem deutschen Reinheitsgebot

alc. 5.3% / vol (this has overprinted with a black stripe,
and I could not make it out, though I assume
it to be the same as the first bottle)

e 0,5 l

(on central area of label):

Kulmbacher
Kapuziner
Weizen
Kristallklar

Kulmbacher Premium-Weizen

1 Pint
1 fl. oz. (again, overprinted)

Imported beer
Product of W.-Germany (overprinted)

(on right side of label):

(list of refund states - overprinted)

Hersteller: Monchshofbrau Kulmbach

Mindestens
haltbar bis

25.12.90

Can anyone help to translate this one?

I assume that here so many overprints because the beer was imported. The 'e' by the 0,5 l probably means it is an 'export' bottle of 0.5 liters (which it is). The dates are either when the beer was bottled, or when it should be drunk by - but which? I bought both of these in the Spring of 1991, and drank them this week. The Weizen beer did taste old. The Schwarze was not too bad, probably because the stronger taste was able to disguise some of the old taste. Both beers had tremendous heads - like I'm used to seeing with the Spaten Weiss beer. The Schwarze had a bit of sediment in it - when I poured the first half of the bottle into a glass, it was okay, but when I swirled the sediment and poured that into the glass, the beer in the glass started to produce bubbles on it's own...

Thanks - Ihor

Fm: Jack Schmidling

RE: Article 240 (86 more) in rec.crafts.brewing:
From: Paula Burch
Subject: nitrosamines in homebrew?

>I have read that beer is full of nitrosamines. I rarely
drink commercial beer, and so I wonder:

Does homebrew contain nitrosamines?

ARF says:

I have been patiently waiting for someone to clear up this
issue but not seeing any knowledgeable response, I will put
forth what I know, which is just enough to be dangerous.

Years ago, in the late seventies, I think, when the
nitrosamine business was first recognized, a report was
published listing the concentrations in commercial beers.

I only recall a few benchmarks but it should provide fuel
for thought.

At the very top was Heinekens and lots of imports.

Bud was right up there with them but I don't remember the
exact position of amount.

Coors was at the very bottom with no detectable level.

The "media" told us that there was something in Coors'
process that had something to do with heat (or lack of) that
prevented nitrosamines from forming.

Shortly thereafter, "they" told us that all breweries had
switched to this process and the problem just went away.

I didn't believe a word of this whitewash but that was about
the time I quit drinking and I am now very sorry that you
brought it up.

From: Martin A. Lodahl <hpfcmr.fc.hp.com!hplabs!pbmoss!malodah>
Subject: Mashing Wheat, Revisited

In HOMEBREW Digest #717, Al Marshall raised an intriguing question:

>In TCJOHB, Papazian states that wheat malt is weak in diastatic
>enzymes and must be mashed in conjunction with barley malt
>of great diastatic power. I have seen this opinion stated elsewhere
>I think; Gary Bauer's article in the Zymurgy All-Grain Issue comes
>to mind.

And that has always been my understanding, too, but I don't know
where I got it.

>I am aware of some dissenting opinions and (I think) some counter
>examples:

>
>Miller, Fix and Foster in their books on Continental
>Pilsener, Brewing Science and Pale Ale respectively state that
>wheat malt has plenty of enzymes (Miller and Foster say this in
>text, Fix shows the DP of Wheat Malt in a table).

Well, yes and no. In the Miller and Foster examples, they're using
the wheat malt as such a small portion of the mash that its distatic
power isn't really needed. Fix's hard numbers are buttressed by
similar numbers in Hough, et al.'s authoritative "Malting and
Brewing Science". Hmmm ...

>The Widmer Brewing Company of Portland Oregon mashes Briess wheat malt
>and Klages 2-row pale in a 50/50 ratio without any diastatic crutches
>that I am aware of. Anchor uses an even higher ratio of wheat/barley
>according to their outstanding tour-guide and only has problems
>with the runoff, not the mashing.

Standard German Weizen ratio is 2 parts wheat malt to one part
barley malt, which I've used with great success. My one attempt at
a higher percentage yet (4 lbs wheat malt, 1 lb barley malt) was
much less successful, with poor extract efficiency and the Mother of
All Set Mashes.

>Are Papazian and Bauer completely wrong? Do I understand the problem?

Could it be that this is an area where brewing tradition is at
variance with science? It seems possible to me that the real reason
brewers discovered that wheat shouldn't be mashed alone was that it
has no separate husk, as barley does, so the mash turns the
consistency of library paste. Extract is usually substandard from a
set mash, since its impermeability protects some of the grain from
the sparge water, and since cutting the mash to open it up often
releases water that hasn't contacted grain. Ergo, the "low
diastatic power" rap. An interesting question ...

From: joshua.grosse@amail.amdahl.com
Subject: Underpitching Liquid Yeast

On 8/15 I pitched Wyeast directly from the package into wort, according to the directions on the package. You may recall my letter on refridgerated fermentation, and my wondering about the seeming lack of significant activity. I was unable to determine if the inactivity was from refridgeration or from underpitching.

I wanted folks to know that at the 2-1/2 week point, the fermentation suddenly kicked into gear. There is active carbonation, and the kreusen has gone from thick to foamy. To date, the wort has been in the primary for more than three weeks now, and the way the wort is progressing, will likely stay in the primary for another week or two.

I believe that the 2.5 week lag is due to directly pitching the liquid yeast, instead of creating an intermediate starter of 1-2 quarts with dry malt extract. Next time, by pitching incrementally, I'll be able to save myself more than half a month on a 4 month lager.

From: Peter Glen Berger <pblp+@andrew.cmu.edu>
Subject: Status and Stout

Well, my amber ale has been bottled for about a week now, and it has survived. The ferment stopped after 2 days, and then started up again after another 2. Ingredients: 1 can malt extract, 3 cups corn sugar, and luck. It's slightly cidery, low alcohol, but it doesn't suck.

QUESTION for experienced homebrewers: I want to make a high-alcohol beer next. My initial idea was a 5-gallon batch using about 6.6 pounds of (liquid) malt extract, and then maybe 2 cups sugar to boost alcohol content. One of my friends said that Ale yeast couldn't survive in that high an alcohol environment, and I should mix ale and champagne yeasts. Is this true?

I'd also *really* like to make a stout. Anyone have a good, SIMPLE recipe that doesn't involve mashing? When the Cat's Meow lists "malt extract", do they mean dry or liquid? Can I make Papazian's honey lager recipe at room temperature? Will this make it a "steam beer", and what will it taste like? Is anyone annoyed by all of these stupid questions?

Thanks,

From: JWHITE@maine.maine.edu (Jim White)
Subject: First mash..... resulting questions....

Tied mashing some grains last night, for the first time. As a result I have a couple questions.

Iodine testing:

Having never done this before, I decided I'd do an iodine test right at the beginning of the mash, so I'd have a benchmark comparison. I took a tablespoon or so of the mash and put it in a white saucer and dabbed a couple drops of 'tincture of iodine' into it. Though I didn't expect the sample to, instantly, turn jet black.... I was unable to notice any significant color change!

The tincture is a dark reddish color to begin with, so when mixed it did effect a color change, but nothing like I expected. After about 45 minutes at 152 F, I repeated the test, and again noticed no color change.

Did I use the right stuff? This iodine was like what we used to apply to cuts, etc. Is there a colorless iodine I should've used?

Is there a better way to ascertain the status of the starch conversion? I also tried a taste test, hoping to notice a difference in sweetness, but I felt this was also inconclusive. Sigh

Modification:

The malt I attempted to mash, was purchased locally at a Gourmet/Health/Natural food store. It was labelled Pale Grain Malt and upon asking, I was told it was a 2 row 'European'. That's all fine, but they didn't know if it was modified or not. Since I couldn't be sure I decided to do a protein rest prior to starch conversion, but now to my question. Is there a way to determine if a grain is modified, fully modified, or unmodified? If so can this be accomplished at home, and without sophisticated equipment?

Subject: O2

Here's a data point on adding oxygen after ferment has started. I made a full mash (!) recipe this weekend, but ended up with only 3 gallons of wort in the carboy. I pitched the yeast (Wyeast Chico ale slurry from the previous batch) and went to sleep. The next day there was a nice small but very dense krausen on the brew. I added 2 gallons of boiled cooled water to it (and of course it foamed and splashed a lot), and within 2 hours it was fermenting harder than any I've ever seen. I've pitched slurry before and the ferment was strong, but this was still *much* stronger, so I blame the O2. Yeast use up the O2 in their reproductive phase, correct? So the O2 should have helped them to make lots of other little yeasties, all of whom like to eat. Hopefully too, there'll be a nice thick slurry to save for the next batch.

Subject: The Home Brewery

Having just recently moved from Iowa, I did quite a bit of business with The Home Brewery out of Ozark, MO. All mail-order business, that is; I never actually visited them. I have the following to say about the operation:

* Their prices are ordinarily good, but not outstandingly so. They were cheaper than our local homebrew shop, but only marginally so with P&H, so we usually only ordered things that we couldn't get locally.

* They do have good delivery time to the midwest, no doubt due to their rather central location. We would typically receive orders within 2-3 days after placing them.

* My only major complaint: They had very poor accuracy in filling orders. I would guess that over half of the orders we placed with them had some sort of error - usually just a wrong item, such as the incorrect type or brand of malt extract or hops, but annoying nonetheless. If they could clear this up, I would wholeheartedly recommend them; it happened so frequently to us, though, that I can't believe it was just a statistical anomaly.

That's about it. I don't want to imply that nobody should order from The Home Brewery, but take care that they understand exactly what you want and understand that you're probably taking your chances with them anyway.

Subject: questions: copper cleaning and old recipes

Thanks for the replies to my query about a beer-proof plug.

I have two questions: 1) I have a 8ft or so length of soft copper tubing

I can use for an immersion wort chiller. It has green spots on it where water splashed on it a few times while it was sitting neglected out in the

shed. I would like to clean it off non-abrasively so I don't scratch the tubing. Beside boiling vinegar, what else can I use to clean the outside?

And is it better to run the cold water to the bottom of the coil and let it

cool as it comes up and exits, or should I run the cold water through the top of the coil and let the coldest water cool the hottest wort?

2) Two of my brothers are civil war nuts, and I would like to surprise them

by brewing an authentic 1860's style beer. What where americans drinking in 1860, and where can I find a recipe? Did they use any ingredients we don't

use anymore (like sassafras)? Any substitutions?

Thank You,
Thomas Manteufel, B.S.

From: Bob_Konigsberg@3mail.3com.com
Subject: Wort Chillers

Regarding John Otten's query about the copper tubing based chiller with the cooling fins attached: I would be concerned with the solder in such a thing. Unless you can verify that lead free solder (house plumbing now requires such) was used in manufacturing the cooling unit, acidic liquids (such as wort) can extract lead from the solder. If it is lead free, then the fins should increase the heat transfer efficiency of the unit.

Subject: Fermenters

Thanks for the wealth of replies I got asking about fermenters. The consensus seemed to be that I cut a hole in the lid of the bin to fit a lock. I was also warned of other possible areas for infection. A couple of people suggested I try getting Carboys from the chemistry lab, and this I intend to try.

Thanks again.

Subject: HD 718 Lost In Space...

I did not receive HD 718 nor did quite a few people between Ontario and California by the sounds of it (I tried many personal appeals to have it forwarded to me). Furthermore, it's not to be found in the mthvax archives.

What's up?! Anyone get it? I was kinda disappointed after synthesizing and submitting a few letters to this issue which appears to be lost in space. If you received HD 718 and would be kind enough to forward it to me I'll gladly return the favour to many others.

Can I make Papazian's honey
lager recipe at room temperature? Will this make it a "steam beer",
and what will it taste like?

I made this recipe for my first batch 1 1/2 years ago. I think it came
out
good. I used lager yeast, and did the initial fermentation at room temp.
It
was in the secondary for about three weeks in my garage (about 60-65F). I
remember it tasted pretty good at first, and aged really well. I didn't
finish
it off until last fall.

Subject: Cooling

I'd like to know what systems folks have used/are using to keep their fermenting beer down to acceptable levels. Ideas that have come to my mind (but I don't know about the effectiveness/affordability of) are refrigerators on a time clock, small boxed rooms with small air conditioners and such. Any ideas? Thanks in advance.

From: Kent Dinkel <dinkel@hpmtaa.lvld.hp.com>
Subject: Fast Fermentation
Full-Name: Kent Dinkel

Hello Homebrewers,

Hoping to benefit from the collective wisdom of the more experienced brewers!

On Saturday (9/7) I started brewing my 4th batch. It's an attempt to brew a bitter consisting of:

6.6 lbs Munton Fison Amber Malt Extract
13.2 bittering units (bu) worth of hops (bu = alpa content * ounces)
.5 ounces Cascade hops (finishing)
2 pkgs Munton Fison Ale Yeast

The problem (or maybe it's not a problem) is that the fermentation seems to be completing in half as much time as my previous batches (from ~10 days to ~4 days). Here are the gory details

After pitching the yeast (I pitch the yeast immediately after adding enough cold water to fill the carboy), fermentation was going great guns after only 2 hours! (usually it takes at least twice this long). However, things have slowed down considerably and I went from the blowout hose to the fermentation lock after only 1 day (usually it takes 2-3 days before it's slowed down enough to go to the fermentation lock). After only 2 days in the carboy, I'm down to 1 bubble/minute out of the fermentation lock (usually this takes at least seven days). At this pace, it looks like fermentation will be finished in a couple more days.

I've used Munton Fison yeast and malt extract before (although I used specialty malts in previous brews), but fermentation took about twice as long as this batch. I don't *think* the temperature is involved since I ferment in my basement and it's *cooler* now than my during my previous fermentations. Are 4 - 5 day fermentations uncommon? Am I worrying too much? If my worrying is justified, any suggestions for remedies?

Sorry, I don't have specific gravity readings -- I'm trying to keep my time down to 3-4 hours/batch (excluding drinking, of course!). A couple of the homebrewers that got me started suggested not bothering with specific gravity readings. Their opinion was that the additional risk of infection from opening the fermenter was not worth getting the specific gravity reading which is useful only to tell friends the alcohol content of the beer. (I'm sure that specific gravity is useful to the more serious all-grain homebrewers.) They convinced me that determining when the fermentation is complete can be adequately performed visually by counting the bubbles/minute out of the fermentation lock. Should I break down and buy a hydrometer?

Thanks in advance for your help,
Kent -- the worry wort (pun intended :-))

From: florianb@chip.cna.tek.com
Subject: wheat malt and mashing

In as much as a wheat seedling has the ability to convert the starch in the kernel to sugar necessary for pre-photosynthetic growth, it seems reasonable that wheat has sufficient enzymatic content to convert the starch in a mash. Perhaps it is a matter of temperature and time that dictates just how well the conversion takes place.

I normally use 3# wheat malt, 3# 6-row barley malt, and 1# munich malt for a medium wheat beer. I usually calculate the expected og of my beers before mashing. This recipe comes out within a few points of the theoretical value, so the 50/50 ratio is good for wheat and 6-row.

>From time to time, I read and note various techniques for settling the mash and sparging. The usual technique mentioned in the books involves spraying or sprinkling 178 F water over the mash to sparge. In former times, I did this, but was always unhappy with the results, which were cloudy finished beer. In the last year, I have been using a different technique suggested by my brother-in-law. Its success in my case has been born out by 20-30 batches of beer. It is the following:

The mash is performed in a picnic cooler of the rectangular variety, large enough to hold all of the mash and all of the sparge water. After the mash is complete, I add all the sparge water at once, at the temperature 178 F. Then, I stir it to evenly distribute the grain slurry throughout the water. I then let it sit for a "long time", usually 1/2 to 1 hour. When I can open the lid and see that the mixture appears clear on top, I begin to draw off wort from the tap at the bottom of the picnic cooler. This initial runoff (about 1-2 gallons) is poured back into the top of the cooler, making damn sure that the contents of the cooler are not violently disturbed. After that, the wort is allowed to run out at whatever rate it wants to into the boiler pot. I don't pay any attention to how fast it comes out. My only objective is to get it out. As soon as I have half of it run out, I begin to heat it on the stove, using a second pot to catch the second half of the runoff. By the time it is all run out, there is only a little while left before the boil begins.

This technique differs from the usual in that I don't use fresh sparge water to rinse the "end" of the grains. Noting once more that my conversion efficiencies come out close to the theoretical values and also that the clarity of my final beers has improved, I must conclude that this technique is better. It certainly makes mashing more enjoyable for me, since I don't have to let the runoff go at some attenuated rate in order to improve sparging efficiency. Being an impatient person, I hated that part anyway.

Explanation? Perhaps the "long time" sitting in the cooler allows the water to fully dissolve the available sugars, so that longer runoff times are not needed. In any case, it sure works for me!

Subject: Grain mill

This past weekend I visited the Brimfield Fair.
(the flea market to end all flea markets,
I walked for 5 1/2 hours and covered less than half of it)

Among other things, I came home with a grain mill that appears
to be able to a fine job of crushing malt without pulverizing the
husk. Or making relatively fine flour.

The problem? The hopper is rather small. I would like to be
able to put in more than 10oz of grain at a time. True, I can
increase the capacity with careful use of a cut-off 2 or 3 litre
soda bottle. But I might be interested in a larger hopper for it
if I could find one.

Which leads to the other problem; I don't know what make it is.
It says `MADEinPOLAND' on the handle and has `OB' in a circle on
the side of the main casting. The whole thing is tinned castiron
except for the grinding plates which aren't tinned.
Any ideas what make it is? What *did* I get anyway?

From: polstra!norm@uunet.UU.NET (Norm Hardy)
Subject: Decoctions are a stirring experience

This being the summer of the decoction mash for me, I thought I would pass along some observations of the process and the results so far:

- (1) Some people erroneously think that doing a decoction mash will produce a maltier beer with aromas reminding them of Munich (or thereabouts). I have found that this is true when using German malted barley. But when using Klages, don't count on it.
- (2) Doing decoctions (double or single) with Klages leads to a further attenuated beer. This was true while using Wyeast 1056 Sierra yeast. Example: my typical 1056 ale goes from OG 1.046 to FG 1.013 or 1.014 as a rule, doing a step mash or a single infusion. With decoction mashes, here is what has happened: (Case 1) OG 1.048 to FG 1.010; (Case 2) OG 1.048 to FG 1.011; (Case 3) OG 1.044 to FG 1.009. These were all my "typical" ale of 7-8 lbs Klages, .5-1 lb Crystal, etc. The temperatures were 65-70f. Again, it seems that the decoction mashes cause more of the maltose to be available to be eaten by the yeast.
- (3) The taste is as expected dryer than usual, but smooth.

Is it worth the time and arm strength? For German malts, yes; you can get more of the malt character with the extended mashing process. For Klages I would say yes for a dryer beer only. Those who prefer a heavier body (for their beer) should shy away from the aerobic workout of decoction stirring.

RE: Article 240 (86 more) in rec.crafts.brewing:
From: Paula Burch
Subject: nitrosamines in homebrew?

>I have read that beer is full of nitrosamines. I rarely
drink commercial beer, and so I wonder:

Does homebrew contain nitrosamines?

ARF says:

I have been patiently waiting for someone to clear up this
issue but not seeing any knowledgeable response, I will put
forth what I know, which is just enough to be dangerous.

Years ago, in the late seventies, I think, when the
nitrosamine business was first recognized, a report was
published listing the concentrations in commercial beers.

I only recall a few benchmarks but it should provide fuel
for thought.

At the very top was Heinekens and lots of imports.

Bud was right up there with them but I don't remember the
exact position of amount.

Coors was at the very bottom with no detectable level.

The "media" told us that there was something in Coors'
process that had something to do with heat (or lack of) that
prevented nitrosamines from forming.

Shortly thereafter, "they" told us that all breweries had
switched to this process and the problem just went away.

I didn't believe a word of this whitewash but that was about
the time I quit drinking and I am now very sorry that you
brought it up.

Subject: Translations of teh German Beer Labels

I asked for a translation of a German beer label and got some excellent responses - thanks! Here's a summary... (I think the last comments for each item are the real version, as they were posted to me by a fellow from Germany :-)

> (on the neck label):
>
> Kulmbacher
> Kapuziner Schwarze
> Dunkles, Hefetrubes Weizenbier

Kulmbacher is a famous German brewer. "Kapuziner" is a brand name, and "Schwarze" means "black". "Dunkles" means "dark". "Hefetrubes" means there is yeast in the bottle. "Weizenbier" is wheat beer. So what you have is a bottle of Kulmbacher's "Kapuziner" dark wheat beer, naturally carbonated.

Capuchin Black, Dark, Yeast-containing Wheat Beer from Kulmbach

Kulmbacher is the brewer.
Kapuziner is a name, Schwarze means black,
Dunkles is dark, Hefetrubes Weizenbeer is a bottle conditioned
Wheat beer (yeast on bottom).

Kulmbacher: The Brewery. Located in Kulmbach, northwest of Nuernberg.
Kapuziner Schwarze: The 'style' of beer. A "Kapuziner" is a Capuchin Monk, and "Schwarze" means literally "black". The brewery is located in a monastery, so this should come as no surprise.
Dunkles, Hefetrubes Weizenbier: "Dark, cloudy with yeast, wheat-beer"

> (on the main label):
> (on the left side of label):
>
> Imported by Dieter Steinmann Inc.
> Garden City, NY (this is overprinted in the label)
>
> Gebraut nach dem deutschen Reinheitsgebot

"Brewed according to the German Purity Law"

Gebraut nach dem deutschen Reinheitsgebot: Brewed according to the German Beer Purity Law.

> alc. 5.3% / vol (this has overprinted with a black stripe,
> but I could just make it out)

Overprinted because American law forbids the printing of alcohol content on beer labels. (Go figure.)

> e 0,5 l

"Contents 0.5 liters"

"e" could be short for Enthalt, meaning contents.

The "e" stands for "einhalt" or "contents" as in contents: 0.5 liter.

e 0,5 l: "euronorm" 1/2 Liter

It was 1/2 l, but the 'e' has to do with standard measures as agreed to by the European community. Their 1/2liter isn't any different from our 1/2 liter, but is it indicated as being the 'euronorm'.

> (on central area of label):
>
> Kulmbacher
> Kapuziner
> Schwarze
> Hefeweizen

Again, "Kulmbacher Kapuziner black wheat beer"

> Kulmbacher Premium-Weizen

"Premium" means "best", just like in English.

Premium Wheat (beer) from Kulmbach

Kulmbacher Premium-Weizen: Kulmbacher Premium Wheat-Beer

> 1 Pint
> 1 fl. oz. (again, overprinted)

Strange...0.5 liters is about 17 ounces.

1 Pint : for those who can't hack the metric system
1 fl. oz.

> Imported beer
> Product of W.-Germany (overprinted)
>
> (on right side of label):
>
> (list of refund states - overprinted)
>
> Hersteller: Monchshofbrau Kulmbach

"Brewery: Kulmbach's 'Monchshofbrau'"; that is, the name of the Kulmbach's brewery that brewed this beer is "Monchshofbrau".

Manufacturer: The Kulmbach Monastic Brewery

Hersteller: MonchshofbrauKulmbach
Manufacturer: Monastery-Brewery (in) Kulmbach

> Mindestens
> haltbar bis
>
> 22.11.89

"Best when used by November 22, 1989"

Leastwise holdable (will remain fresh at least) until November 22, 1989.

Mindestens haltbar bis 22.11.89
Consume before 11/22/89 (this was oooooooold beer, probably didn't taste too good, eh?. Maybe a bit sour?)
Drink by. Literally translated, it means "keepable until at least:".

> and on the second bottle, it says:

>
> (on the neck label):
>
> Kulmbacher
> Kapuziner Weizen
> Kristallklares Weizenbier

"Kristallklar" is the opposite of "Hefetrube"; there is no yeast in the bottle.

Capuchin Wheat Beer. Crystal Clear Wheat beer.

Kristallklares Weizenbier: "crystal-clear" (filtered) wheat-beer

> (on the main label):
> (on the left side of label):
>
> Imported by Dieter Steinmann Inc.
> Garden City, NY (this is overprinted in the label)
>
> Gebraut nach dem deutschen Reinheitsgebot
>
> alc. 5.3% / vol (this has overprinted with a black stripe,
> and I could not make it out, though I assume
> it to be the same as the first bottle)
>
> e 0,5 l
>
> (on central area of label):
>
> Kulmbacher
> Kapuziner
> Weizen
> Kristallklar
>
> Kulmbacher Premium-Weizen
>
> 1 Pint
> 1 fl. oz. (again, overprinted)
>
> Imported beer
> Product of W.-Germany (overprinted)
>
> (on right side of label):
>
> (list of refund states - overprinted)
>
> Hersteller: Monchshofbrau Kulmbach
>
> Mindestens
> haltbar bis
>
> 25.12.90

"Best when used by December 12, 1990"

Mindestens haltbar bis 25.12.90: ditto except 12/25/90, again oooooold.

>I bought both
>of these in the Spring of 1991, and drank them this week. The
>Weizen beer did taste old. The Schwarze was not too bad, probably
>because the stronger taste was able to disguise some of the old taste.

Dark Weizen (aka Weissbier, weizen is a more Bavarian name) is always

stronger-tasting.

>Both beers had tremendous heads - like I'm used to seeing with the
>Spaten Weiss beer. The Schwarze had a bit of sediment in it - when
>I poured the first half of the bottle into a glass, it was okay, but
>when I swirled the sediment and poured that into the glass, the beer
>in the glass started to produce bubbles on it's own...

All weizen beers have tremendous heads, especially if you don't pour them correctly. The one with the sediment in it is unfiltered, so you get your full day's supply of B vitamins. Frankly, I can't drink Kristallweizen (filtered), don't like the sweet taste. The yeast in the Hefeweizen (unfiltered) moderates the taste. It is considered very healthy in Bavaria. In the North, they drink far and away more Kristallweizen. They think the yeast makes you fat.

The shelf life of weizen is reputed to be pretty short. And the hefeweizen does not travel well. When it gets old, it gets sour. It should be kept and drunk cold. Unfortunately, it can get pretty warm in the holds of those Polish freighters and in those warehouses in NJ. I have bought all of 6 bottles of weizen in the States and 3 of them were bad. I drink it when I go to Germany only. Or when it's fresh brewed here. stronger-tasting.

So, again, thanks for the replies - Ihor

From: gregg@maddog.anu.edu.au (michael gregg)
Subject: Dinkel, White, and CatsMeow.PS

Hello everyone,

In reply to Kent Dinkel re short ferments and SG testing:

I am always interested in these stories about fermentations taking "only" four days when they usually take 10. Except for a couple of batches I've had which turned out to have wild yeast contamination, I have never (in my short career of 22 batches) had a ferment go longer than 4 or 5 days and even then the exciting part is over in 2-3 days. Maybe I'm the one with the problem! So much depends on the yeast, the malt, the oxygen, etc.

Soapbox, please.

There are several good reasons to buy a hydrometer and do SG tests. A hydrometer is inexpensive, so cost is not an issue. It takes only a few minutes to test the wort, so it will not increase your time brewing. Once you've used it awhile, you'll need to test only at the start and end of fermentation when you have to open the fermenter anyway, so there is no additional risk of contamination (just don't put the test wort back in the batch!) It is a good idea to know the alcohol content of your beer, not just to tell your friends but so you can exercise responsible judgment in drinking your creation. 6% beer affects me a lot more than 3.2 and it's not always obvious from the taste how much alcohol is in there. The difference between final and ending SG is a measure of the quality of your technique and ingredients. Not that high alcohol means you did it better, but the SG tests before and after are another way to gauge how close you've come to your intended goal, and the next time you brew that recipe provide some measure of your repeatability (the hardest part of homebrewing I believe). Finally, for those of us copying a recipe we've seen or tasted, knowing the start and end SG is a good (but not sufficient) guide to duplicating the brew we liked. I, for one, am always a little annoyed to read a recipe that does not list the start and end SG's; alcohol content is often a consideration in deciding what to brew. (I know, it is possible to estimate from the ingredients, but that is tedious if you are flipping through a recipe book.) And if those aren't enough reasons, don't YOU want to know the alcohol content of your beer, just out of curiosity?

So don't be a worry wort; buy a hydrometer, relax, and have a homebrew.

On iodine testing (Jim White's question)

I bought my iodine at the drug store and it is indeed the stuff one puts on cuts. It turns jet black immediately in unconverted wort. I just put about 1/2 tsp of wort on a white plate and then add a drop of iodine at the edge of the puddle. If the iodine goes black or turns dark in a few seconds, the mash is not done. Don't use the grains, just the wort. To test your iodine (I don't think it can go bad, but I'm not a chemist) put a drop on a slice of raw potato. If it doesn't turn blue-black, get a different kind of iodine. If your mash at the start can't make the iodine black, maybe your malt is at fault. I have found the iodine test to be quite definite; suddenly after about 60 min of infusion mashing, the iodine no longer turns black. The only trouble I've had is doing stouts, which I make very dark. It is a

little hard to tell if the iodine turns black when you add it to a black liquid! So if there are other methods, I would be interested too.

And finally, about the PostScript version of Cat's Meow.

I had two problems printing it out, and find I am not alone. From a Sun Sparcstation, I could get only the last page of each ps file to print and some of the characters were incorrect, like apostrophes became U's, so I got CatUs Meow. After several suggestions from helpful brewers, the problem was solved by ftp-ing the files to a MacII and using a postscript downloader to send them to a laser printer. I would like to request that someone with a UNIX (Sun or otherwise) printable copy put it in the archives to save future generations the hassle I experienced.

Subject: english ales

Just delivered to my office: One bottle of Pilsner Urquell, direct from Czechslovakia, via Hungary, dated OCT91. I had also requested a Budvar, but that didn't happen for a number of reasons. My friend tells me that the Budvar he had was delicious. Hungarian beer was so-so.

Just by chance, I just received a case of Pilsner Urquell as a gift (when it rains it pours. That's a pun.). So I plan to do a blind taste test of the US version and the Czech version. Life is good.

And it will stay good. This world traveller friend of mine is off for England next week, and he says "I'll have much more luggage space available this time"! So, I'm looking for recommendations for English brews that are unavailable in the US. Hmm, a lambic would be a good idea too...

From: krweiss@ucdavis.edu
Subject: EZ test for sugar content?

And no, I'm not sure a specific gravity reading will tell me what I need to know...

About 4 batches ago I bought a 5 lb. sack of "corn sugar" to use for priming, instead of the little bags of "priming sugar" available at my homebrew shoppe. The "priming sugar" also contained a bit of citric acid and some heading agent, but I figured the bulk of it had to be corn sugar, so what the heck.

I've had several batches of beer come out totally flat since changing my priming sugar. The most recent batch used Wyeast Irish Ale yeast, which fermented like mad in the primary. I bottled with a priming syrup made of 3/4 cup corn sugar in about 1 pint of water, boiled for five minutes. I pour the priming syrup into the big glass carboy and siphon the beer out of my secondary on top of the syrup. Then I stir for a full minute with the racking tube, and proceed with bottling.

The bottles clear nicely, and leave a nice layer of yeast sediment at the bottom, so I know there's yeast in the brew. I suspect that there's simply nothing in my priming syrup that the yeast can eat.

I'm curious about whether I'm a victim of a labelling error or something. I tasted the "corn sugar", and it's sweet, but not as sweet as table sugar.

Is there an easy way to test this stuff at home, without benefit of access to a chem lab? I'd like to find out if it really *is* dextrose, and not lactose or some other non-fermentable sugar, and I'd like to find out if it is pure dextrose, or whether there is a non-fermentable adulterant in this sack. After three consecutive batches of flat beer, I'd like to know whether I've got a process problem or an ingredient problem.

The beers, BTW, taste just fine. They simply don't have enough carbonation to raise a head or tickle my nose.

The easist method of controlling temperature I've found was simply to put the fermentation vessel in a bathtub and fill the tub with water up to the level of the wort in the vessel. I monitored the temp of the water in the tub and when it reached 75 degrees, I put a couple of gallon milk jugs of ice in until the temperature was back down to 65 degrees.

With the mass of water in the bathtub, I was able to keep the tub temperature within that 10 degree range with just one ice immersion per day. You could probably get a finer temp range by more frequent immersion, as long as you have enough ice. With a 24 hour dipping, I was able to refreeze the milk jugs and use them the next day.

Subject: Rampant Infections... CURED!

Many thanks to those of you who responded to my desperate pleadings a while back.

I scrubbed the dickens out of my kitchen with a weak chlorine solution, and I now make sure that the A/C fan is off when beer is exposed to the air. I believe that what I had was an airborne infection of some sort, either a mold or a wild yeast. I have also taken to liberally spraying the air with Lysol several minutes prior to exposing my beer.

I have changed nothing else in my procedures and have already gotten one excellent batch of beer, with a 2nd batch to be kegged today. For my first batch under the new "Clean Air Act" :-), I used the same yeast that I had used when I was getting bad infections. I did this to see if it really was the air or if it was the yeast. The beer came out superb so I guess it was the air. The yeast was Whitbread Ale, my usual favorite.

The batch going into the keg today was fermented with Wyeast #1056. The quality of this beer remains to be seen, but I have a good feeling about it. (It probably won't last long enough for any latent infections to take hold anyway. :-)

Thanks again to all you helpful folks, and a big thanks to Rob for running the best damned digest on the net.

- --
Kevin

ning
and BFDers who are curious can try it at the October meeting (if there is any left.)

Thanks to Mike Sharp for the enormous bag of Cascade hops that he sold to me for dirt cheap. I'm glad you got tired of Cascade, Mike, cause I love 'em. If you've got any more, I'll take 'em cause I've almost used that whole bag already.

Jim,

I had the same problem with my first mash. The answer is that
there are two types of Tincture of Iodine sold over
the counter. One works for this test and the other doesn't.
I *think*
they put a coloring in one that interferes with the test.
Try a different brand.

Subject: Cooling

I used to use an AC in a small room. This was much too inefficient though.
Now I have a spare fridge with a Hunter Air Stat Energy Monitor (+- 2 degree control :-). You can get the Air Stat for \$20-25 and it will work much better than a timer could to keep an accurate temperature. Oh yeah you gotta punch a hole in the side of the fridge, cut the temp probe wire, run it through the hole, and wire it back together, but that's pretty minor...

Subject: Cooling

Reply to Bob Konigsberg regarding cooling :

I picked up an old restaurant milk cooler at the Salvation Army several years ago. You know the kind where you lift the ball to get some milk. It is all stainless steel and holds two 5 gal carboys including airlocks or blow-off tubes. I rewired to allow for a commercial thermostat to better control temp. Really required since most frigs won't adjust warm enough for fermentation. I also have a glow coil heater connected to thermostat allowing me to make ales in the winter. Works great! Granted it was luck finding this thing, you might try used restaurant supply places if you feel lucky. An old frig. obviously will work well, however they take more room and use more power but hold more stuff.

I also recently installed a window air conditioner in my wine/beer cellar. You need to vent the hot air outside or under the house as I did. You will also need to re-wire with a similar thermostat to better control unit. I use a 1/2 ton for a small room located off my garage. It keeps the liquids in the room at 60f within about a 1/2 degree. You need lots of thermal mass (ie beer and wine) to keep the temp constant. Don't skimp on the insulation around the room, its money in the bank. My unit only runs a few hours a day on the hottest days. Warning. Fermentation temps. below 65f will result in slow fermentations. Yeast need to be selected and acclimate themselves to cool temps to work well. Low temperatures and low pitching volumes make for slow fermentations and result in poor attenuation. I primarily use my air conditioned room for long term storage. Makes a big difference on the long term life of beer (as if you might have this problem).

From: Norm Pyle <pyle@intellistor.com>
Subject: liquid yeast cultures

My latest brew - a English bitter recipe - was my first try with a liquid yeast culture. I read on the package (Wyeast London Ale) that it should take about 12 hours for the yeast to be viable (at 70 - 80 F) after rupturing the internal yeast packet. It also said to add one day to this number for each month past the date stamped on the package.

I ruptured the packet in the morning, figuring on brewing the following evening. I just left it out on the counter since the air temperature was around 70 F. Well, within 8 - 10 hours the package was swelling to alarming proportions and I decided that I should brew as soon as possible to prevent an exploded yeast package and a contaminated culture (a friend had this happen to him).

Since I was ill-prepared to brew that evening, I had not pre-boiled and cooled my water. So I ended up with hot wort and hot water in my fermenter, with no hope of cooling it that night (I don't have a chiller and it was 11 pm). I threw the yeast package in the fridge to prevent further swelling until I could pitch in the morning.

To make a long story long, I pitched the following morning and didn't get any activity for about 30 hours. Now it seems to be fine, but I'm concerned (not worried, mind you) that the long lag time may have allowed other beasties to work on my wort.

Should I have left the yeast package out of the fridge overnight and risked explosion? Should I have made a starter wort instead and just brewed the following night when I would have been more prepared? What are some of the methods that you HBD'ers have used to make starter worts? Do you leave them in a small pot, put it in a jar, or ...?

It seems to me that the pure yeast strains are a better way to go but I hate spending an extra almost \$4 for something that leaves my wort (and work) hanging out in the wind for a day and a half. The dry yeasts I've used in the past have been very active in 8 hours or less.

As always, we thank you for your support.

From: Martin A. Lodahl <hpfcmr.fc.hp.com!hplabs!pbmoss!malodah>
Subject: Chiller; Fast Fermentations

In HOMEBREW Digest #720, Thomas Manteufel observed:

> ... I have a 8ft or so length of soft copper tubing
> I can use for an immersion wort chiller ...

I use 50', and sometimes feel it isn't enough. With that little surface area, you really won't get much heat transfer. When I was using 1/4" tubing instead of my present 3/8", I used 100', which seems like a nice round number.

And in the same issue, Kent Dinkel had a problem with Fast Fermentation:

>The problem (or maybe it's not a problem) is that the fermentation seems to
>be completing in half as much time as my previous batches (from ~10 days to
>~4 days). Here are the gory details

I've had the "going great guns" stage take anywhere from 3 weeks to 18 hours, depending on the recipe, yeast, degree of aeration, temperature, and for all I know, phase of the moon and conjunction of the stars. It can vary quite a bit ...

> I don't *think* the temperature is involved since I
>ferment in my basement and it's *cooler* now than my during my previous
>fermentations.

It's possible, though unlikely, the the previous fermentations were actually warmer than that yeast considers optimal ...

> Are 4 - 5 day fermentations uncommon?

By no means.

> ... Am I worrying too
> much? If my worrying is justified, any suggestions for remedies?

Possibly, or possibly not. It's possible that fermentation is "stuck" and only partially complete, and only your hydrometer readings could tell you for sure. The problem with bottling in that case is that if fermentation restarts, you could end up with glass grenades.

>Sorry, I don't have specific gravity readings -- I'm trying to keep my time
>down to 3-4 hours/batch (excluding drinking, of course!). A couple of the
>homebrewers that got me started suggested not bothering with specific
>gravity readings.

Bad advice.

> Their opinion was that the additional risk of infection
>from opening the fermenter was not worth getting the specific gravity
>reading which is useful only to tell friends the alcohol content of the
>beer.

Au contraire, it's most useful in exactly this case. Frankly, I could care less about the alcohol content of my beer. But I DO care if it's ready to bottle or not! Your friends have a very strong point in that the daily checks we're all tempted to do at first are more of an infection risk than anything else. But you really should divert a little wort before pitching to measure the SG and to taste, and when you think it might be done, measure the gravity again. I virtually never measure more than 3 times in a batch.

> (I'm sure that specific gravity is useful to the more serious
> all-grain homebrewers.)

Less so than to extract brewers, actually, because of the relationship between stuck fermentations and extracts described in earlier HBD items on the study by Ingledew, et al., at the University of Saskatchewan.

> They convinced me that determining when the
> fermentation is complete can be adequately performed visually by
> counting the
> bubbles/minute out of the fermentation lock.

That's all well and good, but it really tells you more about the present rate of fermentation than about its cumulative progress. It would be enough, if the only reason fermentations ever stopped was that the yeast ran out of grub. But that just ain't so ...

> ... Should I break down and buy a hydrometer?

Yes. And a good book (Miller or Papazian).

But for this present batch, even if you don't know the initial gravity, the present gravity might give you a clue to its status. Frankly, I'd bottle without worry if it were below 1.012 or so.

> next batch.

Russ, I don't want to start you worrying, but introduction of oxygen
after
the yeast have begun fermentation can cause excessive levels of diacetyl
to be
produced. So much, in fact, that the yeast's diacetyl reducing capability
can't
handle it all. The reason is that certain fermentation by-products
(sorry, don't
have my reference material with me) will combine with dissolved oxygen to
form
diacetyl. The dissolved oxygen introduced at pitch time is meant to be
consumed
by the yeast reproduction process.

But don't worry, diacetyl perception is highly variable in different
people. And
I happen to like it in low concentrations (i.e. Sam Adams Boston Lager).

Subject: brewpubs in Seattle

OK, OK, I know the Digest isn't really about this kinda thing, but I find myself in a desparate position and I guess I'm weak. I need suggestions about brewpubs in Seattle, particularly those close to (in?) Bellevue. Isn't there one in Kirkland?

OB homebrew note: I started a barley wine over the weekend. Mashing twelve pounds of grain is a chore. I did decide that an advantage to decoction mashing is that some of the hot break material forms in the final boil for the last decoction, and this stuff will settle into the grain bed. The wort was unbelievably clear, and I got relatively little boiler trub (especially considering I used 2 pounds of flaked barley). I guess if **too** much break material is in the lauter tun one could get kinda stuck.

From: Mike Zulauf <zulauf@orbit.Colorado.EDU>
Subject: begging kegging info

Hi everybody!

I've got a few questions about kegging equipment. I am looking into getting a system for a minimum of time and fuss. Does anyone know, for example, what a complete system from Foxx would cost? By complete, I mean keg, CO2 cylinder, regulator, two guages, and all hoses, connector's, etc. Since Foxx has an outlet in Denver, and I live in Boulder, would I be able to save by picking it up from them directly?

In the Classified section of the latest _Zymurgy_ there are some other possibilities. East Coast Brewing Supply in Staten Island has a system for \$205. Black Mountain Homebrew Supply has a system for \$150, shipping included. IMO Homebrew and Meadery Supply has a system with 2 kegs for \$199. Other suppliers, that don't list prices, include Braukunst in Carleton Minnesota, Koepl's Brewing in Rolling Meadows Illinois, and Ozzies (?) in Comstock Park Michigan.

Has anyone had any experience with any of these businesses? Does anyone have any other suggestions? I would prefer to be able to buy the entire system in one place, with a minimum of effort. Of course I would also like to do this without bankrupting myself!

Thanks in advance!

From: MIKE LIGAS <LIGAS@SSCvax.CIS.McMaster.CA>
Subject: CABA All About Ales Contest

As promised when I first notified HD readers about the upcoming Canadian Amateur Brewers Association (CABA) "All About Ales Contest", here are the recently released details of what, where, when and how to enter.

ENTRY DEADLINE:

Entries must arrive at 'To Your Taste' before 5:00 pm, Friday, October 4th, 1991. Late entries will not be judged. No exceptions will be made!

WHAT TO ENTER:

1. Only homebrewed beer can be entered.
2. Homebrewed beer includes beer crafted by the entrant at an "on premise" commercial establishment.
3. Beer must be classified as one of the classes listed (see CLASS DESCRIPTIONS below).
4. Beer must be bottled in brown or green 284-355 ml glass beer bottles clean and free from any identifying marks.
5. Three bottles of each entry are required. The first bottle must be submitted by October 4th, 1991. For those passing to the second round, two more bottles will be required by October 22nd, 1991.
6. CABA entry forms and recipe sheets must be filled out and submitted.

HOW TO ENTER:

1. Select as many beer classes as you wish to enter.
2. Submit one clean, unmarked 284-355 ml brown or green glass beer bottle of beer for each class entered.
3. Complete a recipe sheet for each class entered and attach it along with the entry fee (\$5.00 for members, \$7.50 for non-members). Attach the entry form to each bottle with a rubber band (DO NOT USE GLUE OR ADHESIVE TAPE). Entry fees must be made payable to CABA.
4. Deliver or send your entries to 'To Your Taste'.
5. Only one bottle of each entry is required for the first round of judging. Those individuals passing on to the second round will be notified by telephone between 7:00 and 10:00 pm, Thursday and Friday, October 10th and 11th. A further two bottles will then be required by 5:00 pm, October 22nd, 1991.

Note: This change in rules is hoped to lessen the shipping cost for members.

If however you wish to submit all three bottles for the October 4th

deadline, attach the recipe sheet and entry fee to bottle one, and the labels provided to the other two entries. *LATE ENTRIES WILL NOT BE JUDGED*.

WHERE TO SEND ENTRIES:

'To Your Taste' has generously offered to assist with the collection of entries. Take or send your entries to:

To Your Taste
317 Jane Street
Toronto, Ontario
Canada, M6S 3Z3

The phone number for 'To Your Taste' is: (416) 767-8951

If you are sending your entries, you may use either Bus Parcel Express (BPX) or United Parcel Service (UPS). Check the white pages in your telephone directory.

If you are asked the contents of the package, answer "Bottles but they are double boxed and well padded".

Please pack your entries well. Broken entries cannot be judged!

Line the inside of the carton with a plastic garbage bag. Partition and pack each bottle with adequate material, top, sides and bottom.

JUDGING

First round judging will be done by recognized beer judges between October 7th and 10th, 1991. Those passing to second round will be notified as described above.

Second round and best of show judging will be done by recognized beer judges on October 26th. The decisions of the judges will be final.

AWARDS

Awards for first, second and third in each beer class, best of show and novice will be presented on October 26th, 1991, at the Awards Dinner following the Annual General Meeting. Prizes which have been donated by suppliers will also be presented at that time. All entrants will receive the judging sheets used to evaluate their entry.

CLASS DESCRIPTIONS

Class 1: Canadian Ale
- a mild, pale, light bodied ale about 4.75% alc/vol. Full hop and malt flavour.

Class 2: Pale Ale

- this class represents the classic pale ale. With original gravities greater than 1.050, these ales are usually dry and hoppy, due in part to hard water high in calcium carbonates and sulphates.

Class 3: English Bitter

- gold to copper coloured. Low carbonation. Medium bitterness. May or may not have hop flavour and/or aroma. Low to medium maltiness. Light to medium body. Original gravity less than 1.050.

Class 4: Brown Ale

- typically a sweet, dark brown brew from Southern England, with 3 to 3.5% alc/vol. Drier and more reddish-brown further north, 4.4 to 5% alc/vol.

Class 5: Trappist

- amber to copper. Spicy with slight sourness. Fruity/estery. Hints of banana or clove. Alcohol evident. Malty. Medium bitterness. Hop flavour can be evident. Hop aroma low.

Class 6: Porter

- a dark English medium-bodied ale originating in London. Its darkness comes from the use of black patent malt rather than roasted barley as in Stout. High hopping lightens the mouth feel to give a clean, quick finish to an otherwise heavy beer. Varying in style from bitter to mild to sweet, dark brown to black. London style Porter can be from 5 to 7.5% alc/vol.

Class 7: Dry Stout

- heavy hopping and the use of roasted, unmalted barley create a clean, bitter, roasted coffee-like character with little hop flavour or bouquet. This is the Irish stout style and is 3.5 to 6% alc/vol.

OBTAINING ENTRY FORMS AND RECIPE SHEETS

Members will receive this information by mail. Non-members should request entry forms and sheets from:

CABA
19 Cheshire Drive
Islington, Ontario
Canada, M9B 2N7

If you have any questions feel free to send them my way. I will also send info about the CABA to anyone who is interested and who missed the advertisement posted in HD a few months ago.

Subject: Re: Fast Fermentation

Kent Dinkel <dinkel@hpmtaa.lvld.hp.com> talks about a recipe of his:

> On Saturday (9/7) I started brewing my 4th batch. It's an attempt to
> brew
> a bitter consisting of:
>
>6.6 lbs Munton Fison Amber Malt Extract
>13.2 bittering units (bu) worth of hops (bu = alpa content * ounces)
 ^^^^^^^^^^^^^^^^^^^
>.5 ounces Cascade hops (finishing)
>2 pkgs Munton Fison Ale Yeast

I'd like to point out that there are more than one "bittering unit" definition/"standard". The one that is mentioned here is really "AAU"s (Alpha-Acid Units). I don't know how widespread this is, but I've only seen "bu" and "bittering units" (as in "40 bittering units") used only in conjunction with "IBU"s (Internation Bittering Units), which is quite different from AAUs.

For more information, see the article "Calculating Hop Bitterness in Beer" by Jackie Rager, in the special 1990 issue of Zymurgy.

I now (from experience) advise people to **always** make a
starter. Pitching straight in from the packet is a sure way to
make one worry. :-)

Here is how I make my starter culture. I use an old orange juice
bottle that fits the stopper I use on my primary--that way I just
transfer the airlock and stopper from the starter to the primary.

I boil some water in and around the starter bottle, letting it
boil away. During this time I boil up about a quart of 1.020
wort (no hops). (Calculating the 1.020 is slightly unsettling to
me, since I invariably do it in my head at the last moment.
It usually comes out to be a couple of ounces of dry malt
extract. One quart is 1/20 of a 5 gallon batch, etc.)

When the wort has boiled ten minutes or so, I pour out the
boiling water from the starter bottle and pour in the boiling
wort. This sits on a trivet in the air for awhile until it is
just hot to the touch. Then I cool it in a cold water bath in
the sink (trying to avoid temperature shock that would break the
glass).

Then I flame the outside of the yeast package, cut open, flame
again, and pour into the starter wort. Put the airlock on, and
use it in the next day or three, making sure it gets a krausen
on it first.

This inevitably leads to a fast start, within hours, of fermentation.
Really makes it easy for me to relax and enjoy the fermentation process.

I had a similar thing happen to me this past weekend. I received my
order
from Alternative Beverage containing the supplies for my Christmas beer.
I had
intended to wait a couple of days to brew it because there are a couple
of guys
at work who are interested in brewing and they wanted to come over and
sit in.
Well, UPS had performed their famous drop-test on the package with
sufficient
force to rupture the bubble in the yeast packet (WYeast Irish Stout
#1084) and
it was threatening to explode when I opened the box. I made a starter
solution
with 1/2 cup DME and 1 cup water and put it into a beer bottle with an
airlock.
I then set off to buy the spices and planned to brew the next day
(Saturday).
I brewed the beer on Saturday evening and the whole house smelled
Christmasy.
At about 11:30 p.m. I pitched the yeast into the carboy, put on an air
lock,
and went to bed. When I got up Sunday morning, the foam was threatening
to
blow the stopper out so I put on a blowoff tube (5 gallons of beer in a
6.5

gallon carboy). Now, I have used this same yeast in a stout and I did not make a starter for it that time. It took 12 - 14 hours before *any* signs of fermentation occurred. The stout turned out fine but I like the fact that, with a starter, fermentation takes off much more quickly. Making a starter would have allowed you to wait until the next day to brew and also not have such a long lag time after pitching. Your beer will probably be alright but you may want to consider a starter in the future. You'll then get the yeast to take off more like the dry yeast to which you are accustomed.

By the way, I racked the Christmas brew into the secondary last night and it smells wonderful!!

From: keng@ic.MENTORG.COM (Ken Giles)  
Subject: Re: liquid yeast cultures

Regarding making yeast starter cultures:

Wyeast yeast is manufactured in my area, so I never have a packet more than a month old. I break the inner seal 12 hours before preparing the starter. This equates to 36 hours before I expect the brewing to be finished, because I let the starter do its thing for 24 hours before pitching.

When preparing to pitch in 5 gallons, I boil 3 cups of water with 3/4 cups of dry malt extract. I boil for 20-30 minutes. I then pour this into a 750 ml champagne bottle which I then cool in a sink full of cold water (sometimes using ice to hasten the process). The champagne bottle was previously sanitized and pre-heated with hot tap water. When the temp of the starter wort reaches 70F, I pitch the Wyeast packet and put on an airlock. Actually, I keep the airlock on while it's cooling, too. I have an airlock stopper that fits the champagne bottle.

When preparing to pitch in 10 gallons, I use a 1 gallon apple juice jug instead of the champagne bottle. I boil 1/2 gallon (plus 1 cup for evaporation) of water with 2 cups of DME, using the same procedures as above. My carboy stopper fits nicely into the 1 gallon jug.

Sometimes I add hops in arbitrary amounts if the mood strikes me.

From: richer@ionic.HQ.Ileaf.COM (Al Richer)  
Subject: Bottling technique

On the advice of Carl West, I've decided to send out a short missive on my bottling technique. May this help you avoid too much trouble with a non-drinking spouse, as it has with me.

This technique involves the use of the family dishwasher as a bottling table, thereby avoiding spills and drips all over the kitchen. It also allows you to go directly into dishwasher-sterilized bottles without having to unload them, avoiding potential source of contamination.

First, the bottles. I load the dishwasher with the quantity of containers I'm going to need for a run (usually two cases. I also add the proper number of caps in a mesh bag, so that they will also be sterilized. I then run the dishwasher without soap and with heat dry on, producing sterile glass as an end product.

While all of this is happening, I am racking my beer into my primary and priming it. The primary is then carries from the cellar into the kitchen and placed directly above the dishwasher, with the capper on the counter next to the sink. On the other side of the sink is a clear counter area, reserved for the bottled brew, covered with an old towel whose purpose will become evident.

After the bottles are done the dishwasher cycle, I open the dishwasher door. It then becomes my bottle holder for racking. With the siphon ready to go, I line up 12 bottles on the dishwasher door. I then run down the row, filling each bottle with the racking tube. The dishwasher door catches all of the runoff, avoiding unnecessary later cleanup. The bottles are then capped, passed through a stream of water to rinse of overspill, and arranged on the old towel to dry off. In this method, cleanup becomes a breeze, as all I have to do is close the dishwasher door and turn it on!

In this way, I can usually get 2 cases of beer racked, primed and capped in a total time of ~ 1.5 hours, counting the cleanup before and after.

Thought you'd be interested,

ajr

From: "MR. DAVID HABERMAN" <habermand@afal-edwards.af.mil>  
Subject: Honey Ales

I have finally caught up on all the digests that I received while on vacation for 3 weeks in Germany, Belgium, and Denmark. There was some discussion and requests for honey ale recipes. Here are 2 that I have brewed that came out very well.

#### HONEY ALE

for 5 US.gallons  
4 lbs. Buckwheat honey  
4 oz. Styrian Goldings hops  
7 grams Red Star Ale yeast  
1 tsp. acid blend  
1 tsp. yeast nutrient  
1 cup corn sugar

SG: 1.031  
FG: 0.997

Boil honey and 3 gal. water with 3 oz. hops for 47 min., add 1 oz. last 7 min. Before adding hops, skim off the skum that rises to the top. Cool and pour into fermenter and top to 5 gallons. Add acid blend, nutrients and re-hydrated yeast. When fermentation completes, mix with 1 cup sugar, a little yeast and bottle.

This was the very first beer I ever made and 7 years ago most people I knew didn't worry about the bittering units of the hops. I would guess that they were around 3% AAU's. Red star was the main yeast used at the time. Yeast nutrient is necessary since the honey does not have the required food for the beasties. I used buckwheat honey because I like the flavor. Do not drink this beer until at least 1 month after bottling. Since it is made from honey the ale improves with age. A bottle that I saved for 4 and a half years tasted so good that I wish I had saved more! I plan on trying to reproduce this beer again. The beer had a very nice honey aroma and flavor. The hops were enough to balance the sweetness. I don't think that I would change anything except try to make more and keep it a while before drinking.

#### ROCKET J. SQUIRREL HONEY WHEAT ALE

for 5 US.gallons  
3 lbs. Bavarian dry wheat extract  
2 lbs. Clover honey

1/2 lb. Buckwheat honey  
1/2 lb. light Crystal malt (20 lovibond?)  
1 oz. Centennial hops 11.1% AAU's  
24 oz. Wyeast 1056 slurry from a batch 3 months previous and stored in 'fridge

SG: 1.050  
FG: 1.005

Bring 1 and a half qts. water to 170 deg. F and turn off heat. Add crystal malt and steep for 40 min. Temperature was 155 deg. after adding malt and stirring. In another pot, start 3 gallons water boiling. When it comes to a boil, strain in liquid from crystal malt and also pour another quart of hot water through the grains. Add the wheat extract and honey. Skim the skum off and then add 3/4 oz. hops for 1 hour. Turn off heat and add the last 1/4 oz. hops. Whirlpool and let stand to let the trub collect. Siphon into carboy and top to 5 gallons. Add yeast and shake vigorously. Used the "wet t-shirt" method to keep it cool during the Southern California summer. Bottle with 4 oz. corn sugar. Has a very nice floral honey/clove aroma. Nice clear golden color. My beers have been much clearer since using the whirlpool technique to get rid of most of the trub before fermenting. Has a clove/wheat beer flavor not much honey flavor, I didn't want to use too much buckwheat honey in order to let the wheat flavor come through. I haven't had this very long, so I don't know what it will do with age.

I was on the way to a Maltose Falcons meeting with some friends and we were trying to decide on the next beer to make. I saw the Rocky Raccoon Honey Lager recipe and thought it looked interesting. It called for Cascade hops, but I knew I had Centennials at home which are high alpha cascades (called CFJ90 last year). I don't have any lagering facility yet, but I did have some ale yeast. The resipe also calls for malt extract and as I was walking around the store, I saw a new product, the dry Bavarian Wheat extract. I used that instead. I also put in a half pound buckwheat honey instead of all clover. Since only the proportions resembled the original recipe, I decided to keep the Rocky part and change the rest of the name. Rocket J. Squirrel is the full name of the squirrel in the Rocky and Bullwinkle cartoon.

Hi there,  
I just called the Zip City brew pub (3 W. 18th St. Manhattan 212-366-6333) and they said that it looked like they'd be opening sometime in the first few weeks of October. They are sending out a mailing in a week or so, you can call and get onto their mailing list.

About this clove taste... Over the weekend I had Anchor's wheat beer. I liked it a lot, but I'm not sure if it was all that clovey. It tasted less of cloves (or what Joe Germani called a clove taste) than my brown ale did. Now I hadn't noticed this flavor (aftertaste?) in my beer as a clove taste. Until Joe brought it to my attention as something I might want to try to get rid of, I thought my beer tasted fine :( (pout) Can someone suggest a beer that tends to taste strongly of cloves so I can experience this for real? Or is the Anchor wheat strongly cloved (cleaved?) and I just have a high clove tolerance?

From: Ted Manahan <tedm@hpcvcbp.cv.hp.com>  
**Subject: Yeast starters**  
Full-Name: Ted Manahan

This note is to thank the participants of this digest for helping me improve my brews immensely. Following advice given in the digest, I have changed my procedure for pitching yeast. I now have very strong fermentations with short lag times, using liquid yeast cultures. Here's how I do it:

I now always use a starter of about 3/4 quart. I give the starter a good shake to aerate it before adding the liquid yeast. Before pitching, I also aerate the wort by stirring vigorously with a spoon. These two changes alone have decreased the lag time to about six hours or less.

I purchased a "yeast bank" from William's brewing. This allows you to freeze yeast cultures for up to a year. I get six or seven batches from a single package of liquid yeast. To restore these cultures, you have to do a two or three step process, using only about two tablespoons of weak wort at first, then about 1/3 cup, then about 3/4 quart. Each of these steps will take a day.

There will be a beer judge certification exam on September 21st in Grants Pass, Oregon. Is anybody else reading this digest going to be there?

Subject: Chico Ale Yeast?????

First a question:  
=====

Is Wyeast #1056 "American" the same as the "Chico Ale Yeast" that I've heard everyone talking about?

Is the "Chico Ale Yeast" really the same stuff that Sierra Nevada uses?

Now some comments:  
=====

I used the Wyeast #1056 in my most recent batch (an IPA.) THIS WAS MY FIRST EXPERIENCE WITH A LIQUID YEAST. Boy was that stuff slow to start! The date on the package indicated that it was slightly less than a month old, yet it still took two days for the package to puff up. It took another day and a half for the one quart starter-in-a-wine-bottle to reach full krausen. It took about 10 hours in the fermenter before there were really visible signs of fermentation.

The fermentation was even somewhat different than I am accustomed to. The krausen never got really tall, but what was there was pretty dense. Fermentation proceeded at a moderate and steady pace of about 80 bubbles per minute for about 3 days. Aside from the spiciness of the Cascade hops, there was very little else in the way of "aroma" emanating from my airlock. I particularly did not notice a lot of the diacetyl or ester aromas that usually come out with an ale yeast.

The keg is soaking as I type this. I will keg the beer this morning and BFDers who are curious can try it at the October meeting (if there is any left.)

Thanks to Mike Sharp for the enormous bag of Cascade hops that he sold to me for dirt cheap. I'm glad you got tired of Cascade, Mike, cause I love 'em. If you've got any more, I'll take 'em cause I've almost used that whole bag already.

From: R\_GELINAS@UNHH.UNH.EDU (Russ Gelinias)  
Subject: starter, O2

To Norm who is starting to use liquid yeast: Learn how to make a yeast starter. Liquid yeast is well worth the effort, but the unpredictability of the swelling of the package, and the low yeast count even after it has swelled, makes the use of starters almost required. They're easy. Relax. Check the HBD archives for howto.

Ken sez: O2 introduced after ferment can increase diacetyl. News to me. May not be a bad thing (I like Sam Adams a lot too). Seems weird though, since you can duplicate the diacetyl buttery flavor of Sam Smith by pitching into O2 \*deficient\* wort. I do remember reading an article about some research where adding O2 to the wort 12-18 hours after pitching helps out the yeast, but they made no mention of diacetyl. Someone also pointed out that I actually added O2 deficient water (boiled/cooled), so I might not have added all the much O2 to the wort, even with the splashing. Fortunately, the yeast is neutral (Wyeast Chico ~ Sierra Nevada), so any diacetyl should be noticeable. Just have to wait and see.

Date: Wed, 11 Sep 91 11:35:48 PDT  
From: ek@chem.UCSD.EDU (Ed Kesicki)  
Subject: Corn vs. Cane

Does anyone have first hand knowledge of what happens to the taste of beer that has been primed with cane sugar instead of corn sugar? I'm afraid my partner and I might have done this (the oldest mistake in the book--storing things in unmarked containers). The resulting beers have an unpleasant bitter aftertaste. I read somewhere that fermenting cane sugar gives a "cidery" taste, but I don't really know what that means. Any feedback would be appreciated.

Another question--a survey question: I would like to see some postings by people who have experience using liquid and dry yeast on similar beers under similar conditions. How do the tastes compare? How much of a difference was there? Our beers done with liquid yeasts had less off-flavors (harsh bitterness) than those done with dry yeast. However, they were different types of beers, so it's hard to compare, and there is the added variable of the cane sugar that we might or might not have used. Specifically, the dry yeast we used was English dry yeast from William's Brewing (used on 3 IPA's: one all-extract and 2 partial mashes as per Dave Miller); the liquid yeasts were included in the kits we bought from William's (dry stout and wheat beer). All were done in coastal San Diego, temp's in the 70's, but may have gotten above 80 many times. One of the IPA's, in particular, was very strange: after racking from primary (at 3 days, after most activity had stopped), the beer started to clear up and not much fermentation was evident. After one week, the fermentation kicked in again, producing one glug every 30 sec in the airlock, and continued 2 weeks like this. We finally bottled it but the beer is raunchy--harsh clinging bitter aftertaste--almost completely undrinkable (except maybe at the end of a party). Anyway, the other IPA's were better behaved, but still have that slight harsh off-flavor, not what we would expect just from the hops. Different hops were used to bitter each batch, but that off-flavor is still there. We'd like to blame the dry yeast, but I'm not sure if that's fair. Anyone?

Date: Wed, 11 Sep 91 13:46:41 PDT  
From: chad@mpl.UCSD.EDU (Chad Epifanio)  
Subject: Mead, Dry-Hop, Wort Chiller

Hola senors:

I thank the fellow who slapped me around and told me to chill about my mead. Just as he predicted, it became violently active within 4-6 days. My problem was that I use a plastic primary, and the only way to judge fermentation is by a bubbling airlock. The odor definitely has sulfur overtones, which I regard as good, since that means the fermentation is scrubbing the mead clean of the metabisulfite used for sterilization(I hope!).

In times past, I regarded dry-hopping as dangerous and nonproductive. I always just let the finishing hops steep in the pot for awhile. A month ago, I noticed several discussions on the merits of dry-hopping, and, well, curiosity got the best of me. I made a batch of India Pale Ale; or a close facsimile 8>) After racking to the secondary, I threw in an ounce of Mt.Hood pellets and 8oz of oak chips. This I let sit for a week, and bottled. I chose Mt.Hood because it is described as spicy and flavorful. I popped open a two-week old bottle yesterday to test the carbonation. Holy hops, Batman! The smell was like a flowering wild bush, and the taste I reckon was similar to sucking on a handful of hop cones. I'm not sure that I liked it. Aging will probably improve it dramatically, but if I ever dry hop again, I'm damn sure not going to put in a full ounce. Just one man's opinion.

I disagree with some of whats been said about immersion wort chillers. I presently have 30' of tubing, and granted, that just won't so the job in under 30 min. However, simply increasing the total length of the wort chiller may Not increase your efficiency appreciably. My reason is thus:

The wort chiller is a heat exchanger, transferring the heat of the wort to the running cold water in the chiller(basically). The temperature gradient is what causes the heat to transfer. Basic. Now, by increasing the length of the tube, you increase the total surface area. However, the effective surface area of transfer will remain the same after a certain length. Say the tap water temp is 50F. At the start of the chiller, the temp diff will be from wort temp(say 200F) to chiller temp(50F). The water picks up heat, and say 15' into the pipe the water temp is 125F. The temp gradient is getting smaller. Say 30' into the pipe the water has heated to 200F. The temp gradient is zero past this point. No more heat can be removed. By only increasing the chiller length, the efficiency is not increased. Hold those flame guns, boys. This is just an illustration and not an equation. The transfer rate is also effected by the water volume flow and the temperture of the water.

Obvious solutions to the problem are to increase the water flow or make the water colder. For most occasions, these options are either a pain or impossible. I propose that making the effective surface area of transfer larger will speed up the process considerably. Instead of one coil of tube, make two. Have a T-joint at the start of the chiller. Make one section into an inside coil, and the other side into an outside coil. Connect them at the ends with another T-joint, and you're in business. In fact, this is exactly the strategy employed by an ingenious inventer in the Gadgets special issue of Zymurgy(Can't remember his name). I am in the process of

constructing one of these, and after the first trial, I'll report on the effectiveness.

Date: 11 Sep 91 16:46:08 EDT  
From: Jeff Frane <70670.2067@compuserve.com>  
Subject: Nitrosamines in Beer

I've been eavesdropping on your Homebrew Digest from the Compuserve network; are you all on Unix networks?

Anyway, to the point: Nitrosamines in beer. I remembered this vaguely from a tour of Great Western Malting in Vancouver, Washington years ago. I just spoke with one of their lab people, John Cutie (sp?) who explained the following. There is a natural precursor, dimethylamine (sp?) in \*germinating\* barley. It is easily nitrosated in Nitrosadimethylmine, which is carcinogenic particularly in the presence of oxides or nitrogen. If the malt comes in direct contact with these combustion biproducts, nitrosadimethylmine will result. Great Western no longer has any direct gas-fired malting kilns; theirs are either indirect hot water or air to air. There \*are\* malting houses which use direct-fired kilns and they subsequently purge the malt with SO<sub>2</sub>.

If this is at all garbled, or the terminology is imprecise, please put the blame on me where it belongs, not on John. I'm pretty sure this is where the question of nitrosamines in beer originated, and it seems pretty clear that there should be none in commercial beers \*or\* in homebrew. CAVEAT: there are some homebrewers making their own malt, and they would do well to pay attention to this problems. I'm not sure what they use for heat, but a gas oven sounds like a BAD idea.

Date: Wed, 11 Sep 91 15:16:32 -0600  
From: Norm Pyle <pyle@intellistor.com>  
Subject: Hot Break

Since this question seems to have been lost in the mysterious missing HBD's,  
I'll try again:

What is this business called "hot break"? I assume from my reading that it has to do with quickly chilling the wort in order to pull trub out of solution. If this is true, I also assume one would then rack the wort off of this trub before fermentation. Am I in the ballpark? Is it worthwhile (taste-wise) to risk contaminating your (my) wort for this? After all, it is a cooled vat of microorganism food just waiting to be eaten...

I may be in left field for all I know. Anyone like to set me straight?  
Thanks.

Norm

From: eisen@kopf.HQ.Ileaf.COM (Carl West)  
Subject: Loose hops, Wort chiller

Loose hops:

Last night I used loose hops for the first time. I think I'm interested in a hop sock. Any reason I can't use a portion of a pair of panty hose?

Also, there were a whole bunch of what looked like seeds floating around in there, I was under the impression that hops aren't generally allowed to go to seed. I never noticed any seed-like objects while using hops plugs.

I saved a few of them to see if they'll sprout. I don't know what I'll get but I'll know that their mother was a Fuggles.

Wort chiller:

Last night was also the first use of my new immersion wort chiller. It consists of:

a 5' long 3/8" id utility sink hose hooked to the faucet and clamped onto 25' of 3/8" copper refrigeration coil with

5' of 5/16" vinyl tubing stuck on the other end and leading back to the sink

It took 2 1/2 gal (yeah, extract) from a slow boil to 80F in about 20 min. Seemed quick enough to me.

The problem with the vinyl tubing was, when it got hot, it got really soft, and when it got really soft it fell over and kinked, and when that happened, it blew right off the copper tubing which then shot hot water all over the ceiling.

Now the vinyl is twist-tied to the input hose so it won't kink.

I'm learnin'. When I stop, bury me.

Carl

70 F.  
> Well, within 8 - 10 hours the package was swelling to alarming  
proportions and

So far, I've brewed using only liquid yeast (Wyeast), and I've noticed the following: if the date on the package is less than ~2 weeks old, the packet will usually swell to "alarming proportions" within 12 hours. If the date is a month or so old, the package will take from 18-24 hours on up to reach that stage. All this assumes that I haven't thrown the unruptured package in my ~40 deg.F refrigerator for awhile (note that the package was kept refrigerated at my local supply shop, but warmed up while I took it home). If I have thrown the package in my refrigerator, the packet can take 48 hours or more to reach that stage.

I'm not sure what is going on. I have heard that yeast do not like going from a high temp to a low temp (they weaken or die?). If this is true, it does help to explain what I am seeing.

> Since I was ill-prepared to brew that evening, I had not pre-boiled and cooled

. I  
> threw the yeast package in the fridge to prevent further swelling until  
I  
> could pitch in the morning.

You might want to consider making a yeast starter. Advantages:

- \* Once the package has swelled, you just use it to make a starter, which is very easy. You don't have to put the package in the refrigerator and risk killing or weakening any yeast.
- \* When pitching, you have a larger yeast population, which will decrease the lag time and make it more difficult for other beasties to contaminate your wort. For me, this is a \*BIG\* plus. I use liquid yeast to reduce the chances of contamination, and so I want to avoid long lag times.

Disadvantages:

- \* You need a little extra equipment (a jug, perhaps an extra airlock, etc.).
- \* It's a little extra work.

Some people don't use yeast starters, and they are quite happy with the results. Other people, who are perhaps used to dry yeast, do not like long lag times, and so they use yeast starters. You'll have to decide if using a yeast starter is right for you.

Making a yeast starter is easy. Just boil and cool:

- \* A quart or so of water (I try to use about 600 ml, which is about 2/3rds of a quart).
- \* 6-8 heaping tablespoons of DME.
- \* A pinch of yeast nutrient.

Pour this into a sanitized jug (don't forget to aerate the "wort"), add the liquid yeast (after letting the package swell very large), and fit an airlock to the jug. After a couple of days, just pitch into your primary fermenter.

I use a 1-liter Erlenmeyer flask to make my yeast starter. I just dump everything (but the yeast) into the flask, boil for several minutes (I just place the flask directly on my gas stove), cool, add the yeast, and stick a sanitized rubber stopper with an airlock on top. This is very easy, as I don't have to sanitize a jug, or worry about how to pour the wort into the jug.

From: Dave Rose <CHOLM@HUBIO2.HARVARD.EDU>  
Subject: Trouble-shooting.

I am a new subscriber to the digest and thought I would start off by asking three questions that have bothered me for some time. I am an all-grain brewer and am generally satisfied with the results, but I have some chronic trouble.

First: Many of my beers have a subtle but noticable off taste which I would describe as "plastic-y." This plastic taste is not evident when tasting the beer but rather (if you'll excuse me) when burping after drinking it. Some-times I can detect a hint of this taste/smell if I smell the CO2 coming out of the airlock during fermentation. Does this sound familiar?

Second: I have a pretty constant problem with hazes. Sometimes these are chill hazes and I figure that is because I do a one-step infusion mash so there is sometimes residual protein, although I am using only pale ale malt.

But other times the haze is even at room temp. Any hints?

Finally, my head retention is usually ok but doesn't compare to that of good commercial brews. I am careful about cleanliness so I don't think it is grease or detergent related. Short of using artificial heading agents, does anyone have any ideas? These questions paint a pretty dismal picture of my brewing, but actually these problems are rather minor. But I won't be truly happy until I can solve them. Any input is appreciated. thanks. d.

PUBLIC ANNOUNCEMENT

I would like to publicly announce the creation of a new electronic mailing list. This new list was created for the promotion of beer related activities in the North East. This is not a competitive list to the Home Brew Digest and is not for discussions of homebrewing issues.

The charter of this list is to promote homebrew clubs, homebrew competitions, tasting, picnics, pub crawls, brewpubs, breweries, homebrew suppliers and any other organization, news or activity related to beer in the New England area.

So it is with great pleasure that I announce:

THE NEW ENGLAND BEER CLUB

This list is an un-moderated public forum and may be joined by anyone. It is expected to be a low volume mailing list. If the number of mailings per day gets large then it will be digested.

To subscribe: beer-request@rsi.com -or- uunet!semantic!beer-request  
To post: beer@rsi.com -or- uunet!semantic!beer

On subscription please include your Full Name and Email Address in the message text.

Brought to you by:  
The Wort Processors  
Boston's Oldest Brewing Club  
Cheers,

In HD 719, "Ihor W. Slabicky" <iws@sgfb.ssd.ray.com> writes

>> I am wondering whether someone can translate some of this  
>> German language text that I found on two German beer labels:  
>> Kulmbacher  
from the town of Kulmbach. I think that's in northern Bavaria, between  
Nu"rnberg and Hof, but I am not sure. It is quite famous in Germany  
for its beer.

>> Kapuziner Schwarze  
Kapuziner is a type of monk, probably the type they have at the  
monastery that started the brewery. Kapuze = hood (on clothing).  
Schwarze is a form of schwarz = black, but I can't figure out how the  
ending fits in here. It is either a feminine or plural ending, but I  
see no feminine words or plurals here.

>> Dunkles, Hefetrubes Weizenbier  
Dark wheat beer, murky from yeast. (Murky doesn't sound very good,  
but I can't think of a better word right now).

>> Gebraut nach dem deutschen Reinheitsgebot  
brewed according to the German Purity Law

>> e 0,5 l  
standardized half liter bottle.

>> Hersteller: Monchshofbrau Kulmbach  
Producer: Mo"nchshofbra"u in the town of Kulmbach. Don't forget the  
umlauts; they are important in German. Same for tru"b, above. Anyway,  
Mo"nch = monk  
Hof = court or estate  
Bra"u = brew

>> Mindestens haltbar bis 22.11.89  
can be preserved until at least November 22, 1989.

>> Kulmbacher  
>> Kapuziner Weizen  
>> Kristallklares Weizenbier  
Kapuziner Wheat from Kulmbach; crystal-clear wheat beer

>> I assume that here so many overprints because the beer was imported.  
>> The 'e' by the 0,5 l probabably means it is an 'export' bottle of  
>> 0.5 liters (which it is).  
Nope. e = Einheitsflasche = standardized bottle (I think, anyway; you  
find that on a lot of glasses, too.)

>> The dates are either when the beer was  
>> bottled, or when it should be drunk by - but which?  
When it should be drunk. See above.

>> I bought both of these in the Spring of 1991, and drank them  
>> this week.  
Obviously, this beer doesn't sell too fast at that store.

SN Big Foot Ale is a Barleywine, which means it is brewed to be very high  
in alcohol. Personally, I dislike an "alcohol-taste" in my beer, which  
distracted me from all the other flavors in the SNBFA, so I'm afraid I  
cannot provide more commentary on it. I suggest you try SN Pale Ale (one  
of my favorite beers) for what \*I\* would consider a more "conventional"  
tasting beer. SNPA is flavorful and has a wonderful hop nose.

I recommend against punching any holes in the walls of refridgerators.  
I was going to do this to mount my four faucets, but was talked out of  
it by my dad. He pointed out that, between the inner and outer walls  
of your fridge is a layer of insulation (usually fiberglass). Since the  
inner wall is cold, it would attract moisture which would condense on it  
and soak into the insulation. Wet insulation (besides being a home for  
mold) simply does not insulate. If the temp probe does not reach around  
to  
the door of the fridge with the Hunter Airstat plugged into the wall,  
I recommend that you mount the Airstat on the side of the fridge with  
double stick tape, run the temp probe in through the fridge door (mine  
is on the hinge-side so it doesn't get in the way) and use an extension  
cord to bring power to the Airstat.

Subject: Klages malt

What is the deal with Klages malt? Is it more like Pale Ale malt or Lager malt or is it another thing entirely? I have always used pale ale malt in my all-grain beers. Some things I've read in the homebrew archives suggest that Klages has a higher enzyme content and might thus be easier to deal with. But does that mean that I need to do a step mash? What sort of beers can be brewed with this stuff? I have a number of books including Papazian and Miller (two of the latter, in fact) and I don't remember reading any Klages info there. Help? -d.

Article written by: Dan Kislenko (Wine Columnist)

#### RARE BREWS SHARE STAGE WITH WINES

It's been a part of civilization for 6,000 years. It has its own patron saint, Gambrinus. And the great epic poem of Finland, the Kalevala, spends more time talking about it than about the creation of the world.

It, if you haven't guessed, is beer. And it will be in the limelight this weekend at the International Beer, Wine and Food Show.

Several hundred of the world's finest and most unusual brews will rub shoulders with wines and lots of good things to eat. Among the prize winners on hand will be Zambezi Export from Zimbabwe, Grimbergen Optimo Bruno from Belgium, and some of the new wave of premium microbrewery beers from across Canada.

Best of all, apart from simply tasting them, most of what's on show will be available to buy to take home, through a liquor store on site.

The show runs this Friday and Saturday, Sept. 13 and 14, from noon to 10:00 pm and Sunday from noon to 6:00 pm. The place is the International Centre, 6900 Airport Road in Toronto (to get there head for the airport but exit on Dixon Road, turn left onto Airport Road, and go a few kilometres along to Derry Road. The centre is on the right, with lots of free parking).

Admission is \$10 per person, plus you have to buy alcohol samples at cost (most are under \$1). Only folks 19 years of age or over are allowed in, so leave the kids at home. Don't forget the designated driver either.

From: Kent Dinkel <dinkel@hpmtaa.lvld.hp.com>  
**Subject: Thanks for replies**  
Full-Name: Kent Dinkel

Thanks to everyone who replied to my problem (directly to me and via HBD) about my "fast" fermentation. It sounds like 3-4 day fermentations aren't that uncommon. In addition, the consensus is that I should have paid more attention when Papazian listed "hydrometer" as a necessary piece of brewing equipment. It will eliminate the guess-work in determining when the brew is ready for bottling. I'll try to pick on up tonight on the way home!

If the SG is still too high, how exactly do I introduce more yeast into the carboy? My guess is that there won't be enough oxygen left for the new yeast to complete its respiration cycle. (Bad guess?) Therefore, although I didn't notice Papazian explicitly addressing the problem of stuck fermentations (other than "don't worry, have a homebrew"), I assume that I should follow his instructions on culturing yeast (create a small wort, let it cool, add the yeast and slap on an air lock, let it hang around at room temp until active fermentation is visible, pitch the yeast -- all in the company clean room, of course!). Is my assumption correct?

Thanks again for all the help!

Kent

>  
>jeanne

I'll bet you got a shock. The Bigfoot Ale is  
a barleywine. Barleywine is to beer what Jolt Cola is to  
coke. Most barleywine recipies call for nearly  
double the ingredients  
that a "normal" beer has, and a "normal" beer for this alias  
is going to have more body and flavor than michelob.

If you want recommendations for good beer, this is  
the alias. If you can get Anchor Steam, that's a great one.  
Pilsner Urquel is a Czech. beer that's wonderful. If you're on  
the West Coast, Red Tail Ale is also first rate in flavor.  
Keep trying different brands. When you find one you like, ask  
you local homebrew shop (or this alias) how to reproduce it.

From: <S94TAYLO%USUHSB.BITNET@CUNYVM.CUNY.EDU>  
Subject: Alcohol tolerance of Red Star Ale Yeast??

I am wondering how much alcohol my Red Star Ale Yeast can stand. I understand that your average ale yeast doesn't start to tail off until above 6%, but I also heard that it doesn't actually die off until above 12%. Can anyone verify this for me? I may need to toss in a little champagne yeast to finish off a batch of killer cider I've got going. In case you're curious, the recipe is as follows:

1 gallon pasteurized apple cider  
1 12 oz. can (Seneca?) 100% Granny Smith apple juice concentrate  
1 cup white sugar

Pour out enough cider to make room in the glass jug for the concentrate and the sugar and the pre-re-hydrated yeast (I would recommend using champagne yeast). Mix thoroughly and put an airlock on it. Come back about a week later, check the gravity and if it bottoms out, prime it with 1/5 of 3/4 cup of white sugar, then bottle it in two 2-liter plastic soda bottles, well-cleaned, of course. Let it condition for about a week and...enjoy!

Subject: 718 where are you?

Richard says to relax, that 718 will be in the monthly archive. Well, I have found many of the monthly archives that were missing a digest or two. Mr. Mossberg does a good job down there, but some slip through the cracks.

I have a small pile of requests here for 718. I still haven't received it.

If anyone did, (and I'm beginning to wonder), I'd appreciate a copy and will be most pleased to send it on to the requests I already have and the ones I'll probably get as a result of this posting.

On another subject: I talked to the folks at Catamount brewery in White River Jct. in Vermont yesterday. They were going on at some length about the upcoming Christmas Ale. I didn't discover this micro until after last Christmas. Sounds like it will be good. The brewmaster says it is his personal favorite of all they brew. Those in the Northern New England area, keep an eye peeled.

Lee> Or is the Anchor wheat strongly cloved (cleaved?) and I just have a  
Lee> high clove tolerance?

I also just tried the Anchor Wheat this weekend. Very disappointing --  
lacks the full body and the smooth complexity of the South German Weizens  
it tries to emulate. Bummer. No cloves to speak of, either.

For a good commercial example, you could try the Franziskaner Hefeweizen  
(by Spaten). If you're in NYC, the Manhattan Brewing Co has (4 weeks ago,  
anyway) a good Hefeweizen you should try... can't recall the  
clove-coefficient, tho...

Subject: P.Urquell taste test

Somehow, in the middle of an evening full of crying baby and bratty 2-year old, I managed to do a side-by-side taste test of a Pilsner Urquell brought back by hand from Czechslovakia, and one that had arrived in the regular imported way. I wasn't able to set it up as a blind test; I was more concerned with keeping track of which was which and not spilling. Here's the results:

The bottles were slightly different. The Czech bottle was 11 oz., the US was 12 oz. The labels were similar, but had some small differences. The major difference was that the Czech bottle had the words "Ur-Pils" and "Alc 4, 1%Vol" on it. The Czech bottled was dated "Oct 91", I couldn't figure out the US date.

Unfortunately, the Czech bottle was slightly light-struck; medium skunkiness, which went away about halfway through the glass. The Czech version was also lighter in color. It also didn't have nearly the hops aroma as the US version, but a non-light-struck bottle might have fared better. Both had a strong malt flavor, but the US version was much sweeter. I couldn't tell if it was malt sweetness or finishing hops sweetness, though. They both had about the same amount of hops bitterness.

My wife chacterized the Cz. version as "more robust, more hearty", and I have to agree. The US version seemed smoother, the Cz. version was more aggressive, notably in the carbonation, but still very smooth too.

An interesting and enlightening session. 2 quite different and delicious beers.

From: mcnally@Pa.dec.com

Subject: wort chilling

Chad Epifanio, in HBD722, says that using colder-than-from-the-tap water with an immersion chiller is "a pain or impossible". Here's a suggestion: throw a little money at the problem and buy a pump. Mine cost about \$70 at a local hardware store; you could probably do better. I use my lauter tun (which has a garden-hose spigot) as a reservoir of chilled water, and simply pump it through the chiller. In less than an hour, atmospheric moisture begins to condense on the outside of my boiler. I also save water, which in northern California is considered a good thing.

Subject: Re: Immersion Coolers

Comment on Chad Epifanio's recommendation on parallel coil immersion wort cooler.

I indeed came to the same conclusion a few years ago with my 50 foot long immersion cooler. I modified it to be two 25 foot coils in parallel. You should talk with someone about balancing the flows in each leg to maximize the efficiency. There are tables that indicate equivalent tubing lengths for T's and L's. Find a mechanical engineer and give him/her a few brews for some help designing. My parallel cooler does indeed cool faster than the single long cooler. I can cool 11 gal of wort in a 15 gal keg in about 20-25 min depending on tap water temp. You can pre-cool your water before it goes to the cooler by running your tap water through another immersion cooler placed in a 5 gal pale in some ice water. This helps during those summer months when the tap water temp. can be very high in some areas. Fast cooling is very important  
in minimizes DMS in your final brew.

Subject: Re: O2 deficient wort

In HBD #722, R\_GELINAS@UNHH.UNH.EDU (Russ Gelinias) says:

> you can duplicate the diacetyl buttery flavor of Sam Smith by pitching  
> into O2 \*deficient\* wort.

I have not heard this before. I was aware that an oxygen deficient wort will increase ester production. Could you be confusing the two? Or maybe I have confused the two. It is my impression (from the books I've read) that diacetyl production requires the presence of oxygen. I'm not trying to be quarrelsome, but I genuinely would like to know what your source is for this statement.

From: John\_Zettler.ADFMcLean\_CSD@xerox.com  
Subject: Sierra Nevada Bigfoot Ale - Jeanne Sova

IMHO, Sierra Nevada Bigfoot Ale is extremely malty and hoppy. I guess a good generic description is overpowering flavor, very strong.

It is truly a "Barleywine", and the local Safeway claims it to be "the strongest beer/ale made in the USA". I have noticed no difference between the Sierra Nevada Bigfoot Ale purchased here in Virginia and that which I have purchased and consumed in California. Apparently it travels well and "keeps" for a reasonable amount of time. By the way, it retails between \$8.00 and \$12.00 per six pack here, where the Commonwealth of Virginia takes a reasonable attitude on sale of beer and wine (grocery stores, 7-11, etc.), and thus fosters competition that allows good selection at reasonable prices (case sales of premium american lawnmower beer at \$10 - \$12 per case).

From: rich@progress.COM (Rich Lenihan)  
Subject: Priming questions / recipe input wanted

A couple questions on priming:

1. I've been brewing for a few years now, and I've never used a bottling bucket when priming. I pour the boiled corn sugar syrup directly into the carboy, cap, slosh it around a bit, wait 20-30 minutes, then siphon directly from the carboy. I get pretty good carbonation with this method (sometimes too much). The only time my beer was under-carbonated was the one time I substituted DME extract for corn sugar (in equal amounts). I'm not sure if this was due to my method or due to insufficient DME (maybe both). My question: Is there a compelling reason why I *should* use a bottling bucket? My method was born out of ignorance. Until recently, I was unaware that anyone bottled this way.

2. DME vs. corn sugar for priming. The one time (see above) I used DME for priming, my beer was under-carbonated. There was some carbonation, but not much (much finer bubbles, too). This may have been due to not enough DME (4oz, my usual amount for corn sugar), but I decided using DME wasn't worth the effort. I'm not a beer purist, so again, is there a compelling reason (ie. from a taste or aesthetic standpoint) why I should switch to DME?

Finally, my birthday is approaching and I was thinking of brewing a birthday bock to celebrate the occasion. This will be made with probably 6lbs light DME, 1 can hopped Pilsener extract (I've had this for a while and need an excuse to use it) and maybe 1 or 2 lbs. of honey for 5 gals. This will be fermented warm (okay, so maybe it'll be a barley wine). I'm looking for suggestions for other things to add to this brew (hops, spices, etc.). I'm looking to make something that's distinctive but not too unusual. Any pointers, suggestions, or even recipes would be appreciated.

Thanks...

Rich

Subject: Re: Hot break

In HBD #722, Norm Pyle asks:

> What is this business called "hot break"? I assume from my reading  
that it  
> has to do with quickly chilling the wort in order to pull trub out of  
solution.

You are describing the "cold break". The hot break happens in the boil.  
I've  
found that the hot break is much more apparent in an all-grain brew than  
in an  
extract brew. What happens is that the agitation of the wort, along with  
the  
heat, causes complex proteins (albumins?) to collide and combine  
(coagulate)  
into clumps. This forces them out of solution. Depending on the protein  
content  
of the malt being used, the clumping appearance can vary from small  
particles to  
small pieces of rags. The protein material settles out once the agitation  
stops  
(i.e. heat turned off) and is usually left behind in the kettle. Some  
people  
believe that the mechanical action of loose hops (not in a hop bag)  
encourage the  
formation of hot break material. And in my kettle with an outlet at the  
bottom,  
the loose hops act as a filter bed for the hot break material.

The cold break involves coagulation of less complex proteins (and other  
materials) by chilling.

> If this is true, I also assume one would then rack the wort off of this  
trub  
> before fermentation. Am I in the ballpark? Is it worthwhile (taste-  
wise) to  
> risk contaminating your (my) wort for this? After all, it is a cooled  
vat of  
> microorganism food just waiting to be eaten...

Is it worthwhile? My current opinion is that it's primarily a religious  
issue.  
Will your beer be different? Probably. Will you notice it? Maybe. At any  
rate,  
I believe it's a question that each brewer must answer for themselves.

Date: Thu, 12 Sep 91 12:13:08 CDT  
From: tomm@pet.med.ge.com (Thomas Manteufel 5-4257)  
Subject: questions: copper cleaning and old recipes REDUX

In HD.720 I posted several questions re: wort chillers and old recipes. Thanks to those that sent cleaning suggestions, and yes, those that pointed out that 8 ft is just too short (actually the chunk of coil is 13 ft [as if it made a difference]). I hang my head in shame (notice the lower case?). OK, so I have resigned myself to having to buy a new 50 ft coil. Now I don't have to worry about cleaning the chunk I have, but the cleaning suggestions will help keep it shiny.

What size do I get? I did a few calculations in the classical physics class style (ignore messy factors such as heat diffusion rates, densities, and tube thickness) and compared 3/8" O.D. to 1/4" tubing. Given a 50 ft length of tubing, 3/8" has a volume of 66.24 cubic inches and a surface area of 706.86 square inches. The ratio of volume to surface area is 10.67%. For the same length of 1/4" tubing having a volume of 29.45 cubic inches and a surface area of 471.23 square inches, the ratio is 16%. In theory, the 1/4" tubing has more surface area per volume, hence better cooling efficiency. It costs less, is more readily available, is easier to work with, and would displace less wort. (How much of a gallon is 29 cubic inches anyway?) A disadvantage I see is that due to the smaller size, I will be able to run only half the amount of water through it over time, so cooling time will/may not be as rapid as with 3/8" tubing. Has anyone done even an empirical test of tubing diameters? Should I go ahead with the 1/4" tubing, or is there something wrong with my assumptions?

I also posted a request for any leads on 1860's style american beer. The only response (thanks, Jay) suggested the library, which I will do, but without a lot of confidence. Second call for help. Anyone?

Thank You,  
Thomas Manteufel

From: tima@apd.MENTORG.COM (Tim Anderson)  
Subject: Yet Another Liquid Starter Comment

I've brewed only with Wyeast liquid yeast. At first, I didn't make a starter at all, just pitched from the packet. Then, a few months ago, I started making a starter in a wine bottle (as several have described). This cut lag time to active fermentation about in half. For my last batch, I made a "double" size starter: a 1.5 liter wine bottle nearly full for a 5 gallon batch. I had very active fermentation in just a little over 4 hours! (I also go to great pains to aerate) I'm convinced. Big starters and extreme aeration: The only way to go.

I made the starter in two steps, starting with a 750 ml bottle, then pitching to the larger bottle. Next batch, I intend to skip the small bottle step and see how that goes.

From: kla!kirkish@Sun.COM (Steve Kirkish)  
Subject: Easy bottling and How do you flame a yeast?

I've been reading the HBD for a while now, but haven't seen mention of this method of bottling. I used to bottle using the familiar but messy siphon technique, whereby you may get a good, air-bubble-free siphon going through all the various tubes and sundry plumbing for your bottling if you start trying when you pitch the yeast :-). But when I went out to buy my own equipment, my local brewshop was selling 6 gallon plastic buckets with plastic taps you could screw into the side of the bucket, down low. Now, bottling's a cinch. I just rack to this bucket, put it up on the counter, and draw off a flat one into the bottle. No muss, no fuss, cleaning out the bucket is easy, and you don't have to fret about losing that precious siphon (or beer!). I do try to minimize splashing when I'm filling, and had no problem with the first batch I made this way (a tasty porter/stout-like ale)

Now, then. John DeCarlo mentions in HBD #722...

>Then I flame the outside of the yeast package, cut open, flame  
>again, and pour into the starter wort.

Maybe it's that I'm still just a novice, dry-yeast user, and not up on these colorful terms used for liquid yeast, but pray tell, how do you "flame" a yeast package? Do you insult it openly, in public ;-)? Actually, it's a real question...I'd like to understand the terminology.

Lastly, great entries lately in the HBD, especially #722, the "special" liquid yeast issue. Destined to be reference as much as the special Zymurgy issue. One thing I like about this digest is that all the advanced techniques encourage me to improve my process! Keep up the good work.

From: James Carmin <JCARMIN@OREGON.UOREGON.EDU>  
Subject: Bottles

Homebrewers:

Having just uncapped a homebrew--very carefully--the top of the bottle broke, making my ginger/pepper laden Tumultuous Porter good only for drawing slugs in my garden.

As I have had an average of one bottle breaking every two batches of homebrew, I'm wondering if others have had this problem.

I (re)use a variety of bottles. Henry Weinhard Ale (green bottles; screw caps) have had problems in the past been the only plastic bottles I've had problems with in the past, but tonight it was a Negra Modelo bottle.

Does anyone know how many times commercial breweries reuse their bottles?

Any suggestions?

James

Subject: The Joy of Barleywine

In HBD 722, our pal Algis addressed "No-Caps" Jeanne's question:

```
>jeanne writes:
>>overwhelming urge to try new, "real" beers.  so last night i had a
sierra
>>nevada big foot ale.  and let me tell you, michelob is like water
compared
>>to it.
>
>> ... my question is, to you connoisseurs, how would this beer
>>be described?  is it considered hoppy, fruity, or what?
>
>SN Big Foot Ale is a Barleywine, which means it is brewed to be very
high
>in alcohol.  Personally, I dislike an "alcohol-taste" in my beer, which
>distracted me from all the other flavors in the SNBFA, so I'm afraid I
>cannot provide more commentary on it.
```

Barleywines, as a rule, are quite intentionally out of balance, in the direction of malt. They are sweet (sometimes overpoweringly so), both from their high alcohol content as Al. has pointed out, and from the large residuum of unfermented sugars. They are very heavy in body, and usually blonde to red in color, but rarely hoppy. They sometimes have a raisiny or Madeira-like complexity. I love them, but because they are such an extreme style, prefer them in the little "nip" bottles of 6 or 7 ounces, at cool room temperature, on a winter's night next to a warm fire, while reading a good book. In that sense, they're the beer world's answer to vintage Oporto. The first one I tasted was Young's "Old Nick" at a semi-formal tasting, and like most of the others present, dumped most of my sample into the spit-bucket. They take some getting used to ...

```
> ... I suggest you try SN Pale Ale (one
>of my favorite beers) for what *I* would consider a more "conventional"
>tasting beer.  SNPA is flavorful and has a wonderful hop nose.
```

Each to their own taste. SNPA is, in my opinion, a world-class beer, marred only by its cloyingly perfumey hopping. Heck, if we all liked the same things, there'd only be one brand of beer! But Jeanne, I imagine that bottle of Bigfoot pretty convincingly demonstrated that Michelob represents one of the least interesting corners of the beer world ...

Subject: The Famed Chico Yeast

In HBD 722, Kevin asked:

>Is Wyeast #1056 "American" the same as the "Chico Ale Yeast" that I've  
>heard everyone talking about?

Yes.

>Is the "Chico Ale Yeast" really the same stuff that Sierra Nevada  
>uses?

Reputedly. I haven't done any rigorous A:B comparison tests, but my  
impression from using both 1056 and yeast cultured from a SNPA  
bottle is that the cultures behave differently, but produce very  
similar results. My bottle-cultures seem to give a more  
vigorous-appearing fermentation.

>The fermentation was even somewhat different than I am accustomed to.  
>The krausen never got really tall, but what was there was pretty  
>dense. Fermentation proceeded at a moderate and steady pace of about  
>80 bubbles per minute for about 3 days.

Dry yeasts lead a hard life. After living in a dilute molasses  
solution, they're kiln-dried into dormancy, only to be yanked  
abruptly from their torpor later, possibly in a sugar solution,  
which subjects them to substantial osmotic stress. The survival rate  
is not good, for most strains. I don't know this, but have always  
suspected that dry yeast producers must select their strains with a  
sharper eye to simple survival than to the final brewing  
characteristics, a constraint liquid cultures don't impose. That  
may explain why most dry yeast really seem to "get with the  
program": the process selects for vigor. I was suprised and  
uncomfortable with the leisurely pace of my first liquid-culture  
fermentations. Now they seem normal to me.

On Thu, 12 Sep 91 09:45:08 EDT,  
Chris Shenton <chris@asylum.gsfc.nasa.gov> said:

Chris> I also just tried the Anchor Wheat this weekend. Very  
disappointing --  
Chris> lacks the full body and the smooth complexity of the South German  
Weizens  
Chris> it tries to emulate. Bummer. No cloves to speak of, either.

Anchor Wheat isn't trying to emulate South German Weizen. Fritz Maytag  
has called Anchor Wheat his "lawnmower beer", it's the lightest beer  
in the Anchor line. There's a local (I'm in San Diego) brewpub that  
also makes it's lightest beer with a proportion of wheat. And Byron  
Burch, brewer/author, mentioned somewhere (I think it was the Yeast  
issue of Zymurgy) that one of the Wyeast strains was well suited  
to "California style wheat beer". It seems to be a lighter (color,  
body, alcohol), more balanced/less hoppy version of Pale Ale.

Speaking of "lawnmower beer", did Fritz invent this term, or did  
he take it and apply it to his wheat beer? The Anchor brewery tour  
was the first place I'd heard it.

Date: Fri, 13 Sep 91 10:46:32 EDT  
From: srussell@snoopy.msc.cornell.edu (Stephen Russell)  
Subject: priming bucket, DME vs corn sugar

Greetings, mad scientists....

In HBD #723, Rich Lenihan asks:

>A couple questions on priming:

>1. [text omitted] My question: Is there a compelling reason why I  
>\*should\* use a bottling bucket?

Two reasons I can think of: one, to insure proper mixing of the priming  
solu-  
tion and the wort (I put the priming solution in the bucket first, then  
siphon  
the wort in with it); two, to minimize the amount of sediment that gets  
carried into the bottles. These are interrelated, for in order to mix  
well  
you might stir up the sediment. Disadvantage: one more siphoning step  
that  
may introduce oxygen and microorganisms.

>2. [text omitted] is there a compelling reason (ie. from  
>a taste or aesthetic standpoint) why I should switch to DME [for  
priming]?

Caveat: I have not performed the A-B comparison experiment on this  
topic.

According to Miller in TCHoHB, you will find a distinct taste difference.  
This is due to corn sugar being fully fermentable whereas malt extract is  
not.

(this is also why you have to use more DME...1 1/4 cups vs 3/4 cups, I  
believe

I read in Zymurgy last year) Esters, diacetyl, etc., get produced from a  
DME fermentation, not from one with corn sugar. These levels will be  
higher

in your beer as a result. Miller therefore recommends against extract  
priming

for lagers and gives cautious approval for ales, in which esters and  
diacetyl

are an acceptable part of the flavor/aroma profile.

Na zdrojcie,

STEVE

I use either 3/4 cup corn sugar or over a cup of DME for the same level of carbonation. No, I haven't really noticed the difference, but it makes me feel better as a beer purist :-)

From: Christopher Gene BeHanna <cb2s+@andrew.cmu.edu>  
Subject: Re: Fear and Loathing in the Great PPM vs. mG/L Debate...

One mole of water weighs about 18 grams and has  $6.02252E+23$  molecules.  
One liter of water weighs exactly 1000 grams at 4 degrees centigrade.  
That  
gives  $1000/18.0 = 55.6$  moles of water in one liter of water. 55.6 times  
Avogadro's number is  $3.35E+25$  molecules in one liter of water. So, if  
you  
have a ppm figure, you then need to change it to a parts per liter  
figure,  
which is done like so:

$\text{ppm}/1000000 * 3.35E+25/\text{Liter} = \text{ppL (parts per Liter)}$ .

Now, change ppL to milligrams by finding the molar weight of the ion,  
the number of moles of the ion, and multiplying:

$n = \text{ppL}/6.02252E+23 = \text{number of moles}$ .

$n * \text{molar weight} = \text{g/L}$ . Now multiply by 1000 and you'll have mg/L.

Hope this helps,  
Chris BeHanna

> syrup directly into the carboy, cap, slosh it around a bit, wait  
> 20-30 minutes, then siphon directly from the carboy. I get

I, too, used this priming method for years, out of simple ignorance of  
any  
alternative for a while, and then out of a belief that it minimized risk  
of  
infection. I now use the priming bucket (actually I use a priming carboy)  
method. The main advantages are that I get \*much\* less sediment in the  
bottles using this technique, and the beer seems to clear faster and more  
completely.

From: Donald Oconnor <oconnor@chemistry.UCSC.EDU>  
Subject: DME vs corn sugar; bottling bucket

In HBD 723 Rich Lenihan wonders about using DME as a substitute for corn sugar in priming. Only about 2/3 of the sugars contained in DME are fermentable while corn sugar (glucose) is completely fermentable. Thus, you should use about 50% more DME than corn sugar to get the same level of carbonation. It's unlikely that one could detect the taste difference resulting from priming with one or the other in most full-bodied beers. A cup of corn sugar is only about 1/3 lb.

Rich also wonders why people use bottling buckets. Good question since transferring the beer to another container before bottling has many disadvantages such as (1) adding oxygen to the beer (2) exposure to additional surfaces which increases the risk of contamination (3) increased

time in bottling. Its very easy to use a carboy headpack to start the siphon directly from the carboy and avoid these worries.

From: Frank Tutzauer <COMFRANK@UBVMS.BITNET>  
Subject: A sweet ending

Several weeks ago, in this august forum, I asked for help with my problems of too-sweet beer. The answer most people suggested, you'll recall, was: more hops. The stout I brewed subsequent to receiving this advice is now done, and I can report back, like I promised. In addition to the hops in the hopped extract, I used 1 oz. of Bullions (alpha = 9) at the beginning of the boil, a half ounce of Northern Brewers halfway through the boil (alpha = ?) and a half ounce of Cascades to finish. Therein followed a short fermentation in the mid to high 70's. When I opened the first bottle, it wasn't at all sweet. It was, in fact, bitter (yaayy!), with a nice creamy head that lasts nearly to the end of the glass. The beer has less body than I expected, and the roasted barley flavor comes through stronger than I expected. In addition to the hops, I suspect that the roasted barley may be covering up some of the sweetness. The beer won't win any awards, but when I finished the first glass, I said to myself, "Hmm, I think I'll have another." So, I'm on the right track.

Again, thanks.

Subject: corn sugar

In reference to Ken Weiss' comment about "corn sugar", several years ago I ran into the same problem. I had purchased some dextrose that was used for making candy. It turned out to have only 15% fermentables in it.

You might ask your homebrew shop to sell you larger amounts(they will usually discount for larger amounts).

From: larryba@microsoft.com  
Subject: HBD #733 & Dave Rose

Dave Rose has several questions. Here are some of my Opinions:

Klages: Universal malt. Can mashed any old way. Low husk content, low husk tannins, high diastatic power, good yields, dirt cheap. Klages are "fully Modified" meaning protein rest is optional. I made a stout with 7lb of klages, 1lb flaked barley, 1lb roast barley - single infusion mash and it cleared out fine after a couple of months. I did a step mash of the same recipe and it also cleared just fine.

Haze: if you have haze even when the beer is warm it could be one of the following: starch (incomplete conversion), Yeast: non-flocculent or Infection. My beers (ales) never cleared until I started adding gelatine when racking to the keg (1/2 tsp dissolved in 1 cup boiling water). Of course they never were allowed to age very long either %-]

Head: commercial beers sometimes use head helpers. You can use a little wheat or barley flakes to get a similar effect. If you keep it down to 4oz/5gal batch you probably won't see any protein haze even if you only do a single infusion mash. Head retention also seems to be a function of conditioning - maybe you are just drinking too fast?

Plastic taste: My wife claims/complains that all my beers have a unique aroma in the burps. As best I can tell it is due to the late addition of hops in the kettle, typically 1 oz of something aromatic for the last minute before chilling. My stouts, which have no late additions, don't have that effect. Perhaps this is what you are noticing?

From: Dave Rose <CHOLM@HUBIO2.HARVARD.EDU>  
Subject: Extract yields...

I am curious about how high extract yields are among the all-grain brewers out there. The oft-quoted number from Miller is 33. I have rarely gotten above 30, and though I am working on solving this, I wonder whether others are doing better on a regular basis. If you want a real eye-opener, go through some of the Zymurgy special issues and look at the award-winning recipes. I don't have an issue with me, but when I figured out the yields for all the recipes (excluding those that add adjuncts which make the calculation more complicated) I didn't find anyone getting over 30. The average was something like 25 and some were as low as 17! There seemed to be an inverse relationship between the yield and the amount of grains being used, i.e. the worst yields were in barley wines and the like where lots of grains were being handled. This makes me suspect that a lot of the loss comes in sparging, since it is hard for me to understand why starch conversion efficiency would be dependent upon the size of the mash. In open defiance of all the laws of homebrewing, I am \*worrying\* about improving my extract, and I'm interested in hearing the experiences of others. Thanks. d.

Subject: Raspberry Stout

Hi All,

Well, my second batch has been in the bottle about a week. It's the Raspberry Stout from "The Winners Circle".

I opened a bottle last night to see how it's getting along and was immediately disappointed. Very undercarbonated. In my first batch I had used 3/4 cup of corn sugar and ended up with overcarbonation and so I back off to 1/2 cup. Am I going to see any more carbonation over time?

Also, though the smell is wonderful and has the mouth feel of a good stout, there is a very harsh aftertaste. I'm hoping that it will smooth out as it ages, but wondered if anybody has any comments.

>vigorous-appearing fermentation.
```

All the recent discussion of preparing yeast cultures leads me to ask how one would culture the yeast from a SNPA bottle. I've never seen a bottle of this beer - does it have a layer of sediment at the bottom from which to start? Or is there a method of culturing the yeast from a filtered beer? There are some locally-produced microbrews I'd love to try to culture from...

Waiting patiently for my Zymurgy yeast issue to arrive,

Tom

From: dbreiden@mentor.cc.purdue.edu  
Subject: High temp fermentation

Hey all,

I've heard this and that about various schemes to keep a fermenter cool, but what I'd be really charged about is a strain of yeast that allows high temperature fermentation without too much in the way of bizarre flavors.

So, does anyone know of a yeast strain that can stand fermenting at an average ambient temp of 80 deg (F)? By stand it, I mean will ferment at that temperature without producing an inordinate amount of esters or phenols or whatever get produced at high temps. If anyone does know of such a critter, I'd also appreciate it if I could find out where to get it.

All I can get at my local shop is red star and Whitbread.

Thanks and good day, all.

Danny

From: dbreiden@mentor.cc.purdue.edu  
Subject: Shelf life of cultures

Hey all,

Let's say I go out tonight and buy some Sierra Nevada Pale Ale. Let's say I drink two while I cook up a quart of wort. Now suppose I do the voo-doo necessary to culture the yeast out of the SNPA bottles, and in two days I've got my yeasties munching away at the wort.

What if I don't want to brew for say, 3 weeks? Is it possible to keep my solution around for that long and gently awaken it a day or 3 before I brew? Or should I just wait and culture the yeast later?

Whatever the case, that Pale Ale is starting to sound pretty good ...

There are two reasons for NOT priming the way that you do: 1) the possibility of uneven carbonation (more priming sugar in some bottles, less in others) and 2) stirring up trub. When you rack the beer off the trub into the priming bucket, it is easier to stir the priming sugar into the beer since you don't have to worry about stirring up the trub.

Dextrose (corn sugar) is 100% fermentable. DME is not. On the average, you should use about 20% more DME (\*BY WEIGHT\*) than dextrose to get the same amount of fermentable sugar. I use DME, not really because I feel that the small amount of dextrose used for priming would cause a detectable change in the flavor, but rather because I simply feel better using all malt.

Aha! Therein lies the problem. Screwtop bottles are capped with a different kind of capper (actually, I don't know of one, other than a bottling machine, that will do it). The Negra Modelo come in an attractive bottle, but one that's made of very thin glass.

>Does anyone know how many times commercial breweries reuse their  
>bottles?

The twist-offs are not reused -- in civilized communities, they are recycled. Most types of bottles are not reused. The only type from the US that I \*know\* are reused are the thick, brown longnecks sold in bars. You know, the kind you can drop from waist-high onto a wooden floor and they won't break? Before I switched to kegging, I only used those. Since starting to keg, I've been collecting only four \*special\* types of bottles: Chimay 750ml, Westmalle Trappist Ale (cool looking, very thick glass), Weizen 500ml, and St. Sebastiaan (sp?) (750ml (?), ceramic bottles, really cool looking, perfect for those beers with a really nasty chill-haze ;^)

From: andy@wups.wustl.edu (Andy Leith)  
Subject: More yeast

Kent Dinkel asks about introducing more yeast into the carboy if the SG is too high.

Apart from there being too little oxygen in the wort, another possible cause of a stuck ferment is having the yeast flocculate out too early. Rather than pitching more yeast it is not a bad idea to first rack the wort plus a little of the sediment in the bottom into another carboy, to see if the fermentation starts up again. This has the effect of rousing some of the yeast back into suspension, and is a sort of homebrew equivalent of the Yorkshire square system used by Samuel Smith who use a very flocculating yeast.

Also Conn Copas feels that if a beer comes in a bottle it can't be called a bitter.

While this may be technically true, it is possible to rack bitter from a keg into a bottle, this is the method I used to win the English and Scottish bitter class at this years AHA National competition, and I was satisfied that the resulting bottled beer was almost indistinguishable from the real thing. I was trying to produce a reasonable facsimile of Brakespears Bitter, which is my drink of choice when I visit home.

Subject: Priming

In HOMEBREW Digest #723, Rich Lenihan asked:

> ... My question: Is there a compelling reason why I  
> \*should\* use a bottling bucket?

If you rack to a fresh, sanitized container, you leave behind all the trash on the bottom of the fermentor. None of that will end up in bottle or keg, no matter how vigorously you mix in the priming solution. That's the advantage.

> 2. DME vs. corn sugar for priming. The one time (see above)

You don't need to be a "purist" to add to your technique. DME is not necessarily better than corn sugar for priming purposes, but it definitely is different, and if you have control of both, you can apply whichever gives the effect you want, in a given batch. Yes, it takes more DME than it does corn sugar to achieve a given carbonation level. If I were making a pale ale, for example, I might use 1/2 cup corn sugar, or I might use 2/3 to 3/4 cup DME. The difference would be "beadier" bubbles and better head retention in the DME batch, but also more "fruitiness", a wider array of esters, which you may not always want. In this year's batches, I've made about 3 DME-primed batches for every corn sugar-primed one, but that's primarily a reflection on the styles I've been brewing in. And remember, a DME-primed batch needs more time to condition!

In HOMEBREW Digest #723, Thomas Manteufel asked:

> ... In theory, the  
>1/4" tubing has more surface area per volume, hence better cooling  
>efficiency ...  
> ... A disadvantage I see is that due to the smaller size, I will be  
able  
>to run only half the amount of water through it over time, so cooling  
time  
>will/may not be as rapid as with 3/8" tubing. Has anyone done even an  
>emphirical test of tubing diameters? Should I go ahead with the 1/4"  
>tubing, or is there something wrong with my assumptions?

My first immersion chiller used 100' of 1/4" tubing, and in many ways it worked very well indeed, but I must agree with your reasoning about throughput. At any reasonable pressure (defined as a pressure where I wasn't plagued with leaks) the water would just drool out of the output hose, piping hot. I always had the feeling that it transferred all the heat it was going to in the first few feet of the coil. I never tested this, but it always appeared that the rate of temperature change of the wort was very slow at first, gathering speed later. Last winter, I foolishly stored it with some cooling water still in it, and an exceptionally hard freeze destroyed it. The replacement was made with 3/8" tubing, which seem to chill more quickly, especially after I connect the icewater recirculation pump (I always needed a wastegate system with the other chiller, to keep the pressure within range). Interestingly, the water coming out the other end isn't nearly as hot.

Subject: Flaming Yeast! (Levuer Flambe')

In HOMEBREW Digest #723, Steve Kirkish asked:

>Now, then. John DeCarlo mentions in HBD #722...  
>  
>>Then I flame the outside of the yeast package, cut open, flame  
>>again, and pour into the starter wort.  
>  
>Maybe it's that I'm still just a novice, dry-yeast user, and not up on  
>these  
>colorful terms used for liquid yeast, but pray tell, how do you "flame"  
>a  
>yeast package? Do you insult it openly, in public ;-)?

Personally, I've never found flaming (in the Usenet sense) to be at all effective in discouraging pests, no matter where in the food chain they may be. What John was talking about was straight from the realm of microbio lab technique. If you have a Bunsen burner (or equivalent), pass the item gently and fairly quickly through the flame. You want to singe the beasties on the outside, not bake the ones on the inside. You can achieve the same effect by wiping it down with alcohol, then flaming it with a cigarette lighter. Try not to flame your fingers in the process ... it hurts! (Voice of Experience)

From: BAUGHMANKR@CONRAD.APPSTATE.EDU  
Subject: Blow-off, hoses, pot-scrubbers

Greetings All:

I feel like a stranger in these parts, it's been so long since I posted. School has begun in these Appalachian mountains and my students have me grading papers, studying and reading instead of brewing and playing on the computer.

Here come a few comments:

Randy, who may no longer be on the net pointed out:

>I learned a lesson in my present batch. Watch out that leftover hops (from  
>pellets) does not plug your blowoff hose! Kinda makes a mess on the floor,  
>the walls, and the ceiling.....

I suspect Randy's been reading The Complete Joy of Homebrewing, a good book except that Charlie thinks you can blow off through siphon hose. You may get away with it for a while but sooner or later you get burned. So for all you new brewers, tear out that page in Charlie's book and buy 1" ID hose from the plumbing store and jam it down into the neck of the carboy and blow-off through it. You'll NEVER pop a cork with one of those monster hoses. Blow-off is a great technique. Don't give up on it because you've been using the wrong equipment.

Elsewhere:

>The problem with the vinyl tubing was, when it got hot, it got really soft,  
>and when it got really soft it fell over and kinked, and when that happened,  
>it blew right off the copper tubing which then shot hot water all over the ceil  
>Now the vinyl is twist-tied to the input hose so it won't kink.

Use washing machine hose if you can. It takes hot water without getting soft.

And from a couple of weeks ago:

>I usually fill the carboy with hot  
>water and bleach and let it soak overnight if there's serious scum in it.

>Chris Shenton

A minor point, which you probably know but some of the newer brewers may not. The hot water and bleach solution IS good for loosening the scum. But hot water breaks down clorox and shouldn't be used to sterilize a full carboy since the heat of the water and the clorox would work against each other. B-Brite, by the way, is good for loosening that gunk.

And here's one I'm responsible for since I'm the one who advocated pot scrubbers on the end of the pick-up tubes in the first place.

>I've been plagued by a slight metallic taste in some of my brews, not all.

>It couldn't be sterilant. I overrinse, if that's possible.

>I think I've discovered the source. The copper scrubbers that I use over the end of my siphon pickup. They are NOT pure copper, just copper coated..a thin one at that. I've been reusing them instead of using a new one each time. For those that use them, use a new one each time. It's not worth sacrificing 5 gals of homebrew to save 59 cents.

>Also, I boil my new ones in a vinegar/water solution to remove any tarnish

>and/or manufacturing oils/gunk.

>

>Darren E. Evans-Young

>The University of Alabama

Sorry Darren. I've never noticed a metallic taste in my beers but I'm bothered by the fact that it might be possible. SO, right beside the shelf in the grocery store where you found the Copper wound pot scrubbers, look for the STAINLESS STEEL pot scrubbers. They should take care of the problem without having to buy a new one each time.

Good to see you derelicts again. (You, too, Darryl.) And a pat on the back to Rob for providing the HBD for us all.

And now, back to the books.

From: Brian Capouch <brianc@zeta.saintjoe.EDU>  
Subject: Two Requests

This first one I'm somewhat ashamed of, but until we get a good, updateable, on-line database of the ever-changing world of micro- and pub breweries, we're going to see this sort of thing.

My erstwhile brewing partner is headed on a several-day trip to Scottsdale, Arizona, and wonders if there are more interesting ways to spend his beer time than bar-hopping sports bars and swilling Bud Light. Anyone out there know?

Secondly, I'm about to embark upon a project that involves scaling up my production by several orders of magnitude. I need to find a source of bulk 5-gal pin-lock soda kegs. I can do the reconditioning; that they be cheap is the item of highest priority.

I appreciate any pointers anyone out there can give me.

One comment on a recent thread: (inviting flames, I might add)  
I don't know how anyone can call him/herself a brewer and be without a hydrometer. I use mine constantly, and have found as a result how pitifully slow extract reduction is in my beers compared to commercial breweries. I'm fixing that by now being so retentive about sanitation that I neglect getting sufficient oxygen into my beers, and to try to repitch yeast to the greatest degree practicable.

From: jmellby@iluvatar.dseg.ti.com  
Subject: Wyeast

A friend asked me where the name WYeast originated from. Apparently the name originally had nothing to do with yeast. Help?

Is anyone going to the Great American Beer Festival in Denver October 4-5.

I have heard both good and bad things about this event and would still like more feedback.

Finally, after a lapse of 14 months I have started brewing again with a hopefully-Christmas ale from one of the earlier recipes posted here. Unfortunately it started out at 1072, after 2 days was 1040, after 5 days was 1032, after 12 days 1028, and it has seemed to stay there.

This seems to be a high specific gravity to bottle at. Any suggestions?

Thanks,

Subject: comparing festbier yeasts, NYC competition

WHICH FESTBIER YEAST TO USE....

'Tis the season for Festbiers, lager fans! Get those palates warmed up and ready to go! I know you're supposed to brew them up in March, store them in your nearby cave over the summer, and drink them now, but I have always been a poor planner. :-) But what yeast do you recommend for this style?

Wyeast has two yeast strains appropriate for the styles Vienna/Maerzen/Oktober-fest: #2308 Munich Lager and #2206 Bavarian Lager. I have used both with success but have \*not\* been systematic in my experimentation (too many %?@\$@& variables varied!!) In the Zymurgy Yeast Special Issue, Vol. 12 No. 4 (1989), Byron Burch says of these strains (p. 57):

2308: sensitive to fermentation conditions, prone to diacetyl flavor, complex, accents maltiness but brings out the hops more than 2206  
2206: "less fussy", malty and complex, good for bocks but can be generally substituted for 2308

2206 was a relatively new strain at that time, and so Mr. Burch was unable to go into as much detail about it. By the way, his article is \*extremely\* good for comparing yeasts in general; I recommend it highly.

My experience suggests that 2308 is the more attenuative yeast, perhaps even too much so for style -- BUT a different recipe would have produced vastly different results, so please take that remark with a grain (or pound) of salt.

What I want to know is this: how have your results compared from using these two strains?? Attenuation, flocculation, flavor balance, temperature sensitivity...whatever you've got would be most appreciated.

AND A CONTEST IN NEW YORK CITY....

I have information on the Nov. 2nd AHA- and HWBTA-sanctioned competition being put on by the New York City Homebrewers Guild if anyone is interested. It's an open competition -- all beer styles will be accepted (not meads). E-mail to me directly to avoid cluttering up the net; I'll be prompt in replying.

Prosit,

STEVE

Subject: raspy raspberries

Jerry Gaiser asks for comments on the harsh aftertaste of raspberries...

...I tried a batch a year or two ago. It wasn't a stout like Jerry's, but a moderately heavy ale (starting gravity about 1.055, some crystal and roast barley, and moderate hops (probably Cascades) to about bu 15 in a full grain mash of pale malt). I tossed in a couple pounds of frozen raspberries with the finishing hops, so the heat would sterilize them but not boil them. It mucked and glopped in the primary for quite awhile (Chico yeast), then plopped in the secondary for several weeks more (I'm usually not that patient, but there were many successive phases of clearing and settling). (The transfer from the primary to the secondary was of legendary mess, and worthy of not repeating the experiment alone).

The result was very weird. It tasted like a fair (but not great) ale, with raspberries on the side -- the two tastes were distinct, and didn't blend well. The smell was heavenly, and the initial taste was even quite good, but the aftertaste was indeed harsh and acidic. Time (months) mellowed it a little, but not a lot. I'll admit that many of my non-beer-appreciating friends thought it was great stuff, but that did little to help.

In retrospect, I don't think I should have expected more. The taste of raspberries is smooth to the nose, and sharp to the tongue -- it makes a great vinegarette salad dressing. I would love to try it again if somebody knows a recipe that offsets this properly, but I'm not anxious to repeat the experiment...

...ask me about sour cherries, though...

From: darryl@ism.isc.com (Darryl Richman)  
Subject: re: Extract yields...

Dave Rose expresses his concern about extract yields, where he mentions that he is getting about 30 specific gravity points \* lb. / gal.

Dave, I experience just about the same yields. The highest I've had in my equipment, which is a picnic cooler/copper manifold lauter tun, is about 32.5, but I've had as little as 27. My average is about 30.5.

I think that Miller's numbers must be "Fine Ground" numbers from his maltster, which represent the maximum extract that can be coaxed out in a lab. (I know he doesn't say that and in fact leads us to believe that he gets those numbers himself, however, a quick check of his 2 row yield is 35, but his recipe for Pilsner, which uses only 2 row as a fermentable, shows an extract more like 33.)

Indeed, your extract relies on a number of variables: age of malt, mashing temperatures (do you really have uniform temperatures in your mashing vessel?), mash pH, and sparging technique. This last probably has the largest effect on extract. It's important to keep the temperature up in the sparging vessel so that the sugars will flow freely.

I'm always interested in improving the extract, but not at the expense of the flavor of my beers, or at an unreasonable amount of time. You'll be pleased to note that many brewpubs do far worse than you; several I have visited seemed to be achieving between 25 and 28, and making good beer at the same time. The bottom line is to produce good beer with your materials. Consider that we are speaking of small quantities of grain here, and that the cost in lost extract is probably on the order of \$1 for a batch.

It may be of interest to note that professional maltsters and brewers don't use this form of measurement. Instead, they quote extract as a percentage of the dry weight of the grain, and this usually turns out to be in the high 70s. They also read specific gravity to 5 places (i.e. 1.12345) in quoting these numbers, and take into account the percent moisture in the grain.

From: CHOLM@HUBIO2.HARVARD.EDU (Dave Rose)  
Subject: Yeast and other issues

First, thanks for replies to my previous postings. Second, a recent posting asked about the shelf life of yeast cultures. I actually have not done too much culturing related to brewing, but I am a yeast geneticist by trade. The most stable way to store yeast is as a "stationary culture." This is just a culture which has been allowed to hgrow until all the nutrients in the culture medium have been exhausted. A stationary culture will keep at 40 C C (approximately refridgerator temperature) for at least a month. It is important that the culture really be in stationary phase, since stationary cells go into a kind of dormancy which protects them during storage. Now, this is all based on lah experience, but requirements in the lab are somewhat more stringent than those in thebrewing, so I imagine the same rules apply.

fFinally, a question about yeast. I have been using edme dried yeast lately primarily becuae it is cheap and so am I. Also, it got a good write up in the yeast special issue of zymurgy. For three batches,now, I have a had a wi eird experience with it. Fermentation starts quickly and proceeds vigorouslyfor 1-2 days. Then, very rapidly, fermentation activity comes to an apparent standstill, with virtually no CO2 evolution and no production, and NO bubbling, ie the surface of the w wort is completely clear. It w stays like this for about a week, and then foam appears on the top and fermentation begins anew. I first suspected contamination, but I don't think that's it. I looked a the wort with a microscope and there are only yeast in there, and when I culture the wort on plates I only get one type of colony, which suggests (but doesn't prove) that there is no mixture in there (ie the real yeast and some wild yeast). There is also no off odor or flavor associated with the second fermentation. So basicallyit isy it is just really odd. Has anyone heelse had this experience? thanks. d.

From: nolan@lhevax.DNET.NASA.GOV (Tom Nolan)  
Subject: Plastic-y taste

One simple possibility for the origin of the "plastic-y" taste in some homebrews might be the use of plastic milk-type jugs for cooling water that has been pre-boiled. I boiled a bunch of water and poured it hot into the plastic jugs that it originally came out of. When I tasted the cooled water a day later it was awful! Overwhelming taste of plastic! I had made a couple of batches this way and not noticed any real problems, so either it goes away eventually or something in the beer masks the taste. Anyway, I threw that water out, and now I cool the water before putting it into any kind of plastic.

Subject: Re: Homebrew Digest #724 (September 16, 1991)

Regarding raspberry stouts, I have brewed a couple and here are my observations.  
First, I have always brewed a very high gravity stout, about 1.11 OG for a resulting brew in the 7% alcohol range. At this high gravity, there were all kinds of "off-flavors" if I drank the stout too young (ie., less than 10 months in the bottle).

If the questioner can wait, do so. You will be very rewarded. I too experienced flat stout in the first months. Now I get a creamy head, wonderful raspberry aroma, and my four favorite flavors on the mouth. Raspberry, chocolate, stout, & coffee. Note that I didn't use either chocolate or coffee but the tastes are definitely there. I brew this every year in September when the local raspberries are available to be drunk the following christmas.  
(ie, 15 months in the future--secondary often takes 9 weeks at cellar temp-- here in Vermont, as low as 42 degrees)

From: larry@evi.com (Larry McCaig)  
Subject: Using a hydrometer

Brian Capouch writes

> One comment on a recent thread: (inviting flames, I might add) I don't  
> know how anyone can call him/herself a brewer and be without a  
> hydrometer.

According to the above, I cannot be called a brewer.

I have been making beer since 1968 when the only malt available in the states was Ma Bells Blue Ribbon Malt. I have always recommended to any beginner to use a Hydrometer, and own several myself. When I make wine, I use the hydrometer, when I make beer, I don't. Based upon the type of malt used, the quantity of the same, the brewing temperature and the type of yeast used, I can pretty well determine when fermentation should be done. I also know the approximate alcohol content, and don't really care. At any rate, when the bubbles stop (around the expected time), It's time to bottle. The point I am trying to make is:

I don't give a damn about how much or how little alcohol is in the beer, I'm going to get a good idea the first time I drink it! What is important to me is taste. I don't say this is great 4.5% beer, I say this is Great tasting beer.

I am not trying to say there is anything at all wrong with using a hydrometer, If you can't determine when fermentation is done without one, by all means use it, that is not the point. This is sort of like using a measuring spoon in cooking, I know how much a teaspoon is by pouring whatever into my palm and looking at it.

By the way, the definition of a brewer is as follows:

- 1.)One who makes beer from malt and hops by infusion, boiling, and fermentation.
- 2.)One who makes a beverage by boiling or steeping.

I see nothing about a hydrometer! Nuff said.

Subject: No cloves in Lawnmower Beer

A local brewpub here in Chicago also makes its "lightest" beer, which is targeted at the lawnmower beer market, as a wheat beer. Goose Island Tanzen Ganz Kolsch is light, and actually made with a Cologne yeast and a portion of wheat as per the style. Some batches really have been reminiscent of the beer at the brewpubs of Cologne. (Technically, however, it is illegal to make a beer called Kolsch outside of the metropolitan area of Cologne, Germany; Kolsch is a legal appellation, like Bourbon in Kentucky or Champagne in France.)

As far as I know, the term "Lawnmower Beer" was coined by none other than Michael Jackson, some years ago.

Inside the packaging of my hygrometer was the tabular data allowing me to convert for ?? deg. to 60 deg. The data was supplied as the number to add or subtract from your present temperature spec. grav. reading to convert to 60 deg. I plotted these values vs. temperature in both C and F. I keep this graph in the back of my brewing note book for quick reference. I thought about generating an equation but the function turns out to be nonlinear and plugging numbers into a calculator in more work than just looking at the graph and pulling off the number I need. In all cases your only correcting the 0.00X position of your spec. grav. reading.

Subject: Lagering

Help!

I am attempting my first lager. We brewed yesterday from a Williams Light Lager Extract kit. The yeast (Wyeast Bavarian Lager) was pitched last night, and the carboy is currently in my living room. Should I leave it there (~70F) until fermentation catches? I had then planned to move the carboy to my fridge which doesn't seem to go above 40F. Is that too cold? If so, what can I do to protect my yeast from the beautiful Southern California weather.

Also, some guidelines on how long to leave the beer in primary, secondary and how long to bottle condition would be much appreciated.

In general, the experiences of people who have lagered in warm climates would be welcome.

You can reply directly to me (stevec@retix.com), or if you think your reply is of general interest, go ahead and post it here. But please HURRY, the beer is getting warm!

Thanks in advance  
Steve

Subject: Priming

Hey all --

I've read the stuff about priming buckets and stuff with a moderate amount of interest. I use a bottling bucket. One thing I don't do is stir! I boil up my priming syrup, let it cool just a bit and dump it in the bottling bucket. At the same time that I put in the syrup, I start my siphon into the bucket. I am careful not to splash or slosh as to avoid getting O<sub>2</sub> in the beer. I also contrive to get the beer going into the bucket in such a way that it kind of swirls around.

I figure that the heat of the syrup, putting it in the \*bottom\* of the bucket, and the swirling of the beer give me enough mixing. I've done this for quite a few batches and have never had uneven carbonation.

From: Conn Copas <C.V.Copas@loughborough.ac.uk>  
Subject: Plastic tastes

I can vouch for the fact that strange hop aromas can leave a plastic aftertaste upon, shall we say, expiration. Last season I tried some of the local wild hops, which looked vaguely Fuggle-like, for the first and last time. They smelt totally exciting fresh, but were totally objectionable in the final brew. I have also never found a hop extract/emulsion/oil which did not taste artificial when used as part of an aroma technique. Disappointingly, even some of the real ale here is boosted with extracts as a substitute for dry hopping.

Some other sources of plastic : the 'new fermenter taste', and some surface film infections can give this sensation as well. Incidentally, Hough talks about the use of nylon to reduce chill hazes in commercial brews. My memory is dim, but I don't think he was talking about filtration. Presumably, the theory goes that polyamides such as nylon are a synthetic approximation of protein, and will precipitate some natural proteins from the brew in a similar fashion to gelatine or isinglass. The mind boggles at the aftertastes this practice might potentially leave.

From: eisen@kopf.HQ.Ileaf.COM (Carl West)  
Subject: Wheat

In HBD 719 Martin postulated:  
>It seems possible to me that the real reason  
>brewers discovered that wheat shouldn't be mashed alone was that it  
>has no separate husk, as barley does, so the mash turns the  
>consistency of library paste.

Well, actually it has a separate husk, so separate that it stays with the stalk when the grain is threshed. (this is based on my small experience with the bag-full of winter wheat I picked in the neighboring stripmine/development, they seem to have planted it to hold the dirt in place). It seems that what is needed is a wheat whose husk comes off the stalk with the seed. A friend sent me this little tidbit (thanks Corwin!):

Tabernaemontanus was the Latin name for Jacob Theodor von Bergzabern who wrote an Herbal (1588) which said:

"They take wheat, barley, spelt, rye, or oats, either one kind (for good beer can be prepared from all these cereals) or two or three together; they steep them in a fresh spring or good running water or (which is even better) in boiled hop water, until the grain bursts out. Then the water is run off and the grains dried in the sun. The water in which the grain is steeped is kept; when the grains are dry they are ground in the mills and the meal put into the aforementioned steep water. It is let boil for 3-4 hours and the hops added and all boiled up to a good froth. When that is done it is filled into other vessels. Some put a little leaven into it and this soon gains a sharp biting flavour and is pleasant to drink.

The English sometimes add to the brewed beer, to make it more pleasant, sugar, cinnamon, cloves, and other good spices in a small bag."

from:  
H. S. CORRAN  
A HISTORY OF BREWING  
DAVID & CHARLES, LONDON, 1975, page 47

Webster's says:

spelt (spelt) n. [ME < OE < LL spelta < Gmc \*spelto < IE base \*(s)p(h)el-, to split off > spill] 1 a primitive species (Triticum spelta) of wheat with grains that do not thresh free of the chaff: now seldom cultivated.  
2 local name for EMMER

Well, tracking down emmer leads to `durum' which apparently doesn't thresh free either, perhaps this is the wheat to mash with.

From: grumpy!cr@uunet.UU.NET (C.R. Saikley)  
Subject: How efficient??

From: Dave Rose <CHOLM@HUBIO2.HARVARD.EDU>

>I am curious about how high extract yields are among the all-grain  
brewers out  
>there. The oft-quoted number from Miller is 33.

I don't get 33 degrees per pound, and I don't know anyone who does. I get  
30 at best and 27 is more typical. Dr Lewis at UC Davis makes his  
"standard  
wort" with 8 lbs of grain (usually Klages) and gets a gravity of 1048.  
This  
works out to 30 degrees per pound. Miller tends to get religious about  
his  
technique, so why worry about a somewhat lower efficiency? If I have to  
add  
another pound of grain to Miller's recipes to get the same gravity, it's  
no  
big deal.

>There seemed to be an inverse relationship  
>between the yield and the amount of grains being used, i.e. the worst  
yields  
>were in barley wines and the like where lots of grains were being  
handled.

This is normal. Sparging is a process of dilution, so you will never get  
all of the sugar out of the mash. You can only approach that  
asymptotically.  
The more you sparge, the higher your yield will be, and you will end up  
with lots of low gravity wort. If you want a high gravity beer, you must  
reduce the amount of sparge water used per pound of grain. When the folks  
at Anchor make a batch of Old Foghorn, they do not not sparge - \*at all\*  
.  
Obviously this will reduce your yield.

When making malt extract syrups (the ultimate in high gravity worts!),  
the manufacturers take the first runnings from the mash to the boiler.  
They then sparge the grains and use the runoff as strike water for the  
next mash. The yield is low, but this is cheaper for them then boiling  
off all of the water that it would take to get a good yield.

In short, extract efficiency is a function of wort density. As the  
density increases, efficiency decreases.

Subject: re:raspberry stout

Date: 16-Sep-91 Time: 04:00 PM Msg: EXT01945

Hi,

Jerry Gaiser asks about harsh tastes and raspberry stout. It seems that when you add much acid (like the acid in berries), you need to give more time for the flavors to blend. I know that raspberry wine needs at least a year to be drinkable, and more to be really good. No idea about beer, how long does it take a framboise lambic to be drinkable?

On a related note, I just made a "holiday porter" with grated orange rind, cinnamon, cloves and ginger. It's happily fermenting in the heat. Why do we get a heat wave every time I brew (twice so far :)? But really, how long will this sort of brew need to age? I expect to bottle in 2-3 weeks, and was hoping to drink the brew for Thanksgiving. Anyone familiar with the type?

There was also a recent thread about cleaning gunk from inside kegs. I had some really carbonized burnt on glue in my kettle. Heloise (as in hints from) advised dumping some baking soda in and letting it sit overnight. It works phenomenally. Just had to wipe the stuff off. I think baking soda is cheaper than b-bright, you can use it with hot water (unlike bleach?) and you can polish your silver with it (and a little aluminum foil and boiling water).  
Amazing stuff.

From: Greg\_Habel@DGC.MCEO.DG.COM  
Subject: Reply to Jerry Gaiser in HBD 724

Replying to Jerry Gaiser's question about undercarbonated bottled beer. Jerry, normally I don't use less than 3/4 cup corn sugar for priming bottles because it would give extremely low levels of carbonation. I would guess that when you used 3/4 cup CS in your first batch, it overcarbonated because you bottled too soon. For me, that amount of CS produces little carbonation. Your second batch is undercarbonated simply because you did not use enough CS to prime. If you enjoy warmer beers, I would suggest allowing the bottles in your second batch to warm to 60 deg F to expand the CO2 and give more carbonation, then consume.

Date: Mon Sep 16 14:09:44 1991  
From: larryba@microsoft.com  
Subject: Re: All Grain Extract Efficiency

In HBD 724, Dave Rose asks another good question: What kinds of grain extract efficiency are homebrewers getting?

Some more Opinion: I think extract efficiency reports are sort of a weinie wag among the brew community. A couple of things to keep in mind when comparing yours to anothers:

1. The volume at the end of the boil vs the amount that actually makes it into the Keg/bottle can be quite a bit different. That will affect the appereant extract efficiency. For example if you think you will get 1.050 in 5.0 gal, but you actually have 5.5 gallons in your kettle the reading will be  $5 / 5.5 * 50$  or 1.046 - a big difference.
2. The extract yeild is different based on the grain type. I use Dave Miller's numbers.
3. Some people may actually extract \*less\* than possible to avoid getting husk tannins or because they are doing a high gravity brew and don't want to boil off 5 gallons of extra water.
4. Calcium ion makes a big difference in enzyme activity (actually the Ph, but it is easiest to control by simply having enough calcium in your water) See HBD #671 and 672 for a good summary by John Polstra.

I think # 1 and #4 are the biggest factors. Your sparge bucket might also be a factor. Having a poor crush (lots of whole grain) might be a factor as well. Also, I have heard that step mashing and decoction mashing result in better yeilds.

All that said, (wag, wag) I routinely get rates comparable to Dave Miller (e.g. +/- 3pt in a batch of 1.050 beer). I have sparged from 4 min/gal to 10min/ gal and have used both a sparge bag and a false bottom lauter tun. Poor crush or lack of calcium is highly correlated with my batches with poor extract rates. Well, actually, drinking too many homebrews is also correlated with my mistakes %-].

Date: 16 Sep 91 17:29:44 EDT  
From: Jeff Frane <70670.2067@compuserve.com>  
Subject: Nitrosamines & also yeast

Having read my notes on Nitrosamines, I realize I need to clarify one sentence in particular, altho none of it is particularly clear. So the whole paragraph should read:

"There is a natural nitrosamine precursor, dimethylamine (sp?) in \*germinating\* barley. It is easily nitrosated (particularly in the presence of oxides or nitrogen) into Nitrosadimethylmine--a carcinogen. If malting barley (since malting is merely an artificial germination process) comes in direct contact with combustion byproducts, Nitrosadimethylamine will result. Great Western no longer has any direct gas-fired malting kilns; theirs are either indirect hot water or air-to-air. There \*are\* malting houses which use direct-fired kilns and they subsequently purge the malt with SO2."

In re WYeast packaging, bursting, exploding, etc.: WYeast's recommendation is that a swollen package be stuck into the refrigerator until it's needed for pitching. Certainly this will keep it from bursting. I kept a package in the refrigerator for one year so I could show my students what it should look like when ready for use. This doesn't mean I would try to \*brew\* with this yeast, but a day or two in the refrigerator doesn't seem to be a problem.

Those who recommended a yeast starter to Norm Pyle are absolutely correct. If at all possible, the starter should be pitched at high krausen, which is generally about 8 to 12 hours from the time of the previous pitching (e.g., the time the yeast package is pitched into the starter). "High krausen" doesn't necessarily indicate a huge head on the starter, although it's usually possible to rouse one by agitating the starter. During high krausen, however, the starter should be noticeably cloudy with yeast; if the starter is clear fermentation has progressed too far and the starter should be fed some more wort. With adequate aeration of the wort, and proper timing of the pitching, results should be spectacular.

Incidentally, WYeast's Dave Logsdon and I are in the process of writing The Yeast Book, which WYeast will be providing to their retailers to pass on to

customers. The book will be detailing procedures for using yeast;  
fermentation;  
and the characteristics of specific yeast varieties. I requested some  
feedback  
from members of the Compuserve Beer Forum and got some very useful  
requests.  
Please, if you have any specific needs relating to yeast or to WYeast  
products,  
direct them to me at Compuserve; I try to pick up all the HB Digests from  
the  
Compuserve library but occasionally they get missed.

Subject: One more thing...

> and if you have a partial mash porter, please send it to me. thanks.

Of course I meant to say "partial mash recipe for a porter", but if you want to send me a porter, I won't turn it down :-)

One more question:

if instead of priming with the usual 3/4 cup of corn sugar, I want to prime with honey, how much do I use? 3/4 cup? seems like I should use more, since it is probably not 100% fermentable. Also, how do I add it? boil it in some water? add it straight? seems like I should at least heat it so it is less viscous. Thanks for the help.

Subject: Extract Efficiency Musings

In HOMEBREW Digest #724, Dave Rose observed:

> I am curious about how high extract yields are among the all-grain  
> brewers out there. The oft-quoted number from Miller is 33.

That's right about my norm, too. General range, 30-35, stovetop  
step mash with Klages. Deduct 5 points for pale ale malt.

> If you want a real eye-opener, go through some of the Zymurgy special  
> issues and look at the award-winning recipes ... average was something  
> like 25 and some were as low as 17! There seemed to be an inverse  
> relationship between the yield and the amount of grains being used,  
> i.e. the worst yields were in barley wines and the like where lots  
> of grains were being handled. This makes me suspect that a lot of  
> the loss comes in sparging ...

Exactly! And the loss is deliberate. What's happening in the case  
of high-gravity beers is intentional under-sparging, sacrificing  
efficiency to avoid a 6-hour boil. In theory, there is a most  
efficient ratio of water to grain, and if this ratio is maintained,  
adding more grain will increase the volume of collected sweet wort,  
at a constant specific gravity. To produce a higher gravity wort  
would require a (much) longer boil. Shortening the sparge reduces  
that need, but at the expense of lost efficiency.

Another factor that I suspect but have never been able to prove is  
the shape of the volume of grain. Unusually small batches, leading  
to unusually shallow lauter tun fills, seem less efficient in my  
equipment, but this makes less sense to me.

Subject: Bottle Culturing

In HOMEBREW Digest #724, Tom Quinn sez:

>All the recent discussion of preparing yeast cultures leads me to ask  
>how one would culture the yeast from a SNPA bottle. I've never seen  
>a bottle of this beer - does it have a layer of sediment at the bottom  
>from which to start?

Yep. Fairly good-sized, and densely packed. A microbiologist from Sierra Nevada told me that after brewing, they cold-filter the beer to remove the yeast, then bottle with an acid-washed inoculation of the (same type) yeast from another batch. So the yeast you can culture from yer average SNPA bottle may not have been the critters that made your particular bottle of beer, but unlike Worthington and most of the Hefeweizens, it's at least the same type.

Culturing yeast from any bottle-conditioned beer is pretty straightforward. First, chill the beer overnight, to encourage the yeast to settle. Then take it from the 'fridge, and while it's warming, prepare a starter solution and sanitize your gear. For a starter solution I boil 4 Tbsp DME and a pinch of yeast energizer in 2 cups of water for 20 minutes, but I'm not attached to that; many other solutions will work. I usually boil in an Erlenmeyer flask, which I transfer directly to a water bath to cool. When it's cool, I wipe the neck of the beer bottle with alcohol, flame it, open with a sanitized opener, and decant to a pitcher (to drink when I'm done). If the beer bottle is 750ml or so, I'll then flame the necks of the bottle and the flask, transfer some starter solution to the bottle, swish it around to bring the yeast into suspension, add the rest of the starter solution, and fix a fermentation lock to the bottle. If it's a smaller bottle, I'll dump the starter and suspended yeast back into the flask, and put the fermentation lock on that. In either case, the lock will be blurping away within a few days.

> Or is there a method of culturing the yeast from a filtered beer?

Not that I know of.

> There are some locally-produced microbrews I'd love  
> to try to culture from...

A word of caution: though many microbrews contain live yeast, many also contain a lot of other stuff too. One of the reasons for SNPA's popularity for this sort of thing is that it's so biologically clean, while the others ...

> Waiting patiently for my Zymurgy yeast issue to arrive,

Yes, it's a goodie.

Brewers,

I look to the learned of this list for info about growing my own hops. Does anyone have experience with this?

I have been told that, under suitable conditions, hopvines are quite prolific, can be trained to grow up a trellis, and require little maintenance. Just what kind of conditions are required? Are hops sensitive to soil & microclimate like grape vines are? Is growing hops an art and science like viniculture, or is it more like raising cabbage?

Me thinks that a home-grown hop would be a nice adjunct to a home-brewed beer. Any tips, tricks, or stories (especially those relevant to growing in North Carolina and/or Florida) would be welcome.

Subject: Hydrometer Correction Table

Greetings All . . .

A posting to HBD #724 got me to thinking . . . Last spring, my brewpartner extrapolated the table that came with our hydrometer, typed it into his computer, and put it on our system. The result is an ASCII file that has hydrometer corrections by temperature in 1 degree C increments over a reasonably large range. I'd be more than happy to share this with any HBDers who are interested.

If you are, please e-mail me (privately!) and I'll compile a list. At the top of said list already is PB1P+@andrew.cmu.com, whose posting yesterday started me on this. If there is truly OVERWHELMING response, I'll throw bandwidth to the wind and just post the whole thing (it's not THAT big, after all) to the HBD.

From: John Buchanan <buchanan@cs.ubc.ca>  
Subject: Soya sauce.

I just noticed on my soya sauce bottle the words 'naturally fermented'. Naturally this caught my eye. I checked on the japanese soya sauce and sure enough this one said 'Naturally brewed'.

Ok, so what process is used to produce soya sauce? Has anyone brewed their own or is the process beyond the home production stage? I know that home brewers en masse will not want to do this, in fact I would probably not be interested in much more than a academic discussion.

This leads me to another question which I have had for a while. Does the germination of other seeds (such a beans ) produce the required starch reducing enzymes or is this particular side effect of germination only found in grains? Maybe beans do produce the required enzymes but the beers have been found to be perfectly awfull.....

Just some questions hoping for some answers.

Subject: Soya sauce.

Hi Everybody,

I just made up a yeast starter to culture some yeast from a Cooper's Stout. I used about 2 tblsp of light dry malt extract boiled for a few minutes in 1 cup of water. When the "wort" was done boiling, it had a lot of apparently insoluble crud in suspension. I have been using this brand of malt for over 1 year but now wonder if this is normal, or should I look for a better extract? It tastes fine, but I suspect it might have some sort of extender added to lower the manufacturer's cost. It comes in unmarked plastic bags and I don't even know what company produces it. The only other brand of malt I can get easily is ground to a powder the consistency of flour and it is very hard to dissolve it, even in boiling water (it does eventually, but makes big gooey lumps that last many minutes in a rolling boil.) I also don't think it tastes as malty as the variety that leaves crud in my yeast starter. Any advice on these malts? I live in Australia, so I don't have 24 different malts and suppliers to choose from; these are the only two I can get locally.

>The result was very weird. It tasted like a fair (but not  
>great) ale, with raspberries on the side -- the two tastes were  
>distinct, and didn't blend well. The smell was heavenly, and  
>the initial taste was even quite good, but the aftertaste was  
>indeed harsh and acidic. Time (months) mellowed it a little,

Well, I don't have the recipe with me, but I made a raspberry  
ale, fairly light (I think around 1.044 or so, pre-raspberries),  
no roast barley, just light malt extract and about 1/2 lb. of  
crystal.

I tossed in 3.5 lbs of fresh raspberries that had been put in the  
freezer about half a day.

Everyone (even Michael Jackson, visiting our club when he was in  
town) liked this beer. Some at the club were mildly surprised,  
given some of my early efforts I had brought in for tasting. I  
had graduated to using liquid yeast by this time (last fall).

Actually, one person didn't like it--my wife. But she doesn't  
like the taste of beer and hoped the raspberries would mask that  
taste (they didn't). It does have that strong, sour raspberry  
taste to it.

From: CHOLM@HUBIO2.HARVARD.EDU (HOLM LAB, HARVARD UNIVERSITY)  
Subject: RE: Homebrew Digest #725 (September 17, 1991)

In HBD #725 there is a general question about growing one's own hops.

I have been growing my own for three years now and am happy with the results.

I got root cuttings (cascade and williamette) from my local homebrew shop and

planted according to directions. Each year, vines come up from each 'hill' in

the spring, and I cut back all but the most vigorous 1 or 2. These then grow

very rapidly throughout the spring. I use a very simple and cheap trellis

which is just a big 22x4 (maybe 10') in the center of my six vines, with strings leading from each vine up to the top in a sort of "maypole" config-

uration. The vines climb up and sort of hang off the top. I just water them

and I usually mulch over with some good organic mulch like grass clippings.

I harvest in september when the first signs of brownness appear on some of

the hops. I have been told to harvest just before they turn brown, but I haven't figured out how to do that yet. After picking, which takes a

while,

I dry the hops for 1-2 days on window screens set up on milk crates; this is

low tech but it works. Then I pack the dried hops into Ball jars and store

them in the freezer. In the past I haven't used the whole harvest in a year

of brewing (this year I'm brewing more and probably will), and even last years

crop still seems OK, but I just use the freshest ones I've got for dry hopping or

aromatic hops. Note that I end up with a cascade-williamette 'blend,' which

might bug some people, but I like it. So, it is a pretty easy thing to do,

although I am sure I could worry a lot more about it and maybe get better results.

Scott> I look to the learned of this list for info about growing my  
Scott> own hops. Does anyone have experience with this?

I planted some last year: 5 varieties with two rhizomes each, from  
Freshhops. Because I have a postage stamp instead of a yard, they are  
very  
close together. I put up string to the roof of my house (about 25 feet),  
and when the hops emerged from the soil, wound them onto strings.

Some of the varieties didn't do anything, but the Cascade in particular  
really  
took off. This year, they came up by themselves in the early spring, and  
I  
repeated the string thing. Again, the Cascades went crazy: they've run  
out  
of string and are looking more like a hop \*bush\* in my upstairs porch.

Here in DC, we have pretty hot summers, and the hops get a lot of sun  
during they day. I'm a pretty lazy gardener, so I didn't do much soil  
prep  
except chopping it up a bit and adding some peat moss...

Scott> Me thinks that a home-grown hop would be a nice adjunct to

Yeah, but it would help if they had an alpha content sticker on them :-)  
. I  
haven't brewed with them, but will probably try aroma hopping with this  
year's Cascades.

Hoppy trails!

From: hplabs!decwrl!inetgw!decvax!wslack!wrs (Bill Slack)  
Subject: Loose keg top

I recently acquired a five gallon stainless soda keg made by Firestone for Pepsi. It has a rubber top with two handles molded in. One side of the top has come loose. What's the best way to re-attach it? Is there an adhesive that bonds to rubber and stainless steel? How did the manufacturer do it?

So far, I've had the following suggestions:

1. It can't be done.
2. Use RTV silicon seal but first verify that the acetic acid won't hurt the rubber or steel.
3. Use two-part epoxy (epoxy plus hardener).
4. There should be a little bit of rubber still stuck to the steel. Try to go with a rubber-to-rubber bond.
5. RDWHAHB

Can anyone help?

Thanks,

Bill--

From: flowers@csrd.uiuc.edu  
Subject: Hop growing basics

Some generally accepted facts about getting started with hop growing--

Hops grow best at northern latitudes. North Carolina and/or Florida are not great hop growing areas. That's not to say they won't grow there, just might need a little extra care etc. Hearing from someone growing hops in those regions would be a big help.

Hops are propagated from root cuttings called rhizomes. They are usually only available in the spring. You can get them from some homebrew supply stores as well as Freshops (can someone help with a phone #) and Nichols Garden Nursery (I can provide this number tomorrow). I suggest ordering early (like in the fall) just so you don't miss out. Nichols offers at least three varieties and sells out early.

They are VERY hardy and can stand frosts so they should be planted early. The first year you may not get many hop cones. This is normal. The second year (sometimes you have to wait to the third year) should be a good crop.

Give them plenty of room to grow up. They can grow a foot per day during the 'growth spurt'. (A couple people on this digest were going to try growing hops horizontally. No word from them yet about their success.)

Pick hops when they are spongy and you can see the little yellow sacs at the base of the cones.

Hops should be dried before using. Placing them in an attic seems to work well. I use an old electric hairdryer connected to a wooden box to make a drying bin.

Homegrown hops will probably be a bit stronger than store bought hops. Most likely because they are EXTREMELY fresh. Hops lose strength very rapidly.

Cut the stalks to the ground for the winter. They will return in the spring.

Certain pests like hops. I will refrain from comment in this area as my hops have not been bothered (knock on wood). Listen to someone with experience in taking care of pests.

Again, these are GENERALLY accepted points about hops. Like any other aspect of brewing, you can get lost in the details of hop growing if you like. In fact, it's just about the right time for a good hop discussion around here.

Have I left any of the basics out?

> cabbage?

Hops are indeed, quite prolific, given the proper circumstances. During  
my pilgrimage to the Northwest last August, I spent a day at the Oregon  
State Hop Research Center in Corvallis, then went for a visit to a large  
(~400 acre) hop grower in the Willamette Valley.

A couple of things that I found most interesting are that 1) hops really  
\*have\* to be trained onto poles or strings up into the air to be  
productive, and when I say up, I mean UUUUP!!--18 to 20 feet is the  
standard out there. Propagation beds are untrained, so hops will in  
fact grow that way, but they won't be very productive and will be  
subject to all sorts of fungi and insects that otherwise wouldn't bother  
them.

2) Also of prime importance is the variety of hops in question. Don't  
just plant some generic "hops" and hope to get big yields of tasty  
cones. You must know what sort of alpha you desire in the variety you  
plant, and (the real rub) since there isn't a lot of modern data about  
varietal acclimation to most of the US, you'll have to experiment a bit  
to find out which varieties are best suited to your area.

To sum up, I'd have to say that growing hops is more like viniculture  
than coliculture (new word i just coined) in that there's a lot of  
finickiness in growing hops, and after you've got the cones, you have to  
be very careful to dry them properly and store them properly if you want  
them to be worth using in your brewery.

From: DAVID KLEIN <PAKLEIN@ccit.arizona.edu>  
Subject: Dead yeasties

Got me a small problem...

Earlier this summer I made me a bock that turned out excellent. Everything was done in the fridge, and seemed to work fine (but slow).

I bottled over a month ago, and placed the bottles in a fridge for the yeast to go at it. The first bottle was beautifully carbonated about 1 week into the process. But bottles tried over the next two weeks were not carbonated. I then turned the fridge off, but after about a week, nothing.

Last week I tried an experiment... One (and only one) bottle was a grolch. So I opened it up, and put about 1-2 tsp of sugar in. I got instant fizzing (bit 'o dissolved gas...) but then after a week, I tried the bottle and there was no improvement.

So now, I have 2 casses of bock with bearylly any carbonation (very slight fizz when the bottle opens, no head) The addition of sugar does not seem to help (i.e. I did not forget to add sugar when botteling). Alchol is not high enough to cause trouble (O.G. about 1.055 F.G. about 1.02) (yeast: Wyeast Braverian lager).

But I think by yeast went to that pearly beer in the sky. The best guess is that somewhere in the lager process, it got too cold for too long (And that one fizzy bottle was one that may have had some of the sludge, and a nordic yeast in it.) Has anyone ever saved a beer in this situation. I am considering pouring all the beer into a bucket and adding new yeast, but I really don't want to. I would like to add yeast to each bottle, but am not sure of a way to do this and make sure that there is enough yeast and not enough baddies.

Ideas?  
Dave

From: greg@cemax.com (Greg Wageman)  
Subject: Divers and sundry

Subject: Plastic-y taste

A common source of a "plastic-y" tastes in homebrew is phenols, as in "phenolic". As I recall, and please don't hesitate to correct me if I'm wrong, production of phenols can be reduced by brewing at cooler temperatures and/or by changing your strain of yeast.

Larry McCaig writes:

>I don't give a damn about how much or how little alcohol is in the  
>beer, I'm going to get a good idea the first time I drink it!  
>What is important to me is taste. I don't say this is great 4.5% beer,  
>I say this is Great tasting beer.  
>  
> I am not trying to say there is anything at all wrong with using a  
>hydrometer, If you can't determine when fermentation is done without  
one, by  
>all means use it, that is not the point. This is sort of like using a  
>measuring spoon in cooking, I know how much a teaspoon is by pouring  
whatever  
>into my palm and looking at it.

This is the classic "Brewing as a Science vs. Brewing as an Art" debate.

Yes, it's true I have never seen a Gourmet Chef measure seasonings; it's all done by eye (and taste) based on long experience. He KNOWS the effect he's after, and just how to get it. And there's no arguing that the results don't suffer for it (quite the contrary). On the other hand, chances are a dish is slightly different (depending on his mood) every time he makes it.

In the other camp, any lab technician who measured "by eye" would be laughed out of his lab. And given sufficient care, that tech can reproduce his results within very small tolerances, time and again. With careful notes of variations in ingredients and method, favorable results can also be replicated at will.

I'm not going to take sides on the validity of either approach; in any case it would be pointless, as what I say is unlikely to change anyone's opinion.

Just remember, the Gourmet Chef didn't START OUT measuring by eye, and many Great Chefs were \*formally trained\* at schools in their art.

You do a disservice to homebrewers of the scientific bent to suggest that hydrometers are only useful for determining alcohol content. When attempting to replicate someone else's recipe it is useful to know if you've achieved the same O.G. as they, and the hydrometer allows one to adjust it if necessary.

Given variations in yeast attenuativeness and fermentation conditions, it's often useful to know just how far down the wort fermented with a particular strain of yeast. Without the O.G and F.G. readings, there's no \*objective\* basis for comparison.

Do you think successful commercial brewers produce thousands of bbls. of identical-tasting beer, year after year, without quantifying every

step of the process?

For beginners' sakes, I recommend instrumentation such as scales for weighing hops and hydrometers for measuring S.G. When the beginner is no longer a beginner, understands the brewing art/science well enough to know what the effect is of altering the ratios of ingredients, then he can choose for himself whether to continue with the instrumentation, or go by instinct. But we do beginners no good to suggest that they dispense completely with measurement, toss the ingredients together, and stand back to Ohh!, Ahh! and marvel at the end result.

OK, I guess I have taken a stand after all; my science background is showing. But I'm not suggesting that every step of the \*homebrewing\* process need be quantized and controlled to the point of anal-retentiveness, and neither am I suggesting that excellent beer cannot be brewed using the methodology of a chef. But the more you know about what happened to your ingredients along the way to their becoming beer, the more you can understand \*and control\* the process.

An enlightened brewer is almost certainly a better brewer.

End of diatribe. Flames directly to me, please.

Actually, I humbly suggest that AAUs and HBUs are the same. 1001 ;-)  
One ounce of a 1% alpha hop == 1 AAU == 1 HBU. The concept of HBUs was,  
I believe, introduced by the late Dave Line (if he wasn't the  
originator, he did popularize the idea). I don't know where AAUs came  
from, although Dave Miller talks about it in TCHOHB.

Subject: Another Momily?

I was roundly criticized by the first "expert" to review the preliminary cut of "BREW IT AT HOME" and I am wondering if the fraternity is suffering from another "momily". (That's one of those things we believe because mom said so.)

He refused to believe that the beer made in the video could have been drinkable because I let the syphon outfall drop into the priming vessel. (Great shot, beautiful billowing foam, nice splashing sound.)

He was particularly outraged at the foam. When I reminded him that the foam was CO<sub>2</sub> and building a nice anerobic blanket over the beer, he just shook his head and dared me to bring him a bottle of the beer but that is another story.

My thoughts on the subject are as follows:

1. The amount of surface area exposed to air in the narrow column of falling beer is trivial and steadily shrinking.
2. The CO<sub>2</sub> blanket keeps rising to cover more and more of the column making exposure to air, near zero near the end.
3. If the pros inject oxygen while pitching yeast and homebrewers are supposed to splash it around to oxygenate at pitching time, what harm can a little oxygen do when we want to re-invigorate the fermentation at bottling time?

Jack Schmidling

P.S. He also claims that a tsp of vitimin C at bottling time will cure the ills of oxygenation. Any thoughts?

Subject: hops comments

I haven't tried growing hops, but I just finished reading a book about an old English garden at Barton's End, in Kent, England. They mention that hops were grown by the Barton's and other Kentish farmers. The hop fields used to be burned to get rid of aphid infestations. Hops have male and female plants. You really should have one or two male plants and many female plants to have a lot of hops.

Aphid infestations have been mentioned here, but I don't think that anyone has mentioned anything about the male/female plants. When you order hop rhizomes, are you give the choice of which you get? Do you get whatever happens to be there when they pack your order?

Subject: hydrometer

Another good use for a hydrometer is to check the results of a mash. For instance, I mashed a pale ale, and wanted it to be dry (ie. low mash temp to give a more fermentable wort). Well, with the help of a hydrometer, I realized that I was too succesful; FG was 1.005, down from 1.038. So next time I'll mash at a little higher temp. I probably would have realized that it was too dry by tasting it, but without the help of the hydrometer, I might not have been able to pinpoint the problem at the mash (it could have been a dry astringency caused by grain tannins, for example). So scientific "stuff" has it's uses.

On the other hand, I never weigh hops.

Subject: re: scales

I have two scales. One is a food scale, one of those cheap spring scales that is intended for weighing out food portions. It has no claim to accuracy--my experience tells me it's accurate to about 2 ounces, with a range of up to 10 lbs. It has a plastic tray which holds just over 2 lbs. of malt. The other scale is an old triple beam gram scale that I use for hops, water salts, and occassionally for very small amounts of grain. This is accurate to 1/20 gram, so it is useful for other hobbies like coke dealing on the side. (Honest, officer, that big jar is full of white powder is gypsum! I just call it "rock" because it is! ;-)) I have a student balance also, good for 1/2 gram accuracy, which I bought before I got the triple beam from a friend. If anyone wants to make an offer on it, it's in very good shape and retails for \$50...

Subject: Freezing your hop harvest

For all of you people that are interested in starting to grow your own hops, maybe you can learn from some of my mistakes. I also have a question about harvesting.

For the past two years I have grown my hops at the back of my garden and used lattice work to support there growth. This works ok but the harvesting ends up taking LOTS of time because the vine weaves between every cross member. I think the string idea might work better in that I would imagine that you coule simply cut the string and slide the vine off of it (comments from anyone?). One good thing about the lattice is that when the vines reach the top (10') they mushroom all over it. I got a record 6 1/4 pound harvest (wet weight) this year from the one vine that actually survived and probably half of this harvest was mounded around the top.

Another problem is that as the root gets larger it pops new growth EVERYWHERE!  
I've been thinking of surrounding the hops with something to block their expansion but a little forethought would probably make control easier.

My question: It took me close to 12 hours to harvest all of the hops and I really didn't have any idea how I might dry that many. Since I have successfully used the hops straight off the vine I decided that I could pack the hops into freezer bags and freeze them fresh. Has anybody else every tried this method of hop preservation?

Russ> What do the rest of you all-grain brewers use for a scale?

I use a Sohnle (or something like that). It was about \$15-\$20 at a kitchen store in a mall. It seems to be pretty well constructed: your basic German engineering... Capacity is 4 pounds, so it's a slight bother to do my double (10 gallon) batches. I seem to recall it's got marks down to 1 or 2 ounce increments.

OK, my turn: what do people use to measure the small stuff, like hops or chemicals? I use one of those cheesy drug scales (no comments, please) with the alligator clip and the quarter-circle ruler-guage thing, but doubt it's accuracy.

Bis spaeter!

From: zentner@ecn.purdue.edu (Michael Zentner)  
Subject: priming & stirring

Danny Breidenbach writes two digests ago about stirring.

I say, stir till your heart's content! Stirring is NOT going to cause any problems. By stirring, I mean establishing circulating currents, and not breaking the liquid surface while doing this (stirring gently). If you don't cause any "choppiness" on the surface, the O<sub>2</sub> introduced is minimal. If it'll make you feel better about your mixing, go right ahead and stir (again, gently).

I've used three methods for bottling: Plain bottling bucket, bottling carboy, and spigoted bucket with bottle filler. By far, my favourite method is using a second carboy. It's more reliably sanitized than plastic buckets, and the siphon tube does not come flopping out of the wort if you pull on it the wrong way. As for the bottle filler, it saves me no time and is an additional sanitation hassle. Before a level of brew is established on the bottom of the bottle, a significant amount of O<sub>2</sub> is introduced as well. Simply letting my siphon hose slowly trickle down the side of the bottle has not so far caused any aerobic/oxidation problems. Just my opinions, but use whatever makes you happy...that's the most important thing.

From: Tom Dimock <RGG@CORNELLC.cit.cornell.edu>  
Subject: Flat beer rescues

Several homebrewers have recently reported brews that did not carbonate well, if at all. My experience closely matches that of Dave Klein in HBD 726. I finally swallowed hard, unbottled all of the beer (a very hoppy ale which had been fermented with MeV English Ale yeast) back into my priming bucket, repitched it with a starter of Whitbread dry ale yeast and re-primed it with 3/4 cup of corn sugar. Then back into fresh bottles. A week later it produces a head (YAYY!) and is quite drinkable. So don't throw it away yet, Dave.....

> attempting to replicate someone else's recipe it is useful to know if  
> you've achieved the same O.G. as they, and the hydrometer allows one to  
> adjust it if necessary.

All valid points on hydrometer use. I have never used one thus far  
in my brewing but I think I'll buy one and start. Now, let's say that I've  
just brewed up a batch of whatever using someone else's recipe. I take a  
hydrometer reading and, lo and behold, my specific gravity is off the mark by  
several points. So what? At this point there is absolutely nothing I can do.  
I'm certainly not going to toss the batch because I didn't hit it on the  
head. It will give me an idea of how close I came but my point is that the  
hydrometer has bought me nothing in the way of being able to fix \*this\* batch. I am  
an extract/adjunct brewer and I think I can see where a hydrometer would be  
of a great deal more service for all-grain brewers. As I said though, I am  
going to buy a hydrometer and start using it. I am adding several pieces of  
brewing equipment to my inventory and that is one thing that I had intended to  
add all along. Just playing devil's advocate.

> Christmas recipes and favourite Christmas brews.

I'll bite. I brewed a Christmas beer based unashamedly on Phil Flemming's recipe that was posted in this forum. I made some adjustments to move it a few degrees towards a darker beer and I toned down the spices a bit since this was my first attempt at a spiced beer. I mistakenly put in a cup of Black Patent malt instead of 1/2 cup because I ordered it that way and I forgot until after I had added it. I will be bottling it this coming weekend and I'll have a taste at that time. Here it is:

Christmas in Ireland  
5 Gallons

4 pounds Mountmellick Irish Stout Extract  
3 pounds Munton & Fison Amber DME  
1/2 pound ( 2 cups ) Crystal Malt ( 60 Lovibond )  
1/4 pound ( 1 cup ) Black Patent Malt  
1 ounce Bullions hops ( bittering - 55 minutes )  
1/2 ounce Hallertau hops ( finishing - 5 minutes )  
1 pound Clover Honey  
12 inches Cinnamon sticks ( or 6 tsp ground cinnamon )  
4 ounces Ginger Root, freshly peeled and grated  
2 tsp. Allspice  
1 tsp. Cloves  
4 each Grated rinds from medium size oranges  
1 package WYeast #1084 Irish Stout Yeast

Simmer honey and spices in covered pot for 45 minutes.

Add cracked grains to 2 gallons cold water and bring to a boil. As soon as boiling starts, remove grains with a strainer. Add malt extracts and bittering hops and boil for 55 minutes. Add finishing hops and boil for 5 more minutes. Remove from heat. Stir in honey and spice mixture and cool. Strain into fermenter containing 3 gallons cold (previously boiled) water and pitch yeast. After vigorous primary fermentation subsides, rack into secondary. Bottle with 7oz. corn sugar or 1.25 cups DME when fermentation completes.

\* \* \* \* \*  
\* \* \* MERRY CHRISTMAS \* \* \* \* \*

\*\* \* \* \* \* \* \* \* \* \* \* \*

As I said, I haven't tried it yet but it smells great. I hope it will become a favorite. Enjoy.

From: mcnally@Pa.dec.com

Subject: berry beers

If we're going to brag about our bizarre berry beers, then I'll gladly join in. The batch I made started with a mild all-grain wort, involving 2-row and some unmalted wheat flakes. It was mildly hopped with Hallertauer hops. I fermented it for about a week with Chimay yeast, then racked it over ten (!) pounds of boysenberries and added 2 pounds of honey. The second fermentation lasted about another week. I then racked into another carboy and added some dry Goldings hops and a couple handfuls of French oak chips, and let it relax for about three weeks.

The result is, as you might guess, thoroughly bizarre. It's really, really red; about the color of Big Red cream soda, in fact. It has a very crisp carbonation and a tart, complex flavor. The bouquet is really amazing.

I'd do this again, for sure. I've just recently bottled a Weizen that was re-fermented with 6 pounds of picked-from-a-friend's-tree peaches. To this one I added 8 oz of lactose to balance the acid tang of the fruit, and I think it's going to turn out well.

Subject: Seattle

Thanks to everybody that sent me information about beer in Seattle. I've returned from my two-day business trip there. I was pretty busy, so I was only able to visit four brewpubs (well, some are pubs serving beer made nextdoor): Trolleyman, Big Time, Kirkland Roaster, and the Pacific something-or-other downtown. I was impressed that so many places served cask-conditioned ales (even Trolleyman, where I experienced cask RedHook ESB).

I also found Libery Malt Supply, which was a fabulous experience. They don't have a catalog yet, but they're building a mailing list. They carry an amazing variety of English, Belgian, and German malts (including Rachmalz, for those who want to make BBQ beer). I also noticed little 1lb bags of roasted rye. Wow.

Subject: Sierra Nevada yeasties

People have been conversing much on the topic of culturing yeasties from SNPA bottles. What I'm curious about is the possibility that SN uses a different yeast for its bottle-conditioning, so you're getting a different yeast out of the bottle than they actually use for their fermentation. Does this sound like a possibility?

Date: Wed, 18 Sep 91 14:24:04 CDT  
From: tony@spss.com (Tony Babinec)  
Subject: all-grain efficiency/all-grain to extract recipe conversion

Recent HBD entries have talked about extract efficiency. Also, someone posed the question about substituting extract for grain, or vice versa.

My experience with all-grain brewing efficiency matches others. If the theoretical extract yield is 35 points SG per pound per gallon, or 7 points SG per pound in a 5-gallon batch, I have routinely attained about 30 points SG per pound per gallon, or 6 points SG per pound in a 5 gallon batch. These numbers refer to basic pale malts, such as 6-row American, Klages malt, German pilsner malt, or pale ale malt.

Properly cracked malt is an important success factor for brewing. Homebrewers I have known have obtained pre-cracked malt that turned out to be poorly cracked, with consequent loss of efficiency. Also, sparging is important. I've had conversations at our homebrew gatherings in which someone tells me that it took 25 minutes to sparge, and I have to think that's not enough time. You should be recirculating the wort to clarify it, and then topping it off with sparge water at the correct temperature and volume. Sparging ought to take around an hour or more.

To convert between extract recipes and all-grain recipes, an approximate guide is that 4 parts pale grain equals 3 parts of dry malt extract. Using these numbers, it is easy for the extract brewer to make the transitional step to partial mashing. Specialty grains, such as crystal malt, chocolate malt, or black malt, can be added to the boil water prior to boil, and then strained from the boil water before addition of extract (and before boil), OR mashed with the pale grain. In the absence of a real lauter tun, at least pour the sweet wort through the mash grain a few times. Colanders and/or spaghetti strainers work well here. Specialty grain amounts in a recipe can be the same, regardless of whether it is an extract, partial mash, or all-grain mash.

The above are rules of thumb. I highly endorse the use of a hydrometer along with Dr. Bob Technical's Amazing Wheel of Wort (the latter available through AHA or found in brewing supply stores) to determine your own process capability relative to these norms. I believe that you should "relax and don't worry," but it's nice to brew to a target style and approximately attain it in a way that is approximately replicable. Plus, you'll be well on your way to formulating your own recipes, even if you use a published one as a starting point.

Subject: Garbage and Plastic Fermentors

Hello. First, an apology and a plea for help. Apparently many or all of my postings (maybe this one too) have been marred by garbage characters which come up whenever I hit 'backspace.' I don't see them either when entering the message or when reading it later. Apparently I've got some terminal emulation problem that is causing this. I'm using an IBM running Procomm Plus (home) and a Mac running Versaterm Pro (work) to

log into a VAX running VMS. Any suggestions are welcome, and I'm sorry for

using space to ask what is essentially a non-beer-related question.

But, on to beer. Has anyone out there used \*plastic\* carboys as fermentors? I am talking about clear blue (looks like polycarbonate) water

containers. I usually use glass but a stepped-up brewing schedule and some slower-than-usual fermentations have tied them all up. Also the plastic

ones would be a cheap alternative, since I get them for a \$5 deposit from my water company. I've used them to hold beer temporarily (like between the secondary and the bottle, when mixing in the priming sugar) but have been too chicken to try a full fermentation. Any braver souls out there? Sorry if this posting is filled with /010's. Unfortunately I rely very heavily on the backspace key....

From: David J. Murphy <djmurphy@wam.umd.edu>  
Subject: Re Soya Sauce

John Buchanan in HBD #726 asked about making soya sauce.

Here is a description of making soy sace in the Japanese village of Shinohata, circa 1975. The author notes that only four or five families still made their own and that the rest of them relied on the commercial sauces.

"You started with equal volumes of soya [soy] beans boiled enough to be soft, and wheat roughly ground into a very course flour--in the average household about 15 kilogrammes of each. This you entrusted to a specialist in the next hamlet who kept it in a sealed room at the right temperature, injected the right sort of yeast and so 'put flowers on it [nice phrase].' Then, having got it back home, you added equal quantities of salt and water, and miscellaneous other things according to taste--left over rice, some monosodium glutimate, etc.--stirred vigorously and left it in a shed for a year to let nature take its course, aided by a vigorous stir from any passer-by who happened to think of it; the more frequent and energetic the stirring, the more impressively the mixture would rumble and erupt. When it was thought to be finally ripe you ladled the concoction into especially strong muslin bags and rigged up a screw-jack (locally known as a 'giraffe' [ the word for 'giraffe' is the same as the one for 'dragon']) above it to squeeze all the liquid out. Finally, to make it go further, you boiled that up with extra water, using a thing like a thermometer which measured salt content, to tell you when you were letting your lust for quantity--your fear that your soya sauce would not last the year and you would be forced to \*buy\* some--go to far at the expense of quality. Several of the hamlet's neighbourhood groups kept a set of this equipment in common, though that caused occasional problems when someone in the neighbourhood, over-desperately keen to get the last drop from the mixture, would screw the jack to tight and split an expensive bag."

Subject: AA measurement + peristaltic pumps

Here are two questions I've tried asking in the past, but they either got lost (HBD718) or noone had any data at the time (I guess):

1. Is there a way to measure the Alpha Acid % of hops in the privacy of our homes?
2. Does anyone know of a supplier of peristaltic pumps ("hose pumps") that has small (1 gal/min is ok), reasonably priced (under \$100) pumps? A pump like this would end my racking hose sanitation woes forever!!!

From: polstra!norm@uunet.UU.NET (Norm Hardy)  
Subject: Hop growing (Seattle)

I concur with the articles about hop growing in your own backyard.

This year, the 5th year of growing hops, found 3 varieties being harvested:

- (1) Hallertau (1 plant) - 10 oz dried
- (2) Cascade (1 plant) - 9 oz dried
- (3) Herzbrucher (4 plants) - 12 oz dried

The cones were just starting to turn brown (actually just a few) and the harvest was done in three successive days. Drying was novel this year: I put each variety on a window screen and placed in inside my car, sitting in the sun for the day (inside temp 115f). Only a few hops were in direct sunlight. The windows were obviously closed. Seemed to work quite well and the bagging into the freezer bags (with Seal-a-meal) went well also.

The Cascade hop is in its 3rd year. Last year it produced 53 cones (.25 oz).

The Hallertau had 3 others like it, but the dog ate one and winter got the other 2. The Hallertau is 5 years active here.

The Herzbruchers are the best lager hops of the bunch with an Alpha of (estimated after several batches) of 4-5 AAU. They are 5 years old here.

I used rabbit droppings for occasional fertilizer and lots of water.

Finally, the car smelled great for a week.

Subject: re: more uses for the hydrometer

Since Russ Gelinas pointed out that there are some other reasons to use a hydrometer, and since we've been discussing the extract efficiency of mashing, I thought I'd point out how I use a hydrometer to get a good idea of how well my mash went before I start sparging.

Let us suppose that I've mashed and transferred into my lauter tun, and am starting to recirculate for clarity. I take a sample of the sweet wort and cool it down and take a reading. Of course, this reading is not going to be anywhere near my expected original gravity.

But, assuming that my newly created sugar is all in solution, I can take that reading and multiply it by the ratio of mash water to batch size and get a maximum prediction for my original gravity.

For example, I have 10 gallons of mash, 25 lbs. of grain, and my batch is intended for 15 gallons. If my reading is 1.075, then  $10/15 * 75$  is 50, so my maximum OG is 1.050. So,  $15 * 50 / 25 = 30$ , or my extract efficiency is 1.030 specific gravity points \* lb. / gal.

Naturally, I have other losses in my system that prevent this maximum reading from being obtained at the finish, but the more you know about where the losses occur in your system, the more prepared you are to have an effect on them.

One can do this at each stage if one knows the correct volume. I must admit that it is a bit depressing to see a really great extract being whittled away to mere mediocrity...

Subject: re: plastic carboys

Dave Ros asks about using the plastic (polycarbonate) carboys that more and more of the water companies are switching to. I've been using them for three or four years now and I love them.

\* They don't break.

\* They're very lightweight.

\* I sanitize them with boiling water so I don't care whether they have scratches; I figure that if the polycarbonate is about 200F, it doesn't matter whether the evil nasties are in direct contact with the water or not. (And it works, no infected batches in that time.) In fact, I brew entirely in plastic fermenters for this reason.

\* Rodney Morris claims that they are moderately impermeable to oxygen, but I lagered my Bock Aasswards doppelbock for about 5 months in them, and the judges seemed to like it. ;-)

\* If I really don't like the looks of a carboy, I trade it in for a new one.

\* Because they are not completely rigid, you can have problems when you move them because they will suck the airlock sterilant after you set them down.

I have found several other uses for them, like transporting grain to/from having it crushed, and bring in mash and sparge water to the brewery (no running water in the garage).

--Darryl Richman

P.S. Dave, if you use the left arrow key instead of the delete key, it leaves "escape codes" that direct the cursor left rather than actually deleting the character. You won't see this on your PC since it can interpret the escape code correctly, but most folks are reading this on UNIX systems and they see each of the codes instead.

Subject: scales

I have two scales. For weighing grains, I have a Krups scale that ranges from 0 to 5 pounds in increments of an ounce, and also has a metric scale. It comes in two pieces: the scale part, and a bowl. The bowl easily holds a couple of pounds of grain. I typically weigh and then grind as I go. The scale can be found in gourmet food stores or gourmet sections of large retail stores, such as Marshall Field's in the Midwest. It cost under \$20. For weighing hops, I broke down and bought one of those counterweight "science" scales, along with a set of gram weights. I believe one should calculate hop additions in grams, as this is a more precise scale. Spring scales, diet scales, and the like, simply aren't scaled to enough precision. This scale must have cost about \$50-\$60. You can find it in "science" stores (American Science Center in Chicago) or some homebrew supply stores.

Having just made a case for precision in measuring hops, I find that after doing the hop addition calculations, I can often round things a bit so that additions are conveniently done in units of one-half ounce, which conforms to the packaging of the wonderful Crosby and Baker compressed hops! If you have never used them, they are packaged in 5 ounce volumes with alpha content printed on the package, and are indented so that they break off in half-ounce chunks.

Subject: homegrown hops

I put in my first batch of hops this past spring here in Vermont (down the road from Greg Noonan's place!). I planted Hallertau, Fuggles, & Cascade. I couldn't find any rhizome cuttings so I bought actually cuttings just barely rooted. Things were slow to start, but the Cascades took a very early lead. The fuggles were very slow (they had poorer light) and Hallertau somewhere in the middle. That was until about halfway through the summer (in Vermont, halfway through the summer means the first of July!). The Cascade stopped growing, put out all their flowers, coned, and then just sat there, about 6-10 feet high. Meanwhile the Hallertau started to spurt. They eventually hit 22 feet high (my roof off the back of a walk out basement house), went over the edge and crawled up the roof. I've not seen so much vegetation from any vine. They produced easily 4 times what the other varieties did and were less susceptible to pests (the Cascade were quite eaten).

More about pests. I can't quite tell why or what they did, but my vines were often covered by wasps. They didn't eat anything as near as I can tell. I would often watch one buzzing around (looking out the window of my house so as not to disturb them) and I never saw them munch anything. Yet there were dozens of them on each vine. Could it be they were lying in wait for hop-eating insects?

>to have a lot of hops.

A local commercial purveyor of hops told me that you do not need any male plants. The female produces the hop buds, the male does not. The only reason to have a male plant is to pollinate the female in order for the seeds to have the ability to germinate. We, as homebrewers, want the hops for the buds and not the seeds... therefore, don't waste your time with male plants.

In HBD#727 Norm Hardy wrote:

I have a pamphlet provided by a commercial hop grower in Oregon which explains the growing and harvesting of your own hops. It says DO NOT dry the hops at over 105f, otherwise, the aromatic oils (which we are most interested in!) will go away. In fact, another book I have on drying herbs (yes, hops are herbs.) states not to dry them at over 95f. Essentially, the higher the drying temperature the more of the volatile aromatic oils you lose. I dried this years crop in a food dryer at room temp. and have never smelled more aromatic hops!

Ahhhh... the life it is!... Living in Washington and growing hops!

I'd be curious to know more about this. I believe hops are a polyploid (maybe a diploid?) of marijuana... Marijuana flower and resin production is optimized by having NO male plants at all. Since the hop rhizomes will re-germinate every year, unless you're trying to grow new hop plants from seed I don't think you'd want male plants.

From: mcnally@Pa.dec.com

Subject: aeration at bottling time

I would say that it's unlikely that the foam on top of the beer is formed by CO<sub>2</sub>; if there's that much CO<sub>2</sub> in solution, it's probably not ready to bottle. Although you're correct that the stream of liquid has only a limited surface area, remember that that splashing noise means that air is being carried into the wort by the collision of the stream with the surface of the fluid already in the carboy.

Think of what happens when you pour a stream of water into a bucket of water containing a little detergent: you get bubbles, right? This happens because the detergent has increased the foamability of the water, and the air dissolved into the water is trapped by the surface tension.

I would probably agree that the aeration won't do to much damage, but I also doubt it's necessary. Aeration is important at pitching time because it's important to propagate the yeast. At bottling time, even though a lot of yeast has settled to the bottom, there's still plenty in suspension. Thus it's not necessary to induce another respiratory "breeding" phase; all you want is more fermentation. It *is* possible to damage beer by oxidation (though it's never happened to me), so I feel that if it can be avoided, one might as well.

Subject: male and female hops

I have to take issue with the suggestion that you want both male and female plants. Wrong. Only females produce the cones, and if they are fertilized, they will produce seeds, which you DON'T want in your beer. When one buys rhizomes or cuttings for their first planting, they can be assured that they get only females. Also, since hops are a rhizome producing plant, you can get more hops than you need letting them reproduce asexually.

All in all it's a situation very similar to another somewhat popular plant grown under lights in many places, though without the rhizomes...

Subject: weiss question

Howdy,

OK, so here I am in Germany. Got two questions:

1. What is the difference between a weiss and a weizen? I know that weiss translates to 'white' and weizen as 'wheat', but what's the deal. I've been told every thing from they are the same, to one is just a light beer while the other is made from wheat. I'm sooo confused. Also, why does my local barkeep through a wedge of lemon into my weiss?

2. Does anyone know of a local german distributer for homebrew supplies? I hadn't planned on continuing the hobby, but I'm hooked and my freinds can't wait to try a home brew. How 'bout a US dist. who ships to an APO address, as opposed to UPS.??

BTW, I got a big kick the 2nd day I was here, visiting the local castle. when I looked over the side of the wall, there were several dozen wild hop vines growing. I think I could learn to like this place...

Subject: Reply to Homebrew Digest #727 (September 19, 1991)

I appologize to everyone if this is the fourteenth Jack Schmidling flame that you've waded through today. It is a huge credit to the digest and its subscribers that the SN ratio is consistently so high, and that the contributions so consistently valuable (at least to me).

In this vein, If you do not wish to be further persueded that Jack is probably not qualified to produce the video "BREW IT AT HOME", go on to the next article.

Jack asks:

1. The amount of surface area exposed to air in the narrow column of falling beer is trivial and steadily shrinking.

Initially there will be no CO2 and lots of splashing. This initial phase alone will probably damage the beer. Furthermore, The question presumes that air is being transported into the beer only by diffusion into the falling column of beer. This is not, in fact, the case. The falling beer molecules are not falling through air molecules that are fixed. The falling beer is actively transporting the air immediately surrounding the falling column into the beer. The average velocity of an average air molecule immediately adjacent to the falling column of beer will be the same as the velocity of an average falling beer molecule. (The velocity of an average air molecule will be a function of the distance of the molecule from the column, and the distance of the molecule from the end of the siphon.) Furthermore, the turbulence created by the beer falling into the priming bucket will help to dissolve the air that has been introduced. Finally, if the falling column of beer is not "coherent" It will have a far greater surface area than Jack's question suggests, introducing still more air into the beer.

2. The CO2 blanket keeps rising to cover more and more of the column making exposure to air, near zero near the end.

The CO2 blanket is only helping to keep air from diffusing in through the surface of the beer in the priming bucket. Diffusion is slower than molasses anyway. The problem this solves is not nearly as great a problem as the others you have created.

3. If the pros inject oxygen while pitching yeast and homebrewers are supposed to splash it around to oxygenate at pitching time, what harm can a little oxygen do when we want to re-invigorate the fermentation at bottling time?

This is the question I found most infuriating. It would not be infuriating if asked by a novice home brewer. It's a good question. The problem I have with Jack asking it is that it means he has zero familiarity with the yeast life cycle. This means he has done essentially no reading on the subject of home brewing. He is making this video without trying to understand his subject.

Jack has demonstrated that he is making this video without making a good faith effort to understand his subject matter. It seems

to me that Jack plans to deceive people into thinking that his video is a useful guide to home brewing. It also seems to me that Jack plans to profit from sales of the video that arise from this deception. In Minnesota, this combination of deception and profit is what constitutes the legal definition of fraud.

It probably won't matter. I imagine that most reputable homebrew outlets will quickly recognize the amateurishness of Jack's technique and refuse to carry it.

Sorry for raving.

> When you order hop rhizomes, are you give the choice of which  
> you get? Do you get whatever happens to be there when they pack  
> your order?

You get female plant rhizomes. Only British varieties (notably Fuggles and Kent Goldings) are commercially marketable with the kind of seed content you'll get if male plants are present. Unless you plan on growing several acres of hops, you probably shouldn't have a male plant at all.

Jeff J. Miller:

> ... I think the string idea might work better in that I would imagine  
> that you could simply cut the string and slide the vine off of it  
(comments  
> from anyone?)

Yes, you could do that, but you don't need to. David Beach mentions in his book (Homegrown Hops) the techniques most of my club's hop growers seem to use, that of training a few (3, usually) vines up the string and cutting the rest back, then when those vines reach the top, train 3 more, etc. Harvest then, isn't a single operation, but consists of picking the cones that are ripe, a couple of times a week for as long as the vines still produce. You get a lot of cones from a single plant that way, but you need access to the whole plant, which often means having a good ladder.

> probably half of this harvest was mounded around the top.

My entire harvest was right at the top. Fortunately, I'd trained my vines up to the railing on the deck, so I picked in comfort!

> Another problem is that as the root gets larger it pops new growth EVERYWHERE!

... thanks to the rhizomes. These can be cut off and used to propagate new plants. They make great trade goods!

And Norm Hardy:

> I used rabbit droppings for occasional fertilizer ...

Now why didn't I think of that? I knew the stuff had to be good for something! I use chicken manure & straw, but will add the rabbit dung forthwith!

From: bgros@sensitivity.berkeley.edu (Bryan Gros)  
Subject: Original Gravity Corrections

I made my wheat beer last weekend. my first partial mash. After cooling, i racked into the carboy and added the yeast (first time to use liquid yeast...worked fine). I grabbed a bit of the stuff left in the bucket to measure the original gravity. It came out to about 58. This seemed pretty high. The wort had a lot of trub in it, though, and would this be making the reading much higher? It is also a little high, since I added about 2 qts of water to the carboy to bring it up to about 5 gals.

I mashed two lbs wheat malt, and one lb pale malt, and added three lbs wheat extract and one lb pale extract. What's the theoretical OG??

Thanks.  
- Bryan

p.s. the main difference i noticed between the liquid yeast and the red star i'd been using is the bubble size. the liquid gave much smaller bubbles in the wort and the krausen seems much finer. The wort was not as active during fermentation as it seemed to be with the dry yeast. I used a starter and it worked fine.

> him that the foam was CO2 and building a nice anerobic  
> blanket over the beer, he just shook his head and dared me  
> to bring him a bottle of the beer but that is another story.

It is unclear from the above description if you are racking into a  
secondary  
fermenter or into a priming vessel at bottling time, but in either case  
the  
beer would unlikely be producing sufficient CO2 to form a protective  
blanket  
against oxygen. If the end of the syphon hose is not submerged during the  
racking process then oxygen is coming into contact with the surface of  
the  
stream of beer even before it hits the bottom of the vessel and  
calculations  
are not needed to deduce that a large surface area is exposed to air.

> My thoughts on the subject are as follows:

> 1. The amount of surface area exposed to air in the narrow  
> column of falling beer is trivial and steadily shrinking.

The narrower the column of falling beer the larger the surface area:  
volume  
ratio and the greater the extent of oxidation.

> 2. The CO2 blanket keeps rising to cover more and more of  
> the column making exposure to air, near zero near the end.

As mentioned above, beer syphoned at later stages of fermentation or at  
bottling time is susceptible to oxidation due to a reduced degree of CO2  
production or its absence altogether (which would hopefully be the case  
at  
bottling time to prevent glass grenades). I'd be concerned therefore that  
a CO2  
blanket is either non-existent or fairly thin and easily disrupted by the  
air  
turbulence generated by syphoning. The foam is more likely a result of  
splashing.

> 3. If the pros inject oxygen while pitching yeast and  
> homebrewers are supposed to splash it around to oxygenate at  
> pitching time, what harm can a little oxygen do when we want  
> to re-invigorate the fermentation at bottling time?

The harm is that fermentation has produced many compounds which are  
readily

oxidized and whose oxidation products produce off-flavours. Yeast require O<sub>2</sub> initially during the respiration phase of growth in order to utilize the various nutrients available for cell growth and division as well as to produce a variety of molecules which will serve as a source of energy during the anaerobic fermentation phase. Once the nutrients in the wort are spent and cell density is optimum additional oxygen will not be quickly utilized by the yeast and will be available to initiate redox reactions.

If sufficient oxygen is in the wort at the time of pitching then the yeast will synthesize enough energy reserves for primary, secondary and bottle fermentations.

The processes of oxidation of fermented beer have been well documented. Here are a few examples:

1. Fatty Acid Oxidation
  - oxidation of fatty acids produces aldehydes (eg. oxidation of oleic acid) which taste 'soapy'.
2. Oxidation of Phenolics
  - oxidized phenols produce an 'astringent' taste which can be harsh and burning. Furthermore, oxidized polyphenols contribute to chill haze.
3. Oxidation of Acetohydroxy Acids
  - produces diacetyl in amounts which can exceed the yeasts diacetyl reducing capacity during aging.
4. Oxidation of Amino Acids
  - produces fusel alcohols, esters and aldehydes. Can result in harsh off-flavours and excessive fruitiness. Aldehydes are particularly nasty.

> P.S. He also claims that a tsp of vitamin C at bottling  
> time will cure the ills of oxygenation. Any thoughts?

Vitamin C is an antioxidant but to claim it will "cure the ills of oxygenation" is false. Although ascorbic acid (Vit. C) is an oxygen scavenger, it is not a strong one. Ascorbate (oxidized ascorbic acid) can be an oxidizing agent if sufficient iron is present in the beer!

I'm not attempting to raise the level of worrying amongst HD readers about oxidation. If your beer tastes good then be happy. If you desire better beer then there are an endless variety of ways to improve your homebrewed nectar and reducing oxidation is one of them as borne out by experience, scientific analysis and of course, Mom. ;-)

Subject: Tips for first time all-grain brewing.

or "I kinda wish I'd thought of that before I started this..."

Hi,

My brewpartner and I are about to try all-grain brewing for the first time.

I would like to hear from all you experienced mashers about the mistakes you made during the first time you brewed all-grain and your solutions. This includes what you found lacking in your equipment, technique, planning and execution of mashing grain for the first time. I am going to condense all of this wonderful wisdom into a summary that will be eventually posted to this esteemed forum.

Our immediate goal is to get our equipment ready and our procedures down before we make our first batch. Any information on equipment design and techniques will be greatly appreciated.

Please send your tips via e-mail to me (this digest is getting too long)

.

Thanks,

Bruce T. HillDanford Corp.voice: (213) 514-9334

You used the right stuff but you need to dilute it but you  
need to dilute it about 50:1 with water.

Subject: RE: Dry ice priming ....

g'day!

i have tried dry ice priming, but only to a few bottles. Really, we had a try and it was quite dangerous. We put one pellet of dry ice into the bottle, capped it, and shook it like hell to dissolve the pellet. My friend reckoned he had done it before and was sitting there shaking this bottle saying "you have to shake it real well otherwise the top comes off and ..." you guessed it, beer all over the kitchen!

Why are you trying dry ice? It would take ages to bottle a batch using this method - maybe we did it wrong - it was still bloody funny though!!!

Hope this may have been of some use...

From: MIKE LIGAS <LIGAS@SSCvax.CIS.McMaster.CA>  
Subject: Brewing As Alchemy

It seems that a single letter on the importance of a hydrometer has stimulated a series of replies and counter-replies in the past few issues and these have evolved into discussions of "Brewing as a Science" versus "Brewing as an Art". Well, I can resist no longer. I submit that the "versus" concept be dropped.

IMHO brewing is a wonderful marriage of Science \*AND\* Art. My personal pursuit in brewing is much like that of an alchemist, trying to find the panacea by transforming base ingredients into something precious. A brewer knows his/her objectives, be it a dry stout, a malty porter, a fragrant pilsner or a tart weizen. One's perception of what constitutes perfection within these loosely described styles is personal and is one of the many artistic components of brewing and tasting beer. Fine tuning a successful recipe and procedure to achieve a desired end requires understanding the scientific component of brewing. An attempt, for example, to brew a pale ale with the dry bitterness of Double Diamond could be frustrating without an understanding of the influence of water hardness and calcium on the perception of hop bitterness. Other attributes like colour, body, aroma and flavour to name a few (along with the diversity inherent within each attribute) should all be appreciated for both the artistic component of their perception, balance and appreciation and the scientific components of the brewing process which affect their final outcome. When designing a recipe I find that the creative process must work with the scientific process or the pen should be put down...and another homebrew should be consumed.

Maybe that is why homebrewers are such a fun and unusual lot. Every homebrewer that I have met is independent minded, creative and unique. It is the uniqueness that makes defining a homebrewer singularly impossible. Thank Gambrinus for that.

Ihor--

Male hop plants do not produce cones. The rhizomes, which you get from distributors, are all females. Pollinated females will produce seeds which we don't want in our beermaking hops, so keep male hop plants away.

Subject: Hydrometer use

Here's our two cents from the Congress Street Brewery:

We use a hydrometer during brewing... sort of. We take the S.G. at all the appropriate times, but we have never used the S.G. readings to determine when it is ready for bottling.

When it stops bubbling, we give it a couple days, take the S.G. (out of curiosity, more than anything else), and bottle it. In most circumstances, it comes down .040 or so. If it doesn't, we note that it's a little odd, and bottle anyway.

The best thing (and the major reason why we still do it) about taking the S.G. is that it yeilds about 4oz of beer/mead/whatever that is simply waiting to be tasted.

So we do. Sometimes we think that we took the (unused) gravity wrong and have to do it all over again. Rats.

We calculate the % alc, but we find that the numbers don't come out very well. We find that tasting gives a better measure of the alcoholic content than any S.G. eq'n.

Subject: Plastic Carboys

Well we've been over this before in the past.  
I just looked at the ones on our water cooler here at work.  
They are #7 (whatever plastic that is) and specifically say  
FOR WATER ONLY, DO NOT REFILL WITH ANY OTHER LIQUIDS.

While the results of our previous discussion indicated that there are  
plastics that are supposed to be safe for alcohol (there are some  
alcohol products sold in plastic bottles), my personal suggestion is to  
exercise caution and be sure of what type of plastic you have and that it  
is safe for holding alcohol, since there was a problem in the past with  
the FDA recalling certain types of plastic containers from use for  
holding alcohol because they leached carcinogens.

Subject: Hop Drying

When you folks who grow hops dry them, how do you know when they're dry enough?

When I buy (leaf) hops, my dealer has them bagged and chilled to prevent oxidation. When I get them home I bag them, going so far as to suck the air out of the ziploc bag, and chill them in the 'fridge. In drying, y'all heat them and expose them to air. Seems like a mighty fine line in between...

Seems to me (here I go again) that the safest way to go would be as follows:

Harvest your hops, all at the same time, so you can assume they have a similar moisture content. Draw a small "random sample" and freeze the rest(\*). Weigh the sample, dry it, and re-weigh, so you can say "X ounces of wet hops equals Y ounces dry weight." Any time you need to weigh the hops, weigh the frozen(wet) hops and apply this conversion. If you oxidize and ruin the sample, no big deal.

(\* Freezing isn't be a problem, is it? If anything, it might cause the lupulin sacs to burst or be weakened and actually improve utilization.

Sunlight, as we know, reacts with hops once brewed; obviously, it can't have a harmful effect on living, growing hops. I would presume that it has no effect on harvested hops, either. Right?

From: greeley@kermit.boeing.com (Scott P. Greeley )  
Subject: Homegrown Hops

I have been growing my own hops for several years now here in the Kent Valley, whence the Kent Golding hops were named. I have five varieties that entwine themselves on 1/4" braided nylon rope on the South side of my house. Four of the varieties annually make it to the top of the rope two stories up. Actually, they grow past the second story, but that's another story. I get more hops than I can use annually (I'm a better gardener than a drinker), mostly from a Nugget plant. I usually don't get any appreciable quantity from my Wilamette plant but I don't know why.

I never bother to dry the hops because I think it's too much work. I stuff the fresh hops into tupperware and ziplocks and store them in the freezer.

I've never measured the moisture of my hops but I have found that using four times more undried hops (by weight) than the amount of dried hops you would normally use gives the right amount of hopiness. This appears to work because I've got a five-gallon keg in my basement now that is so hoppy that even Bert Grant would be proud of me.

Harvest is relatively simple. At harvest time, I unhook the rope where it attaches to the roof eaves and cut the vines at the bottom. I then take the whole assembly to the deck, drape it over my lap, grab a mug of homebrew and pick and sip, pick and sip... and plan the next batch of beer.

Subject: LA Times article

Just thought ya'll might find this interesting. Found it on page 2 in the business section of the Sept. 19 edition of the LOS ANGELES TIMES. All typos are probably mine.

>From ASSOCIATED PRESS

WASHINGTON- Agriculture Department scientists are finding that if you brew a better beer, the world will beat a path to your door.

They have developed some new, American varieties of hops and barley that they say provide Old-World flavor and superior malting qualities, and are working on several more.

Last spring, plant geneticist Alfred Haunold said he released the newest hop, call Liberty, said to have the desirable aroma qualities found in its parent, a popular German hop called Hallertauer Mittelfruh.

"Yet Liberty isn't troubled by the disease problems and poor yields that have all but wiped out plantings of Hallertuaer bred in Europe", said a report in the September issue of the USRDA magazine Agricultural Reasearch.

Liberty thrives in the temperate Pacific Northwest and produces double the yields of the Old World variety. A similar hop, Mt. Hood, was released in 1989 in Corvallis, Ore.

About 58 million pounds of hops are harvested each year in Washington, Oregon and Idaho.

In HOMEBREW Digest #727 the hydrometer thread continued. Time to put in my ha'p'orth:

Russ Gelinas:

> Another good use for a hydrometer is to check the results of a  
> mash ...  
[ excellent example deleted ]

Absolutely! Many also use the SG of the runnings to determine when it's time to stop sparging. Yep, IMHO, thermometers, hydrometers, and careful record keeping are the brewers' friends ...

Guy McConnell:

> ... I am an  
> extract/adjunct brewer and I think I can see where a hydrometer  
> would be of a great deal more service for all-grain brewers.

I respectfully disagree. The usefulness of a hydrometer for extract brewers is in monitoring the drop in SG during fermentation, so you have a fighting chance of determining whether the airlock has stopped glugging because it's all done, or because fermentation is "stuck". This is traditionally more of a problem in extract batches, and we now know it's due to lower levels of free amino nitrogen in extract worts. Its usefulness as a tool increases as you use it, if you keep records. Extracts have different degrees of fermentability, yeast have different degrees of attenuation, and both can be affected by temperature and water composition. It will probably take several batches before you can accurately assess your wort and beer using the hydrometer, but it's worth the trouble, when things don't go according to plan.

From: polstra!norm@uunet.UU.NET (Norm Hardy)  
Subject: Hop Growing (pt 2 in Seattle)

Some interesting responses arrived in my mailbox about my drying system in the automobile. I tried to respond to them and two got bounced back.

Two items of interest I would like to relate:

(1) I allowed 3 vines from each plant to start the climb up the twines. I trained each climber on its own twine so I could evaluate the progress.

String or twine works better for me than poles because the hops can better grab on and more quickly make revolutions to be secure to the twine.

For the Hallertau, there were twin poles each 15 feet high. At 8 feet

I strung horizontal twine each about 8 inches from the next one. As the

hop came up I trained the vine around one of the lines. Then I made sure the growth continued along the horizontal twine. Labor intensive

yes but very effective at avoiding a thick brush of vines. Also very pretty to look at when in full bloom with cones.

(2) A trellis system worked better for the multiple Herzbruchers. After growing for 10 feet, the vines were allowed to meander over the trellis

with its crosshatched twine about 8 inches apart. Maintenance was low

and the thick leaf growth was impressive. Harvesting was a chore until

I just cut the twine and let it all come down.

A quick glance through Shotgun News shows many suppliers of powder scales.

I would recommend especially:

Graf & Sons (Missouri) - 314-581-2266  
Midway (Missouri) - 1-800-243-3220 \$25 min order  
Natchez Shooters' Supply (Tennessee) - 615-899-0499 (info)  
800-251-7839 (orders)

These are all large and reputable mail order houses, and I expect their prices will be similar on most items. I've personally done business with Midway, and friends have dealt with Natchez, with no problems.

In an event, you can get an inexpensive Lee powder measure for about \$20 from Graf (the others didn't list prices for this item in their ads; again, I'd expect them to be similar). For \$35, you can buy a Hornady measure in either grains or grams.

> They're compact and very accurate, but are, unfortunately,

You won't need a CRC... it's surprising what you can find in a good dictionary. Webster's New World tells me a grain is 0.0648 grams and 1/7000th of a pound (Avoirdupois), meaning 437.5 grains in an ounce.

And of course, there's nothing wrong with recording "I added 95 grains of Burton salts" instead of "1 1/2 tsp" or whatever. You'd want to convert these weights to grams if you ever give someone the recipe, but for your own use, use whatever units are convenient.

Tom Hamilton wrote:

From: STROUD%GAIA@sdi.polaroid.com  
Subject: Lightstruck beer

I recently came across an article entitled "Photochemistry of Beer", published in The Spectrum, Vol. 4, Issue 2, Summer 1991. The author is Denis De Keukeleire, State University of Gent, Gent, Belgium.

Much of the article is very technical, with a description of the reaction mechanisms of various hop constituents with light, heat, singlet oxygen, etc.

However, I thought that the following section from the article would be of interest to the (home)brewing community and would help clarify some of the ongoing debate about light/hops/skunkiness.

Enjoy! (any typos are probably mine) - Steve Stroud

#### THE LIGHTSTRUCK FLAVOR OF BEER

To protect beer against the influence of light, it is stored in green or brown bottles. This effect has been known for more than a century (1). At that time green glass was readily available, hence the tendency to store beer in green-colored bottles. However, green glass transmits part of the visible light below 500 nm, while brown glass is almost opaque in the high-energy part of the visible spectrum (2). As a result, beer in green-colored bottles is exposed to harmful radiation, while brown-colored bottles are safe in this respect. On the other hand, beer in a can is totally protected.

Since many chemical substances are present in beer, it can be advanced that a number of photochemical reactions are occurring. It is assumed that most of the photochemical events do not affect the odor and taste of beer, except the photolysis of the iso-alpha-acids [these are the isomerized alpha acids, or isohumulones]. The resulting off-flavor is called the light-struck flavor. The light-sensitive chromophore in the iso-alpha acids is the acyloin structure. Activation of isohumulone with ultraviolet light leads to bond rupture.....leading to a ketyl-acyl radical pair (3). Subsequent loss of carbon monoxide from the acyl radical generates the 3-methyl-2-butenyl radical, that recombines with a thiol radical delivered by sulfur-containing proteins. The formation of 3-methyl-2-butene-1-thiol causes an offending light-struck

flavor (4). The flavor threshold is so low that even sub-ppb concentrations spoil the beer quality in a very adverse way.

The thiol is formed by direct UV-radiation, but also by visible light or sunlight. Since the iso-alpha-acids do not absorb in the visible region, the reaction is very probably sensitized by riboflavin (Vitamin B2). Colored substances, such as polyphenols, may also affect the light-induced decomposition of the iso-alpha-acids (5). Indeed, it is well-known that dark-colored beer is more susceptible to the development of the lightstruck flavor than light-colored beer (6).

The mechanism for the formation of the lightstruck flavor was confirmed by the unambiguous identification of 3-methyl-2-butene-1 thiol in illuminated beer (7) and by the light-stability of the so-called p-iso-alpha acids, or p-isohumulones (8). In these compounds the carbonyl group of the light-sensitive acyloin function has been reduced to a secondary alcohol by treatment with sodium borohydride. Consequently, beer that has been bittered with p-iso-alpha acids can be stored in colorless bottles [this is what Miller does-S.S.].

It should be noticed that a conversion yield of only 0.01% of the iso-alpha-acids in a concentration of 25 ppm in beer corresponds to the formation of several ppb of 3-methyl-2-butene-1-thiol, which is sufficient to be detected by smell and taste. When beer is poured in a glass, it is bound to be photolyzed instantaneously. Therefore, to savor beer in the most favorable conditions, it should be consumed immediately after it is being served.

Thanks to Martin and those who replied to me via email. As I mentioned, I am going to purchase a hydrometer and begin using it. I am already quite a meticulous record keeper and specific gravity readings are a glaring omission at this point. I also, horror of horrors, have never used a thermometer in my brewing. I intend to buy one of those as well. I have yet to have a problem by not using these instruments though. My rule of thumb for bottling has been to wait until the beer in the secondary has a still, bubble free surface and no bubbles are coming through the airlock. I then wait another week and bottle. The reason that I didn't start out using these instruments is that I started with a minimum of equipment and expense to make sure that I really wanted to pursue this hobby before plunging in whole hog as I usually do in anything I undertake. I am in the brewery upgrade mode now and I'm acquiring a number of things that I left out in the beginning. I borrowed a friend's hydrometer to take a finishing gravity reading of my Christmas brew when I bottle this weekend.

- - - - -

In HBD#728 Norm Pyle wrote:

>I have heard a lot  
>about dry hopping but don't know how many of you have  
>done it. Do you just throw fresh hops in the brew  
>after primary fermentation? How long do you leave them  
>in? Do you prepare them in any way? Blah, blah, blah?

I use Byron Burch's method. I simply break up the hop buds and place them in the bottom of my secondary before I rack my primary into it. Then, the next day, I stir them down with a steril spoon. The second day I do the same. The idea is to keep them wet and in the beer. The third and fourth etc. days I rotate the secondary 1/4 turn and back to kinda stir the hops without opening my fermentor. When my brew is done ... I rack it through a steril nylon mesh bag (tied onto the end of my syphon hose... and under the beer surface to avoid splashing). I then prime it and bottle.

This will keep any hophead happy with aromatics!

Bill Thacker wrote:

>When you folks who grow hops dry them, how do you know when they're dry  
>enough?

My pamphlet by Dave Mills of Freshops in Oregon states that the hops are dry when the stem inside the hop bud snaps instead of bending. When you are drying periodically sacrifice a precious bud by removing the petals and try snapping the stem...

Ahhhhh... the life.... growing hops in Washington...

Art".  
>Well, I can resist no longer. I submit that the "versus" concept be  
dropped.

In a similar note...  
I consider computer programming and painting both to be art (brewing I'm  
sure fits here too). To be a successful artist involves two parts. The  
first is discipline. If you can not control your media sufficiently,  
then  
you can not get the results you want. In the case of programming, the  
amount of discipline required to get \*anything\* useful is rather high. In  
brewing, there is more latitude. The second part is creativity  
(inspiration, what have you).

Without sufficient discipline, no amount of creativity will get usable  
results.

Without creativity, you can not improve on what exists.

Many of the postings here really boil down to: How much discipline  
(control) do you have over what you are doing? The rest is recipies and  
techniques and their myriad variations.

Subject: Re: Homebrew Digest #728 (September 20, 1991)

'Morning, folks

I'm interested in some efficient methods for crushing grain. In the past I have used:

1) One of those hand-held chopping jars with the spring loaded chopping blade (you know, like the one you give your mom for mother's day when you were about 10). Due to the small size and large amount of work, definitely NOT recommended for more than, say, 1/4 lb. of grain.

2) A blender with a pulse feature.

Neither of these methods are any good. They tend to be very uneven - some grains are pulverized to dust while others are untouched. My local supply shop sells something called a "Corona Mill". Is this the solution? Or are there other, better methods?

From: tony@spss.com (Tony Babinec)  
Subject: dry hopping/brewing spiced beers

Here are some ways to dry hop:

(1) Just throw the damn things in. I've done this a few times and have not infected the beer. We've all read at one point or another that brewers would spice their beer with one thing or another--juniper, ginger, what have you--and that they empirically discovered the preservative qualities of the hops. Your wort is hopped from the first bittering additions, so presumably you should benefit from this quality of the hops. Of course, we also add hops for their wonderful bittering, flavoring, and aromatic qualities. Yes, the concern is that the hops, like anything else, harbor bacteria, wild yeast, and other nasties, and that's what makes us nervous.

(2) Briefly boil the hops first. Bring a small amount of water to boil, boil the hops for about a minute, let them cool, then toss in the hops and the water.

(3) I think I just read this in a recent HBD. You value the dry hops for their aromatics, and don't want to boil them because you'll destroy the volatile oils. So, instead, soke the hops in some vodka, and warm the solution (not too warm!). Then, pitch hops and vodka into your secondary. The alcohol in the vodka will sanitize the hops.

What quantity of hops should you dry hop? Try 1 ounce. For how long? At least 1 week. A good time to do this is when racking from primary to secondary. I recall someone (source unknown) arguing that you should dry hop for 3 weeks to adequately use the hops, but I don't know if this is true or not.

The last idea can also be extended to the treatment of herbs and spices for spiced beer. Instead of throwing the ginger, coriander, orange rinds, etc., into your boil, soak them first for several weeks in a vodka solution. The argument here is the same as above. You sanitize the spices and herbs and preserve the volatiles which are an important component of aroma and taste. When you get around to brewing, you'll have your spices ready to add to secondary.

Well Martin, as you know, I make very good use of my reloading scale!

I have a RCBS scale, the 505 model I think, without looking. It will handle up to about 1000 grains. It also has a conversion scale to grams, as grams are what bb's and shot are weighed.

There are a number of manufactures, for instance RCBS, Lyman, and Lee. A scale can typically range in the \$50 range, but as with any other item, can get into the \$100's. They are easy to find at many sporting goods stores.

As far as accuracy, mine goes to 0.10 grains, which is pretty reasonable.

From: auspex!tooch@uunet.UU.NET (Michael J. Tuciarone)  
Subject: Re: more uses for the hydrometer

Q. 14: Describe how one determines alcohol content of a brew using a hydrometer.

PREFERRED ANSWER:

Take a specific gravity reading of the unfermented wort. Upon completion of fermentation, measure the specific gravity of the resulting beer or ale. Apply a factor to the difference to yield percent alcohol.

OTHER ACCEPTABLE ANSWERS:

1) Carefully measure one kilogram of beer into a vessel. Heat to precisely 195 degrees Fahrenheit, and hold at that temperature for ten minutes, stirring constantly with the hydrometer. Cool and weigh the result; the difference is the percent alcohol.

2) Seek out the brewmaster. Say, "If you tell me the alcohol content of your beer, I will give you this hydrometer."

In other news, Ken writes:

> I'd be curious to know more about this. I believe hops are a polyploid  
> (maybe a diploid?) of marijuana...

I presume the preposition you wanted was "like," not "of."  
And yes, most of the "commercial" strains of marijuana now grown in the U.S. are polyploid: they have redundant sets of chromosomes to enhance the expression of characteristic traits. This is quite common in cultivated plants; corn is another example.

Rumor has it that those clever botany majors at Davis had something to do with the genetic manipulation of California pot.

From: ek@chem.UCSD.EDU (Ed Kesicki)  
Subject: cooler pump

This is in response to the person who wanted info on recirculating pumps for his wort chiller. We use these in the lab to recirculate icewater through condensers. I've seen them in hardware stores also--they are used to recirculate water in those babbling brook things that people put in their yard/patio. They are made by the Little Giant Pump Co. We use Model #1. Here is full info if you can't find them in a store:

Little Giant Pump Company  
3810 North Tulsa St.  
Oklahoma City, OK 73112  
Tel. (405) 947-2511

They are also available from Fisher Scientific, Pgh, PA. Here is the info Fisher gives for Model #1:

List price \$65 (probably cheaper in hardware stores)

Flow rate 12.9 liter/min at 1 foot head  
4.9 liter/min at 6 foot head  
Able to lift water 7 feet

This is a submersible pump, so you would just have to attach it to your wort chiller and put it in a bucket of icewater; the outlet hose of the chiller would then be put into the bucket. To avoid excess ice use, probably best to use RT water at first. I don't know how much time this set-up would save, but since someone asked, I thought I'd post what I knew.

From: Sean Dyer <C03601SD@WUVMD.Wustl.Edu>  
Subject: If you build a better siphon the world will.....

I've noticed alot of recent discussion about oxidation of wort/green beer while racking. I am also concerned about this problem but have not yet figured out how to rack my siphon without a substantial amount of bubbling and obvious oxidation. I have dealt with this problem by keeping racking to a minimum. That is I ferment only in a primary and rack only at bottling time. I would like to be able to rack my fermented beer to a new vessel and fine it but I can't seem to establish a bubble free siphon when the little cap is attached to my racking tube. The inadequate siphon that I am able to establish is rather slow and therefore increases exposure to infection. I would also like to be able to chill my unpitched wort for about 12 hours and rack it off the precipitated trub. Obviously oxidation would not be a problem but I am hesitant to expose the unpitched/unprotected wort to infection in the racking process. Does anyone have a better solution than siphoning or a better way to siphon?

Subject: male hop plants

I agree that you don't want to introduce male plants. If you or your neighbors have different varieties, the resulting cross-pollination will result in some indeterminate hybrid if any plants are grown from the seeds produced. This is an undesirable situation as much work goes into producing and characterizing hybrids.

I have a fuzzy memory of reading somewhere that it either is, or has been illegal to introduce male plants in some regions in which the growth of hops is an important industry.

 From: "Spencer W. Thomas" <Spencer.W.Thomas@med.umich.edu>  
 Subject: AA Brewers Guild meeting report

Somebody, a while back, had a question about what one might do at a club meeting. Well, I went to my first such meeting this week, and it was a blast!

I should start out by saying that, apparently, not all meetings of the Ann Arbor Brewer's Guild reach this high level.

The meeting took place at a member's house (as, indeed they all do), but this particular member lived a good 45 minute drive away. I couldn't have found the place without the map he sent out with the newsletter (it was back in the woods, down a dirt road, after following all manner of twists and turns through the nearest town.) The meeting started at 7:30; I got there about 8:00, and the club secretary came in shortly after I did.

This meeting was titled "brewing^2", and involved the brewing of two almost identical batches by a couple of good brewers. They had gotten hold of some Budweiser kegs and gone wild in the metal shop. (Dave West, the host, has an amazingly well equipped metal shop in his garage. One of the other members commented that he had seen service stations that were less well equipped.) There were at least 6 modified kegs in evidence. A few details on the brewpot construction: The tops had been cut out of the kegs (with a grinding wheel, I think). Some were cut bigger than others, the larger pieces made good lids for the pots with the smaller holes. They had drilled holes at three locations up the side and soldered in (1/4"?) copper tubing (there was a fitting involved, as I believe that you can't solder to stainless steel), crimped at the inside end, to hold dial thermometers. The tubing was slightly flattened to make good contact with the thermometer probe. Near the bottom (3" up?) were three stainless crossbars, welded to holes drilled in the side of the pot, that served to support the mesh that took the place of a lauter tun during sparging (more on this later). Below these was installed a spigot and pipe (3/4"?) with an elbow pointing to the bottom to draw out the wort. Here is a lousy ASCII picture that may help:

The copper mesh was interesting. It was made in two "half moon" pieces, each with a rim around the edge (two pieces so that it can be fit in through the top of the pot!) The holes were at least 1/4" in diameter, much larger than I would have thought would work. However, almost no grain or husks came out the spigot!

When I got there, both pots were full of grain and water, having reached mash temperature about 15 minutes earlier. One mash was going about 150, the other around 160 (as I recall); the intent that one brew would end up dryer than the other. One of the brewers had attached a pump to his spigot (using a quick-connect fastener) and was recirculating the wort to the top of the pot. The idea was that he wouldn't have to do any recirculation when he sparged.

As mash-out time approached, they both started to heat sparge water over some industrial-strength burners (most homemade, I think one was a "Cajun Cooker") that sounded a bit like jet engines when they were fired up. They lit the burners with a propane torch ("I don't want to get my fingers too close."). While heating, the bottoms of the pots reached a dull orange glow. 10 gallons of water took about 20 minutes to come from well temperature (50deg F) to a boil. Although the night was chilly, we all had no problem keeping warm!

Anyway, they sparged and boiled (one had problems with his pot boiling over, the other didn't) and cooled the wort with some monstrous immersion chillers. Looked like 1/2" copper tubing to me. I think smaller tubing would have been better, as the water coming out the end of the chiller was not really hot (agitating the chiller helped some). (A side note: Dave claimed that a Cornelius keg makes a fantastic form for rolling a coil the right size to chill a Budweiser keg full of boiling wort.)

By the time the wort was chilled enough to pitch, it was after 11, and I had to leave. I don't know what time they finished (especially the clean-up), but it must have been late.

Around this brewing activity was lots of homebrew sampling, conversation, recipe trading, and so on. A good time was had by all. Next month, we'll sample the results.

From: bryan@tekgen.bv.tek.com

**Subject: Hydrometer and fixing the current batch.**

If you take a specific gravity reading on your batch while you are still boiling it, it's easy to hit a target O.G. (Put a little of the wort in the freezer to cool it to 60 degrees before making the measurement.)

If the reading is too high, add a little water. If it's too low, boil a little longer.

Subject: wet hops

Bill Thacker's suggestion that we hop growers "harvest all our hops a the same time so we can assume they have similar moisture contents" is a good one (sorry I'm not doing real quotations today--I'm on a public machine without my favorite utilities). Bill, can I expect you next year to help so that you and I and a few dozen other folks can get all my stuff harvested in one day? :-)

Seriously, I don't thing one could assume that ones cones were of a similar moisture content even if harvested the same hour. I noticed that upper cones were moister then lower cones. There was also a certain amount of variation from one plant to the next. I'm not a chemist (or an alchemist for that matter--I dutifully keep detailed records of all the measurements, but I do it backasswards. I trained as a chef for years--I grab the hops and say to myself "Hmm, that's enough." and then I measure them to find out how much I had decided on!), but I also wonder about "breaking the lupulin"s (sp? ) by freezing wet hops as being a good idea. I know when I was young and foolish and was an afficionado of another special plant's flower, that you definitely didn't want to break its lupulins even if frozen. Any of you chemistry/biology guys care to comment?

Date: Fri, 20 Sep 91 16:45:44 EDT  
From: eisen@kopf.HQ.Ileaf.COM (Carl West)  
Subject: Yet more hops questions

I got my rizhomes late in the season, put 'em in anyway, and got four relatively short hop plants. Just the other day I harvested all twenty cones off the Bullion (the only one that produced).

Now I'm thinking that there is a better place to have put the plants. Im not much of a gardener so:  
Do I want to dig them up now and move them?  
Wait till spring? (seems wrong)  
Wait till the end of next season and move rizhomes?  
Or wait till the spring after next and move rizhomes?  
BTW I live in southern Massachussetts for whatever difference that might make.

Meanwhile I've rooted some clippings and they're starting to take off, has anyone grown hops as a house or office plant through the winter? I'm gonna try.

Carl

When I stop learning. Bury me.

Date: Sat, 21 Sep 91 10:47 CDT  
From: arf@ddswl.mcs.com (Jack Schmidling)  
Subject: SNRATIO

To: Homebrew Digest  
Fm: Jack Schmidling

RE: rsd@silk.udev.cdc.com

>I appologize to everyone if this is the fourteenth Jack Schmidling flame that you've waded through today. It is a huge credit to the digest and its subscribers that the SN ratio is consistently so high, and that the contributions so consistently valuable (at least to me).

>In this vein, If you do not wish to be further persuaded that Jack is probably not qualified to produce the video "BREW IT AT HOME", go on to the next article.

Jack says:

I am not sure just what affect flames have on SN ratio but in spite of your attempt to reduce my efforts to an evil conspiracy to extort money from unwitting neophytes, I would like to point out that I am capable of learning as I go and do modify my thinking as I learn. How bout you?

>Jack asks:

>> 1. The amount of surface area exposed to air in the narrow column of falling beer is trivial and steadily shrinking.

>Initially there will be no CO2 and lots of splashing. This initial phase alone will probably damage the beer. Furthermore, The question presumes that air is being transported into the beer only by diffusion into the falling column of beer. This is not, in fact, the case. The falling beer molecules are.....

Jack says:

A very excellent argument which I will take under advisement.

However, yesterday I taped a segment at the Baderbrau brewery (Jackson's favorite American beer) and saw something that seems to blow your whole argument to hell.

Just before the caps go on, a very thin, high pressure stream of sterile water is squirted into the bottle. The result is immediate foaming and frothing, up and out of the bottle. This fills the headspace with CO2 and drives out the air.

>> 2. The CO2 blanket keeps rising to cover more and more of the column making exposure to air, near zero near the end.

>The CO2 blanket is only helping to keep air from diffusing in

through the surface of the beer in the priming bucket. Diffusion is slower than molasses anyway. The problem this solves is not nearly as great a problem as the others you have created.

Jack Says:

You are ignoring the point I made and pursuing your own with vigor. As the beer rises the column gets shorter, blanket or no.

>> 3. If the pros inject oxygen while pitching yeast and homebrewers are supposed to splash it around to oxygenate at pitching time, what harm can a little oxygen do when we want to re-invigorate the fermentation at bottling time?

>This is the question I found most infuriating. It would not be infuriating if asked by a novice home brewer. It's a good question. The problem I have with Jack asking it is that it means he has zero familiarity with the yeast life cycle. This means he has done essentially no reading on the subject of home brewing. He is making this video without trying to understand his subject.

Jack says:

And you are making personal attacks without trying to understand the person you are attacking.

As anyone knows, who HAS read the literature over the years, it is replete with errors, myths and contradictions. I just finished reading Noonan's \$20 tome and find it not only full of hard to find "facts" but just as full of "momilies" as this digest and every other book I have read.

My main objective in "BREW IT AT HOME" is to demonstrate a process that works every time and produces an acceptable beer, at minimum expense in energy and dollars. The secondary objective is to whet the appetite for more advanced procedures and better beer.

What I refuse to do is repeat and perpetuate unproven myths and discussions such as this help me to sort them out.

>Jack has demonstrated that he is making this video without making a good faith effort to understand his subject matter. It seems to me that Jack plans to deceive people into thinking that his video is a useful guide to home brewing. It also seems to me that Jack plans to profit from sales of the video that arise from this deception. In Minnesota, this combination of deception and profit is what constitutes the legal definition of fraud.

>It probably won't matter. I imagine that most reputable homebrew outlets will quickly recognize the amateurishness of Jack's technique and refuse to carry it.

>Sorry for raving.

Jack says:

I left your "raving" in tact, just to make my point. It requires no further comment than to mention that I do not plan on selling it to the choir. The market I am targetting are the masses who never dreamed that decent beer could be made at home.

I am not quite sure of your motivation but I appreciate the opportunity to exchange ideas and squash momilies.

BTW, you remind me a bit of the guy who did a scathing review of "THE ROTTEN WORLD OF FUNGUS", in an obscure little mushroom hunters journal. He took the opportunity to play big time movie critic and played it to the hilt. Most of comments were technically correct, but totally irrelevant to the objective of my film.

Jack

p.s. An experiment occured to me that I will try the next time I prime a batch. I will hold a lighted batch in the priming bucket. If it goes out, I win.

From: Paul Dodd <pdodd@tetons.eecs.umich.edu>  
Subject: Avoiding a wort-chiller

I'm a newcomer to brewing, and I just started my second batch last night. My first batch took too long to cool (overnight) so I thought I'd try to get the wort to cool faster this time. I'd like to see what others think of this:

I used 5 1/2 gallons of bottled (in plastic) water for my brew, since Ann Arbor water sucks. What I did was put 1 1/2 gallons into the boiling pot and the other 4 to the back of the fridge, and I cranked the fridge cooling way up. The result was a semi-slushy mix of ice and water. When I added the hot wort and cold water-slush in my fermenter, the resulting temperature was 62 degrees F! Who needs a wort chiller? Any potential problems?

From: darryl@ism.isc.com (Darryl Richman)  
Subject: re: large batches

David, I use a food grade "trash" can for most primaries and then go into 3 carboys for secondary, although I have done it all in carboys in the past.

Since the amount of time and effort to make 15 gallons is the same as for 5 of all grain beer, it makes a lot of sense to make the larger size.

David> What the heck do you use for primary and secondary for a batch that  
David> big? Is it all done in one vessel or do you use multiple carboys?

I mash in a large, rectangular, Coleman-style cooler (slotted pipe), boil in a topless Bud keg, and ferment in a pair of carboys (typically one 7 gallon, one 5 gallon).

The amount of work/time seems to be only a little more than for a 5 gallon batch, so I think this is a win.

>

I've primed every batch with honey (which is only 15, all from malt extract), and have never had this problem. I usually drink my first beer one week after it has been in the bottle (it's still pretty flat, but I can't wait the month that it takes to fully carbonate), and have never noticed a vomit like taste. By the time the month is up, the batch is usually more than half gone.

As for how much honey to use, I only use about four ounces (liquid ounces), as I like my beer with less carbonation than my fellow homebrewers with whom I compete. I find my beer has good carbonation in the mouth, not that much head, and I don't get full (of gas) from drinking it. I can also drink it at basement temperatures this way (I don't always have the foresight to keep enough in the fridge).

Just to me on the safe side, I make sure that I boil the honey with some water for at least 10 or 15 minutes to kill any wild yeast that might be in with the honey.

Subject: Re: SNRATIO

In HD729 arf@ddswl.mcs.com (Jack Schmidling) replied to a posting in HD728 by rsd@silk.udev.cdc.com (Richard Dale). The following letter is in response to Jack's letter to Richard. In HD729 Jack Says:

> .... I would like to point out that I am capable of learning  
> as I go and do modify my thinking as I learn. ....

It is your receptiveness which makes replying to you, even in contradiction, worthwhile.

> However, yesterday I taped a segment at the Baderbrau brewery (Jackson's favorite American beer) and saw something that seems to blow your whole argument to hell.  
>  
> Just before the caps go on, a very thin, high pressure stream of sterile water is squirted into the bottle. The result is immediate foaming and frothing, up and out of the bottle. This fills the headspace with CO2 and drives out the air.

This is a good lead-in to a discussion of what procedures are undertaken during bottling to minimize oxidation. The beer to be bottled, unlike the beer being racked and primed in Jack's first letter in HD727, is already carbonated. In order to prevent foaming during the bottle filling process the automated bottle filler will flush the bottle with CO2 and then raise the internal CO2 pressure to 25-30 psi. The CO2 line is then shut and the line from the carbonated beer is opened. The beer is under the same pressure at this point as the bottle. A side valve then slowly bleeds off the CO2 from the bottle allowing the beer to enter, displacing the CO2. This filling under a steadily decreasing pressure prevents foaming and has the added benefit of filling the bottle in the absence of oxygen. Once full the bottles are at the stage described above by Jack (with the bottle filler now removed). The sterile water which induces a small release of CO2 which "drives out the air" (containing O2) is itself deoxygenated. The little bit of air surrounding the "high pressure stream of sterile water" is probably carried into the beer by the process described by Richard in HD727 and this is a small caveat.

The time that this stream is in contact with the beer is in the order of tenths of a second and isn't comparable to the stream of beer filling the priming bucket. To be fair Jack, you'd also need to flush your priming vessel with CO2 to draw an analogy since the small space between the meniscus of the beer and the top of the bottle would also contain some CO2 from the filling process.

All this may seem petty but it seems that details need to be discussed to solve an argument which is growing more intense with each issue of HD. The bottle filling process itself is a clear demonstration of the need to reduce oxidation of fermented wort and further dispels the notion that reducing air contact with fermented beer is a "Momily". Oxidation is a real phenomenon and reducing it can only help improve your beer.

Try priming half of your next batch of beer using your usual method and the other half by filling the priming vessel with the draining end of the syphon tube submerged in the beer to reduce turbulence. A month of aging and a taste comparison may provide interesting results. ;- ) (BTW, I did this many moons ago and noticed a difference...I noticed a slight cardboardy taste in my 'oxidized' beer but it was still drinkable). Anyways, experimenting is fun!

> I am not quite sure of your motivation but I appreciate the opportunity to  
> exchange ideas and squash momilies.

I hope we are all motivated by the desire to brew better beer! Although momilies

do exist, avoiding oxidation never was one.

RDWHAHB,  
Mike

Subject: Relax

Time:10:19 AM Date: 9/23/91

Subject: Relax

Before I begin:

Please, please, please restrict the flame-fest to direct email. We are AMATEUR brewers here. If you don't like Jack's video, please post TECHNICAL problems with it. If you don't like Jack, either email him or post to alt.flame.

Now, I have a number of items:

1) I just had to junk an entire batch of Canadian Ale. )-: I was suspicious of it all along, because the primary fermentation was late and occurred while my A/C was down. I'm guessing that bacteria managed to get a foothold before the yeasties had a chance to do their duty. My question on this is whether you can tell by tasting the "beer" before you bottle it whether it will be worth bottling.

2) I HATE sanitizing my bottles. Can I run them through the dish-washer before bottling (perhaps with no soap, or with B-Brite) instead of dunking and rinsing by hand?

3) I recently toured the Happy Valley Brewery at Penn State (Good Scotch Ale, but awful "Light" which tasted not unlike the Canadian Ale I pored down the drain). The brewmaster made reference to the Seibul (sp?) brewing school in Chicago (where he went) as well as apprenticing. Anyone have info on the school or how to get into an apprentice position anywhere?

4) Does anyone know of any homebrewing clubs in North/Central Jersey? If not, does anyone have any good ideas on how to start one?

That ought to do it for now...

-Bob Hettmansperger

>Does anyone have a better solution than siphoning or a better way  
>to siphon?

Oh well, Sean, you asked. It was as a result of all the above concerns that Mike Morrissey and I designed the BrewCap 8 years ago. You drain the yeast away with the BrewCap instead of racking the beer away. It's not a better way to siphon. It's the elimination of post-pitching siphoning altogether. Bottling is more like draining than siphoning the beer into the bottles.

My 2 cents worth on the splashing of post fermented wort:

I deep-sixed the first 3 or 4 batches of beer I kegged because I oxidized the hell out of 'em when I drained them to the keg. Good beer in the fermenter. Bad beer out the tap. I, therefore, take my stand in the camp that says one must be EXTREMELY gentle with the beer when you start moving it around after it's fermented out. Splashing it around may form a CO2 layer above the beer. That still doesn't mean that it hasn't picked up some O2 as it falls through the air. I pour about a pint of boiled water into the bottom of my kegs after injecting them with CO2 and begin the siphon GENTLY with the end of the siphon hose beneath the surface of the water so that the new beer exits the siphon hose into liquid instead of air. This has eliminated my oxidation problems. (BTW, good luck on the video, Jack. As you're finding out, everyone has his opinions when it comes to the BEST way to make beer.) :-)

From: eisen@kopf.HQ.Ileaf.COM (Carl West)  
Subject: Benign infection?

Last night I made up a starter of CWE yeast, which I pitched this morning.  
No problem.

I looked at my starter bottle and said to myself, "Hey, there's enough yeast left in there to make another starter if I just add some of my sterile wort to that bottle, I'll have enough to start yet another batch". So I go grab a bottle of sterile wort that I put up a month or two ago and open it.

PFFFFFFFT! It ain't sterile!

It smells kinda like beer and doesn't taste at all bad. It has a medium-strong honey taste which is surprising to me because there's only malt in there, and it was over-carbonated which is no surprise because the entire 'fermentation' happened in a sealed container. There's little evidence of alcohol.

I'm thinking of trying to culture it if there's anything left alive in there.  
Any good way of finding out what I've got?

Carl West

From: rsd@silk.udev.cdc.com  
Subject: Flaming in the HBD, an apology, and discussion of a couple of points

This is out of order.

Jack says:

...And you are making personal attacks without trying to understand the person you are attacking.

Agreed.

The tone of my post was generally inappropriate, and the attack at the end was completely out of place in the digest. I appologize.

I agree with you that it is difficult to separate essentially groundless "conventional wisdom" from "science."

Your goal in "BREW IT AT HOME" , "...to demonstrate a process that works every time...", is certainly laudable, and everyone

Just before the caps go on, a very thin, high pressure stream of sterile water is squirted into the bottle. The result is immediate foaming and frothing, up and out of the bottle. This fills the headspace with CO2 and drives out the air.

I am not a chemical engineer.

My knowledge of fluid mechanics is based entirely on a course I took in grad school 15 years ago, so the following is "semi-informed" and hardly authoritative.

If the column of water is moving at high speed, and is thin, the flow will be characterized by a high reynolds number and be what they call "turbulent". This means that the water jet will tend to stir the surrounding air molecules into eddies, rather than establish a nice laminar flow of air molecules into the beer.

If the process you describe takes place in an ordinary atmosphere, It can't help but introduce "some" air into the beer. The amount could be very small. The brewer has surely determined analytically that vastly more air was being eliminated than introduced and adjusted the technique as appropriate. Small refinements like --say-- bathing the jet of water with CO2 could be employed if necessary.

As anyone knows, who HAS read the literature over the years, it is replete with errors, myths and contradictions. I just finished reading Noonan's \$20 tome and find it not only full of hard to find "facts" but just as full of "momilies" as this digest and every other book I have read.

Ironic! Noonan was the book I had in mind. The life cycle of yeast is (I think) well enough understood to not be characterized as a momily. The description in Noonan explains why excess oxygen

at pitching time is not a problem later, and why oxygen introduced at bottling time will not benefit the yeast. Other posts dealt with the mechanics of how oxygen introduced late introduces off flavors.

My impression of Noonan is not so much that it is filled with momilies, as that it is the Readers Digest version of Malting and Brewing Science. Noonan certainly does often make pronouncements, for which he offers little support. I would be interested to hear one or two examples (from Noonan) of what you would consider "momilies."

**Subject: On Scales, significant digits, and reasonable expectations**

Pardon my manners here, but I have been amused by all the discussion about scales; particularly those folks discussing accuracies as high as 1/100th of a gram. Come on guys, this isn't nuclear chemistry we are talking about.

Well, enough of this flame mongering.

Practically speaking, don't go out and spend money on these high precision scales. Get whatever you can find that will be accurate to 1/4 oz for 1 to six ounces of hops and 1/4 pound for 10 pounds of grain. It's all too easy to spend money on brewing supplies anyway, so spend it wisely.

Why so grossly inaccurate?

Because your ingrediants (and your ultimate analytical tool - people) are so variable themselves, thats why. Hops vary in HBU's from supplier to supplier, and even from plant to plant; and extraction rates depend on your technique and skill. Grains vary likewise in modification level and starch convertability. Even your water supply will vary in analysis from season to season. This variation is over such a wide range, that measuring to 1/100 th (or even +/- 1 gram) gram is a little like buying an oral fever thermometer good to 1/1000th of a degree.

Well, I'm afraid I've offended enough people for one lunch hour (and I didn't even throw in my anology about the type of stereos guys from MIT buy).

/greg (and you can take this with +/- 1/4 oz of salt) %^)>

Subject: Kettle Alert!

A month or so ago there was a stimulating discussion in this forum on the use of the commonly-available 33 qt enameled steel canning kettles as boilers. One poster pointed out that the handles really didn't seem up to the task of safely lifting a full kettle. He was right.

Saturday I was mashing my Thanksgiving Scotch Ale in one of these kettles; 12.5 pounds of grain and 18 quarts of water. As I started to lift the kettle from the insulated box I use for mashing temperature control, one of the handles simply came off in my hand! The kettle was only about 3 cm off the floor of the box, so there was no spill -- lucked out again! By sheer coincidence, this was my first batch since an email discussion with Mike McNally had produced a chiller configuration that made it possible to avoid moving the kettle from the start of the boil until after the kettle was empty, so there was no longer a potential for anything worse than a very considerable mess, but still ...

Y'all be careful out there, y'hear?

Date: Mon, 23 Sep 91 13:07:03 PDT  
From: rfozard@slipknot.pyramid.com (Bob Fozard)  
Subject: Lager questions

I've been brewing at home now for about 6 months, and have recently tried my first grain batch, also my first lager. It's the "Vienna" recipe from Winner's Circle. I've been thru Papazian, Miller, and Noonan, and now would like to hear from you folks concerning the following items that seem to be mostly having to do with lager brewing:

- 1) Yeast starter. To avoid shocking the yeast, I would think that the yeast starter should be generated and kept at about the same temperature as you intend on pitching, in this case, about 50F. This would probably mean that you have to plan the brew 3 or 4 days ahead, as the starter would likely be slow to start. I didn't. I had the starter going at room temp., and pitched at 50F. Lag time was about 25-30 hours.  
How do you do it?
- 2) Diacetyl rest. Noonan suggests that it's common to raise the fermentation temperature to 52F just after the krausen has fallen, to aid in diacetyl reduction. This is to go on for a few days, after which you would go back down to 40F or so and continue with a racking/secondary fermentation. It's supposed to allow the lagering period to be significantly reduced. Do any of you have experience with this? I have the Hunter Air-stat controlling the fridge, so it's really no trouble.
- 3) Bottling/Lagering. I believe it's Miller that suggests lagering after bottling. This seems to me to be a better way, in that there are likely to be more yeast in suspension just after fermentation has finished, that will aid in carbonating in the bottle. If I lager at 35-40F for 6 weeks or so in the secondary, it seems there would be quite fewer (and sleepier) yeasts to take care of carbonation once I bottle.

ps. This batch was weeks in the planning, as I was studying and fashioning my equipment. I used a cardboard box and had some friends spray insta-foam into it in a perfect-fit mold around my mash tun (a 5.25 gallon enamel pot) for holding mash temps. Worked like a charm! (insta-foam is the stuff they sometimes use in packaging electronic equipment). For wort-chilling, I made a simple coiled 25' copper tubing unit. Immersed in 2 bags of ice (14 lbs) in a 5 gallon plastic bucket, topped off with cold tap water, it cooled my hot wort down to 70F in less than 10 minutes. No kidding!

Thanks for any info,  
Bob Fozard - rfozard@pyramid.com

Jack says:

You make an excellent case for the fact that what actually works isn't always theoretically correct (TC?). Just as many "momilies" are right for the wrong reasons, as are just simply wrong and many of them are wrong for the right reasons but work anyway, (most of the time).

Everything I described in that particular Baderbrau process seems to invite disaster according to theory but it is an incredibly simple solution to a very complex problem and it works.

I suspect I can prove with a lighted match in the primer that it is full of CO2 and my aesthetically pleasing video shot is no worse than what Baderbrau is doing.

As anyone knows, who HAS read the literature over the years, it is replete with errors, myths and contradictions. I just finished reading Noonan's \$20 tome and find it not only full of hard to find "facts" but just as full of "momilies" as this digest and every other book I have read.

Jack says:

My impression is that it is book covering very technical material, written by a person with little technical background. He is simply parroting the words of scientists without really understanding what he/they is/are saying.

Whenever he attempts to ad lib an explanation, he makes little or no sense at all.

> I would be interested to hear one or two examples (from Noonan) of what you would consider "momilies."

I was afraid you were going to ask that but I did highlight a few of the more obvious.

p. 70 Top fermenting yeast strains are only effective at 55 to 70 degs F.

p. 79 ...no pathogenic bacteria can survive in beer.

p. 151 ...it [foam/scum] must be eliminated from the fermenter by skimming.

p. 131 his explanation of the terms hot break and cold break are not only incomprehensible but also leave one wondering how the hell to apply them to the procedures he attempts to describe.

p. 142 He implies that too much water in the fermentation lock can put enough pressure on the beer to ruin it.

p. 159 Secondary fermentation should be conducted... as low as 30 degs F.

p. 202 The beer must be below 50 degs F for the [gelatin] finings to have any effect.

I can't find it at the moment, but somewhere he describes a procedure using the terms hot and cold break as though they were things you walk around with and decant from one test tube to another.

The index sucks and I never found a single word I was interested in, in the glossary.

The book purports to be a handbook for the pro but describes homebrew

process, the equipment for which is only poorly described in the text.

Many of the drawings and sketches either are not captioned or don't make much sense.

The fact that he devoted 33 pages to water and only 9 pages to hops leads one to believe that filling pages was more important than telling readers what they really need to know.

Aside from all that, assuming it is correct, I gleaned enough new information from the book to justify the \$20 I spent on it.

I was particularly delighted in the description of the crystal malting process because it explains why my homemade malt tastes sweet and malty. It also explains why it makes such lousy beer.

To wit... Normal malt is bone dry before kilning. Crystal malt is cured at 155 degs F while still containing 50 moisture. It is essentially, mashed in the husk and requires only a short boil in the wort to extract it.

In summation, I fully expect that "Brew It Home" will have its share of critics and criticisms but it is my intent to make sure they are limited to issues about which rational people can agree to disagree.

beg your pardon!) to get a siphon started. At any outboard motor  
(the kind that go on boats) dealer you should be able to purchase for  
\$5-10 a rubber primer bulb that is used to pump gas from a remote fuel  
tank to prime the carb. The bulb has two barbed ends which fit  
perfectly into 3/8" plastic hose which is typically the size used for  
bottling and racking. It even has a little arrow in the rubber that  
shows the direction of flow. Inside the bulb is a check valve that  
will keep your wort/beer from running backwards while you position the  
hose into whatever you are filling. Also helpfull is one of those  
plastic pinch thingies that will keep the hose primed while you set up  
the sterilized bottles that you just kicked over while looking for  
your beer. Usually two pumps of the bulb will fill about 5' of 3/8  
hose and if you do get over zealous and pump a little wort through the  
bulb, just rinse it by pumping through some tap water or the beer will  
stick the check valve open as it dries. I got mine at an Evinrude  
dealer 2 years ago and it has survived numerous abuses and  
sterilizations (back when I used to bleach EVERYTHING). Try it you'll  
like it!

PS. Bill Thacker asks about 58 million pounds of hops in a 5 gallon  
batch. It might get you the hopiness of a Liberty Ale but it  
might have a little too much mouth feel :->

From: oopwk%msu.dnet@terra.oscs.montana.edu (Warren R. Kiefer)  
Subject: 24 hour fermentation ??

Howdy,

And how are we all doing today ??

I have a question about repitching yeast slurry, I fermented a batch of porter with the liquid British ale yeast, then made up a batch of my annual Christmas cheer ( actually this is the first year :'). The ingredient list is something like this :

- 7lbs. malted barley
- 1 lb. crystal malt
- 1 lb honey
- 4 orange rinds
- 1 lemon rind
- 3 cinnamon sticks
- 1/2 tsp cardamom
- 1/2 tsp cloves
- 12 oz. huckleberries

Soooo, after dumping the slurry from the porter batch into this surprisingly great smelling mess around 6:00pm that night, I went onto other things and checked the batch around 11:00am the next day. There was only about 1 bubble every 30 seconds out of the airlock. The next time I checked was somewhere around 6:00pm that night and the airlock wasn't gurgling at all. I could make out the ring from the krausen about 1 to 1 1/2 inches above the beer in the fermenter. I used a plastic 7 gallon fermenter for this batch since I was afraid the huckleberries may clog my usual blow-off tube set up on the 5 gallon carboy. To sum up what I'm wondering is if anyone has had a 24 hour fermentation when repitching yeast slurry from a previous batch, there was a significant amount of slurry from the bottom of the porter primary fermenter. I have heard that honey is notoriously slow to ferment, so I was kind of shocked to say the least. The temp. has been steady at 65 F so I don't think that's the problem. Anyone have any ideas ???

Thanks to all for the info on all-grain brewing and the procedures for using liquid yeasties. My first 5 all-grain batches have turned out really great. So many thanks to the contributors and also to Rob for doing such an excellent job !!!!!!!!!!!!!

I think a homebrew is now in order --- cheers to all !!!

Hi,

I use various glass wine jugs[for the those who have to know they are called damigian(sp?)] They come is sizes ranging from 10litres to at least 60litres. Plus they are much easier to carry then carboys and at least in Toronto much cheaper by the litre. 54litre units are selling for about \$25cdn. 25litre units for less then \$20.

From: TSAMSEL@ISDRES.ER.USGS.GOV  
Subject: Science or Art/ A rhetorical question.

I have been homebrewing off and on for 25 years and I came to it through cooking, rather than science. However I do have a degree in Biology so I do have a scientific understanding of the process of fermentation.

Since I cook (both professionally and as a teacher) I find I get better results by brewing in a primarily intuitive (i.e. cooking) mode. I do use a thermometer and a hydrometer and adhere to the germ theory of disease, so I am not New-Aging the yeast daemons or sacrificing to the Godette o' Hops.

I see an awful lot of empirical brewers on this list and one of my questions is:

Did you cook before you began brewing?  
and if so,  
Do you always need to follow a recipe?

.....  
I only follow recipes if i am trying to brew a style I have never tried to brwe before.

Subject: Guinness Stout Recipe

Steve,

I was looking for the same not long ago. I just made a batch which is a variation on

Toad Spit Stout from TCJOHB. It looks real good. It has about a week to go

before I can try it. Here it is. 1 can John Bull Dark Hopped Extract.

3 lb M&F extra dark DME. 1/2 lb crystal malt. 1/2 lb roasted barley. 1/2

lb choc. malt. 1 1/2 oz Bullion hops boil. 1/2 oz Kent Golding Finish.

Cracked grain and brought to 170 F. Removed grain. Added malt,DME

brought to

a boil. added hops at 15 minutes and at 58 minutes. total boil 60 minutes.

Pitched with Wyeast Irish ALe Yeast. Almost blew the top off the primary.

OG = 1.052 FG = 1.013.

Several people mentioned on CIS that Guinness adds some sour wort back in at bottling so that as a homebrewer it will be real hard to get that real Guinness twang. Good Luck.

From: CHOLM@HUBIO2.HARVARD.EDU (HOLM LAB, HARVARD UNIVERSITY)
Subject: RE: Homebrew Digest #730 (September 24, 1991)

I was pleased recently to see a posting asking for good Christmas beer recipes; I have been considering doing one myself. The response, though, has been less than staggering. Two recipes have appeared, and while each looks interesting, neither author had tried the beer yet! So, I'm asking again:

Anyone got any good christmas beers that they've brewed AND tasted? And thanks to those who have responded already. It's not that I don't trust you, I'm just looking for a (relatively) sure thing.

Has anyone done any cider fermentation? I've done the standard thing of taking a gallon of preservative free cider and allowing it to ferment, but that's sort of dicey since all sorts of things are in there. I was planning on doing a 5 gallon batch this year, boiling the cider first and then pitching a good beer yeast, doing a proper primary and secondary fermentation, and then priming and bottling. Anyone else tried anything similar? Thanks.

Subject: stuff

Well, I want to change my opinion of the Commonwealth Brewery in Boston. The last time I was there, I was not thrilled. This time, I was very pleased. I actually only had time for a pint of amber, but it was fresh, clean, crisp, malty and hoppy. Sound good? It was. And "pulled" rather than poured, which gave it a nice creamy head.

Unfortunately, that experience contrasted with the one I had at the Cambridge Brewery, which *was* my brewpub of choice. There I had an insipid amber, and a just good Scotch ale. Dissappointing. But they were catering a wedding at the time, so maybe the brewing cycle had gotten disrupted in the planning for the wedding.

Now on to more important things. Can someone tell me more about Corsendonk Monk's Ale? It's from Belgium, and is a Flander's Brown, I believe. It had a mild sour tang to it. It is bottle conditioned, and has a good slab of yeast on the bottom. Any worth in culturing the dregs?

I want to make some cuttings on my hops, to send to a friend, and to start another plant (in a sunnier place). How big a piece should I cut, and where should I cut?

Subject: Juniper and spruce

Greetings,

As long as there's been talk of spices in beer I have a few questions. Has anyone out there ever used juniper berries in beer? I've seen a lot of juniper trees around here with lots of wonderfully fragrant berries on them.

Could I just pick some in the wild and put them in at the end of the boil?

How much should I use? Any idea when the berries should be picked?

Also, I tasted a spruce beer recently and it was great. I think that it was made with spruce essence. I heard that it could be made with new growth

of a spruce tree. Has anyone tried this? Again, is it just tossed in toward

the end of the boil? Will any old spruce tree do?

Thanks,

Joe

Subject: hydrometer usage

O.K., so you talked about whether or not a person should use a hydrometer, but you never said HOW a person should use one...

My first batch of homebrew is merrily bubbling away in my basement...

After having read this digest for several months (during a very busy summer), I decided that its about time for me to brew some beer. I bought a homebrew kit at my local brew shop, but instead of the 1 can of extract and x amount of sugar, I got 2 cans of extract (Geordie Bitter) and I got some whole hops (i.e., not pelletized) for "finishing". Anyway, the kit included only a large plastic bucket and no carboy, so I went to a local grocery that sells 5 gal glass carbouys of "Artesian spring water" for ~\$4 plus a \$6 deposit.

So, I went home and dumped ~2 gal of the bottled water into my recently purchased 16 qt SS pot that I bought at Target for \$17 (its very thin SS)

As the water was heating on the stove, I dumped out about ~.5 gal of the remaining water in the carbouy, so that I had room for the 2 cans of extract.

After boiling the 2 gal of water + 2 cans of extract for ~15 min, I put my

.5 oz of hops (in a hops bag) in for another minute or so. Meanwhile, I took a clean (but not sterilized of all life forms) glass of warm water, and dumped in the 2 packets of dry (boo, hiss!!) yeast in to "activate".

After my boil was done, I cooled the pot of hot wort in my kitchen sink, and dumped it into the carbouy for a total volume of almost 5 gal. Finally, I pitched in my "activated" yeast, and affixed a stopper with a "blowoff" tube and swirled the whole thing around on my way down to the basement.

I started it on Sun pm, and Mon am it was bubbling away; tonite I will replace the blowoff tube with the fermentation lock. But, I never did measure the SG...

I never had the whole thing together until it was in the carbouy, so how was

I supposed to get a "sample" to measure...siphon, but how...I don't know if I

want to "suck on the hose"...and if I want to measure the SG to see when its

ready to bottle, how do I avoid the "sucking" problem (sorry).

Not worried,

Yes. At least, what I do when I'm concerned is: draw a sample with a
wine thief, cool it or warm it to 60 F, measure its gravity, then drink
the sample. I always adjust the sample to 60 F because I find that its
easier than doing math to adjust the gravity measurement. I find that
if the wort tastes sweet, it isn't done, and that if it tastes flat and
dry, its probably done. My testing equipment includes thermomter,
hydrometer, iodine, and my mouth. I'm always looking for a bad taste
that would indicate infection. Since I switched from open to closed
fermentation, I've not had a problem, but I always want to check.

>2) I HATE sanitizing my bottles. Can I run them through the dish-
washer before

I do. I clean them first. My dishwasher doesn't get the insides of the
bottles clean, but it does get them hot enough to sanitize 'em. I use
no detergent or sanitizer; instead I just run the dishwasher making sure
the heater is turned on to get the water above 170 F.

Subject: Noonan, Chloride, and USP Grade Chemicals

Ohhhh boy, don't get me started about G. Noonan's "Lager Beer".
But since I'm starting to get interested in brewing lighter beers,
a question about something Noonan says:

In TCJOHB, Papazian states that wheat malt is weak in diastatic
enzymes and must be mashed in conjunction with barley malt
of great diastatic power. I have seen this opinion stated elsewhere
I think; Gary Bauer's article in the Zymurgy All-Grain Issue comes
to mind.

I am aware of some dissenting opinions and (I think) some counter
examples:

Miller, Fix and Foster in their books on Continental
Pilsener, Brewing Science and Pale Ale respectively state that
wheat malt has plenty of enzymes (Miller and Foster say this in
text, Fix shows the DP of Wheat Malt in a table).

The Widmer Brewing Company of Portland Oregon mashes Briess wheat malt
and Klages 2-row pale in a 50/50 ratio without any diastatic crutches
that I am aware of. Anchor uses an even higher ratio of wheat/barley
according to their outstanding tour-guide and only has problems
with the runoff, not the mashing.

I have only mashed tiny amounts and ratios
of wheat/barley up to now; and so am without direct experience.

Are Papazian and Bauer completely wrong? Do I understand the problem?

To: homebrew@hpfcmi.fc.hp.com
Subject: Chloride ions & USP; First posting was botched

Sorry about the last botched posting (old mail text inserted by mistake).

Now, the REAL questions:

1. Noonan in "Lager Beer" makes an offhand remark about Chloride levels > 100 mg/l being inappropriate for a "light" beer. (He then says that up to 350 mg/l is acceptable above 1047, which makes it sound like the rules suddenly change at that exact gravity; I'm sure this is not literally true nor his intent).

When using CaCl₂ or NaCl, what have folks discovered about acceptable levels of Chloride in mg/l for lagers around 1045 OG?

2. By my calculations, adding enough Calcium Chloride to achieve 100 mg/l Ca also gives 170 mg/l Chloride. Does this seem right?

3. I'd like to get some CaCl₂*2H₂O from a local lab supply to experiment with mash conditioning. Is USP the right grade for this purpose?

Subject: Banana beer

Cole,

Are you kidding?

I've got over a case of banana bock you can have for the shipping. I made it without any bananas. It was a partial mash from Miller's recipe made with Munich Lager yeast (Wyeast). The primary and secondary fermentations were conducted in my basement at a reasonable temp. The beer tasted very promising at bottling. I moved the day after bottling to a house without a basement, so the bottle conditioning was done in a garage which was considerably warmer than optimal for a lager. The net result: a strong odor and flavor of banana... undrinkable.

Interestingly enough, I bought a bottle of Paulaner Salvator this weekend and noticed a little of that same banana ester in that brew. Maybe a little of that is to style, but I don't like it. I find the Spaten Optimator to be cleaner and more enjoyable.

From: Jeff Frane <70670.2067@compuserve.com>
Subject: Comments in General

On the subject of oxidation and momilies, etc. and on and on, I would weigh in heavily in support of Mike Ligas' comments in HD730: his explanation of the difference between bottling carbonated and un-carbonated beer is the central point. It's also not even faintly clear to me why anyone would *want* to let their beer fall several feet through the air when placing the end of the syphon hose under the level of liquid is so simple--except as a visual device for a video. Not enough reason, IMHO, to take the very real risk of oxydizing beer. Has Jack Schmidling never tasted oxydized beer? If that's the case, I would be happy to let him join us in judging homebrew at the Oregon State Fair next May; I'm sure we'll find him some good--well, bad--examples.

On sterilizing bottles, in response to Bob Hettmansperger:

>I HATE sanitizing my bottles.

Amen. I have found the simplest and most effective way to deal with this nagging problem (on advice from WYeast's Dave Logsdon). I put my clean bottles in an oven, turn the temp to 350^ and leave them for 1-1/2 hours, turn off the oven and let them cool down to be filled. This can be done the night before bottling, or if I want to do it well ahead of time, I put little foil caps on each bottle before sterilizing, then put them back in their cases (with the caps intact) until I'm ready to bottle. No problem! This has made the whole concept of bottling *much* more palatable.

The school in question, is the Siebel Institute, which seems to specialize in training people already in the brewing business for advancement in their trade. Other than the brewing program at UC Davis, I believe this is the only brewing school in the US. Here in Oregon, it seems that most of the brewers got their start working as flunkies for other brewers. Teri Fahrendorf at Steelhead Brewing in Eugene and Jamie Emmerson at Hood River graduated from Siebel. The founding brewer at BridgePort, Karl Ockert, graduated from the Davis program. Most of the first generation microbrewers were just very brave homebrewers who might have taken a short course from UC Davis. I think the only way to get on

as an "apprentice" is to be lucky enough to take a low-paying job as a brewer's assistant and slowly work your way up--or get some real breaks.

On scales, and accuracy, in response to Greg Roody:

>accuracies as high as 1/100th of a gram.

Yup, pretty silly, given the raw materials. I use a shotgun loading scale calibrated in grams (no, I don't know why it is, but my dad purchased it from a scientific supply company many years ago, maybe that's why), for measuring pelletized hops. *Primarily,* though, I borrowed it from the old man to use in weighing out gypsum and such for water additions.

On Greg Noonan's book:

I have heard the book retitled elsewhere as "Everything You Know Is Wrong", which pretty much sums up my attitude toward it. I found the writing turgid and the methodology questionable. According to Noonan, as I recall, a normal brewing day would run to about 18 hours and the next six months would be taken up drawing samples for specific gravity. At one point, we calculated the end result would be about 1 bottle of very good lager after all your work and time.

To Warren Kiefer:

What makes you think you got 24 hour fermentation? From what I read, your fermentation pooped out after a pretty vigorous start. Did you aerate the wort really thoroughly? It's not too late to agitate things and try to stir up some action.

+++++
===Yeast Washing for the Homebrewer===

The following notes were taken from a demonstration given to the Oregon Brew Crew by Dave Logsdon of WYeast Labs, on September 12th. According to Dave, it was important for healthy yeast to be washed free of trub and hop residue so that it could be stored for future use. Dave said that the problem with simply storing the mixed contents from a carboy after fermentation was that the unwanted particulates would suffocate the yeast over a period of time. Most breweries, Dave stressed, use an acid wash; the sterile water wash is much more practical for homebrewers.

Objective: To recover yeast from a finished batch of beer for repitching or storage for future brewing.

Materials: One primary fermenter after beer has been siphoned off or otherwise

removed.

Three sanitized 1-quart Mason jars with lids, half full of sterile or boiled water. They should be cooled down, then chilled to refrigerator temperature (ca. 38°F).

Procedures:

- 1) Sanitize the opening of the carboy (flame or wipe with chlorine or alcohol)
- 2) Pour the water from one of the quart jars into the carboy. Swirl the water to agitate the yeast, hop residue and trub from the bottom.
- 3) Pour contents from the carboy back into the empty jar and replace the cover.
- 4) Agitate the jar to allow separation of the components. Continue to agitate periodically until obvious separation is noticeable.
- 5) While the viable yeast remains in suspension, pour off this portion into the second jar. Be careful to leave as much of the hops and trub behind as possible.
- 6) Agitate the second container to again get as much separation of yeast from particulate matter as possible. Allow contents to rest (about 1/2 hour to 1 hour) then pour off any excess water--and floating hop particles--from the surface.
- 7) Pour off yeast fraction which suspends above the particulate into the third container.* Store this container up to 1 month refrigerated. Pour off liquid and add wort 2 days before brewing or repitch into a new brew straight away.

*It should be noted that in the actual demonstration, Dave eliminated the final step; the yeast in the second jar was essentially clean at this stage and seemingly fine for storage.

Subject: Mail order grain...

What experiences have other people had in securing a source for cheap, quality malt?

In my experience, there are 2 stores nearby, here in Chicago. One has good quality grain, if you're willing to pay \$1.25/lb, with no volume discount. The other has moderate prices, a volume discount, and bugs in the grain...

So, I tried a couple mail-order places. The Malt House in Indiana sent me 25lbs. of 2-row for \$17, but shipped it in a brown-paper grocery bag, sealed with masking tape. It was not completely dry, developed mold, and had some dormant (and some not-so-dormant) bugs that looked curiously like malted grain, except for the fact that barley doesn't have six legs. The last place I ordered from was The Malt Shop/Kettle Moraine Vineyards, in Wisconsin. except for Rye malt, everything they had for sale was under \$1/lb, and they have a volume discount. They also shipped it in thick, sealed, plastic bags of small size - definite plus...

Does anyone have a good source for grain in the midwest (i'd like to stay in UPS zone 2 to reduce shipping cost)??? Otherwise, it seems like the Malt Shop is the way to go...

Subject: sex, beer, and TV

Norm Hardy reviews some recent TV commercials:

>good sex, and bad beer. The Silver Bullet sure comes UP nicely at the
end
>and finishes with a nice explosion of apparent pleasure. Hey, I'm not
for
>censureship, but sometimes I wonder....
>
>Like, how many skinny homebrewers do you know? Okay, so how many stay
that
>way? Not me.

This is the common trouble with TV anyway. Using women's bodies to sell
products is everywhere on TV. I believe this is a form of rape and is
part of the basis for why there is so much violent crime against women
in this country. Fortunately, I live in a part of the country where I
can receive only one channel (which wigs in and out). Somehow, I don't
think I'm missing much. I have much more time to spend on family and
home brewing.

Oh, and by the way, if a contest is ever held to award the skinniest
homebrewer, I will win it hands down.

Subject: dry hopping

Hello all.

I have a question that I posted to rec.crafts.brewing, and got no reply. Since the weather has gotten cooler in the midwest, I am getting ready to start brewing again. I have taken advantage of the HBD during the hiatus and picked up a lot of helpful tips and techniques (Thanks to one and all).

I am planning on brewing an India Pale Ale, and I want to try dry-hopping in the secondary. There has been lots of discussion lately about hops and dry-hopping technique, and this may be a stupid question, but if you plan on dry hopping, should you use any finishing hops?

Dry hopping supposedly gives you a much more pronounced aromatic hop character, why should I "waste" hops by tossing them into the boil to get aromatics? I'm not referring to bittering hops, which I plan on using as usual.

Thanks in advance,

^C^C^C

shit... reminds me of the Monty Python skit where the policemen come in and arrest everybody for the crime of having the policemen come in and arrest everybody at the end of the skit.

Oh well, I suppose If I don't want to be a hypocrite, I should post something substantial:

Munich Beer:

10 lbs pale alt Malt
5 lbs munich malt
.5 lb dextrin malt
1.5 lb amber crystal malt
1 Oz gypsum
.333 oz burton H2O salts
5.5 g hallertauer 90 min
1.5 oz cascade 60 min
.25 oz cascade 30 min
.25 cascade 15 min
weast munich beer yeast

the sparge stuck, so i got out a big strainer and sparged individual 1 lb strainerfulls of grain. I let the stuff settle, and it cleared up. After the boil, I had 3 gal 1.077 S.G. wort. fermented 2 months, added polyclar, racked and dryhopped with 1/4 oz hallertau pellets two days later, moved to room temp a week later, let sit for a week, and bottled. Finished the last bottle the other night.

You should get twice as much with a good sparge. The wort really needed to to be dry hopped longer - the pellets never really completely dissolved, and kind of filtered themselves out in the siphon.

Serve very cold or very warm.

>
> I noticed in a store the other day a small brew kit that consisted of a
> little keg (holds 28 beer), a CO2 cartridge, a tap, and a few other
gizmos.

A few years ago, someone gave me a beer kit that essentially consisted of a heavily reinforced (nylon mesh) plastic bag containing liquid malt. The bag had a tap spigot and a cap (w/pressure valve) for filling (just add water and the included packet of dry yeast, and, voila, beer in a couple of weeks). There was absolutely no boiling, etc., involved. Just add water and yeast.

After adding the water and yeast, and waiting for a couple of weeks, I tried the beer. While it was "drinkable", it had a pronounced acidic taste, which I believe was caused by a mild bacterial infection. Once you got used to the taste, it wasn't bad, but you had to get used to it (drinking more than one pint at a time certainly helped ;-).

Now, I don't know what instructions come with the brew kit that you've seen. If it comes with instructions on sanitizing the keg, etc., the beer may turn out all right. If it doesn't, you're probably taking a chance.

>The bottle filling process itself is a clear demonstration of the need
to
reduce oxidation of fermented wort and further dispels the notion that
reducing air contact with fermented beer is a "Momily". Oxidation is a
real
phenomenon and reducing it can only help improve your beer.

I am about ready to upgrade it from momily to factoid. The science
seems to
support it as do the anecdotal experiences reported.

>Try priming half of your next batch of beer using your usual method and
the
other half by filling the priming vessel with the draining end of the
syphon
tube submerged in the beer to reduce turbulence.

The outcome of this experiment will qualify it as a candidate for the
Xith
Commandment.

It just so happens that I will be racking a batch today and will conduct
the
experiment. You will be happy to note that I will be taping it with the
syphon under the beer to replace the segment previously shot.

From: BAUGHMANKR@CONRAD.APPSTATE.EDU

>I deep-sixed the first 3 or 4 batches of beer I kegged because I
oxidized
the hell out of 'em

> (BTW, good luck on the video, Jack. As you're finding out, everyone
has
his opinions when it comes to the BEST way to make beer.) :-)

Indeed! As they say, "too many cooks, spoil the broth". However, they
can't
spoil it by talking about it. In this case, talking about it can save
the
broth as long as we know how to apply the momily filter.

~~~~~

Interesting question! I have been an enthusiastic, if non-professional cook for more than 15 years, while my credentials as a scientist are strictly those of an interested amateur.

I hadn't really thought of it this way, but yes, I approached brewing (which I have been doing for about three or four years now) very much as I do cooking: Read a lot and use recipes at first, but thereafter, go by intuition and invent my own recipes, except when I want to duplicate a new style, in which case I always follow a recipe (more or less) for the FIRST batch.

I'll post this question (or an intuitive variation) on the CompuServe Beer Forum to see how an overlapping group of brewers responds.

Subject: Sex, beer, and non-sexist ads...

Jeanne Sova writes:

> In response to Ken Weiss' response to Norm Hardy, sorry guy, but I'm  
> VERY tired of seeing "skinny ladies with big busts and come-on faces  
with  
> a lot of skin." Beer commercials have always been very sexist, and  
> one sidedly so (if that's a word). Not very appealing to us females,  
> although the idea of good food, good company and good sex is.

How about applauding the good ads out there? What do you all think of  
the new ad for Lite? The one with the TV repairman who says "looks  
like we gotta drain it"? That actor is great....(the tv owner).  
Watching last weekend during the football game, my wife and I decided  
he did a great job of simultaneously portraying a "you've got to be  
kidding" look and a "but, hey, cool if it works" look.

But calling commercials with the swedish bikini team selling beer with  
sex seems a little strong. I think the intent is a little more at  
presenting a very humourous, totally unbelievable situation....  
some people respond to that  
type of humour and some don't (at least I thought it was funny, and  
definitely did not see it as being very sexy (to me)).

What about the commercial with a whole group of people playing  
volleyball on the beach? Both men and women in bathing suits? Is is  
mutually offensive or non-offensive?

But the following from florianb@chip.cna.tek.com:!

> This is the common trouble with TV anyway. Using women's bodies to  
sell  
> products is everywhere on TV. I believe this is a form of rape and is  
> part of the basis for why there is so much violent crime against women  
> in this country.

This is ridiculous. Rape? By definition, a rape victim is not willing  
to perform the act, whatever the "act" is. These women sure don't look  
to be under duress to me, and they take the money for the work. If you  
have to say something criminal is going on, I'd guess you meant to say  
prostitution. Either way, such a statement is wrong.

And....commercials being the reason for violent crime? I don't believe  
commercials, pornography, etc...has anything to do with violent crime.  
The same violent crimes were being committed prior to the existance of  
"dirty pictures". Violent crimes are the result of humans having a  
lack of respect for anything but themselves...plain and simple. Rotten  
people are rotten people, whether they read/watch scantily clad women  
commercials or go to church 7 days a week.

Mike Zentner zentner@ecn.purdue.edu

PS. So as not to feel guilty about not posting anything brewing  
related, don't forget to clean out the inside of your copper tubing:-)

> just tossed in toward the end of the boil? Will any old spruce tree  
> do?

Yes, I've done this twice. I leave the spruce in for the entire boil,  
and use mostly dark extract in the recipe, and less hops than I would  
if I didn't have the spruce. It seems to matter that the growth be  
new growth; the flavor the time I mixed in some old twigs was more  
aggressively spruce than I really wanted. I don't know anything about  
the taxonomy of spruce trees; both the trees I used seemed to be OK.

From: joshua.grosse@amail.amdahl.com  
Subject: Homebrew-digest address

In HBD #731 (9/25), Al Marshall writes:

>In TCJOHB, Papazian states that wheat malt is weak in diastatic  
>enzymes and must be mashed in conjunction with barley malt  
>of great diastatic power. I have seen this opinion stated elsewhere  
>I think; Gary Bauer's article in the Zymurgy All-Grain Issue comes  
>to mind.

I've got a light wheat lager sitting in a secondary fermenter now. My partial mash recipe for 5 gallons:

- 3.3 lb M&F light extract
- 1 lb Malted wheat
  - 3/4 oz Hallertauer (boiling)
  - 1/4 oz Hallertauer (finishing)
- 2 tsp Gypsum
  - 1/4 tsp Alpha Amylase
- 1 tsp Irish Moss
  - 3/4 cup Dextrose (conditioning)
- Wyeast Pilsner Culture

Mash the wheat with Alpha Amylase at 135 F for 1-3 hours in 1 qt of water. Test with Iodine. Sparge with 3 qt of water and boil before adding the extract to avoid enzymatic changes to the barley malt. Irish Moss for the last 10 minutes of the boil and the finishing hops for the last 2 minutes. Ferment at 40-45 F for 6 weeks to 3 months.

I found that all the starch completed conversion at the end of one hour. I held the mash temp at 130-135 in about 1 quart of water by mashing in a microwave oven with a temperature probe. The dissolved sugars were fairly low. SG was 1.027.

My thinking was that I wanted to extract as much fermentable sugars as possible from the wheat I was using as an adjunct, as the wort is an extremely light one. I made it lightly hopped so that the hopping wouldn't overpower the tanginess of the small amount of wheat. I also lagered to hopefully get a smoother, less estery quality.

You might consider mashing wheat with added enzymes. I did it because I partial-mashed; you might wish to do so because of a high wheat to barley ratio.

Thanks for the yeast washing report.

My subsequent experiment with yeast washing bore out what Jeff says about the 2 jar abbreviation: when doing the wash on a primary that had already had much of the trub (cold break and hot break) removed before pitching, the yeast sediment in the second jar was almost pure white in color. The water in the second bottle after sedimentation was straw colored; I tend to think this is not a problem, the main point being getting rid of trub.

Logsdon's demonstration fermenter had a tremendous amount of trub in the bottom, yet as Jeff says, the second jar looked pretty good.

P.S.: I'm looking forward to the Wyeast pamphlet Jeff and Dave are working on.

From: Marty Albini <martya@sdd.hp.com>  
Subject: banana beer

I have not brewed any myself, but I tasted some at a club meeting. I'm going to try to reproduce the "interview" our Glorious Leader conducted of the perpetrator of this concoction.

Glorious Leader: So this is your banana beer?

Perpetrator: Yep.

GL: So what was your procedure?

P: I made up a medium bodied ale, and threw the bananas into the boil.

GL: Whole bananas?

P: Peels and all.

GL: How much did you use?

P: Fifteen pounds.

GL: Why so much?

P: They were on sale!

The setting was a "Dr. Beer"-like tasting, and this stuff was mouth-puckeringly bad. Horribly astringent, probably from the peels. I can't imagine the starchy fruit adding much besides chill haze to a brew, but if it were mashed along with some malt you might get some fermentables out of it. The banana esters, if present in this glop, were so overpowered they were undetectable.

Subject: taking a sample for hydrometer reading

Tim Carlson wants to know how you get a sample from your fermenter to take a hydrometer reading.

I use a (dedicated) basting bulb, the thing you use to baste turkeys. Sanitize it and then suck out as much as you need from the fermenter, put it into the tube your hydrometer came in and drop the hydrometer in. Take a reading. Taste the brew (or throw it out, but don't put it back in the fermenter!). And keep relaxing.

From: Hans Lindberg <d7hansl@dtek.chalmers.se>  
Subject: Banana beer, oh no ; Carlsberg emulator wanted.

Let me start by saying that I'm a beginner so don't laugh.  
I read in HD#731 something about banana tasting beer, and that that means the brew has gone wrong. That worries me, because I have my first batch brewing right now, and it's been bubbling off a pleasant smelling banana like scent from about half a day or so after it started bubbling. It's an extract brew, Muntons Traditional Bitter. It said on the can that it should brew at 18 to 21 deg c, but I had a hard time keeping the temp down at first (I overlooked one radiator) but it never was more than 22 degs in the room. From the second day or so the temp has been around 20 deg c. Have I messed it up completely?

Whatever happens with this kit, I have plans or dreams of brewing pilsner from raw material. My all time favourite pilsner (or Lager as most people wrongfully call it, at least in eng talking countries) is Carlsberg Hof. It tastes almost as their export type, but not as good (in my mouth anyway). I know that it isn't an all grain brew but has some corn in it (did I get that right?), that's just about all i know. Has anyone got the recipe of a good Carlsberg emulator? Do you think the brewery would help out with a recipe (not likely I guess) or even a rough description? If you wonder why I'm so keen on brewing the stuff myself, just consider the following: 33cl of real beer (not almost alc free) is at least 10 SEK that is about 1.4 USD or 10 GBP here in Sweden.

Thanx in advance.  
Hans

"Carlsberg, probably the best beer in the world."

From: "Spencer W. Thomas" <Spencer.W.Thomas@med.umich.edu>  
Subject: extract double stout recipe

I made this recipe in November or December 1986. I've still got a few bottles, and I took one to the Ann Arbor Brewer's Guild meeting a couple of weeks ago. All who tried it (I poured out \*small\* tastes!) agreed that it was quite good. So I dug it out and am posting it for your amusement/edification/use. I have a "mod.recipes" n/troff source for the recipe (it looks sort of like a Unix man page, but requires special recipe macros for formatting). If you would prefer that form, I can send it to you upon request.

#### Double stout beer

I would not recommend making this as your first beer, but if you are into brewing, and like a strong stout, then give this one a try. Don't be in a hurry to drink it, though, it really benefits from a long aging. I got the original recipe from Peter Lester in rec.food.drink, and formatted it for my local brewfriends. Then I thought that the net at large might enjoy it, too, so here it is with some additional notes from my experience at making it.

#### INGREDIENTS (Makes about 2 cases)

3 U.S. gallons  
water  
2 1/2 oz Bullion hops  
10 lbs dark malt extract  
1 lb black patent malt  
2 lbs crystal malt  
1/2 lb flaked barley  
1/4 lb roasted barley  
1/2 licorice stick (see note below)  
1 tsp ascorbic acid  
1/2 tsp citric acid  
1 tsp Irish moss  
1 1/2 oz Golding hops  
2 tsp yeast nutrient  
3/4 oz ale yeast (three standard packages)

#### PROCEDURE

- (1) Combine water and Bullion hops. Boil for 20 minutes.
- (2) Add dark malt extract. Boil for 20 minutes.
- (3) Add black patent malt through Irish moss. Boil for 5 minutes.
- (4) Remove from heat and add Golding hops. Steep for 5 minutes.
- (5) Cool and add yeast nutrient and ale yeast.
- (6) When fermentation has "stopped", add priming sugar and bottle.

#### NOTES

Lester's initial specific gravity was 1.086 and his final specific gravity was 1.020 (alcohol about 8%). His fermentation time was 11 days (a slow batch).

My batch fermented in about a week (house temperature ranging between 60 and 68). It was barely drinkable after 6 weeks, but delicious after 3 months. It's now been almost 5 years, and the last few bottles are a little faded and mellow but still quite good.

Subject: Mail Order Malt

In HBD731, Kurt Swanson asks...

What experiences have other people had in securing a source for cheap, quality malt?

In my experience, there are 2 stores nearby, here in Chicago. One has good quality grain, if you're willing to pay \$1.25/lb, with no volume discount. The other has moderate prices, a volume discount, and bugs in the grain...

So, I tried a couple mail-order places. The Malt House in Indiana sent me 25lbs. of 2-row for \$17, but shipped it in a brown-paper grocery bag, sealed with masking tape. It was not completely dry, developed mold, and had some dormant (and some not-so-dormant) bugs that looked curiously like malted grain, except for the fact that barley doesn't have six legs. The last place I ordered from was The Malt Shop/Kettle Moraine Vineyards, in Wisconsin. except for Rye malt, everything they had for sale was under \$1/lb, and they have a volume discount. They also shipped it in thick, sealed, plastic bags of small size - definite plus...

Does anyone have a good source for grain in the midwest (i'd like to stay in UPS zone 2 to reduce shipping cost)??? Otherwise, it seems like the Malt Shop is the way to go...

- ---- here's my experiences....

I have purchased mail-order grain from the Malt House and Stew's Brew so far.

I have had the best results from Stew's Brew, with each batch getting a good extract yield, and with very good clearing. He won't say what kind of malt it is, but it looks and acts like a 6-row variety. It's good quality, and a good price, (\$17.50/32 lbs + shipping) so I'll continue to use it.

The 50# of 2-row Klages I bought from the Malt House came in a brown paper sack, and was clean and bug-free. I immediately removed it from the bag and put it in double plastic bags inside of a large plastic container with a lid, so it has stayed fresh just fine. The extract rates have been OK, but not as consistent as with Stews malt. I try to do about the same mashing procedure each time, but variances are inevitable. The biggest problem I have had is with haze. The beer is slow to clear, and I have found it necessary to use Polyclar to get acceptable clarity. I'm sure by finding the "right" mashing

schedule, the haze can be reduced, but I haven't hit it yet. At \$29/50 lbs + shipping, the price is reasonable.

For what it's worth,  
Alan Gerhardt

From: FATHER BARLEYWINE <rransom@bchml1.aclcb.purdue.edu>  
Subject: Recipes, Cooking

Hello Brewnuts!

I've been asked to contribute a recipe to the general fund of human knowledge, so here goes:

Wanking Fresh Deathbrew

(not for the faint of heart)

This is an all-malt brew, and the recipe is designed for a ten gallon batch, which is my standard.

crush:

20 lbs. 2-row brewer's malt\*  
4 lbs. 80 l crystal malt

add crushed malt (I use a relatively fine grind; the grain is de-husked and the kernel broken into roughly square bits, perhaps three or four pieces per kernel) to:

5 gallons water at 135 degrees

stir, add a bit of near boiling water to get about 120 - 125 degree

protein rest.

After thirty minutes of stir-well-every-10-minutes (by the way, I use a pair of 40 quart cooler chests for mashing) add boiling water gradually (usually takes 2 gallons) to raise temperature to 155 degrees. Do this in stages...add a quart or two, stir well, stick in your thermometer, give it 5, read, add, repeat. It takes a while to equilibrate temps in the porridge, and you can easily bring your mash to 170 degrees (a no no) if you add too fast. Let this sit with periodic (I usually figure that when my glass [16 ozs for the precisionists] is empty I need to stir the mash) stirring for a few hours (relax, get shit-faced). The cooler chests hold heat very well, and I never did like messing with iodine.

I sparge in another chest using a piece of anodized aluminum sheet with many little holes punched in it for a sparge filter. The mundane use for this item is as a screen replacement for screen doors...it has 3 - 4 mm holes, and is available at hardware stores. I merely cut and folded the whole sheet and screwed stainless steel screws into the bottom to hold the bottom about 2 inches from the bottom of the chest, stuck it in (being extremely careful about keeping the sides of this contraption right against the sides of the chest to prevent channeling of the sparge water down the sides), and then to use it:

Add enough sparge water (170 - 180 degrees) to cover bottom of sparge filter, carefully scoop in mash to form a nice filter bed, and gradually let the stuff settle, maintaining a slow flow. Another essential part of the sparger is a siphon break. This is a piece of tubing connecting the cooler drain to a T-junction, with one leg of the T open and the other connected to a piece of tubing leading to your boiler. The open leg breaks any siphon effect, and by keeping the T at just below the fluid level in your sparger you maintain just that amount of hydrostatic pressure on your filter bed.

Merely draining your sparger out the drain puts too much pressure on the bed, compacting it and causing a stuck sparge.

I sparge with:

11 gallons water

This allows me to leave most of the bed intact and still suspended in fluid, minimizing the particulates. Run some of the first runnings back into the sparger until you get some filtration effect. Sparge until the wort ain't sweet no more...my most scientific method for insuring good brew. Periodically disturb the top inch or two of the sparge bed...you get more particulates that way, but it prevents some of the worst channeling.

Collect up all that good stuff (I sparge off between 11 and 13 gallons depending on how long I want to drink while boiling) and boil roil troil and trouble (Ah, how Shakespeare would have loved me). About 30 minutes before you finally tire of boiling, add:

5 ozs. Fuggles leaf hop\*\*

Rejoice in the aroma! Offer up a joyous shout to the various and exquisite spirits of brewing and Bacchanalia (sp?). If you're following my directions, you're probably fairly soused by now, so they are smiling upon you.

Turn off the boil. Caper briefly. Add:

2 ozs. Hallertauer leaf hop

Ponder the irony of English and Germans producing hops which meet in splendid harmony. Offer another shout to barbaric war-like tribes peacefully inbibing.

Cover.

Cool.

Slam that wortski onto a fermenting morass, the cake(s) from your last brew, recently stripped of their beery covering. Or be conventional, and use Whitbread Ale from the packet.

Oh yes, the gravity on my last Deathbrew was about 1.063, which I consider on the light side. Very nice red color.

\*I buy all my grain with a consortium of homebrewers from Briess Maltster near Madison, WI. I'll get the address if anyone is interested. We buy in >1000 lb lots, and get the nice price break (my two row was about \$38/100 lb).

\*\*I buy all hops from Freshops, which is somewhere out in CA. I'll get that address too...our last buy was in >10 lb batches, and we paid about \$7 - 9/lb., depending on variety. Actually, I think they're in OR, in the Willamette valley. Exquisite hops. Knock your nose off.

Well, there it is, in all of it's verbage and splendour. I'll post a Christmas recipe without all the instructions sometime. Love and kisses.

..

Father Barleywine

From: russo@carlos.sps.mot.com (Russell L. Oertel)  
Subject: Strange flavor in bock

Last spring I made my first attempt at a lager beer - an American bock style to be precise. Everything went well and I have aged the beer in the bottles all summer in the refrigerator, sampling one occasionally. Early on, I noticed an odd flavor - I can't really describe it as I've never encountered anything like it before, but I decided that it might be described as "mediciney", which I have heard indicates phenols. Whatever it is, I had hoped that it would go away with age, but instead it became stronger and the beer is almost undrinkable now.

The interesting thing is, I just got back from visiting a friend to whom I'd given some of this beer just after it was bottled. I told him to age it in the fridge for awhile, but he forgot and kept it in a warm closet for 3 months or so before putting it in the fridge. His bottles taste good! There is a hint of the off-flavor in his bottles, but it is very faint.

So why is the beer that was treated right bad and the beer that was treated wrong good? Anybody have any theories on this?

Subject: PME (Petrified Malt Extract)

The return of cooler weather here in Texas has me starting up my homebrewery again. While making up a batch of India Pale Ale last night, I discovered that the summer humidity had turned my DME into something better suited to building a house out of rather than brewing beer from. After several hours with a hammer and lots of hot water, I finally managed to get it all dissolved.

I can assure you that I intend to store my water-loving DME more carefully in the future, and to try not to keep any over the summer, but, should it happen again, do any of you brew-experts have any suggestions on how to soften it up again?

From: Jeff Frane <70670.2067@compuserve.com>  
Subject: cooks & thieves

To Tsamsel:

I've been brewing for seven years, mostly all-grain; I've been cooking considerably longer than that, mostly East Asian (Chinese, Thai, etc.), even spent some time cooking professionally. I \*always\* use a recipe to brew, although it is generally self-generated. I model everything in advance on a computer spreadsheet--very primitive, but it works. This allows me to control the water chemistry, the hopping rate, and the mash cycle (therefore the starting and finishing gravities): in other words, I know in advance how the beer should turn out. The mental state of cooking is very different, for me, than for brewing. During the brewing process, everything seems to move very slowly and the final result is weeks or months away; while I'm cooking, I can get instant feedback in terms of taste and aroma just by dipping into the food, and I can make adjustments as I go. Then again, I'm usually trying to replicate either a past creation or a classic (Lion's Head or Su Tung Po Pork), so I work from a recipe of some sort when I cook. I'm not a \*slave\* to it, mind you, but the recipe provides the framework.

To Tim Carlson:

Use the poor man's "wine thief": a \*new\* turkey baster. Sanitize it with chlorine solution and suck out enough for the gravity reading. (Usually it takes a couple of slurps; keep it sanitized in between.) DON'T put the sample back. Drink it; even when it hasn't begun fermenting, the wort will give you lots of clues about the final product. Besides, it tastes good, or it should.

To Anton Skaugset:

You're not "wasting" hops by adding them to the boil if you're going to dry-hop; you are simply increasing the punch, and ensuring more hop \*flavor\*. In my hoppiest ale, I add hops every 15 minutes through the 90 minute boil, add hops in the hopback, and dry-hop in the keg. Whoosh. But then, I love hops!

> is:  
> Did you cook before you began brewing?  
> and if so,  
> Do you always need to follow a recipe?  
> .....

> I only follow recipes if i am trying to brew a style I have never  
tried to  
> brwe before.

I grew up on a farm in the Ozarks, where I was taught by my parents how to cook, can, and also butcher and preserve meats. I carried the canning hobby to college with me when I went to Oregon State University for grad school. Corvallis was a great place for obtaining cheap fruits and vegetables. Later, I moved to Central Oregon, where fresh vegetables and fruit are very difficult to find. Home brewing became a good substitute for the canning hobby, and even has its more enticing reward.

I have never followed a recipe exactly, out of a book, and I have only tried to reproduce a particular recipe of my own two or three times. I like the variety of trying different things. Normally, I don't measure any of the ingredients carefully, nor do I use strict measurement in the amounts of water. However, I do pay strict attention to temperature, both during the mash and during the fermentation of my lagers. I give ales a free rein of temperature.

From: caa@com2serv.c2s.mn.org (Charles Anderson)  
Subject: Grain Prices

I originally sent a message containing this part of this article to the HBD a while back but I think it went into the ill fated HBD #718 because I don't ever remember reading it in a digest.

I've found that James Page brewery (which has started selling homebrew supplies as well as beer) has some pretty good prices.

Pale 2 row malt (klages) and pale 6 row malt  
1 lb.....\$.89  
10 lbs.....\$6.90 (69 cents per lb)  
50 lbs....\$29.50 (59 cents per lb)

They have a wide variety of specialty malts here they are. (lovibond ratings)  
Munich Malt (10), (20), (30)  
Crystal Malt (10), (20), (32), (40), (50), (60), (70), (80), (90), (120)  
Vienna Malt (5)  
Victory Malt (25) (says it's the same as toasted malt)  
Cara Pils  
Special Roast Malt (45) (a double malted barley)  
Roasted Unmalted Barley (300)  
Chocolate Malt (350)  
Black Malt or Black Prinz (550) (can you say black...sure you can, the catalog says this malt has a bland flavor profile and is used mainly as a coloring agent)  
Black Barley (550) (this is the black stuff with flavor)  
Wheat Malt  
1 lb.....\$1.25  
10 lbs.....\$9.90 (99 cents per lb)  
50 lbs....\$39.50 (79 cents per lb)

Other Brewing grains that they have are Wild Rice (I was suprised to find out talking to James that wild rice is a member of the barley family, and is not closely related to the regular rice that A-B adds to bud.) Rolled Oats, Flaked Corn, and Flaked Barley, all of these are \$1.25 a pound, or \$5.00 for 5 lbs.

All of the above are american grains, I know that that they also have some british grains including a british crystal malt that tastes really different than the crystal made from american grains. They're order line is 1-800-234-0685, hours from 9-5 M-F and the regular phone if have questions or want them to send you a catalog or something is 612-331-2833.

I have been very happy doing business with them, they're real nice folks.

-Charlie

Subject: Adventures in Bock

Batch #22  
Helles Belles Maibock  
Cat's Meow p.86  
"My First Lager"

9# pale DME  
1# crystal 40L  
1# Munich malt  
1# 2-row toasted  
7 HBU Hallertauer = 1.53 oz (4.5%) -leaf  
7 HBU Tettnanger = 1.84 oz (3.8%) -leaf  
~1/2 oz Hallertauer finish  
~1/2 oz Tettnanger finish  
Whitbread lager yeast

"The toasted malt was done 5 minutes in a 350F oven." My toasted malt caught fire and filled the house with smoke. Fortunately only toasted 1/2# at a time. Boiling 3 gal. H2O. Will pour into fermenter & add chilled wort later. Took all the shelves out of refrigerator to make room for fermenter - there's hardly any room for beer!  
As usual, put grains in bag in kettle, added 2 gal cold water, brought to a boil. Meantime, put ~4 oz cold water, ~2 tbsp corn sugar, yeast in beer bottle w/airlock to hydrate.

I should call this "Murphy's Maibock" because everything went wrong. I put the preboiled water in the refrigerator, but it doesn't get cold enough in there, so I dropped in one of those reuseable ice packs to help cool it. When grains began to boil (over) I took the bag out and added 3 gallons of water, hops, DME. Boiled 50 min. Added finishing hops. Boiled 10 minutes. Cooled to ~75F. Preboiled water was still warm to the touch, but what the hell. Removed (melted) ice pack and started syphon. Clogged. Cleared. Clogged. Cleared. etc. Hed to restart syphon each time. Finally got tired of this, so I rinsed out the grain bag, hung it in the fermenter, and poured from the kettle. Filled bucket to top because I should have added ~1.5 gallons instead of 3. Syphoned out 1 gallon of beer and **POURED IT OUT**. There are hops all over my kitchen. There are probably harmful bacteria all over my beer. It's not nearly heavy enough.

Oh well.

gak

yeasts,  
>I was hoping on some suggestions for liquid yeasts. I don't want a  
still  
>mead and I'm using about 7.5 lbs. of clover honey.  
>Any suggestions?

Finding liquid cultures of quality wine yeasts has not been that easy for  
me  
(any good leads HD readers?). I have managed to obtain some strains from  
a  
local small winery and I maintain them on agar plates. I have also  
acquired a  
variety of strains in dried form and isolated/purified them on agar  
plates as  
well. Wyeast supplies the Pasteur strain in liquid form which is a good  
general purpose wine/mead making yeast. Looking through my recipe notes I  
see  
that I have used S. bayanus (Lalvin) for a fruit mead that was my all  
time  
favorite and a strain called UCD594 for a pyment/metheglen which was also  
a  
fine aphrodisiac. Lalvin yeasts are easy to find and come in dried form.  
The  
UCD594 strain was obtained from the above mentioned winery and may be  
more  
difficult to track down. "The Beverage People News", Summer/Fall 1991,  
published  
by Great Fermentations of Santa Rosa, contains a mead recipe which calls  
for  
the use of Prise de Mousse wine yeast.

>alchol because the effects are different and nearly instaneous.  
>I read that by using a blow out tube at the begining of fermentation you  
will  
>get rid of something that is known to cause "beer headaches" is this the  
same  
>little something that causes the homebrew buzz.

The "happy hyper" buzz is a poorly understood phenomenon but it has been  
suggested that it is a result of generous hopping, undoubtedly something  
which  
is lacking in beers made by the big breweries. It is something which I'd  
be

interested in learning more about biochemically since I have the physiological experience down pat. ;-). Blow out tubes and surface skimming are both ways of removing fusel alcohols from the foaming krausen of an actively fermenting wort. Fusel alcohols taste solventlike and bitter and can be oxidized later on and thereby contribute to off-flavours in the final product. Most professionals don't bother with removing the krausen and I personally have found that it made no detectable difference in my final beer or my "happy hyper" buzz.

rfozard@slipknot.pyramid.com (Bob Fozard) writes about lager brewing:

> I didn't. I had the starter going at room temp., and pitched at  
> 50F. Lag time was about 25-30 hours.  
> How do you do it?

I grow my starter culture at room temperature and pitch the yeast into the wort at 17-19C (62-67F) and immediately place the five gallon vessel into a 10C(50F) environment. The beer slowly cools and is at 10C by the time the lag phase ends which is typically 20-24 hours.

>all.

Sounds like a job for The Hydrometer.

>I have heard that honey is notoriously slow to ferment, so I was kind of  
>shocked to say the least.

Straight meads are slow fermenting due to low levels of essential nutrients. I doubt that is the case with your beer since a little malt extract can go a long way in nourishing yeast. Your problem may be due to insufficient oxygen in the wort at the time of pitching.

NOTES ON HD731

CHOLM@HUBIO2.HARVARD.EDU (HOLM LAB, HARVARD UNIVERSITY) writes:  
> Has anyone done any cider fermentation? I've done the standard thing  
>of taking a gallon of preservative free cider and allowing it to  
ferment, but  
>that's sort of dicey since all sorts of things are in there. I was  
planning  
>on doing a 5 gallon batch this year, boiling the cider first and then  
pitching  
>a good beer yeast, doing a proper primary and secondary fermentation,  
and then  
>priming and bottling. Anyone else tried anything similar? Thanks.

Here my recipe for Fall Cider:

22 litres (6 US gal) fresh apple cider (no preservatives)  
3 tsp. acid blend  
1 tsp. yeast nutrient  
2.5 tsp. pectic enzyme  
1 cup Dextrose  
1.25 tsp. sulfite crystals (potassium metabisulphite)  
2 sachets dried yeast (Edme)

OG=1.055 (60F correction)

Mix all ingredients except the yeast into the primary, cover and let  
stand for  
24 hours to dissipate SO2 from sulfite. Hydrate yeast in approx. 250 ml  
(1 cup)  
water at 35-40C (95-104F) for 5-10 minutes and then pitch into cider with  
vigorous stirring to aerate. Primary = 5 days. Secondary = 3 weeks. Prime  
and  
bottle as usual. This stuff is peaking after 3 months in the bottle,  
IMHO.

GERMANI%NSLVAX@Venus.YCC.Yale.Edu writes:  
> As long as there's been talk of spices in beer I have a few  
questions.

growth  
>of a spruce tree. Has anyone tried this? Again, is it just tossed in  
toward  
>the end of the boil? Will any old spruce tree do?

I've got some dried Juniper berries tucked away in my brewing closet so  
I'm  
dying to hear responses on that subject too!

As far as Spruce beer is concerned I have brewed a batch using fresh, new spring growth sprigs picked off the ends of the tree branches. The recipe for

The Legendary Mike Brown's Spruce Ale is as follows:

1.5 kg (3.3 lbs) Steel City Ale Kit  
1.0 kg (2.2 lbs) John Bull plain light malt extract  
500 g (1.1 lbs) plain light dried malt extract  
165 g (1/3 lb) crushed chocolate malt  
125 g (1/4 lb) crushed crystal malt  
180 g (approx. 6 oz) fresh spring spruce sprigs (boil)  
8 spruce sprigs (finishing)  
500 ml (2 cup) culture of Munton & Fison Ale yeast

OG = 1.046 (60F correction) for 22 litres (6 US gal)

Crystal and chocolate malts placed in 4 litres (1 gal) cold water and temp. raised to 70 C and immediately strained into the brew kettle and sparged with 2 cups of 70C water. Added malt extracts and water to bring volume to 23 litres. Added boiling sprigs when boil commenced and boiled for 60 minutes. Added finishing sprigs and boiled for 3 minutes. Chilled via wort chiller. Yeast pitched at 20C (68F). Single stage fermented in glass for 14 days then bottled using 1 cup corn sugar to prime.

I didn't like this beer at first because I felt that a spruce essence was lacking in the flavour. However, two months in the bottle cured that problem and the beer was exquisite and "sprucey" and improved with further aging. My friends are always enquiring as to when my next batch will be brewed.

>Dry hopping supposedly gives you a much more pronounced aromatic hop character, why should I "waste" hops by tossing them into the boil to get  
>aromatics? I'm not referring to bittering hops, which I plan on using as  
>usual.

Actually, hops can influence a beer at three levels. Bitterness, hop flavour and hop aroma. Hop flavour and aroma are lost when the delicate compounds responsible for these traits are driven off during a prolonged boil. I never seem to get sufficient hop aroma but I get plenty of hop flavour when I add a generous dose of hops at the end of the boil. Dry hopping seems to bring out the most in aromatics, in my hands anyways. The beta acids and the poorly characterized "soft resins" are varied in chemical structure and it is likely that some forms of these molecules are made more soluble in the wort by a brief exposure to heat while others are more volatile and are best assimilated via dry hopping. "The Principles of Brewing Chemistry" by George Fix has a nice chapter on hop chemistry, a field which is no doubt in need of further study.

To: Homebrew Digest  
Fm: Jack Schmidling

Subj: Plastic Bottles, bactericidal?

Remember that batch of beer in "BREW IT AT HOME" with the syphon sloshing beer into the primary and the nice billowy foam?

Well, the jury may still be out on the oxidation issue but the beer is definately vile. This batch was used and abused to demonstrate many different processes and sterilization was not high on the list during the shoots. The bottles, however were carefully sterilized under the assumption that if I am going to invest the aging time, they might as well do it in sterile bottles.

After sampling several bottles, that all tasted moldy I noticed a bacterial film on the surface of the beer in the bottles.

In addition to glass bottles, I bottled the beer in 4 plastic pop bottles. Two pint and two liter bottles. They were all processed, cleaned and sterilized in the same manner and at the same time.

All the glass bottles are contaminated and vile and all of the plastic bottles have no bacterial film and taste normal.

Ready for another momily?

TOOT! TOOT!

In addition to being soluble in beer,

PLASTIC BOTTLES ARE BACTERICIDAL!

I didn't really say that, MOM did. I was just thinking out loud.

From: subotic@erim.org (Nik Subotic)  
Subject: hop extraction efficiency curve

Hi all,

A while ago (1 yr.?) someone posted a curve to calculate hop extraction efficiency as a function of boiling time. I seem to remember that the curve was linear for boils up to 60 min. What happens after that amount of time is a mystery (how quickly the efficiency approaches 100%). This curve would be helpful in calculating the amount of bittering in a beer. Could someone point me to the appropriate digest (or email or repost for that matter) where this appeared?

Thanks much for your help.

Subject: Beer Ads

Michael Zentner writes:

>What about the commercial with a whole group of people playing  
>volleyball on the beach? Both men and women in bathing suits? Is is  
>mutually offensive or non-offensive?

This is totally non-offensive to me because this is real life. If you've ever gone to a volleyball beach (try Manhattan Beach, or Hermosa Beach) you'll see both sexes playing volleyball in their swimsuits. This is not only true for amateurs but also with the pros, so don't knock it, enjoy it.

Of course, I don't know anyone who can actually drink beer \*and\* play volleyball. I like my volleyball and my beer drinking as pretty much mutually exclusive activities.

Now back to homebrewing: I too, am waiting for some good holiday recipes that have actually been tried before. Although I haven't seen anything on the digest yet, a friend tells me he's got a apricot-ginger ale recipe that got rave reviews last year. If he gives it to me, I'll pass it on.

From: krweiss@ucdavis.edu  
Subject: attenuation, recipe request

Ted Samuel asks:

> Pardon my (seeming) ignorance, but what exactly is attenuation re:  
> yeast?

I should probably leave this for one of the more experienced and knowledgeable brewers, but what the heck... Attenuation refers to the amount of residual sugar a yeast will leave when fermentation is complete.

More attenuative yeasts will convert more of the sugar to alcohol and CO<sub>2</sub>, resulting in a drier beer with a lower final specific gravity. Less attenuative yeasts will leave more sugar unconverted, resulting in a sweeter beer. Edme dry yeast might be the ultimate example of an attenuative yeast (at least the batches I used). Wyeast Irish Ale is a fairly non-attenuative yeast.

Now for the recipe request. I'd like to produce a Thanksgiving festival of gluttony beer. I'm looking for an extract/adjunct based recipe that won't take more than four weeks in the bottle to age into a drinkable form. The timeline probably rules out anything involving fruit flavorings, as it seems fruity beers need to age for longer periods before they get drinkable. Suggestions, please...

From: larryba@microsoft.com  
Subject: Re: High Gravity Wheat beer...

I sent this out last week, but it never made it into the HBD... So here is a repeat.

In HBD #728 Bryan Gros wonders if his partial mash wheat beer gravity of 1.058 is unusual... Well, do the math, with the numbers suggested by Miller:

|               |                   |                            |
|---------------|-------------------|----------------------------|
| Wheat Malt    | 2lb @ .038/lb/gal |                            |
| Barley Malt   | 1lb @ .035        |                            |
| Wheat extract | 3lb @ .040        | - I assume you used syrup? |
| Malt Extract  | 1lb @ .040        |                            |
| -----         |                   |                            |
|               | .271              |                            |

Divide by 5 gal = .054 or 1.054 original gravity.

If you used dry extracts, bump the yeild to .044 to get an OG of 1.057

I suspect that if your OG is 1.058 and you used syrups, then you probably have something less than 5 gallons in your fermenter. It would take only three pints to bump the OG from 1.054 to 1.058.

From: Peter Glen Berger <pblp+@andrew.cmu.edu>  
Subject: Maturing Beer

Just what is the benefit gained by maturing beer in the bottle?

I just bottled my Stout (I'll post the recipe when I'm satisfied that it's good, thanks to all who helped), and have noticed two things: the hop flavor is much more assertive than I expected, as is the bitterness. I used fresh hops, and strained them out when adding the wort to the fermenter. Will these flavors mellow with age? I think we could all benefit from a discussion of just what aging does to flavor, body, aroma, etc.

From: Peter Glen Berger <pblp+@andrew.cmu.edu>  
Subject: Malt Extract Sources

Okay, I'm not a grain-brewer yet, because I don't have the time. But I hate using "kits" and liquid malt extract; maybe I'm paranoid, but I don't think it's possible to can ANYTHING without causing some pretty severe chemical changes; and, at least, my nose seems to confirm this.

So I pretty much have decided to use dry malt extracts until I can advance to mashing. Does anyone know of any cheap sources for dry malt extract? The place near me, in Pittsburgh, sells dark malt extract at \$8.50 for 3 pounds, and around \$3 for 1 pound. This place is expensive on most items, so I assume they're expensive in this regard, too.

And how about a comparison of yeasts? What characters do they impart? So far I've had dissapointing results with red star, and impressive results with Whitbread (although, to be fair, this could be due to differences in the wort and in ambient temperature).

From: larryba@microsoft.com  
Subject: Re: Lager Questions

In HBD #730 Bob Fozard asks some great questions. His first question was regarding starter yeast and planning a head so that he could pitch active yeast at ferment temperatures. A little digression follows regarding the need to pitch "actively fermenting" yeast:

I have been corresponding with Dave Rose (professional yeast propagator) regarding yeast culturing. He questions the need to pitch starter yeast that is actively fermenting. As far as he knows pitching dormant yeast (e.g. the scum from the bottom of your primary/secondary after things have really settled out) should work fine.

I have several personal experiences that support his claim:

1. I made a vienna lager using wyeast bavarian lager yeast. It sat in the secondary for two months. For at least one month it had no bubbles in the air lock. I collected the grey/tan gloopy yeast from the bottom and stored it in a pint ball jar for another week. Recently I pitched that gloop into a pint of starter to "feed" it. It practically exploded into activity blowing a fair amount of foam through the airlock and was completely fermented out in less than 24 hours. This was all at 48f. Seems like it was plenty lively. I wish, now, that I had waited another week and simply pitched the stuff into my next lager.
2. I made an xmas ale using the father barleywine method of repitching yeast: chill the wort directly onto the previous yeast cake. It too exploded into fermentation and was mostly fermented out in 36 hours. Again, the cake was "dormant" as the previous batch stopped producing bubbles for several days (whitbread yeast @ 72f)
3. I routinely collect yeast goop from the primary (swirling a little beer left behind when racking - trying to avoid the trub that is usually under the yeast) store it in the fridge w/o an airlock and pitch within 1-3 weeks and get great ferment starts (e.g. < 12 hours to high krausen)

My call is to do the starter, but don't worry about pitching at high krausen: just let it do it's thing and brew whenever you have the time (within a couple weeks). when pitching, pour off most of the spent wort, swirl up the yeasties and pitch away.
