Subject: Some hopefully useful code snippets...

Two useful things I came up with over the last couple of weeks.   Hope they help
somebody.

/* HostPicker Method

Assumptions:

* you have an instance variable named hostField where you store the hostname.
*every hostname in every netinfo subdomain is accessible to your system.
*add libni_s.a to your libraries in ProjectBuilder.
*Connect a button to this and voila!
*/

```
- pickHostName:sender
{
    id      thePanel = [NIOpenPanel new];
    [thePanel setListTitle: "Machine Names"];
    [thePanel setPanelTitle: "Machine Name Picker" ];

    if ([thePanel runModal] == NX_OKTAG)
    {
        const char *fullDomain = [thePanel directory];
        if (fullDomain && *fullDomain){
            [hostField setStringValue: (char *)fullDomain];
            //[self changeHostName:self];
            //optional, add this method if you want to trigger the change.
        }
    }
    return self;
}
```
