CHAPTER 10 *Common Questions* 105

Overview 105

This chapter describes how you can use the Internet Gopher system to easily publish and retrieve information on a network.

Introduction

The internet is a wide vast place with many resources available. Searching, finding and retrieving these resources has been difficult in the past. The Internet Gopher was developed to let an average user access these resources quickly and simply.

What is the Internet Gopher?

All over the world, data is stored on computers, many of which are connected by the Internet, a confederation of computer networks. With Internet Gopher you can easily access publicly available information stored on many of these connected computers.

Gopher combines features of electronic bulletin board services and databases, allowing you to either browse a hierarchy of documents, or search for documents that contain certain words or phrases.

The Internet Gopher software was conceived at the Computer and Information Services department of the University of Minnesota. Software developed at the University of Minnesota is freely distributable for non-commercial purposes.

Types of Information

Gopher supports a diverse range of data, all of which can be accessed by a simple keystroke or click of the mouse. Here are some of the most popular data types:

Directories

The most basic information type in gopher is a directory. A directory is a list of documents. Directories allow easy browsing of information. Items can be organized into specific areas, making it easy to find the information you need.

In addition, a special type of directory called a “link” allows gopher to reference directories on a different computer. This allows gopher to traverse a hierarchy of information residing on multiple machines. These links are transparent, you won’t notice that you’re connecting to another machine.

Text Files

Most of the information in gopher is stored in ASCII text files. These files can be used with most popular computer applications

Search Items

This is a special kind of directory. You can specify any number of keywords to a search item. Only those documents that match the given criteria will show up in the resulting list.

Finding Information

Telnet/3270 Sessions

This item type is a reference to a public telnet connection. Selecting one of these items will connect you to a system using the appropriate terminal emulation.

Phone Books

This document type is a special version of the search item based upon the Ph/Qi server developed at the University of Illinois.

The phone book search allows you to search on certain fields of a specialized user database. Some common fields are phone number, e-mail address, or name.

Multimedia

Gopher supports a number of multimedia file formats including images, audio and video file formats. Images such as weather maps are available. Digitized audio data files such as the 1992 presidential debates are available. Movies in Quicktime and MPEG are available.

Formatted Text

Some Gopher servers will allow you to view documents in formats other than text. Postscript is one of the most popular formats for this "Rich Text."

Finding Information

When using Gopher, looking for information located in other continents is as easy as looking for information residing on a computer in the next room. When using Gopher, you begin at the first or root level of your home Gopher Server. From there you can choose between two methods of locating information: browsing and searching.

Browsing

You may want to follow the paths in Gopher from level to level until you find the data you're looking for. From the first level, you can choose a topic, which leads to another level, and another, until you finally come to an item that looks interesting.

For instance at the University of Minnesota, you might look for a salmon recipe by looking in the *Fun & Games* directory, then in the *Recipes* directory, and then in the *Seafood* directory until you see an item with *salmon* in its title.

Searching

Alternatively, you may want Gopher to do the work for you by using a search item. For instance, at the University of Minnesota you could select a search item called *Search Recipes*. A message prompts you to type in the words you're looking for; you type *salmon*. The server searches the text of a collection of items and lists the ones that have the word salmon in them. You can then examine these items until you find one that contains a recipe that strikes your fancy.

Additionally, some search items will let you specify a complex search expression for your query. If you only had sugar, eggs and chocolate chips, you could search for items that contained all of these words by specifying *sugar and eggs and "chocolate chip"* to the *Search Recipes* item.

Some Example Information

We think the easiest way to get a grasp of the information inside of GopherSpace is to try it. However, here is a listing of some of the more popular information:

- Weather Forecasts and current conditions for the United States and Canada.
- Recipes
- Movie Reviews.
- Computer Questions and Answers.
- Weather Maps.
- Movies of Chemical reactions.
- E-mail addresses and phone books for most major institutions
- Newspapers and USENET news.
- Full electronic versions of many of the major classics, Shakespeare, Moby Dick, etc.
- Library Catalogs from around the world.
- GENE Sequences.
- Song Lyrics

- Job listings
- University Course Catalogs
- And much, much, more!

Using this Manual

You do not need to read this entire manual to use the Internet Gopher. Most likely, you will only need to read the chapters about the Internet Gopher *client* for your software.

If you wish to publish information you will want to pay attention to the chapters referring to the Internet Gopher servers for your system.

The First Steps

See “*Getting the Internet Gopher Software*” on page 15 for information about retrieving and installing the necessary software. Then read the chapter appropriate for your system.

Common Questions

It’s a good idea to read through the “*Common Questions*” on page 105. This chapter contains answers to the most frequently asked questions about the Internet Gopher - from installing it to serving data.

Platforms Supported

The Internet Gopher works on a number of platforms and operating systems. The operating system for all of the following must have TCP/IP networking support and a connection to a network.

Gopher Clients

Clients to *access* data are available for the following platforms:

- Macintosh

- DOS
- Microsoft Windows
- Unix, full-screen, emacs and Xwindow
- VMS full screen.
- NeXTstep
- OS/2
- VM/CMS
- MVS

Gopher Servers

Servers to *publish* information are available for the following platforms:

- Unix
- VMS
- Macintosh
- VM/CMS
- DOS
- OS/2
- MVS

Conventions used in this Manual

This manual uses these conventions:

- The `Courier` font is used to show sample output of textual clients. **Bold Courier** is used whenever you have to enter text or commands.
- In reference to the Unix Server, *gophertop* refers to the directory where the gopher source code is installed.
- Figure boxes are used to show usage.

Support Questions?

We hope you enjoy using Gopher and that it helps you in you to access and publish data quickly and easily.

If you have questions or comments, please send us electronic mail at gopher@boombox.micro.umn.edu. Or send paper mail to the following address:

Internet Gopher Development Team
100 Union Street SE #152
Shepherd Labs - University of Minnesota
Minneapolis, MN 55455

Or fax us at +1 (612) 625-6817.

Getting the Internet Gopher Software

This chapter will show you how to get the Internet Gopher software. You should only need to read the first section “*Getting the Software*” on page 15 and the sections appropriate to your platform.

Getting the Software

You will need to retrieve the Internet Gopher Software from the software repository at the University of Minnesota. Follow these instructions to do so.

The First Retrieval

Most of the software for the Internet Gopher is available on the machine boombox.micro.umn.edu. This machine is on the Internet network. To retrieve the software for the first time you’ll need to use an FTP client on a local machine connected to the internet.

FTP, the file transfer protocol, is a quick, reliable and widely popular means of transferring files across the Internet.

FTP clients come in many varieties. On a Unix or VMS system the command is called `ftp`. On the Macintosh there are two ftp applications, `Fetch`, and `Xferit`. NCSA has developed a version of ftp for the IBM-PC called 'ftp'. Refer to your local network administrator if you don't have an ftp client.

Once you connect to the boombox server you will want to change to the directory

`/pub/gopher`

The different portions for gopher are in this directory. The file `00README` contains descriptions of each directory. Refer to Table 1, "Available Gopher Software," on page 16 for a breakdown of the contents of each directory.

TABLE 1. Available Gopher Software

Directory	Description
Mac_server	Gopher server for the Macintosh
Macintosh-TurboGopher	A graphical Gopher client for the Macintosh
NeXT	A graphical Gopher client for NeXTstep
PC_client	A graphical Turbovision based client for PCs running DOS and using the Clarkson/Crynwr packet drivers
PC_server	Two PC Gopher server implementations, one based on Phil Karn's NOS, another using Clarkson/Crynwr packet drivers.
Rice_CMS	A Gopher server and client for VM/CMS systems written at Rice University.
Unix	Gopher for Unix. Includes a Gopher server, full screen client, Xwindow client, and an emacs client.
VMS	Gopher for VMS. Includes a Gopher server and full screen client
VieGopher	A Gopher Server and client for VM/CMS written at Vienna.
Windows	Gopher clients for Microsoft Windows.
gopher_protocol	Descriptions of the Gopher network Protocol are stored here.
incoming	Submitted untested gopher software.
mvs	A Gopher server and client for MVS.
os2	A Gopher client for OS/2.

TABLE 1. Available Gopher Software

Directory	Description
amiga	Gopher Software for the amiga.
docs	Gopher Documentation
misc	Things that didn't fit in the above sections.

Each directory contains gopher software for a specific platform. You should retrieve the software from the specific directories that are compatible with your hardware and operating system. There are README files inside of each directory that will help you decide which files to transfer.

Once you find a file that interests you, you should use the GET function of your FTP client. This usually means typing “get filename”, or clicking on the appropriate file with your mouse..

Some clients, notably Unix, VMS, and IBM-PC will require you to specify a binary “transfer mode.” You can set this mode by typing **binary** at the `ftp>` prompt.

Refer to Figure 1, “Using FTP with Unix,” for an example ftp session to `boombox.micro.umn.edu`

FIGURE 1. Using FTP with Unix

```
% ftp boombox.micro.umn.edu
Connected to boombox.micro.umn.edu
220 boombox FTP server (Version 4.1 Tue Apr 10 05:15:32 PDT 1990)
ready.
Name (boombox.micro.umn.edu:lindner): anonymous
331 Guest login ok, send ident as password.
Password:™
230 Guest login ok, access restrictions apply.
ftp> cd /pub/gopher/Unix
250 CWD command successful.
ftp> binary
200 Type set to I.
ftp> get gopher1.12.tar.Z
200 PORT command successful.
150 Opening BINARY mode data connection for gopher1.12.tar.Z (306512 bytes)
226 Transfer complete.
306512 bytes received in 2.4 seconds (1.3e+02 Kbytes/s)
ftp>
```

Subsequent Retrievals

Things get easier after the first retrieval. You don't have to use the arcane ftp command to get the Gopher software, you can use Gopher itself.

You will want to familiarize yourself with your gopher client before doing this though. See the chapters that follow to find out about clients.

You can use your Gopher client to connect to the software repository at

boombox.micro.umn.edu

And choose the files, just as you would with ftp. Now you can just select the software you want from a menu instead of typing commands to retrieve the file.

TurboGopher is a Gopher client for the Macintosh. The following chapter contains information on using, configuring and administrating the TurboGopher application.

A Websters definition is:

TurboGopher n. 1. A small rodent with a turbocharger strapped on its back to increase its speed and ferocity. 2. (Amer. colloq.) Native or inhabitant of Minnesota after consuming three double espressos. 3. (Amer. colloq.) An Olympic sprinter who runs errands, does odd-jobs, fetches or delivers documents for office staff. 4. (computer tech.) Speed-optimized Macintosh software following a simple protocol for tunneling through a TCP/IP internet; network speed is achieved by using turbo-charged software; incoming bits spin the turbine that pumps out the outgoing bits.

Note that this chapter documents version 1.0.7 of the TurboGopher application.

Overview

TurboGopher is a Macintosh application that we believe is (still!) the fastest Macintosh Gopher client available. Beyond optimizing TurboGopher for raw speed while fetching documents and directories, we turbocharged the user interface by display-

ing information as soon as possible... you can read the first part of a document or directory while the rest is being fetched. This version of TurboGopher also supports many of the Gopher+ extensions to the original Internet Gopher protocol.

In spite of the design goal to run fast as possible, TurboGopher is a good Mac citizen: it shares time with other applications. You can put TurboGopher in the background to fetch lengthy items in the background while you work in another application in the foreground.

Requirements

You will need a copy of the TurboGopher application, if you haven't retrieved this yet refer to "*Getting the Internet Gopher Software*" on page 15. You will also want to retrieve the "helper applications." These applications will allow you to connect to telnet sites, view graphics, etc.

TurboGopher requires a Macintosh running a system 6.0.7 or later. We highly recommend using System 7 or higher. Without it you won't be able to automatically launch the "helper applications."

You should have at least one megabyte of memory, more if you're using Multifinder or System 7.

You will need a correctly configured copy of MacTCP and a network connection. If you don't have MacTCP you can get it from the Apple Programmers and Developers Association (APDA). MacTCP is a licensed product, it is not free.

Getting Help

The information in this chapter can also be found by picking the menu item "Help" from the "Gopher" menu of TurboGopher.

In addition to this information you are reading right now, if you are using System 7 (and we strongly recommend that you do), some Balloon Help is available in TurboGopher. See your Macintosh System 7 documentation for information on using Balloon Help.

FIGURE 2. TurboGopher-Top Level

Navigating Gopherspace

To navigate through gopherspace, double-click on any interesting items to open (fetch) them. If you double-click on a file, TurboGopher will fetch and display the file. Opening a folder will let you view its contents. Double-clicking on the question-mark (Search) icons will let you search a database. On most gopher servers these databases are full-text indexes of a collection of information. Full-text index means that every word in every document is considered a keyword. The best way to search a gopher full-text database is specify the words for which to search when TurboGopher presents you with a dialog box. The results of the search are returned as a list of documents containing those words.

Phone Books

If you double-click on the phone-book icons you can search electronic phone books. Phone book databases are structured in the sense that they have fields (i.e. a

name field, an address field, and a phone number field). The simple phone-book lookup dialog assumes that you want to search for someone by name. Click on the 'More Choices' button if you wish to specify exactly which fields to search in, when you formulate a query. The result of the query is displayed in a document.

FIGURE 3. TurboGopher- Phone Book Search

Software Archives

Disk icons represent archived Mac software or documents that you can fetch; these items will be saved to your hard disk. Such items are often stored in compressed form to save space. You need to have certain Mac utilities to 'uncompress' such items. The most common such utilities are StuffIt and Compactor. Both may be obtained from the Info-Mac archives with gopher. If you are running System 7 and TurboGopher retrieves an item that needs to be 'unstuffed' or 'uncompacted', it will ask you if it should open them via Finder and the appropriate decompress utility. We recommend that you use CptExpand and SitExpand for your decompress needs; both of these are available with the TurboGopher software distribution as well as from the Info-Mac archives.

Items that are specific to MS-DOS are seen as documents with a tiny ‘PC’ emblazoned on them; similarly items specific to UNIX show up as documents with a tiny ‘UX’ on them. You can retrieve either of these kinds of items if you like. TurboGopher will ask you if you wish to save them to your disk. You may not ‘view’ these items as text. In fact it will probably make very little sense to fetch such items unless you intend to further transfer them later from your Mac to another kind of computer, or if you have some special tools on your Mac that will allow you to use these kinds of items.

Pictures

Items appearing as documents with a starburst on them are probably graphics or picture files (typically in GIF, JPEG, or PICT format). TurboGopher will transfer such files, save them on your disk, and optionally launch a picture-viewing application if you wish to view the picture.

Alternate Views

Gopher+ server may store more than one representation of a document (an image, text, sound, video, etc.). If more than one view of a document is available, you can select between the views by choosing the ‘Get Alternate Views’ item from the Gopher menu. When alternate views are available, an alternate view window will be displayed with descriptions of the views.

For many alternate views of documents, TurboGopher will save a copy of the item to your Macintosh’s disk, and then (under System 7) ask the Finder to launch a helper application to actually display the item. You can configure which applications should be used as TurboGopher helpers; to do this see the section on configuration options.

Connecting to Terminal-based Services

Opening the ‘terminal’ icons will make TurboGopher launch NCSA Telnet (or TN3270 if appropriate) and start a terminal session to a terminal-based information system. Typically these are library catalogs or other such services. Note that for this

to work, you need to have Telnet or TN3270 installed on your Macintosh. If you are still running System 6, TurboGopher will only save a Telnet session file rather than launch Telnet; this is another good reason to run System 7 on your Mac.

Following the Macintosh guidelines, TurboGopher starts out displaying text in the standard application font. The Font and Size menu items let you change font appearance for documents and lists. TurboGopher will attempt to display phonebook lookup results in a monospaced font (Monaco), effectively ignoring your font selection. It IS possible to change the font of a phonebook results lookup window after it has been opened; however things will not line up correctly and generally look icky.

Advanced Navigation Features

If you double-click on a folder while holding down the Option key, TurboGopher will re-use the current window instead of using a new one to display the folder contents. Some folks like to do this to prevent screen clutter and keep from having too many open windows.

You may use the up and down arrow keys on your keyboard to move up and down lists in windows. The Enter or Return key opens an item (and is equivalent to double-clicking on an item). Use of the arrow keys is not supported on the Mac Plus.... (sorry).

You may also type the first letter (or first few letters) of an item name in a list and TurboGopher will highlight the first item it finds that matches (sort of like the Finder does in list views). The Find menu item is available to locate an item in a list: just type a string in the Find dialog. Find can also be used to search for text in open document windows, by the way.

To delete any item in any list window, click once on the item to select it. Then choose 'Delete Item' from the Gopher menu.

TurboGopher remembers the last full-text index search (item with question-mark icon) you used. If now you hold down the Option key and double-click on a word in a document window, TurboGopher will query that search service for all documents containing the word you selected. You must use a search service before this pseudo-hypertext capability is accessible (TurboGopher needs to know which search service to use in your hypertext query).

Authenticated Servers

The Recent menu lets you go back to any directory window you have viewed during your Gopher session. The left and right arrow keys may be used to go to previous or next windows; they are equivalent to traversing the recent menu upwards or downwards. Note that the Recent menu only remembers directory windows you visit. Document or phone-book lookup windows are not listed.

If you close a window by clicking in its close box while holding down the Option key, then (like Finder) TurboGopher will close all open windows.

If you click in the close box while holding down the Shift key, then the cache of information about that window will be released. So the next time you open this window from the recent menu, TurboGopher will have to fetch the contents over the net once more.

Of course, if you hold down both Option and Shift keys then all windows are closed and all caches released. Caches are explained below.

For the terminally curious, if you hold down the Shift key while single clicking on an item in a list, TurboGopher will display the item's Gopher selector string, host name, port number and Gopher+ baggage in the status pane. This is a quick peek. If you want to copy-paste this information, use the Get Attribute Info menu item found under the Gopher menu; the information you want is in the +INFO attribute (the first line).

If wish to fetch an item that is a Macintosh file (binhexed file, shows up with the icon of a disk), but don't want TurboGopher to automatically dehex it as it fetches, you may force TurboGopher to fetch the document as a raw, unprocessed file. To do this, hold down the Control key while you double-click on the item. For folks using DownLine or other applications for de-binhexing and de-archival, this is one way to do what you want.

Authenticated Servers

TurboGopher now supports AdmitOne Authentication for Gopher+ servers that restrict access to information on a per-user basis. When you attempt to open a directory that has such access restrictions, TurboGopher will prompt you for your username and password on the restricted-access server. TurboGopher and the server negotiate to establish a valid ticket, and subsequent requests to the server use a new

ticket for each request. This means that your password is never sent over the network, and that you only have to enter your password to get the initial authorization.

Bookmarks and Bookmark files

If you formulate a search or find a folder you would like to come back to quickly later, you can use the Set Bookmark menu item to save your place. Set Bookmark saves a reference to a folder, file, search, terminal session... in fact any Gopher item. If nothing is selected in the front list window, a bookmark is made for a folder representing the window. Try it, it's easier to do than to say.

Bookmarks are placed in a special Bookmarks window. Use the Show Bookmarks menu item to open the Bookmarks window. Bookmarks are remembered even after you quit TurboGopher; contents of the Recent menu are however forgotten. It might be useful to consider the Bookmarks window to be a special kind of 'work-sheet' or 'construction area' for you to build your own scratch-pad of useful gopher resources.

You can save your Bookmarks window or ANY list window or ANY selected item as a Bookmark file ('Save as Bookmark File' menu item). Bookmark files are small and may be exchanged with other Gopher users if you wish.

The 'Import Bookmarks' menu item lets you read a Bookmark file right into your Bookmarks window. The 'Open Gopher Bookmark File' menu item on the other hand, places the contents of a bookmark file in a window of its own. The latter is equivalent to double-clicking on bookmark files from the Finder. If you launch TurboGopher by double-clicking on a bookmark file, it will not immediately connect to the Home Gopher server, but will open the Bookmark file instead. So you may use bookmark files as custom Home Gopher servers.

Item Attributes

More sophisticated Gopher servers (referred to as Gopher+ servers) can provide you with information about any selected item, much like the Finder's Get Info menu lets you get information about a Mac item.

Use the 'Get Attribute Info' menu item of the Gopher menu for this.

Canceling Slow Network Operations

TurboGopher executes most requests in a few seconds. A document or directory is displayed as it is received. However, if a server is especially slow or busy or if you have started to fetch what appears to be a very long and uninteresting document or directory, you may cancel the fetching process by closing the document or directory window. Once you have closed the window, TurboGopher assumes that it does not need to fetch the remainder of the item. Note that when you fetch a file that is saved to your Mac disk, TurboGopher displays a window with the status of the fetch. Again, to cancel the fetch operation you can simply close the window.

A more extreme method for canceling a network operation is to choose the Cancel All Requests item from the Gopher menu (or by holding down the command key and typing a period). If you open a file or folder by double-clicking while holding down the Option key (to conserve screen space as described earlier), TurboGopher will also cancel the running network transaction if one is outstanding; and this is in fact exactly what you want over low speed connections such as SLIP. Both these features make TurboGopher seem faster and more responsive over SLIP links.

TurboGopher runs happily in the background (if you wish to fetch something very large or from a very slow server). You may also fetch an item (file or directory) while another one is still being fetched, since TurboGopher supports multiple concurrent streams. Command-Period will cancel all active streams.

Starting and Configuring TurboGopher

The 'Start Gopher' item under the File menu opens a window containing the initial directory fetched by connecting to your home Gopher server. TurboGopher is pre-configured to connect on startup to one of the University of Minnesota's Gopher servers. You may change your home Gopher server by using the 'Configure' item under the Setup menu. To do this you need the full Internet domain name and port of the desired primary server. You can configure TurboGopher to use one of two alternate primary servers. This distributes the load for a campus over two different (but equivalent) primary servers and it prevents a single point of failure. TurboGo-

pher will randomly try one of the two and then try the other if the first is down. If you don't understand this, you don't have to bother with it or with the Another Gopher item under the File menu.

TurboGopher attempts to speak Gopher+ to all Home Gopher servers, and then backs off if it sees that the server does not have Gopher+ style items. This is a bit presumptuous, and it confuses some servers. These servers should be revised in the future so they don't confuse so easily. If configured to connect to a Home Gopher server and nothing is displayed, you may want to try using the 'Another Gopher' item under the file menu and making sure that the gopher+ check box is NOT checked.

TurboGopher Options

You can use the Options item under the Setup menu to customize some behaviors of TurboGopher. The Single Directory Window checkbox makes TurboGopher recycle its windows whenever you open a new directory (and not just when you hold down the Option key).

Use the ISO Latin-1 checkbox if you need to use Latin/Romance language characters. Many sites in Europe have a need for this to display their national characters. If you visit European gopher servers and the accented characters don't display correctly, you may want to choose this option.

The Extended Directory listings checkbox is disabled; it's for a future feature.

If you visit Gopher servers with Japanese or Chinese documents, and you use a Japanese or Chinese font while running System 7.1's WorldScript, Gopher will display Japanese SJIS (MS Kanji) or traditional Chinese characters (BIG-5).

When you save documents, TurboGopher normally saves them as MacWrite II TEXT documents (we like MacWrite II). If you'd rather save them as TEXT documents of your favorite word processor or editor, use the appropriate 'Set' button in the Options dialog to select the word processor of your choice.

With Gopher+ servers, items may be available in a number of alternate views. When fetched, these alternate views are typically saved as a file to be viewed by a Mac application. If you are a network/macintosh cowboy, you can change the Mac application and Mac filetype associated with a Gopher+ alternate view.... this

changes the helper application that TurboGopher asks the finder to launch to view the document. Double-click the view in the list and you will be presented with a dialog in which you can select the application to be used as a TurboGopher helper.

By the way, you won't be able to do this if you're running System 6...

Miscellaneous

TurboGopher saves or caches the item lists for all visited directories (even when windows are closed). Since these lists don't ever have to be fetched from the server again, this dramatically increases speed when choosing any item from the Recent menu. If TurboGopher runs out of memory it will first inform you and then automatically release the caches for closed windows.

As mentioned earlier, you may selectively release a directory's cache by closing the window while holding down the Shift key if you wish more control over memory.

TurboGopher stores what it needs in a file called TurboGopher Settings; this lives in the Preferences folder, which is found in your System Folder. If you drag this file out from the Preferences folder and place it in the same folder as TurboGopher, it will still be found and used.

For Experts

This section describes features of TurboGopher that either network administrators or Gopher weenies would want to know.

Waking up TurboGopher.

When TurboGopher starts up, it looks for the TurboGopher Settings file first in its own folder, and failing that in the Preferences folder. If it finds the TurboGopher Settings file, it uses the settings and resources (more on this later) it finds inside. If it cannot find the file, it creates a new one in the Preferences folder based on its internal defaults (more on this later too). If there are any bookmarks the user had set in the Bookmarks worksheet window, the Bookmark worksheet window is opened.

If the user had deleted all bookmarks, the Bookmarks window is not opened (the contents of the Bookmark worksheet window are remembered via the Settings file).

Next TurboGopher looks to see if the user has launched it by double-clicking on a Bookmark file (or by dropping a Bookmark file on it under System 7). If this is so, the contents of the Bookmark file (more on format later) are read and placed in a list (directory) window; in this case TurboGopher will not make a connection immediately to the Home Gopher Server.

If TurboGopher was launched directly (not via a Bookmarks document) then it connects to the Home Gopher Server, retrieves the contents of its top directory, and places this in a list (directory) window. At this point, TurboGopher is fully up and running. Next we need to describe the various parts alluded to above.

The Home Gopher Servers

Out of the box, TurboGopher comes preconfigured to connect AT RANDOM to one of the two primary gopher clones (gopher.tc.umn.edu or gopher2.tc.umn.edu; the former is also known to old Gopher folks as gopher.micro.umn.edu) at the University of Minnesota. It must be emphasized that these are NOT a primary and secondary server: they contain exactly the same information and changes made to one are automatically propagated to the other. If the first connection attempt fails, TurboGopher will try the next. This has two purposes. First, initial connections are very reliable for users and since we serve as the world's Gophermeisters, this is good. More importantly for us, the randomization ensures that users will spread the load over our two small, economical, primary servers (Mac Iici's). If your campus' primary Gopher server experiences heavy use, we suggest you make a clone too.

The user may of course reconfigure for only one primary server. TurboGopher remembers this via the Settings file. A campus network administrator may directly set TurboGopher's internal primary server defaults by altering STR# ID 3002 using ResEdit. The first 3 strings are for one alternate server, the next 3 are for the other. Leaving one or the other triplet empty implies that no clone servers are available. The first string in the triplet is the server's domain name, the second is the port, the third denotes whether it is a Gopher+ server (ignore this for now).

Other Built-in Information

A campus network administrator may also change the default bookmark set that TurboGopher carries around with him. This is stored in a 'TEXT' resource called

‘BookMarks’. It contains Gopher item descriptors EXACTLY as they come in off the net, ie:

```
Display-String<TAB>Selector-String<TAB>hostName<TAB>port<CR><LF>
```

NOTE: Ugly linefeed after the <CR>

The built-in manual is stored as ‘TEXT’ resource called “HeLp”. While you can replace that, we certainly don’t encourage you to do so.

Finally, most of the important English text for status messages etc. are stored in STR# resources, The primary one of these is STR# resource ID 3003. This is important for international localization purposes.... but read on.

Bookmark file formats

Bookmark files contain just the Gopher item descriptor lines that a Gopher client would ordinarily retrieve over the net. Please read the Internet Gopher protocol document for more information on this. Gopher bookmark files contain text. The fileType is not ‘TEXT’ however, so if you wish to edit one with a word processor or text editor, you will have to either change its fileType or use a permissive editor. Each line contains the familiar:

```
Display-String<TAB>Selector-String<TAB>hostName<TAB>port<CR>
```

NOTE: This is Mac text... SO NO LINEFEEDS AFTER THE <CR>

Bookmark files have the type ‘BKMK’ and creator ‘MDDF’. The Import Bookmarks menu item allows you to ATTEMPT to read any filetype you want and treat it as a Bookmark file. Please use this with caution. While TurboGopher will attempt to make sense out of the file, and will reject most junk files, you definitely are on thin ice here. The Open Gopher Bookmark File menu item however will only let you open bonafide Bookmark Files.

ISO Translation Table

The ISO Latin-1 character set translation tables used by TurboGopher were kindly supplied by Jean-Pierre Kuypers <Kuypers@sri.ucl.ac.be>, Pascal Maes <Maes@elec.ucl.ac.be>, and Andre Pirard <Pirard@VM1.ulg.ac.be> They are stored in taBL resources with ID 1001 and 1002.

The TurboGopher Settings file

We don't want you mucking around inside the data fork of a Settings file, so we aren't going to encourage you to do it by spelling out the format (though anyone with a disk editor and a room temperature IQ can figure it out).

We DO want you mucking around inside the resource fork of the Settings file though. When it is created by TurboGopher, the TurboGopher Settings file has no resource fork. If you add one by opening the file with ResEdit, then TurboGopher will place the Settings file in its resource search path. This means that if you want some custom resource to be used by TurboGopher, you may place it in the resource fork of the Settings file rather than munging around inside TurboGopher's application resource fork.

We would like you to place things like string localizations, custom code resources, and overridden configuration resources here for your local users. This way, you can distribute a localized TurboGopher Settings file on your campus and you shouldn't have to scramble to patch the application every time we release a new version. Certainly we might add more strings to various STR# resources... but if you drop us a line and tell us what you are doing with the resources, we will inform you before we release any new versions of TurboGopher that might affect you.

We have made provision for TurboGopher to execute external code resources to do certain tasks. At this point we're deciding if we should adopt some new interface for these code resources or to use the interface that Mac folks are very familiar with: XCMDs. We will probably wind up giving you access to various internal parts of TurboGopher via XCMDs.

This chapter describes PC Gopher III, hereafter referred to as Gopher, a program for IBM and compatible microcomputers that run the MS-DOS operating system. PC Gopher III is a program that lets you search for and retrieve information stored on other computers, known as "gopher servers".

System Requirements

Gopher runs under DOS version 3.3 or greater and requires 640K of conventional memory. Gopher will run on a wide range of IBM PCs and compatibles, including the earliest PCs which contained only a monochrome display adapter, with no graphics support.

A Microsoft-compatible mouse is helpful but optional. You must load mouse driver software before running Gopher. If your mouse contains more than one mouse button, you will only need to use the left mouse button when running Gopher.

You must also install a Clarkson (a.k.a. Crynwr) packet driver, a small piece of software that allows Gopher to communicate with your ethernet card or modem.

As of this writing, Gopher supports ONLY the Clarkson packet driver interface to your ethernet card or modem. Gopher will not run properly if you are using FTP Software's PC-TCP drivers, nor will it work with LAN Workplace for DOS, PC-NFS, or Banyan Vines.

How to Obtain the Software

The Gopher software consists of one file: GOPHER.EXE. There are two ancillary files that Gopher will create if it can't find them: GOPHER.REZ, which stores your configuration settings, and GOPHER.BMK, which stores "bookmarks" that you can use to easily re-visit interesting places in gopherspace. You can obtain the software over the internet via anonymous FTP from

`boombox.micro.umn.edu`

Look in the directory called

`/pub/gopher/PC_client`

You can also find the Clarkson packet driver collection in the directory called

`/pub/gopher/PC_client/packet_drivers`

Installation

Connecting To The Internet

To run Gopher, your microcomputer must be connected to a local area network (LAN). Usually, the LAN will be connected to the global internet allowing you to find information located on gopher servers outside of your network. If you have access to a dial-up SLIP server, you can also use Gopher with a modem instead of a LAN connection.

LAN Operation

For your microcomputer to operate on the LAN, you must have a network adapter card installed. In order to run Gopher, your network adapter card must be one supported by the Clarkson packet drivers.

Dial-up Operation

If you have access to a SLIP server, you can use Gopher with a modem instead of a network adapter. You will still need a packet driver; we recommend `UMSLIP.COM`, which is available via anonymous ftp to `boombox.micro.umn.edu`, in the directory

`/pub/phone`

In the same directory, you can find `PHONE.EXE`, a phone-dialer program that may be helpful in establishing your SLIP server connection.

Installing the Packet Driver

In order to run Gopher, the appropriate packet driver must first be loaded into memory; it's easiest to do this automatically each time you start up your computer.

Each packet driver is a specialized piece of software designed to "talk" to a specific type of network adapter card; since all of the packet drivers have the same interface, this allows one version of Gopher to run on a wide range of network adapters. The packet driver collection includes documentation that you can use to determine which driver you need to use with your network adapter.

To load the packet driver, type the packet driver name, followed by the necessary parameters, as described in the documentation that comes with the packet driver set. For example, suppose you have a 3Com 3c523 ethernet card installed in your PC. To load it, you would type

3C523 0x60 0x3 0x300

and hit the enter key (note that different packet drivers require different parameters; see the packet driver documentation for the correct parameters for your packet driver). As long as you do not turn the power off to your computer, you can run Gopher, quit and do other things, and then start Gopher again without re-loading the packet driver. Also, if you already have the packet driver loaded for other pro-

grams like FTP, Telnet, or tn3270, you do not need to re-load the packet driver before running Gopher.

If you'd like the packet driver to load automatically whenever you start up your computer, you can add the packet driver command and parameters to your `AUTOEXEC.BAT` file; most people find it easier to let the computer load the packet driver automatically, rather than remember the complicated and arcane parameters necessary.

Installing the Gopher Software

After you have installed the appropriate packet driver, copy all of the Gopher files into a directory on your hard disk. For example, if you wanted to install Gopher in a directory called GOPHER, you'd type

```
cd c:\
```

to get to the root directory of your hard disk,

```
mkdir gopher
```

to make a new subdirectory for Gopher,

```
cd gopher
```

to switch to the new subdirectory, and

```
copy a:\*.*
```

to copy the files from the floppy drive to the hard disk.

If you already have an older version of Gopher, such as PC Gopher II v1.05, you must delete all of your old Gopher files BEFORE installing this version. The one exception to this is your old bookmark file; you can use the included conversion utility called `BMKCVT` to update this file to the format used by PC Gopher III.

FIGURE 4. PC Gopher Top Level

Configuring Gopher

When you use Gopher for the first time, you may need to enter some configuration information specific to your microcomputer. Gopher needs these configuration parameters in order to identify your computer on the network. This information is stored in a "resource file" called (by default) `GOPHER.REZ`. Gopher will automatically create this file if it can't be found.

First, start Gopher by typing

GOPHER

at the DOS prompt. Once Gopher starts up, pull down the Configure menu; the menu item called "Application..." will open up Gopher's application configuration dialog box (to pull down a menu, either click on its title with the mouse cursor, or hold down the Alt key and type the first letter of the menu title; to choose an item, either click with the mouse, or use the arrow keys to highlight the item, and hit the ENTER key; to close a menu without choosing any item, hit the ESC key).

To enter or edit any of the parameters in the configuration dialog boxes, use the TAB key (or up and down arrow keys) to advance to the appropriate field. If the field is a text field, type in the information. If the field is a series of checkboxes (a pair of square brackets followed by some text), use the space bar to toggle the checkmark on and off, and the arrow keys to move between checkboxes.

Application Configuration

Home Gopher Server

This is the name of any gopher server on the network. Your organization may be running its own gopher server; if not, you are welcome to use our server, which goes by the name of :

`gopher.tc.umn.edu`

Gopher will attempt to connect to this server when you issue a "New Gopher" command. Your explorations are not restricted to information stored on this particular server, but you will always start off here.

Port Number

This is the port number that Gopher will use to attempt to connect to the gopher server named above. Currently, gopher servers use port 70 for connections.

Alternate Gopher Server and Port Number

If your home server doesn't respond when you try to open a new browser window, Gopher will try to connect to this server instead. You might want to configure this to `gopher2.tc.umn.edu`, port 70; this server replicates the information on `gopher.tc.umn.edu`.

Terminal Sessions

Some services available in gopherspace require a standard terminal interface, rather than Gopher's point-and-click interface. To access these services, you need a piece

of software called a terminal emulator. The two most popular terminal types used by non-gopher services are the DEC VT100 and IBM 3270 terminals; consequently, Gopher allows you to configure two terminal emulation programs, one for each kind of session (you don't need to worry about which program to use with which service; Gopher will automatically launch the right one for the job).

In the input line title "Telnet Session Command Line", enter the path and filename of your VT100 emulator, and the parameters you want to pass to the program. Gopher knows how to interpret certain symbols within the command line, replacing them with information that can't be generated until immediately before the session is started. The symbols and what they're replaced by at runtime are:

TABLE 2. PC Gopher Telnet Command Substitutions

Symbol	Meaning
%a	address of target machine
%n	name of target machine
%p	port number of service on target machine

At a minimum, you need to include the symbols %n and %p as parameters; Gopher will replace these with the name and port number of the machine it needs to connect to.

For example, if the VT100 emulator you're using was in the same directory as gopher, C:\GOPHER, and it was called VT100.EXE, you'd set the command line up like this:

```
C:\GOPHER\VT100.EXE %n %p
```

If your VT100 program needs a "#" in front of the port number, set the command line up like this:

```
C:\GOPHER\VT100.EXE %n #%p
```

Below the command line is an input line for you to enter the amount of memory necessary to run the program. If you leave this at zero, Gopher will always try to run the program; if you set it to a number other than zero, Gopher will warn you if

memory is too low to run the program, and allow you to cancel the operation or, if you are brave, continue.

By default, Gopher will try to swap itself to disk before running external programs, so normally you'll want to set the memory required to zero. If allowing Gopher to swap to disk is causing problems, you may need to disable swapping with the /NOSWAP switch; in this case, you should set the memory requirement to whatever your external program needs, as a safety measure.

The line entitled "TN3270 Session Command Line" works in exactly the same fashion as the Telnet Session Command Line item. The program that you enter here will be used to connect to IBM3270 based services.

Options: New Gopher On Startup

If this checkbox is checked, the program will automatically attempt to connect to the gopher server entered in the Home Gopher Server input line, whenever Gopher is started. If not checked, you will have to select New Gopher from the File menu or the status bar to start the initial gopher session.

Options: Single Window Mode

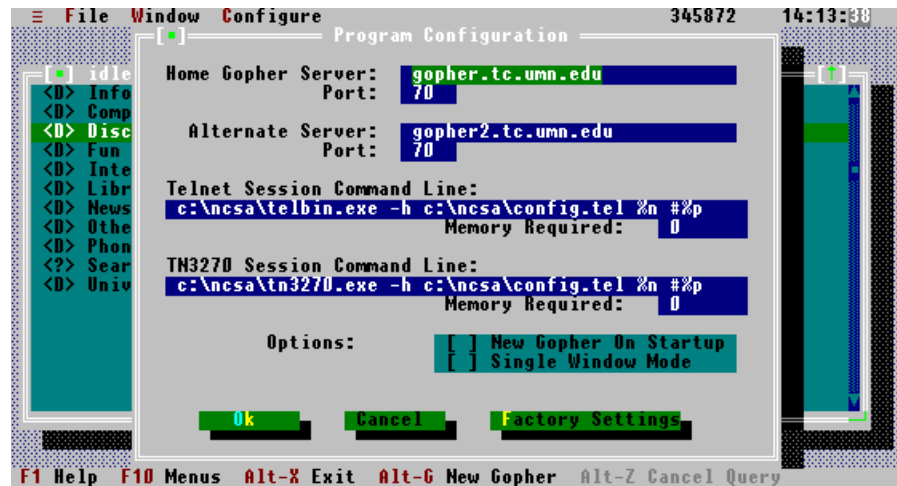

Ordinarily, Gopher will open a new window each time you look in a directory. If you check this checkbox, Gopher will reuse the same window, and will add a "Go Back" button to the bottom of the window to allow you to quickly return to directories that you've already seen.

Network Configuration

To open Gopher's network configuration dialog box, choose "Network..." from the "Configure" menu.

All computers that use the internet need addressing information, so that data gets "delivered" to the right place. There are two ways to set up this information in Gopher; by hand, or automatically, via the BOOTP protocol. BOOTP allows your microcomputer to ask a server for network addressing information.. Your network administrator will know if you have access to BOOTP.

FIGURE 5. PC Gopher Application Configuration

Gopher is set up to use BOOTP by default. If you have access to BOOTP, you don't need to enter any addressing information at all; you can skip to the next section.

Microcomputer IP Address

This is the IP address of your individual microcomputer or workstation. See your network administrator for a microcomputer IP address assignment.

Microcomputer Netmask

The netmask parameter has to do with how your local area network is configured and connected to the backbone network at your work site. See your network administrator for the correct value to enter here. Many sites are configured to use a netmask of 255.255.255.0.

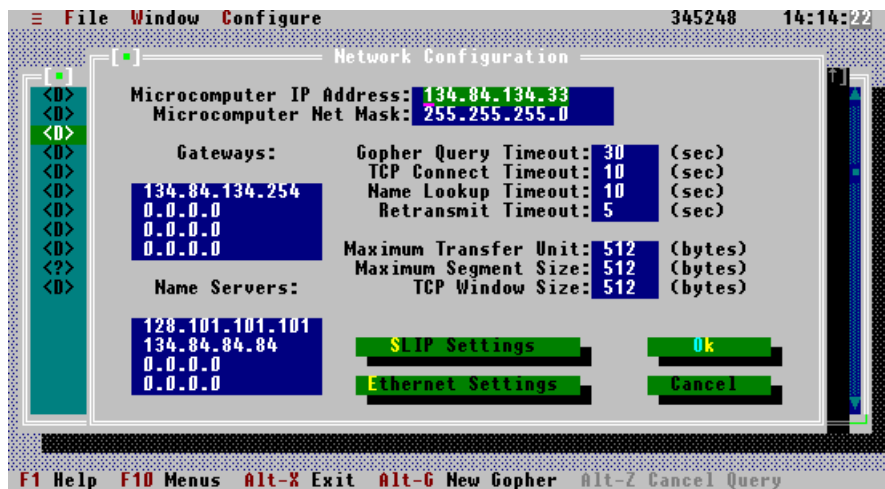

Nameservers

A name server converts a gopher server name into machine-readable address. Gopher relies heavily on nameservers; if you don't have access to one, you won't be able to use Gopher. You may enter up to four nameserver addresses; they will be tried in the order in which they are entered.

Gateways

A gateway is a device which gives your computer access to the outside world. If you want to use Gopher to look at information on servers beyond your local area network, you must specify the address of your gateway. You may enter up to four gateway addresses; they will be tried in the order in which they are entered. Your network administrator can tell you the addresses of gateways accessible to you.

FIGURE 6. PC Gopher Network Configuration

Advanced Network Configuration Options

There are several advanced configuration parameters that can be used to tune network performance; these parameters can usually be left at the default settings.

Gopher Query Timeout

This is the maximum number of second that Gopher will wait for a response from a server, after sending a query.

TCP Connect Timeout

This is the maximum number of seconds that Gopher will wait for acknowledgment of an attempt to open a connection to a server.

Name Lookup Timeout

This is the maximum number of seconds allowed for the nameserver on the network to convert a gopher server name to a machine-readable address.

Retransmit Timeout

This is the maximum number of second that Gopher will wait before retransmitting a packet of data that hasn't been acknowledged.

Maximum Transfer Unit

This is the largest size TCP/IP packet that Gopher will send.

Maximum Segment Size

This is the maximum size packet that Gopher will accept; since Gopher cannot accept "fragmented" packets, this number must be small enough that the server won't be tempted to fragment packets as they are sent.

TCP Window Size

This is the size of the TCP/IP data buffer.

When you've finished setting up the network configuration parameters, confirm your changes by choosing the "OK" button, or cancel them by choosing the "Cancel" button.

Configuration Data File

All of the parameters that you enter in the configuration dialog boxes are stored in a file called (by default) `GOPHER.REZ`. If this file is damaged or lost, all of your configuration data will have to be reentered.

You can tell Gopher to use an alternate configuration file by using the `/R` command line switch. See the section entitled "Gopher and Command Line Switches" for further information.

Gopher and Command Line Switches

To start Gopher, type

GOPHER

at the DOS prompt.

Gopher understands several command line switches, which can be used to modify its default behavior. Note that if you install all of the Gopher files in a single directory on your hard drive, you won't need to use most of these.

The usage of command line switches is as follows:

`/SWITCH=VALUE`

if the switch requires a value, or just

`/SWITCH`

if it doesn't. You will need to substitute a "-" for the "=" if you're trying to pass these parameters into a batch file, since DOS will eat all of the "=" characters

The /R Switch

By default, Gopher expects to get resources and configuration information out of a file called GOPHER.REZ, in the same directory as GOPHER.EXE. You can use a different directory and/or filename by starting Gopher like this:

```
GOPHER /R=D:\PATH\FILE.EXT
```

replacing D:\PATH\ with the path to the alternate resource file, and FILE.EXT with the alternate file's name and extension.

Network administrators can use this switch to create separate configuration files for each client on the network; however, since Gopher reads from AND writes to the resource file, it CANNOT BE PLACED IN A READ-ONLY DIRECTORY.

The /B Switch

This switch also works like the /R switch, but it tells Gopher where to store bookmarks. By default, Gopher will save any bookmarks you create in GOPHER.BMK, in the same directory as GOPHER.EXE; you can use a different bookmark file by starting Gopher like this:

```
GOPHER /B=D:\PATH\FILE.EXT
```

replacing D:\PATH\ with the path to the alternate resource file, and FILE.EXT with the alternate file's name and extension.

If you're installing Gopher on a Novell server, the bookmark file must be in a writeable directory.

The /T and /X Switches

These switches can be used to tell Gopher where you'd like to store saved text and binary files, respectively. Ordinarily, Gopher offers to save files in the same directory as the file GOPHER.EXE; you can "aim" at a different directory by starting Gopher like this:

```
GOPHER /T=D:\PATH /X=D:\PATH
```

replacing D:\PATH with the directory that you want to use. You will still be prompted for a filename when saving a file, and you'll be able to navigate through the directory hierarchy on your hard disk with the file-save dialog box; this switch just sets the directory that you're shown first.

Switches Used to Pass IP Address Information

There are four switches that you can use to pass addressing information to Gopher, overriding the information in the configuration dialog box. They are:

TABLE 3. PC Gopher IP Address Switches

/MYIP	IP address of your microcomputer
/MYMASK	Netmask of your microcomputer
/MYGW	Your gateway's address
/MYDNS	Your nameserver's address

These switches all work the same way. For example, to use an IP address of 127.0.0.1, start Gopher like this:

```
GOPHER /MYIP=127.0.0.1
```

Other Switches

There are three other switches that don't fall into any particular category.

The /SHUTUP switch will prevent Gopher from beeping at you if there's some sort of fatal error.

The /NOSWAP switch will prevent Gopher from swapping itself to disk before executing a DOS shell or external program. Note that if you use this switch, you may not have enough memory for terminal sessions! This switch is only necessary if your computer crashes when Gopher swaps itself to disk, which happens with some combinations of TSR programs and hardware.

Finally, the /? switch will print a summary of all of the switches on your screen.

The Gopher User Interface

Gopher uses the standard IBM character set to emulate a graphical user interface (GUI). For this reason, Gopher runs on a wide range of IBM PCs and compatibles, including the earliest PCs which contained a monochrome display adapter (with no graphics support). In other words, Gopher does not require that you install a special graphics display adapter in your computer., or that you run a windowing operating system like Microsoft Windows or IBM OS/2.

With a GUI, you interact with the program by responding to graphical symbols which appear on the computer screen, rather than by issuing single line commands (as with the MS-DOS operating system). Because of its graphical user interface, Gopher is largely self-explanatory. If you are familiar with the GUI in Microsoft Windows or the Apple Macintosh operating system, you will be able learn how to use Gopher very quickly; you may want to skip to the section entitled "Using Gopher", and come back to this section later.

Gopher's user interface consists of several elements:

Lists

Lists are boxes containing one or more lines of text, with a "scroll bar" along the right side of the box. The scroll bar allows you to see items in the list that aren't displayed on the screen; to scroll the list, click on the up or down arrows at the top and bottom of the scroll bar with the mouse, or use the arrow keys.

There is always one item in the list that's the "currently selected" item; if you click on it, or hit the enter key, the list will perform its default action on that item. The currently selected item is indicated by highlighting; the text and background colors of the currently selected item are colored differently than the rest of the list, or are shown in inverse video on a monochrome monitor.

Buttons

Buttons are rectangular areas of the screen which will respond to a mouse click by performing some action.

Some buttons have one letter of their label highlighted; you can operate these buttons by holding down the Alt key, and typing the highlighted letter. Other buttons

have all of their label highlighted; this indicates that the button is the "default" button, and can be operated by hitting the ENTER key.

Dialog Boxes

Dialog boxes allow Gopher to ask you for information. For example, when you choose a search item from the list of available items, a dialog box will pop up to allow you to enter the text to search for.

Dialog boxes are also used to inform you of errors while Gopher is running. When one of these error dialog boxes pops up, you must click on the OK button (or hit ENTER on the keyboard) before you can continue using the program.

A dialog box can consist of many elements; buttons, fields to enter text, list boxes, and so on. If you are using a keyboard rather than a mouse, you'll need to use the TAB key to select these various elements before you can use them.

Windows

Gopher uses windows to display information. There are two main types of windows in Gopher; the browser window, which displays lists of items for you to choose from, and the file display window, which displays the contents of a text file that you've chosen.

Both windows can be positioned anywhere on the screen, with the mouse or the keyboard. To move a window with the mouse, position the cursor over the title bar of the window (the horizontal line marking the window's top edge), then press and hold the mouse button as you move the mouse. To move a window with the keyboard, type Ctrl-F5, and use the arrow keys to move the window around the screen. When the window is positioned the way you want, hit the ENTER key.

In the upper left-hand corner of each window is a small rectangle enclosed in square brackets. This is the window's close box; clicking with the mouse in the close box will close the window. To close a window using the keyboard, type Alt-F3.

Some windows can also be resized; resizable windows have a resize box in the lower right-hand corner. To resize the window with the mouse, position the cursor in the resize box, press the mouse button, and move the mouse. To resize the window from the keyboard, type Ctrl-F5, hold the shift key down, and use the arrow

keys to resize the window. When the window is sized the way you want, hit the ENTER key.

The Menu Bar

The very top line of the computer screen contains Gopher's menu bar with three menu labels. The menu bar looks like this:

```
#      File      Window      Configure
```

The menu bar is the primary mechanism you use to communicate with Gopher. The menus have pull-down labels; that is, when you select a title in the menu bar, a list of specific commands are displayed underneath the menu label.

If one of the commands in a pull-down menu is followed by an ellipsis, choosing that command will display a dialog box, requesting further information. If a command in a pull-down menu is not followed by an ellipsis, the indicated action will occur as soon as you select the item and release the mouse button or hit the ENTER key.

You can use either a mouse or keyboard to select commands. To use a mouse, click on the desired menu title to display the pull-down menu (use only the left mouse button if your mouse has more than one button). Then click the desired command. Alternatively, you can push the mouse button down over a menu title and then continue to hold the mouse button down while you drag straight down from the menu title to the desired menu command, and then release the mouse button. If you decide not to choose a command, just drag out of the boundaries of the pull-down menu and no action will be performed.

To choose menu commands using the keyboard, first pull down the menu. Press the F10 key to make the menu bar active; when the menu bar is active, one menu title is highlighted. If the menu title you want is not the one currently highlighted, use the arrow keys to move to the right or left along the menu bar, until you select the menu title you want. Press the ENTER key to pull down the menu. Now use the up and down arrow keys to select the command you want. To execute the command, hit the ENTER key; to close the menu without executing any commands, hit the ESC key.

There is also hot-key alternative to pulling down a menu. Hold the Alt key down while typing the letter corresponding to the first letter of the menu title you want;

for example, type Alt-F to pull down the File menu (the hot key to pull-down the # menu is Alt-Spacebar).

Once the menu you want is pulled down, you can press the key corresponding to the highlighted letter of the desired command.

In addition to the four menus, there are two indicators at the left end of the menu bar. The first indicator shows how much memory is available to the program; the second one is a clock.

Menu Structure

The individual items under the pull-down menus are organized as follows. Highlighted letters (shown here as capital letters) are used to perform the various shortcuts described in the previous section and elsewhere in this manual.

Note that the hot-key letter associated with each command is not always the first letter of the command. In addition, some menu commands are used often enough that they can be activated with a keyboard alternative (in other words, without having to pull down any menu first). These keys are also shown below.

The Preferences menu has a submenu listing user-configurable preferences; this submenu works the same way that the other menus do.

TABLE 4. PC Gopher Menus

Menu Name	Item Names	Action When Selected	Keyboard Alternatives
#			Alt-Spacebar
	About PC Gopher III	displays program credits	
	Calculator	pop-up calculator	
	CaLender	Perpetual Calendar	
	Puzzle	Challenging Puzzle	
	DOS Shell	Temporarily use DOS	
File			Alt-F

TABLE 4. PC Gopher Menus

Menu Name	Item Names	Action When Selected	Keyboard Alternatives
	new Gopher	opens a browser for your home server	Alt-G
	Save file...	saves foremost text window to a file	Alt-S
	Open bookmark file	opens the bookmark list dialog	F9
	eXit	quits PC Gopher III	Alt-X
Window			Alt-W
	Next	brings the back window to the front	F6
	Zoom	makes a window full-screen sized	F5
	Move	allows keyboard positioning of a window	Ctrl-F5
	cLose	closes the front window	Alt-F3
Configure...			Alt-C
	Application...	displays application configuration dialog	
	Network...	displays network configuration dialog	
	Preferences	displays submenus	
	Mouse...	displays mouse configuration dialog	
	Video Mode	toggles video mode between 25&50 lines	

The Status Bar

Gopher's status bar is located across the bottom line of the screen. The status bar looks like this:

F1 Help F10 Menus Alt-X Exit Alt-G New Gopher Alt-Z Cancel

The status bar contains "hot spots". Hot spots are located wherever words occur in the status bar. For example, "Alt-G New Gopher" constitutes one hot spot. Hot spots are separated from each other by more than one space. When you click on a hot spot with a mouse, the indicated function will occur. For example, when you click on the words "Alt-G New Gopher", Gopher will open a new browser window, and when you click on the words "Alt-X Exit", Gopher will shut down and return you to the DOS prompt. To activate a hot spot without using a mouse, hold down the Alt key, and type the letter indicated in the status bar.

Using Gopher

To start exploring gopherspace, choose "New Gopher" from the File menu, or click on the words "Alt-G New Gopher" on the status line (if you'd rather use the keyboard, type Alt-G). Gopher will attempt to connect to the first server that you specified in the configuration dialog box. If the attempt is successful, Gopher will retrieve a list of the items that the server knows about. The list will look something like this:

```
<F>About Internet Gopher
<B>GIF picture of Joey Ramone
<D>Really Interesting Administrative Information
<P>U of MN Phone Book
<S>Search Pyrotechnics Recipes
<T>Card Catalog via Telnet
```

Any item on the list can be selected either by moving the selection bar with the arrow keys and hitting ENTER, or by double-clicking with the mouse.

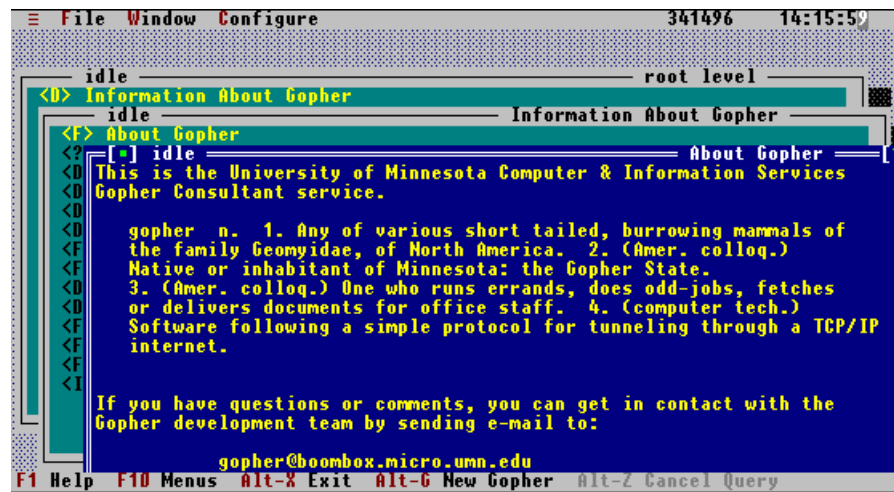

Gopher Item Types

At the beginning of each line in the item list is a character enclosed in brackets; this character tells you what the item is. Gopher knows about the following item types:

TABLE 5. PC Gopher Item Types

Character	Type Name	Action When Selected
<F>	Text File	retrieves and displays the file
	Binary File	retrieves the file
<D>	Directory	shows you more items
<S>	Search Item	prompts for text to search for
<P>	Phone book	prompts for person to look up
<T>	Terminal Session	connects you to a non-Gopher service
<??>	Error	none

FIGURE 7. PC Gopher Text Files

Text Files

In the above example, line one refers to a file called "About Internet Gopher". To see the contents of this file, select the item with either the mouse or the keyboard. Gopher will attempt to retrieve the file, and display it in a separate window. If the file is too large for Gopher to fit into available memory, it will put up a dialog box requesting that you specify a filename and directory to save the file in. You can then open the file with your favorite word processor to see the contents.

You may also choose to save the information that you get back as a file, even if it is small enough for Gopher to display immediately in a window. Just choose "Save File..." from the File menu, and enter the filename and directory that you want to save the file in.

Binary Files

The second item in the list above is a binary file, a GIF picture of one of our favorite rock stars. Choosing this item will pop up a dialog box, prompting you for a filename to save the picture in; once you've entered a filename and chosen the "OK" button, Gopher will retrieve the file. Instead of displaying the file in a window, Gopher will show you a progress indicator so that you can tell when the file has been retrieved. To view the file, you'll have to quit Gopher and run a separate program capable of displaying GIF pictures.

Directories

The third item in our example listing is a directory. Directories are like folders or drawers full of other items. When Gopher first connects to the gopher server that you specify as your starting point, the list that you get back shows the contents of the main or "root" directory of that server.

To see the contents of a directory, select it from the list using either the mouse or the keyboard. Gopher will request a list of the contents of the subdirectory that you selected, and will present this list in the browser window.

If you anticipate returning to a particular directory on a particular server, you can use the Bookmark List to save that position in gopherspace. To save a bookmark, first navigate to the place that you want to remember, and then choose Open Bookmark File from the File menu. Once the bookmark list opens up, click on the Add

button; you will be prompted for a name for the bookmark. To return to the bookmarked position later, just open the bookmark list and choose the bookmark you wish to return to.

FIGURE 8. PC Gopher Phone Book Search

Phone Book Items

The fourth item in the example is a Phone Book item. Phone book items are pointers to databases that contain information about people's phone numbers, office locations, e-mail addresses, and so on; these databases are called CSO or PH servers. When you select a phone book item, a dialog box will pop up, and Gopher will ask the database server for a list of items that you can ask about. Once the list of these items is built, you can look a person up by typing her name into the dialog box and choosing the "Lookup" button. Any matching items will be displayed in a separate window, and can be saved to disk using the File menu's Save File command.

If you want to enter more information to narrow the search, you can choose the "More Choices..." button, and you'll be presented with a larger dialog box, containing a list of fields that you can use in a query. You build up a query by selecting an item from the list, and typing in the search key next to the item name when it pops up on the screen. You can build queries of up to five items; if you want to change

the query, selecting the Clear button will clear all of the items you've chosen. Once the query is set up, select the Lookup button, and the query will be sent to the server.

FIGURE 9. PC Gopher Searches

Search Items

Next in the listing is a Search item for an interesting set of recipes. A search item is a computer that can search various gopher servers for files containing text that you specify. If you select a search item, a dialog box will pop up for you to enter your search text in. To start the search, click on the "Search" button, or just hit the ENTER key.

The search item returns a list of files that it knows about that contain ALL of the text that you enter in the input box. If you entered the word "salmon", the search item would return a list of all of the files containing that word. If you entered "salmon spinach", the search item will return a list of files that contain both the word "salmon" and the word "spinach"; it would NOT return the names of files that had only one of the two words.

Search Items and Logical Operators

Logical operators are special words that allow you to set up specific search conditions. The logical operators "and", "or", and "not" are supported by many search items. You can use one or more of these operators to narrow the field of your search.

There are three different types of search items in gopherspace. The first type assumes an implicit "and" between words, and will let you use logical operators to change this behavior. The second assumes an implicit "or" between words, and will also allow the use of logical operators to alter the default. The third assumes "or", and ignores logical operators. Unfortunately, the only way to find out which type of search item you're dealing with is to experiment (unless it is explicitly labeled as one of these three types).

For example, assume you've found a search item that assumes "and" between words, and also understands logical operators. Suppose you want to find files that contain the word "salmon" or the word "spinach", but not both. You can do this by entering "salmon or spinach" in the input box. You can also use the word "and" to explicitly indicate that the files you're searching for must contain both words; this allows you to set up specific search conditions by using multiple logical operators. Logical operators are evaluated in right-to-left order; the search pattern "spinach and salmon or broccoli" would result in a list of files that contained the word spinach and the word salmon, or just the word broccoli.

To exclude words from the search pattern, use "not". The search phrase "Minnesota not snow" would produce a list of files containing at least one instance of the word "Minnesota", and no instances of the word "snow".

Terminal Session Items

The last item in the example listing is a Terminal Session item. A terminal session item is a way to allow you access to information services that expect to communicate with a terminal rather than a program like Gopher. When you select a terminal session item, Gopher will execute the terminal emulator if your choice, passing the name, address, and/or port number required to connect to the terminal-based service. See the section entitled "Configuring Gopher" for information about how to configure Gopher to access these services.

Multiple Concurrent Queries

Gopher is capable of handling more than one query at a time, although it is limited to no more than three simultaneous queries. This allows you to continue to navigate through gopherspace while you're receiving a large binary file, and even to fetch other files at the same time.

Query Progress Indicators

The browser window and the text display window both have query progress indicators in the lower left-hand corner of their window frames. This indicator will tell you exactly what the status of the query is; usually, you'll see either "receiving", meaning that Gopher is receiving a response to your query, "waiting", meaning that Gopher is waiting for the server to continue the transaction, or "idle", meaning that the query is complete and that Gopher has closed the connection with the server.

The progress indicator can be helpful in diagnosing problems with slow or sick servers, misconfigured or broken networks, or (heaven forbid) PC Gopher itself.

Canceling a Query

Any query can be canceled at any time. If you want to cancel a query and throw away any directory listing or text that you've received so far, you can close the window associated with the query. To cancel a query without closing its window, type Alt-Z or choose the "Alt-Z Cancel Query" hotspot in the status line.

Help!

If you run into difficulties installing or using Gopher, or have bug reports, suggestions, or general comments, you can send e-mail to us at:

`gopher@boombox.micro.umn.edu`

Although we greatly prefer e-mail, you can also contact us via paper mail at:

The Gopher Development Team
Computer and Information Services
University of Minnesota

Acknowledgments

Room 190 Shepherd Labs
100 Union St. SE
Minneapolis, MN 55455
U.S.A.

In all of your correspondence pertaining to PC Gopher III, please indicate:

- your PC Gopher III version number
- your operating system and version number (e.g., DOS 5.0)
- your computer brand and model
- your ethernet card brand and model (if applicable)

Acknowledgments

Thanks to Borland International of Scotts Valley, California, for Borland Pascal version 7.0, and for TurboVision.

Thanks to Clarkson College of Potsdam, New York, for the use of the Clarkson Packet Drivers.

Thanks to Ralf Brown for allowing us to use his Turbo Pascal swapping unit, Spawn0.

Thanks to George Gonzalez and Earl Schleske for their tireless maintenance of the TCP/IP driver used in PC Gopher III.

Finally, thanks to Shih-Pau Yen for having a lot of faith, Farhad Anklesaria and Mark McCahill for having a lot of nerve, and all of the beta-testers for having a lot of patience.

This chapter describes how to use the UNIX Gopher client, version 2.0.

Overview

Internet Gopher for Unix is distributed as C source code. You will need to compile this source code into binary executables for your system. To make it generally available to the rest of the users on the system, you should install the software into a central directory.

Requirements

You will need a working gopher client, to see if it's been installed just type:

gopher

If you get an error message, then you will have to install the UNIX Gopher client, see “*Installing the Unix Gopher Distribution*” on page 69, or you'll have to use one of the public gopher systems listed in the Common Questions chapter.

Starting the UNIX Gopher Client

To start the UNIX Gopher client, simply type **gopher**. You'll be presented with a screen that looks like this:

FIGURE 10. Unix Gopher Client-Top Level

```
Internet Gopher Information Client 2.0 pl10
Root gopher server: gopher.tc.umn.edu

--> 1. Information About Gopher/
    2. Computer Information/
    3. Discussion Groups/
    4. Fun & Games/
    5. Internet file server (ftp) sites/
    6. Libraries/
    7. News/
    8. Other Gopher and Information Servers/
    9. Phone Books/
   10. Search Gopher Titles at the University of Minnesota <?>
   11. Search lots of places at the University of Minnesota <?>
   12. University of Minnesota Campus Information/

Press ? for Help, q to Quit                                     Page: 1/1
```

This is what you would see if you used gopher at the University of Minnesota, other systems may have localized and customized the client for their own sites.

Navigating Gopherspace

Once you've started the client you can move around Gopherspace using a few different keys, the most common ones are the cursor keys, the u key, and the RETURN key.

The cursor keys control the arrow pointer; pressing the cursor down key moves the arrow to the next item, pressing the cursor up key moves the arrow to the previous item.

Pressing the RETURN key or right arrow key displays the item that the arrow is pointed at.

Special Items

Each item is tagged with special characters to make it easy to predict what each item is. Items ending with a slash (/) are Gopher directories, selecting one of these items will cause a new directory to be displayed.

An item that ends with a period (.) are text files. Pressing RETURN on these items will view the file. For instance pressing RETURN on the file “About Gopher” will retrieve the file and result in a screen that looks like the following:

FIGURE 11. Unix Gopher Client-Text File

```

About Gopher (1k) 75% █
This is the University of Minnesota Computer & Information Services
Gopher Consultant service.

gopher n. 1. Any of various short tailed, burrowing mammals of
the family Geomyidae, of North America. 2. (Amer. colloq.)
Native or inhabitant of Minnesota: the Gopher State.
3. (Amer. colloq.) One who runs errands, does odd-jobs, fetches
or delivers documents for office staff. 4. (computer tech.)
Software following a simple protocol for tunneling through a TCP/IP
internet.

If you have questions or comments, you can get in contact with the
Gopher development team by sending e-mail to:

gopher@boombox.micro.umn.edu

If you are interested in news about new gopher servers and software
you can subscribe to the gopher-news mailing list by sending e-mail
to:

gopher-news-request@boombox.micro.umn.edu

[PageDown: <SPACE>] [Help: ?] [Return to Menu: u]
```

Press the space bar to view the next page. To view the previous page press the **b** key. To search for some text press the **/** key and enter the words you want to search for. Press the **u** key when you’re finished viewing a file to return to the directory screen.

Once you’ve finished with viewing the directory you can, if you wish, return to the previous directory by pressing the ‘u’ key or the left arrow key. This moves you *up* to the previous directory.

Special Items

This section details how to use the Unix Gopher Client to access services other than text files and directories.

Index Searches

Items with a <?> tag at the end of the name are searchable indices. When you select one of these items you will get to type in search words. These words will determine the items in the resulting directory listing. For instance a search on “*Search Recipes*” with word *salmon* would result in a listing of recipes related to salmon.

Phone Book Servers

Phone Book Servers show up with the tag <CSO> at the end of the name. Selecting one of these items results in a screen that looks like this:

FIGURE 12. Unix Gopher Client-Phone Book Search

```
Internet Gopher+ Information Client v1.2beta3
                                North America
                                National Institutes of Health
+-----+
| name   | lindner |
| email  |          |
| alias  |          |
| proxy  |          |
| nickname |        |
| phone  |          |
| address |        |
| ICD    |          |
| fax    |          |
| title  |          |
| pager  |          |
| localmail |      |
| lastname |     |
| miscel |          |
+-----+
[Switch Fields - TAB]           [Cancel ^G] [Accept - Enter]
--> 60. National Institutes of Health <CSO>
Press ? for Help, Q to Quit, U to go up a menu ...
```

You can fill in the fields in any way you wish. In this example we want to see if there are any people with the name “lindner” at the National Institutes of Health.

Telnet/tn3270 Servers

Gopher can connect to telnet sites such as Library Catalogs rather easily, if you see an item tagged with <TEL> or <3270> you’ll be presented with a screen similar to the following

FIGURE 13. Unix Gopher Client-Telnet/tn3270 services

```
Internet Gopher+ Information Client v1.2beta3

Australia

1. Australian Bibliographic Network <TEL>
2. Australian Bibliographic Network.
3. +-----James Cook University-----+
4. |
5. | Warning!!!!, you are about to leave the Internet
6. | Gopher program and connect to another host. If
7. | you get stuck press the control key and the ] key,
8. | and then type quit
9. |
10. | Connecting to jculib.jcu.edu.au, port 23 using telnet.
11. |
12. | Use the account name "opac" to log in
13. |
14. |                                     [Cancel - ^G] [OK - Enter]
15. |
16. |-----+
17. Griffith University <TEL>
18. Griffith University.
--> 19. James Cook University <TEL>
    20. James Cook University Library.

Press ? for Help, Q to Quit, M to go up a menu                                Page: 1/4
```

In this example we’re connecting to the “James Cook University” library system. If there’s a special login required Gopher will tell us. In this case it’s “opac” If we press RETURN, Gopher will connect us to the host `jculib.jcu.edu.au` and let us login.

Advanced Navigation Features

There are many other keys that you can use with the UNIX client. Instead of the cursor keys you can use the the equivilant cursor control keys for vi or emacs. In vi the keys are `h`, `j`, `k`, and `l`. In emacs the keys are `^B`, `^N`, `^P`, and `^F`.

The following table summarizes the other keys:

TABLE 6. UNIX Gopher Client-Advanced Navigation Keys

Key	Action
>, +, SPACE	Move to the next directory page.
<, -, b	Move to the previous directory page.
0-9	View a specific item.
m	Go back to the first “main” directory screen.

Bookmarks

If you formulate a search or find a folder you would like to come back to later, you can set a bookmark for the item. Then you can easily find the item later in your personal bookmark directory.

Move the arrow to the interesting item and press the ‘a’ key to add a bookmark. You will see a screen like this:

FIGURE 14. Unix Gopher Client-Adding a Bookmark

```
Internet Gopher+ Information Client v1.2beta3
      Australia
1.  Australian Bibliographic Network <TEL>
2.  Australian Bibliographic Network.
3.  Australian Defense Force Academy <TEL>
4.  Australian Defense Force Academy.
5.  Australian National University <TEL>
-----+-----
Name for this bookmark?  James Cook University
                        [Cancel ^G] [Accept - Enter]
-----+-----
13. Deakin University <TEL>
14. Deakin University.
15. Flinders University <TEL>
16. Flinders University.
17. Griffith University <TEL>
18. Griffith University.
--> 19. James Cook University <TEL>
    20. James Cook University Library.

Press ? for Help, q to Quit, u to go up a menu           Page: 1/4
```

Type in a meaningful name. Later on, when you wish to access this item again, press the ‘v’ key to view your personal bookmark list. You’ll get a directory listing screen that contains all of your bookmarks. If you wish to delete a bookmark entry you can press the ‘d’ key when the arrow is pointed to the item.

Saving and Downloading

If you want a permanent copy of an item in Gopherspace, not just a reference, which a bookmark is, you should press the ‘s’ key. This will save the current item into a filename on your system.

Saving and Downloading

If you are connected to a Unix machine through a modem using terminal emulation software you can press the 'D' key to download the item using either of several file-transfer protocols such as Zmodem, Ymodem, Xmodem, and Kermit.

Installing the Unix Gopher Distribution

This chapter describes how to compile and install the Internet Gopher for Unix Distribution. The two main parts of this distribution are the Gopher Server, *gopherd* and the Gopher client, *gopher*.

Overview

Internet Gopher for Unix is distributed as C source code. You will need to compile this source code into binary executables for your system.

To use the gopher client or server you will need to compile the code using a C compiler. To make it generally available to the rest of the users on the system, you should install the software into a central directory.

Requirements

You should have a copy of a compressed tar file containing the source. You should consult “*Getting the Software*” on page 15 if you don’t have this file.

You will need a Unix machine with a C compiler and development environment to compile the software. The source code requires about one megabyte of disk space when uncompressed. The source takes up about two megabytes of disk space when compiled.

Your UNIX machine will need to be connected to a TCP-IP network for the software to function properly.

Some experience with Unix software installation is recommended. A knowledge of C programming and Makefiles will be useful.

If you want to index files with your server you will need to get some additional software. There are two file indexing kits supported by the Internet Gopher server, NeXT indices and WAIS indices.

NeXT indexing comes bundled with the NeXTstep operating system. It is the basis for many NeXT applications, including the Webster dictionary and the Digital Bookshelf.

WAIS indexing is a freely available indexing kit for many Unix machines. It includes an index generator called *waisindex*, a database server called *waisserver*, and client programs for Xwindow, full-screen and command line searching. WAIS is an acronym for Wide Area Information Server.

If you are compiling a server on a NeXT machine you will want to consult “*NeXT Indexing*” on page 71 before continuing. Follow the instructions in “*WAIS Indexing*” on page 72 if you want to use WAIS indexing with your server. You may skip these sections if you don’t want indexing or don’t want to bother with it just yet.

Compatibility

The Gopher source should compile on most UNIX systems. Here are a few that we know it has worked on:

- Suns running SunOS 4.1.x
- RS/6000s running AIX 3.2
- NeXTs running NeXTstep
- SCO ODT systems

- Apples running A/UX
- DECstations running Ultrix
- Silicon Graphics Iris' running Irix

Don't worry if your system isn't listed above, the code has been written with compatibility in mind. Most systems should work just fine.

NeXT Indexing

For NeXT indexing you will need the file `NeXTtext.tar.Z`. Use anonymous ftp to `boombox.micro.umn.edu` and get the file

```
/pub/gopher/Unix/NeXTtext.tar.Z
```

The files `libbtree.a` and `libtext.a` are in this compressed tar file, along with the directories `btree` and `text`.

The files `libbtree.a` and `libtext.a` need to be installed in the directory

```
/usr/local/lib
```

The `btree` and `text` directories need to be installed in the directory

```
/usr/local/include.
```

Type the following commands as root to install the NeXT indexing libraries.

1. **`uncompress NeXTtext.tar.Z`**
2. **`tar xvf NeXTtext.tar.Z`**
3. **`mv libtext.a libbtree.a /usr/local/lib`**
4. **`ranlib /usr/local/lib/libbtree.a /usr/local/lib/libtext.a`**
5. **`cp -r text btree /usr/local/include`**

WAIS Indexing

For WAIS indexing you will need to get the freely available WAIS software. There are three different versions of WAIS software: the software from Thinking Machines Inc., the modified software from Don Gilbert at the University of Indiana and the freeWAIS software from the Coalition for Networked Information Discovery and Retrieval (CNIDR).

The Don Gilbert and freeWAIS versions supports boolean searches and phrase matching. The Thinking Machines WAIS software does not support these features.

To retrieve the Thinking Machines Inc. version of WAIS, use anonymous ftp to the host `ftp.think.com` and retrieve the file `/wais/wais-8-b5.1.tar.Z`

To retrieve Don Gilbert's version of WAIS use anonymous ftp to the host `ftp.bio.indiana.edu` and retrieve the file `/util/iubio-wais-8b5.tar.Z`

To retrieve the freeWAIS version of WAIS use anonymous ftp to the host `ftp.cnidr.org` and retrieve the file `/pub/NIDR.tools/freeWAIS-0.202.tar.Z`

The source code to the WAIS system is in this compressed tar file. You should extract the archive and compile the software. The installation instructions are in the file `INSTALLATION` inside the `wais doc` directory.

Note that you do not need to make the Xwindow or emacs client. Many systems will not compile these cleanly.

When you are finished you will have a `bin` directory that contains the programs: `waisindex`, `waisserver`, and `waissearch`. These binaries allow you to create, serve and search indices respectively.

The `bin` directory contains the libraries necessary for compiling the gopher server. These are `inv.a`, `libftw.a`, `client.a`, and `wais.a`. The `ui` directory contains one module necessary for the WAIS gateway, `source.o`.

Go to your Gopher source code directory and type the following commands to let the Gopher code know you want to use WAIS. Substitute the WAIS source code directory for *waisdir* in the following commands.

```
ln -s /waisdir/ir .
```

```
ln -s /waisdir/bin .
ln -s /waisdir/ui .
```

Preparing to Compile the Distribution

There are some options you will want to check before compiling the Gopher server, some of these options are for compatibility with various platforms, others are for special features.

Two files control the compilation process: `Makefile.config` and `conf.h`. You will find both of them in the top level of the Gopher source directory. Most sites will not need to make major changes to these files, in fact you might just want to try typing “make” and see if it works for you.

There are comments in these files that you will want to read before you compile. The following tables document some of the more popular ones.

TABLE 7. Configuration Parameters in Makefile.config

Parameter	Default	What it is
CC	cc	Your favorite C compiler
OPT	-O	Use -O for faster code, -g for debugging
RANLIB	ranlib	Use touch if you don't have the ranlib command.
PREFIX	/usr/local	The base directory where the software will be installed. Many other parameters use this value.
CLIENTDIR	\$(PREFIX)/bin	Where the client “gopher” is installed.
CLIENTLIB	\$(PREFIX)/lib	Where the help files for the client are installed.
SERVERDIR	\$(PREFIX)/etc	Where the server files are installed.
SERVEROPTS		Optional server features. See below.
DOMAIN	.micro.umn.edu	Set this to the portion of your hostname that the “hostname” command doesn't return.

TABLE 7. Configuration Parameters in Makefile.config

Parameter	Default	What it is
SERVERDATA	/home/gopher	The default location of gopher data for the gopher server.
SERVERPORT	70	The default port for the Gopher server.

TABLE 8. Configuration Parameters in conf.h

Parameter	Default	What it does
CLIENT1_HOST	gopher.tc.umn.edu	The default host to connect to.
CLIENT2_HOST	gopher2.tc.umn.edu	The alternate host to connect to.
CLIENT1_PORT	70	The default port for the first host.
CLIENT2_PORT	70	The default port for the alternate host.
PAGER_COMMAND	more -d %s	Command used to display text.
PLAY_COMMAND		Command used to play sounds.
MAIL_COMMAND	mail	Command used to mail files.
TELNET_COMMAND	telnet	Command used to connect to other hosts using telnet protocol.
TN3270_COMMAND	tn3270	Command used to connect to IBM mainframe hosts.
IMAGE_COMMAND	xloadimage -fork %s	Command used to view image files.

Other Optional Features

Many people have submitted nifty options for the server, follow the instructions in the appropriate section if you wish to implement these features.

Load Restriction

Add `-DLOADRESTRICT` to the `SERVEROPTS` variable in `Makefile.config` if you want to restrict access to the Gopher server at a certain load average. You will also need to add `-lkvm` to `SERVERLIBS` in `Makefile.config`.

This has only been tested underneath SunOS 4.1.1

Biological Databases

Add `-DBIO` to `SERVEROPTS` if you're using the biology portion of Don Gilbert's modified `wais8b5` that supports boolean and phrase searching. PLEASE NOTE: the `-DBIO` option is NOT needed nor recommended for use of the boolean and phrase searching portion of this modified `wais`, just the symbol searching. But, you must compile `wais` and `gopher` with the same option setting (`-DBIO` or `NOT`). Otherwise your server will core dump when doing searches.

DL Database Support

Add `-DDL` and define `DLPATH` and `DLOBS` if you want to include support for Tim Cook's 'dl' databases. You will also have to have a working copy of the program with source code in the `DLPATH` directory. The files `getdesc.o` and `enddesc.o` must be there.

Source for dl can be gotten from:

`admin.viccol.edu.au`

as

`/pub/dl/describe-1.8.tar.Z` or higher...

Special Modifications for Compatibility

The Gopher distribution tries to automatically make up for operating system dependencies, however sometimes you have to tweak things for certain operating systems. Follow the appropriate steps if your system is listed below:

UMAX Systems

Uncomment the line that contains UMAXLIBS in Makefile.config

Dynix PTX Systems

Uncomment the line that contains PTXLIBS in Makefile.config.

Dynix systems in the BSD universe

Uncomment the line that contains SEQLIBS in Makefile.config.

SCO Open Desktop Systems

Uncomment out the line that contains SCOLIBS in Makefile.config.

System VR4 Systems

Uncomment out the line that contains SVR4LIBS in Makefile.config.

DEC Ultrix Systems

Change the line that contains -lcurses to have -lcursesX instead.

Other Systems

There is a line in the file Makefile.config for compatibility definitions. Look for the line with COMPAT= at the beginning. If you have problems linking due to unresolved symbols you'll want to edit this line. Consult the following table for the appropriate definitions you should add if you have problems.

TABLE 9. Compatibility Definitions

Unknown symbol	What you should add to COMPAT=
strstr	-DNOSTRSTR
tempnam	-DNO_TEMPNAM
strdup	-DNO_STRDUP
bzero or bcopy	-DNO_BZERO
getwd	-DNO_GETWD

TABLE 9. Compatibility Definitions

Unknown symbol	What you should add to COMPAT=
tzset	-DNO_TZSET
strcasecmp	-DNO_STRCASECMP

You should then type **make clean** and restart the compilation process.

Compiling and Installing the Distribution

You should now be ready to compile the distribution.

If you want to make just the client type

make client

If you want to make just the server type

make server

If you want to make everything just type

make

If you want to install everything in the directories specified in Makefile.config type:

make install

If you want to install just the client type:

(cd gopher; make install)

If you want to install just the server type:

(cd gopherd; make install)

Testing

To test the software go to the `test` directory and type **make**. You can compare the results of your run with the files in the `good-results` directory.

Configuring the Unix Server

This chapter will show you how to configure and run the UNIX gopherd server.

Overview

The UNIX Gopher server allows you to publish documents using the Gopher+ protocol. It has many features.

Requirements

You should have a working copy of *gopherd* installed. If you don't refer to "*Installing the Unix Gopher Distribution*" on page 69 for more information about compiling and installing the software. You will need a Unix machine with a TCP-IP network connection to use the Unix Gopher Server. You will also most-likely need to have a connection to a machine that is running a Domain Name Server (DNS).

What is gopherd?

The gopherd server is a program that accepts requests from gopher clients and “serves” the information to them. It uses a number of methods to supply this information. Most of this information comes from a portion of a file system called the *gopher-data* directory.

Gopherd can also “gateway” to other network services such as ftp and WAIS. The gopher clients do not need to understand these protocols, the gopher server does the necessary translations

First Steps

The first thing you will want to do is create your “gopher-data” directory. This directory will contain all of the information that gopher clients will see. In all the examples below the term *gopher-data* will refer to this directory. Whenever you see this reference fill in your local gopher data directory.

So, let’s create this directory. Make sure there’s sufficient space on the filesystem and use the `mkdir` command to create the directory. You will probably have to do this as root. Here is an example of creating the gopher-data directory:

```
mudhoney# mkdir /home/mudhoney/gopher-data
```

Now we can add data for the clients to this directory.

Adding Information to the Server

The gopher server gets its information from the files and directories in *gopher-data*. By making changes in this directory tree, you will change what the gopher clients see. The following list summarizes the default translations that

Default Translations¹

- Directories inside of *gopher-data* are served as Gopher Directories.
- Text files are represented as Gopher Text/plain items.
- µlaw sound files (as used by Sun and NeXT workstations) are represented as Gopher audio/basic files.
- GIF files are represented as Gopher image/gif (I) files.
- All files/directories that start with a dot (i.e. *.foo*) or are named *etc*, *usr*, *bin*, *dev*, or *core* are ignored by the server.
- The title of each object presented to the client is the filename of the file/directory.
- Files compressed with “compress” and files compressed with GNU zip (gzip) files are supported. They will be sent to the client uncompressed. The filename will not contain the *.Z* or *.gz* extension.
- Mail spool files are represented as directories. When the mail-spool file is viewed, each mail message is represented as a Gopher Text item. The title of the item is gotten from the Subject: line of the mail message.
- Executable shell scripts are represented as a Gopher Text item. The output of the script is sent when the client requests to view the item. The shell script must start with the magic three characters *#!/*
- Files that end with *.src* are assumed to be WAIS database files generated by the *waisindex* program. The server will make these into searchable WAIS gateway items.
- The server sorts directories it sends out alphabetically. The server does distinguish between upper and lower case when sorting.

Links to Other Servers

You can add data to your server by creating what are known as *Links* in the *gopher-data* directory tree. Links allow you to connect Gopher servers together.

The ability to make links to other hosts is how Gopher distributes itself among multiple hosts. To make a link create a file starting with a period that contains the data needed by the server. By default all files in the *gopher data* directory starting with a period are taken to be link files. A link file can contain multiple links, just separate

1. The defaults mentioned in this section apply to the default *gopherd.conf* file that comes with the gopher server. If you change this file then the default behavior will be different.

the different links with a blank line or a comment. To define a link you need to put five lines in a link file that define the needed characteristics for the document. Here is an example of a link.

```
Numb=1
Name=National Weather Service Forecasts
Type=1
Port=70
Path=1/Weather
Host=ashpool.micro.umn.edu
```

The `Name=` line is what the user will see when cruising through GopherSpace. In this case the name is “National Weather Service Forecasts”.

The `“Type=”` defines what kind of document this object is. The following is a list of the more common types.

```
0 -- Text File
1 -- Directory
2 -- CSO name server
4 -- Mac HQX file.
7 -- Full Text Index
8 -- Telnet Session
9 -- Binary File
s -- Sound
I -- Image
```

The `“Path=”` line contains the selector string that the client will use to retrieve the actual document. The `“Numb=”` line specifies that this entry should be presented first in the directory list (instead of being alphabetized). The `“Numb=”` line is optional.

The `“Port=”` and `“Host=”` lines specify a fully qualified domain name (such as `mud-honey.micro.umn.edu`) and a port respectively. You may substitute a plus `+` for these two parameters if you wish. The server will insert the current hostname and the current port when it sees a plus in either of these two fields.

An easy way to retrieve links is to use the Curses Gopher Client. By pressing `’=’` You can get information suitable for inclusion in a Link file.

A Simple Example of Adding Information

Okay, let's add some information to the gopher server. The following commands will add the Gopher directories "News", "Fun and Games" and "Recipes" to our server.

```
mudhoney# cd gopher-data
mudhoney# mkdir News
mudhoney# mkdir "Fun and Games"
mudhoney# mkdir "Recipes"
```

Now that the directory structure is created we can add some text files. Let's say that we have a file called "about" that describes the server and two recipes for clam chowder in two files called "chowder1" and "chowder2." Also assume that these files are in the directory /tmp. These steps will put the files in their proper place.

```
mudhoney# cd gopher-data
mudhoney# cp /tmp/about "About This Server"
mudhoney# cp /tmp/chowder1 "Recipes/Yummy Clam Chowder"
mudhoney# cp /tmp/chowder2 "Recipes/Icky Clam Chowder"
```

Let's now add a link to another server. The weather forecasts link in the previous section is a real, live link. Put the link information into a file in the *gopher-data* directory. Your server will now have the following entries in the top-level:

```
National Weather Service Forecasts
About This Server
Fun and Games
News
Recipes
```

Additionally you will have the following files in the Recipes directory

```
Yummy Clam Chowder
Icky Clam Chowder
```

Customizing Your Server

The gopher server allows you to customize the various aspects of the server. You can set the default administrator, how long to cache items, and what filename extensions become which gopher type.

There are two types of files that control these interactions. Files that begin with a dot in the *gopher-data* directory and *gopherd.conf* files.

Ignoring Certain Files

You can specify that a class of files are to be ignored by modifying the *gopherd.conf* file. Say you wanted to ignore all files named moo on your server. To have the server ignore them (and never show them to the client) add the following line to the *gopherd.conf* file.

```
ignore: moo
```

If the files you want ignored can be specified by a regular expression you can use the `ignore_patt:` keyword in your *gopherd.conf* file. Say you want to ignore all files starting with A and ending with foo. To ignore these files put the following line in your *gopherd.conf* file:

```
ignore_patt: A.*foo
```

You'll need a knowledge of regular expressions to get this to work properly. Consult the manual page for `ed` for more information about regular expressions.

Setting the Hostname

The Gopher server tries to find the default hostname. Some systems use a hostname alias (also called a CNAME) to ease moving the server between different machines. By modifying the *gopherd.conf* file you can change the hostname that the client sees:

```
hostalias: gopher.umn.edu
```

Starting the Gopher Server

Now that we have some data to serve to clients we can start the gopher server.

There are two separate ways to start the *gopherd* program. The first method starts the gopher server at boot time, the other starts the server as it is needed via the *inetd* superserver.

Continuous Servers

Continuous servers are started at boot time. You will need to add an entry to the boot sequence of your unix machine to insure that the server is available at all times. Typically this entry will be put into the file `/etc/rc.local` (for BSDish systems) or `/etc/inittab` (for System V systems).

Here is a typical entry in the `rc.local` file:

```
if [ -f /home/mudhoney/gopher-data ]; then
    /usr/local/etc/gopherd -u nobody \
    -l /home/mudhoney/GopherLog70 \
    gopher-data 70
fi
```

The parameters to the `gopherd` program are described later in the chapter.

Here is a typical entry in the `inittab` file:

```
loc0:2:once:/etc/start-gopher-server
```

Put what would normally go into the `rc.local` file into the file `/etc/start-gopher-server`.

Reboot the system and the gopher server will run.

As Needed Servers

If your system supports the `inetd` program then you can run the server using it instead of continuously. The main advantage is that the gopher server is only started when a connection is made by a gopher client, instead of running all the time.

To use gopher in this manner you must modify two files: `/etc/services` and `/etc/inetd.conf`

Add the following line to the `/etc/services` file:

```
gopher 70/tcp
```

If you are running on a machine that runs NIS/YP you will need to remake your database. Other systems may require you to do something similar, consult the “services” manual page on your system.

Next, you will add an entry to the `/etc/inetd.conf` file similar to the one below.

```
gopher stream tcp nowait nobody /usr/local/etc/gopherd gopherd
```

Add any options to the end of the line if you want. However be aware that some systems only support a limited number of arguments. (Suns running 4.1.x only support five for instance.)

To start the gopher server you should either reboot, or send a HUP signal to the process id of the inetd process. If the process number was 12356 then you would do the following:

```
kill -HUP 12356
```

Testing

Once you have the server running you can test it by using the telnet program to connect to the gopher port. Here is an example of testing the server:

```
mudhoney% telnet mudhoney 70
Trying 134.84.132.7 ...
Connected to mudhoney.micro.umn.edu.
Escape character is '^]'.
{Press RETURN}
.... Gopher output here....
```

If you don't see an error message you're ready to use your gopher server.

Optional Features for the Gopher Server

In addition to the simple functionality provided above, the gopher server does many other things, such as logging, security, etc. You can control these features of the server two ways: by editing the file `gopherd.conf` or by using command line options.

The *gopherd.conf* File

Most of the optional parameters for the gopher server can be set by editing the file *gopherd.conf*. The `gopherd.conf` file contains a list of directives that alter the behavior of the gopher server. It is composed of lines of the form:

```
Parameter: Value
```

Parameters are case insensitive. A pound sign (#) at the beginning of a line denotes a comment.

TABLE 10. gopherd.conf parameters

Parameter	Example	Description
hostalias:	gopher.turnip.com	The hostname that is returned by the server. This is useful when the gopher server has an associated CNAME alias in the DNS system.
Admin:	Greg Brady	The name of the administrator of the server. It may contain a name, phone number etc.
AdminEmail	bob@turnip.com	An email address where the administrator can be reached.
Site:	Turnip Labs	The name of the site running the server
Loc:	New York, NY, USA	The physical location of the site. Put the City, State/province and country in here.
Geog:	44 58 48 N 93 15 49 W	The latitude and longitude of the server.
Language:	En_US	The ANSI language of the site, as used by setlocale(). See below.
viewext:	.gif I 9/ image/gif	Maps a filename extension onto a particular gopher type. See below for more information about viewext.
ignore:	core	Specifies a filename extension to ignore completely. Files matching the ignore criteria are never presented to the gopher client. However, ignoring files doesn't protect them from prying eyes.
Blockext:	.abstract ABSTRACT	Specifies that a file with a particular extension is to be mapped to a specific gopher+ attribute block.

TABLE 10. gopherd.conf parameters

Parameter	Example	Description
Bummermsg:	Hasta la vista baby	Specifies a message that will be presented to a client when access is denied.
Access:	.edu browse,!read	Allows you to set who can browse directories, read files, and search your server. See the section on limiting access later in this chapter for more information about this.

Command Line Options

Some options cannot be set using the gopherd.conf file. These options can be set by adding parameters to the command line of the gopherd program. Here is a quick guide to the various options:

```
gopherd [-DCIc] [-o options] [-L load] [-l logfile] [-u
user] gopher-data gopher-port
```

The following table summarizes the various command line options.

TABLE 11. Command Line Options for gopherd

Option	Description
-D	Enable copious debugging output
-L <i>load</i>	Restrict connections when the load average is above <i>load</i> . Your server must be compiled with the LOADRESTRICT option for this to work.
-C	Disables caching of directory retrievals. Otherwise a directory retrieval is cached in the file .cache.
-l <i>logfile</i>	For each connection the server will log the time, host and transaction to the file <i>logfile</i> .
-I	Specify when running the server from inetd.
-o options	Specify an alternative “gopherd.conf” file instead of the default.
-c	Do not use the system call chroot(2) before processing connections. This relies on code that (tries to) ensures that files outside the <i>gopher-data</i> directory cannot be retrieved. Use with care and with the -u option.

TABLE 11. Command Line Options for gopherd

Option	Description
-u user	Run as the user named user. The server is run with reduced permissions (i.e. other than root) which can ensure that only publically readable file are available from the server.
gopher-data	The directory where the Gopher information resides
gopher-port	The port number (usually 70) that the server runs at.

Macintosh Gopher Server

This chapter details setting up a server on a Macintosh Computer to publish information using the Gopher+ protocol. This chapter describes version 1.0.b4 or the Gopher Surfer Software.

Overview

The Gopher Surfer application lets your Macintosh function as a Gopher server. This implementation of the server is a full implementation of the Gopher+ Protocol.

Requirements

You will need the *Gopher Surfer* Software, available via anonymous ftp from boombox.micro.umn.edu.

To run this software you need to have MacTCP installed on your Macintosh. You will have to configure MacTCP so that your Mac has a static IP address; you will also need to register a name for your Macintosh with your local domain name system.

You will also need to install the Thread Manager in your System Folder. it ends up in the Extensions folder. Then, restart your machine. *GOPHER SURFER WILL NOT WORK UNLESS THE THREAD MANAGER IS INSTALLED AND LOADED.*

Note that the server requires System 7.

Setting up the Server

Follow these steps to set up a Gopher+ Server using Gopher Surfer:

- Double-click on the icon for the Gopher Surfer application. A window will be displayed.
- Type over the stuff that is in the text field boxes with information that is pertinent to your Gopher+ Server. Characters may extend beyond the end of the box that delineates the text field. Select the options that you wish to have for your server (options explained below).
- Click on the Publish Directory button and select the folder that contains the files for your Gopher+ Server. Click on the button directly below the file/folder list that says "Select folder-name." Note: if the entire name of the folder is too long to display on the button, the first and last part of the name will be displayed.
- Organize and modify files that will appear on your server. (See the next section, SETTING UP INFORMATION.)
- Click in the box next to "Run Gopher Server."
- Save your changes and name your Gopher+ Server. Your Macintosh is now a Gopher server!

Basic Configuration

The Gopher Surfer window has the following controls:

- Hostname: The domain name of the computer you are using for your server, which you should have already registered with your network administrator. The name must be a full domain name, such as boombox.micro.umn.edu
- Host Port: The port that is specified for the Gopher process. The default is port 70.

FIGURE 1. Gopher Surfer Control Window

- **Publish Directory Button:** Click on this button to designate the folder that will contain the files and folders to be published on your Gopher+ Server.
- **Run Gopher Server:** Click in this box to start up your Gopher+ Server. If this box is not checked, the Gopher+ Server will not run.
- **Save Log Button:** Click on this button to set up a file that will list all of the traffic on your Gopher+ Server.
- **Log by host name:** When this box is checked, the connecting client computer is identified by its name. Otherwise, clients are identified by their IP addresses.
NOTE: It is much faster NOT to identify by name.
- **Language:** The default language of text items that are available on your server. This is a pop-up menu. If the language you wish is not in the list, please send an e-mail to gopher@boombox.micro.umn.edu and the development team will see what it can do.
- **ISO Latin-1 characters:** When this box is checked, the special characters on the Mac that are used to indicate accents are translated into ISO Latin-1. Otherwise, these special characters might appear as garbage when viewed by someone with a Gopher Client that runs on another kind of computer. NOTE: If you are using an Asian character set in your text files, do not check this option.

- Administrator: The person or group who is responsible for the server. You may also include the department or institution that is maintaining the server and a telephone number.
- Organization: The organization that is maintaining the server.
- Site: The street address of the organization.
- Location: The city, state or providence, zip or postal code, and country where the server is located.
- Latitude/Longitude (optional): This information will be used in a future Gopher+ Server feature, which will display where the server is located on a map of the world.

In the same window is a scrolling field which shows connections as they happen. Each connection is numbered consecutively.

Ok, lets start with the basic file types supported and recognized automatically.

- Images (Which are of type 'g' or type 'I'.) GIFf JPEG JFIF PICT
- Sounds (Which are of type 's') ULAW
- Video (Which are of type ';') MooV - Quicktime movies. MPEG - MPEG movies.

Keep in mind however that if a file has a resource fork then it will be advertised as a Binhex type. A good example are some of the video samples. If they are of the special platform independent quicktime format they show as movies, with the film icon in TurboGopher. If they have a resource fork making them Macintosh only files, they will appear as BinHex items and that is how the server will send them. MPEG videos have no resource fork and show as film icons always.

As the server looks in a directory preparing to send the listing to a client this is what it does.

Standard Files

6. It checks the base type of a file and determines how it should be advertised to a gopher client.
7. It then checks to see if there exists an alias file. One which has the same name with an '4' (option-8 character) appended. If so it checks there to read in possibly a different host, port, gopher type or possibly a location to save the results of an ASK response.

8. The proper information line is then constructed and sent out.

Server Assumption #1

If the file type is 'TEXT' or 'GIF' or 'JPEG' or 'JFIF' or 'PICT' or 'ULAW' then server advertises it as the corresponding gopher type

else if it is 'MPEG' in the special platform independent format it is a gopher movie type

else if it is 'MooV' in the special platform independent format it is a gopher movie type

else if it is 'MooV' but has a resource fork then we have to advertise it as a binhex type.

else we have to advertise it as a binhex type.

Forms/ASK Documents

In the case of the ASK document the gopher type read in from the alias signals to the server to advertise it differently. By adding a '?' as the plus flag. Thus when the client requests an ASK item it treats the file differently. It starts by sending some header information.

Then it reads the text from the 'TEXT' file that goes with the alias file and sends it to the client.

For instance a sample ASK file might contain the following:

Note: This is testing the mac Gopher+ server.

Note:

Ask: Your Name

Choose: IQ:GeniusAverageSub-human

Note: Please write your life story AskL:

On the client side this appears as an electronic form with one line of instructions. One blank line for them enter their name. A group of radio buttons for them to

choose how they rate their Intelligence Quotient and a box for them to write up to 32,000 characters describing their life achievements.

Standard Directories

Folders are advertised as a directory with possibly an alias to allow a longer than 32 character macintosh filename.

Alternate View Directories

Server Assumption #2

All directory names that end with 'W' (option-shift-v) denote a directory that is for alternate views and requires special handling.

Server Assumption #3

If the directory name is 'GlassW' then in the 'GlassW' directory is a file named 'Glass' that is the default view and is one of the above described base gopher views. This default view is what the server advertises for this folder. The client doesn't know or care that there is a folder containing multiple views of a single item.

Server Assumption #4

All files/views besides 'Glass' have as their name their MIME/Gopher+ type. So in the 'GlassW' folder we have the file named 'Glass' which is a file of type 'GIFf' which is advertised as a gopher type 'g' for gif files. Alternate view files might be named as:

Image/JPEG

Image/PICT

What if the views were all for textual information? Then for an alternate view folder called 'Mac Computers 22 July 93W' we might have a base view called 'Mac Computers 22 July 93' which is a simple 'TEXT' file. The alternate views might be files called:

application/MSWord -- An actual MSWord file

application/rtf -- An MSWord rtf file

Server Assumption #5

If an alternate view file has any one of the following 5 character strings at the end of their name it is used to override the default language specified in the server setup document.

If I wished to specify a language for these or text based files I would add 'Jp_JP' to specify that it is a file in Japanese Language. The default language I specify overall for the server applies to all files unless the last 5 characters of their name is one of the following:

"Da_DK" "Danish/Denmark"

"Nl_BE" "Dutch/Belgium"

"Nl_NL" "Dutch/Netherlands"

"En_GB" "English/United Kingdom"

"En_US" "English/United States"

"Fi_FI" "Finnish/Finland"

"Fr_BE" "French/Belgium"

"Fr_CA" "French/Canada"

"Fr_CH" "French/Switzerland"

"Fr_FR" "French/France"

"De_CH" "German/Switzerland"

"De_DE" "German/Germany"

"El_GR" "Greek/Greece"

"Is_IS" "Icelandic/Iceland"

"It_IT" "Italian/Italy"

"Jp_JP" "Japanese/Japan"

"No_NO" "Norwegian/Norway"

"Pt_PT" "Portuguese/Portugal"

"Es_ES" "Spanish/Spain"

"Sv_SE" "Swedish/Sweden"

"Tr_TR" "Turkish/Turkey"

Go4gw - The Gopher Gateway

Go4gw is a program that provides gateways to many popular internet services, such as USENET news, whois, and archie. The following chapter describes go4gw and how to install and manage it.

Overview

There is quite a bit of information that could be in gopher, but isn't. The use of a Gopher Gateway makes it possible to include this information inside of Gopher-space.

Go4gw is designed to channel these other forms of information into a format suitable for gopher. It is written in perl and allows easy extensibility, a number of pre-written gateways and easy administration.

Gateways to the following services are provided with go4gw1.01

- Archie - a database of files available for anonymous ftp.
- Finger - a service that provides information about people logged in to UNIX or VMS hosts.
- Geo - the geographic name server at the University of Michigan.

- NNTP - the USENET news transport protocol.
- Webster - the Webster dictionary service available on some NeXT machines.
- Whois - services that provide information about users and organizations.

Requirements

You will need a UNIX machine on a network with a working version of perl. The source code for Perl can be gotten from various FTP sites on the Internet. The canonical location of perl is the anonymous ftp site `prep.ai.mit.edu`, as

```
perl-4.036.tar.z
```

You will, of course, need the go4gw software distribution. See “*Getting the Internet Gopher Software*” on page 15 if you don’t have the go4gw software.

Installation

Copy all of the perl scripts that comprise go4gw into a common directory, in our examples we’ll use `/usr/local/etc/go4gw` as our directory.

You need to put the following line in `/etc/services`:

```
go4gw 4320/tcp
```

And the following line in `/etc/inetd.conf` (depending on your system type):

```
go4gw stream tcp nowait /usr/local/etc/go4gw go4gw
```

The go4gw script has a few variables you might want to change:

```
$Gconf_file = "/usr/local/etc/go4gw.conf";  
$Gport=4320;  
$Ghost="Slapshot.Stanford.EDU";
```

You need to set `Gport` to the same port as in `/etc/services`, and `Ghost` to your fully qualified host name.

Why aren't these two auto-magically figured out? Mainly for speed, but also because some 'hostname' commands don't have the domain, some do, etc. Its easier just to define them here. Since all the other gateways are run in the context of this perl script, the gateways don't need any of this stuff in them.

Gconf_file should be set to the location of your go4gw.conf file. The format of this file is:

```
#
# format
# gateway : user : module : gopher title :
whois:-2:/usr/local/etc/g2whois:Whois:
nntp:-2:/usr/local/etc/g2nntp:USENET News:
webster:-2:/usr/local/etc/g2webster:Webster:
```

Where gateway is the name of the gateway, user is either a numeric uid or name, module is the name of the perl script that go4gw will dynamically load, and title is the title that will show up in the gopher menu if go4gw is sent the empty string "". If the gateway doesn't take an empty string, the title should be "" and it won't show up in the menu. By writing all your gateways so they take a "" command, you can point a link at the go4gw daemon with path set to "" and get a menu of all your gateways. The menu order will be the same order as the go4gw.conf file.

Writing New go4gw Gateways

go4gw gateways need to follow a few simple conventions:

You need to have a routine called "\${gateway}_main", where gateway is the name of your gateway. For example, if your gateway is called whois, then you need:

```
whois_main {
    local($_) = @_;
    ...
}
```

In your module, for example /usr/local/etc/g2whois.

Your `*_main` will be passed the string sent to go4gw WITHOUT your gateway prefix. For example, if someone sends the following string to go4gw:

```
nntp ls su.jobs
```

Then go4gw will call `&nntp_main("ls su.jobs")`, after loading `g2nntp`.

You should define any variables that users might have to change at the front of your script, and prefix them with your gateway name.

When your gateway has to return selector string, hostname, and port, it should use the following variables:

`$Ggw` -> name of this gateway
`$Gport` -> port this gateway is running on
`$Gghost` -> host this gateway is running on

For example, `nntp` might do the following:

```
&Greply("0$Subject\t$Ggw article $group $article\t$Gghost\t$Gport");
```

So when the user selects this the client will send:

```
nntp article su.jobs 104
```

Back to the go4gw daemon, which will figure out that "article su.jobs 104" needs to get passed to `g2nntp`.

The following variables and routines are defined in go4gw, and can be used by gateways:

TABLE 12. Go4gw variables and routines

Variable/Routine	Function
<code>\$GnotServer</code>	You can define this in perl scripts that want to include the go4gw script without running the server. See the <code>g2nntp_groups</code> script.
<code>\$Ggw</code>	Can be used by gateway routines to determine their gateway name.
<code>\$Gport</code>	Can be used by gateway routines to determine which port go4gw is running on.

TABLE 12. Go4gw variables and routines

Variable/Routine	Function
\$Ghost	Can be used by gateway routines to determine which host go4gw is running on.
GSERVER	File handle which is opened when GopenServer is called.
&Grepy(reply)	Sends string back to gopher client with <code>\r\n</code> on the end.
&Gabort(message)	Sends error message back to gopher client with <code>"3mess\r\n.\r\n"</code> on end.
&GopenServer(server,port)	Opens TCP port on server or calls &Gabort().
&GcloseServer	Closes server opened by &GopenServer()
\$Gdebug	Controls debug messages in &Gsend() and &Grecv()
\$Gport	Can be used by gateway routines to determine which port go4gw is running on.
&Gsend(cmd)	Sends <code>"cmd\r\n"</code> to GSERVER.
\$_ = &Grecv;	Gets a response from GSERVER and strips <code>\r</code> and <code>\n</code>
&Gsorry	Sends a message about data that cannot be delivered due to restrictions.

Other “standard” routines and variables may be added. They will start with a ‘G’.

This chapter contains some of the more common questions that we've had the pleasure to answer, and answer, and answer.

Overview

The most recent version of these "Common Questions can be gotten through gopher, or through anonymous ftp to the host:

```
rtfm.mit.edu
```

as

```
/pub/usenet/news.answers/gopher-faq
```

Those without FTP access should send e-mail to mail-server@rtfm.mit.edu with "send usenet/news.answers/finding-sources" in the body to find out how to do FTP by e-mail.

.

Where are there publicly available logins for Gopher?

Here is a short list, use the site closest to you to minimize network lag.

TABLE 13. Public Gopher Sites

Hostname	IP#	login as	area
consultant.micro.umn.edu	134.84.132.4	gopher	North America
panda.uiowa.edu	128.255.40.201	panda	North America
gopher.sunet.se	192.36.125.2	gopher	Europe
info.anu.edu.au	150.203.84.20	info	Australia
gopher.chalmers.se	129.16.221.40	gopher	Sweden
tolten.puc.cl	146.155.1.16	gopher	South America
ecnet.ec	157.100.45.2	gopher	Ecuador
gopher.msu.edu	35.8.2.61	gopher	North America
gan.ncc.go.jp	160.190.10.1	gopher	Japan

We recommend running your own local gopher client though. The response time will be much faster, and you'll be able to save and print files.

How can I get my server published in the “Other Gophers” list?

When you have your server ready you can publish it to the world by sending e-mail to the maintainers of the “Other Gophers” list:

If your gopher server is in Europe, send mail to: gopher@ebone.net

Otherwise send mail to:

gopher@boombox.micro.umn.edu

How can I set up a “CSO” phone book server? Where is the software?

CSO phone book servers are also known as “qi” servers. The software implementation can be gotten via anonymous ftp from

```
uxc.cso.uiuc.edu (128.174.5.50)
```

as

```
/pub/qi.tar.Z
```

You may also see this referred to as “ph”, which is what most of the clients are called. A collected set of clients for Macs, PCs, VMS, VM, etc, are in the

```
/pub/ph.tar.Z
```

 file.

There is also an archive of the mailing list for qi/ph software on the same machine. It’s in /pub/info-ph.archive. You may join the list by sending email to info-ph-request@uxc.cso.uiuc.edu.

This software is supported by Paul Pomes <p-pomes@uiuc.edu> Contact him for more information.

Why can’t I access the University of Minnesota’s UPI news?

The University of Minnesota has a site license for UPI news, we are not allowed to distribute it off of our campus. We get our UPI news from Clarinet. For more information about getting UPI news send mail to info@clarinet.com. For information about setting up your own gopher-UPI server search the gopher-news archive for UPI.

When I do full-text searches I always get every document back, Why?

This is a problem occasionally encountered with Unix full-text indexes. It is caused by setting up the link incorrectly to a gindexd port.

The Path= field should be *blank* when pointing to a gindexd index.

Otherwise the client will send the path to the gindexd daemon, which interprets everything as a keyword. This path is likely to contain a pathname that is common to all of the indexed files. Thus a search generates hits on everything.

**When I try to build the UNIX software I get an error from make:
“Must be a separator on rules line #. Stop” Why?**

This is a problem with older makes that don't understand the “include” keyword. One easy way to cope with this problem is compiling GNU make, which does understand the include keyword.

If this is too difficult, remove the line:

```
include Makefile.config
```

from all the Makefiles and paste in a copy of Makefile.config at the top of each Makefile.

Or, instead of pasting you can make the client/server by going into the appropriate directory and typing:

```
make -f ../Makefile.config -f Makefile
```

Are papers or articles describing Gopher available?

Gopher has a whole chapter devoted to it in :

The Whole Internet Users Guide and Catalog by Ed Krol (publisher O'Reilley & Associates, Inc; ISBN: 1-56592-025-2). (Editors note: ...Great book, go out and buy a bunch!)

The Internet Passport: NorthWestNet's Guide to Our World Online By Jonathan Kochmer and NorthWestNet. Published by NorthWestNet, Bellevue, WA. 1993. 516 pp. ISBN 0-9635281-0-6. Contact info: passport@nwnet.net, or (206) 562-3000

A Students Guide to UNIX by Harley Hahn. (publisher McGraw Hill, Inc.; 1993 ISBN 0-07-025511-3)

Other references include:

The Internet Gopher, “ConneXions”, July 1992, Interop.

On a DECstation I get the error message “/etc/svc.conf no such file or directory” when running the gopherd server, why?

A14: This is caused by the `chroot()` call in `gopherd`. It can be easily fixed by running `gopherd` with the `-c` option.

Alternatively you can copy `/etc/svc.conf` into a directory named “etc” inside the `gopher-data` directory.

The boolean searching terms don't work for my full-text index, why?

This is probably because the searching is being provided by WAIS. WAIS opts to return all documents that contain a search phrase within certain limits. WAIS searches do return the documents with the highest “score” at the top, those documents will have the closest relevance.

Alternatively you could get a booleanized version of `wais` from <ftp.bio.indiana.edu>.

When linking the Unix gopher server with WAIS I get undefined symbols, such as:

```
log_file_name logfile PrintStatus find_value Sources NumSources
```

This happens if you make gopherd before linking in the WAIS ir/ui directories. The fix is to “make clean” or remove gopherd/{waisgopher.o,Waisindex.o} and then remake gopherd. Or link the ir/ui directories first.

Why don't my WAIS indexes work? I never get anything back for searches. or Why do I get “Dangling file” error messages in my logfile?

The problem could be in the server. The server should be run using the -c option if you want WAIS to work. Another solution is to patch the WAIS code so that it doesn't check the files on the disk. Search the gopher-news archive for “dangling”. This will turn up a single document with the patch.

My gopher server doesn't work under inetd, why?

It could be that your inetd server only supports a limited amount of arguments. For instance, the maximum number of arguments to an inetd server is 5. You can get around this by combining arguments: i.e.

```
gopherd -I -c
```

becomes:

```
gopherd -Ic
```

You may also leave the port specifier off of the command line. The gopher server automagically finds out the port it's running on.

Help! I have PC-NFS and want to use the PC-Gopher client. How?

Use a piece of software called PKTMUX, available at fine ftp sites everywhere. This will let you use any packet driver application.

Or, acquire a client that supports PC-NFS.

Is there somewhere I can retrieve a list of announced gopher links? I'd like to keep a local, up-to-date list of available gopher holes without requiring our users to gopher to umn just to scan GopherSpace.

In the Unix client/server distribution is a perl script called "gopherdist". Gopherdist can fetch the contents of any point in GopherSpace.

To dump the contents of all the North American links from gopher.tc.umn.edu do the following:

```
% gopherdist gopher.tc.umn.edu 70 "1/Other Gopher and Information Servers/  
North America" > .Links
```

Why doesn't my unix gopher client display ISO-Latin-1 characters properly?

It is the client's problem, the server is perfectly 8-bit transparent. The BSD curses library uses bit 8 in order to remember, whether a character has been displayed reverse. So use just /usr/5bin/cc and you get the System V curses version which is 8 bit clean.

Note that this may be a problem under other versions of UNIX too...

What is veronica?

veronica: Very Easy Rodent-Oriented Net-wide Index to Computerized Archives.

veronica offers a keyword search of most gopher-server menu titles in the entire gopher web. As archie is to ftp archives, veronica is to gopherspace. A veronica search produces a menu of gopher items, each of which is a direct pointer to a gopher data source. Because veronica is accessed through a gopher client, it is easy to use, and gives access to all types of data supported by the gopher protocol.

To try veronica, select it from the "Other Gophers" menu on Minnesota's gopher server, or point your gopher at:

```
Name=veronica (search menu items in most of GopherSpace)  
Type=1  
Port=70
```
