

Known Bugs

Undo (COMMAND-z) kills the program when it involves *large* groups. This is the only *known* bug in undo, but it is a very complicated feature and may have other less commonly occurring bugs; therefore, it is best to save before using Undo (when working with computers, it is best to save often anyway!)

When rotating groups, Arcs and Protractors within the group do not perform quite correctly.

Documents will not print correctly if the title bar is printed and text is being edited. The simple fix to this problem is to make sure that no text is being edited (simply click on any tool other than the text tool) when printing with the title bar on. This bug is actually a carryover bug from Draw that was discovered in the later stages of development of OrthoDraw.

The protractor inspector in some orientations reports the wrong angle by reporting 360 degrees minus the correct angle and 2π radians minus the correct angle.

All of the currently known bugs (as of 8-10-92) are listed in this document. If you ever encounter a bug (something doesn't work right, the

program bombs, etc.) that is not documented in this document, please try to duplicate your steps to cause the problem. If you can find a series of actions that consistently cause the problem, please send pertinent information so we can fix the problem (see the document "*About_IFYCSEM*" help file in the *Other_Information* directory for addresses.)
