initWithController:key:destination:
Getting association members controller
destination
Getting the key and value key
value

(EOController *)controller

initWithController:(EOController *)aController
    key:(NSString *)aKey
    destination:destination

Initializes a newly allocated EOAssociation with aController. aKey is the name of the property rep
association, and is used as the identifier for value transfers to and from destination (typically a use
another EOController). This is the designated initializer for the EOAssociation class. Returns self.

addAssociation: (EOController)

(NSString *)key

Returns the name of the property that the association transfers to and from its destination.

value

Returns the value of the association's destination as an instance of an appropriate value class (see ª
Database to Objectsº in the access layer's EOAttribute class specification). For example, the value
value is NSString.

For applications using the access layer, if the value class specified for an enterprise object's attribu
NSString or NSData, it must match exactly the value class used by the association.

key, takeValuesFromDictionary: (EOKeyValueCoding informal protocol)
