1. Input Extension Overview

This document describes an extension to the X11 server. The purpose of this extension is to support the use of additional input devices beyond the pointer and keyboard devices defined by the core X protocol. This first section gives an overview of the input extension. The following sections correspond to chapters 7 and 8, "Window Manager functions" and "Events and Event-Handling Functions" of the "Xlib - C Language Interface" manual and describe how to use the input extension.

1.1. Design Approach

The design approach of the extension is to define functions and events analogous to the core functions and events. This allows extension input devices and events to be individually distinguishable from each other and from the core input devices and events. These functions and events make use of a device identifier and support the reporting of n-dimensional motion data as well as other data that is not currently reportable via the core input events.

1.2. Core Input Devices

The X server core protocol supports two input devices: a pointer and a keyboard. The pointer device has two major functions. First, it may be used to generate motion information that client programs can detect. Second, it may also be used to indicate the current location and focus of the X keyboard. To accomplish this, the server echoes a cursor at the current position of the X pointer. Unless the X keyboard has been explicitly focused, this cursor also shows the current location and focus of the X keyboard.

The X keyboard is used to generate input that client programs can detect.

The X keyboard and X pointer are referred to in this document as the *core devices*, and the input events they generate (**KeyPress**, **KeyRelease**, **ButtonPress**, **ButtonRelease**, and **MotionNotify**) are known as the *core input events*. All other input devices are referred to as *extension input devices* and the input events they generate are referred to as *extension input events*. This input extension does not change the behavior or functionality of the core input devices, core events, or core protocol requests, with the exception of the core grab requests. These requests may affect the synchronization of events from extension devices. See the explanation in the section titled "Event Synchronization and Core Grabs".

Selection of the physical devices to be initially used by the server as the core devices is left implementation-dependent. Functions are defined that allow client programs to change which physical devices are used as the core devices.

1.3. Extension Input Devices

The input extension controls access to input devices other than the X keyboard and X pointer. It allows client programs to select input from these devices independently from each other and independently from the core devices. Input events from these devices are of extension types (**DeviceKeyPress**, **DeviceKeyRelease**, **DeviceButtonPress**, **DeviceButtonRelease**, **DeviceMotionNotify**, etc.) and contain a device identifier so that events of the same type coming from different input devices can be distinguished.

Extension input events are not limited in size by the size of the server 32-byte wire events. Extension input events may be constructed by the server sending as many wire sized events as necessary to return the information required for that event. The library event reformatting routines are responsible for combining these into one or more client XEvents.

Any input device that generates key, button or motion data may be used as an extension input device. Extension input devices may have 0 or more keys, 0 or more buttons, and may report 0 or more axes of motion. Motion may be reported as relative movements from a previous position or as an absolute position. All valuator reporting motion information for a given extension input device must report the same kind of motion information (absolute or relative).

This extension is designed to accommodate new types of input devices that may be added in the future. The protocol requests that refer to specific characteristics of input devices organize that information by **input device classes**. Server implementors may add new classes of input devices without changing the protocol requests.

All extension input devices are treated like the core X keyboard in determining their location and focus. The server does not track the location of these devices on an individual basis, and therefore does not echo a cursor to indicate their current location. Instead, their location is determined by the location of the core X pointer. Like the core X keyboard, some may be explicitly focused. If they are not explicitly focused, their focus is determined by the location of the core X pointer.

1.3.1. Input Device Classes

Some of the input extension requests divide input devices into classes based on their functionality. This is intended to allow new classes of input devices to be defined at a later time without changing the semantics of these functions. The following input device classes are currently defined:

KEY The device reports key events.

BUTTON

The device reports button events.

VALUATOR

The device reports valuator data in motion events.

PROXIMITY

The device reports proximity events.

FOCUS

The device can be focused.

FEEDBACK

The device supports feedbacks.

Additional classes may be added in the future. Functions that support multiple input classes, such as the **XListInputDevices** function that lists all available input devices, organize the data they return by input class. Client programs that use these functions should not access data unless it matches a class defined at the time those clients were compiled. In this way, new classes can be added without forcing existing clients that use these functions to be recompiled.

1.4. Using Extension Input Devices

A client that wishes to access an input device does so through the library functions defined in the following sections. A typical sequence of requests that a client would make is as follows:

- **XListInputDevices** - list all of the available input devices. From the information returned by this request, determine whether the desired input device is attached to the server. For a description of the **XListInputDevices** request, see the section entitled "Listing Available Devices".
- **XOpenDevice** - request that the server open the device for access by this client. This request returns an **XDevice** structure that is used by most other input extension requests to identify the specified device. For a description of the **XOpenDevice** request, see the section entitled "Enabling and Disabling Extension Devices".
- Determine the event types and event classes needed to select the desired input extension events, and identify them when they are received. This is done via macros whose name corresponds to the desired event, i.e. **DeviceKeyPress**. For a description of these macros, see the section entitled "Selecting Extension Device Events".
- **XSelectExtensionEvent** - select the desired events from the server. For a description of the **XSelectExtensionEvent** request, see the section entitled "Selecting Extension Device Events".

- **XNextEvent** - receive the next available event. This is the core **XNextEvent** function provided by the standard X library.

Other requests are defined to grab and focus extension devices, to change their key, button, or modifier mappings, to control the propagation of input extension events, to get motion history from an extension device, and to send input extension events to another client. These functions are described in the following sections.

2. Library Extension Requests

Extension input devices are accessed by client programs through the use of new protocol requests. The following requests are provided as extensions to Xlib. Constants and structures referenced by these functions may be found in the files **XI.h** and **XInput.h**, which are attached to this document as appendix A.

The library will return **NoSuchExtension** if an extension request is made to a server that does not support the input extension.

Input extension requests cannot be used to access the X keyboard and X pointer devices.

2.1. Window Manager Functions

2.1.1. Changing The Core Devices

These functions are provided to change which physical device is used as the X pointer or X keyboard. Using these functions may change the characteristics of the core devices. The new pointer device may have a different number of buttons than the old one did, or the new keyboard device may have a different number of keys or report a different range of keycodes. Client programs may be running that depend on those characteristics. For example, a client program could allocate an array based on the number of buttons on the pointer device, and then use the button numbers received in button events as indices into that array. Changing the core devices could cause such client programs to behave improperly or abnormally terminate, if they ignore the **ChangeDeviceNotify** event generated by these requests.

These functions change the X keyboard or X pointer device and generate an **XChangeDeviceNotify** event and a **MappingNotify** event. The specified device becomes the new X keyboard or X pointer device. The location of the core device does not change as a result of this request.

These requests fail and return **AlreadyGrabbed** if either the specified device or the core device it would replace are grabbed by some other client. They fail and return **GrabFrozen** if either device is frozen by the active grab of another client.

These requests fail with a **BadDevice** error if the specified device is invalid, has not previously been opened via **XOpenDevice**, or is not supported as a core device by the server implementation.

Once the device has successfully replaced one of the core devices, it is treated as a core device until it is in turn replaced by another **ChangeDevice** request, or until the server terminates. The termination of the client that changed the device will not cause it to change back. Attempts to use the **XCloseDevice** request to close the new core device will fail with a **BadDevice** error.

To change which physical device is used as the X keyboard, use the **XChangeKeyboardDevice** function.

The specified device must support input class **Keys** (as reported in the **ListInputDevices** request) or the request will fail with a **BadMatch** error.

```

int
XChangeKeyboardDevice (display, device)
    Display *display;
    XDevice *device;

```

display Specifies the connection to the X server.

device Specifies the desired device.

If no error occurs, this function returns **Success**. A **ChangeDeviceNotify** event with the request field set to **NewKeyboard** is sent to all clients selecting that event. A **MappingNotify** event with the request field set to **MappingKeyboard** is sent to all clients. The requested device becomes the X keyboard, and the old keyboard becomes available as an extension input device. The focus state of the new keyboard is the same as the focus state of the old X keyboard.

Errors returned by this function: **BadDevice**, **BadMatch**, **AlreadyGrabbed**, and **GrabFrozen**.

To change which physical device is used as the X pointer, use the **XChangePointerDevice** function. The specified device must support input class **Valuators** (as reported in the **XListInputDevices request**) and report at least two axes of motion, or the request will fail with a **BadMatch** error. If the specified device reports more than two axes, the two specified in the *xaxis* and *yaxis* arguments will be used. Data from other valuators on the device will be ignored.

If the specified device reports absolute positional information, and the server implementation does not allow such a device to be used as the X pointer, the request will fail with a **BadDevice** error.

```

int
XChangePointerDevice (display, device, xaxis, yaxis)
    Display *display;
    XDevice *device;
    int      xaxis;
    int      yaxis;

```

display Specifies the connection to the X server.

device Specifies the desired device.

xaxis Specifies the zero-based index of the axis to be used as the x-axis of the pointer device.

yaxis Specifies the zero-based index of the axis to be used as the y-axis of the pointer device.

If no error occurs, this function returns **Success**. A **ChangeDeviceNotify** event with the request field set to **NewPointer** is sent to all clients selecting that event. A **MappingNotify** event with the request field set to **MappingPointer** is sent to all clients. The requested device becomes the X pointer, and the old pointer becomes available as an extension input device.

Errors returned by this function: **BadDevice**, **BadMatch**, **AlreadyGrabbed**, and **GrabFrozen**.

2.1.2. Event Synchronization And Core Grabs

Implementation of the input extension requires an extension of the meaning of event synchronization for the core grab requests. This is necessary in order to allow window managers to freeze all input devices with a single request.

The core grab requests require a **pointer_mode** and **keyboard_mode** argument. The meaning of these modes is changed by the input extension. For the **XGrabPointer** and **XGrabButton** requests, **pointer_mode** controls synchronization of the pointer device, and **keyboard_mode** controls the synchronization of all other input devices. For the **XGrabKeyboard** and **XGrabKey** requests, **pointer_mode** controls the synchronization of all input devices except the X keyboard, while **keyboard_mode** controls the synchronization of the keyboard. When using one of the core grab requests, the synchronization of extension devices is controlled by the mode specified for the device not being grabbed.

2.1.3. Extension Active Grabs

Active grabs of extension devices are supported via the **XGrabDevice** function in the same way that core devices are grabbed using the core **XGrabKeyboard** function, except that a *Device* is passed as a function parameter. The **XUngrabDevice** function allows a previous active grab for an extension device to be released.

Passive grabs of buttons and keys on extension devices are supported via the **XGrabDeviceButton** and **XGrabDeviceKey** functions. These passive grabs are released via the **XUngrabDeviceKey** and **XUngrabDeviceButton** functions.

To grab an extension device, use the **XGrabDevice** function. The device must have previously been opened using the **XOpenDevice** function.

```
int
XGrabDevice (display, device, grab_window, owner_events,
             event_count, event_list, this_device_mode,
             other_device_mode, time)
    Display      *display;
    XDevice      *device;
    Window       grab_window;
    Bool         owner_events;
    int          event_count;
    XEventClass  *event_list;
    int          this_device_mode;
    int          other_device_mode;
    Time         time;
```

display Specifies the connection to the X server.

device Specifies the desired device.

grab_window Specifies the ID of a window associated with the device specified above.

owner_events Specifies a boolean value of either **True** or **False**.

event_count Specifies the number of elements in the *event_list* array.

event_list Specifies a pointer to a list of event classes that indicate which events the client wishes to receive. These event classes must have been obtained using the device being grabbed.

this_device_mode

Controls further processing of events from this device. You can pass one of these constants: **GrabModeSync** or **GrabModeAsync**.

other_device_mode

Controls further processing of events from all other devices. You can pass one of these constants: **GrabModeSync** or **GrabModeAsync**.

time Specifies the time. This may be either a timestamp expressed in milliseconds, or **CurrentTime**.

The **XGrabDevice** function actively grabs an extension input device, and generates **DeviceFocusIn** and **DeviceFocusOut** events. Further input events from this device are reported only to the grabbing client. This function overrides any previous active grab by this client for this device.

The event-list parameter is a pointer to a list of event classes. This list indicates which events the client wishes to receive while the grab is active. If *owner_events* is **False**, input events from this device are reported with respect to *grab_window* and are only reported if specified in *event_list*. If *owner_events* is **True**, then if a generated event would normally be reported to this client, it is reported normally. Otherwise the event is reported with respect to the *grab_window*, and is only reported if specified in *event_list*.

The *this_device_mode* argument controls the further processing of events from this device, and the *other_device_mode* argument controls the further processing of input events from all other devices.

- If the *this_device_mode* argument is **GrabModeAsync**, device event processing continues normally; if the device is currently frozen by this client, then processing of device events is resumed. If the *this_device_mode* argument is **GrabModeSync**, the state of the grabbed device (as seen by client applications) appears to freeze, and no further device events are generated by the server until the grabbing client issues a releasing **XAllowDeviceEvents** call or until the device grab is released. Actual device input events are not lost while the device is frozen; they are simply queued for later processing.
- If the *other_device_mode* is **GrabModeAsync**, event processing from other input devices is unaffected by activation of the grab. If *other_device_mode* is **GrabModeSync**, the state of all devices except the grabbed device (as seen by client applications) appears to freeze, and no further events are generated by the server until the grabbing client issues a releasing **XAllowEvents** or **XAllowDeviceEvents** call or until the device grab is released. Actual events are not lost while the other devices are frozen; they are simply queued for later processing.

XGrabDevice fails and returns:

- **AlreadyGrabbed** If the device is actively grabbed by some other client.
- **GrabNotViewable** If *grab_window* is not viewable.
- **GrabInvalidTime** If the specified time is earlier than the last-grab-time for the specified device or later than the current X server time. Otherwise, the last-grab-time for the specified device is set to the specified time and **CurrentTime** is replaced by the current X server time.
- **GrabFrozen** If the device is frozen by an active grab of another client.

If a grabbed device is closed by a client while an active grab by that client is in effect, that active grab will be released. Any passive grabs established by that client will be released. If the device is frozen only by an active grab of the requesting client, it is thawed.

Errors returned by this function: **BadDevice**, **BadWindow**, **BadValue**, **BadClass**.

To release a grab of an extension device, use **XUngrabDevice**.

```
int
XUngrabDevice (display, device, time)
    Display *display;
    XDevice *device;
    Time     time;
```

<i>display</i>	Specifies the connection to the X server.
<i>device</i>	Specifies the desired device.
<i>time</i>	Specifies the time. This may be either a timestamp expressed in milliseconds, or CurrentTime .

This function allows a client to release an extension input device and any queued events if this client has it grabbed from either **XGrabDevice** or **XGrabDeviceKey**. If any other devices are frozen by the grab, **XUngrabDevice** thaws them. The function does not release the device and any queued events if the specified time is earlier than the last-device-grab time or is later than the current X server time. It also generates **DeviceFocusIn** and **DeviceFocusOut** events. The X server automatically performs an **XUngrabDevice** if the event window for an active device grab becomes not viewable, or if the client terminates without releasing the grab.

Errors returned by this function: **BadDevice**.

2.1.4. Passively Grabbing A Key

To passively grab a single key on an extension device, use **XGrabDeviceKey**. That device must have previously been opened using the **XOpenDevice** function, or the request will fail with a **BadDevice** error. If the specified device does not support input class **Keys**, the request will fail with a **BadMatch** error.

```
int
XGrabDeviceKey (display, device, keycode, modifiers, modifier_device
grab_window, owner_events, event_count, event_list,
this_device_mode, other_device_mode)
    Display      *display;
    XDevice      *device;
    int          keycode;
    unsigned     int modifiers;
    XDevice      *modifier_device;
    Window       grab_window;
    Bool         owner_events;
    int          event_count;
    XEventClass  *event_list;
    int          this_device_mode;
    int          other_device_mode;
```

<i>display</i>	Specifies the connection to the X server.
<i>device</i>	Specifies the desired device.
<i>keycode</i>	Specifies the keycode of the key that is to be grabbed. You can pass either the keycode or AnyKey .
<i>modifiers</i>	Specifies the set of keymasks. This mask is the bitwise inclusive OR of these keymask bits: ShiftMask , LockMask , ControlMask , Mod1Mask , Mod2Mask , Mod3Mask , Mod4Mask , Mod5Mask . You can also pass AnyModifier , which is equivalent to issuing the grab key request for all possible modifier combinations (including the combination of no modifiers).
<i>modifier_device</i>	Specifies the device whose modifiers are to be used. If NULL is specified, the core X keyboard is used as the modifier_device.

grab_window Specifies the ID of a window associated with the device specified above.

owner_events Specifies a boolean value of either **True** or **False**.

event_count Specifies the number of elements in the *event_list* array.

event_list Specifies a pointer to a list of event classes that indicate which events the client wishes to receive.

this_device_mode

Controls further processing of events from this device. You can pass one of these constants: **GrabModeSync** or **GrabModeAsync**.

other_device_mode

Controls further processing of events from all other devices. You can pass one of these constants: **GrabModeSync** or **GrabModeAsync**.

This function is analogous to the core **XGrabKey** function. It creates an explicit passive grab for a key on an extension device.

The **XGrabDeviceKey** function establishes a passive grab on a device. Consequently, in the future,

- IF the device is not grabbed and the specified key, which itself can be a modifier key, is logically pressed when the specified modifier keys logically are down on the specified modifier device (and no other keys are down),
- AND no other modifier keys logically are down,
- AND EITHER the grab window is an ancestor of (or is) the focus window OR the grab window is a descendent of the focus window and contains the pointer,
- AND a passive grab on the same device and key combination does not exist on any ancestor of the grab window,
- THEN the device is actively grabbed, as for **XGrabDevice**, the last-device-grab time is set to the time at which the key was pressed (as transmitted in the **DeviceKeyPress** event), and the **DeviceKeyPress** event is reported.

The interpretation of the remaining arguments is as for **XGrabDevice**. The active grab is terminated automatically when the logical state of the device has the specified key released (independent of the logical state of the modifier keys).

Note that the logical state of a device (as seen by means of the X protocol) may lag the physical state if device event processing is frozen.

A modifier of **AnyModifier** is equivalent to issuing the request for all possible modifier combinations (including the combination of no modifiers). It is not required that all modifiers specified have currently assigned keycodes. A key of **AnyKey** is equivalent to issuing the request for all possible keycodes. Otherwise, the key must be in the range specified by *min_keycode* and *max_keycode* in the information returned by the **XListInputDevices** function. If it is not within that range, **XGrabDeviceKey** generates a **BadValue** error.

A **BadAccess** error is generated if some other client has issued a **XGrabDeviceKey** with the same device and key combination on the same window. When using **AnyModifier** or **AnyKey**, the request fails completely and the X server generates a **BadAccess** error and no grabs are established if there is a conflicting grab for any combination.

XGrabDeviceKey can generate **BadDevice**, **BadAccess**, **BadMatch**, **BadWindow**, **BadClass**, and **BadValue** errors.

XGrabDeviceKey returns **Success** upon successful completion of the request.

To release a passive grab of a single key on an extension device, use **XUngrabDeviceKey**.

```

int
XUngrabDeviceKey (display, device, keycode, modifiers,
                  modifier_device, ungrab_window)
    Display *display;
    XDevice *device;
    int      keycode;
    unsigned int modifiers;
    XDevice *modifier_device;
    Window   ungrab_window;

```

display Specifies the connection to the X server.

device Specifies the desired device.

keycode Specifies the keycode of the key that is to be ungrabbed. You can pass either the keycode or **AnyKey**.

modifiers Specifies the set of keymasks. This mask is the bitwise inclusive OR of these keymask bits: **ShiftMask**, **LockMask**, **ControlMask**, **Mod1Mask**, **Mod2Mask**, **Mod3Mask**, **Mod4Mask**, **Mod5Mask**.
You can also pass **AnyModifier**, which is equivalent to issuing the ungrab key request for all possible modifier combinations (including the combination of no modifiers).

modifier_device Specifies the device whose modifiers are to be used. If **NULL** is specified, the core X keyboard is used as the modifier_device.

ungrab_window Specifies the ID of a window associated with the device specified above.

This function is analogous to the core **XUngrabKey** function. It releases an explicit passive grab for a key on an extension input device.

Errors returned by this function: **BadDevice**, **BadWindow**, **BadValue**, **BadAlloc**, and **BadMatch**.

2.1.5. Passively Grabbing A Button

To establish a passive grab for a single button on an extension device, use **XGrabDeviceButton**. The specified device must have previously been opened using the **XOpenDevice** function, or the request will fail with a **BadDevice** error. If the specified device does not support input class **Buttons**, the request will fail with a **BadMatch** error.

```

int
XGrabDeviceButton (display, device, button, modifiers,
    modifier_device, grab_window, owner_events, event_count,
    event_list, this_device_mode, other_device_mode)
    Display      *display;
    XDevice      *device;
    unsigned int  button;
    unsigned int  modifiers;
    XDevice      *modifier_device;
    Window       grab_window;
    Bool          owner_events;
    int           event_count;
    XEventClass   *event_list;
    int           this_device_mode;
    int           other_device_mode;

```

display Specifies the connection to the X server.

device Specifies the desired device.

button Specifies the code of the button that is to be grabbed. You can pass either the button or **AnyButton**.

modifiers Specifies the set of keymasks. This mask is the bitwise inclusive OR of these keymask bits: **ShiftMask**, **LockMask**, **ControlMask**, **Mod1Mask**, **Mod2Mask**, **Mod3Mask**, **Mod4Mask**, **Mod5Mask**.
You can also pass **AnyModifier**, which is equivalent to issuing the grab request for all possible modifier combinations (including the combination of no modifiers).

modifier_device Specifies the device whose modifiers are to be used. If **NULL** is specified, the core X keyboard is used as the modifier_device.

grab_window Specifies the ID of a window associated with the device specified above.

owner_events Specifies a boolean value of either **True** or **False**.

event_count Specifies the number of elements in the event_list array.

event_list Specifies a list of event classes that indicates which device events are to be reported to the client.

this_device_mode Controls further processing of events from this device. You can pass one of these constants: **GrabModeSync** or **GrabModeAsync**.

other_device_mode Controls further processing of events from all other devices. You can pass one of these constants: **GrabModeSync** or **GrabModeAsync**.

This function is analogous to the core **XGrabButton** function. It creates an explicit passive grab for a button on an extension input device. Since the server does not track extension devices, no cursor is specified with this request. For the same reason, there is no *confine_to* parameter. The device must have previously been opened using the **XOpenDevice** function.

The **XGrabDeviceButton** function establishes a passive grab on a device. Consequently, in the future,

- IF the device is not grabbed and the specified button is logically pressed when the specified modifier keys logically are down (and no other buttons or modifier keys are down),
- AND EITHER the grab window is an ancestor of (or is) the focus window OR the grab window is a descendent of the focus window and contains the pointer,
- AND a passive grab on the same device and button/ key combination does not exist on any ancestor of the grab window,
- THEN the device is actively grabbed, as for **XGrabDevice**, the last-grab time is set to the time at which the button was pressed (as transmitted in the **DeviceButtonPress** event), and the **DeviceButtonPress** event is reported.

The interpretation of the remaining arguments is as for **XGrabDevice**. The active grab is terminated automatically when logical state of the device has all buttons released (independent of the logical state of the modifier keys).

Note that the logical state of a device (as seen by means of the X protocol) may lag the physical state if device event processing is frozen.

A modifier of **AnyModifier** is equivalent to issuing the request for all possible modifier combinations (including the combination of no modifiers). It is not required that all modifiers specified have currently assigned keycodes. A button of **AnyButton** is equivalent to issuing the request for all possible buttons. Otherwise, it is not required that the specified button be assigned to a physical button.

A **BadAccess** error is generated if some other client has issued a **XGrabDeviceButton** with the same device and button combination on the same window. When using **AnyModifier** or **AnyButton**, the request fails completely and the X server generates a **BadAccess** error and no grabs are established if there is a conflicting grab for any combination.

XGrabDeviceButton can generate **BadDevice**, **BadMatch**, **BadAccess**, **BadWindow**, **BadClass**, and **BadValue** errors.

To release a passive grab of a button on an extension device, use **XUngrabDeviceButton**.

```
int
XUngrabDeviceButton (display, device, button, modifiers,
                    modifier_device, ungrab_window)
    Display *display;
    XDevice *device;
    unsigned int button;
    unsigned int modifiers;
    XDevice *modifier_device;
    Window ungrab_window;
```

<i>display</i>	Specifies the connection to the X server.
<i>device</i>	Specifies the desired device.
<i>button</i>	Specifies the code of the button that is to be ungrabbed. You can pass either a button or AnyButton .
<i>modifiers</i>	Specifies the set of keymasks. This mask is the bitwise inclusive OR of these keymask bits: ShiftMask , LockMask , ControlMask , Mod1Mask , Mod2Mask , Mod3Mask , Mod4Mask , Mod5Mask . You can also pass AnyModifier , which is equivalent to issuing the ungrab key request for all possible modifier combinations (including the combination of no modifiers).

modifier_device

Specifies the device whose modifiers are to be used. If **NULL** is specified, the core X keyboard is used as the *modifier_device*.

ungrab_window

Specifies the ID of a window associated with the device specified above.

This function is analogous to the core **XUngrabButton** function. It releases an explicit passive grab for a button on an extension device. That device must have previously been opened using the **XOpenDevice** function, or a **BadDevice** error will result.

A modifier of **AnyModifier** is equivalent to issuing the request for all possible modifier combinations (including the combination of no modifiers).

XUngrabDeviceButton can generate **BadDevice**, **BadMatch**, **BadWindow**, **BadValue**, and **BadAlloc** errors.

2.1.6. Thawing A Device

To allow further events to be processed when a device has been frozen, use **XAllowDeviceEvents**.

```
int
XAllowDeviceEvents (display, device, event_mode, time)
    Display *display;
    XDevice *device;
    int      event_mode;
    Time     time;
```

display Specifies the connection to the X server.

device Specifies the desired device.

event_mode Specifies the event mode. You can pass one of these constants: **AsyncThisDevice**, **SyncThisDevice**, **AsyncOtherDevices**, **ReplayThisDevice**, **AsyncAll**, or **SyncAll**.

time Specifies the time. This may be either a timestamp expressed in milliseconds, or **CurrentTime**.

The **XAllowDeviceEvents** function releases some queued events if the client has caused a device to freeze. The function has no effect if the specified time is earlier than the last-grab time of the most recent active grab for the client and device, or if the specified time is later than the current X server time. The following describes the processing that occurs depending on what constant you pass to the *event_mode* argument:

- If the specified device is frozen by the client, event processing for that continues as usual. If the device is frozen multiple times by the client on behalf of multiple separate grabs, **AsyncThisDevice** thaws for all. **AsyncThisDevice** has no effect if the specified device is not frozen by the client, but the device need not be grabbed by the client.
- If the specified device is frozen and actively grabbed by the client, event processing for that device continues normally until the next key or button event is reported to the client. At this time, the specified device again appears to freeze. However, if the reported event causes the grab to be released, the specified device does not freeze. **SyncThisDevice** has no effect if the specified device is not frozen by the client or is not grabbed by the client.
- If the specified device is actively grabbed by the client and is frozen as the result of an event having been sent to the client (either from the activation of a **GrabDeviceButton** or from a previous **AllowDeviceEvents** with mode **SyncThisDevice**, but not from a **Grab**), the grab is released and that event is completely reprocessed. This time, however, the request ignores

any passive grabs at or above (towards the root) the grab-window of the grab just released. The request has no effect if the specified device is not grabbed by the client or if it is not frozen as the result of an event.

- If the remaining devices are frozen by the client, event processing for them continues as usual. If the other devices are frozen multiple times by the client on behalf of multiple separate grabs, `AsyncOtherDevices` “thaws” for all. `AsyncOtherDevices` has no effect if the devices are not frozen by the client, but those devices need not be grabbed by the client.
- If all devices are frozen by the client, event processing (for all devices) continues normally until the next button or key event is reported to the client for a grabbed device at which time the devices again appear to freeze. However, if the reported event causes the grab to be released, then the devices do not freeze (but if any device is still grabbed, then a subsequent event for it will still cause all devices to freeze). `SyncAll` has no effect unless all devices are frozen by the client. If any device is frozen twice by the client on behalf of two separate grabs, `SyncAll` “thaws” for both (but a subsequent freeze for `SyncAll` will only freeze each device once).
- If all devices are frozen by the client, event processing (for all devices) continues normally. If any device is frozen multiple times by the client on behalf of multiple separate grabs, `AsyncAll` “thaws” for all. If any device is frozen twice by the client on behalf of two separate grabs, `AsyncAll` “thaws” for both. `AsyncAll` has no effect unless all devices are frozen by the client.

`AsyncThisDevice`, `SyncThisDevice`, and `ReplayThisDevice` have no effect on the processing of events from the remaining devices. `AsyncOtherDevices` has no effect on the processing of events from the specified device. When the event_mode is `SyncAll` or `AsyncAll`, the device parameter is ignored.

It is possible for several grabs of different devices (by the same or different clients) to be active simultaneously. If a device is frozen on behalf of any grab, no event processing is performed for the device. It is possible for a single device to be frozen because of several grabs. In this case, the freeze must be released on behalf of each grab before events can again be processed.

Errors returned by this function: **BadDevice**, **BadValue**.

2.1.7. Controlling Device Focus

The current focus window for an extension input device can be determined using the **XGetDeviceFocus** function. Extension devices are focused using the **XSetDeviceFocus** function in the same way that the keyboard is focused using the core **XSetInputFocus** function, except that a device id is passed as a function parameter. One additional focus state, **FollowKeyboard**, is provided for extension devices.

To get the current focus state, revert state, and focus time of an extension device, use **XGetDeviceFocus**.

```
int
XGetDeviceFocus (display, device, focus_return, revert_to_return,
                focus_time_return)
    Display *display;
    XDevice *device;
    Window  *focus_return;
    int      *revert_to_return;
    Time     *focus_time_return;
```

display Specifies the connection to the X server.

device Specifies the desired device.

focus_return Specifies the address of a variable into which the server can return the ID of the window that contains the device focus, or one of the constants **None**, **PointerRoot**, or **FollowKeyboard**.

revert_to_return Specifies the address of a variable into which the server can return the current revert_to status for the device.

focus_time_return Specifies the address of a variable into which the server can return the focus time last set for the device.

This function returns the focus state, the revert-to state, and the last-focus-time for an extension input device.

Errors returned by this function: **BadDevice**, **BadMatch**.

To set the focus of an extension device, use **XSetDeviceFocus**.

```
int
XSetDeviceFocus (display, device, focus, revert_to, time)
    Display *display;
    XDevice *device;
    Window  focus;
    int     revert_to;
    Time     time;
```

display Specifies the connection to the X server.

device Specifies the desired device.

focus Specifies the id of the window to which the device's focus should be set. This may be a window id, or **PointerRoot**, **FollowKeyboard**, or **None**.

revert_to Specifies to which window the focus of the device should revert if the focus window becomes not viewable. One of the following constants may be passed: **RevertToParent**, **RevertToPointerRoot**, **RevertToNone**, or **RevertToFollowKeyboard**.

time Specifies the time. You can pass either a timestamp, expressed in milliseconds, or **CurrentTime**.

This function changes the focus for an extension input device and the last-focus-change-time. The function has no effect if the specified time is earlier than the last-focus-change-time or is later than the current X server time. Otherwise, the last-focus-change-time is set to the specified time. This function causes the X server to generate **DeviceFocusIn** and **DeviceFocusOut** events.

The action taken by the server when this function is requested depends on the value of the focus argument:

- If the focus argument is **None**, all input events from this device will be discarded until a new focus window is set. In this case, the revert_to argument is ignored.
- If a window ID is assigned to the focus argument, it becomes the focus window of the device. If an input event from the device would normally be reported to this window or to one of its inferiors, the event is reported normally. Otherwise, the event is reported relative to the focus window.

- If you assign **PointerRoot** to the focus argument, the focus window is dynamically taken to be the root window of whatever screen the pointer is on at each input event. In this case, the `revert_to` argument is ignored.
- If you assign **FollowKeyboard** to the focus argument, the focus window is dynamically taken to be the same as the focus of the X keyboard at each input event.

The specified focus window must be viewable at the time **XSetDeviceFocus** is called. Otherwise, it generates a **BadMatch error**. If the focus window later becomes not viewable, the X server evaluates the `revert_to` argument to determine the new focus window.

- If you assign **RevertToParent** to the `revert_to` argument, the focus reverts to the parent (or the closest viewable ancestor), and the new `revert_to` value is taken to be **RevertToNone**.
- If you assign **RevertToPointerRoot**, **RevertToFollowKeyboard**, or **RevertToNone** to the `revert_to` argument, the focus reverts to that value.

When the focus reverts, the X server generates **DeviceFocusIn** and **DeviceFocusOut** events, but the last-focus-change time is not affected.

Errors returned by this function: **BadDevice**, **BadMatch**, **BadValue**, and **BadWindow**.

2.1.8. Controlling Device Feedback

To determine the current feedback settings of an extension input device, use **XGetFeedbackControl**.

```
XFeedbackState
*XGetFeedbackControl (display, device, num_feedbacks_return)
    Display          *display;
    XDevice          *device;
    int              *num_feedbacks_return;
```

display Specifies the connection to the X server.

device Specifies the desired device.

num_feedbacks_return
Returns the number of feedbacks supported by the device.

- This function returns a list of **FeedbackState** structures that describe the feedbacks supported by the specified device. There is an **XFeedbackState** structure for each class of feedback. These are of variable length, but the first three fields are common to all. The common fields are as follows:

```
typedef struct {
    XID      class;
    int      length;
    XID      id;
} XFeedbackState;
```

where **class** identifies the class of feedback. The **class** may be compared to constants defined in the file **XI.h**. Currently defined feedback constants include **KbdFeedbackClass**, **PtrFeedbackClass**, **StringFeedbackClass**, **IntegerFeedbackClass**, **LedFeedbackClass**, and **BellFeedbackClass**.

The **length** specifies the length of the **FeedbackState** structure and can be used by clients to traverse the list.

The **id** uniquely identifies a feedback for a given device and class. This allows a device to support more than one feedback of the same class. Other feedbacks of other classes or devices may have the same id.

- Those feedbacks equivalent to those supported by the core keyboard are reported in class **KbdFeedback** using the **XKbdFeedbackState** structure. The members of that structure are as follows:

```
typedef struct {
    XID      class;
    int      length;
    XID      id;
    int      click;
    int      percent;
    int      pitch;
    int      duration;
    int      led_mask;
    int      global_auto_repeat;
    char     auto_repeats[32];
} XKbdFeedbackState;
```

The fields of the **XKbdFeedbackState** structure report the current state of the feedback:

- click** specifies the key-click volume, and has a value in the range 0 (off) to 100 (loud).
- percent** specifies the bell volume, and has a value in the range 0 (off) to 100 (loud).
- pitch** specifies the bell pitch in Hz. The range of the value is implementation-dependent.
- duration** specifies the duration in milliseconds of the bell.
- led_mask** is a bit mask that describes the current state of up to 32 LEDs. A value of 1 in a bit indicates that the corresponding LED is on.
- global_auto_repeat** has a value of **AutoRepeatModeOn** or **AutoRepeatModeOff**.
- The **auto_repeats** member is a bit vector. Each bit set to 1 indicates that auto-repeat is enabled for the corresponding key. The vector is represented as 32 bytes. Byte N (from 0) contains the bits for keys 8N to 8N + 7, with the least significant bit in the byte representing key 8N. Those feedbacks equivalent to those supported by the core pointer are reported in class **PtrFeedback** using the **XPtrFeedbackState** structure. The members of that structure are as follows:

```
typedef struct {
    XID      class;
    int      length;
    XID      id;
    int      accelNum;
    int      accelDenom;
    int      threshold;
} XPtrFeedbackState;
```

The fields of the **XPtrFeedbackState** structure report the current state of the feedback:

- accelNum** returns the numerator for the acceleration multiplier.
- accelDenom** returns the denominator for the acceleration multiplier.

- **accelDenom** returns the threshold for the acceleration.

Integer feedbacks are those capable of displaying integer numbers. The minimum and maximum values that they can display are reported.

```
typedef struct {
    XID      class;
    int      length;
    XID      id;
    int      resolution;
    int      minVal;
    int      maxVal;
} XIntegerFeedbackState;
```

The fields of the **XIntegerFeedbackState** structure report the capabilities of the feedback:

- **resolution** specifies the number of digits that the feedback can display.
- **minVal** specifies the minimum value that the feedback can display.
- **maxVal** specifies the maximum value that the feedback can display. **String** feedbacks are those that can display character information. Clients set these feedbacks by passing a list of **KeySyms** to be displayed. The **XGetFeedbackControl** function returns the set of key symbols that the feedback can display, as well as the maximum number of symbols that can be displayed.

```
typedef struct {
    XID      class;
    int      length;
    XID      id;
    int      max_symbols;
    int      num_syms_supported;
    KeySym   *syms_supported;
} XStringFeedbackState;
```

The fields of the **XStringFeedbackState** structure report the capabilities of the feedback:

- **max_symbols** specifies the maximum number of symbols that can be displayed.
- **syms_supported** is a pointer to the list of supported symbols.
- **num_syms_supported** specifies the length of the list of supported symbols. **Bell** feedbacks are those that can generate a sound. Some implementations may support a bell as part of a **KbdFeedback** feedback. Class **BellFeedback** is provided for implementations that do not choose to do so, and for devices that support multiple feedbacks that can produce sound. The meaning of the fields is the same as that of the corresponding fields in the **XKbdFeedbackState** structure.

```
typedef struct {
    XID      class;
    int      length;
    XID      id;
    int      percent;
    int      pitch;
    int      duration;
} XBellFeedbackState;
```

Led feedbacks are those that can generate a light. Up to 32 lights per feedback are supported. Each bit in `led_mask` corresponds to one supported light, and the corresponding bit in `led_values` indicates whether that light is currently on (1) or off (0). Some implementations may support leds as part of a **KbdFeedback** feedback. Class **LedFeedback** is provided for implementations that do not choose to do so, and for devices that support multiple led feedbacks.

```
typedef struct {
    XID      class;
    int      length;
    XID      id;
    Mask     led_values;
    Mask     led_mask;
} XLedFeedbackState;
```

Errors returned by this function: **BadDevice**, **BadMatch**.

To free the information returned by the **XGetFeedbackControl** function, use **XFreeFeedbackList**.

```
void
XFreeFeedbackList (list)
    XFeedbackState *list;
```

list Specifies the pointer to the **XFeedbackState** structure returned by a previous call to **XGetFeedbackControl**.

This function frees the list of feedback control information.

To change the settings of a feedback on an extension device, use **XChangeFeedbackControl**. This function modifies the current control values of the specified feedback using information passed in the appropriate **XFeedbackControl** structure for the feedback. Which values are modified depends on the `valuemask` passed.

```
int
XChangeFeedbackControl (display, device, valuemask, value)
    Display      *display;
    XDevice      *device;
    unsigned long valuemask;
    XFeedbackControl *value;
```

- display* Specifies the connection to the X server.
- device* Specifies the desired device.
- valuemask* Specifies one value for each bit in the mask (least to most significant bit). The values are associated with the feedbacks for the specified device.
- value* Specifies a pointer to the **XFeedbackControl** structure.

This function controls the device characteristics described by the **XFeedbackControl** structure. There is an **XFeedbackControl** structure for each class of feedback. These are of variable length, but the first two fields are common to all. The common fields are as follows:

```
typedef struct {
    XID      class;
    int      length;
    XID      id;
} XFeedbackControl;
```

Feedback class **KbdFeedback** controls feedbacks equivalent to those provided by the core keyboard using the **KbdFeedbackControl** structure. The members of that structure are:

```
typedef struct {
    XID      class;
    int      length;
    XID      id;
    int      click;
    int      percent;
    int      pitch;
    int      duration;
    int      led_mask;
    int      led_value;
    int      key;
    int      auto_repeat_mode;
} XKbdFeedbackControl;
```

This class controls the device characteristics described by the **XKbdFeedbackControl** structure. These include the `key_click_percent`, `global_auto_repeat` and individual key auto-repeat. Valid modes are **AutoRepeatModeOn**, **AutoRepeatModeOff**, **AutoRepeatModeDefault**.

Valid masks are as follows:

```
#define DvKeyClickPercent    (1L << 0)
#define DvPercent           (1L << 1)
#define DvPitch              (1L << 2)
#define DvDuration           (1L << 3)
#define DvLed                (1L << 4)
#define DvLedMode            (1L << 5)
#define DvKey                (1L << 6)
#define DvAutoRepeatMode     (1L << 7)
```

Errors returned by this function: **BadDevice**, **BadMatch**, **BadValue**.

Feedback class **PtrFeedback** controls feedbacks equivalent to those provided by the core pointer using the **PtrFeedbackControl** structure. The members of that structure are:

```
typedef struct {
    XID      class;
    int      length;
    XID      id;
    int      accelNum;
    int      accelDenom;
    int      threshold;
} XPtrFeedbackControl;
```

Which values are modified depends on the valuemask passed.

Valid masks are as follows:

```
#define DvAccelnum      (1L << 0)
#define DvAccelDenom    (1L << 1)
#define DvThreshold     (1L << 2)
```

The acceleration, expressed as a fraction, is a multiplier for movement. For example, specifying 3/1 means the device moves three times as fast as normal. The fraction may be rounded arbitrarily by the X server. Acceleration only takes effect if the device moves more than threshold pixels at once and only applies to the amount beyond the value in the threshold argument. Setting a value to -1 restores the default. The values of the accelNumerator and threshold fields must be nonzero for the pointer values to be set. Otherwise, the parameters will be unchanged. Negative values generate a **BadValue** error, as does a zero value for the accelDenominator field.

This request fails with a **BadMatch** error if the specified device is not currently reporting relative motion. If a device that is capable of reporting both relative and absolute motion has its mode changed from **Relative** to **Absolute** by an **XSetDeviceMode** request, valuator control values will be ignored by the server while the device is in that mode.

Feedback class **IntegerFeedback** controls integer feedbacks displayed on input devices, using the **IntegerFeedbackControl** structure. The members of that structure are:

```
typedef struct {
    XID      class;
    int      length;
    XID      id;
    int      int_to_display;
} XIntegerFeedbackControl;
```

Valid masks are as follows:

```
#define DvInteger      (1L << 0)
```

Feedback class **StringFeedback** controls string feedbacks displayed on input devices, using the **StringFeedbackControl** structure. The members of that structure are:

```
typedef struct {
    XID      class;
    int      length;
    XID      id;
    int      num_keysyms;
    KeySym   *syms_to_display;
} XStringFeedbackControl;
```

Valid masks are as follows:

```
#define DvString      (1L << 0)
```

Feedback class **BellFeedback** controls a bell on an input device, using the **BellFeedbackControl** structure. The members of that structure are:

```
typedef struct {
    XID      class;
    int      length;
    XID      id;
    int      percent;
    int      pitch;
    int      duration;
} XBellFeedbackControl;
```

Valid masks are as follows:

```
#define DvPercent     (1L << 1)
#define DvPitch       (1L << 2)
#define DvDuration    (1L << 3)
```

To ring a bell on an extension input device, use the **XDeviceBell** protocol request.

Feedback class **LedFeedback** controls lights on an input device, using the **LedFeedbackControl** structure. The members of that structure are:

```
typedef struct {
    XID      class;
    int      length;
    XID      id;
    int      led_mask;
    int      led_values;
} XLedFeedbackControl;
```

Valid masks are as follows:

```
#define DvLed         (1L << 4)
#define DvLedMode     (1L << 5)
```

Errors returned by this function: **BadDevice**, **BadMatch**, **BadFeedBack**.

2.1.9. Ringing a Bell on an Input Device

To ring a bell on an extension input device, use **XDeviceBell**.

```
int
XDeviceBell (display, device, feedbackclass, feedbackid, percent)
    Display *display;
    XDevice *device;
    XID feedbackclass, feedbackid;
    int      percent;
```

display Specifies the connection to the X server.

device Specifies the desired device.

feedbackclass Specifies the feedbackclass. Valid values are KbdFeedbackClass and BellFeedbackClass.

feedbackid Specifies the id of the feedback that has the bell.

percent Specifies the volume in the range -100 (quiet) to 100 percent (loud).

This function is analogous to the core **XBell** function. It rings the specified bell on the specified input device feedback, using the specified volume. The specified volume is relative to the base volume for the feedback. If the value for the percent argument is not in the range -100 to 100 inclusive, a **BadValue** error results. The volume at which the bell rings when the percent argument is nonnegative is:

$$\text{base} - [(\text{base} * \text{percent}) / 100] + \text{percent}$$

The volume at which the bell rings when the percent argument is negative is:

$$\text{base} + [(\text{base} * \text{percent}) / 100]$$

To change the base volume of the bell, use **XChangeFeedbackControl**.

Errors returned by this function: **BadDevice**, **BadValue**.

2.1.10. Controlling Device Encoding

To get the key mapping of an extension device that supports input class **Keys**, use **XGetDeviceKeyMapping**.

```
KeySym
*XGetDeviceKeyMapping (display, device, first_keycode_wanted,
    keycode_count, keysyms_per_keycode_return)
    Display *display;
    XDevice *device;
    KeyCode first_keycode_wanted;
    int      keycode_count;
    int      *keysyms_per_keycode_return;
```

display Specifies the connection to the X server.

device Specifies the desired device.

first_keycode_wanted
Specifies the first keycode that is to be returned.

keycode_count

Specifies the number of keycodes that are to be returned.

keysyms_per_keycode_return

Returns the number of keysyms per keycode.

This function is analogous to the core **XGetKeyboardMapping** function. It returns the symbols for the specified number of keycodes for the specified extension device.

XGetDeviceKeyMapping returns the symbols for the specified number of keycodes for the specified extension device, starting with the specified keycode. The *first_keycode_wanted* must be greater than or equal to *min-keycode* as returned by the **XListInputDevices** request (else a **BadValue** error), and

$$\text{first_keycode_wanted} + \text{keycode_count} - 1$$

must be less than or equal to *max-keycode* as returned by the **XListInputDevices** request (else a **BadValue** error).

The number of elements in the keysyms list is

$$\text{keycode_count} * \text{keysyms_per_keycode_return}$$

and KEYSYM number *N* (counting from zero) for keycode *K* has an index (counting from zero) of

$$(\text{K} - \text{first_keycode_wanted}) * \text{keysyms_per_keycode_return} + \text{N}$$

in keysyms. The *keysyms_per_keycode_return* value is chosen arbitrarily by the server to be large enough to report all requested symbols. A special KEYSYM value of **NoSymbol** is used to fill in unused elements for individual keycodes.

You should use XFree to free the data returned by this function.

If the specified device has not first been opened by this client via **XOpenDevice**, this request will fail with a **BadDevice** error. If that device does not support input class **Keys**, this request will fail with a **BadMatch** error.

Errors returned by this function: **BadDevice**, **BadMatch**, **BadValue**.

To change the keyboard mapping of an extension device that supports input class **Keys**, use **XChangeDeviceKeyMapping**.

```
int
XChangeDeviceKeyMapping (display, device, first_keycode,
    keysyms_per_keycode, keysyms, num_codes)
    Display *display;
    XDevice *device;
    int     first_keycode;
    int     keysyms_per_keycode;
    KeySym  *keysyms;
    int     num_codes;
```

display Specifies the connection to the X server.

device Specifies the desired device.

first_keycode Specifies the first keycode that is to be changed.

keysyms_per_keycode Specifies the keysyms that are to be used.
keysyms Specifies a pointer to an array of keysyms.
num_codes Specifies the number of keycodes that are to be changed.

This function is analogous to the core **XChangeKeyboardMapping** function. It defines the symbols for the specified number of keycodes for the specified extension keyboard device.

If the specified device has not first been opened by this client via **XOpenDevice**, this request will fail with a **BadDevice** error. If the specified device does not support input class Keys, this request will fail with a **BadMatch** error.

The number of elements in the keysyms list must be a multiple of *keysyms_per_keycode*. Otherwise, **XChangeDeviceKeyMapping** generates a **BadLength** error. The specified *first_keycode* must be greater than or equal to the *min_keycode* value returned by the **ListInputDevices** request, or this request will fail with a **BadValue** error. In addition, if the following expression is not less than the *max_keycode* value returned by the **ListInputDevices** request, the request will fail with a **BadValue** error:

$$\text{first_keycode} + (\text{num_codes} / \text{keysyms_per_keycode}) - 1$$

Errors returned by this function: **BadDevice**, **BadMatch**, **BadValue**, **BadAlloc**.

To obtain the keycodes that are used as modifiers on an extension device that supports input class **Keys**, use **XGetDeviceModifierMapping**.

```
XModifierKeymap
*XGetDeviceModifierMapping (display, device)
    Display *display;
    XDevice *device;
```

display Specifies the connection to the X server.
device Specifies the desired device.

This function is analogous to the core **XGetModifierMapping** function. The **XGetDeviceModifierMapping** function returns a newly created **XModifierKeymap** structure that contains the keys being used as modifiers for the specified device. The structure should be freed after use with **XFreeModifierMapping**. If only zero values appear in the set for any modifier, that modifier is disabled.

Errors returned by this function: **BadDevice**, **BadMatch**.

To set which keycodes that are to be used as modifiers for an extension device, use **XSetDeviceModifierMapping**.

```
int
XSetDeviceModifierMapping (display, device, modmap)
    Display *display;
    XDevice *device;
    XModifierKeymap *modmap;
```

display Specifies the connection to the X server.
device Specifies the desired device.
modmap Specifies a pointer to the **XModifierKeymap** structure.

This function is analogous to the core **XSetModifierMapping** function. The **XSetDeviceModifierMapping** function specifies the keycodes of the keys, if any, that are to be used as modifiers. A zero value means that no key should be used. No two arguments can have the same nonzero keycode value. Otherwise, **XSetDeviceModifierMapping** generates a **BadValue** error. There are eight modifiers, and the modifiermap member of the **XModifierKeymap** structure contains eight sets of max_keypermod keycodes, one for each modifier in the order Shift, Lock, Control, Mod1, Mod2, Mod3, Mod4, and Mod5. Only nonzero keycodes have meaning in each set, and zero keycodes are ignored. In addition, all of the nonzero keycodes must be in the range specified by min_keycode and max_keycode reported by the **XListInputDevices** function. Otherwise, **XSetModifierMapping** generates a **BadValue** error. No keycode may appear twice in the entire map. Otherwise, it generates a **BadValue** error.

A X server can impose restrictions on how modifiers can be changed, for example, if certain keys do not generate up transitions in hardware or if multiple modifier keys are not supported. If some such restriction is violated, the status reply is **MappingFailed**, and none of the modifiers are changed. If the new keycodes specified for a modifier differ from those currently defined and any (current or new) keys for that modifier are in the logically down state, the status reply is **MappingBusy**, and none of the modifiers are changed. **XSetModifierMapping** generates a **DeviceMappingNotify** event on a **MappingSuccess** status.

XSetDeviceModifierMapping can generate **BadDevice**, **BadMatch**, **BadAlloc**, and **BadValue** errors.

2.1.11. Controlling Button Mapping

To set the mapping of the buttons on an extension device, use **XSetDeviceButtonMapping**.

```
int
XSetDeviceButtonMapping (display, device, map, nmap)
    Display      *display;
    XDevice      *device;
    unsigned char map[];
    int          nmap;
```

display Specifies the connection to the X server.
device Specifies the desired device.
map Specifies the mapping list.
nmap Specifies the number of items in the mapping list.

The **XSetDeviceButtonMapping** function sets the mapping of the buttons on an extension device. If it succeeds, the X server generates a **DeviceMappingNotify** event, and **XSetDeviceButtonMapping** returns **MappingSuccess**. Elements of the list are indexed starting from one. The length of the list must be the same as **XGetDeviceButtonMapping** would return, or a **BadValue** error results. The index is a button number, and the element of the list defines the effective number. A zero element disables a button, and elements are not restricted in value by the number of physical buttons. However, no two elements can have the same nonzero value, or a **BadValue** error results. If any of the buttons to be altered are logically in the down state, **XSetDeviceButtonMapping** returns **MappingBusy**, and the mapping is not changed.

XSetDeviceButtonMapping can generate **BadDevice**, **BadMatch**, and **BadValue** errors.

To get the button mapping, use **XGetDeviceButtonMapping**.

```
int
XGetDeviceButtonMapping (display, device, map_return, nmap)
    Display      *display;
    XDevice      *device;
    unsigned char map_return[];
    int          nmap;
```

display Specifies the connection to the X server.

device Specifies the desired device.

map_return Specifies the mapping list.

nmap Specifies the number of items in the mapping list.

The **XGetDeviceButtonMapping** function returns the current mapping of the specified extension device. Elements of the list are indexed starting from one. **XGetDeviceButtonMapping** returns the number of physical buttons actually on the pointer. The nominal mapping for the buttons is the identity mapping: map[i]=i. The nmap argument specifies the length of the array where the button mapping is returned, and only the first nmap elements are returned in map_return.

Errors returned by this function: **BadDevice**, **BadMatch**.

2.1.12. Obtaining The State Of A Device

To obtain information that describes the state of the keys, buttons and valuator of an extension device, use **XQueryDeviceState**.

```
XDeviceState
*XQueryDeviceState (display, device)
    Display *display;
    XDevice *device;
```

display Specifies the connection to the X server.

device Specifies the desired device.

The **XQueryDeviceState** function returns a pointer to an **XDeviceState** structure. This structure points to a list of structures that describe the state of the keys, buttons, and valuator on the device.

```
typedef struct {
    XID      device_id;
    int      num_classes;
    XInputClass *data;
} XDeviceState;
```

- The structures are of variable length, but the first two fields are common to all. The common fields are as follows:

```
typedef struct
{
    unsigned char    class;
    unsigned char    length;
} XInputClass;
```

The **class** field contains a class identifier. This identifier can be compared with constants defined in the file **XI.h**. Currently defined constants are: **KeyClass**, **ButtonClass**, and **ValuatorClass**.

The **length** field contains the length of the structure and can be used by clients to traverse the list.

- The **XValuatorState** structure describes the current state of the valuator on the device. The **num_valuators** field contains the number of valuator on the device. The **mode** field is a mask whose bits report the data mode and other state information for the device. The following bits are currently defined:

```
DeviceMode    1 << 0    Relative = 0, Absolute = 1
ProximityState 1 << 1    InProximity = 0, OutOfProximity = 1
```

The **valuators** field contains a pointer to an array of integers that describe the current value of the valuator. If the mode is **Relative**, these values are undefined.

```
typedef struct {
    unsigned char    class;
    unsigned char    length;
    unsigned char    num_valuators;
    unsigned char    mode;
    int              *valuators;
} XValuatorState;
```

- The **XKeyState** structure describes the current state of the keys on the device. Byte N (from 0) contains the bits for key 8N to 8N+7 with the least significant bit in the byte representing key 8N.

```
typedef struct {
    unsigned char    class;
    unsigned char    length;
    short            num_keys;
    char              keys[32];
} XKeyState;
```

- The **XButtonState** structure describes the current state of the buttons on the device. Byte N (from 0) contains the bits for button 8N to 8N+7 with the least significant bit in the byte representing button 8N.

```
typedef struct {
    unsigned char    class;
    unsigned char    length;
    short           num_buttons;
    char            buttons[32];
} XButtonState;
```

You should use **XFreeDeviceState** to free the data returned by this function.

Errors returned by this function: **BadDevice**.

```
void
XFreeDeviceState (state)
    XDeviceState *state;
```

state Specifies the pointer to the **XDeviceState** data returned by a previous call to **XQueryDeviceState**.

This function frees the device state data.

2.2. Events and Event-Handling Functions

The input extension creates input events analogous to the core input events. These extension input events are generated by manipulating one of the extension input devices. The following sections describe these events and explain how a client program can receive them.

2.2.1. Event Types

Event types are integer numbers that a client can use to determine what kind of event it has received. The client compares the type field of the event structure with known event types to make this determination.

The core input event types are constants and are defined in the header file **<X11/X.h>**. Extension event types are not constants. Instead, they are dynamically allocated by the extension's request to the X server when the extension is initialized. Because of this, extension event types must be obtained by the client from the server.

The client program determines the event type for an extension event by using the information returned by the **XOpenDevice** request. This type can then be used for comparison with the type field of events received by the client.

Extension events propagate up the window hierarchy in the same manner as core events. If a window is not interested in an extension event, it usually propagates to the closest ancestor that is interested, unless the `dont_propagate` list prohibits it. Grabs of extension devices may alter the set of windows that receive a particular extension event.

The following table lists the event category and its associated event type or types.

Event Category	Event Type
Device key events	<i>DeviceKeyPress</i> , <i>DeviceKeyRelease</i>
Device motion events	<i>DeviceButtonPress</i> , <i>DeviceButtonRelease</i> , <i>DeviceMotionNotify</i>
Device input focus events	<i>DeviceFocusIn</i> , <i>DeviceFocusOut</i>
Device state notification events	<i>DeviceStateNotify</i>
Device proximity events	<i>ProximityIn</i> , <i>ProximityOut</i>
Device mapping events	<i>DeviceMappingNotify</i>
Device change events	<i>ChangeDeviceNotify</i>

2.2.2. Event Classes

Event classes are integer numbers that are used in the same way as the core event masks. They are used by a client program to indicate to the server which events that client program wishes to receive.

The core input event masks are constants and are defined in the header file `<X11/X.h>`. Extension event classes are not constants. Instead, they are dynamically allocated by the extension's request to the X server when the extension is initialized. Because of this, extension event classes must be obtained by the client from the server.

The event class for an extension event and device is obtained from information returned by the **XOpenDevice** function. This class can then be used in an **XSelectExtensionEvent** request to ask that events of that type from that device be sent to the client program.

For **DeviceButtonPress** events, the client may specify whether or not an implicit passive grab should be done when the button is pressed. If the client wants to guarantee that it will receive a **DeviceButtonRelease** event for each **DeviceButtonPress** event it receives, it should specify the **DeviceButtonPressGrab** class in addition to the **DeviceButtonPress** class. This restricts the client in that only one client at a time may request **DeviceButtonPress** events from the same device and window if any client specifies this class.

If any client has specified the **DeviceButtonPressGrab** class, any requests by any other client that specify the same device and window and specify either **DeviceButtonPress** or **DeviceButtonPressGrab** will cause an **Access** error to be generated.

If only the **DeviceButtonPress** class is specified, no implicit passive grab will be done when a button is pressed on the device. Multiple clients may use this class to specify the same device and window combination.

The client may also select **DeviceMotion** events only when a button is down. It does this by specifying the event classes **DeviceButton1Motion** through **DeviceButton5Motion**. An input device will only support as many button motion classes as it has buttons.

2.2.3. Event Structures

Each extension event type has a corresponding structure declared in `<X11/extensions/XInput.h>`. All event structures have the following members:

<i>type</i>	Set to the event type number that uniquely identifies it. For example, when the X server reports a DeviceKeyPress event to a client application, it sends an XDeviceKeyPressEvent structure.
<i>display</i>	Set to a pointer to a structure that defines the display the event was read on.

send_event Set to **True** if the event came from an **XSendEvent** request.

serial Set from the serial number reported in the protocol but expanded from the 16-bit least-significant bits to a full 32-bit value.

Extension event structures report the current position of the X pointer. In addition, if the device reports motion data and is reporting absolute data, the current value of any valuator the device contains is also reported.

2.2.3.1. Device Key Events

Key events from extension devices contain all the information that is contained in a key event from the X keyboard. In addition, they contain a device id and report the current value of any valuator on the device, if that device is reporting absolute data. If data for more than six valuator is being reported, more than one key event will be sent. The *axes_count* field contains the number of axes that are being reported. The server sends as many of these events as are needed to report the device data. Each event contains the total number of axes reported in the *axes_count* field, and the first axis reported in the current event in the *first_axis* field. If the device supports input class **Valuators**, but is not reporting absolute mode data, the *axes_count* field contains 0.

The location reported in the *x,y* and *x_root,y_root* fields is the location of the core X pointer.

The `XDeviceKeyEvent` structure is defined as follows:

```
typedef struct
{
    int          type;          /* of event */
    unsigned long serial;       /* # of last request processed */
    Bool         send_event;    /* true if from SendEvent request */
    Display      *display;      /* Display the event was read from */
    Window       window;        /* "event" window reported relative to */
    XID          deviceid;
    Window       root;          /* root window event occurred on */
    Window       subwindow;     /* child window */
    Time         time;          /* milliseconds */
    int          x, y;          /* x, y coordinates in event window */
    int          x_root;        /* coordinates relative to root */
    int          y_root;        /* coordinates relative to root */
    unsigned int state;         /* key or button mask */
    unsigned int keycode;       /* detail */
    Bool         same_screen;   /* same screen flag */
    unsigned char axes_count;
    unsigned char first_axis;
    unsigned int device_state; /* device key or button mask */
    int          axis_data[6];
} XDeviceKeyEvent;

typedef XDeviceKeyEvent XDeviceKeyPressedEvent;
typedef XDeviceKeyEvent XDeviceKeyReleasedEvent;
```

2.2.3.2. Device Button Events

Button events from extension devices contain all the information that is contained in a button event from the X pointer. In addition, they contain a device id and report the current value of any valuator on the device, if that device is reporting absolute data. If data for more than six valuator is being reported, more than one button event may be sent. The *axes_count* field contains the number of axes that are being reported. The server sends as many of these events as are needed

to report the device data. Each event contains the total number of axes reported in the `axes_count` field, and the first axis reported in the current event in the `first_axis` field. If the device supports input class **Valuators**, but is not reporting absolute mode data, the `axes_count` field contains 0.

The location reported in the `x,y` and `x_root,y_root` fields is the location of the core X pointer.

```
typedef struct {
    int         type;           /* of event */
    unsigned long serial;       /* # of last request processed by server */
    Bool        send_event;     /* true if from a SendEvent request */
    Display     *display;       /* Display the event was read from */
    Window      window;         /* "event" window reported relative to */
    XID         deviceid;
    Window      root;           /* root window that the event occurred on */
    Window      subwindow;      /* child window */
    Time        time;           /* milliseconds */
    int         x, y;           /* x, y coordinates in event window */
    int         x_root;         /* coordinates relative to root */
    int         y_root;         /* coordinates relative to root */
    unsigned int state;         /* key or button mask */
    unsigned int button;        /* detail */
    Bool        same_screen;    /* same screen flag */
    unsigned char axes_count;
    unsigned char first_axis;
    unsigned int device_state; /* device key or button mask */
    int         axis_data[6];
} XDeviceButtonEvent;

typedef XDeviceButtonEvent XDeviceButtonPressedEvent;
typedef XDeviceButtonEvent XDeviceButtonReleasedEvent;
```

2.2.3.3. Device Motion Events

Motion events from extension devices contain all the information that is contained in a motion event from the X pointer. In addition, they contain a device id and report the current value of any valuators on the device.

The location reported in the `x,y` and `x_root,y_root` fields is the location of the core X pointer, and so is 2-dimensional.

Extension motion devices may report motion data for a variable number of axes. The `axes_count` field contains the number of axes that are being reported. The server sends as many of these events as are needed to report the device data. Each event contains the total number of axes reported in the `axes_count` field, and the first axis reported in the current event in the `first_axis` field.

```

typedef struct
{
    int            type;           /* of event */
    unsigned long  serial;        /* # of last request processed by server */
    Bool           send_event;    /* true if from a SendEvent request */
    Display        *display;      /* Display the event was read from */
    Window         window;        /* "event" window reported relative to */
    XID            deviceid;
    Window         root;          /* root window that the event occurred on */
    Window         subwindow;     /* child window */
    Time           time;          /* milliseconds */
    int            x, y;          /* x, y coordinates in event window */
    int            x_root;        /* coordinates relative to root */
    int            y_root;        /* coordinates relative to root */
    unsigned int   state;         /* key or button mask */
    char           is_hint;       /* detail */
    Bool           same_screen;   /* same screen flag */
    unsigned int   device_state;  /* device key or button mask */
    unsigned char  axes_count;
    unsigned char  first_axis;
    int            axis_data[6];
} XDeviceMotionEvent;

```

2.2.3.4. Device Focus Events

These events are equivalent to the core focus events. They contain the same information, with the addition of a device id to identify which device has had a focus change, and a timestamp.

DeviceFocusIn and **DeviceFocusOut** events are generated for focus changes of extension devices in the same manner as core focus events are generated.

```

typedef struct
{
    int            type;           /* of event */
    unsigned long  serial;        /* # of last request processed by server */
    Bool           send_event;    /* true if this came from a SendEvent request */
    Display        *display;      /* Display the event was read from */
    Window         window;        /* "event" window it is reported relative to */
    XID            deviceid;
    int            mode;          /* NotifyNormal, NotifyGrab, NotifyUngrab */
    int            detail;
    /*
     * NotifyAncestor, NotifyVirtual, NotifyInferior,
     * NotifyNonLinear, NotifyNonLinearVirtual, NotifyPointer,
     * NotifyPointerRoot, NotifyDetailNone
     */
    Time           time;
} XDeviceFocusChangeEvent;

typedef XDeviceFocusChangeEvent XDeviceFocusInEvent;
typedef XDeviceFocusChangeEvent XDeviceFocusOutEvent;

```

2.2.3.5. Device StateNotify Event

This event is analogous to the core keymap event, but reports the current state of the device for each input class that it supports. It is generated after every **DeviceFocusIn** event and **EnterNotify** event and is delivered to clients who have selected **XDeviceStateNotify** events.

If the device supports input class Valuators, the mode field in the **XValuatorStatus** structure is a bitmask that reports the device mode, proximity state and other state information. The following bits are currently defined:

```

0x01    Relative = 0, Absolute = 1
0x02    InProximity = 0, OutOfProximity = 1

```

If the device supports more valuators than can be reported in a single **XEvent**, multiple **XDeviceStateNotify** events will be generated.

```

typedef struct
{
    unsigned char class;
    unsigned char length;
} XInputClass;

typedef struct {
    int          type;
    unsigned long serial;      /* # of last request processed by server */
    Bool         send_event;  /* true if this came from a SendEvent request */
    Display      *display;    /* Display the event was read from */
    Window       window;
    XID          deviceid;
    Time         time;
    int          num_classes;
    char         data[64];
} XDeviceStateNotifyEvent;

typedef struct {
    unsigned char class;
    unsigned char length;
    unsigned char num_valuators;
    unsigned char mode;
    int          valuators[6];
} XValuatorStatus;

typedef struct {
    unsigned char class;
    unsigned char length;
    short        num_keys;
    char         keys[32];
} XKeyStatus;

typedef struct {
    unsigned char class;
    unsigned char length;
    short        num_buttons;
    char         buttons[32];
} XButtonStatus;

```

2.2.3.6. Device Mapping Event

This event is equivalent to the core MappingNotify event. It notifies client programs when the mapping of keys, modifiers, or buttons on an extension device has changed.

```
typedef struct {
    int            type;
    unsigned long  serial;
    Bool           send_event;
    Display        *display;
    Window         window;
    XID            deviceid;
    Time          time;
    int            request;
    int            first_keycode;
    int            count;
} XDeviceMappingEvent;
```

2.2.3.7. ChangeDeviceNotify Event

This event has no equivalent in the core protocol. It notifies client programs when one of the core devices has been changed.

```
typedef struct {
    int            type;
    unsigned long  serial;
    Bool           send_event;
    Display        *display;
    Window         window;
    XID            deviceid;
    Time          time;
    int            request;
} XChangeDeviceNotifyEvent;
```

2.2.3.8. Proximity Events

These events have no equivalent in the core protocol. Some input devices such as graphics tablets or touchscreens may send these events to indicate that a stylus has moved into or out of contact with a positional sensing surface.

The event contains the current value of any valuator on the device, if that device is reporting absolute data. If data for more than six valuators is being reported, more than one proximity event may be sent. The `axes_count` field contains the number of axes that are being reported. The server sends as many of these events as are needed to report the device data. Each event contains the total number of axes reported in the `axes_count` field, and the first axis reported in the current event in the `first_axis` field. If the device supports input class **Valuators**, but is not reporting absolute mode data, the `axes_count` field contains 0.

```

typedef struct
{
    int            type;        /* ProximityIn or ProximityOut */
    unsigned long  serial;      /* # of last request processed by server */
    Bool           send_event; /* true if this came from a SendEvent request */
    Display        *display;    /* Display the event was read from */
    Window         window;
    XID            deviceid;
    Window         root;
    Window         subwindow;
    Time           time;
    int            x, y;
    int            x_root, y_root;
    unsigned int   state;
    Bool           same_screen;
    unsigned char  axes_count;
    unsigned char  first_axis;
    unsigned int   device_state; /* device key or button mask */
    int            axis_data[6];
} XProximityNotifyEvent;

typedef XProximityNotifyEvent XProximityInEvent;
typedef XProximityNotifyEvent XProximityOutEvent;

```

2.2.4. Determining The Extension Version

```

XExtensionVersion
*XGetExtensionVersion (display, name)
    Display *display;
    char     *name;

```

display Specifies the connection to the X server.

name Specifies the name of the desired extension.

This function allows a client to determine if a server supports the desired version of the input extension.

The **XExtensionVersion** structure returns information about the version of the extension supported by the server. The structure is defined as follows:

```

typedef struct
{
    Bool  present;
    short major_version;
    short minor_version;
} XExtensionVersion;

```

The major and minor versions can be compared with constants defined in the header file **XI.h**. Each version is a superset of the previous versions.

You should use **XFree** to free the data returned by this function.

2.2.5. Listing Available Devices

A client program that wishes to access a specific device must first determine whether that device is connected to the X server. This is done through the **XListInputDevices** function, which will return a list of all devices that can be opened by the X server. The client program can use one of the names defined in the **XI.h** header file in an **XInternAtom** request, to determine the device type of the desired device. This type can then be compared with the device types returned by the **XListInputDevices** request.

```
XDeviceInfo
*XListInputDevices (display, ndevices)
    Display *display;
    int      *ndevices;           /* RETURN */
```

display Specifies the connection to the X server.

ndevices Specifies the address of a variable into which the server can return the number of input devices available to the X server.

This function allows a client to determine which devices are available for X input and information about those devices. An array of **XDeviceInfo** structures is returned, with one element in the array for each device. The number of devices is returned in the **ndevices** argument.

The X pointer device and X keyboard device are reported, as well as all available extension input devices. The use field of the **XDeviceInfo** structure specifies the current use of the device. If the value of this field is **IsXPointer**, the device is the X pointer device. If the value is **IsXKeyboard**, the device is the X keyboard device. If the value is **IsXExtensionDevice**, the device is available for use as an extension input device.

Each **XDeviceInfo** entry contains a pointer to a list of structures that describe the characteristics of each class of input supported by that device. The **num_classes** field contains the number of entries in that list.

If the device supports input class **Valuators**, one of the structures pointed to by the **XDeviceInfo** structure will be an **XValuatorInfo** structure. The **axes** field of that structure contains the address of an array of **XAxisInfo** structures. There is one element in this array for each axis of motion reported by the device. The number of elements in this array is contained in the **num_axes** element of the **XValuatorInfo** structure. The size of the motion buffer for the device is reported in the **motion_buffer** field of the **XValuatorInfo** structure.

The **XDeviceInfo** structure contains the following information:

```
typedef struct _XDeviceInfo
{
    XID          id;
    Atom         type;
    char        *name;
    int          num_classes;
    int          use;
    XAnyClassPtr inputclassinfo;
} XDeviceInfo;
```

The structures pointed to by the **XDeviceInfo** structure contain the following information:

```

typedef struct _XKeyInfo
{
    XID          class;
    int          length;
    unsigned short min_keycode;
    unsigned short max_keycode;
    unsigned short num_keys;
} XKeyInfo;

typedef struct _XButtonInfo {
    XID          class;
    int          length;
    short        num_buttons;
} XButtonInfo;

typedef struct _XValuatorInfo
{
    XID          class;
    int          length;
    unsigned char num_axes;
    unsigned char mode;
    unsigned long motion_buffer;
    XAxisInfoPtr axes;
} XValuatorInfo;

```

The **XAxisInfo** structure pointed to by the **XValuatorInfo** structure contains the following information.

```

typedef struct _XAxisInfo {
    int resolution;
    int min_value;
    int max_value;
} XAxisInfo;

```

The following atom names are defined in the file **XI.h**:

MOUSE
 TABLET
 KEYBOARD
 TOUCHSCREEN
 TOUCHPAD
 BUTTONBOX
 BARCODE
 KNOB_BOX
 TRACKBALL
 QUADRATURE
 SPACEBALL
 DATAGLOVE
 EYETRACKER
 CURSORKEYS
 FOOTMOUSE
 ID_MODULE
 ONE_KNOB
 NINE_KNOB

These names can be used in an **XInternAtom** request to return an atom that can be used for comparison with the type field of the **XDeviceInfo** structure.

This function returns NULL if there are no input devices to list. You should use **XFreeDeviceList** to free the data returned by **XListInputDevices**.

```

void
XFreeDeviceList (list)
    XDeviceInfo *list;
  
```

list Specifies the pointer to the **XDeviceInfo** array returned by a previous call to **XListInputDevices**.

This function frees the list of input device information.

2.2.6. Enabling And Disabling Extension Devices

Each client program that wishes to access an extension device must request that the server open that device. This is done via the **XOpenDevice** request. That request is defined as follows:

```

XDevice
*XOpenDevice(display, device_id)
    Display *display;
    XID     device_id;
  
```

display Specifies the connection to the X server.

device_id Specifies the ID that uniquely identifies the device to be opened. This ID is obtained from the **XListInputDevices** request.

This function opens the device for the requesting client and returns an **XDevice** structure on success. That structure is defined as follows:

```
typedef struct {
    XID                device_id;
    int                num_classes;
    XInputClassInfo    *classes;
} XDevice;
```

The **XDevice** structure contains a pointer to an array of **XInputClassInfo** structures. Each element in that array contains information about events of a particular input class supported by the input device.

The **XInputClassInfo** structure is defined as follows:

```
typedef struct {
    unsigned char input_class;
    unsigned char event_type_base;
} XInputClassInfo;
```

A client program can determine the event type and event class for a given event by using macros defined by the input extension. The name of the macro corresponds to the desired event, and the macro is passed the structure that describes the device from which input is desired, i.e.

```
DeviceKeyPress (XDevice *device, event_type, event_class)
```

The macro will fill in the values of the event class to be used in an **XSelectExtensionEvent** request to select the event, and the event type to be used in comparing with the event types of events received via **XNextEvent**.

Errors returned by this function: **BadDevice**.

Before terminating, the client program should request that the server close the device. This is done via the **XCloseDevice** request.

A client may open the same extension device more than once. Requests after the first successful one return an additional **XDevice** structure with the same information as the first, but otherwise have no effect. A single **XCloseDevice** request will terminate that client's access to the device.

Closing a device releases any active or passive grabs the requesting client has established. If the device is frozen only by an active grab of the requesting client, any queued events are released.

If a client program terminates without closing a device, the server will automatically close that device on behalf of the client. This does not affect any other clients that may be accessing that device.

```
int
XCloseDevice(display, device)
    Display *display;
    XDevice *device;
```

display Specifies the connection to the X server.

device Specifies the device to be closed.

This function closes the device for the requesting client, and frees the **XDevice** structure.

Errors returned by this function: **BadDevice**.

2.2.7. Changing The Mode Of A Device

Some devices are capable of reporting either relative or absolute motion data. To change the mode of a device from relative to absolute, use the **XSetDeviceMode** function. The valid values are **Absolute** or **Relative**.

```
int
XSetDeviceMode (display, device, mode)
    Display *display;
    XDevice *device;
    int      mode;
```

display Specifies the connection to the X server.

device Specifies the device whose mode should be changed.

mode Specifies the mode. You can specify one of these constants: **Absolute** or **Relative**.

This function allows a client to request the server to change the mode of a device that is capable of reporting either absolute positional data or relative motion data. If the device is invalid, or the client has not previously requested that the server open the device via an **XOpenDevice** request, this request will fail with a **BadDevice** error. If the device does not support input class **Valuators**, or if it is not capable of reporting the specified mode, the request will fail with a **BadMatch** error.

This request will fail and return **DeviceBusy** if another client has already opened the device and requested a different mode.

Errors returned by this function: **BadDevice**, **BadMatch**, **BadMode**, **DeviceBusy**.

2.2.8. Initializing Valuators on an Input Device

Some devices that report absolute positional data can be initialized to a starting value. Devices that are capable of reporting relative motion or absolute positional data may require that their valuators be initialized to a starting value after the mode of the device is changed to **Absolute**. To initialize the valuators on such a device, use the **XSetDeviceValuators** function.

```
Status
XSetDeviceValuators (display, device, valuators, first_valuator,
    num_valuators)
    Display *display;
    XDevice *device;
    int      *valuators, first_valuator, num_valuators;
```

display Specifies the connection to the X server.

device Specifies the device whose valuators should be initialized.

valuators Specifies the values to which each valuator should be set.

first_valuator Specifies the first valuator to be set.

num_valuators Specifies the number of valuators to be set.

This function initializes the specified valuator on the specified extension input device. Valuator are numbered beginning with zero. Only the valuator in the range specified by `first_valuator` and `num_valuators` are set. If the number of valuator supported by the device is less than the expression

```
first_valuator + num_valuators,
```

a **BadValue** error will result.

If the request succeeds, Success **is returned**. **If the specified device is grabbed by some other client, the request will fail and a status of AlreadyGrabbed will be returned.**

This request can fail with **BadLength**, **BadDevice**, **BadMatch**, and **BadValue** errors.

2.2.9. Getting Input Device Controls

Some input devices support various configuration controls that can be queried or changed by clients. The set of supported controls will vary from one input device to another. Requests to manipulate these controls will fail if either the target X server or the target input device does not support the requested device control.

Each device control has a unique identifier. Information passed with each device control varies in length and is mapped by data structures unique to that device control.

To query a device control use `XGetDeviceControl`.

```
XDeviceControl
*XGetDeviceControl (display, device, control)
    Display *display;
    XDevice *device;
    int control;
```

<i>display</i>	Specifies the connection to the X server.
<i>device</i>	Specifies the device whose configuration control status is to be returned.
<i>control</i>	Identifies the specific device control to be queried.

This request returns the current state of the specified device control. If the target X server does not support that device control, a **BadValue** error will be returned. If the specified device does not support that device control, a **BadMatch** error will be returned.

If the request is successful, a pointer to a generic `XDeviceState` structure is returned. The information returned varies according to the specified control and is mapped by a structure appropriate for that control. The first two fields are common to all device controls:

```
typedef struct {
    XID      control;
    int      length;
} XDeviceState;
```

The control may be compared to constants defined in the file `XI.h`. Currently defined device controls include `DEVICE_RESOLUTION`.

The information returned for the `DEVICE_RESOLUTION` control is defined in the following structure: include:

```
typedef struct {
    XID      control;
    int      length;
    int      num_valuators;
    int      *resolutions;
    int      *min_resolutions;
    int      *max_resolutions;
} XDeviceResolutionState;
```

This device control returns a list of valuator and the range of valid resolutions allowed for each. Valuator are numbered beginning with 0. Resolutions for all valuator on the device are returned. For each valuator *i* on the device, `resolutions[i]` returns the current setting of the resolution, `min_resolutions[i]` returns the minimum valid setting, and `max_resolutions[i]` returns the maximum valid setting.

When this control is specified, `XGetDeviceControl` will fail with a `BadMatch` error if the specified device has no valuator.

Other errors returned by this request: `BadValue`.

2.2.10. Changing Input Device Controls

Some input devices support various configuration controls that can be changed by clients. Typically, this would be done to initialize the device to a known state or configuration. The set of supported controls will vary from one input device to another. Requests to manipulate these controls will fail if either the target X server or the target input device does not support the requested device control. Setting the device control will also fail if the target input device is grabbed by another client, or is open by another client and has been set to a conflicting state.

Each device control has a unique identifier. Information passed with each device control varies in length and is mapped by data structures unique to that device control.

To change a device control use `XChangeDeviceControl`.

```
Status
XChangeDeviceControl (display, device, control, value)
    Display *display;
    XDevice *device;
    int control;
    XDeviceControl *value;
```

<i>display</i>	Specifies the connection to the X server.
<i>device</i>	Specifies the device whose configuration control status is to be modified.
<i>control</i>	Identifies the specific device control to be changed.
<i>value</i>	Specifies a pointer to an <code>XDeviceControl</code> structure that describes which control is to be changed, and how it is to be changed.

This request changes the current state of the specified device control. If the target X server does not support that device control, a `BadValue` error will be returned. If the specified device does not support that device control, a `BadMatch` error will be returned. If another client has the target device grabbed, a status of `AlreadyGrabbed` will be returned. If another client has the device open and has set it to a conflicting state, a status of `DeviceBusy` will be returned.

If the request fails for any reason, the device control will not be changed.

If the request is successful, the device control will be changed and a status of Success will be returned. The information passed varies according to the specified control and is mapped by a structure appropriate for that control. The first two fields are common to all device controls:

```
typedef struct {
    XID      control;
    int      length;
} XDeviceControl;
```

The control may be set using constants defined in the file XI.h. Currently defined device controls include DEVICE_RESOLUTION.

The information that can be changed by the DEVICE_RESOLUTION control is defined in the following structure:

```
typedef struct {
    XID      control;
    int      length;
    int      first_valuator;
    int      num_valuators;
    int      *resolutions;
} XDeviceResolutionControl;
```

This device control changes the resolution of the specified valuator on the specified extension input device. Valuator are numbered beginning with zero. Only the valuator in the range specified by first_valuator and num_valuators are set. A value of -1 in the resolutions list indicates that the resolution for this valuator is not to be changed. num_valuators specifies the number of valuator in the resolutions list.

When this control is specified, XChangeDeviceControl will fail with a BadMatch error if the specified device has no valuator. If a resolution is specified that is not within the range of valid values (as returned by XGetDeviceControl) the request will fail with a BadValue error. If the number of valuator supported by the device is less than the expression

$$\text{first_valuator} + \text{num_valuators},$$

a BadValue error will result.

2.2.11. Selecting Extension Device Events

Device input events are selected using the **XSelectExtensionEvent** function. The parameters passed are a pointer to a list of classes that define the desired event types and devices, a count of the number of elements in the list, and the id of the window from which events are desired.

```

int
XSelectExtensionEvent (display, window, event_list, event_count)
    Display      *display;
    Window       window;
    XEventClass  *event_list;
    int          event_count;

```

display Specifies the connection to the X server.

window Specifies the ID of the window from which the client wishes to receive events.

event_list Specifies a pointer to a list of XEventClasses that specify which events are desired.

event_count Specifies the number of elements in the event_list.

This function requests the server to send events that match the events and devices described by the event list and that come from the requested window. The elements of the XEventClass array are the event_class values returned obtained by invoking a macro with the pointer to a Device structure returned by the **XOpenDevice** request. For example, the DeviceKeyPress macro, invoked in the form:

```
DeviceKeyPress (XDevice *device, event_type, event_class)
```

returns the XEventClass for DeviceKeyPress events from the specified device.

Macros are defined for the following event classes: **DeviceKeyPress**, **DeviceKeyRelease**, **DeviceButtonPress**, **DeviceButtonRelease**, **DeviceMotionNotify**, **DeviceFocusIn**, **DeviceFocusOut**, **ProximityIn**, **ProximityOut**, **DeviceStateNotify**, **DeviceMappingNotify**, **ChangeDeviceNotify**, **DevicePointerMotionHint**, **DeviceButton1Motion**, **DeviceButton2Motion**, **DeviceButton3Motion**, **DeviceButton4Motion**, **DeviceButton5Motion**, **DeviceButtonMotion**, **DeviceOwnerGrabButton**, and **DeviceButtonPressGrab**. To get the next available event from within a client program, use the core **XNextEvent** function. This returns the next event whether it came from a core device or an extension device.

Succeeding XSelectExtensionEvent requests using XEventClasses for the same device as was specified on a previous request will replace the previous set of selected events from that device with the new set.

Errors returned by this function: **BadWindow**, **BadAccess**, **BadClass**, **BadLength**.

2.2.12. Determining Selected Device Events

To determine which extension events are currently selected from a given window, use **XGetSelectedExtensionEvents**.

```

int
XGetSelectedExtensionEvents (display, window, this_client_count,
                             this_client, all_clients_count, all_clients)
    Display      *display;
    Window       window;
    int          *this_client_count; /* RETURN */
    XEventClass **this_client;      /* RETURN */
    int          *all_clients_count; /* RETURN */
    XEventClass **all_clients;      /* RETURN */

```

display Specifies the connection to the X server.

window Specifies the ID of the window from which the client wishes to receive events.

this_client_count

Specifies the number of elements in the *this_client* list.

this_client Specifies a pointer to a list of XEventClasses that specify which events are selected by this client.

all_clients_count

Specifies the number of elements in the *all_clients* list.

all_clients Specifies a pointer to a list of XEventClasses that specify which events are selected by all clients.

This function returns pointers to two event class arrays. One lists the extension events selected by this client from the specified window. The other lists the extension events selected by all clients from the specified window. This information is analogous to that returned in the fields *your_event_mask* and *all_event_masks* of the **XWindowAttributes** structure when an **XGetWindowAttributes** request is made.

You should use **XFree** to free the two arrays returned by this function.

Errors returned by this function: **BadWindow**.

2.2.13. Controlling Event Propagation

Extension events propagate up the window hierarchy in the same manner as core events. If a window is not interested in an extension event, it usually propagates to the closest ancestor that is interested, unless the *dont_propagate* list prohibits it. Grabs of extension devices may alter the set of windows that receive a particular extension event.

Client programs may control event propagation through the use of the following two functions.

XChangeDeviceDontPropagateList adds an event to or deletes an event from the *do_not_propagate* list of extension events for the specified window. There is one list per window, and the list remains for the life of the window. The list is not altered if a client that changed the list terminates.

Suppression of event propagation is not allowed for all events. If a specified XEventClass is invalid because suppression of that event is not allowed, a **BadClass** error will result.

```

int
XChangeDeviceDontPropagateList (display, window, event_count,
                                events, mode)
    Display      *display;
    Window       window;
    int          event_count;
    XEventClass  *events;
    int          mode;

```

display Specifies the connection to the X server.

window Specifies the desired window.

event_count Specifies the number of elements in the events list.

events Specifies a pointer to the list of XEventClasses.

mode Specifies the mode. You may use the constants **AddToList** or **DeleteFromList**.

This function can return **BadWindow**, **BadClass**, and **BadMode** errors.

XGetDeviceDontPropagateList allows a client to determine the `do_not_propagate` list of extension events for the specified window.

```

XEventClass
*XGetDeviceDontPropagateList (display, window, event_count)
    Display *display;
    Window  window;
    int     *event_count;    /*RETURN */

```

display Specifies the connection to the X server.

window Specifies the desired window.

event_count Specifies the number of elements in the array returned by this function.

An array of **XEventClasses** is returned by this function. Each XEventClass represents a device/event type pair.

This function can return a **BadWindow** error.

You should use **XFree** to free the data returned by this function.

2.2.14. Sending An Event

XSendExtensionEvent allows a client to send an extension event to another client.

```

int
XSendExtensionEvent (display, device, window, propagate,
                    event_count, event_list, event)
    Display      *display;
    XDevice      *device;
    Window       window;
    Bool         propagate;
    int          event_count;
    XEventClass  *event_list;
    XEvent       *event;

```

display Specifies the connection to the X server.

device Specifies the device whose ID is recorded in the event.

window Specifies the destination window ID. You can pass a window ID, **PointerWindow** or **InputFocus**.

propagate Specifies a boolean value that is either True or False.

event_count Specifies the number of elements in the *event_list* array.

event_list Specifies a pointer to an array of XEventClasses.

event Specifies a pointer to the event that is to be sent.

The XSendExtensionEvent function identifies the destination window, determines which clients should receive the specified event, and ignores any active grabs. This function requires a list of XEventClasses to be specified. These are obtained by opening an input device with the XOpenDevice request.

This function uses the **window** argument to identify the destination window as follows:

- If you pass **PointerWindow**, the destination window is the window that contains the pointer.
- If you pass **InputFocus**, and if the focus window contains the pointer, the destination window is the window that contains the pointer. If the focus window does not contain the pointer, the destination window is the focus window.

To determine which clients should receive the specified events, XSendExtensionEvent uses the *propagate* argument as follows:

- If *propagate* is **False**, the event is sent to every client selecting from the destination window any of the events specified in the *event_list* array.
- If *propagate* is **True**, and no clients have selected from the destination window any of the events specified in the *event_list* array, the destination is replaced with the closest ancestor of destination for which some client has selected one of the specified events, and for which no intervening window has that event in its *do_not_propagate* mask. If no such window exists, or if the window is an ancestor of the focus window, and **InputFocus** was originally specified as the destination, the event is not sent to any clients. Otherwise, the event is reported to every client selecting on the final destination any of the events specified in *event_list*.

The event in the **XEvent** structure must be one of the events defined by the input extension, so that the X server can correctly byte swap the contents as necessary. The contents of the event are otherwise unaltered and unchecked by the X server except to force *send_event* to **True** in the forwarded event and to set the sequence number in the event correctly.

XSendExtensionEvent returns zero if the conversion-to-wire protocol failed, otherwise it returns nonzero.

This function can generate **BadDevice**, **BadValue**, **BadWindow**, or **BadClass** errors.

2.2.15. Getting Motion History

```

XDeviceTimeCoord
*XGetDeviceMotionEvents (display, device, start, stop,
                        nevents_return, mode_return, axis_count_return);
Display *display;
XDevice *device;
Time     start, stop;
int      *nevents_return;
int      *mode_return;
int      *axis_count_return;

```

display Specifies the connection to the X server.

device Specifies the desired device.

start Specifies the start time.

stop Specifies the stop time.

nevents_return Specifies the address of a variable into which the server will return the number of positions in the motion buffer returned for this request.

mode_return Specifies the address of a variable into which the server will return the mode of the nevents information. The mode will be one of the following: **Absolute** or **Relative**.

axis_count_return Specifies the address of a variable into which the server will return the number of axes reported in each of the positions returned.

This function returns all positions in the device's motion history buffer that fall between the specified start and stop times inclusive. If the start time is in the future, or is later than the stop time, no positions are returned.

The return type for this function is a structure defined as follows:

```

typedef struct {
    Time time;
    unsigned int *data;
} XDeviceTimeCoord;

```

The data field of the **XDeviceTimeCoord** structure is a pointer to an array of data items. Each item is of type int, and there is one data item per axis of motion reported by the device. The number of axes reported by the device is returned in the axis_count variable.

The value of the data items depends on the mode of the device. The mode is returned in the mode variable. If the mode is **Absolute**, the data items are the raw values generated by the device. These may be scaled by the client program using the maximum values that the device can generate for each axis of motion that it reports. The maximum value for each axis is reported in the max_val field of the **XAxisInfo** structure. This structure is part of the information returned by the **XListInputDevices** request.

If the mode is **Relative**, the data items are the relative values generated by the device. The client program must choose an initial position for the device and maintain a current position by accumulating these relative values.

Consecutive calls to this function may return data of different modes, if some client program has changed the mode of the device via an **XSetDeviceMode** request.

You should use **XFreeDeviceMotionEvents** to free the data returned by this function.

Errors returned by this function: **BadDevice**, **BadMatch**.

```
void
XFreeDeviceMotionEvents (events)
    XDeviceTimeCoord *events;
```

events Specifies the pointer to the **XDeviceTimeCoord** array returned by a previous call to **XGetDeviceMotionEvents**.

This function frees the array of motion information.

The following information is contained in the `<X11/extensions/XInput.h>` and `<X11/extensions/XI.h>` header files:

```

/* Definitions used by the library and client */

#ifndef _XINPUT_H_
