

Photos from NASA's (National Aeronautics and Space Administration) polar spacecraft show that Earth is being sprayed by a steady stream of water-bearing objects similar to small comets. These objects, which are said to be the size of a small house, pose no threat to astronauts or people on earth. They break up and disintegrate into clouds of water vapor at 600 to 15,000 miles above the earth. All these objects contain water and arrive at a rate of from 5 to 30 small comets a minute. This has just recently been discovered, even though it's been suggested before. No one believed it until the photographs provided proof.
