## 1. INTRODUCTION

The Windows SNMP API specification defines a programming interface for network management applications running under the Microsoft Windows family of GUI/operating system products, enabling those applications to make use of a logically external SNMP engine or service layer.

For the purpose of exposition, the original Internet-standard Network Management Framework, as described in RFCs 1155, 1157, and 1212, is termed the SNMP version 1 framework (SNMPv1). The new framework that is currently a proposed Internet standard, as described in RFCs 1441, 1442, 1443, 1444, 1445, 1446, 1447, 1448, 1449, 1450, 1451, and 1452, is termed the SNMP version 2 framework (SNMPv2). In addition, there are three proposed Internet standards, as described in RFCs 1418, 1419, and 1420, that address the use of transports other than UDP over IP for SNMPv1. These RFCs describe SNMPv1 over OSI, AppleTalk, and IPX. Note that these transports are directly addressed in SNMPv2 by RFC 1449.

The Windows SNMP API specification introduces no constraints on the use of SNMPv1 or SNMPv2, nor on the functionality supported by those protocols as prescribed in the relevant Internet RFCs.

For the purposes of this specification, SNMPv1 is seen as a subset of SNMPv2.

Hereinafter the terms "WinSNMP" and "Windows SNMP" will be used as shorthand for "the Windows SNMP API Specification" (which is the full and formal name for this document itself).

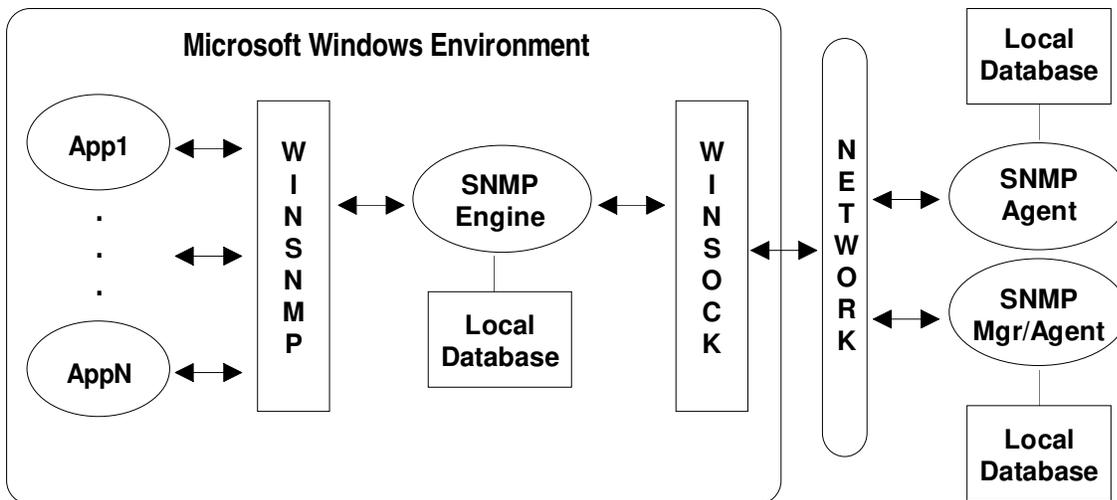

This specification avoids introducing new or different meanings for terms which have established definitions in the existing SNMP literature (especially the RFCs). Readers are encouraged to consult the "Glossary" and "References" sections (and to point out lapses in terminological correctness).

## 1.1. What is Windows SNMP?

The purpose of WinSNMP is to promote the development of SNMP-based network management applications running under the Microsoft Windows family of GUI/operating system products.

WinSNMP provides a single interface to which application developers can program and multiple SNMP software vendors can conform. This specification thus defines the procedure calls, data types, data structures, and associated semantics to which an application developer can program and which an SNMP software vendor can implement.

The following diagram shows where WinSNMP fits in one possible rendition of end-to-end SNMP connectivity from an entity acting in a manager role (far left) to an entity acting in an agent role (far right). This diagram is a high-level rendition of the model embodied in the current version of WinSNMP. Other models are both possible and supported by the specification, particularly as regards network transport independence.

## 1.2. Compliance

Software which conforms to this Windows SNMP specification will be considered "Windows SNMP compliant".

Suppliers of implementations which are "Windows SNMP compliant" shall be referred to as "Windows SNMP suppliers". Nothing in the WinSNMP specification is meant to dictate or preclude particular implementation strategies. This specification allows for various overlapping levels of SNMP support on the part of an implementation:

- **Level 0** = Message encoding/decoding only
- **Level 1** = Level 0 + interaction with SNMPv1 agents
- **Level 2** = Level 1 + interaction with SNMPv2 agents
- **Level 3** = Level 2 + interaction with other SNMPv2 managers

To be Windows SNMP compliant, a vendor must implement 100% of this Windows SNMP specification, as appropriate to the level of SNMP interaction the given implementation supports. Windows SNMP vendors are encouraged to state clearly the level of SNMP interaction they support in all of their marketing and technical literature.

Applications which are capable of operating with any "Windows SNMP compliant" implementation which supports at least the level of SNMP interaction required by the application will be considered as having a "Windows SNMP interface" and will be referred to as "Windows SNMP applications".

This version of the Windows SNMP specification defines and documents the use of the API by management applications. A future revision or separate extension may include features for use by SNMP agents. A companion document, the Windows MIB API specification, provides definitions of elements used as operands to SNMP operations.

### 1.3. SNMP

SNMP is a request-response protocol used to transfer management information between entities acting in a manager role and entities acting in an agent role. Managers are often configured as management stations and agents are often configured as managed nodes. A manager can also act as an agent to another manager in both vertical (hierarchical) and horizontal (distributed) relationships. Likewise, a physical node might be managed by multiple agents, and an agent might manage multiple physical nodes. When hereinafter we use the prototypical management station/managed node perspective for the sake of simplicity and clarity of presentation, that practice is not meant to preclude other forms of SNMP interactions.

Each managed device or application contains monitoring and (possibly) control instrumentation. This instrumentation is accessed by the agent. The agent represents its access to this instrumentation to the manager via a MIB, filtered by the SNMP security mechanisms. Management applications communicate with agents via SNMP to monitor and (possibly) control managed devices or applications.

A management application may issue several requests to an agent, before waiting for a response. Alternately, it may issue a request and wait for a response, operating in a lock-step fashion with the agent. Furthermore, SNMP may be implemented on a wide range of transport protocols, each with varying delivery mechanisms and reliability characteristics. The normal transmission mechanism (UDP) is through non-guaranteed messages which may be dropped, duplicated, or re-ordered. Thus, with SNMP, it is the responsibility of each management application to determine and implement the desired level of reliability for its communications. This means that the management application decides on its own re-transmission and timeout strategy.

Note, also, that an agent may send asynchronous messages--called traps (SNMPv1) or notifications (SNMPv2)--to a management application. This important feature of SNMP is also fully supported by WinSNMP. Note that in this document, the term "traps" is used to refer both to traps and notifications, unless specifically qualified as otherwise in a given instance.

## 1.4. Microsoft Windows

This API is intended to be usable within all implementations and versions of Microsoft Windows "family" of operating systems and graphical user interface environments from Microsoft Windows Version 3.0 onwards, including Windows 3.1 and Windows NT (among others). It thus provides for Windows SNMP implementations and Windows SNMP applications in both 16- and 32-bit operating environments, and in both single- and multi-threaded execution environments.

Windows SNMP makes provisions for multi-threaded Windows processes. A process contains one or more threads of execution. In the Win16 non-multi-threaded world, a task corresponds to a process with a single thread. All references to threads in this document refer to actual "threads" in multi-threaded Windows environments. In single-threaded environments (such as Windows 3.0 and Windows 3.1), use of the term thread refers to a Windows process.

## 1.5. The Status of this Specification

This specification is released for implementation as of this revision (v1.0g). It is the product of collaboration among an informal, *ad hoc*, self-organized group of vendors, developers, and users with an interest in SNMP-based network management applications and the Microsoft Windows family of development and runtime supporting environments for such applications.

Readers of this specification are assumed to have a high degree of knowledge and understanding of SNMP (through SNMPv2) and Microsoft Windows programming conventions. Contributions aimed at reducing the level of detailed knowledge of these specific technologies required for users of this specification are invited.

At the present time, it is believed that this version (v1.0g) of the Windows SNMP API specification permits the development of interoperable implementations and applications supporting at least "SNMP Level 1" as defined herein and that applications developed in accordance with this version of the specification will, additionally, be structured for future compatibility through "SNMP Level 3" as defined herein. Due to limitations in the understanding and specification of "local database" functions in the current version, it is likely that full SNMPv2 operational support can be achieved without additional functions and data structures being defined. It is expected that implementation, development, and interoperability experience gained with this v1.0 of this specification will identify those additions, and that they will appear in v2.0 of the specification by May of 1994.

Consensus on the release of this version of the specification was reached on the mailing list and confirmed at the third BOF meeting of the WinSNMP group held at the August '93 Interop in San Francisco. On-going edits to v1.0 will be accepted to:

1. correct errors and inconsistencies;
2. add explanatory and/or expository text and graphics;
3. add essential new functions, variables, error codes, data types, or data structures required for usability of the baseline specification.

Contributions oriented toward new and/or expanded functionality outside the scope of the preceding three objectives will be accepted, but will be considered for inclusion in v2.0 of this specification.

## 1.6. References

This section consists of two parts: Primary sources (mainly RFCs) and secondary sources.

## 1.7. Glossary: Abbreviations, Acronyms, and Definitions

The following table of abbreviations and definitions presents terms frequently used in the SNMP RFCs and related literature along with the official, customary, or consensual meaning(s). An editing objective of this specification is to use none of these terms in any sense other than that shown in the corresponding definition, nor to invent or employ new terms with meanings functionally equivalent to those of these established terms.

Short	Term	Definition
	Access Control	Restriction of access to MIB objects either in scope or function or both, on the basis of party.
ACL	Access Control List	An indication of what actions ( <code>aclPrivileges</code> ) may be performed by a given party ( <code>aclTarget</code> ) on behalf of another party ( <code>aclSubject</code> ) within a given context ( <code>aclResources</code> ).
API	Application Programming Interface	A defined set of procedure calls, data types, data structures, and associated semantics used to incorporate a logically external service layer into an application program.
	Authentication	Verification of message source and timeliness. Achieved in SNMPv2 normally by message component transformation via secret codes.
	Authorization	Defining and controlling the levels of legitimate access to data and/or resources. Achieved in SNMPv2 with the use of ACLs, and in SNMPv1 with the use of Community strings.
	Bilingual Entity	A protocol entity that can handle both SNMPv1 and SNMPv2 operations, semantics, and communications.
	Community	An administrative relationship between SNMPv1 entities; identified by a "community string".
CTX	Context	A collection of managed object resources accessible by an SNMP entity.
	Dual-Role Entity	A protocol entity capable of acting in both a manager and an agent role.
Entity	Protocol Entity	An SNMP-conversant process, operating in either and agent role or in a manager role, or both, which performs network management operations by generating and/or responding to SNMP protocol messages.
GUI	Graphical User Interface	A visually rich user interface (as contrasted with a Command Line Interface [CLI]).
	Local Database	An entity-specific collection of information about parties, contexts, views, and access control policies.
M2M	Manager-to-Manager MIB	Used to define conditions and thresholds at a manager that will trigger notifications to other managers.

MIB	Management Information Base	A virtual information store holding a collection of managed object definitions.
View	MIB View	A subset of the universal set of all instances of all MIB objects; defined as a collection of view subtrees.
	Mid-Level Manager	A dual-role protocol entity acting primarily in a manager role except when acting in an agent role vis-à-vis other managers.
smiOID	Object Identifier	A data type denoting an authoritatively named object; a sequence of non-negative integers.
	Party	A conceptual, virtual execution environment who operation is restricted to an administratively defined subset of all possible operations of a particular entity. A set of specific security characteristics.
	Party MIB	Used to configure parties at protocol entities with various security characteristics, including use or non-use of authentication and/or privacy and access control constraints.
	Privacy	Protection of transmitted data from eavesdropping. Achieved in SNMPv2 normally by message component encryption.
PDU	Protocol Data Unit	A data structure containing SNMP message components and used for communication between SNMP entities.
Proxy	Proxy Agent	
RFC	Request for Comments	The document series describing the Internet suite of protocols and related experiments.
SNMP	Simple Network Management Protocol	The application protocol offering network management service in the Internet suite of protocols. Abbreviation used for both SNMPv1 and SNMPv2.
variable	SNMP variable	An object's identity and its instance value encoded as an smiOID.
varbind	Variable-Binding	A pairing of an object instance name and an associated value or pseudo-value and syntax.
varbindlist	Variable-Bindings List	A grouping of one or more variable-bindings

## 1.8. Contributors

The following individuals and their sponsoring organizations have contributed ideas, time, and (in some cases) other valuable resources, to the creation of the Windows SNMP API specification:

## 2. PROGRAMMING WITH WINDOWS SNMP

This section outlines some of the high level considerations relevant to the programming "model" envisioned by WinSNMP. This model is meant to add background and context for evaluating the specification itself.

- Levels of SNMP Support
- Entity/Context Translation Modes
- Session Characteristics
- Asynchronous Messages
- Asynchronous Program Flow
- Retransmit Behavior
- Local Database
- Common Error Codes
- Data Types

## 2.1. Levels of SNMP Support

This specification allows for multiple levels of SNMP support--explicitly for implementations and implicitly for applications.

Note that these "Levels" are independent of and unrelated to the "Modes" of interpretation of entity and context arguments (described later).

Note that the implementation will report its maximum level of SNMP support in response to the **SnmStartup** function (described later).

### 2.1.1. Implementations

The WinSNMP API specification allows an *implementation* to support any of four overlapping levels of SNMP operations:

- **Level 0** = Message encoding/decoding only
- **Level 1** = Level 0 + interaction with SNMPv1 agents
- **Level 2** = Level 1 + interaction with SNMPv2 agents
- **Level 3** = Level 2 + interaction with other SNMPv2 managers

#### 2.1.1.1. "Level 0" Implementations

"Level 0" implementations must support all WinSNMP specifications *except* those which require communication with other SNMP entities, namely:

- **SnmSendMsg**
- **SnmRecvMsg**
- **SnmRegister**

"Level 0" implementations exist to provide SNMP message encoding and decoding services to applications which do not require the communications transport services of the WinSNMP implementation, but still require WinSNMP services, such as:

- Local Database Functions
- **SnmEncodeMsg**
- **SnmDecodeMsg**

All WinSNMP implementations *must* include full "Level 0" support.

#### 2.1.1.2. "Level 1" Implementations

"Level 1" implementations support communications with SNMPv1 agents, in addition to providing full "Level 0" support.

Since WinSNMP applications are *structured* to support SNMPv2, "Level 1" implementations *must* support the requisite transformations specified in the "Coexistence" document (RFC1452). For example, if a WinSNMP application submits a GetBulkRequest PDU to a "Level 1" implementation, the WinSNMP implementation will transform this into a GetNextRequest PDU, per Section 3.1.1.(2) of RFC1452, and proceed accordingly.

Note that WinSNMP always returns traps in SNMPv2 format, whether the trap emanates from an SNMPv1 agent or, as a notification, from an SNMPv2 agent. This behavior is also defined by RFC1452.

"Level 1" implementations *must* support the use of target agent addresses and community strings; but are *not required* to support any SNMPv2 mechanisms, other than the "Coexistence" transformations mentioned above.

### 2.1.1.3. "Level 2" Implementations

"Level 2" implementations support communications with SNMPv2 agents, in addition to providing full "Level 1" and "Level 0" support.

In particular, "Level 2" implementations **must** support the Party MIB and the use of parties, contexts, authentication, and privacy mechanisms, but are **not required** to support the Manager-to-Manager MIB or protocol operations relating to the InformRequest PDU type.

### 2.1.1.4. "Level 3" Implementations

"Level 3" implementations support communications with other SNMPv2 management entities via the Manager-to-Manager MIB and protocol operations relating to the InformRequest PDU type, in addition to providing full "Level 2", "Level 1", and "Level 0" support.

## 2.1.2. Applications

The WinSNMP API is oriented toward the writing of **applications** which are SNMPv2-enabled, at least in terms of their structure. A WinSNMP application may always use the relevant PDU types defined for SNMPv2 (as specified in WinSNMP.h, the "Declarations" section of this document) with the assurance that the implementation will perform the necessary transformations--in accordance with the "Coexistence" document (RFC1452)--when communicating with an SNMPv1 agent on behalf of the application. Likewise, a WinSNMP application will always receive Trap PDUs (via **SnmprcvMsg** from the implementation) as SNMPv2 traps, even when the issuing entity is an SNMPv1 agent.

Note that it is possible for WinSNMP applications to operate in such a way as to utilize the implementation merely for SNMP message encoding and decoding and to bypass the WinSNMP implementation with respect to communications with the destination entities. In this mode, the application must perform the necessary GetResponse and Trap PDU transformations for itself, at its own discretion.

## 2.2. Entity/Context Translation Modes

WinSNMP applications have the capability of instructing the implementation to interpret entity and context arguments as either literal SNMPv1 agent address and community string, respectively, or as literal SNMPv2 party and context IDs, respectively. The preferred alternative to either of these modes is that in which these arguments are interpreted as user-friendly names for entities and managed object collections to be dereferenced ("translated") into their respective SNMPv1 or SNMPv2 components via the implementation's local database.

The three entity/context translation modes are:

```
SNMPAPI_NORMAL           = Translate via Local Database look-up
SNMPAPI_UNTRANSLATED_V1 = Literal transport address and community string
SNMPAPI_UNTRANSLATED_V2 = Literal SNMPv2 party and context IDs
```

The WinSNMP implementation will always identify its current default entity/context translation mode setting in the return value from the **SnmStartup** function. A WinSNMP application may request a different entity/context translation mode setting via the **SnmSetTranslateMode** function. An implementation may elect to not support a requested translation mode, in which case it must return an error and set **SnmGetLastError** to `SNMPAPI_MODE_INVALID`.

All WinSNMP implementations and applications are encouraged to support `SNMPAPI_NORMAL` mode as their default mode of operation.

Note that the sample code which follows in sections 2.2.1 through 2.2.4 includes literal string representations of some of the arguments to the WinSNMP functions. This is merely for expository purposes. In the interests of internationalization and localization--and generally good software engineering practices--application writers are encouraged to isolate all such text string values in `StringTables` in separate resource files or to use some similar technique to modularize such strings out of the operating logic of their applications.

### 2.2.1. SNMPAPI\_NORMAL Mode

When the translation mode is set to `SNMPAPI_NORMAL`, an application will make calls similar to the following:

```
hAgent = SnmpStrToEntity (hSomeSessin, "Accounting_Hub");
hView  = SnmpStrToContext (hSomeSession, "Traffic_Stats");
```

The implementation will use its selected access method to look-up "Accounting\_Hub" and "Traffic\_Stats" in its local database and, if successful, will assemble the appropriate internal data structures and return `HANDLE` values for use by the application.

### 2.2.2. SNMPAPI\_UNTRANSLATED\_V1 Mode

When the translation mode is set to `SNMPAPI_UNTRANSLATED_V1`, an application will make calls similar to the following:

```
hAgent = SnmpStrToEntity (hSomeSession, "192.151.207.34");
hView  = SnmpStrToContext (hSomeSession, "public");
```

The implementation will assume--based on the `SNMPAPI_UNTRANSLATED_V1` setting for `hSomeSession`--that "192.151.207.34" equates to an IP address to be reached via UDP port 161, and that this value--like the "public" parameter to **SnmStrToContext**--is being passed as a far pointer to a `NULL` terminated text string (`LPSTR`) that it must first convert to dotted decimal notation.

### 2.2.3. SNMPAPI\_UNTRANSLATED\_V2 Mode

When the translation mode is set to SNMPAPI\_UNTRANSLATED\_V2, an application will make calls similar to the following:

```
hAgent = SnmpStrToEntity (hSomeSession, "1.3.6.1.6.3.3.1.3.134.141.40.162.1");  
hView  = SnmpStrToContext (hSomeSession, "1.3.6.1.6.3.3.1.4.134.141.40.162.1");
```

The first string is an initialPartyID with an agent from 134.141.40.162; the second string is an initialContextID with the same agent.

The implementation will assume--based on the SNMPAPI\_UNTRANSLATED\_V2 setting for hSomeSession--that "1.3.6.1.6.3.3.1.3.134.141.40.162.1" equates to an a PartyID instance at IP address 134.141.40.162 to be reached via UDP port 161, and that this value--like the "context" string parameter to **SnmpStrToContext**--is being passed as a far pointer to a NULL terminated text string (LPSTR) that it must first convert to an OID.

## 2.3. Sessions

The "session" created by the **SnmOpen** function is used to manage the link between the Windows SNMP application and the Windows SNMP interface implementation. That is, the session is the unit of resource and communications management between a calling WinSNMP application and its supporting WinSNMP implementation. A well-behaved WinSNMP application will use the session construct to logically organize its operations and to minimize resource requirements on the implementation. The following statements summarize the role and certain attributes of WinSNMP sessions:

1. A "session" is opened with **SnmOpen**, and closed with **SnmClose**.
2. A "session-id" is returned by the **SnmOpen** function to the application as a HANDLE variable, which the implementation may use internally to manage resources.
3. An application can have multiple sessions open at one time, subject to the limitations stated below.
4. The minimum number of concurrent sessions which an implementation must support is one.
5. The maximum is undefined and is implementation-specific and, possibly, resource-dependent.
6. When an application's request to open a session cannot be granted because of the limitations stated above, the implementation will return NULL to **SnmOpen** and will set **SnmGetLastError** to report SNMPAPI\_ALLOC\_ERROR.
7. All WinSNMP API functions--except **SnmOpen**--which return HANDLE variables will include a "session-id" handle as an input parameter, so that the implementation can use it internally to manage and account for resources on behalf of the session.
8. HANDLE variables created under one open session can be utilized by other open sessions (if any) *within* a given application (task). Optionally, an implementation may internally share HANDLE variables among sessions in separate applications. (Note this optional resource efficiency, if it is supported by an implementation, is totally transparent to the application.)
9. When an application closes a session by executing the **SnmClose** function, all resources created on behalf of that session by the implementation, and not previously freed by the application, will be freed automatically by the implementation. (If an implementation supports the optional sharing of HANDLE variables among open sessions across multiple applications, then the resources will not be physically freed until the final open session which "created" the resources closes.)
10. Sessions may have other attributes, above and beyond those discussed above (e.g., the 'dstEntity' and 'context' interpretation modes of NORMAL, UNTRANSLATED\_V1, and UNTRANSLATED\_V2).

## 2.4. Asynchronous Messages

One contemporary programming model has applications "driven" by the receipt and processing of asynchronous message-events. This asynchronous message-driven model maps well to modern object-oriented theory, the SNMP distributed management paradigm, and the Microsoft Windows programming and runtime environments. Likewise, although WinSNMP does not presume any particular transport mechanism for the conveyance of SNMP messages between managers and agents, it is to be noted that, fundamentally, SNMP is a datagram-based protocol, in which no actual channel (virtual circuit) is established between remote entities. This behavior also maps well to the message-driven programming model. For those reasons, among others, this is the programming model adopted by WinSNMP.

Modern message-driven applications typically must respond to other kinds of important events, some of which may rely on synchronous relationships. Actually, all of the functions specified in the Windows SNMP API have a synchronous component--most are totally synchronous; three critical ones have an asynchronous dimension:

- **SnmpSendMsg**
- **SnmpRecvMsg**
- **SnmpRegister**

Of these, **SnmpRecvMsg** has the most impact on asynchronous operations.

## 2.5. Asynchronous Program Flow

The basic asynchronous model for programming with Windows SNMP follows these steps:

1. The application opens a session with the Windows SNMP implementation (with the **SnmOpen** function).
2. If the application is interested in receiving traps, it indicates this (with the **SnmRegister** function).
3. The application prepares one or more PDUs for transmission to and processing by the WinSNMP implementation via WinSNMP "messages" (using **SnmCreatePdu** and other PDU, Variable-Binding, and Utility functions).
4. The application submits one or more asynchronous requests consisting of an SNMP PDU and message "wrapper" elements (with the **SnmSendMsg** function).
5. The application receives notification that a response to a request is available or that a registered trap has occurred (via the message "channel" specified in the **SnmOpen** function).
6. The application retrieves the response (with the **SnmRecvMsg** function).
7. The application processes the response as appropriate (using application-specific logic).
8. The application closes the Windows SNMP session (with the **SnmClose** function).

Note that, in general, steps 2 through 7 can take place in nearly any order and at any time during program execution.

## 2.6. Retransmit Behavior

Given the asynchronous nature of both SNMP itself and the WinSNMP **SnmplibSendMsg**, **SnmplibRecvMsg**, and **SnmplibRegister** functions, users of this specification (i.e., implementors and applications writers) must be concerned with timeout and retry issues. Taken together, timeout and retry will be referred to hereinafter as "retransmit". (Note that no "back-off" mechanisms are currently included.)

The application has the *primary* responsibility in this regard, both for managing the retransmit policy and for the runtime execution of that policy. An implementation may optionally provide retransmit execution support. Accordingly, in WinSNMP applications, the timeout period, in practice, refers to the elapsed time between an application's issuance of an **SnmplibSendMsg** request and receipt of the corresponding message via the **SnmplibRecvMsg** function. From the perspective of the implementation, the timeout period will refer to the elapsed time between the actual sending of an SNMP request message to a destination entity and the receipt of the SNMP response message from that destination.

The fundamental retransmit policy mechanism will be the Local Database. Each potential destination entity entry in the Local Database will include--among other attributes--timeout (elapsed time in seconds) and retry (count) elements. These values can be stored in and retrieved from the Local Database by an application with the **Snmplib[Get/Set]Timeout** and **Snmplib[Get/Set]Retry** functions. At runtime, an application may elect to use, update, or ignore the default values in the Local Database. When an implementation which supports retransmit execution is operating in retransmit mode, it *must* use the timeout and retry values from the Local Database for the respective destination entities.

Note that none of the foregoing precludes or impedes the "out-of-the-box" mode of operation. An implementation can (and should) "boot up" with some generic default values in its (conceptual) Local Database for use when an application initializes entities in the SNMPAPI\_UNTRANSLATED\_V[1|2] modes.

So, for V1 of WinSNMP, the following summarizes the timeout/retry approach:

1. The application manages the policy via the Local Database functions.
2. The application executes the policy, at its discretion. That is, when it issues a request (via **SnmplibSendMsg**) and wants to monitor the timeout event, it sets a timer (most likely using the
3. timeout value retrieved from the local database). If the response comes in before the timer goes off, it cancels the timer and that's the end of it. If the timer expires, it decides then whether to do a(nother) retry (most likely, but not only, based on the retry count value retrieved from the local database).
4. If, during the course of execution, the application determines that either the default timeout and/or retry values are inappropriate in can either ignore that fact, or change its runtime behavior accordingly, and/or modify the default values for the respective entities in the Local Database.
5. It may well be, given the above, that certain "network smart" apps might populate and update the default values in the Local Database, while many more "network agnostic" applications just using the default data, whether just for its policy (when the implementation actually does the execution) or for both policy and execution parameters.
6. Applications may request that the implementation execute the retransmit policy (using the values in the Local Database) via the **SnmplibSetRetransmitMode** function. A valid response to this request by a compliant implementation is either "success" or SNMPAPI\_MODE\_INVALID. In the former case, the application may elect to leave retransmit execution entirely to the implementation or to augment it with its own execution as it might deem necessary; and an application can use **SnmplibSetRetransmit** again to "turn off" the implementation in this regard. When the implementation responds to the **SnmplibSetRetransmitMode** (SNMPAPI\_ON) request with the SNMPAPI\_MODE\_INVALID error, the application must assume all responsibility for execution of the retransmit policy.

7. A "standard" set of timer support functions (e.g., TIMER.DLL) for use by WinSNMP applications developers might be added in one form or another (i.e., DLL, API, etc.) to the WinSNMP specification at a future date. In the meantime, each WinSNMP implementor could chose to offer them as an 'extension' to be used at his customers' discretion, now or in the future.

## 2.7. Local Database

An SNMPv1 message includes version information and a community string, in addition to the PDU. An SNMPv2 message includes source party, destination party, context, and authentication information, in addition to the PDU (and the entire message may optionally be encrypted). Given these facts and the stated mission to accommodate both existing versions of SNMP, WinSNMP must meet at least the following four objectives:

1. A WinSNMP application must have full access to all components of the SNMP message issued by the WinSNMP implementation. At the extreme, the **SnmEncodeMsg** and **SnmDecodeMsg** functions enable access to and manipulation of fully-serialized, "ready-for-transport" SNMP messages.
2. A WinSNMP application must not have to incorporate WinSNMP implementation-specific routines or data structures to utilize any of the functionality defined by WinSNMP itself. Each WinSNMP implementation may use private mechanisms external to the WinSNMP applications, but any and all *necessary* interfaces to these mechanisms will be via the defined WinSNMP APIs only.

This means that this specification *must* ultimately define functions by which a local database can be initialized, interrogated, and modified *before* a compliant implementation supporting all modes of operation can be fielded.

3. A WinSNMP application must not have to know the SNMP version level of the target SNMP entities acting in an agent role. The WinSNMP implementation will perform any and all necessary mappings between SNMPv1 and SNMPv2 in accordance with the appropriate RFCs.
4. One implication of the foregoing requirement is that the SNMPv1 message format must fit neatly within the structure adopted for the SNMPv2 message format. This statement applies to WinSNMP "messages" only--it is not meant in any way to limit or modify anything in the "Coexistence" RFC.

Taking the view that SNMPv1 message semantics can be housed within SNMPv2 message semantics, we will first focus on the SNMPv2 message components:

For SNMPv2 communications, the "source party" (srcEntity) components refer to the management application and will largely be supplied by the WinSNMP implementation layer via the Local Database. For SNMPv1 communications, srcEntity basically is a no-op.

For SNMPv2 communications, the "destination party" (dstEntity) components refer to the target agent and must come, at least in part, from logically remote SNMP entities. Given a dstEntity transport address and protocol and the assumption of at least one noAuth/noPriv "entrance" into the target agent (i.e., InitialPartyID), an application can initiate SNMP exchanges via the WinSNMP implementation. For SNMPv1 communications, dstEntity refers to the transport address of the target agent entity.

For SNMPv2 communications, the "context" identifies a collection of managed object resources accessible to a management application under the control of the target agent. For SNMPv1 communications, the context parameter refers to "community string".

A driving force behind the approach taken in this specification with respect to these issues is the need to accommodate SNMPv2 administrative and protocol constructs in a symmetrical fashion, and at the same time transparently subsume SNMPv1 administrative and protocol constructs.

The major assumption is that the "local database"--which *must* be supported by yet to be defined WinSNMP functions--contains source party, destination party, and context entries (and possibly other data). Consequently, the **SnmSendMsg** function does not need to include "qos", "timeout", "retry", or similar values since these are available in the Local Database.

## 2.8. Error Codes

The bifurcation into "common" and "context-specific" error codes in this section serves merely to allow an abbreviation of error condition descriptions in the function reference sections. The distinction between "SNMP error codes" and "SNMP API error codes" in the "context-specific" section is somewhat more significant. The former are fixed by the RFCs; the latter are creations of this specification.

### 2.8.1. Common Error Codes

Any WinSNMP function can fail with any one of the following error codes returned via **SnmGetLastError**:

```
SNMPAPI_NOT_INITIALIZED
SNMPAPI_ALLOC_ERROR
SNMPAPI_OTHER_ERROR
```

SNMPAPI\_NOT\_INITIALIZED signals that **SnmStartup** was not successfully executed, either since program execution began or since **SnmCleanup** successfully completed. Note that if **SnmStartup** fails, an immediate call to **SnmGetLastError** (i.e., before any other WinSNMP calls) will return the error code applicable to the failure of **SnmStartup**; all subsequent calls to WinSNMP functions before a successful **SnmStartup** execution will fail with SNMPAPI\_NOT\_INITIALIZED.

SNMPAPI\_ALLOC\_ERROR signals that the implementation was unable to obtain sufficient resources to carry out the requested action. Applications should respond by freeing resources, or by reducing the resource requirements of the request, or by informing the user (e.g., via MessageBox or log file entry) and facilitating a graceful shutdown via **SnmClose** calls and/or **SnmCleanup**.

SNMPAPI\_OTHER\_ERROR signals an unknown, undefined, or otherwise indeterminate error occurred. Implementations may provide an optional, ancillary, and independent means of providing additional feedback to the user for subsequent problem resolution. In most cases, applications should attempt to shutdown gracefully via **SnmClose** calls and/or **SnmCleanup** after receiving this error.

Since each of these error conditions could arise on each and any of the WinSNMP API functions, they are documented here only. The error information section of each function description refers to these collectively as "Common Error Codes" and documents any other error conditions which might be specific to the given function.

## 2.8.2. Context-Specific Error Codes

The following lists are excerpted from the "Declarations" section of this document (which essentially constitutes the WinSNMP.h include file). They are included here mainly as a placeholder for a future elaboration of each error condition, similar to what was done in the preceding section for "Common Error Codes".

```
/* Exception Values for Response Varbinds */
#define SNMP_VALUE_NOSUCHOBJECT (ASN_CONTEXT | ASN_PRIMITIVE | 0x0)
#define SNMP_VALUE_NOSUCHINSTANCE (ASN_CONTEXT | ASN_PRIMITIVE | 0x1)
#define SNMP_VALUE_ENDOFMIBVIEW (ASN_CONTEXT | ASN_PRIMITIVE | 0x2)

/* SNMP Error Codes Returned in Error_status Field of PDU...Not API Error Codes */
/* Error Codes Common to SNMPv1 and SNMPv2 */
#define SNMP_ERROR_NOERROR 0
#define SNMP_ERROR_TOOBIG 1
#define SNMP_ERROR_NOSUCHNAME 2
#define SNMP_ERROR_BADVALUE 3
#define SNMP_ERROR_READONLY 4
#define SNMP_ERROR_GENERR 5
/* Error Codes Added for SNMPv2 */
#define SNMP_ERROR_NOACCESS 6
#define SNMP_ERROR_WRONGTYPE 7
#define SNMP_ERROR_WRONGLENGTH 8
#define SNMP_ERROR_WRONGENCODING 9
#define SNMP_ERROR_WRONGVALUE 10
#define SNMP_ERROR_NOCREATION 11
#define SNMP_ERROR_INCONSISTENTVALUE 12
#define SNMP_ERROR_RESOURCEUNAVAILABLE 13
#define SNMP_ERROR_COMMITFAILED 14
#define SNMP_ERROR_UNDOFAILED 15
#define SNMP_ERROR_AUTHORIZATIONERROR 16
#define SNMP_ERROR_NOTWRITABLE 17
#define SNMP_ERROR_INCONSISTENTNAME 18

/*WinSNMP API Function Return Codes */
#define SNMPAPI_FAILURE 0 /* Generic error code */
#define SNMPAPI_SUCCESS 1 /* Generic success code */
/*WinSNMP API Error Codes (for SnmGetLastError) */
/* Error conditions reported by the API, other than SNMP Response-PDU error_status codes. */
#define SNMPAPI_ALLOC_ERROR 2 /* Error allocating memory */
#define SNMPAPI_CONTEXT_INVALID 3 /* Invalid context parameter */
#define SNMPAPI_CONTEXT_UNKNOWN 4 /* Unknown context parameter */
#define SNMPAPI_ENTITY_INVALID 5 /* Invalid entity parameter */
#define SNMPAPI_ENTITY_UNKNOWN 6 /* Unknown entity parameter */
#define SNMPAPI_INDEX_INVALID 7 /* Invalid index parameter (into VBL) */
#define SNMPAPI_NOOP 8 /* No operation performed */
#define SNMPAPI_OID_INVALID 9 /* Invalid OID parameter */
#define SNMPAPI_OPERATION_INVALID 10 /* Invalid or unsupported operation */
#define SNMPAPI_OUTPUT_TRUNCATED 11 /* Insufficient output buffer length */
#define SNMPAPI_PDU_INVALID 12 /* Invalid PDU parameter */
#define SNMPAPI_SESSION_INVALID 13 /* Invalid session parameter */
#define SNMPAPI_SYNTAX_INVALID 14 /* Invalid syntax in smiVALUE */
#define SNMPAPI_VBL_INVALID 15 /* Invalid VBL parameter */
#define SNMPAPI_MODE_INVALID 16 /* Invalid mode parameter */
#define SNMPAPI_SIZE_INVALID 17 /* Invalid size/length parameter */
#define SNMPAPI_NOT_INITIALIZED 18 /* SmpStartup not called successfully */
#define SNMPAPI_MESSAGE_INVALID 19 /* Invalid SNMP message format */
#define SNMPAPI_OTHER_ERROR 99 /* For internal or undefined errors */
/* Others will be added as needed */
```

## 2.9. WinSNMP Data Types

The following is an excerpt from the "Declarations" section of this document (and is part of the standard WinSNMP.h include file):

```
/* Include Windows Declarations */
#include <windows.h>
/* Windows-related types */
typedef HANDLE HSNMP_SESSION, FAR *LPHSNMP_SESSION;
typedef HANDLE HSNMP_ENTITY, FAR *LPHSNMP_ENTITY;
typedef HANDLE HSNMP_CONTEXT, FAR *LPHSNMP_CONTEXT;
typedef HANDLE HSNMP_PDU, FAR *LPHSNMP_PDU;
typedef HANDLE HSNMP_VBL, FAR *LPHSNMP_VBL;
/* WinSNMP API Type Definitions */
/* The smiBYTE types are included only to ensure we can define smiOCTETS correctly */
typedef unsigned char smiBYTE, FAR *smiLPBYTE;
/* SNMP-related types from RFC1442 (SMI) */
typedef signed long smiINT, FAR *smiLPINT;
typedef smiINT smiINT32, FAR *smiLPINT32;
typedef unsigned long smiUINT32, FAR *smiLPUINT32;
typedef struct {
    smiUINT32 len;
    smiLPBYTE ptr;} smiOCTETS, FAR *smiLPOCTETS;
typedef struct {
    smiOCTETS smiOCTETS, FAR *smiLPBITS;
    smiBITS,
typedef struct {
    smiUINT32 len;
    smiLPUINT32 ptr;} smiOID, FAR *smiLPOID;
typedef smiOCTETS smiIPADDR, FAR *smiLPIPADDR;
typedef smiUINT32 smiCNTR32, FAR *smiLPCNTR32;
typedef smiUINT32 smiGAUGE32, FAR *smiLPGAUGE32;
typedef smiUINT32 smiTIMETICKS, FAR *smiLPTIMETICKS;
typedef smiOCTETS smiOPAQUE, FAR *smiLPOPAQUE;
typedef smiOCTETS smiNSAPADDR, FAR *smiLPNSAPADDR;
typedef struct {
    smiUINT32 hipart;
    smiUINT32 lopart;} smiCNTR64, FAR *smiLPCNTR64;
/* Structure used to compose a value member for a variable binding */
typedef struct { /* smiVALUE portion of VarBind */
    short type; /* Insert SNMP_SYNTAX_<type> */
    union {
        smiINT sNumber; /* SNMP_SYNTAX_INT
                        SNMP_SYNTAX_INT32 */
        smiUINT32 uNumber; /* SNMP_SYNTAX_UINT32
                        SNMP_SYNTAX_CNTR32
                        SNMP_SYNTAX_GAUGE32
                        SNMP_SYNTAX_TIMETICKS */
        smiCNTR64 hNumber; /* SNMP_SYNTAX_CNTR64 */
        smiOCTETS string; /* SNMP_SYNTAX_OCTETS
                        SNMP_SYNTAX_BITS
                        SNMP_SYNTAX_OPAQUE
                        SNMP_SYNTAX_IPADDR
                        SNMP_SYNTAX_NSAPADDR */
        smiOID oid; /* SNMP_SYNTAX_OID */
        smiBYTE empty; /* SNMP_SYNTAX_NULL
                        SNMP_SYNTAX_NOSUCHOBJECT
                        SNMP_SYNTAX_NOSUCHINSTANCE
                        SNMP_SYNTAX_ENDOFMIBVIEW */
    } value;
} smiVALUE, FAR *smiLPVALUE;
```

### 2.9.1. Integers

The "standard" integer type used in this specification is "unsigned long" (smiUINT32). In a few places, parameters are specified as "signed long" (smiINT) to comply with data elements defined in the respective RFCs. (This is especially true of some of the PDU components.)

### 2.9.2. Pointers

All pointer variables used in this specification are "far" pointers.

### 2.9.3. Function Returns

All return values from WinSNMP functions fall into two categories:

- A HANDLE to a resource allocated by the implementation on behalf of the application, including:
  - Sessions (HSNMP\_SESSION)
  - Entities (HSNMP\_ENTITY)
  - Contexts (HSNMP\_CONTEXT)
  - PDUs (HSNMP\_PDU)
  - Variable Binding Lists (HSNMP\_VBL)
- A long unsigned integer (smiUINT32) value representing a status (SNMPAPI\_STATUS).
  - SNMPAPI\_FAILURE (equates to 0 or NULL)
  - SNMPAPI\_SUCCESS (equates to 1 or a positive count)

### 2.9.4. Descriptors

Two important WinSNMP data types--namely, Octet Strings and Object Identifiers--take the form of "descriptors". A descriptor is a structure consisting of length member ("len") and a pointer to the actual data item of interest ("ptr" member). WinSNMP API routines that ask the implementation to write into the "ptr" member of an smiOCTETS or an smiOID structure use the "len" member for bounds checking on input and return the actual length written in the SNMPAPI\_STATUS return variable. They do not modify the "len" member of the input parameter directly.

### 3. WINDOWS SNMP INTERFACES

This section comprises the function reference for WinSNMP. In general, not a lot of significance attaches to the categorization or ordering of the functions. Some may argue that the "Entity/Context Functions" belong in the "Local Database Functions" category, or that the "Variable Binding Functions" belong in the "PDU Functions" category. Those, and similar assertions, could be true. The point for now is simply not to attach any significance to the grouping or the order of appearance.

- Local Database Functions
- Communications Functions
- Entity/Context Functions
- PDU Functions
- Variable Binding Functions
- Utility Functions

### 3.1. Local Database Functions

The functions in this section concern manipulation of the "local database" of SNMP administrative information.

The term "database" in this context is not meant to imply any particular data storage, access, or manipulation techniques. The WinSNMP implementation is the "owner" of the "local database" and may utilize any proprietary mechanisms it considers best, as long as all the functions defined in this section are fully supported and no additional implementation-specific functions are required of a WinSNMP application to utilize the "local database". Compliant WinSNMP implementations may require additional implementation-specific mechanisms external to a WinSNMP application (e.g., setting an environment variable in AUTOEXEC.BAT to point to a "local database" file or adjusting settings in a private <app>.ini file).

The functions in this section are:

Return Type	Procedure Name	Parameters
SNMPAPI_STATUS	SnmpGetTranslateMode	(OUT smiLPUINT32 nTranslateMode);
SNMPAPI_STATUS	SnmpSetTranslateMode	(IN smiUINT32 nTranslateMode);
SNMPAPI_STATUS	SnmpGetRetransmitMode	(OUT smiLPUINT32 nRetransmitMode);
SNMPAPI_STATUS	SnmpSetRetransmitMode	(IN smiUINT32 nRetransmitMode);
SNMPAPI_STATUS	SnmpGetTimeout	(IN HSNMP_ENTITY hEntity, OUT smiLPTIMETICKS nPolicyTimeout, OUT smiLPTIMETICKS nActualTimeout);
SNMPAPI_STATUS	SnmpSetTimeout	(IN HSNMP_ENTITY hEntity, IN smiTIMETICKS nPolicyTimeout);
SNMPAPI_STATUS	SnmpGetRetry	(IN HSNMP_ENTITY hEntity, OUT smiLPUINT32 nPolicyRetry, OUT smiLPUINT32 nActualRetry);
SNMPAPI_STATUS	SnmpSetRetry	(IN HSNMP_ENTITY hEntity, IN smiUINT32 nPolicyRetry);

### 3.1.1. SnmpGetTranslateMode()

The **SnmpGetTranslateMode** function informs the calling application as to the entity/context translation mode in effect at the time of the call..

#### Syntax:

```
SNMPAPI_STATUS SnmpGetTranslateMode (  
    OUT smiLPUINT32 nTranslateMode);
```

Parameter	Description
nTranslateMode	Pointer to variable to receive the current translation mode.

#### Returns:

The **SnmpGetTranslateMode** function returns SNMPAPI\_SUCCESS if successful. In this case, the resultant value of nTranslateMode will be one of the following:

SNMPAPI\_NORMAL = Translate via Local Database look-up  
SNMPAPI\_UNTRANSLATED\_V1 = Literal transport address and community string  
SNMPAPI\_UNTRANSLATED\_V2 = Literal SNMPv2 party and context IDs

The **SnmpGetTranslateMode** function returns SNMPAPI\_FAILURE if it fails. In this case, the value of nTranslateMode is undefined and meaningless to the application, and the value of **SnmpGetLastError** will be set to one of the following:

SnmpGetLastError()	Description
"Common Error Codes"	See Section 2.8.1 for details.

#### Comments:

None.

### 3.1.2. SnmpSetTranslateMode()

The **SnmpSetTranslateMode** function enables the calling application to inform the implementation as to the desired entity/context translation mode to use for subsequent **SnmpStrToEntity** and **SnmpStrToContext** function calls...

#### Syntax:

```
SNMPAPI_STATUS SnmpSetTranslateMode (  
    IN smiUINT32 nTranslateMode);
```

Parameter	Description
nTranslateMode	Value used to set the current translation mode--must be one of the following:  SNMPAPI_NORMAL SNMPAPI_UNTRANSLATED_V1 SNMPAPI_UNTRANSLATED_V2

#### Returns:

The **SnmpSetTranslateMode** function returns SNMPAPI\_SUCCESS if successful.

The **SnmpSetTranslateMode** function returns SNMPAPI\_FAILURE if it fails and the value of **SnmpGetLastError** will be set to one of the following:

SnmpGetLastError()	Description
"Common Error Codes"	See Section 2.8.1 for details.
SNMPAPI_MODE_INVALID	Indicates that the implementation does not support the requested translation mode.

#### Comments:

SNMPAPI\_NORMAL = Translate via Local Database look-up  
SNMPAPI\_UNTRANSLATED\_V1 = Literal transport address and community string  
SNMPAPI\_UNTRANSLATED\_V2 = Literal SNMPv2 party and context IDs

Upon successful execution of the **SnmpSetTranslateMode** function, the requested translation mode remains in effect for all subsequent **SnmpStrToEntity** and **SnmpStrToContext** function calls until another **SnmpSetTranslateMode** call with a different nTranslateMode value is executed successfully.

### 3.1.3. SnmpGetRetransmitMode()

The **SnmpGetRetransmitMode** function informs the calling application as to the retransmission mode in effect at the time of the call..

#### Syntax:

```
SNMPAPI_STATUS SnmpGetRetransmitMode (  
    OUT smiLPUINT32 nRetransmitMode);
```

Parameter	Description
nRetransmitMode	Pointer to variable to receive the current retransmission mode.

#### Returns:

The **SnmpGetRetransmitMode** function returns SNMPAPI\_SUCCESS if successful. In this case, the resultant value of nRetransmitMode will be one of the following:

SNMPAPI\_ON = The implementation *is* doing retransmission.  
SNMPAPI\_OFF = The implementation is *not* doing retransmission.

The **SnmpGetRetransmitMode** function returns SNMPAPI\_FAILURE if it fails. In this case, the value of nRetransmitMode is undefined and meaningless to the application, and the value of **SnmpGetLastError** will be set to one of the following:

SnmpGetLastError()	Description
"Common Error Codes"	See Section 2.8.1 for details.

#### Comments:

None.

### 3.1.4. SnmpSetRetransmitMode()

The **SnmpSetRetransmitMode** function enables the calling application to inform the implementation as to the desired retransmission mode (i.e., timeout/retry) for subsequent **SnmpSendMsg** operations.

#### Syntax:

```
SNMPAPI_STATUS SnmpSetRetransmitMode (
    IN smiUINT32 nRetransmitMode);
```

Parameter	Description
nRetransmitMode	Value used to set the current retransmission mode--must be one of the following:  SNMPAPI_ON SNMPAPI_OFF

#### Returns:

The **SnmpSetRetransmitMode** function returns SNMPAPI\_SUCCESS if successful.

The **SnmpSetRetransmitMode** function returns SNMPAPI\_FAILURE if it fails and the value of **SnmpGetLastError** will be set to one of the following:

SnmpGetLastError()	Description
"Common Error Codes"	See Section 2.8.1 for details.
SNMPAPI_MODE_INVALID	Indicates that the implementation does not support the requested translation mode.

#### Comments:

SNMPAPI\_ON = The implementation **is** doing retransmission.  
SNMPAPI\_OFF = The implementation is **not** doing retransmission.

Changing the retransmission mode from SNMPAPI\_OFF to SNMPAPI\_ON has no effect on any SNMP communications initiated via **SnmpSendMsg** function calls which might be outstanding prior to successful return from the subject **SnmpSetRetransmitMode** function call. That is, an implementation does **not** have to execute the retransmission policy for messages which it initially sent when the retransmission mode was set to SNMPAPI\_OFF and to which it has not yet received a response. An implementation **may elect** to execute the retransmission policy on behalf of such messages in this case, but this behavior is **not a requirement** and applications should not count on it. The purpose of this particular specification is to enable the implementations to take maximum advantage of the SNMPAPI\_OFF retransmission mode when it is in effect.

When an application changes the retransmission mode from SNMPAPI\_ON to SNMPAPI\_OFF, the implementation **should (but is not required to) cancel** all further retransmission attempts for any outstanding SNMP communications operations in effect prior to the call (and, of course, **must not initiate** any for subsequent **SnmpSendMsg** functions until the application might set the mode back to SNMPAPI\_ON). Applications, however, should assume that the implementation has done so. The reason this behavior is so specified is that it might not be possible for an implementation run through a list of outstanding SNMP communications operations and turn each one off, while also receiving new **SnmpSendMsg** requests and traps and notifications from prior **SnmpRegister** requests, without one or more previously set retransmit timers waking up. Since this may be the "critical loop" for WinSNMP implementations, we need to ensure that the implementations can handle it efficiently.

### 3.1.5. SnmpGetTimeout()

The **SnmpGetTimeout** function returns current values for the retransmission timeout value on a per-entity basis. The timeout value is expressed in units of hundredths of seconds. The `nPolicyTimeout` value refers to the timeout value currently stored in the local database for the subject agent. The `nActualTimeout` value refers to the last measured or estimated response receipt interval reported by the implementation.

#### Syntax:

```
SNMPAPI_STATUS SnmpGetTimeout (  
    IN HSNMP_ENTITY hEntity,  
    OUT smiLPTIMETICKS nPolicyTimeout,  
    OUT smiLPTIMETICKS nActualTimeout);
```

Parameter	Description
<code>hEntity</code>	Indicates the destination entity of interest.
<code>nPolicyTimeout</code>	Points to a variable to receive the timeout value for this entity as stored in the implementation's local database.
<code>nActualTimeout</code>	Points to a variable to receive the last measured or estimated response time interval from the destination agent.

#### Returns:

The **SnmpGetTimeout** function returns `SNMPAPI_SUCCESS` if successful.

The **SnmpGetTimeout** function returns `SNMPAPI_FAILURE` if it fails and the value of **SnmpGetLastError** will be set to one of the following:

<b>SnmpGetLastError()</b>	Description
"Common Error Codes"	See Section 2.8.1 for details.
<code>SNMPAPI_ENTITY_INVALID</code>	Indicates that an entity parameter is invalid.

#### Comments:

Implementations may provide utilities to load initial timeout values for the retransmission policy on a per destination entity basis, or may automatically assign some initial default value. Subsequent modifications to this value are made by applications with the **SnmpSetTimeout** function.

Implementations may or may not return measured or estimated values for the "actual timeout" parameter to the **SnmpGetTimeout** function. In the latter case, the implementation should return zero.

Applications should monitor the "actual timeout" value...if it is near, equal to, or greater than then current "policy timeout" value, the latter should be increased accordingly (or other corrective action taken).

### 3.1.6. SnmpSetTimeout()

The **SnmpSetTimeout** function enables an application to set the "policy timeout" value--in units of hundredths of seconds--on a per destination entity basis in the implementation's local database.

#### Syntax:

```
SNMPAPI_STATUS SnmpSetTimeout (  
    IN HSNMP_ENTITY hEntity,  
    IN smiTIMETICKS nPolicyTimeout);
```

Parameter	Description
hEntity	Indicates the destination entity of interest.
nPolicyTimeout	Indicates the timeout value for this entity to be stored in the implementation's local database.

#### Returns:

The **SnmpSetTimeout** function returns SNMPAPI\_SUCCESS if successful.

The **SnmpSetTimeout** function returns SNMPAPI\_FAILURE if it fails and the value of **SnmpGetLastError** will be set to one of the following:

SnmpGetLastError()	Description
"Common Error Codes"	See Section 2.8.1 for details.
SNMPAPI_ENTITY_INVALID	Indicates that an entity parameter is invalid.

#### Comments:

The timeout value is expressed in units of hundredths of seconds. If this value is zero, and both the application and the implementation agree to **SnmpSetRetransmitMode** (SNMPAPI\_ON), then the implementation will select an operating value for this parameter when actually executing the retransmission policy.

### 3.1.7. SnmpGetRetry()

The **SnmpGetRetry** function returns current values for the retransmission retry value on a per-entity basis. The retry value is expressed as a unit count. The nPolicyRetry value refers to the retry value currently stored in the local database for the subject agent. The nActualRetry value refers to the last measured or estimated response retry count reported by the implementation.

#### Syntax:

```
SNMPAPI_STATUS SnmpGetRetry (  
    IN HSNMP_ENTITY hEntity,  
    OUT smiLPUINT32 nPolicyRetry,  
    OUT smiLPUINT32 nActualRetry);
```

Parameter	Description
hEntity	Indicates the destination entity of interest.
nPolicyRetry	Points to a variable to receive the retry count value for this entity as stored in the implementation's local database.
nActualRetry	Points to a variable to receive the last measured or estimated response retry count from the destination agent.

#### Returns:

The **SnmpGetRetry** function returns SNMPAPI\_SUCCESS if successful.

The **SnmpGetRetry** function returns SNMPAPI\_FAILURE if it fails and the value of **SnmpGetLastError** will be set to one of the following:

SnmpGetLastError()	Description
"Common Error Codes"	See Section 2.8.1 for details.
SNMPAPI_ENTITY_INVALID	Indicates that an entity parameter is invalid.

#### Comments:

Implementations may provide utilities to load initial retry count values for the retransmission policy on a per destination entity basis, or may automatically assign some initial default value. Subsequent modifications to this value are made by applications with the **SnmpSetRetry** function.

Implementations may or may not return measured or estimated values for the "actual retry" parameter to the **SnmpGetRetry** function. In the latter case, the implementation should return zero.

Applications should monitor the "actual retry" value...if it is near, equal to, or greater than then current "policy retry" value, the latter should be increased accordingly (or other corrective action taken).

### 3.1.8. SnmpSetRetry()

The **SnmpSetRetry** function enables an application to set the "policy retry" count on a per destination entity basis in the implementation's local database.

#### Syntax:

```
SNMPAPI_STATUS SnmpSetRetry (  
    IN HSNMP_ENTITY hEntity,  
    IN smiUINT32 nPolicyRetry);
```

Parameter	Description
hEntity	Indicates the destination entity of interest.
nPolicyRetry	Indicates the retry count for this entity to be stored in the implementation's local database.

#### Returns:

The **SnmpSetRetry** function returns SNMPAPI\_SUCCESS if successful.

The **SnmpSetRetry** function returns SNMPAPI\_FAILURE if it fails and the value of **SnmpGetLastError** will be set to one of the following:

SnmpGetLastError()	Description
"Common Error Codes"	See Section 2.8.1 for details.
SNMPAPI_ENTITY_INVALID	Indicates that an entity parameter is invalid.

#### Comments:

The retry value is expressed as a simple unit count. If this value is zero, and the application and the implementation have agreed to **SnmpSetRetransmitMode** (SNMPAPI\_ON), then the implementation will select an operating value for this parameter when actually executing the retransmission policy.

### 3.2. Communications Functions

The functions in this section concern communications between the calling WinSNMP application and the serving WinSNMP implementation. Communications to and from other management entities--whether they reside on the local machine, on a connected LAN or WAN, or an internet--are handled by the WinSNMP implementation on behalf of the WinSNMP application, and without any overt orchestration by the latter.

The functions in this section are:

<b>Return Type</b>	<b>Procedure Name</b>	<b>Parameters</b>
SNMPAPI_STATUS	SnmpStartup	(OUT smiLPUINT32 nMajorVersion, OUT smiLPUINT32 nMinorVersion, OUT smiLPUINT32 nLevel, OUT smiLPUINT32 nTranslateMode, OUT smiLPUINT32 nRetransmitMode);
SNMPAPI_STATUS	SnmpCleanup	(void);
HSNMP_SESSION	SnmpOpen	(IN HWND hWnd, IN UINT wMsg);
SNMPAPI_STATUS	SnmpClose	(IN HSNMP_SESSION session);
SNMPAPI_STATUS	SnmpSendMsg	(IN HSNMP_SESSION session, IN HSNMP_ENTITY srcEntity, IN HSNMP_ENTITY dstEntity, IN HSNMP_CONTEXT context, IN HSNMP_PDU PDU);
HSNMP_PDU	SnmpRecvMsg	(IN HSNMP_SESSION session, OUT LPHSNMP_ENTITY srcEntity, OUT LPHSNMP_CONTEXT context);
SNMPAPI_STATUS	SnmpRegister	(IN HSNMP_SESSION session, IN HSNMP_ENTITY srcEntity, IN HSNMP_ENTITY dstEntity, IN HSNMP_CONTEXT context, IN smiLPOID notification, IN BOOL enabled);

### 3.2.1. SnmpStartup()

The **SnmpStartup** function notifies the implementation that the calling application is going to use its services, enabling the implementation to perform any required start-up procedures and allocations.

**Note:** Every WinSNMP application must call **SnmpStartup** at least once and this call must precede any other WinSNMP API function call.

#### Syntax:

```
SNMPAPI_STATUS SnmpStartup (  
    OUT smiLPUINT32 nMajorVersion,  
    OUT smiLPUINT32 nMinorVersion,  
    OUT smiLPUINT32 nLevel,  
    OUT smiLPUINT32 nTranslateMode  
    OUT smiLPUINT32 nRetransmitMode);
```

Parameter	Description
nMajorVersion	Pointer to variable to receive the major version number of the WinSNMP API implemented.
nMinorVersion	Pointer to variable to receive the minor version number of the WinSNMP API implemented.
nLevel	Pointer to variable to receive the highest level of SNMP communications supported by the implementation.
nTranslateMode	Pointer to variable to receive the default entity/context translation mode in effect for the implementation.
nRetransmitMode	Pointer to variable to receive the default retransmission mode in effect for the implementation.

#### Returns:

Upon success, the return value will be `SNMPAPI_SUCCESS`. In this case, the output parameters will contain appropriate values, as follows:

`nMajorVersion` will contain the major version number of the WinSNMP API implemented. For the initial release of the WinSNMP API specification, this value will be 1.

`nMinorVersion` will contain the minor version number of the WinSNMP API implemented. For the initial release of the WinSNMP API specification, this value will be 0.

`nLevel` will contain the highest level of SNMP communications supported by the implementation. This value may be one of the following:

```
SNMPAPI_NO_SUPPORT    = "Level 0" ( Message builder)  
SNMPAPI_V1_SUPPORT    = "Level 1" (SNMPv1 agents)  
SNMPAPI_V2_SUPPORT    = "Level 2" (SNMPv2 agents)  
SNMPAPI_M2M_SUPPORT  = "Level 3" (Manager-to-Manager)
```

`nTranslateMode` will contain the current default mode of translation of the entity and context parameters when used as inputs to **SnmpStrToEntity** and **SnmpStrToContext** functions. This value may be one of the following:

```
SNMPAPI_NORMAL        = Friendly names for translation via the Local Database  
SNMPAPI_UNTRANSLATED_V1 = Literal SNMPv1 transport address and community string  
SNMPAPI_UNTRANSLATED_V2 = Literal SNMPv2 party and context IDs
```

nRetransmitMode will contain the current default retransmission mode in effect for the implementation. This value may be one of the following:

SNMPAPI\_OFF= The implementation is **not** executing the retransmission policy  
SNMPAPI\_ON = The implementation **is** executing the retransmission policy

If this call fails, it will return SNMPAPI\_FAILURE, and the application must use **SnmGetLastError** to determine the reason.

<b>SnmGetLastError()</b>	<b>Description</b>
"Common Error Codes"	See Section 2.8.1 for details.

**Comments:**

When this call fails, the application must not make any further WinSNMP API calls, other than **SnmGetLastError** and, if appropriate, retries to **SnmStartup**. If an application calls other WinSNMP API functions without a preceding successful **SnmStartup**, the implementation should, if possible, return SNMPAPI\_NOT\_INITIALIZED.

An application which receives SNMPAPI\_FAILURE and SNMP\_ALLOC\_ERROR in response to **SnmStartup** may elect to wait or do other tasks and try again later in the hope that the implementation will have adequate free resources.

**SnmStartup** is idempotent. This means that an application can call it multiple times with impunity. Multiple **SnmStartup** calls do not require multiple **SnmCleanup** calls. Every application must call **SnmStartup** at least once, before any other WinSNMP API call, and must call **SnmCleanup** at least once, as the last WinSNMP API call.

### 3.2.2. SnmpCleanup()

The **SnmpCleanup** function informs the implementation that the calling application is disconnecting and no longer requires any open resources which might be allocated to it by the implementation. The implementation will deallocate all resources allocated to the application, unless they have also been allocated to other active applications.

#### Syntax:

```
SNMPAPI_STATUS SnmpCleanup (void);
```

#### Returns:

The **SnmpCleanup** function returns `SNMPAPI_SUCCESS` if successful. Every subsequent WinSNMP API function call--until a successful **SnmpStartup** call--will return `SNMPAPI_FAILURE` with **SnmpGetLastError** set to report `SNMPAPI_NOT_INITIALIZED`.

The **SnmpCleanup** function returns `SNMPAPI_FAILURE` if it fails. The application should behave as though it had returned `SNMPAPI_SUCCESS`. As an additional step the application could call **SnmpGetLastError** to ascertain the reason for failure:

<u>SnmpGetLastError()</u>	<u>Description</u>
"Common Error Codes"	See Section 2.8.1 for details.

#### Comments:

Note: It is the responsibility of an application to use the respective **SnmpFree<xxx>** functions to free specific resources created on its behalf and to use **SnmpClose** to clean-up after every session opened via **SnmpOpen**. However, in the event that an application must perform an emergency exit and call **SnmpCleanup** without performing those steps, an implementation must perform all necessary clean-up of any resources under its control which were created on behalf of or otherwise allocated to that application. Even in this emergency situation, however, the application *must* call **SnmpCleanup** to enable this functionality in the implementation.

### 3.2.3. SnmpOpen()

The **SnmpOpen** function enables the implementation to allocate and initialize memory, resources, and/or communications mechanisms and data structures for the application. The application will continue to use the "session identifier" returned by the implementation in subsequent WinSNMP function calls to facilitate resource accounting on a per session basis. This mechanism will enable the implementation to perform an orderly release of resources in response to a subsequent **SnmpClose** function call for a given session.

#### Syntax:

```
HSNMP_SESSION    SnmpOpen (  
    IN HWND       hWnd,  
    IN UINT       wMsg);
```

Parameter	Description
hWnd	Identifies the application's notification window.
wMsg	Identifies the application's notification message.

#### Returns:

If the function is successful, the return value is a HANDLE which identifies the WinSNMP session opened by the implementation on behalf of the calling application.

If the function fails, the return value is NULL. Use the **SnmpGetLastError** function to obtain extended error information.

<b>SnmpGetLastError()</b>	Description
"Common Error Codes"	See Section 2.8.1 for details.

#### Comments:

An application can open multiple sessions. Each such session for the same hWnd should provide a different wMsg. An **SnmpOpen** call using an hWnd and wMsg identical to an existing open session will return a handle to that same existing session.

The hWnd parameter specifies the window handle to be notified when an asynchronous request completes or trap occurs and the wMsg parameter specifies the message number that the window will be sent. Upon receipt of this message, the application should call **SnmpRecvMsg** to retrieve the PDU for immediate or subsequent processing.

In other programming models (e.g., synchronous, CLI-driven, or "curtained" applications), the WinSNMP implementation may interpret hWnd and hMsg differently. Likewise, the session model *may* be used to facilitate multi-threaded programming in supporting environments.

Note: A well-behaved WinSNMP application will call **SnmpClose** for each session opened by **SnmpOpen**. When an emergency exit is required of the application, it *must* at least call **SnmpCleanup**. A well-behaved WinSNMP implementation *must* react to an **SnmpCleanup** call as though it were a series of **SnmpClose** calls for each open session allocated to the calling application.

### 3.2.4. SnmpClose()

The **SnmpClose** function causes the implementation to deallocate and/or close memory, resources, communications mechanisms and data structures associated with the specified session, on behalf of the calling application.

#### Syntax:

```
SNMPAPI_STATUS SnmpClose (  
    IN HSNMP_SESSION session);
```

Parameter	Description
session	A handle specifying the session to close.

#### Returns:

SNMPAPI\_SUCCESS if the function successfully closes the WinSNMP session

If **SnmpClose** fails, it will return SNMPAPI\_FAILURE. Use **SnmpGetLastError** to obtain extended error information.

SnmpGetLastError()	Description
"Common Error Codes"	See Section 2.8.1 for details.
SNMPAPI_SESSION_INVALID	Indicates session parameter is invalid.

#### Comments:

Closing a session on which asynchronous requests are outstanding will cause any outstanding requests and/or replies for that session to be discarded by the implementation.

Note: A well-behaved WinSNMP application will call **SnmpClose** for each session opened by **SnmpOpen**. When an emergency exit is required of the application, it *must* at least call **SnmpCleanup**. A well-behaved WinSNMP implementation *must* react to an **SnmpCleanup** call as though it were a series of **SnmpClose** calls for each open session allocated to the calling application.

### 3.2.5. SnmpSendMsg()

The **SnmpSendMsg** function requests the specified PDU be transmitted to the destination entity, using the specified context and--for SNMPv2 communications--the designated source entity.

When a transmission request is received by the implementation via the **SnmpSendMsg** function, the WinSNMP implementation determines which version of SNMP and which transport to use based on its own capabilities and the corresponding properties associated with the requesting session and with the remote entity which holds the context to be accessed, based on values in the Local Database.

#### Syntax:

```
SNMPAPI_STATUS SnmpSendMsg (  
    IN HSNMP_SESSION session,  
    IN HSNMP_ENTITY srcEntity,  
    IN HSNMP_ENTITY dstEntity,  
    IN HSNMP_CONTEXT context,  
    IN HSNMP_PDU PDU);
```

Parameter	Description
session	Identifies the session that will perform the operation.
srcEntity	Identifies the subject management entity.
dstEntity	Identifies the target management entity.
context	Identifies the target context of interest.
PDU	Identifies the SNMP protocol data unit containing the requested operation.

#### Returns:

If the function is successful, the return value is SNMPAPI\_SUCCESS.

If the function fails, the return value is SNMPAPI\_FAILURE. Use **SnmpGetLastError** to obtain extended error information.

<b>SnmpGetLastError()</b>	Description
"Common Error Codes"	See Section 2.8.1 for details.
SNMPAPI_SESSION_INVALID	Indicates that a session parameter is invalid.
SNMPAPI_ENTITY_INVALID	Indicates that an entity parameter is invalid.
SNMPAPI_CONTEXT_INVALID	Indicates that the context parameter is invalid.
SNMPAPI_PDU_INVALID	Indicates that the PDU parameter is invalid.
SNMPAPI_OPERATION_INVALID	Indicates that the PDU_type element is inappropriate for the destination entity.

#### Comments:

This function returns immediately. If the return indicates an error, **SnmpGetLastError** should be called immediately to find out the error type. When the asynchronous request completes, the hWnd specified in the **SnmpOpen** call is sent the wParam specified. The application should call **SnmpRecvMsg** with this HSNMP\_SESSION to retrieve the results from the request.

Note: It is the responsibility of the WinSNMP implementation to verify the correctness of the PDU structure (and other arguments) and to return failure to the caller and an extended error code via **SnmGetLastError**. For example, for a PDU\_type other than SNMP\_PDU\_GETBULK and SNMP\_PDU\_RESPONSE (if allowed), passed values (other than zero) for error\_status/num-repeaters and/or error\_index/max\_repetitions would constitute an invalid PDU structure and the implementation should return SNMPAPI\_FAILURE and set **SnmGetLastError** to report SNMPAPI\_PDU\_INVALID.

Note: As SNMP replies do not necessarily come back in the same order as requests were sent, the application should check the request\_id of the received message to match it with the appropriate request.

If an SNMPv2 feature is requested, but the dstEntity implies an entity using SNMPv1, then the down-grading procedures defined in the SNMPv2 "coexistence" specification (RFC1452) are used. If down-grading is not possible (e.g., an InformRequest-PDU directed at an SNMPv1 agent), then the function will fail and **SnmGetLastError** will return SNMPAPI\_OPERATION\_INVALID.

### 3.2.6. SnmpRecvMsg()

The **SnmpRecvMsg** function retrieves the results from a completed asynchronous request made on a given HSNMP\_SESSION. It also receives traps registered for that session.

#### Syntax:

```
HSNMP_PDU SnmpRecvMsg (  
    IN HSNMP_SESSION session,  
    OUT LPHSNMP_ENTITY srcEntity,  
    OUT LPHSNMP_CONTEXT context);
```

Parameter	Description
session	Specifies the session that will receive the message.
srcEntity	Identifies the entity (agent role) which sent the message.
context	Identifies the context from which the entity issued the message.

#### Returns:

If the function is successful, the return value identifies the received SNMP protocol data unit.

If the function fails, the return value is NULL. Use the **SnmpGetLastError** function to obtain extended error information.

SnmpGetLastError()	Description
"Common Error Codes"	See Section 2.8.1 for details.
SNMPAPI_SESSION_INVALID	Indicates that the session parameter is invalid.
SNMPAPI_NOOP	Indicates that this session has no messages in its queue at this time

#### Comments:

The application is responsible for freeing the memory returned by this function when it is no longer needed by the application, by calling **SnmpFreePdu**, **SnmpFreeEntity**, and **SnmpFreeContext**.

Replies are not necessarily received in the same order as their originating requests were sent.

When a trap is delivered by **SnmpRecvMsg**, it is returned in the SNMPv2 format, even if a SNMPv1 entity generated the trap. The SNMPv2 "coexistence" specification, as described in RFC 1452, specifies the mapping rules between the SNMPv1 and SNMPv2 trap formats. However, for the convenience of management applications, the final variable binding for a SNMPv1-generated trap will always be snmpTrapEnterpriseOID.0, even if the trap is a generic trap such as coldStart. (See **Appendix A** for the mapping convention.)

### 3.2.7. SnmpRegister()

The **SnmpRegister** function registers the application's desire to receive or discontinue trap and inform notifications from the specified entity of interest, which will act in an agent role.

#### Syntax:

```
SNMPAPI_STATUS SnmpRegister (  
    IN HSNMP_SESSION session,  
    IN HSNMP_ENTITY srcEntity,  
    IN HSNMP_ENTITY dstEntity,  
    IN HSNMP_CONTEXT context,  
    IN smiLPOID notification,  
    IN BOOL enabled);
```

Parameter	Description
session	Identifies the session which is interested in registering.
srcEntity	Identifies the management entity (manager role) of interest.
dstEntity	Identifies the management entity (agent role) of interest.
context	Identifies the context of interest.
notification	Identifies the notification to be registered or un-registered.
enabled	Indicates whether to register or un-register.

#### Returns:

If the function is successful, the return value is SNMPAPI\_SUCCESS.

If the function fails, the return value is SNMPAPI\_FAILURE. Use the **SnmpGetLastError** function to obtain extended error information.

<b>SnmpGetLastError()</b>	Description
"Common Error Codes"	See Section 2.8.1 for details.
SNMPAPI_SESSION_INVALID	Indicates that the session parameter is invalid.
SNMPAPI_ENTITY_INVALID	Indicates that the entity parameter is invalid.
SNMPAPI_CONTEXT_INVALID	Indicates that the context parameter is invalid.
SNMPAPI_OID_INVALID	Indicates that the notification parameter is invalid.

#### Comments:

Notifications, traps or informs, are defined using OBJECT IDENTIFIERS, as specified in SNMPv2. Hence, an application interested in receiving coldStart traps should construct an OBJECT IDENTIFIER corresponding to this trap and use this as the notification parameter (see **Appendix A** for mappings for SNMPv1).

If the notification parameter is NULL, then the application is indicating that it is interested in [un-] registering any and all notifications.

Upon receipt of a notification, the hWnd parameter specified in the **SnmpOpen** call is sent the wMsg specified. The application should call **SnmpRecvMsg** with this session to retrieve the appropriate results.

Note that it is the responsibility of the implementation to acknowledge the receipt of an InformRequest-PDU. This tells the issuing management entity that the inform made it to the implementation "platform", but not necessarily to any particular application(s).

### 3.3. Entity/Context Functions

The functions in this section enable the application to use human-oriented string identifiers for the entity and context "objects" and concepts, while permitting the WinSNMP implementation to adopt proprietary repository, access method, and runtime representation strategies vis-à-vis the "local database", entities, parties, and contexts.

The functions in this section are:

<b>Return Type</b>	<b>Procedure Name</b>	<b>Parameters</b>
HSNMP_ENTITY	SnmpStrToEntity	(IN HSNMP_SESSION session, IN LPSTR entity);
SNMPAPI_STATUS	SnmpEntityToStr	(IN HSNMP_ENTITY entity, IN smiUINT32 size, OUT LPSTR string);
SNMPAPI_STATUS	SnmpFreeEntity	(IN HSNMP_ENTITY entity);
HSNMP_CONTEXT	SnmpStrToContext	(IN HSNMP_SESSION session, IN HSNMP_ENTITY entity, IN LPSTR context);
SNMPAPI_STATUS	SnmpContextToStr	(IN HSNMP_CONTEXT context, IN smiUINT32 size, OUT LPSTR string);
SNMPAPI_STATUS	SnmpFreeContext	(IN HSNMP_CONTEXT context);

[DTP: Need functions:

SnmpGetEntityData: For SNMPv1, returns transport type and transport address.  
For SNMPv2, returns src/dst parties and party info.

SnmpEnumEntities: Returns list of (available) SNMP entities.

SnmpGetContextData: For SNMPv1, returns community string and access flag.  
For SNMPv2, returns context OID and other stuff.

SnmpEnumContexts: Returns all contexts for a given entity.]

### 3.3.1. SnmpStrToEntity()

The **SnmpStrToEntity** function accepts a pointer to a null-terminated text string identifying an entity of interest and, if successful, returns a handle to an implementation-specific representation of entity information. Note that the resulting entity handle may be used as either a srcEntity value or as a dstEntity value. Note, also, that the semantics of the input string are governed by the value of entity/context translation mode in effect at the time of the call.

#### Syntax:

```
HSNMP_ENTITY    SnmpStrToEntity (  
    IN HSNMP_SESSION    session,  
    IN LPSTR            entity);
```

Parameter	Description
session	Handle of the allocating session.
entity	Pointer to a text string identifying the management entity of interest.

#### Returns:

If the function is successful, the return value is an HSNMP\_ENTITY handle.

If the function fails, the return value is SNMPAPI\_FAILURE. Use the **SnmpGetLastError** function to obtain extended error information.

SnmpGetLastError()	Description
"Common Error Codes"	See Section 2.8.1 for details.
SNMPAPI_SESSION_INVALID	Indicates an invalid session handle.
SNMPAPI_ENTITY_UNKNOWN	Indicates entity parameter is unknown.

#### Comments:

When the application no longer needs to utilize this entity handle, the **SnmpFreeEntity** function should be called to release the resources associated with it.

When the current entity/context translation mode is SNMPAPI\_NORMAL, the "entity" parameter is assumed to be a user-friendly textual name to be de-referenced via the Local Database.

When the current entity/context translation mode is SNMPAPI\_UNTRANSLATED\_V1, the "entity" parameter is assumed to be a literal transport address (in textual form). The implementation will attempt to identify Local Database resources associated with this SNMPv1 "address" and will supply working defaults when no such entry exists in the Local Database. This is to enable "out-of-the-box" SNMPv1/UDP operation with WinSNMP.

When the current entity/context translation mode is SNMPAPI\_UNTRANSLATED\_V2, the "entity" parameter is assumed to be a literal PartyID (in textual form). The implementation will attempt to identify Local Database resources associated with this SNMPv2 "party" and will supply working defaults when no such entry exists in the Local Database. This is to enable "out-of-the-box" SNMPv2/InitialPartyID operation with WinSNMP.

### 3.3.2. SnmpEntityToStr()

The **SnmpEntityToStr** function returns a string value identifying an entity.

#### Syntax:

```
SNMPAPI_STATUS SnmpEntityToStr (  
    IN HSNMP_ENTITY    entity,  
    IN smiUINT32       size,  
    OUT LPSTR          string);
```

Parameter	Description
entity	A handle specifying an entity.
size	The size of the buffer the application is providing to contain the string.
string	Points to a buffer that will receive the string that identifies the management entity.

#### Returns:

If the function is successful, the return value is the number of bytes, including the NULL terminating byte, output to "string"--this value may be less than or equal to "size", but not greater.

If the function fails, the return value is SNMPAPI\_FAILURE. Use the **SnmpGetLastError** function to obtain extended error information.

<b>SnmpGetLastError()</b>	Description
"Common Error Codes"	See Section 2.8.1 for details.
SNMPAPI_ENTITY_INVALID	Indicates entity parameter is unknown.
SNMPAPI_OUTPUT_TRUNCATED	Indicates that the buffer was too small.

#### Comments:

Note that the current setting of the entity/context translation mode affects this function:

If the setting is SNMPAPI\_NORMAL, then the implementation returns the user-friendly textual name of this entity from the Local Database. If no such name exists in the Local Database, then the function returns either of the following, depending upon whether the entity is known to be SNMPv1 or SNMPv2.

If the setting is SNMPAPI\_UNTRANSLATED\_V1 and the subject entity is an SNMPv1 creature, then the implementations returns the transport address of the entity (in textual form). If the subject entity is an SNMPv2 creature, then the implementation behaves as though the entity/context translation mode setting were SNMPAPI\_UNTRANSLATED\_V2 for the purposes of this call only.

If the setting is SNMPAPI\_UNTRANSLATED\_V2 and the subject entity is an SNMPv2 creature, then the implementations returns the PartyID of the entity (in textual form). If the subject entity is an SNMPv1 creature, then the implementation behaves as though the entity/context translation mode setting were SNMPAPI\_UNTRANSLATED\_V1 for the purposes of this call only.

### 3.3.3. SnmpFreeEntity()

The **SnmpFreeEntity** function releases resources associated with a entity returned by the **SnmpStrToEntity** function.

#### Syntax:

```
SNMPAPI_STATUS SnmpFreeEntity (  
    IN HSNMP_ENTITY entity);
```

Parameter	Description
entity	An entity handle to be released.

#### Returns:

If the function is successful, the return value is SNMPAPI\_SUCCESS.

If the function fails, the return value is SNMPAPI\_FAILURE. Use the **SnmpGetLastError** function to obtain extended error information.

<b>SnmpGetLastError()</b>	Description
"Common Error Codes"	See Section 2.8.1 for details.
SNMPAPI_ENTITY_INVALID	Indicates entity parameter is invalid.

#### Comments:

Unfreed resources created on behalf of the application will be freed by the implementation upon execution of an associated **SnmpClose** function or upon execution of an **SnmpCleanup** function. Nonetheless, a well-behaved WinSNMP application will individually free all such resources using the atomic "free" functions. The reason for this is to eliminate or, at least, minimize any "batch-like" loads on the implementation, so that other applications can be serviced in a timely fashion.

### 3.3.4. SnmpStrToContext()

The **SnmpStrToContext** function accepts a text string naming the collection of managed objects of interest and--if this requested context is available to the target entity--returns a handle to an implementation-specific representation of context information for use with the **SnmpSendMsg** and **SnmpRegister** functions.

#### Syntax:

```
HSNMP_CONTEXT  SnmpStrToContext (  
    IN HSNMP_SESSION  session,  
    IN HSNMP_ENTITY   entity,  
    IN LPSTR          context);
```

Parameter	Description
session	Handle of the allocating session.
entity	A handle specifying the entity of interest.
context	A string identifying a collection of managed objects available to the entity of interest.

#### Returns:

If the function is successful, the return value is a HSNMP\_CONTEXT handle.

If the function fails, the return value is SNMPAPI\_FAILURE. Use the **SnmpGetLastError** function to obtain extended error information.

<b>SnmpGetLastError()</b>	Description
"Common Error Codes"	See Section 2.8.1 for details.
SNMPAPI_SESSION_INVALID	Indicates an invalid session handle.
SNMPAPI_ENTITY_INVALID	Indicates entity parameter is invalid.
SNMPAPI_CONTEXT_UNKNOWN	Indicates context parameter is unknown.

#### Comments:

When the application no longer needs to utilize this context handle, the **SnmpFreeContext** function should be called to release the resources associated with it.

When the current entity/context translation mode is SNMPAPI\_NORMAL, the "context" parameter is assumed to be a user-friendly textual name to be de-referenced via the Local Database.

When the current entity/context translation mode is SNMPAPI\_UNTRANSLATED\_V1, the "context" parameter is assumed to be a literal community string (in textual form).

When the current entity/context translation mode is SNMPAPI\_UNTRANSLATED\_V2, the "context" parameter is assumed to be a literal ContextID (in textual form). The implementation will attempt to identify Local Database resources associated with this SNMPv2 "context" and will supply working defaults when no such entry exists in the Local Database. This is to enable "out-of-the-box" SNMPv2/InitialContextID operation with WinSNMP.

### 3.3.5. SnmpContextToStr()

The **SnmpContextToStr** function returns a string value identifying a context.

#### Syntax:

```
SNMPAPI_STATUS SnmpContextToStr (  
    IN HSNMP_CONTEXT context,  
    IN smiUINT32 size,  
    OUT LPSTR string);
```

Parameter	Description
context	A handle specifying a context.
size	The size of the buffer the application is providing to contain the string.
string	A pointer to a buffer that will receive the string which identifies the context.

#### Returns:

If the function is successful, the return value is the number of bytes, including the NULL terminating byte, output to "string"--this value may be less than or equal to "size", but not greater.

If the function fails, the return value is SNMPAPI\_FAILURE. Use the **SnmpGetLastError** function to obtain extended error information.

<b>SnmpGetLastError()</b>	Description
"Common Error Codes"	See Section 2.8.1 for details.
SNMPAPI_CONTEXT_INVALID	Indicates that the context handle is invalid.
SNMPAPI_OUTPUT_TRUNCATED	Indicates that the buffer was too small.

#### Comments:

Note that the current setting of the entity/context translation mode affects this function:

If the setting is SNMPAPI\_NORMAL, then the implementation returns the user-friendly textual name of this entity from the Local Database. If no such name exists in the Local Database, then the function returns either of the following, depending upon whether the entity is known to be SNMPv1 or SNMPv2.

If the setting is SNMPAPI\_UNTRANSLATED\_V1 and the subject entity is an SNMPv1 creature, then the implementation returns the raw community string (in textual form). If the subject entity is an SNMPv2 creature, then the implementation behaves as though the entity/context translation mode setting were SNMPAPI\_UNTRANSLATED\_V2 for the purposes of this call only.

If the setting is SNMPAPI\_UNTRANSLATED\_V2 and the subject entity is an SNMPv2 creature, then the implementation returns the raw ContextID (in textual form). If the subject entity is an SNMPv1 creature, then the implementation behaves as though the entity/context translation mode setting were SNMPAPI\_UNTRANSLATED\_V1 for the purposes of this call only.

### 3.3.6. SnmpFreeContext()

The **SnmpFreeContext** function releases resources associated with a context returned by the **SnmpStrToContext** function.

#### Syntax:

```
SNMPAPI_STATUS SnmpFreeContext (  
    IN HSNMP_CONTEXT context);
```

Parameter	Description
context	A context handle to be released.

#### Returns:

If the function is successful, the return value is SNMPAPI\_SUCCESS.

If the function fails, the return value is SNMPAPI\_FAILURE. Use the **SnmpGetLastError** function to obtain extended error information.

SnmpGetLastError()	Description
"Common Error Codes"	See Section 2.8.1 for details.
SNMPAPI_CONTEXT_INVALID	Indicates context parameter is invalid.

#### Comments:

Unfreed resources created on behalf of the application will be freed by the implementation upon execution of an associated **SnmpClose** function or upon execution of an **SnmpCleanup** function. Nonetheless, a well-behaved WinSNMP application will individually free all such resources using the atomic "free" functions. The reason for this is to eliminate or, at least, minimize any "batch-like" loads on the implementation, so that other applications can be serviced in a timely fashion.

### 3.4. PDU Functions

This section defines functions which construct PDUs for use in the **SnmpSendMsg** and **SnmpEncodeMsg** functions and which decompose PDUs received via the **SnmpRecvMsg** and **SnmpDecodeMsg** functions. The following section--Variable Binding Functions--also pertains to PDU [de]composition, but is retained as a separate section both for consistency with the earlier versions of this document and for modularization.

Actual PDU and variable binding data structures are private to the WinSNMP implementation. The PDU and Variable Binding functions enable applications to extract the component data elements which are then available for whatever use the application deems appropriate. The elements comprising a PDU from the perspective of a WinSNMP application are:

```
/* This typedef is for expository purposes only. It is not a required component of WinSNMP */
typedef struct {
    smiINT      PDU_type;
    smiINT32    request_id;
    smiINT      error_status;    -- "non_repeaters" for BulkPDU
    smiINT      error_index;    -- "max_repetitions" for BulkPDU
    HSNMP_VBL  varbindlist;}    -- we'll examine this one in the next section
PDU;
```

The functions in this section are:

Return Type	Procedure Name	Parameters
HSNMP_PDU	SnmpCreatePdu	(IN HSNMP_SESSION session, IN smiINT PDU_type, IN smiINT32 request_id, IN smiINT error_status/non_repeaters, IN smiINT error_index/max_repetitions, IN HSNMP_VBL varbindlist);
SNMPAPI_STATUS	SnmpGetPduData	(IN HSNMP_PDU PDU, OUT smiLPINT PDU_type, OUT smiLPINT32 request_id, OUT smiLPINT error_status/non_repeaters, OUT smiLPINT error_index/max_repetitions, OUT LPHSNMP_VBL varbindlist);
SNMPAPI_STATUS	SnmpSetPduData	(IN HSNMP_PDU PDU, IN smiLPINT PDU_type, IN smiLPINT32 request_id, IN smiLPINT non_repeaters, IN smiLPINT max_repetitions, IN LPHSNMP_VBL varbindlist);
HSNMP_PDU	SnmpDuplicatePdu	(IN HSNMP_SESSION session, IN HSNMP_PDU PDU);
SNMPAPI_STATUS	SnmpFreePdu	(IN HSNMP_PDU PDU);

The following table illustrates the possible PDU\_type values used in WinSNMP functions:

#### PDU\_types Table

SNMP_PDU_GET	Indicates a Get Request-PDU
SNMP_PDU_GETNEXT	Indicates a GetNextRequest-PDU
SNMP_PDU_GETBULK	Indicates a GetBulkRequest-PDU
SNMP_PDU_SET	Indicates a SetRequest- PDU
SNMP_PDU_INFORM	Indicates an InformRequest-PDU
SNMP_PDU_RESPONSE	Indicates a Response-PDU
SNMP_PDU_TRAP	Indicates a SNMPv2-Trap-PDU

The following table illustrates the possible SNMP error values used in the error\_status element of an SNMP PDU:

#### SNMP Error Values Table

SNMP_ERROR_NOERROR	Specifies the noError error.
SNMP_ERROR_TOOBIG	Specifies the tooBig error.
SNMP_ERROR_NOSUCHNAME	Specifies the noSuchName error.
SNMP_ERROR_BADVALUE	Specifies the badValue error.
SNMP_ERROR_READONLY	Specifies the readOnly error.
SNMP_ERROR_GENERR	Specifies the genErr error.
SNMP_ERROR_NOACCESS	Specifies the noAccess error.
SNMP_ERROR_WRONGTYPE	Specifies the wrongType error.
SNMP_ERROR_WRONGLENGTH	Specifies the wrongLength error.
SNMP_ERROR_WRONGENCODING	Specifies the wrongEncoding error.
SNMP_ERROR_WRONGVALUE	Specifies the wrongValue error.
SNMP_ERROR_NOCREATION	Specifies the noCreation error.
SNMP_ERROR_INCONSISTENTVALUE	Specifies the inconsistentValue error.
SNMP_ERROR_RESOURCEUNAVAILABLE	Specifies the resourceUnavailable error.
SNMP_ERROR_COMMITFAILED	Specifies the commitFailed error.
SNMP_ERROR_UNDOFAILED	Specifies the undoFailed error.
SNMP_ERROR_AUTHORIZATIONERROR	Specifies the authorizationError error.
SNMP_ERROR_NOTWRITABLE	Specifies the notWritable error.
SNMP_ERROR_INCONSISTENTNAME	Specifies the inconsistentName error.

### 3.4.1. SnmpCreatePdu()

The **SnmpCreatePdu** function allocates and initializes an SNMP protocol data unit for subsequent use in **SnmpSendMsg**, **SnmpEncodeMsg**, and other functions.

Note that all input parameters to **SnmpCreatePdu** must be present; but, with the exception of the "session" parameter, all may be NULL, resulting in a default PDU as defined below.

#### Syntax:

```
HSNMP_PDU      SnmpCreatePdu (  
    IN HSNMP_SESSION    session,  
    IN smiINT           PDU_type,  
    IN smiINT32         request_id,  
    IN smiINT           error_status,    -- "non_repeaters" for BulkPDU  
    IN smiINT           error_index,    -- "max_repetitions" for BulkPDU  
    IN HSNMP_VBL       varbindlist);
```

Parameter	Description
session	Handle of the allocating session.
PDU_type	NULL or one of the values shown in the PDU_types table shown in the introduction to the PDU Functions section. If NULL, the WinSNMP implementation will supply SNMP_PDU_GETNEXT.
request_id	An application-supplied value used to identify the PDU or NULL, in which case the WinSNMP implementation will supply a value.
error_status	Ignored (and may be NULL) on input for all PDU types except SNMP_PDU_GETBULK, in which case it represents the value for non_repeaters. For all other PDU types, the WinSNMP implementation will supply SNMP_ERROR_NOERROR.
error_index	Ignored (and may be NULL) on input for all PDU types except SNMP_PDU_GETBULK, in which case it represents the value for max_repetitions. The WinSNMP implementation returns 0 (zero) for all other PDU types.
varbindlist	A handle to a varbindlist data structure (or NULL).

#### Returns:

If the function is successful, the return value identifies the created SNMP protocol data unit

If the function fails, the return value is SNMPAPI\_FAILURE. Use the **SnmpGetLastError** function to obtain extended error information.

SnmpGetLastError()	Description
"Common Error Codes"	See Section 2.8.1 for details.
SNMPAPI_SESSION_INVALID	Indicates an invalid session handle.
SNMPAPI_PDU_INVALID	Indicates an invalid PDU_type value.
Other errors are likely...needs work.	

**Comments:**

Assuming NULL values for all input parameters (other than "session"), the created protocol data unit defaults to the following attributes:

PDU_type:	SNMP_PDU_GETNEXT
request_id:	<WinSNMP-generated value>
error_status:	SNMP_ERROR_NOERROR
error_index:	0
varbindlist:	NULL

After completing operations with the created PDU, the **SnmpFreePdu** function should be called to release the resources allocated to the PDU by the **SnmpCreatePdu** function..

### 3.4.2. SnmpGetPduData()

The **SnmpGetPduData** function extracts selected data elements from the specified PDU and copies them to the respective locations given as corresponding output parameters.

Note that all output parameters must be supplied to the function call, but any (or all) of them may be NULL. No values are returned for output parameters passed as NULL.

#### Syntax:

```
SNMPAPI_STATUS      SnmpGetPduData (
    IN HSNMP_PDU     PDU,
    OUT smiLPINT      PDU_type,
    OUT smiLPINT32    request_id,
    OUT smiLPINT      error_status,    -- "non_repeaters" for GetBulkRequest-PDU
    OUT smiLPINT      error_index,    -- "max_repetitions" for GetBulkRequest-PDU
    OUT LPHSNMP_VBL  varbindlist);
```

Parameter	Description
PDU	Identifies the SNMP protocol data unit.
PDU_type	If not NULL, points to an smiINT variable that will receive the PDU_type of the PDU.
request_id	If not NULL, points to an smiINT32 variable that will receive the request_id of the PDU.
error_status	If not NULL, points to an smiINT variable that will receive the error_status (or non_repeaters) of the PDU.
error_index	If not NULL, points to an smiINT variable that will receive the error_index (or max_repetitions) of the PDU.
varbindlist	If not NULL, points to an HSNMP_VBL variable that will receive the handle to the varbindlist of the PDU.

#### Returns:

If the function is successful, the return value is SNMPAPI\_SUCCESS.

If the function fails, the return value is SNMPAPI\_FAILURE. Use the **SnmpGetLastError** function to obtain extended error information.

<b>SnmpGetLastError()</b>	Description
"Common Error Codes"	See Section 2.8.1 for details.
SNMPAPI_PDU_INVALID	Indicates that the PDU parameter is invalid.
SNMPAPI_NOOP	Indicates that all output parameters were NULL

#### Comments:

On a successful return and if the parameter was not NULL, PDU\_type will contain one of the values from the PDU\_Types Table shown in the introduction to the PDU Functions section.

On a successful return and if the parameter was not NULL, error\_status will contain one of the values from the SNMP Error Values Table shown in the introduction to the PDU Functions section.

As always, a well-behaved application must handle the case when an unexpected value (PDU\_type and error\_status are just possible examples) might be returned by a procedure call.

### 3.4.3. SnmpSetPduData()

The **SnmpSetPduData** function updates selected data elements in the specified PDU.

Note that all parameters must be supplied to the function call, but any (or all) of them--except the PDU--may be NULL. No values are changed in the PDU for input parameters passed as NULL (and they are passed as pointers to values to allow for the case when NULL is the desired update **value**).

#### Syntax:

```
SNMPAPI_STATUS SnmpSetPduData (  
    IN HSNMP_PDU PDU,  
    IN smiLPINT PDU_type,  
    IN smiLPINT32 request_id,  
    IN smiLPINT non_repeaters, -- for GetBulkRequest-PDU only  
    IN smiLPINT max_repetitions, -- for GetBulkRequest-PDU only  
    IN LPHSNMP_VBLvarbindlist);
```

Parameter	Description
PDU	Identifies the SNMP protocol data unit.
PDU_type	If not NULL, points to an smiINT variable that will update the PDU_type of the PDU.
request_id	If not NULL, points to an smiINT32 variable that will update the request_id of the PDU.
non_repeaters	If not NULL, points to an smiINT variable that will update the non_repeaters of the GetBulkRequest-PDU (ignored for other PDU_types).
max_repetitions	If not NULL, points to an smiINT variable that will update the max_repetitions of the GetBulkRequest-PDU (ignored for other PDU_types).
varbindlist	If not NULL, points to an HSNMP_VBL variable that will update the handle to the varbindlist of the PDU.

#### Returns:

If the function is successful, the return value is SNMPAPI\_SUCCESS.

If the function fails, the return value is SNMPAPI\_FAILURE. Use the **SnmpGetLastError** function to obtain extended error information.

<b>SnmpGetLastError()</b>	Description
"Common Error Codes"	See Section 2.8.1 for details.
SNMPAPI_PDU_INVALID	Indicates that the PDU parameter is invalid.
SNMPAPI_NOOP	Indicates that all input parameters were NULL

#### Comments:

Not all possible combinations of individually legal component values are valid. Ultimately, the WinSNMP implementation must verify the validity of the PDU (and other message elements) when the application calls the **SnmpSendMsg** or **SnmpEncodeMsg** function and reject and ill-formed or otherwise illegal PDU structures

### 3.4.4. SnmpDuplicatePdu()

The **SnmpDuplicatePdu** function duplicates an SNMP protocol data unit structure identified by the PDU parameter.

#### Syntax:

```
HSNMP_PDU          SnmpDuplicatePdu (  
    IN HSNMP_SESSION session,  
    IN HSNMP_PDU    PDU);
```

Parameter	Description
session	Handle of the allocating session.
PDU	Identifies the SNMP protocol data unit to duplicate.

#### Returns:

If the function is successful, the return value identifies the new (duplicated) SNMP protocol data unit.

If the function fails, the return value is NULL. Use the **SnmpGetLastError** function to obtain extended error information.

<b>SnmpGetLastError()</b>	Description
"Common Error Codes"	See Section 2.8.1 for details.
SNMPAPI_SESSION_INVALID	Indicates an invalid session handle.
SNMPAPI_PDU_INVALID	Indicates that the PDU parameter is invalid.

#### Comments:

After using the duplicated message, **SnmpFreePdu** function should be called to release the resources allocated to the PDU by the **SnmpDuplicatePdu** function.

### 3.4.5. SnmpFreePdu()

The **SnmpFreePdu** function releases resources associated with a protocol data unit previously created by the **SnmpCreatePdu** or **SnmpDuplicatePdu** function.

#### Syntax:

```
SNMPAPI_STATUS SnmpFreePdu (  
    IN HSNMP_PDU PDU);
```

Parameter	Description
PDU	Identifies the SNMP protocol data unit to be freed.

#### Returns:

If the function is successful, the return value is SNMPAPI\_SUCCESS.

If the function fails, the return value is SNMPAPI\_FAILURE. Use the **SnmpGetLastError** function to obtain extended error information.

<b>SnmpGetLastError()</b>	Description
"Common Error Codes"	See Section 2.8.1 for details.
SNMPAPI_PDU_INVALID	Indicates that the PDU parameter is invalid.

#### Comments:

Unfreed resources created on behalf of the application will be freed by the implementation upon execution of an associated **SnmpClose** function or upon execution of an **SnmpCleanup** function. Nonetheless, a well-behaved WinSNMP application will individually free all such resources using the atomic "free" functions. The reason for this is to eliminate or, at least, minimize any "batch-like" loads on the implementation, so that other applications can be serviced in a timely fashion.

Varbinds and varbindlists are re-usable independently of any given PDU. In WinSNMP, a varbind does not exist outside of a varbindlist (even if the latter consists of only a single varbind). There is a separate atomic function--**SnmpFreeVbl**--to deallocate varbindlist resources. Of course, upon execution of **SnmpFreePdu**, the WinSNMP implementation must free any *internal* resources allocated to VBLs for that PDU. That's different from the HSNMP\_VBL resources requested and held by a session in the calling application.

### 3.5. Variable Binding Functions

WinSNMP relies on a varbindlist structure (VBL), and drops the concept of a separate varbind structure (VB). No capability is lost, since an individual varbind structure can be represented by a varbindlist structure of one member. A WinSNMP **application** accesses the varbindlist structure via handles--of type HSNMP\_VBL. A WinSNMP **implementation** hides the details of this structure from the application using whatever proprietary mechanisms and techniques it considers optimal.

These functions allow applications to easily construct and manipulate varbindlists for inclusion in PDUs. Note that a varbind is not directly associated with a PDU, only indirectly through inclusion in a varbindlist. A varbindlist gets associated with and de-referenced from a PDU with the **SnmSetPduData** and **SnmGetPduData**, respectively.

The functions in this section are:

Return Type	Procedure Name	Parameters
HSNMP_VBL	SnmCreateVbl	(IN HSNMP_SESSION session, IN smiLPOID name, IN smiLPVALUE value);
HSNMP_VBL	SnmDuplicateVbl	(IN HSNMP_SESSION session, IN HSNMP_VBL vbl);
SNMPAPI_STATUS	SnmFreeVbl	(IN HSNMP_VBL vbl);
SNMPAPI_STATUS	SnmCountVbl	(IN HSNMP_VBL vbl);
SNMPAPI_STATUS	SnmGetVb	(IN HSNMP_VBL vbl, IN smiUINT32 index, OUT smiLPOID name, OUT smiLPVALUE value);
SNMPAPI_STATUS	SnmSetVb	(IN HSNMP_VBL vbl, IN smiLPOID name, IN smiLPVALUE value);
SNMPAPI_STATUS	SnmDeleteVb	(IN HSNMP_VBL vbl, IN smiLPOID name);

## Table of Syntax Values Used in Variable Binding Data Structures

SNMP\_SYNTAX\_INT32  
SNMP\_SYNTAX\_OCTETS  
SNMP\_SYNTAX\_OID  
SNMP\_SYNTAX\_BITS  
SNMP\_SYNTAX\_IPADDR  
SNMP\_SYNTAX\_CNTR32  
SNMP\_SYNTAX\_GAUGE32  
SNMP\_SYNTAX\_TIMETICKS  
SNMP\_SYNTAX\_OPAQUE  
SNMP\_SYNTAX\_NSAPADDR  
SNMP\_SYNTAX\_CNTR64  
SNMP\_SYNTAX\_UINT32  
SNMP\_SYNTAX\_NULL  
SNMP\_SYNTAX\_NOSUCHOBJECT  
SNMP\_SYNTAX\_NOSUCHINSTANCE  
SNMP\_SYNTAX\_ENDOFMIBVIEW

### 3.5.1. SnmpCreateVbl()

The **SnmpCreateVbl** function creates a new varbindlist structure for the calling application. If the "name" and "value" parameters are not NULL, **SnmpCreateVbl** uses them to construct the initial varbind member of the varbindlist.

#### Syntax:

```
HSNMP_VBL          SnmpCreateVbl (  
    IN HSNMP_SESSION session,  
    IN smiLPOID     name,  
    IN smiLPVALUE   value);
```

Parameter	Description
session	Handle of the allocating session.
name	If not NULL, points to an OID for initialization of the varbindlist.
value	If not NULL, points to a value for initialization of the varbindlist.

#### Returns:

If the function is successful, the return value identifies a newly created varbindlist structure.

If the function fails, the return value is SNMPAPI\_FAILURE. Use the **SnmpGetLastError** function to obtain extended error information.

<b>SnmpGetLastError()</b>	Description
"Common Error Codes"	See Section 2.8.1 for details.
SNMPAPI_SESSION_INVALID	Indicates an invalid session handle.
SNMPAPI_SYNTAX_INVALID	Indicates that the syntax field of the value parameter is invalid.

#### Comments:

IF the "name" parameter is not NULL and the "value" parameter is NULL, the varbindlist will still be initialized, with the value set to NULL and with syntax of SNMP\_SYNTAX\_NULL. If the "name" parameters is NULL, the varbindlist will not be initialized, and the "value" parameter will be ignored.

Every call to **SnmpCreateVbl** must be matched with a corresponding call to **SnmpFreeVbl** to release the resources associated with the varbindlist. A memory leak will result if a variable used to hold an HSNMP\_VBL value returned by **SnmpCreateVbl** (or **SnmpDuplicateVbl**) is re-used for a subsequent **SnmpCreateVbl** (or **SnmpDuplicateVbl**) operation before it has been passed to **SnmpFreeVbl**.

### 3.5.2. SnmpDuplicateVbl()

The **SnmpDuplicateVbl** function creates a new varbindlist structure for the specified session in the calling application and initializes it with a copy of the input vbl (which may be empty).

**Syntax:**

```
HSNMP_VBL          SnmpDuplicateVbl (  
    IN HSNMP_SESSION session,  
    IN HSNMP_VBL    vbl);
```

Parameter	Description
session	Handle of the allocating session.
vbl	Identifies the varbindlist to be duplicated.

**Returns:**

If the function is successful, the return value identifies a newly created varbindlist structure.

If the function fails, the return value is SNMPAPI\_FAILURE. Use the **SnmpGetLastError** function to obtain extended error information.

SnmpGetLastError()	Description
"Common Error Codes"	See Section 2.8.1 for details.
SNMPAPI_SESSION_INVALID	Indicates an invalid session handle.
SNMPAPI_VBL_INVALID	Indicates that the vbl parameter is invalid.

**Comments:**

Every call to **SnmpDuplicateVbl** must be matched with a corresponding call to **SnmpFreeVbl** to release the resources associated with the varbindlist. A memory leak will result if a variable used to hold an HSNMP\_VBL value returned by **SnmpDuplicateVbl** (or **SnmpCreateVbl**) is re-used for a subsequent **SnmpDuplicateVbl** (or **SnmpCreateVbl**) operation before it has been passed to **SnmpFreeVbl**.

### 3.5.3. SnmpFreeVbl()

The **SnmpFreeVbl** function releases resources associated with a varbindlist structure previously allocated by **SnmpCreateVbl** or **SnmpDuplicateVbl**. It is the responsibility of WinSNMP applications to free varbindlist resources allocated through calls to **SnmpCreateVbl** and **SnmpDuplicateVbl**.

#### Syntax:

```
SNMPAPI_STATUS SnmpFreeVbl (  
    IN HSNMP_VBL vbl);
```

Parameter	Description
vbl	Identifies the varbindlist to be released.

#### Returns:

If the function is successful, the return value is `SNMPAPI_SUCCESS`.

If the function fails, the return value is `SNMPAPI_FAILURE`. Use the **SnmpGetLastError** function to obtain extended error information.

<b>SnmpGetLastError()</b>	Description
"Common Error Codes"	See Section 2.8.1 for details.
<code>SNMPAPI_VBL_INVALID</code>	Indicates that the vbl parameter is invalid.

#### Comments:

Every call to **SnmpCreateVbl** must be matched with a corresponding call to **SnmpFreeVbl** to release the resources associated with the varbindlist. A memory leak will result if a variable used to hold an `HSNMP_VBL` value returned by **SnmpCreateVbl** is re-used for a subsequent **SnmpCreateVbl** operation before it has been passed to **SnmpFreeVbl**. The foregoing comments apply equally to varbindlists originating via the **SnmpDuplicateVbl** function.

Unfreed resources created on behalf of the application will be freed by the implementation upon execution of an associated **SnmpClose** function or upon execution of an **SnmpCleanup** function. Nonetheless, a well-behaved WinSNMP application will individually free all such resources using the atomic "free" functions. The reason for this is to eliminate or, at least, minimize any "batch-like" loads on the implementation, so that other applications can be serviced in a timely fashion.

### 3.5.4. SnmpCountVbl()

The **SnmpCountVbl** function counts the number of varbinds in the varbindlist identified by the vbl input parameter.

**Syntax:**

```
SNMPAPI_STATUS      SnmpCountVbl (  
IN HSNMP_VBL        vbl);
```

<b>Parameter</b>	<b>Description</b>
vbl	Identifies the subject varbindlist.

**Returns:**

If the function is successful, the return value is the count of varbinds in the varbindlist.

If the function fails, the return value is SNMPAPI\_FAILURE. Use the **SnmpGetLastError** function to obtain extended error information.

<b>SnmpGetLastError()</b>	<b>Description</b>
"Common Error Codes"	See Section 2.8.1 for details.
SNMPAPI_VBL_INVALID	Indicates that the vbl parameter is invalid.
SNMPAPI_NOOP	Indicates that the vbl resources contained no varbinds at this time.

**Comments:**

The value returned when the result is SNMPAPI\_SUCCESS will be used as the "index" value in the **SnmpGetVb** function.

### 3.5.5. SnmpGetVb()

The **SnmpGetVb** function retrieves the object instance name and its associated value from the varbind identified by the index parameter. The SnmpGetVb function copies the object instance name to the location pointed to by the name parameter and its associated value to the location pointed to by the value parameter.

#### Syntax:

```
SNMPAPI_STATUS SnmpGetVb (  
    IN HSNMP_VBL vbl,  
    IN smiUINT32 index,  
    OUT smiLPOID name,  
    OUT smiLPVALUE value);
```

Parameter	Description
vbl	Identifies the subject varbindlist.
index	Identifies the offset of the subject varbind within the varbindlist.
name	Points to a variable to receive the OID portion of the varbind.
value	Points to a variable to receive the value portion of the varbind.

#### Returns:

If the function is successful, the return value is SNMPAPI\_SUCCESS.

If the function fails, the return value is SNMPAPI\_FAILURE. Use the **SnmpGetLastError** function to obtain extended error information.

SnmpGetLastError()	Description
"Common Error Codes"	See Section 2.8.1 for details.
SNMPAPI_VBL_INVALID	Indicates that the vbl parameter is invalid.
SNMPAPI_INDEX_INVALID	Indicates that the index parameter is invalid.
SNMPAPI_OUTPUT_TRUNCATED	Indicates that the buffer was too small.

[DTP: Need additional errors: 1) Invalid Syntax, 2) ASN.1 Encoding Error, 3) Value Too Big, 4) Object Instance Too Big, 5) Other VB Error]

#### Comments:

Valid values for the "index" parameter come from the **SnmpCountVbl** function and from the "error\_index" component of GetResponse PDUs returned via the **SnmpRecvMsg** function.

On a successful return, the syntax field of the "value" variable will contain one of the object syntax types shown in the Table of Syntax Values included in the introduction to this section.

### 3.5.6. SnmpSetVb()

The **SnmpSetVb** function adds and updates varbind entries in a varbindlist.

#### Syntax:

```
SNMPAPI_STATUS SnmpSetVb (  
    IN HSNMP_VBL vbl,  
    IN smiLPOID name,  
    IN smiLPVALUE value);
```

Parameter	Description
vbl	Identifies the target varbindlist.
name	Points to a variable containing the object instance name to be set.
value	Points to a variable containing the associated value to be set.

#### Returns:

If the function is successful, the return value is `SNMPAPI_SUCCESS`.

If the function fails, the return value is `SNMPAPI_FAILURE`. Use the **SnmpGetLastError** function to obtain extended error information.

<b>SnmpGetLastError()</b>	Description
"Common Error Codes"	See Section 2.8.1 for details.
<code>SNMPAPI_VBL_INVALID</code>	Indicates that the vbl parameter is invalid.
<code>SNMPAPI_OID_INVALID</code>	Indicates that the name parameter is invalid.
<code>SNMPAPI_SYNTAX_INVALID</code>	Indicates that the syntax field of the value parameter is invalid.

#### Comments:

If the "name" parameter identifies an existing member of the varbindlist identified by the "vbl" parameter, then the "value" parameter is used to update the existing varbind entry. If the "name" parameter identifies a new varbind entry for the indicated varbindlist, then the new varbind is logically appended to the varbindlist. If the "value" parameter is `NULL`, the varbind will still be initialized, with the value set to `NULL` and with syntax of `SNMP_SYNTAX_NULL`.

### 3.5.7. SnmpDeleteVb()

The SnmpDeleteVb function removes a varbind entry from a varbindlist.

#### Syntax:

```
SNMPAPI_STATUS SnmpDeleteVb (  
    IN HSNMP_VBL vbl,  
    IN smiLPOID name);
```

Parameter	Description
vbl	Identifies the target varbindlist.
name	Points to a variable that contains the object instance name of the varbind to be deleted from the varbindlist.

#### Returns:

If the function is successful, the return value is SNMPAPI\_SUCCESS.

If the function fails, the return value is SNMPAPI\_FAILURE. Use the **SnmpGetLastError** function to obtain extended error information.

SnmpGetLastError()	Description
"Common Error Codes"	See Section 2.8.1 for details.
SNMPAPI_VBL_INVALID	Indicates that the vbl parameter is invalid.
SNMPAPI_OID_INVALID	Indicates that the name parameter is invalid.

#### Comments:

If the "name" parameter identifies an existing member of the varbindlist identified by the "vbl" parameter, then that varbind is deleted from the varbindlist. If the "name" parameter does not identify an existing member of the varbindlist, but is otherwise valid, the function will return successfully.

A "name" parameter is required, rather than an "index" parameter, for added protection against inadvertent varbind deletion.

A typical use for this function will be when a GetResponse PDU includes an SNMP error and the user elects to resubmit the original "request" PDU *sans* the offending varbind:

```
-- Omitting error-checking the function calls for clarity's sake...  
PDU = SnmpRecvMsg (session, agentEntity, context);  
SnmpGetPduData (PDU, PDU_type, request_id, error_status, error_index, varbindlist);  
-- Assuming PDU_type == GetResponse-PDU and  
-- Assuming error_status != SNMP_ERROR_NOERROR...  
SnmpGetVb (varbindlist, error_index, name, value);  
-- Assuming the error is something we cannot or do not want to fix...  
    -- If error_index == 1, do an SnmpCountVbl ();  
    -- if count <= 1 follow another strategy  
-- Assuming error_index > 1 || count > 1...  
SnmpDeleteVb (varbindlist, name);  
-- And assuming we want to re-try the SNMP operation  
SnmpSetPduData (PDU, PDU_type, request_id, NULL, NULL, varbindlist);  
SnmpSendMsg (session, agentEntity, context, PDU);  
-- Go back to doing what we were doing before all of this started...
```

### 3.6. Utility Functions

The utility functions are offered to ease the tasks of bookkeeping and dealing with objects passed across the Windows SNMP interface.

Return Type	Procedure Name	Parameters
SNMPAPI_STATUS	SnmpGetLastError	(IN HSNMP_SESSION session);
SNMPAPI_STATUS	SnmpStrToOid	(IN LPSTR string, IN OUT smiLPOID dstOID);
SNMPAPI_STATUS	SnmpOidToStr	(IN smiLPOID srcOID, IN smiUINT32 size, OUT LPSTR string);
SNMPAPI_STATUS	SnmpOidCopy	(IN smiLPOID srcOID, IN OUT smiLPOID dstOID);
SNMPAPI_STATUS	SnmpOidCompare	(IN smiLPOID xOID, IN smiLPOID yOID, IN smiUINT32 maxlen, OUT smiLPINT result);
SNMPAPI_STATUS	SnmpEncodeMsg	(IN HSNMP_SESSION session, IN HSNMP_ENTITY srcEntity, IN HSNMP_ENTITY dstEntity, IN HSNMP_CONTEXT context, IN HSNMP_PDU pdu, IN OUT smiLPOCTETS msgBufDesc);
SNMPAPI_STATUS	SnmpDecodeMsg	(IN HSNMP_SESSION session, OUT LPHSNMP_ENTITY srcEntity, OUT LPHSNMP_ENTITY dstEntity, OUT LPHSNMP_CONTEXT context, OUT LPHSNMP_PDU pdu, IN smiLPOCTETS msgBufDesc);

[DTP: Contributed a long and detailed note about the need for additional utility functions that get/set the "instance components" from OIDs used for names of managed object instances. I [BobN] have yet to incorporate these into this version of the specification (due to time constraints). DTP's additions might also address some of BEM's concerns raised earlier.]

### 3.6.1. SnmpGetLastError()

The **SnmpGetLastError** function returns an indication of why the last WinSNMP operation executed by the application failed.

**Syntax:**

```
SNMPAPI_STATUS      SnmpGetLastError (  
    IN HSNMP_SESSION session);
```

Parameter	Description
session	Indicates the session for which error information is requested. If NULL, the application-wide error information is returned.

**Returns:**

This function returns the last Windows SNMP error that occurred for the indicated session or for the application (task) if the session is NULL (as when, for example, **SnmpStartup** fails.)

**Comments:**

This function should be called immediately after any API call that fails, as the value is overwritten after each API call.

The session input parameter is provided to facilitate accommodation of multi-threaded Windows operating environments. Single-threaded applications can always pass a NULL session value and retrieve the last error information for the overall application.

Note that **SnmpGetLastError** must be able to return a value to a WinSNMP application even when **SnmpStartup** fails, and/or before any sessions are created with **SnmpOpen**, and/or after all sessions are closed with **SnmpClose** and/or the application disconnects from the implementation with the **SnmpCleanup** function.

### 3.6.2. SnmpStrToOid()

The **SnmpStrToOid** function converts a textual representation of the dotted numeric form of an OBJECT IDENTIFIER into an internal OBJECT IDENTIFIER representation.

#### Syntax:

```
SNMPAPI_STATUS SnmpStrToOid (  
    IN LPSTR string,  
    IN OUT smiLPOID dstOID);
```

Parameter	Description
string	Points to a NULL terminated string to be converted.
dstOID	Points to an smiOID variable to receive the converted value.

#### Returns:

If the function is successful, the return value is the number of sub-identifiers in the output OBJECT IDENTIFIER. This number will always be less than or equal to the value of the "len" member of the dstOID structure.

If the function fails, the return value is SNMPAPI\_FAILURE. Use the **SnmpGetLastError** function to obtain extended error information.

SnmpGetLastError()	Description
"Common Error Codes"	See Section 2.8.1 for details.
SNMPAPI_OID_INVALID	Indicates that the string was invalid.
SNMPAPI_OUTPUT_TRUNCATED	Indicates that the dstOID buffer was too small.

#### Comments:

Note that the "len" member of the smiOID structure pointed to by the dstOID parameter is used on input by the implementation to ensure that the output of the converted string will fit into the array addressed by the "ptr" member. Upon successful return from this call, the application can use the return value to update the "len" member of the dstOID structure (and keep track separately of its original dimension, if different) or may elect to allocate an appropriately sized chunk of memory, copy out the newly encoded OID, and then re-use the original buffer (which might be one of MAXOBJIDSIZE dimension, just for that purpose).

A useful routine in this context--but not defined in this specification--is one which just counts the dots in an input OID "string" and returns that number plus one...this number would represent the extension of the smiUINT32 array need for the output of the **SnmpStrToOid** function.

This function has nothing to do with the MIB database APIs described elsewhere. The purpose of this function is to translate from the dotted numeric string representation of an OID (e.g. "1.2.3.4.5.6") to the internal object identifier format.

This function can fail with SNMPAPI\_OID\_INVALID, for example, if the "string" input parameter is not NULL terminated, is of insufficient length, is longer than MAXOBJIDSTRSIZE, or does not constitute the textual form of a valid OID.

Note that the application should use an smiOID structure of MAXOBJIDSIZE length for this call, to be safe. If, as will normally be true, a shorter OID is actually encoded, the application can copy it using **SnmpOidCopy** to one of appropriate length and either re-use or free the space allocated to former smiOID structure.

### 3.6.3. SnmpOidToStr()

The **SnmpStrToOid** function converts an internal representation of an OBJECT IDENTIFIER into a dotted numeric string representation of an OBJECT IDENTIFIER.

#### Syntax:

```
SNMPAPI_STATUS SnmpOidToStr (  
    IN smiLPOID srcOID,  
    IN smiUINT32 size,  
    OUT LPSTR string);
```

Parameter	Description
srcOID	Points to a variable holding an object identifier to be converted.
size	The size of the buffer the application is providing to contain the string.
string	Points to a buffer that will receive the string that identifies the management entity.

#### Returns:

If the function is successful, the return value is the number of bytes, including the NULL terminating byte, output to "string"--this value may be less than or equal to "size", but not greater.

If the function fails, the return value is SNMPAPI\_FAILURE. Use the **SnmpGetLastError** function to obtain extended error information.

<b>SnmpGetLastError()</b>	Description
"Common Error Codes"	See Section 2.8.1 for details.
SNMPAPI_OID_INVALID	Indicates that the srcOID was invalid.
SNMPAPI_OUTPUT_TRUNCATED	Indicates that the buffer was too small.

#### Comments:

This function has nothing to do with the MIB database APIs described elsewhere. The purpose of this function is to translate from the internal object identifier format to the dotted numeric string representation of the OID (e.g., "1.2.3.4.5.6").

Note that the application should use a string buffer of MAXOBJIDSTRSIZE length for this call, to be safe. If, as will normally be true, a shorter OID is actually decoded, the application can copy the resulting string to one of appropriate length and either re-use or free the space allocated to the original buffer.

Note that a NULL-terminated string is returned for convenience. The return value, upon success, will include the terminating NULL byte.

### 3.6.4. SnmpOidCopy()

The **SnmpOidCopy** function copies the srcOID to the dstOID.

#### Syntax:

```
SNMPAPI_STATUS SnmpOidCopy (  
    IN smiLPOID srcOID,  
    IN OUT smiLPOID dstOID);
```

Parameter	Description
srcOID	Points to a variable holding an object identifier.
dstOID	Points to a variable to receive a copy of the srcOID.

#### Returns:

If the function is successful, the return value is the number of sub-identifiers in the output OBJECT IDENTIFIER. This number will always be less than or equal to the value of the "len" member of the dstOID structure.

If the function fails, the return value is SNMPAPI\_FAILURE. Use the **SnmpGetLastError** function to obtain extended error information.

SnmpGetLastError()	Description
"Common Error Codes"	See Section 2.8.1 for details.
SNMPAPI_OID_INVALID	Indicates that the srcOID was invalid.
SNMPAPI_OUTPUT_TRUNCATED	Indicates that the dstOID buffer was too small.

#### Comments:

Note that the "len" member of the smiOID structure pointed to by the dstOID parameter is used on input by the implementation to ensure that the OID array pointed to by the "ptr" member of the srcOID will fit into the array addressed by the "ptr" member of the dstOID structure. Upon successful return from this call, the application can use the return value to update the "len" member of the dstOID structure (and keep track separately of its original dimension, if different) or may elect to allocate an appropriately sized chunk of memory, copy out the newly encoded OID, and then re-use the original buffer (which might be one of MAXOBJIDSIZE dimension, just for that purpose).

Note that **SnmpOidCopy** can also be used to "append" one OID onto another.

### 3.6.5. SnmpOidCompare()

The **SnmpOidCompare** function lexicographically compares two OIDs. If "maxlen" is non-zero, then its value is used as an upper limit on the number of sub-identifiers to compare. This approach will most often be used to identify whether two OIDs have common prefixes or not. If "maxlen" is zero, then the "len" members of the two smiOID structures will determine the maximum number of sub-identifiers to compare.

#### Syntax:

```
SNMPAPI_STATUS SnmpOidCompare (  
    IN smiLPOID xOID,  
    IN smiLPOID yOID,  
    IN smiUINT32 maxlen,  
    OUT smiLPINT result);
```

Parameter	Description
xOID	Points to a variable holding an object identifier to compare.
yOID	Points to a variable holding an object identifier to compare.
maxlen	If non-zero, Indicates the number of sub-identifiers to compare. Must be less than MAXOBJIDSIZE.
result	Points to a variable to receive the result of the comparison:  > 0 if xOID is greater than yOID = 0 if xOID equals yOID < 0 if xOID is less than yOID

#### Returns:

If the function is successful, the return value is SNMPAPI\_SUCCESS.

If the function fails, the return value is SNMPAPI\_FAILURE. Use the **SnmpGetLastError** function to obtain extended error information.

<b>SnmpGetLastError()</b>	Description
"Common Error Codes"	See Section 2.8.1 for details.
SNMPAPI_OID_INVALID	Indicates that either or both of the input OIDs were invalid.
SNMPAPI_SIZE_INVALID	Indicates that the "maxlen" parameter was invalid; that is, greater than MAXOBJIDSIZE.

#### Comments:

The **SnmpOidCompare** function combines the functionality of the **SnmpOidCmp** and **SnmpOidNCmp** functions which appeared in versions earlier than v1.0g of this specification.

When "maxlen" is non-zero (but not greater than MAXOBJIDSIZE), the maximum number of sub-identifiers that will be compared is the *minimum* of the "maxlen" input parameter and the two "len" members of the input OID structures. Either or both of the input OIDs can have a zero length without causing an error.

When "maxlen" is zero, the maximum number of sub-identifiers that will be compared is the minimum of the two "len" members of the input OID structures. Either or both of the input OIDs can have a zero length without causing an error.

If the two OIDs are lexicographically equal when the maximum number of sub-identifiers have been compared, then:

- If the "maxlen" parameter value was used as the maximum number of sub-identifiers to compare, or if the two OID parameters have equal "len" members which are less than the "maxlen" input parameter, the "result" value will be 0 (equal).
- If an OID "len" member was used as the value for the maximum number of sub-identifiers to compare (because it was less than the non-zero "maxlen" input parameter or because "maxlen" was equal to zero), and the other OID "len" member value is greater, the "result" value will be <0 or >0, depending on which OID parameter had which "len" value.

### 3.6.6. SnmpEncodeMsg()

The **SnmpEncodeMsg** routine takes as its first five input parameters the same parameters passed to **SnmpSendMsg**. The implementation will use these parameters to form an SNMP "message" as though they had arrived via the **SnmpSendMsg** function. The implementation will not, however, attempt to transmit the resulting message to the 'dstEntity'. It will, instead, use the 'msgBufDesc' parameter as described herein to return to the application the encoded/serialized SNMP message that it would have transmitted to the 'dstEntity' if **SnmpSendMsg** had been called.

#### Syntax:

```
SNMPAPI_STATUS SnmpEncodeMsg (  
    IN HSNMP_SESSION session,  
    IN HSNMP_ENTITY srcEntity,  
    IN HSNMP_ENTITY dstEntity,  
    IN HSNMP_CONTEXT context,  
    IN HSNMP_PDU pdu,  
    IN OUT smiLPOCTETS msgBufDesc);
```

Parameter	Description
session	Identifies the session that will perform the operation.
srcEntity	Identifies the subject management entity.
dstEntity	Identifies the target management entity.
context	Identifies the target context of interest.
PDU	Identifies the SNMP protocol data unit containing the requested operation.
msgBufDesc	Identifies the buffer to receive the encoded SNMP message.

#### Returns:

If the input parameters were all valid and the resulting encoded/serialized SNMP message was less than or equal to "len" then **SnmpEncodeMsg** returns the number of bytes actually consumed by the resulting SNMP message.

If any of the first five input parameters fail the normal integrity checks performed for **SnmpSendMsg** then **SnmpEncodeMsg** will return **SNMPAPI\_FAILURE** and **SnmpGetLastError** will be set to return the appropriate extended error code. If all input parameters are valid but the resulting encoded/serialized SNMP message is longer than the 'msgBufDesc' "len" value, then **SnmpEncodeMsg** will return **SNMPAPI\_FAILURE** and will set **SnmpGetLastError** to return **SNMPAPI\_OUTPUT\_TRUNCATED**.

If the function fails, the return value is **SNMPAPI\_FAILURE**. Use **SnmpGetLastError** to obtain extended error information.

<b>SnmpGetLastError()</b>	Description
"Common Error Codes"	See Section 2.8.1 for details.
SNMPAPI_SESSION_INVALID	Indicates that a session parameter is invalid.
SNMPAPI_ENTITY_INVALID	Indicates that an entity parameter is invalid.
SNMPAPI_CONTEXT_INVALID	Indicates that the context parameter is invalid.
SNMPAPI_PDU_INVALID	Indicates that the PDU parameter is invalid.
SNMPAPI_OUTPUT_TRUNCATED	Indicates that the buffer was too small.

**Comments:**

**Note:** In the case of the SNMPAPI\_OUTPUT\_TRUNCATED error, the implementation is not required to write anything into "ptr". The application must either allocate a larger "ptr" buffer and adjust the "len" member of the 'msgBufDesc' parameter or reduce the size of the resulting SNMP message (probably by removing varbinds from the varbindlist component of the pdu).

The 'msgBufDesc' parameter is a far pointer to an smiOCTETS structure. This structure is a "descriptor": The first member ("len") is an smiUINT32 quantity representing the length (in bytes) of the buffer; the second member ("ptr") is an smiLPBYTE far pointer to the target buffer. The implementation will write no more than "len" bytes of the encoded/serialized SNMP message into "ptr". The implementation will not update the "len" member directly; the application can use the return value of a successful call to do this or may use the return value to copy the output buffer to some other location.

### 3.6.7. SnmpDecodeMsg()

The **SnmpDecodeMsg** function is the converse of the **SnmpEncodeMsg** function. It takes as input a session identifier and a far pointer to an smiOCTETS structure which describes an encoded/serialized SNMP message to be decoded into its constituent components. The session identifier is required since new resources will be created by the implementation and allocated to the application as a result of calling this function, if it is successful. The 'msgBufDesc' input parameter consists of two elements: The "len" member identifies the maximum number of bytes to process; the "ptr" member points to the encoded/serialized SNMP message to decode.

#### Syntax:

```
SNMPAPI_STATUS SnmpDecodeMsg (  
    IN HSNMP_SESSION          session,  
    OUT LPHSNMP_ENTITY       srcEntity,  
    OUT LPHSNMP_ENTITY       dstEntity,  
    OUT LPHSNMP_CONTEXT      context,  
    OUT LPHSNMP_PDU          pdu,  
    IN smiLPOCTETS           msgBufDesc);
```

Parameter	Description
session	Identifies the session that will perform the operation.
srcEntity	Identifies the subject management entity.
dstEntity	Identifies the target management entity.
context	Identifies the target context of interest.
PDU	Identifies the SNMP protocol data unit.
msgBufDesc	Identifies the buffer holding the encoded SNMP message.

#### Returns:

Upon successful completion, **SnmpDecodeMsg** returns the actual number of bytes decoded. This may be equal to or less than the "len" member of the 'msgBufDesc' input parameter. Also, upon success, **SnmpDecodeMsg** returns handle values in the 'srcEntity', 'dstEntity', 'context', and 'pdu' output parameters. Note that these resources are to be freed by the application using the appropriate **SnmpFree<xxx>** functions, or by the implementation in response to an **SnmpClose** or **SnmpCleanup** function call.

If **SnmpDecodeMsg** fails, the return value will be **SNMPAPI\_FAILURE** and **SnmpGetLastError** will be set to report one of the following:

<b>SnmpGetLastError()</b>	Description
"Common Error Codes"	See Section 2.8.1 for details.
SNMPAPI_SESSION_INVALID	Indicates that a session parameter is invalid.
SNMPAPI_ENTITY_INVALID	Indicates that an entity parameter is invalid.
SNMPAPI_CONTEXT_INVALID	Indicates that the context parameter is invalid.
SNMPAPI_PDU_INVALID	Indicates that the PDU parameter is invalid.
SNMPAPI_OUTPUT_TRUNCATED	Indicates that the buffer was too small. That is, "len" bytes of "ptr" were consumed before reaching the end of the encoded message; no output parameters are created.
SNMPAPI_MESSAGE_INVALID	The SNMP message described by the 'msgBufDesc' parameter is invalid; no output resources are created.

**Comments:**

The **SmpDecodeMsg** function is meant to be symmetrical with the **SmpEncodeMsg** function. Refer to **SmpEncodeMsg** for additional insight into the operation and possible failure modes of the **SmpDecodeMsg** function.

## 4. Declarations

This section offers a prototype of the WinSNMP.h file containing common declarations for SNMP datatypes, attributes, and values and for WinSNMP API datatypes, attributes, and values. When approved, this section (minus this narrative text) must be delivered as WinSNMP.h with every compliant implementation.

Additional declarations required or offered by an implementation must be delivered in a separate include file with an implementation-specific name.

An attempt has been made to balance brevity and clarity in these declarations. In general, however, there has been a slight bias toward brevity. Developers can easily include longer, more descriptive equivalents to the declarations through additional *#define* and *typedef* statements in a private *include* files loaded after WinSNMP.h.

Also, please note that some of the values defined from ASN attributes might need educated revision. This is especially true of those using ASN\_APPLICATION or ASN\_CONTEXT.

Likewise, some educated revision of the SNMP\_SYNTAX\_<value> entries might be necessary.

Additional entries for the "SNMP Limits" section are invited.

Also, feel free to suggest additional generic or specific errors for the WinSNMP API errors section.

```
/* Prototype WinSNMP.h file */
```

```
/* A suggestion has been put forth that we should explicitly define the Windows datatypes (e.g., HANDLE) used herein to facilitate portability of WinSNMP to other operating environments. Given the current charter of the group, however, and given that users might want to avail themselves of optional Windows invocation strategies (e.g., _STRICT_ or not), and in the interest of completing and implementing the first version of the WinSNMP API specification, we are not adopting that otherwise laudable suggestion. */
```

## Appendix A. Mapping Traps Between SNMPv1 and SNMPv2

One of the differences between SNMPv1 and SNMPv2 is a change to the trap format: In SNMPv1, the trap format was unlike the format of the other protocol data units, whilst in SNMPv2 the trap format is identical to the format of the other PDUs.

When the WinSNMP API delivers a trap to a management application, it always uses the SNMPv2 trap format, even if an SNMPv1 agent generated the trap. The SNMPv2 coexistence document, RFC 1452, specifies how an SNMPv1 trap can be translated into the SNMPv2 trap format, and this algorithm is used in all implementations of the WinSNMP API.

In SNMPv1, the trap format had five fields:

- enterprise, which identified the type of device which generated the trap;
- agent-addr, which identified the network address of the device;
- generic-trap/specific-trap, which identified the trap which was generated;
- time-stamp, which identified when the trap was generated; and,
- variable-bindings, which contained the "payload", if any, associated with the trap.

In SNMPv2, the trap format consists simply of a list of "N" variable bindings, in which:

- the first variable binding contains the time-stamp;
- the second variable binding identifies the trap, using an OBJECT IDENTIFIER;
- the third through "N" variable bindings, if any, contain the payload.

Hence, when **SnmPRecvMsg** returns a message whose operation type is `SNMP_PDU_TRAP`, the application need only examine the variable-bindings of that message in order to ascertain the information associated with the trap.

When translating an SNMPv1 trap to the SNMPv2 format, one additional variable binding may be present, at the end of the list, which corresponds to the enterprise field. According to the SNMPv2 coexistence document, this variable binding need only be present if the trap was enterprise-specific. However, in order to simplify the programming of management applications, this variable binding is always added by the WinSNMP API when it translates an SNMPv1 trap to the SNMPv2 format.

The following code fragment shows how an application can examine the variable-bindings in order to retrieve all of the information associated with a trap.

**Note: This example was written for a preliminary document and does not currently reflect the actual functions and data structures incorporated in v1.0g of the Windows SNMP API specification. It is included, nonetheless, because it is an understandable example of the trap transformation process outlined above. It is hoped--and anticipated--that it will be revised in the near future to reflect the current WinSNMP API specification.**

```

HSNMP_PDU      PDU;
HSNMP_ENTITY   entity;
HSNMP_CONTEXT  context;
UINT           qos;
HSNMP_VB       vb1, vb2, vp, vq;
smiOID         name;
smiVALUE       value;
extern smiLPOID      snmpTrapEnterprise; /* snmpTrapEnterprise.0 */

if ((PDU = SnmpRecvMsg (session, &entity, &context, &qos)) == NULL)
    return;
if (SnmpGetOperation (PDU, &operation) == FALSE
    || operation != SNMP_OPERATION_TRAP) {
    (void) SnmpFreePdu (PDU);
    (void) SnmpFreeEntity (entity);
    (void) SnmpFreeContext (context);
    return;
}
/* name is sysUpTime.0, value is the time-stamp field */
vb1 = SnmpRewindVb (PDU);

/* name is snmpTrapOID.0, value is the smiOID identifying the trap
   SNMPv2 defines OIDs for all standard traps... */
vb2 = SnmpNextVb (PDU);

/* find the last variable binding */
for (vp = NULL; vq = SnmpNextVb (PDU); vp = vq)
    continue;
if (vp) {
    (void) SnmpGetVb (vp, &name, &value);
    if (SnmpUtilOidCmp (&name, snmpTrapEnterprise) == 0) {
        smiOID trapname;
        smiVALUE trapvalue;

        /* this was an SNMPv1 trap, so value is the enterprise field */

        /* if you want the generic-trap/specific-trap fields, must look
           at second variable-binding... */
        (void) SnmpGetVb (vb2, &trapname, &trapvalue);
        if (SnmpUtilOidNCmp (&value.type.oid, &trapvalue.type.oid,
            value.type.oid.len) == 0) {
            /* enterprise specific-trap:

                generic-trap field = 6;
                specific-trap field =
                    trapvalue.type.oid.oid[value.type.oid.len + 1];
            */
        }
        else {
            /* generic-trap:

                to get the generic-trap field, do a table lookup
                specific-trap field = 0;
            */
        }
    }
    /* finally, to get the agent-addr field, call SnmpCtxtoStr (context) */
}
}

```

Of course, this example is probably more complex than necessary. Most management applications dealing with traps can be table-driven based on the OID identifying the trap--after examining the second variable-binding, an application can treat the remaining variable-bindings as payload.

## Appendix B. Usage Example

To be written.

## Appendix C. WinSNMP++ Prototype

The following table shows a possible mapping between the C interface of the WinSNMP API specification and a set of C++ wrappers. This is strictly an informational Appendix and does not constitute a part of the official Windows SNMP API specification at this time.

The content was contributed by Maria Greene of Xyplex, and was well-discussed on the list. Unless otherwise noted, obvious differences between the WinSNMP C interface specifications and the WinSNMP++ interface prototypes shown below are simply due to changes being made to the C interface after this Appendix was inserted. Therefore, future edits for consistency--according to the pattern demonstrated herein--can be assumed.

Please note the re-positioning of the varbindlist parameter in the SnmpCreatePdu and SnmpSetPduData C++ equivalents is intentional and permits applications to take advantage of certain C++ language-specific features.

Class/Returns	C++ Interface	C Interface
<b>Session::</b>	Session ( Entity &srcEntity, HWND hWnd, UINT wParam)	SnmpOpen
	~Session (void)	SnmpClose
BOOL	SendMsg ( const Entity &dstEntity, const Context &context, const Pdu &PDU)	SnmpSendMsg
Pdu *	RecvMsg ( Entity &srcEntity, Context &context)	SnmpRecvMsg
BOOL	Register ( const Entity &entity, const Context &context, const Oid &notification = NULL, BOOL enabled = TRUE)	SnmpRegister
<b>Entity::</b>	Entity (const LPSTR entity) Entity (const Entity &entity)	SnmpStrToEntity
	~Entity (void)	SnmpFreeEntity
Entity	operator const char*() const &operator = (const Entity &entity)	SnmpEntityToStr
<b>Context::</b>	Context (const LPSTR context) Context (const Context &context)	SnmpStrToContext
	~Context (void)	SnmpFreeContext
Context	operator const char*() const &operator = (const Context &context)	SnmpContextToStr
<b>SnmpUtil::</b>	SnmpUtil (???)	SnmpStartup
	~SnmpUtil (void)	SnmpCleanup
????	EnumEntities (???)	SnmpEnumEntities
????	EnumContexts (???)	SnmpEnumContexts
int	GetLastError (void)	SnmpGetLastError
DWORD	Version (void)	SnmpUtilVersion

Class/Returns	C++ Interface	C Interface
<b>Pdu::</b>	Pdu ( smiINT PDU_type= SNMP_PDU_GETNEXT, VarBindList *varbindlist = NULL, smiINT32 request_id = 0, smiINT non_repeaters = 0, smiINT max_repetitions = 0)	SnmpCreatePdu
	Pdu (const Pdu &PDU)	SnmpDuplicatePdu
	~Pdu (void)	SnmpFreePdu
BOOL	GetData ( smiLPINT PDU_type = NULL, smiLPINT32 request_id = NULL, smiLPINT error_status = NULL, smiLPINT error_index = NULL, VarBindList **varbindlist = NULL)	SnmpGetPduData
