Introduction to HoTMetaL PRO

Welcome to HoTMetaL PRO 5.0 Evaluation Version!

HoTMetaL PRO is an editor and site management tool that enables you to make leading-edge Websites to put on the World Wide Web or an intranet. HoTMetaL PRO comes with everything you need to create, manage, and publish your Website.

This brief introduction to HoTMetaL PRO includes the following topics:

- System requirements.
- Descriptions of the programs on the CD.
- New features.
- A description of the HoTMetaL PRO documentation and other information resources.
- Internet service providers.
- Accessibility.

The HoTMetaL PRO 5.0 Evaluation Version contains most of the functionality of HoTMetaL PRO 5.0. The following features are **not** present in HoTMetaL PRO 5.0 Evaluation Version:

- Ulead PhotoImpact SE, Ulead Photo Explorer 4.2, and Ulead GIF Animator, a suite of image editing programs.
- HoTMetaL Personal Server: the personal, PC-based version of HoTMetaL Application Server (HoTMetaL APPS).
- Visual Dynamic Keyboard: an on-screen keyboard that makes HoTMetaL PRO and other applications more accessible to users with mobility impairments.
- Document conversion: converting word-processor files to HTML.
- Spell checking and thesaurus.
- Assets: The assets available from the Resource Manager are a subset of those shipped with HoTMetaL PRO 5.0.
- Database Import wizard: import a database or spreadsheet into HoTMetaL PRO.
- Document templates: the document templates available from HoTMetaL PRO **New...** command are a subset of those shipped with HoTMetaL PRO 5.0.
- Site Maker: a wizard for creating an entire site from scratch.
- Microsoft Internet Explorer 4.0: HoTMetaL PRO uses Microsoft Internet Explorer 4.0 components in its implementation of the following features: the Resource Manager, WYSIWYG-Frames view, and Page Preview. Additionally, the Thumbnail View and the **Open** dialog preview window require that Microsoft Active Desktop be installed. HoTMetaL PRO will still operate on Windows 95 and NT 4.0 if Internet Explorer and Active Desktop are not installed, but these features will be unavailable. On Windows 98, these features will always be available.
- Alternative rules files, such as the WebTV rules file.
- Netscape Communicator 4.05.
- The printed **User Guide**.
- The **HTML Reference Guide**, a guide to HTML elements and attributes.

[More on this topic](#)

System requirements

HoTMetaL PRO runs under Windows 95, 98, and NT 4.0. Your system must have the following:

- Pentium processor (Pentium 100 MHz or above recommended)
- 16 MB of available RAM (32 MB RAM or more recommended)
- Super VGA display, 256 colors, 640 x 480 resolution
- 40 MB of disk space (for minimal installation)
- 20 MB extra disk space during installation
- CD drive for installation
- On Windows NT 4.0, Service Pack 3 must be applied before you install and use HoTMetaL PRO 5.0.

HoTMetaL PRO uses Microsoft Internet Explorer 4.0 components in its implementation of the following features: the Resource Manager, WYSIWYG-Frames view, Page Preview, and previewing pages in Site Maker. Additionally, the Thumbnail View and the **Open** dialog preview window require that Microsoft Active Desktop be installed. HoTMetaL PRO will still operate on Windows 95 and NT 4.0 if Internet Explorer and Active Desktop are not installed, but these features will be unavailable. On Windows 98, these features will always be available.

What's new in HoTMetaL PRO

If you have been using HoTMetaL PRO 4.0, you're probably interested in what's new in version 5.0.

- First of all, the HoTMetaL PRO Editor and Information Manager from HoTMetaL PRO 4.0 have been combined into a single application, which offers both editing and **site management** functions. These site management functions appear as separate windows within HoTMetaL PRO and enable you to view links, import existing sites, and check for broken links and orphaned files. See [Managing your Website](#) and [Site-wide find and replace](#) for more information.
- The Resource Manager is an asset management tool that gives you access to all kinds of **Web objects**: images, cascading style sheets, scripts, and dynamic HTML. It organizes Web objects into categories and enables you to perform 'intelligent' drag and drop operations into your documents. The Resource Manager also enables you to select different views, create file filters, and navigate through folders. You can drag and drop these objects into your documents. A Thumbnail View enables you to preview images and HTML files before you insert them into your Web page. See [Working with images](#) and [Managing your Website](#) for more information.
- HoTMetaL PRO now offers four authoring environments: WYSIWYG view for the novice, Tags On view for the intermediate user, HTML Source view for power professionals, and WYSIWYG-Frames view for creating frames. See [Document view modes](#) for more information.
- The Frame Editor now consists of a WYSIWYG document window and has been improved to include borderless frames and easy access to frame contents. You can now create frame pages by choosing from a set of frame templates. See [Creating frames](#) for more information.
- For viewing Web pages in progress as they would appear on the Web, there is now a built-in **Page Preview** window in HoTMetaL PRO. See [Page Preview](#) for more information.
- **Tag tips** appear when you hover your cursor over a tag in the HoTMetaL PRO document window. Tag tips display all set attributes of an element. See [General options](#) in the HoTMetaL PRO online help for more information.
- You can now print your documents in HTML Source view. See [Printing documents](#) in the HoTMetaL PRO online help for more information.
- A full screen option has been added to HoTMetaL PRO to provide a larger viewing space for your HTML documents in progress. See [Full screen mode](#) for more information.
- The HoTMetaL PRO [publishing](#) functionality now supports passive FTP.
- The Cascading Style Sheet editor has new available styles. See [Setting style properties](#) in the HoTMetaL PRO online help for more information.
- Most HoTMetaL PRO windows can be used as docked or floating windows. See [Docked and floating windows](#) for more information.
- The Attribute Inspector is now tabbed to display attributes in three groups: all attributes of the current element, all attributes related to user events, and commonly-used attributes for the current element. It also has a new 'drag and drop' feature for editing document attributes. See [Editing attributes with the Attribute Inspector](#) for more information.
- The **Insert Element** window is also tabbed to display different sets of elements: **Recent**, **Miva**, and **HTML**. The **Recent** tab contains the ten most frequently used elements in this editing session that are valid in this context. The **Miva** tab contains elements in the Miva programming language, supported by the HoTMetaL Personal Server and HoTMetaL Application Server. All of the elements available for editing HTML markup are available in the **HTML** tab.
- HoTMetaL PRO's new **Workbook mode** enables you to easily switch between open documents by clicking on tabs at the bottom of the document window. See [Workbook mode](#) for more information.
- HoTMetaL PRO features several save options to avoid breaking relative links in your documents if you choose to save your files in a different folder. See [Saving a page](#) for more information.
- The **Table Advanced** toolbar allows you to contract cells in a table. Cell contracting allows you to pull the boundary of a cell one cell to the left, right, top, or bottom. See [Contracting cells](#) for more information.
- Toolbar customization allows you to customize and save toolbar configurations. You can create new toolbar areas and turn toolbars on or off. See [Toolbars](#) for more information.
- Text will now **wrap** around left- and right-aligned images in Tags On and WYSIWYG editing views. See [Alignment](#) for more information.
- The ability to save and restore **workspaces** has been added. A workspace saves information about a current project, open files, window layout, and options. See [Using workspaces](#) for more information.
- Preview HTML and image files in the **Open** dialog, and preview images in the **Choose Image** dialog.
- [Indent](#) and outdent block elements.
- Save or close multiple documents simultaneously.
- The **HTML Reference Guide**, a comprehensive guide to HTML elements and attributes, is available from the **Help** menu.
- [Video help](#): live tutorials on several HoTMetaL PRO topics.

Finding information

There are several different ways to find information on HoTMetal PRO.

- **User Guide** – The printed manual. The User Guide covers the core topics that you need to be familiar with to create Web pages and manage a site with HoTMetal PRO. Most chapters have both **tutorial** and **reference** sections. The reference sections are also contained in the online help. The basic information that you need in order to get started is in the following sections: [Creating your first Web page](#), [Links](#) and [Managing your Website](#). Even if you are familiar with HoTMetal 4.0, you should read these chapters to become familiar with changes to the HoTMetal PRO user interface.
- **Online help** – Contains the reference sections of the User Guide, and extra information on special topics. You can access online help by choosing **Contents** or **Search for Help on...** from the **Help** menu, or by pressing **F1**.
- **Video help**: live tutorials on various HoTMetal PRO topics.
- **Help buttons** – Most dialog boxes in HoTMetal PRO have **Help** buttons, which take you directly to the appropriate help topic.
- **HTML Reference** – Links to technical information about HTML elements and attributes can be accessed by choosing **HTML Reference** from the **Help** menu.
- **Tip of the Day...** – Displays a tip about using HoTMetal PRO every time you start up HoTMetal PRO. This feature can be disabled by clicking on the **Show Tips on Startup** check box.
- **Release notes** – You can get the latest release information about HoTMetal PRO by opening the **readme.wri** file in the HoTMetal PRO folder (this file is accessible from the HoTMetal PRO program group).
- **Special Topics** manual – More advanced and specialized topics are covered in the **Special Topics** manual. This manual is supplied in printable electronic form on the HoTMetal PRO CD, in the **Special** folder. The material in this manual can also be found in the online help file.

Internet service providers

In order to use a Web browser and put your HTML documents and images on the Web, you must have access to an account with an **Internet service provider** (ISP). Most ISPs provide you with browser software to access the World Wide Web, and space on their server to put your HTML documents. Once your documents are on a server that is connected to the World Wide Web, they can be accessed from anywhere. See <http://www.sq.com> for a listing of HoTMetaL Power Partner ISPs that have special offers for HoTMetaL PRO users.

Accessibility

HoTMetaL PRO provides methods for checking whether your document is accessible to everyone, including users with disabilities and users of text-only browsers.

The Visual Dynamic Keyboard (VDK) is an on-screen keyboard that provides greater accessibility to Windows applications to users with mobility impairments. It enables users to enter text, select commands, activate dialog box controls, etc., without using the regular keyboard and mouse. It appears on-screen in a resizable window, as a keyboard with rectangular keys. The VDK has special support for HoTMetaL PRO commands. Using the VDK, users can work with applications using alternative access methods: automatic scanning, inverse scanning, direct-dwell selection, direct-click selection, and five-switch directed input.

The Visual Dynamic Keyboard is shipped with HoTMetaL PRO 5.0, but not with the Evaluation Version that you are now using. Choose 'How To Purchase' in the Help menu for ordering information.

The HoTMetal PRO interface

What's covered in this chapter

This chapter describes the HoTMetal PRO interface and how it works. You don't have to read the whole chapter all at once, but you may find it a useful reference if some parts of the interface are unfamiliar. The topics covered include:

- Document view modes.
- HoTMetal PRO options.
- HoTMetal PRO windows.
- Full screen mode.
- Workbook mode.
- Saving and closing multiple documents.
- Using workspaces.
- Right-click commands.
- Toolbars and toolbar customization.
- Menus.

[More on this topic](#)

Introduction to the interface

The HoTMetaL PRO interface lets you perform a variety of tasks, from simple tasks such as opening a document or inserting an image, to complex tasks such as creating frames, designing cascading style sheets, and publishing your files to a server. The interface is designed to make editing Web pages easy for the beginner, the intermediate user, and the expert.

The interface is also customizable. For example, you can configure the interface so that only the toolbars that you use appear. Menus and windows can also be customized to appear as you would like them to.

The HoTMetaL PRO interface consists of:

- Menus.
- Toolbars.
- The main document window, which shows different editing views.
- Additional windows that open when certain functions are invoked, such as the Attribute Inspector and site management view windows.

When you start HoTMetaL PRO for the first time, the HoTMetaL PRO document window opens in Tags On view with a new blank document, Workbook mode is turned on, and the Resource Manager window is open. You can now start editing a document in the document window, and you can drag and drop objects from the Resource Manager.

Document view modes

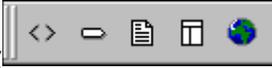

HoTMetal PRO provides you with different ways of displaying your documents, depending on how you want to work with them. To understand the views, you should know a little something about the way that HTML works.

When you edit an HTML file, you are creating **markup**. The markup consists of:

- **Elements**, which surround parts of the document according to their function or appearance. Elements begin with **start-tags** and end with **end-tags**. You can enter elements by using the HoTMetal PRO toolbars or the **Insert** menu.
- **Attributes**, which are values that are associated with elements, but are not part of the content. You can enter and change attributes by choosing **Attribute Inspector** from the **View** menu, right-clicking inside an element and choosing **Attribute Inspector** from the pop-up menu, or pressing **F6**. As well, many elements have special dialog boxes for entering and changing the most important attributes; these can typically be accessed from the **Insert** menu or by double-clicking inside the element or its graphical representation.

It's up to you how much of the detail of the HTML markup you want to see. There are five different viewing modes in HoTMetal PRO: HTML Source, WYSIWYG, WYSIWYG-Frames, Tags On, and Page Preview views. To switch between the different views, do **one of** the following:

- Choose **HTML Source**, **WYSIWYG**, **WYSIWYG-Frames**, **Tags On**, or **Page Preview** from the **View** menu.
- Click on one of the buttons in the lower left corner of the HoTMetal PRO document window (); the activated button is the currently selected view—HTML Source, Tags On, WYSIWYG, WYSIWYG-Frames, or Page Preview.

- Click on one of the buttons in the **Views** toolbar (.
- Press **Ctrl+Alt+H** to switch to HTML Source view, **Ctrl+Alt+W** to switch to WYSIWYG view, **Ctrl+Alt+F** to switch to WYSIWYG-Frames view, **Ctrl+Alt+T** to switch to Tags On view, or **Ctrl+Alt+B** to switch to Page Preview.

Note: The **WYSIWYG-Frames** view is available only if the current document contains frames. Microsoft Internet Explorer must be installed on your PC in order for WYSIWYG-Frames and Page Preview to be available.

 [More on this topic](#)

Tags On view

When you first launch HoTMetaL PRO, any documents you create or edit will be displayed in Tags On view. The Tags On view shows start- and end-tags for HTML elements in your document. It's not an exact representation of the code—for that, you need the HTML Source view. However, the full display of the code can show a lot of detail that you may not always need. The Tags On view is very useful for moving around and working with elements and their attributes. When you hover your cursor over an element, a **Tag tip** appears; displaying all set attributes. You do not have to worry about the details of the HTML markup; HoTMetaL PRO takes care of that for you. You can also use **structured editing** commands, such as **Element...** in the **Insert** menu and **Attribute Inspector** in the **View** menu.

To display the current document in Tags On view, do **one of** the following:

- Choose **Tags On** from the **View** menu.

- Click on the  button from the **Views** toolbar.

- Press **Ctrl+Alt+T**.

- Click on the **Tags On** button from the  in the lower left corner of the HoTMetaL PRO document window

WYSIWYG view

WYSIWYG is an acronym for 'What You See Is What You Get'; that is, the way documents are displayed in this view is pretty much how they're going to look in a Web browser. The display includes images, alignment of block elements, tables, form objects (buttons, check boxes, and so forth) and background colors and images. You can use the same structured editing commands as you can in Tags On view. This display is a good way to get a sense of how your document will look on the World Wide Web. It's also easy and convenient to edit your document in this mode, much as you would in a word processor.

To display the current document in WYSIWYG view, do **one of** the following:

- Choose **WYSIWYG** from the **View** menu.

- Click on the  button from the **Views** toolbar.

- Press **Ctrl+Alt+W**.

- Click on the **WYSIWYG** button from the  in the lower left corner of the HoTMetaL PRO document window

HTML Source view

This view shows the actual HTML code in your document. HoTMetal PRO's HTML Source view is more useful than opening the file in a text editor: the HTML Source view is color-coded and block elements can be indented (this indentation—which makes the HTML Source view much easier to read—is called 'pretty printing').

To display the current document in HTML Source view, do **one of** the following:

- Choose **HTML Source** from the **View** menu.
- Click on the  button from the **Views** toolbar.
- Press **Ctrl+Alt+H**.
- Click on the **HTML Source** button from the  in the lower left corner of the HoTMetal PRO document window

The options for tag color and pretty-printing can be modified by choosing **Options...** from the **Tools** menu and clicking on the **Source View** and **Source Layout** tabs. For more information, see [Source View options](#) and [Source Layout](#).

WYSIWYG-Frames view

The WYSIWYG-Frames view enables you to view and edit frames and frame content. You can also edit frames by using the **Frames** toolbar or the **Frameset** menu. To view how the document will appear in a Web browser with frames and their content, choose **Page Preview** from the **View** menu. For more information on frames, see [Creating frames](#) .

To display the current document in WYSIWYG-Frames view, do **one of** the following:

- Choose **WYSIWYG-Frames** from the **View** menu.
- Click on the  button from the **Views** toolbar.
- Press **Ctrl+Alt+F**.
- Click on the **WYSIWYG-Frames** button from the  in the lower left corner of the HoTMetaL PRO document window

The WYSIWYG-Frames view is available only if the current document contains frames.

Note: Microsoft Internet Explorer must be installed on your PC in order for the WYSIWYG-Frames view to be available.

Page Preview

The Page Preview window enables you to view your document as it would appear in Microsoft Internet Explorer. This is a real browser window in which you can perform browser tasks such as navigating to links. There is no menu bar or toolbar in this window, but by right-clicking you can bring up a pop-up menu, in which you can perform actions such as moving back or forward, saving an image as wallpaper, viewing the properties of the document, and so forth.

Alternatively, you can choose one of the Web browsers from the **Preview** toolbar to preview your document. See [Previewing your document](#) for more information on using the Preview toolbar.

To display the current document in Page Preview view, do **one of** the following:

- Choose **Page Preview** from the **View** menu.
- Click on the  button from the **Views** toolbar.
- Press **Ctrl+Alt+B**.
- Click on the **Page Preview** button from the  in the lower left corner of the HoTMetaL PRO document window

Note: [Microsoft Internet Explorer 3.0 or 4.0](#) must be installed on your PC in order for Page Preview to be available.

HoTMetal PRO options

The **Options...** command in the **Tools** menu of HoTMetal PRO lets you configure some aspects of HoTMetal PRO functionality. You can set:

- Options for viewing your documents, including:
 - Whether documents should be opened by default in Tags On view, WYSIWYG view, or HTML Source view.
 - Whether to show or hide background images, inline images, comments, URLs, and the HEAD element.
 - Setting the font and color of tags in Tags On view and text in HTML Source view.
 - Setting the layout of of the HTML Source view—what elements should be indented, on a separate line (block), or on the same line (inline), and so forth.
- Helper applications – viewers and editors for different file types.
- Options for saving files.
- User and supplementary dictionaries for spell checking.
- Project publishing options.
- Server options.

For more details on options, see **Setting HoTMetal PRO options** in the HoTMetal PRO online help.

HoTMetal PRO windows

HoTMetal PRO 5.0 integrates document editing and site management functions into a single application. You can have one or more windows pertaining to these functions open in your work area at a particular time:

- Attribute Inspector – Enables you to edit attributes of elements. You can open the Attribute Inspector by choosing **Attribute**

Inspector from the **View** menu, right-clicking and choosing **Attribute Inspector** from the pop-up menu, clicking on the  button in the **View** toolbar, or pressing **F6**. For more information on the Attribute Inspector, see [Editing attributes with the Attribute Inspector](#).

- Site management – There are three main windows that enable you to publish, develop, and maintain projects. Before you can display any site management windows, you have to [open or create a project](#). When a project is open, you can open the Project

tab by clicking on the  button to open the Resource Manager, and you can open the Page Links and Web View windows by choosing **Page Links** and **Web View** from the **View** menu, or by clicking on the

and

buttons in the **View** toolbar. For more information on the Project tab, Page Links view, and Web View, see [Managing your Website](#).

- Element List – Enables you to insert HTML elements into your document. You can open the **Element List** window by choosing

Element List from the **View** menu, or **Element...** from the **Insert** menu, or by clicking on the  button in the **View** toolbar. For more information on inserting elements, see [Inserting Elements](#).

- Resource Manager – A file management tool that gives you access to all kinds of **Web objects**: images, cascading style sheets, scripts, and dynamic HTML, and lets you perform 'intelligent insertion' of these objects. You can open the Resource

Manager by choosing **Resource Manager** from the **View** menu, or by clicking on the  button in the **View** toolbar. For more information on using the Resource Manager, see [Managing images and other resources with the Resource Manager](#) and [Managing your Website](#).

Note: [Microsoft Internet Explorer](#) must be installed on your PC in order for the complete Resource Manager functionality to be available.

[More on this topic](#)

Docked and floating windows

Windows in HoTMetaL PRO can be customized and moved. When you first bring up a window, such as the Attribute Inspector, it will be attached to the work area border. The window is said to be **docked**. If you want to turn the window into a floating window that you can move anywhere on your screen, you **undock** the window. To undock a window, do **one of** the following:

Undocking a window

- Double-click on the handles at the top of the function window.

Or:

- Click and hold on the handles at the top of the function window, and drag the window away from its docked position.

Or:

- Right-click on the handles at the top of the function window. A pop-up menu appears.
- Choose **Allow Docking**. This turns off docking.

The window now appears as a floating window.

Moving a window

To move a window:

- Drag the window to position it anywhere on the screen.
- You can resize the window by moving the mouse pointer over an edge until it becomes a two-headed arrow, and then clicking and dragging.

Redocking a window

To **redock** a window, do **one of** the following:

- Double-click on the window's title bar. The window will return to its original docked position.

Or:

- Click and hold on the window's title bar and drag the window to a docked position. See [Rules for the behavior of docked and floating window](#) for more information.

Or:

- Right-click on any grey edge of the window. A pop-up menu appears.
- Choose **Allow Docking** to turn docking back on.
- Right-click on the title bar at the top of the window. A pop-up menu appears.
- Choose **Redock**. The window becomes a docked window again.

Note: If you undocked the window by turning off 'Allow Docking', this is the only way to return it to a docked position.

Rules for the behavior of docked and floating window

If the dialog is floating:

- 1 Dragging the dialog so that the left edge is outside the left edge of the HoTMetaL PRO document window area causes it to dock on the left, with the handles on the top.
- 2 Dragging the dialog so that the left edge is about 2.5 inches from the right edge of the HoTMetaL PRO document window area causes it to dock on the right, with the handles on the top.
- 3 Dragging the dialog so that the top edge is higher than the bottom-most toolbar causes the dialog to dock below the toolbars, with the handles on the left.
- 4 Dragging the dialog so that the top edge is about 2.5 inches from the bottom of the HoTMetaL PRO document window area causes the dialog to dock below the document window, with the handles on the left. If the dialog is docked at the left or right, dragging it so that the top edge is below the top of the document area causes it to float. If the dialog is docked at the top or bottom, dragging it so that the left edge is to the right of the document area causes it to float.
- 5 When in a drag/undock operation, HoTMetaL PRO will draw an outline which represents what will happen if the mouse is released at that instant. The rectangle displayed will have one of two sizes. One size represents the last floating window size. The other represents the last docked size.

Window buttons

Docked windows contain two buttons for closing and expanding the window. These buttons are located at the top right or top left corner (depending on the window's docked position).

The  button closes the docked window. The

 button expands the docked window. This button is selectable only when a window is stacked on top of another window. This option is useful when you want to expand a window's viewing space. Expanding a window will cover up most of another existing window to provide a larger viewing window. To expand a docked window:

- Click on the window's  button.
- The selected window expands, covering up the space of the other window. This gives you more viewing space for the selected window.

You will notice that the handles of the covered window are still visible.

To view the covered window again, click on its  button.

Full screen mode

Full screen mode enables you to display the HoTMetaL PRO window in the entire viewing space of your monitor. To view the HoTMetaL PRO window in full screen mode:

- Click on the  toolbar button or choose **Full Screen** from the **View** menu.

The HoTMetaL PRO document window fills the screen. The menu bar and the full screen toolbar button will be the only toolbars visible. Other views such as the Resource Manager can be made visible in Full Screen mode since Full Screen mode has its own workspace, the view and toolbar configuration will be remembered the next time this mode is entered. If you want to make other toolbars visible, choose **Toolbars...** from the **View** menu and select the toolbars you want.

To return the HoTMetaL PRO document window to its regular size, do **one of** the following:

- Click on the  toolbar button.
- Choose **Full Screen** from the **View** menu.
- Press the **Esc** key.

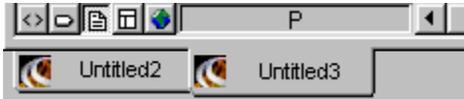

The HoTMetaL PRO document window returns to its original size.

Workbook mode

Workbook mode enables you to access multiple documents quickly and easily. You can have multiple documents open by continually opening new documents from the **File** menu; workbook mode enables you to see and select documents using tabs at the bottom of each document. Workbook mode is particularly useful when you are creating a Website with multiple pages. To select workbook mode:

- Choose **Workbook Mode** from the **View** menu.

When a file is open, a tab will appear at the bottom of the HoTMetaL PRO window, underneath the view icons, containing the name of the document.

- Click on the tab of the document that you want to view.

Saving and closing multiple documents

If you have multiple documents open, you can use the **Save All** command to save any changes. To use the **Save All** command:

- Choose **Save All** from the **File** menu, click on the  button, or press **Ctrl+L**.

All of the documents are saved.

Similarly, if you want to close all of the open documents:

- Choose **Close All** from the **File** menu. All of the open documents will close.

Using workspaces

A **workspace** refers to the current state of a HoTMetaL PRO session, including: which files are open, which project is open, which windows and toolbars are visible, and whether windows are floating or docked, and their position. Saving a workspace saves this state information. For example, if you have a project open in HoTMetaL PRO in Tags On view, with the Attribute Inspector open, Web View open, and with a customized toolbar selected, you can save that workspace. The most recently saved workspace will be opened the next time you start HoTMetaL PRO.

To create and save a workspace:

- Choose **Workspace** from the **File** menu and then choose **Manage...** from the fly-out menu. The **Workspace Manager** dialog box appears.
- Click on the  button. A blank workspace name will appear in the **Workspaces** list.
- Type in a name for your workspace and press **Enter**.
- A dialog box will appear asking if you want to save the workspace. Click on **Yes**.

The current state of HoTMetaL PRO is saved.

To save a workspace:

- Choose **Workspace** from the **File** menu and then **Manage...** from the fly-out menu.
- Choose a workspace.
- Click on **Save**. The workspace is saved.

To open an existing workspace:

- Choose **Workspace** from the **File** menu, then choose a workspace from the list underneath the **Manage...** menu item. The workspace will open.

To open a currently open workspace:

- Choose **Workspace** from the **File** menu and then **Manage...** from the fly-out menu.
- Choose the workspace that you want to open from the list in the **Workspace Manager** dialog box and click on **Open**.

Note: Opening a workspace closes the current workspace. If you want to save your current workspace, do it before opening a new one.

Right-click commands

In addition to the toolbar buttons or menu commands, HoTMetaL PRO has pop-up menus available when you right-click on items such as windows, text, graphics, and links. Right-clicking on an item presents you with different commands; usually the most commonly used commands associated with that that item. It is often more convenient to choose a command from a pop-up menu because the available commands are those that are directly applicable to the object being clicked on.

Right-clicking on a window typically allows you to:

- Hide the window.
- Dock or redock the window.

Right-clicking on a toolbar area or blank document window typically allows you to:

- Toggle toolbars on or off.
- Open the Commands dialog box.

Right-clicking on a piece of text typically allows you to:

- Cut, copy, and paste.
- Insert or select an element.
- Invoke the Attribute Inspector.

Right-clicking on a graphic typically allows you to:

- Edit or view an image file.
- Select an element.
- Invoke the Attribute Inspector.
- Look at the image's properties.

Right-clicking on a link typically allows you to:

- Edit or view a linked item.
- Insert or select an element.
- Invoke the Attribute Inspector.

Right-clicking on a dialog box typically allows you to:

- Dock or redock the dialog box.
- Hide the dialog box.

Toolbars

You can access commands in HoTMetaL PRO through the toolbars. **Tooltips**—short descriptions of what the toolbar button does—appear near the toolbar buttons if you move your mouse cursor over them. There are seventeen toolbars available, though all are not displayed by default. When you open HoTMetaL PRO for the first time, the **Menu**, **Standard**, **Preview**, **Full Screen**, and **Formatting** toolbars are turned on.

[More on this topic](#)

Moving toolbars around

You can move any toolbar to any other position in the toolbar area at the top of the HoTMetaL PRO screen, or move a toolbar off that area, where it becomes a floating toolbar (sometimes called a 'palette'). Floating toolbars can be moved anywhere on the screen.

To turn a toolbar into a floating palette:

- Move your cursor over the toolbar's 'handle' and click and hold on the handle.
- Drag the toolbar anywhere on the screen to make it a floating toolbar.

To resize a toolbar:

- Double-click on the toolbar handles.

Or:

- Place your cursor over the left or right side of the toolbar until it becomes a double-arrow.
- Drag the sides of the toolbar right or left to create different floating toolbar sizes.

To redock a toolbar:

- Drag the toolbar to the left or right edge of the HoTMetaL PRO document window with your mouse and release.

Or:

- Double-click on the title bar.

The toolbar becomes docked, like the toolbar area at the top of the screen.

Turning toolbars on or off

You can turn any toolbars on or off. This is useful for having only the toolbars that you use appear. To turn toolbars on or off, do **one** of the following:

- Right-click on the background of the toolbar area above the HoTMetaL PRO document window. A pop-up menu appears.
- Toggle a toolbar on or off by choosing the toolbar from the pop-up menu.

Or:

- Choose **Toolbars...** from the **View** menu. The **Toolbars** dialog box appears.
- Click on the check box for the toolbar that you want to turn on or off.
- Click on **Close**.

HoTMetaL PRO remembers these toolbar settings the next time you start up.

Creating customized toolbars

You can customize new and existing toolbars in HoTMetaL PRO. To create a new toolbar:

- Choose **Toolbars...** from the **View** menu, or right-click on the toolbar area and choose **Customize...** from the pop-up menu. The **Toolbars** dialog box appears.
- Click on **New....** The **New Toolbar** dialog box appears.
- Type in a name for your new customized toolbar.
- Click on **OK**.

The **Customize** dialog box appears. A small floating dialog box () will also appear to the left of the **Customize** dialog box. This is your customizable toolbar.

- In the **Customize** dialog box, click on the check boxes to turn **Show Tooltips** or **Flat Look** on or off.

To add buttons to a new or existing toolbar:

- Click on the **Commands** tab.
- Select a category from the **Toolbars** menu.
- Select the toolbar button that you would like to add to your customizable toolbar.
- Drag and drop the toolbar button onto the toolbar.
- When you have added the desired buttons, click on **Close**.

Note: You can use only the set of toolbar icons that come with HoTMetaL PRO—you cannot add your own icons.

Toolbar functions

The toolbars are described briefly here. For more details on the functions that each toolbar deals with, see the appropriate section of the manual.

- **Menu** - This toolbar contains all of the menus and their available commands:

- File
- Edit
- View
- Insert
- Format
- Tools
- Table
- Form
- Frameset
- Site
- Window
- Help

- **Standard** - This toolbar contains many basic commands, including file commands such as:

- New Page

- Open

- Save

- Save All

Word-processing commands such as:

- Find text in Site

- Find

- Find Next

- Spell Check (not available in the Evaluation Version)

Indenting commands:

- Indent selection

- Outdent selection

Standard text editing commands such as:

- Cut

- Copy

- Paste

- Undo

- Redo

Insertion commands for many building blocks of Web pages:

- Images

- Links

- Tables

-  - Elements
-  - Resource Manager

Moving between documents:

-  - Previous window
-  - Next document

Web page validation:

-  - For conformance with the the HTML standard
-  - For accessibility guidelines

Accessing online help:

- 
- **Preview** - Use this toolbar to put in specific Web browsers for previewing your documents. By default, Microsoft Internet Explorer is in the toolbar because it is required to enable certain HoTMetal PRO functions. If you choose to install Netscape Navigator, it will appear in the Preview toolbar upon startup as well.

-  - Microsoft Internet Explorer.

-  - Netscape Navigator.

- **Formatting** - Use this toolbar to change the appearance (and hence, HTML code) of both inline text and block elements. You can change the style of the current block element using the pull-down menu:

-  - Change the text style for blocks of text

-  - Change the font of the selected text

- 

-  - Change the size of the text.

-  - Changes decors

- 

- 

-  - Bold, Italic, and Underline

-  - Change the color

The alignment:

- 

- 

- 

- Left, Center, Right

Insert lists:

-  - Ordered list

-  - Unordered list

- **Advanced** - Insert advanced objects in your web page:

-  - ActiveX Controls
-  - Applets
-  - Inserts a Design Time Control (DTC).

• **Full Screen**

-  - Use this toolbar to make the HoTMetaL PRO document window full screen.
- **Views** - Use this toolbar to select the different editing views and function windows.Editing views:

-  - Shows the HTML Source view in the document window.
-  - Shows the Tags On view in the document window.
-  - Shows the WYSIWYG view in the document window.
-  - Shows the WYSIWYG-Frames view in the document window.
-  - Shows the document as it would appear in a Web browser in the document window.

Function windows:

-  - Opens the Page Links window for opened projects.
-  - Opens the Web View window for opened projects.
-  - Opens the Attribute Inspector window.
-  - Opens the Insert Element window.
-  - Opens the Pocket View window.
-  - Opens the Resource Manager window.
-  - Shows the document window in full screen mode.

• **Site** - Use this toolbar to perform site management functions:

-  - Publishes files to a server
-  - Remap the site

• **Table** - Use this toolbar to create and edit tables.

-  - Insert a table
-  - Edit table properties

Edit rows:

-  - Insert row above
-  - Insert row below
-  - Delete row

Edit columns:

-  - Insert column left
-  - Insert column right
-  - Delete column

Moving rows and columns:

-  - Move row up
-  - Move row down

-  - Move column left
-  - Move column right

Merge cells:

-  - Merge cell right
-  - Merge cell left
-  - Merge cell up
-  - Merge cell down

Split cells:

-  - Split cell into rows
-  - Split cell into columns

• **Table Advanced** - Use this toolbar to contract cells in a table.

-  - Pulls the left boundary of the cell one cell to the right
-  - Pulls the right boundary of the cell one cell to the left
-  - Pulls the bottom boundary of the cell one cell up
-  - Pulls the top boundary of the cell one cell down

• **Symbols** - Use this toolbar insert symbols.

-  - A symbol

• **Special characters** - Use this toolbar to insert special characters for letters that have accents.

-  - A special character

• **Frames** - Use this toolbar to insert frames into your web page.

-  - Split selected frame into rows
-  - Split selected frame into columns
-  - Delete selected frame
-  - Toggle selected frame's scrolling attribute
-  - Toggle selected frame's scrolling attribute automatically
-  - do not toggle selected frame's scrolling attribute
-  - Toggle borderless frameset attributes
-  - Frame resizability toggle
-  - Frame size

• **Quick Tools** - Inserts various HTML elements.

-  - A paragraph
-  - A heading

-  - Preformatted text
-  - Blockquote
-  - Address
-  - A comment (not visible in Web browsers)

Insert components of a definition list:

-  - Definition (DL)
-  - Definition list term (DT)
-  - Definition list definition (DD)

Insert:

-  - A line break
-  - A horizontal rule

Format the current text as:

-  - Emphasized
-  - Strong
-  - Teletype
-  - Citation

Insert special characters:

-  - Special character

Insert a bookmark/link:

-  - Bookmarks
-  - Link to bookmark

Remove tags:

-  - Remove tags

• **Forms** - Create forms and insert form elements. Insert a form:

-  - Form

Insert input elements:

-  - Text boxes
-  - Text area
-  - Check box
-  - Option button
-  - List box
-  - Drop-down lists

-  - File upload
- Insert buttons:

-  - Submit button
-  - Reset button
-  - Push button
-  - Image button

Insert hidden elements:

-  - Password field
-  - Hidden input

• **Macros** - Use this toolbar to record and play macros:

-  - Record
-  - Stop recording
-  - Play macros

• **Image Mapping** - Create and edit image maps:

-  - Select an image map area
-  - Create a circle area
-  - Create a rectangle area
-  - Create a polygon area
-  - View the image map areas

Menus

All commands can be chosen from the menus. The following list gives a brief description of the commands in each menu.

- **File** menu:
 - Creating, opening, saving, and closing documents and projects.
 - Previewing documents and projects.
 - Editing document or project page properties.
 - Creating, opening, saving, and closing workspaces.
 - Creating new folders for projects.
 - Print Preview, and printing documents and projects.
 - Exiting HoTMetaL PRO.
- **Edit** menu:
 - Undoing and redoing actions.
 - Cutting, copying, pasting, and deleting text and markup.
 - Commands for markup: selecting, joining, changing, splitting, and removing elements.
 - Finding and replacing text and markup.
 - Finding and replacing URLs.
 - Finding and replacing in files.
 - Renaming folders or files.
- **View** menu:
 - Changing views (HTML Source, WYSIWYG, WYSIWYG-Frames, Tags On, and Page Preview).
 - Showing or hiding toolbars.
 - Showing or hiding inline images and table grids.
 - Opening the Element List to insert HTML elements.
 - Opening the Attribute Inspector to view and modify attributes.
 - Opening the Element List to view the HTML elements available for editing.
 - Making the document window full-screen.
 - Turning on Workbook mode.
 - Opening the Resource Manager.
 - Opening the different site management windows.
 - Opening the Thumbnail View.
- **Insert** menu:
 - Inserting elements, special characters, symbols, comments, and horizontal rules.
 - Inserting links, images, and bookmarks.
 - Inserting ActiveX Controls, Java applets, Design-Time Controls, and Database Tables.
- **Format** menu:
 - Increasing or decreasing text size.
 - Changing text format: bold, italic, underline, color, etc.
 - Changing block alignment (left, right, centered).
 - Indenting and outdenting a selection.
 - Inserting or changing the current element to a numbered list, bulleted list, or definition list.
 - Opening the Cascading Style Sheet editor to: refresh styles, edit element styles, edit document styles, and add or create external styles.
 - Changing decors.
- **Tools** menu:
 - Checking spelling and using the thesaurus (not available in the Evaluation Version).
 - Opening Image Editor and Image Explorer (not supplied with the Evaluation Version).
 - Converting the current document to a frame document.
 - Creating and editing macros.
 - Validating the HTML in your document.
 - Checking your document's accessibility.
 - Modifying HoTMetaL PRO options.
- **Table** menu:
 - Inserting and editing tables and table properties.
- **Form** menu:
 - Inserting and editing forms.
- **Frameset** menu:
 - Edit frame contents.
 - Create and delete frames.

- Add scrollbars.
- Toggle selected frame's resizability attribute.
- Create borderless frames.
- Refresh or stop changes.
- Edit frame properties.
- **Site** menu:
 - Import a site.
 - Remap links.
 - Changing decors.
 - Check site for broken, orphan, or external links.
 - Build a site summary.
 - Show marked site files, legend, duplicate links, and full view.
 - Publish a site.
 - Find and replace links, images, text, and bookmarks.
- **Window** menu:
 - Changing display options for the documents you have open and switching between documents.
- **Help** menu:
 - Accessing online help, technical reference, tip of the day, registration and problem report pages.
 - Getting version information about HoTMetaL PRO.

Note: The Menu toolbar can also be made into a floating toolbar or new toolbar area on the left or right side of the HoTMetaL PRO document window.

Creating your first Web page

What's covered in this chapter

The tutorial and reference sections of this chapter describe the first steps in building a Website: creating, editing, and saving a simple introductory [page](#). The topics covered include:

- Formatting your text, including creating paragraphs, headings, and lists.
- Adding a background color or image.
- Aligning page content.
- Inserting a simple table.

Reference

The following reference guide sections explain how to create HTML markup in both the [WYSIWYG](#) and [Tags On](#) views. If you are familiar with word processor applications, but new to HTML, you may find it easier at first to work in WYSIWYG view. If you like to see how everything actually works, use the Tags On view. Most procedures can be done in either view.

[More on this topic](#)

Creating a new page using a template

The templates available in the Evaluation Version that you are now using are a subset of those provided with HoTMetal Pro 5.0. Choose 'How To Purchase' in the Help menu for ordering information.

You can use a template to help you create a new document. The HoTMetal PRO page templates illustrate various decors and page layouts.

- Choose **New...** from the **File** menu.
- Choose **Page From Template...** from the fly-out menu.

Or:

- Press **Ctrl+T**.

Now:

- Choose a **Template Group**.
- Choose a specific template based on the descriptions displayed.
- Click on **OK**.
- Edit the page to insert your own content.

You may later wish to refer to the ['Working with HTML'](#) help section .

Creating a new, blank page

To create a new, empty document:

- Click on the  toolbar button.

Or:

- Press **Ctrl+N**.

Or:

- Choose **New...** from the **File** menu, and then choose **New Page** from the flyout menu.

Or:

- Choose **New...** from the **File** menu, and then choose **Page from Template...** from the fly-out menu. The **New** dialog appears.
- Choose **Blank Decor Document** from the list.
- Click on **OK**.

This opens an empty document. If you are in WYSIWYG view, the insertion point will appear at the top of the document window. The insertion point will be inside a P element, and the status bar in the bottom left of the document window will reflect that.

From the **File** tab of the **Options** dialog, you can specify a different default template to be opened when you click on the **Choose...** button.

Opening a page

You can open a page that is formatted in HTML by choosing **Open...** in the **File** menu.

In addition to using the **Open...** command, you can open files by dragging and dropping them onto the background of the HoTMetal PRO work area. You can also drag and drop files onto the square area where the horizontal and vertical scrollbars meet; this is particularly useful if the document window is maximized, making the work area background invisible.

By default, the **Open** dialog displays all files in the current folder that have the **.htm**, **.html** file extension.

When you select an **.html** or **.htm** file in the **Open** dialog box, you will see a preview image of the document in the **Preview** window. You can turn this option off by clicking the **Preview** check box.

If you prefer working in Source View, you can choose to have your documents open up in the Source View by clicking on the **Open in the Source View** check box in the **Open** dialog box.

Saving a page

You can save a page using **Save** or **Save As...** in the **File** menu.

The **Save All** command saves all of the documents that you have open in HoTMetaL PRO. If you are creating new documents, the **Save As** dialog box will prompt you to name each file sequentially. If the documents are existing documents, they will all be saved without any prompting.

If a document contains relative links, and you save it to a different folder, some relative links may become broken. To help you avoid this, the **Save As** dialog has three options for what to do with relative links:

- **Update URLs** – any relative URLs in the document will be updated so that they still point to the same linked files, even though the current document is in a new location.
- **Copy Items** – instead of changing the URLs, HoTMetaL PRO will copy the files that those URLs point to so that they are in the same locations relative to the new location of the current document. This option works only for first-level files, that is, linked files that are in the same folder as the current document.
- **No Change** – performs a normal **Save As**. Relative URLs may become broken. **No Change** is the default option.

If you are saving a file for the first time, and you choose **Update URLs** or **Copy Items**, any **file:///** URLs in the document will be converted to relative URLs, provided that the linked files and the current file are on the same disk partition (both on the C: drive, for example).

Adding basic components

The most basic Web page consists of headings, paragraphs, and lists. Headings help to structure the information in the document; paragraphs generally convey the information itself; lists are used for information that is best expressed in point form. While a page doesn't **have** to contain these features, many pages on the World Wide Web use this basic structure. As you learn more, you can build and improve the content and style of your pages.

Inserting headings

Most Web pages contain at least one heading. There are six levels of headings, quite logically numbered from one to six. The topmost level of heading is called H1 (**Heading 1**). These headings imply levels of importance with respect to each other in the document, and they are formatted by Web browsers to indicate this relative importance. While your pages don't have to contain headings, they are useful for structuring your information.

Headings do not have to be in any particular order, but because of the way documents are displayed in browsers, you will get better results by following these guidelines:

- Heading 1 headings (H1) should be used as the highest level of heading, Heading 2 (H2) headings as the next highest, and so on.
- Try to avoid skipping heading levels: for example, a level 3 heading should not come after an level 1 heading unless there is a level 2 heading between them.

The cursor may change size depending on the level of heading you selected. **Heading 1**, for example, is usually displayed in a larger type size, so the cursor will get larger. When you type the text of the heading, HoTMetaL PRO will display the text similar to the way most Web browsers would display that level of heading (for example, bold face type, two points larger than the body type).

To create a new heading:

- Place the insertion point at the end of the existing text and press **Enter**. A new line is created.
- Choose **Heading 1** (or lower level heading) from the pull-down menu of styles in the **Formatting** toolbar.
- Type the text of the heading.
- When you have finished typing the text of the heading, press **Enter**.

If you place the insertion point inside a paragraph and select a heading from the pull-down menu, the paragraph changes to a heading. If you place the insertion point at the end of the existing text and press **Enter**, a new line is created. Then you can enter new text and/or change the new line to any element you wish.

In Tags On view, you can move the insertion point outside of any existing element (P, ADDRESS, PRE, etc.). Then, any element you select from the pull-down menu will be inserted at that location.

Inserting paragraphs

Paragraphs are the most common way to present blocks of text. When you start a new document in HoTMetaL PRO, you are ready to begin typing a paragraph.

To insert a new paragraph in your page:

- Place the insertion point at the end of the existing text and press **Enter**. A new line is created.

Or:

- Choose **Paragraph** from the pull-down menu of styles in the **Formatting** toolbar.

Your Web page has to conform to certain rules. For example, you cannot have a paragraph inside a heading, or a heading inside a paragraph. If the insertion point is inside a paragraph and you choose a heading from the pull-down menu, HoTMetaL PRO will change the whole paragraph into a heading. Similarly, if you have the insertion point inside a heading and you choose paragraph from the menu, you will change the heading to a paragraph.

[More on this topic](#)

Splitting and joining paragraphs

You can create two elements of the same type from a single element, or join elements together. The most common use for joining elements is to join two elements of the same type (combining two paragraphs, for example): when two different elements are joined, the second element becomes part of the first and any special properties of the second element are lost. For example, if you have a heading followed by a paragraph that you have centered and you join the two, the result would be a long heading with default alignment (not centered).

To split a single paragraph into two paragraphs:

- Press **Enter** at any point in the paragraph.

The paragraph will split at the insertion point.

To join two paragraphs together, do **one of** the following:

- Place the insertion point at the start of the second paragraph and press **Backspace**.
- Place the insertion point anywhere in the second paragraph and press **Ctrl+Shift+J**.
- Place the insertion point anywhere in the second paragraph and choose **Join Element to Preceding** from the **Edit** menu.

The second paragraph will join the first. A space is added automatically between the two pieces of text. These methods can be used to split and join other 'block'-style elements as well.

Creating and editing lists

Lists are useful for presenting itemized information, such as sequential steps to perform a task, and definitions.

Web pages can contain several different kinds of lists:

- Numbered or ordered list (OL element) – Items in this type of list are numbered automatically by the Web browser. The numbering style will reflect nested lists .
- Bulleted or unordered list (UL element) – Browsers will format unordered lists with a bullet or other special character. The character usually changes for nested lists .
- Definition list (DL element) – An unordered list that contains pairs of terms (DT) and definitions (DD) .
- Directory list (DIR element) – This unordered list is used to create a directory (for example, a file directory). Items in a directory list should not be longer than 24 characters .
- Menu list (MENU element) – Menu lists are unordered lists. Items in a menu list should be no longer than one line .

Note: All lists, with the exception of definition lists, consist of a list element (such as UL or OL) that contains one or more list item (LI) elements.

You can insert lists in a number of ways:

- By creating a new list.
- By demoting paragraphs.
- By promoting second-level list items.

You can also change the list type after you have created a list. For example, you might create a numbered list and then decide that you prefer bullets.

More on this topic

Inserting a new list

To insert a new numbered, bulleted, directory, or menu list:

- Place the insertion point where you want to insert the list and do **one of** the following:
 - Choose the type of list you want to add from the pull-down menu of styles in the **Formatting** toolbar.
 - Click on the  (numbered list) or  (bulleted list) toolbar button.
- Choose **Bulleted list** or **Numbered list** from the **Format** menu.

A new list is created, containing a single list item.

Pressing **Enter** in a list item inserts a new list item after the current one.

To terminate a list, press **Enter** twice (if you're already in an empty list item, you have to press **Enter** only once).

Inserting a list inside a list

To insert a list inside a list (also called a **nested list** or **sub-list**):

- Create a new list item after the current one (by pressing **Enter**, for example).
- Press **Tab**, or right-click in the new list item and choose **Demote** from the pop-up menu.

This creates a new, empty list of the same type as the original list, inside the original list item. You can edit this list as you would any other list. To terminate this list and return to the outer list, press **Enter** twice.

If you have already created one or more list items that you wish to convert to a nested list:

- Highlight the list item(s) that you want to put in a nested list.
- Press **Tab**, or right-click and choose **Demote** from the pop-up menu.

You can also insert a list at any point in the current list item by choosing **Element...** from the **Insert** menu and inserting one of the list elements (OL, UL, DIR, or MENU).

Converting (demoting) paragraphs to a list

You can turn one or more paragraphs, block quotes, pre-formatted text blocks, or other paragraph-style text blocks into a bulleted list.

- Select one or more paragraphs.
- Press **Tab**.

If you demote paragraphs that are located between two bulleted lists, the two lists and the converted paragraphs will be combined.

Converting (promoting) list items to paragraphs

You can turn one or more list items into paragraphs.

- Select one or more list items.
- Do **one of**:
 - Press **Shift+Tab**.
 - Right-click and choose **Promote** from the pop-up menu.

If you promote list items in the middle of a list, the list will be split.

Changing the list type

To change an existing list to a bulleted or numbered list, you can click on the bulleted list or numbered list toolbar button. For other list types, use the pull-down menu of styles in the **Formatting** toolbar or the **Insert Element** dialog.

To change an existing list to another type of list:

- Put the insertion point inside the list.
- Do **one of** the following:
 - Click on the  or  toolbar button.
 - Choose the new list type from the pull-down menu of styles in the **Formatting** toolbar.
 - Choose the new list type from the **Format** menu.
 - Put the insertion point directly inside the list element, and choose **Change Element...** from the **Edit** menu to change the list element type.

Convert a pasted selection to a list

HoTMetal PRO will convert a selection that has been pasted (or dragged and dropped) from another application into a list if:

- Each line starts with one or more tabs.
- There is only one data item per line (that is, after the initial tab(s) starting the line, there are no more tabs in the line).
- Each line is indented (tabbed) by no more than one tab more or less than the previous line.
- There are at least two lines.

Sub-lists will be created as necessary to reflect the indent levels of the list items.

Depending on its structure, a text selection could also be converted to a table. If the selection cannot be pasted as a list or table, it will be converted to a paragraph.

Using definition lists

Definition lists are a special kind of list because instead of consisting of ordinary list items (LIs), they consist of a combination of **defined terms** and **definitions**. A basic definition list consists of alternating terms and definitions, but you can also have several terms or definitions in sequence. Most browsers will indent the definitions. Of course, you don't have to use this kind of list just for definitions: you can use it for any purpose that is suited to two-part lists.

The most convenient way to work with definition lists is to use the **Quick Tools** toolbar. If this toolbar is not displayed:

- Right-click on the background of the toolbar area and choose **Quick Tools** from the pop-up menu.

To insert a definition list, do one of:

- Choose **Definition list** from the pull-down list of styles in the **Formatting** toolbar.
- Click on the  toolbar button in the **Quick Tools** toolbar.

You can use the following techniques to edit definition lists:

- To create a new instance of the current item (defined term or definition), press **Enter**.
- To change a definition into a defined term, click on the  toolbar button.
- To change a defined term into a definition, click on the  toolbar button.
- To terminate a definition list, press **Enter** twice (if you are in an empty item, you have to press **Enter** only once).
- If a defined term contains an image (usually found at the beginning, functioning as a list bullet), then when you press **Enter** to create a new defined term, that image will be duplicated in the new term.

Inserting tables

Tables are commonly used in Web pages to convey related information in a logical way. They can also be useful as layout tools for design purposes.

To insert a table:

- Choose **Insert Table...** from the **Table** menu.
- Type the number of **Rows** and **Columns** you want in the table in the text boxes.
- Click on **OK**.

Formatting text

You can change the way that your text appears in a number of ways—by changing the text alignment, style, color, or font. It is generally not good design practice to get carried away with these choices: multiple changes of font or color can be distracting and reduce readability, especially for users with visual impairments. Once you find a look for your text that you are happy with, you can apply it to all the documents in your site to create a consistent design style.

 [More on this topic](#)

Aligning blocks of text

You can align blocks of text (block elements) and table cells in your Web page to the left (default), to the right, or in the center. Headings, paragraphs, and table cells are some of the elements you can align.

To set text alignment:

- Put the insertion point in the block of text you wish to align.
- To set the alignment, do one of:
 - Click on the  (**Left Align**),
 (**Right Align**), or
 (**Center**) toolbar button.
 - Press **Ctrl+L** (left align), **Ctrl+R** (right align), or **Ctrl+E** (center).
 - Choose **Align Left**, **Align Right**, or **Align Centered** from the **Format** menu.

Changing the text style

You can add emphasis to inline text by changing the text style. The **Formatting** toolbar includes buttons for bold, italic, and underline.

There are also other HTML character format elements that you can use. Emphasis (EM) and strong (STRONG) are commonly used in place of italic and bold: most browsers will display them as italic and bold but their use gives more flexibility to the browser. Teletype (TT) will be displayed in a fixed-width, typewriter-style font, such as Courier. This is useful in technical documentation: if you are going to include any instructions for viewers on your site, you can use it to indicate text to be entered. All of these text styles are available from the **Format** menu and the **Quick Tools** toolbar.

Emphasized text should be used sparingly, or it will no longer stand out. Since browsers underline text links, underline text for emphasis only in special situations where you are sure it will not be confusing.

To change text style:

- Select the text and do **one of** the following:
 - Click the  (**Bold**),
 (**Italic**), or
 (**Underline**) button in the toolbar.
 - Press **Ctrl+B**, **Ctrl+I**, or **Ctrl+U**.
 - Choose a style from the **Format** menu.

Each of these methods can be used to either apply or remove the chosen style: for example, if you click on  when the selection is already bold, the bold style will be removed.

Changing the text color

Most Web browsers will let you specify different colors for the the text in your document. You can specify the default text color for the whole document in the **Page Properties** dialog box , but you can also change the color for specific text in the document.

To change text color:

- Select the text.
- Click on the  toolbar button, or choose **Text Color...** from the **Format** menu; this brings up the Windows **Color** dialog box.
- Choose a color from the palette.
- Click on **OK**. Your change will be reflected in the document window.

Changing the text size

You can change the size of text, as a relative value (+/-) or as an absolute value. These numbers do not represent actual point sizes, but rather a scale to be interpreted by the browser. Most browsers support font sizes between 1 to 7, with 3 being the default size. When you change the font size in HoTMetal PRO, the size is increased or decreased.

To change text size:

- Select the text, and do **one of** the following:

- Click on the  or  toolbar button.

- Press **Ctrl+Shift+>** (increase size) or **Ctrl+Shift+<** (decrease size).
 - Choose **Increase Text Size** or **Decrease Text Size** from the **Format** menu.

Changing the font

Most Web browsers can display different font faces in your page. Keep in mind that fonts and font names are not the same on all computer platforms. For example, UNIX and Macintosh users may not be able to use the same fonts as Windows users. Make sure that your pages are acceptable without the selected fonts.

To change the font of your text:

- Select the text you want to display in a different font.
- Pull down the menu of fonts in the **Formatting** toolbar.
- Choose the font from the pull-down list. Your font selection will be reflected in the document window.

Adding common design items

This section describes some simple ways to add a little design to your Web page. More complicated methods of design (such as [frames](#) and [tables](#)) are covered later in this guide, but remember that often the simplest designs are the best.

[More on this topic](#)

Page Properties

The **Page Properties** dialog lets you set background images and colors, set text colors, and give the document a title.

Backgrounds

Backgrounds are an easy way to make your Web page more interesting and give it some style. You can specify a background color for your Web page or you can use a graphic, which will be **tiled**—that is, repeated over and over to fill up the background—by the browser.

You can specify either a background color or graphic using the **Page Properties...** command. Take care to ensure that your color choices for text and background have enough contrast for readability. The background image should not contain information (such as a company or site name) that is not also included elsewhere in the document in text form.

To specify a background color:

- Choose **Page Properties...** from the **File** menu.
- Click on the ... button next to the **Color** option; this brings up the Windows **Color** dialog box.
- Choose a color from the palette.
- Click on **OK**.

HoTMetaL PRO will now display your color choice as the background color.

To specify a background image:

- Choose **Page Properties...** from the **File** menu.
- In the **Image** text box, type the full path and filename of the image you want to use for your background. Alternatively, you can click on **Choose...** to find the file.
- Click on **OK**.

The background image you have selected is **tiled**, or repeated, as many times as necessary to fill the background.

Note: Use the Options dialog to choose whether to Show Background Images in the HoTMetaL PRO document window.

Text colors

Click on the ... buttons or enter a hexadecimal red-green-blue value in the text boxes to choose colors for:

- Normal text
- Links (hot text; most browsers display this text in blue by default)
- Visited links (links that have already been accessed)
- An active link (this is the color that the link text will at the moment that someone is clicking on it).

Document title

You should specify a title for your document—most browsers will display this text in the title bar when your document is displayed.

To specify a title:

- In the **Document title** text box, type a title for your document.

Adding horizontal lines

Sometimes you may want to break your page into sections, or add some graphical relief by inserting a horizontal line across the page.

To insert a horizontal rule:

- Choose **Horizontal Rule** from the **Insert** menu. A horizontal line appears across the page at the insertion point.

Double-click on the line if you want to set properties for the rule. The following properties are available:

- **SIZE** – Height of the rule in pixels.
- **WIDTH** – Width of the rule in pixels or percentage of screen width (percentage recommended).
- **NOSHADE** – Indicates whether the rule has a 3D or flat look.
- **SRC** – Specifies a URL to an image that will be displayed in place of the rule in browsers that support this.
- **ALIGN** – Specifies left, center or right alignment for the rule.

Line breaks

Occasionally, you may wish to make the line break in a specific spot and wrap to the line below. This is sometimes the case with especially long headings.

To insert a line break (BR element) into your document:

- Press **Shift+Enter**.

Completing your page

You can save your Web page at any time using **Save** or **Save As** in the **File** menu. However, there are a number of recommended steps you should go through before considering your page complete and ready for public viewing:

- Give the document a title.
- Validate for accessibility to ensure that visitors using different browsers and various assistance tools can easily access this document.
- Validate the HTML to ensure that the document markup is not invalid in any way. Invalid markup can result in browsers not displaying the document properly.
- Preview your document in one or more browsers to see how it looks.

[More on this topic](#)

Validating for accessibility

To ensure that your document is accessible to everyone, including users with disabilities and users of text-only browsers, choose **Check Accessibility** from the **Tools** menu.

To check your document for accessibility:

- Choose **Check Accessibility** from the **Tools** menu. HoTMetaL PRO checks your document against a set of accessibility guidelines. If your document does not meet these guidelines, a message appears with a summary list of the accessibility problems.
- Click on **OK**. A succession of dialog boxes appear, one for each problem. Some problems can be solved immediately using tools in the dialogs. If the problem is more complex, a textual warning appears which explains the problem.

If your document does not pass the accessibility check, it does not mean that the HTML markup is incorrect. It is advising you that your document could be marked up to be more accessible to people with disabilities. For information about creating Web pages that can be accessed by everyone, see [Validating for accessibility](#) in the online help.

Validating your page

You can use the **Check HTML** command in the **Tools** menu to verify that the markup in a document is correct and complete. If the validation process finds an error in the document, a message appears and the insertion point will move to the error so that you can make the necessary change.

To check your document for valid HTML markup:

- Choose **Check HTML** from the **Tools** menu, or press **F9**. The **Validation** dialog box appears.
- Click on the **More...** button to see which elements used in your document may not be supported by all browsers.
- Click on **OK**.

For more information about HTML rules, see [Creating valid HTML](#) in the online help .

Previewing your document

You can preview your document in a Web browser to see what the final product will look like.

To preview a document:

- Select **Page Preview** from the **View** menu or select the Page Preview button, the rightmost button in the  group in the lower left corner of the HoTMetal PRO window.

Or:

- Click on the toolbar button containing the icon for your Web browser.

If your document has not been saved, you will be prompted to save and preview the document, save a temporary file and preview it, or cancel the operation.

If no browser has been chosen, or you wish to choose a new browser:

- Click on a blank toolbar button.

The **Choose Browser** dialog box appears.

- Select the path and filename for your browser and click on **Open**.

You can also preview a document, and add or delete a browser, by choosing **Preview in Browser...** from the **File** menu, or pressing **Ctrl+M**.

Note: If you are previewing the document through a server such as HoTMetal Personal Server, you may need to configure HoTMetal PRO to submit the document's URL in a different form. This is done through the 'Server' Options tab.

Closing the document

To close a document:

- Choose **Close** from the **File** menu, or **Close All Files** from the **File** menu if multiple documents are open. If any changes have been made to the document since the last time it was saved, you will be prompted to save the changes before closing the file.

Exiting HoTMetaL PRO

To exit HoTMetaL PRO:

- Choose **Exit** from the **File** menu. The application will close. If any open files have been changed since the last time they were saved, you will be prompted to save them before exiting.

Printing documents

You can print the HTML Source view of a document directly from HoTMetaL PRO, or you can print the document from a browser.

To print from HoTMetaL PRO:

- Switch to **HTML Source** view.
- Choose **Print...** from the **File** menu.

To print from a browser:

- Choose **Page Preview** from the **View** menu and choose **Print** from the pop-up menu.

Alternatively, you can launch an external browser and print from that application.

Setting HoTMetaL PRO options

To set HoTMetaL PRO options:

- Choose **Options...** from the HoTMetaL PRO **Tools** menu.

This displays a dialog box with eight tabbed sections. You can set the following kinds of options:

- General options
- Options that configure the document window (View)
- Source View for HTML source view options
- Source Layout in HTML Source view and Tags options
- Helper Applications
- Default template, and file saving (File)
- File opening and saving options
- Spelling dictionaries
- Publish options
- Server options

[More on this topic](#)

General options

To set HoTMetaL PRO general options:

- Choose **Options...** from the **Tools** menu.
- Click on the **General** tab.

This dialog box has several sections:

- Enter user information: author name and organization.
- Set the level of HoTMetaL PRO accessibility prompting: this feature helps you create documents that are readable by the widest possible audience, including users with physical impairments.
- Add a menu item for the Visual Dynamic Keyboard (VDK) (not provided with the Evaluation Version) an on-screen keyboard for users with mobility impairments, and position the VDK on the screen.
- Specify the format for server-side image mapping files: this should correspond to the server type that your documents will reside on (you may need to obtain this information from your ISP or system administrator).
- Miscellaneous options:
 - Show Tag tips (hover over a tag in Tags On view to see the set attributes).
 - Restore last open project.
 - Restore last open documents.
 - Map Microsoft Office 97 documents (whether the site management views will map links within Office 97 documents).
 - Rules checking always off (rules checking ensures correct HTML markup).
 - Show icons in menus.

To apply any changes made:

- Click on the **Apply** or **OK** button.
- Close the window by clicking on **OK**.

View options

To set HoTMetaL PRO viewing options:

- Choose **Options...** from the **Tools** menu.
- Click on the **View** tab.

The following options can be set:

- **Show background images:** enable or disable the display of background images.
- **Show inline images:** show or hide images (IMG elements).
- **Show comments:** show or hide HTML comments in the Tags On view. Comments are not displayed in the WYSIWYG view.
- **Open new documents in:** choose which view documents that you create or open will be opened in: HTML Source, Tags On (the default), or WYSIWYG view.
- **Show head element:** show or hide the contents of the HEAD element (document title, meta-information, etc.) in the Tags On view. The HEAD element is not displayed in the WYSIWYG view.
- **Size text to window:** if you turn on this option, wrapped lines will adjust their length to fit the document window if the window is resized. If this option is turned off, wrapped lines will take their length from the global margins. **Size text to window** will cause a lot of reformatting, which may be slow for large documents.
- **Web View smooth scroll:** if you turn on this option, your documents will scroll more smoothly in the Page Preview view.

The **Tag Icons** options let you change the appearance of tags:

- **Font** - changes the font of the tag text. Choose a font from the drop-down list.
- **Size** - changes the size of the tag text. Choose a size from the drop-down list.
- **Foreground** - changes the color of the tag text. Click on the button to choose a color.
- **Background** - changes the color of the tag background. Click on the button to choose a color.

To apply any changes made:

- Click on the **Apply** or **OK** button.
- Close the window by clicking on **OK**.

Source View options

You can change several display properties for the HTML Source view: fonts, colors, word wrapping, how tab characters are used, and line numbering. To set these properties:

- Choose **Options...** from the **Tools** menu.
- Click on the **Source View** tab in the **Options** dialog box.

(These options do not change the contents of the document, but rather how it is displayed in HTML Source view. To configure how the text and markup are laid out, click on the [Source Layout](#) tab.)

Fonts and colors

You can change the font and font size used in HTML Source view, and the colors used to display the following document components:

- Ordinary text (non-markup)
- Start-tags (including attribute names)
- End-tags
- Attributes (that is, attribute values)
- Scripts (the contents of SCRIPT elements)
- Comments
- The DOCTYPE Declaration (located at the top of the document in HTML Source view).

These settings do not affect the way your document is displayed in a browser.

Set any of the following font options, which will apply to the entire HTML Source view:

- **Font** – changes the font. Choose a font from the drop-down list.
- **Size** – changes the font size. Choose a size from the drop-down list.

To change the colors used for ordinary text, set any of these options:

- **Foreground** – changes the text color. Click on the button to select a color.
- **Background** – changes the HTML Source view background color. Click on the button to select a color.

To change the colors of various components of the HTML markup:

- Make sure **HTML Colors** is turned on.
- Click on the buttons for any of the document components and choose a color.

To change the colors of various components of scripts embedded in the document via SCRIPT elements:

- Make sure **Script Colors** is turned on.
- Click on the buttons for any of the script components and choose a color.

Word wrapping

You can change word wrap options. This refers to how lines are displayed in the HTML Source window if they are longer than the current width of the window. The options are:

- **Off** – turns word wrap off, so that the lines extend past the right edge of the window.
- **Break within words** – long lines wrap onto the next line, and can be broken within words.
- **Break between words** – long lines wrap onto the next line, and can be broken only between words. If you choose this option you can also choose to allow or disable line breaking inside tags.

If a line wraps, it does not cause the line number in HTML source view to increase.

Tab options

The **Tab** option lets you choose how tab characters will be treated in HTML Source view. Note that (except in PRE elements) a sequence of one or more tab or space characters will be collapsed to a single space if you switch to Tags On or WYSIWYG view and save the file; this is consistent with the rendering of 'white space' characters by most HTML browsers.

- Enter a **Size** value between 1 and 16 to specify the number of characters between tab positions in HTML Source view.
- By default, pressing **Tab** will cause HoTMetal PRO to enter one or more characters to move the insertion point to the next tab position. You can turn on **Use tab character** to cause a tab character to be inserted instead.

- If **Auto-indent** is turned on, new lines created by pressing **Enter** will be automatically indented at the same level as the previous line.

Line numbering

Line numbering enables you to hide or show line numbering in the HTML Source window.

HTML Source view layout options

HoTMetal PRO uses indentation and line breaking to display HTML source in a way that helps users distinguish content and various kinds of markup. While the default settings should make it easier for you to work with source code (in comparison to a text editor), you may want to adjust the settings to make certain elements stand out. These settings also determine how the file is saved.

To change the HTML Source view layout:

- Choose **Options...** from the **Tools** menu. The **Options** dialog box appears.
- Click on the **Source Layout** tab.

Any options you choose are applied to files saved from Tags On and WYSIWYG views. If you turn on the **Enable automatic layout** checkbox, these options will also be applied when you switch from Tags On or WYSIWYG view to HTML Source view.

Files are saved from HTML Source view 'as-is'. To force layout options to be applied to HTML Source view, turn on **Enable automatic layout**, switch to Tags on or WYSIWYG view, and then switch back to HTML Source view. If you do not want automatic layout options to be applied to your files, turn off automatic layout, and do not save your files in Tags On or WYSIWYG view; from the **View** tab, you can also make HTML source view the default view in which files are opened and created.

Line endings

End of Line sets the line ending options. The options are:

- Each line ends with carriage return (CR) and line feed (LF), as in Windows.
- Each line ends with line feed (LF) only, as in UNIX.
- Each line ends with carriage return (CR) only, as in Macintosh.

Pretty-printing

You can also affect how specific types of elements will be laid out; this is sometimes referred to as **pretty-printing**.

- Choose an **Indent size**: this is the number of characters that the contents of an element will be indented if indent contents (see below) is turned on for that element.
- You can choose layout options for one or more elements (you don't have to click on Apply for each element—choose options for as many elements as you need to and then click on **Apply**).
 - Select the element from the **Elements** list (!- - stands for HTML comments).
 - Turn on **Indent contents** if you want the contents of the element to be indented. This option is commonly chosen for list elements such as OL and UL.
 - You can add a blank line or new line (line break) before or after the start-tags or end-tags.

To restore the Source Layout options to the default options:

- Click on **Restore Defaults**.
- Close the window by clicking on **OK**.

Helper application options

You can change the default editor and viewer for a particular image type. These applications will be launched instead of the default application when you right-click on an image file of a particular type in HoTMetaL PRO, and choose **Edit Image File** or **View Image File** from the pop-up menu.

- Choose **Options...** from the **Tools** menu.
- Click on the **Helper Apps** tab.
- Enter the file extension for the image type in the **File Extension** text box. If files of that type could have more than one extension (for example, **.jpg** and **.jpeg**), you will have to make a separate entry for each.
- Click on **Add New Type**.
- You can choose an editor, viewer, or both. Enter the locations and file names of of the desired applications in the **Viewer** and **Editor** text boxes (you can use the **Choose...** button to select them).
- Click on **OK**.

To apply any changes made:

- Click on the **Apply** or **OK** button.
- Close the window by clicking on **OK**.

File options

To set file options:

- Choose **Options...** from the **Tools** menu.
- Click on the **File** tab.

You can choose a file that will be used as the default document template when you create a new file by clicking on the  toolbar button.

You can enter the default extension that will be used when files are saved without an extension.

You can cause HoTMetaL PRO to create a backup file when you save a file, and choose the backup file extension.

You can cause HoTMetaL PRO to save the current document automatically after a certain number of changes have been made, or after a certain number of minutes have elapsed. You can ask to be prompted before each auto-save.

To apply any changes made:

- Click on the **Apply** or **OK** button.
- Close the window by clicking on **OK**.

Spelling options

Spell checking is available in the full version of HoTMetaL PRO 5.0, but not in the Evaluation version you are now using. Choose 'How To Purchase' in the Help menu for ordering information.

To set spelling options:

- Choose **Options...** from the **Tools** menu.
- Click on the **Spelling** tab.

You can specify up to 24 **supplementary dictionaries**, or lexicons, of specialized terminology for your specific field. Unlike user dictionaries, supplementary dictionaries cannot be modified during a spell checking session. Supplementary dictionaries are created and edited using **Edit Dictionary**, like other dictionaries.

To choose supplementary dictionaries:

- For each dictionary that you wish to add, click on the **Add** button and select the file.

You can add your own list of words to a personal user dictionary. This is a way to avoid having the spell checker stop repeatedly for proper nouns and jargon that you use regularly.

You can load a different dictionary during a HoTMetaL PRO session, but only one user dictionary can be loaded at a time. The default user dictionary is the file **user.dct**, located in the **libspell** folder in the HoTMetaL PRO folder.

To select a default user dictionary:

- Click on **Choose...** to select a user dictionary.

To apply any changes made:

- Click on the **Apply** or **OK** button.
- Close the window by clicking on **OK**.

Publish options

The **Publish** options enable you to [configure a proxy server](#) for [publishing](#) with HoTMetal PRO, and choose [filtering](#) options.

The **Proxy Server** options include:

- **Automatic** – use the proxy settings set in the **Internet** control panel.
- **Manual** – use the **IP Address** and **Port** specified in this dialog box.
- **None** – don't use a proxy server.

Exceptions enables you to contact some addresses directly (without going through the proxy server) even if you are using a proxy server. **Bypass list from registry** uses a list of addresses from the **Internet** control panel; **Local intranet addresses** causes all one-word addresses to be contacted directly.

Note: Setting proxy options in Microsoft Internet Explorer is the same as setting them from the Internet control panel.

Filter options allow you to filter out specific files when publishing a project. The filter options include:

- Exclude [orphan files](#)
- Exclude if up-to-date
- Exclude by matching filename. Enter the specific file names you wish to exclude. Wildcard characters (for example, *.txt and **project1.*** can be used).

To apply any changes:

- Click on the **Apply** or **OK** button.
- Close the window by clicking on **OK**.

For more information about site management options, see [Managing your Website](#) and [Maintaining your Website](#).

Server options

By default, when you preview a document from HoTMetal PRO, it submits a URL starting with **file:///**, followed by your drive name (for example, 'c:') to the browser. If your file is being preprocessed by another server, such as HoTMetal Personal Server, that requires that URLs start with **http://**, you can use the **Server** options tab to change the URL that HoTMetal PRO submits. In effect, this causes HoTMetal PRO to do a find and replace operation, substituting part of the **file:///** URL with a **http://** URL.

If you are using HoTMetal Personal Server, you need to set these options only if the defaults are not working for you. The default **Server URL** used with HoTMetal Personal Server is **http://127.0.0.1/**; if, when you attempt to preview, your browser cannot find this URL, the reason is probably that your site is using a proxy server. In this case you should enter **127.0.0.1** in your browser's **Do not use proxy server** list. This is done in the browser's proxy configuration' dialog. This dialog is accessed in different ways, depending on your browser:

- In Netscape Communicator/Navigator 4.0, choose **Preferences** from the **Edit** menu; click on the **Advanced** category, then on **Proxies**; then click on the **View...** button next to **Manual Proxy Configuration**.
- In Netscape Navigator 3.0, choose **Network Preferences** from the **Options** menu; click on the **Proxies** tab; then click on the **View...** button next to **Manual Proxy Configuration**.
- In Microsoft Internet Explorer 4.0, choose **Internet Options** from the **View** menu; click on the **Connection** tab; then click on the **Advanced...** button in the **Proxy Server** section.

Once you have displayed this dialog, enter 127.0.0.1 in the list (if there is more than one entry in the list, use whichever separator the browser requires) and click on **OK**.

To set server options from in HoTMetal PRO:

- Choose **Options...** from the **Tools** menu.

If you want to choose a different server URL (for example, if your PC is on a local network and you want to refer to the server with your PC's own IP address):

- Enter the server URL in the **Server URL** text box.

If you want to change the list of file extensions for which HoTMetal PRO will make this substitution:

- Click on the **Server** tab.
- Turn on the **Enable Mapping** check box.
- In the **Map Extensions** text box, enter the file extensions, separated by semi-colons (;), of the kinds of files for which you want the URLs changed.

If for some reason you need to specify both the 'find' and 'replace' parts of the substitution (normally this shouldn't be necessary):

- Turn on the **Override server mappings** check box.
- In the **Map from** text box, enter the part of the URL that needs to be changed. In the case of HoTMetal Personal Server, enter your documents folder, as displayed in the **WWW** tab of the HoTMetal Personal Server properties dialog.
- In the **Map site** text box, enter the replacement text. For HoTMetal Personal Server, enter URL used to access HoTMetal Personal Server on your PC, as displayed in the **Status** tab of the HoTMetal Personal Server properties dialog.

To apply any changes made:

- Click on the **Apply** or **OK** button.
- Close the window by clicking on **OK**.

Inserting links

What's covered in this chapter

Links are key features of HTML pages because they enable you to link other documents to your pages and insert graphics and multi-media files. A URL (Uniform Resource Locator) is the part of a link that gives the location of the file that the link points to (and possibly a specific place in that file).

Some things that you can do with links are:

- Create a link to another page .
- Insert an image in your page .
- Create a link to a specific location in a page (bookmark).
- Create a link to an e-mail address .
- Create a link to a file on your local system
- Drag and drop a link from another application

This section also has background material on different kinds of URLs.

Reference

HoTMetaL PRO makes it easy to create and edit links. There are several ways to do this:

- You can create a hypertext link to a file, using the **Link...** command in the **Insert** menu. With this command, you can link to files on your system or to remote files.
- You can insert an image using the **Image...** command in the **Insert** menu.

Dragging and dropping links

- You can make a link to a document or image on your system by dragging and dropping its icon from Windows Explorer or the Desktop into the HoTMetaL PRO document window.

By default, dragging and dropping will create a relative URL if the document that you are working on has been saved at least once (that is, it has an actual filename), and will create an absolute (file:///) URL if the file you are working on has never been saved. The first time you save a file, any file:/// URLs can be converted to absolute URLs.

You can configure HoTMetaL PRO to always create absolute URLs when you drag and drop a file.

- You can copy a link from a file being displayed in a browser by dragging and dropping the link into the HoTMetaL PRO document window.

If you drag a hypertext link, HoTMetaL PRO will create a link whose URL is the same as the URL of the link in the browser, and whose default text is the same as the text of the URL.

From Netscape Navigator, you can also drag the 'Quick Link' icon (just to the left of the URL in the Navigator window) into the HoTMetaL PRO document window. This creates a link to the page currently being displayed in the browser.

You can drag **images** from Microsoft Internet Explorer into the HoTMetaL PRO document window. This creates a link to a copy of the image in the **Temporary Internet Files** folder, which is contained in the **Windows** folder. You will probably find it more useful to copy the image from that folder into one of your working folders, and modify the link accordingly.

- If you paste or drag and drop some text that starts with 'http:/' from another application into the HoTMetaL PRO document window, it will automatically be converted into a link.

More on this topic

Inserting hypertext links

A hypertext link is one in which the user clicks on some text or an image and the browser responds by displaying another document, location (bookmark), or image. To insert this kind of link (sometimes called an anchor):

- Enter the text or image that will represent the the link. If you don't highlight some text or image before you create the link, the URL will be used as the default link text; you can later change this text if you wish.
- Highlight that text or image.
- Do one of:
 - Click on the  toolbar button.
 - Press **Ctrl+K**.
 - Choose **Link...** from the **Insert** menu.

The **Insert Link** dialog box appears: in this dialog, you can enter a URL specifying a file, a bookmark in a file, or both. You can also indicate which frame (in a frames document) that you want the document to be displayed in. (Inserting a link creates an 'A' (anchor) element in your document.)

Linking to a file

To specify a file:

- Enter the file's URL in the **File or URL** text box. You can enter any kind of URL here: an absolute or relative URL to a file on the WWW or on your local system.

You can choose a file on your local system by clicking on **Choose File...** By default, this will create a relative URL if your document has been saved at least once; if your document has never been saved an absolute URL to the location on your system will be created.

You can configure HoTMetaL PRO to always create absolute URLs when you choose a file on yoursystem.

When you have entered the URL, you can, if you wish, add it to the HoTMetaL PRO hotlist by clicking on **Add to Hotlist...** You can choose a URL from your HoTMetaL PRO hotlist by clicking on **Hotlist...**

Linking to a bookmark

If you want the link to point to a bookmark (a specific location in the document that you're linking to):

- Enter the bookmark at the end of the URL you entered in the **File or URL** text box, separated from it by a '#' character. If you didn't specify a file, the bookmark will be the only thing in the text box.

Here are two examples of URLs with bookmarks:

```
http://www.softquad.com/authors.htm#orwell  
#madrid
```

The HoTMetaL PRO **Insert** menu also has the commands **Bookmark...** and **Link to Bookmark...** for creating and linking to bookmarks.

Linking to a frame

If you want the file that you're linking to to be displayed in a particular frame in a frame document when the user clicks on the link:

- Enter the frame name in the **Target Frame** text box.

If a frame of that name is not being displayed by the browser when the link is clicked on, the linked document will be displayed in the same frame as the current document.

[More on this topic](#)

Creating a link to a file in your project

Links to files in your projects, which will eventually be moved to a server, can be either relative or absolute. You should choose whichever type suits your project and style of working.

In general, you should use relative links, especially if one or more of the following are true:

- You know what the folder structure of your site will be.
- You've created a mock-up on your local system of what the site will look like when it's moved to the server.
- Most of the structural changes will be 'incremental'—they will add to the current structure rather than rearranging it.

A disadvantage to using absolute links while you're developing your site is that it's difficult to preview your work in a browser until the links work. If you wish to use relative links while you're developing your pages but change them to absolute links before moving the pages to your server, you can use the **Find and Replace URLs...** command in the **Edit** menu to change all the links at once, or change them at publish time using the **Publish...** command's URL Changes functionality.

To create a link:

- Enter the text or image that will represent the the link.
- Highlight that text or image.
- Do one of:
 - Click on the  toolbar button.
 - Press **Ctrl+K**.
 - Choose **Link...** from the **Insert** menu.
- Enter the URL in the **File or URL** text box.

Creating a link to a file on another Web site

The URL for a document at another site has to be an absolute URL: it must contain a scheme (**http, ftp, etc.**) and site address, followed by folders, a filename, and a bookmark if necessary.

- Enter the text or image that will represent the link.
- Highlight that text or image.
- Do one of:
 - Click on the  toolbar button.
 - Press **Ctrl+K**.
 - Choose **Link...** from the **Insert** menu.
- Enter the URL in the **File or URL** text box.

Creating a link to a file on your local system

You can create a URL that refers explicitly to a location on your local network, hard disk, CD, or floppy drive. For example:

```
file:///c:/data/orwell/homage.htm
```

This kind of URL is useful only in certain circumstances: if you have to make a link to a file on another drive on your network, or if you don't intend to publish your pages to a server. If you do intend to publish your files, it's best to use either relative URLs or **http**-style absolute URLs.

- Enter the text or image that will represent the link.
- Highlight that text or image.
- Do one of:
 - Click on the  toolbar button.
 - Press **Ctrl+K**.
 - Choose **Link...** from the **Insert** menu.
- Enter the URL in the **File or URL** text box. The URL has the following structure:
 - 1 The **file** scheme, followed by the characters **:///**.
 - 2 The drive name: replace the **:** in the drive name with a vertical bar, for example, **'c|'** instead of **'c:'**,
 - 3 The path/filename. You should separate the files and folders with forward slashes, **'/'**.
 - 4 A bookmark, if desired.

You can also choose a file by clicking on the **Choose...** button. By default, however, this will create a relative URL if the current file has been saved at least once; if you would like HoTMetaL PRO to always create absolute URLs when you choose a file:

- Edit the file **hmpro5.ini**, in the HoTMetaL PRO folder, with a text editor such as Notepad.
- Add the line:

```
urls_default_to_relative=false
```

If a setting for **urls_default_to_relative** is already present, change **true** to **false**.

- Restart HoTMetaL PRO.

Now you can use **Choose File...** to create **file:///** URLs.

See the section [Changing your URLs for the Web](#) for information on how to convert 'local' URLs to URLs for the Web.

Inserting images

To insert an image using the toolbars or menu commands:

- Place the insertion point at the location where you want the image to appear in the document.
- Click on the  (**Insert Image**) toolbar button or choose **Image...** from the **Insert** menu.

The **Image Properties** dialog box appears.

- Enter the URL for the image in the **Image File** text box, or click on **Choose...** to browse for the image file.

You can view the selected image file in the preview window of the **Choose Image File** dialog.

You can also specify the [image properties](#).

Using the URL hotlist

HoTMetal PRO lets you maintain a hotlist of frequently used URLs. When you need to insert one of these URLs, you can just pick it from the list instead of having to enter the information over again.

To add the current URL to the hotlist:

- Do one of:
 - Click on the  toolbar button.
- Press **Ctrl+K**.
- Choose **Link...** from the **Insert** menu.
- Enter the URL in the **File or URL** text box.
- Click on **Add to Hotlist...**

You'll then get a dialog box that displays the URL and lets you enter a description. This description is how the URL will be displayed in the hotlist dialog box.

- Enter the description. If you leave the description blank, the URL itself will be used as the description.
- Click on **OK**.

To pick a URL from the hotlist:

- Click on **Hotlist...** in the **Insert Link** dialog box.
- A dialog box will appear, displaying the description of each URL in the hotlist.
- Double-click on the URL you want. Alternatively, you can select a URL and click on **OK**.

To delete a URL from the hotlist:

- Click on **Hotlist...** in the **Insert Link** dialog box.
- Select the URL that you want to remove.
- Click on **Delete from Hotlist**.

To append a Mosaic hotlist or Netscape Navigator bookmarks file to the HoTMetal PRO hotlist:

- Click on **Hotlist...** in the **Insert Link** dialog box.
- Click on **Append Hotlist...** in the dialog box that appears.
- Choose the hotlist or bookmark file that you want to append.
- Click on **OK**.

Pointing to a specific location (bookmark)

Links can point not only to a document but also to a specific location (bookmark) in the document.

To set up this type of link you have to do two things:

- 1 Create the bookmark, using the **Bookmark...** command in the **Insert** menu.
- 2 Create a link to the bookmark, using the **Link to Bookmark...** command in the **Insert** menu.

Creating a bookmark

To create a bookmark:

- Highlight some text at the location you want to link to. (Highlighting text is not mandatory, but some browsers will not be able to jump to the bookmark unless it contains some text.)
- Click on the  button in the **Quick Tools** toolbar, choose **Bookmark...** from the **Insert** menu, or press **Ctrl+G**.
- Enter a bookmark name of your choice in the dialog box that appears. Bookmark names typically consist of one word, but you can enter more. You should not use the same bookmark name twice in the same document.
- Click on **OK**.

Creating a link to a bookmark

To create a link to a bookmark in an open document:

- Highlight the text of the link.
- Click on the  button in the **Quick Tools** toolbar or choose **Link to Bookmark...** from the **Insert** menu.
- Choose the file containing the bookmark from the list of open files. The **Bookmarks in file** list will display all of the bookmarks in the file you chose.
- Click on a bookmark in the list.
- Click on **OK**.

To create a link to a bookmark in a document that isn't open:

- Do one of:
 - Click on the  toolbar button.
 - Press **Ctrl+K**.
 - Choose **Link...** from the **Insert** menu.
- In the **File or URL** text box, enter the URL for the document you want to link to.
- Enter the bookmark name at the end of the URL you entered in the **File or URL** text box, separated from it by a '#' character.

Here are two examples of URLs with bookmarks:

```
http://www.softquad.com/authors.htm#orwell  
#madrid
```

Linking to an e-mail address

You can create a link to an e-mail address so that:

- A user can click on a link in a browser and open an e-mail editing window.
- An online form can be mailed to an e-mail address.

The URL for this kind of link consists of the **mailto** scheme followed by a colon, ':', and then the e-mail address. For example:

```
mailto:charles@windsor.org
```

To create a link that brings up an e-mail editing window:

- If you've already entered the text or image that represents the link, highlight it.
- Do one of:
 - Click on the  toolbar button.
 - Press **Ctrl+K**.
 - Choose **Link...** from the **Insert** menu.
- Enter the URL in the **File or URL** text box.

Note: Some browsers can read a 'subject line' from the URL. For example, 'mailto:charles@windsor.org?subject=Hi there' would generate a subject line of 'Hi there'.

Some browsers do not support **mailto** but will at least display the e-mail address. Also, in order for this feature to work if your system is behind a firewall, you may need to configure your browser to use the correct proxy server. See your system administrator or browser documentation if this is the case.

Updating links when you save a file

If a document contains relative links, and you save it to a different folder, some relative links may become broken.

To help you avoid this, the **Save As** dialog has three options for what to do with relative links:

- **Update URLs** – any relative URLs in the document will be updated so that they still point to the same linked files, even though the current document is in a new location.
- **Copy Items** – instead of changing the URLs, HoTMetal PRO will copy the files that those URLs point to so that they are in the same locations relative to the new location of the current document. This option works only for first-level files, that is, linked files that are in the same folder as the current document.
- **No Change** – performs a normal **Save As**. Relative URLs may become broken. **No Change** is the default option.

If you are saving a file for the first time, and you choose **Update URLs** or **Copy Items**, any **file:///** URLs in the document will be converted to relative URLs, provided that the linked files and the current file are on the same disk partition (both on the C: drive, for example).

Displaying links in the document window

In Tags On view, you can quickly see which URL a link points to by moving the mouse cursor over the start- or end-tag of the link element, and then reading the tag tip. This shows all attributes that have a value. Some common attributes that contain URLs are the HREF attribute of A, the SRC attribute of IMG, and the HREF attribute of LINK. A tag tip will also appear over an image in WYSIWYG view.

Understanding URLs

This section gives you some of the background information for understanding URLs. If you are already familiar with this subject, you can skip over it.

The parts of a URL

A URL can have the following parts:

- A **scheme** that specifies how the browser should retrieve the file. Some common schemes are:
 - **http**: indicates an address on a Web server.
 - **mailto**: indicates that the URL specifies a mail address
 - **file**: indicates a file on a local filesystem.
 - **ftp**: indicates an address on an **ftp** server.
 - **gopher**: indicates an address on a **gopher** server.
- A **site address** (for example, **www.softquad.com**) that specifies which site (server) the file is located on.
- The site address can be followed by a 'port number', for example: '**www.sq.com:8888**'. A port number is required if the Web server is not running on the default port (that is, 80). This normally occurs only if the site has more than one server running on it, so most likely you do not need to specify a port number.
- A **path**, a sequence of folders, usually ending with a **filename**. This specifies the file to be retrieved.
- A **bookmark**, that is, a reference to a specific location in the document that the URL is pointing to.
- A **query**. If the URL points to a program instead of a document, you can attach a query string that specifies some information that the browser will send to the program.

Putting it all together

These components have to be arranged in a way that a Web browser will understand:

- The scheme is separated from the site address by the characters '://'.
- The site address, folder names, and file name are separated by forward slashes, '/'.
- If the URL contains a bookmark, it's separated from the rest of the URL by a '#' character.
- If the URL contains a query, it's separated from the rest of the URL by a question mark, '?'.

Here are some examples:

```
http://www.softquad.com/  
http://www.softquad.com/whatsnew.htm  
http://www.softquad.com/authors/orwell.htm#school
```

What kind of URL should I use?

Most components of a URL are optional: for example, you can create relative URLs that omit the scheme and site address. The kind of URL you use generally depends on where the document that you're linking to is located: on your own site or project, on another site, or on your hard disk or local network.

Mocking up your site

You'll find it easier to keep track of your links if, on your local disk, you create a mock-up of the files that you intend to publish to your Web or intranet server. If you do this, the links you create now will be less likely to break when you move your files to the server. It will also be much easier to move the files to the server using the HoTMetal PRO publishing function.

[More on this topic](#)

Relative and absolute URLs

URLs can be divided into two groups: **absolute** URLs and **relative** URLs.

Absolute URLs

An absolute URL is one that contains at least a scheme (such as **http**) and a site address (such as **www.softquad.com**). It can contain other components too, such as the folder path and filename, but it must have the scheme and site address in order to be an absolute URL.

The filename can be omitted from an absolute URL. In this case the URL implicitly refers to the file **index.html** on the server or folder that is specified in the URL. The URL **http://www.softquad.com/press** means 'the file **index.html** in the folder **press** on the **www.softquad.com** server'. The URL for a site's home page often omits the path and filename: for example, **http://www.softquad.com/** is the URL for SoftQuad's home page.

Relative URLs

A relative URL is one that doesn't have a scheme and site address; other components may be absent too. In this case the browser has to supply the absent information in order to know where to look for the file that the URL is pointing to. Normally the browser gets the absent information from the URL of the document that contains the relative URL.

For example, suppose the document **http://www.sq.com/doc/tutorial.htm** contains a link to **authors/orwell.htm**. This URL contains a path and filename, but no server location. In this case, the browser will search for the document on the same server and folder as **tutorial.htm**.

If you are linking to a file in the same project it's usually better to use a relative URL, for the following reasons:

- If you move all the files to a different location (for example, when you publish them to a web server) but keep the same folder hierarchy, you don't have to revise the URLs.
- Less typing is required to enter them.
- The same file referred to by a relative URL can be accessed by different schemes (for example, both **http** and **ftp**).

Configuring HoTMetaL to create absolute URLs

As long as the current document has been saved at least once, HoTMetaL PRO creates relative URLs by default when you create a link by dragging and dropping, or with the **Choose...** button in the **Insert Link** dialog box.

If you would like HoTMetaL PRO to always create absolute URLs in these situations:

- Edit the file **hmpro5.ini**, in the HoTMetaL PRO folder, with a text editor such as Notepad.
- Add the line:

```
urls_default_to_relative=false
```

If a setting for **urls_default_to_relative** is already present, change **true** to **false**.

- Restart HoTMetaL PRO.

Understanding relative URLs

When the browser fills in the absent information in a relative URL, it usually gets this information from the URL of the document that contains the relative URL (this URL is called the **base** URL). The only exception to this is when the document contains an element called **BASE**, which specifies the base URL explicitly.

A relative URL can start with one of the following:

- A file or folder name.
- A single slash: '/'.
- A double dot '..'.
- A dot '.'.
- A double-slash: '//'.

URLs that start with a folder or file

If the relative URL starts with a folder or filename, then the browser will look for the folder or file in the same folder as the current document. For example, suppose the relative URL is:

```
madrid.htm
```

The browser will look for the file **madrid.htm** in the same folder as the current file.

If the relative URL is:

```
orwell/homage.htm
```

then the browser will look for the file **homage.htm** in a folder called **orwell** that is in the same folder as the current file.

URLs that start with a slash

If the relative URL starts with a single forward slash, '/', then the scheme and the site address are absent. Both of these will be inherited from the current document (that is, the browser will look for the specified folder and file at the top level of the server). For example, suppose the current document is located at:

```
http://www.softquad.com/authors/contents.htm
```

and it contains the relative URL:

```
/images/orwell.gif
```

The browser adds the scheme and site address to the beginning of the relative URL to get:

```
http://www.softquad.com/images/orwell.gif
```

URLs that start with '..'

The characters '..' at the beginning of a relative URL mean 'go up one folder level'. This kind of URL is interpreted the same as one that starts with a file or folder, except that the browser starts looking one level up from the current file. For example, suppose the current document is located at:

```
http://www.softquad.com/authors/english/index.htm
```

and it contains the URL:

```
../french/voltaire.htm
```

Instead of looking for the folder **french** in the current folder (**english**), the browser looks one level up, to the folder **authors**; then it looks for the folder **french**, and then for the file **voltaire.htm**. In this context, the relative URL is equivalent to:

```
http://www.softquad.com/authors/french/voltaire.htm
```

There are a couple of less common cases:

- If the relative URL starts with '//', then the only thing absent is the scheme (**http**, etc.). In this case the browser uses the same scheme as it did for the current document..
- The characters './' at the start of a relative URL means 'the current folder'. When the browser is interpreting a relative URL, the characters './' will simply be removed.

Managing your Website

What you'll learn in this chapter

This chapter introduces **site management** in HoTMetaL PRO. In this chapter, you will learn how to do the following:

- [View the files and folders in your project](#).
- [View your project as it would appear on the WWW](#).
- [View all links into and out of a particular file](#)
- [Set options for your displays](#).
- [Move, copy, delete, and rename files and folders](#).
- [Launch Web browsers from HoTMetaL Pro](#).
- [Create a new project](#) , [open an existing project](#) , and [add files to projects](#) .
- [Create new links between files by dragging and dropping](#) , and [preserve links when you move, copy, delete, and rename files](#) .
- [Change links for publishing](#) .
- [Publish your files](#) : [choose the server](#) , [choose which files to publish](#) , and [finish the publish operation](#) .

Reference

HoTMetaL PRO provides site management functions that manage files and links between files. A collection of files is called a **project**. **Site management** refers to operations that HoTMetaL PRO performs to help you keep track of, edit, and manipulate files and links in a project. HoTMetaL PRO uses four windows to display the results of site management operations. These windows are displayed via commands in the **View** menu, and are explained later on in the chapter.

You can carry out the following site management functions:

- Move and rename files, and have the links to the files automatically updated to reflect the new names and locations of the files.
- Examine your project in different ways to see how it is put together: view your project's links or the actual structure of its files and folders.
- Add new files to your project, or create whole new projects.
- Copy your files quickly and easily to a different computer (server) where they can be seen on the World Wide Web. (This is called **publishing**.)
- Manage your files by keeping track of what you have put on the WWW so that you can replace out-of-date files quickly and easily.

For more details on performing site-wide find and replace operations, see [Managing your Website](#) .

[More on this topic](#)

Displaying your project

The main purpose of site management is to display and manage your project. To understand how the site management functions let you do that, let's take a look at the different site management windows.

The results of site management operations are displayed in four separate windows; none of the windows are available if no project has been loaded.

- The [Project tab](#) in the Resource Manager displays the files and folders in your project.
- The [Web View](#) window indicates the validity of links in your document, displays the shape of your project, and helps show you the route that users will follow when they access your information.
- The [Page Links](#) window shows a quick summary of all of the links going into and coming from a particular file.
- The [Pocket View](#) window shows user-selected groups of files.

Note: The different view windows can be docked, undocked, and moved around the screen.

The site management windows show the same project in different ways: you can see files, links, or selected files depending on whether you are looking at the Project tab, the Web View window, Page Links window, or Pocket View window. As well, when you click on a particular file in any window, the file will also be selected in the other windows. For example, if you select a file in the Pocket View window, the file will also be selected in the Web View window if it is visible, and the Web View will rotate to show the selected file.

You can open or close one or more views by selecting or de-selecting the desired views from the **View** menu. You can have one or more different views open at once. To close an open view, click on the view's  button.

You can resize the windows by moving your mouse cursor over the separators between the windows. When the cursor changes to a double-headed 'size' arrow, drag the separator by clicking the mouse button and holding it down as you move the mouse.

 [More on this topic](#)

Window commands

Right-clicking on a file in any site management window brings up a pop-up menu that lets you edit or browse the file, change view window options, fix broken links, show titles, show duplicate links, change the font for the window, and display the Windows **Properties** dialog. There are other commands that are specific to the various windows and views: look in the sections on the Project tab, Pocket window, Web View window, and Page Links window for the commands that are specific to each.

Launching an editor or browser

Edit File opens the file in the HoTMetal PRO document window, the [cascading styles editor](#), or other editor registered for the file type in question.

View in Browser launches your Web browser with the selected file. (You can set which Web browser you want to launch in the **Options** dialog box. See [site management options](#).)

Changing the font

Font... lets you modify the font, font size, font style and font color used to display the text in the current window (this does not apply to the Project tab).

You can choose a font from the **Font** list. Similarly, the various styles—bold and italic—and the point sizes of the fonts can be selected from the **Font style** list or **Size** list respectively, or entered into the appropriate text box. You can choose **Effects** (strikeout and underline), or select a font color from the drop-down list. **Script** lists the language scripts available for the particular font you have selected. An example of how the chosen font and options will look is shown in the **Sample** area. To apply the current settings, click on **OK**; click on **Cancel** to close the dialog box without making any font changes.

Properties

Properties launches the Windows **Properties** dialog for the file that you have selected.

Viewing the structure of your project

There are three ways of viewing the structure of your project in HoTMetal PRO: the [Project tab](#), [Page Links view](#), and the [Web View](#).

The different views show both local and external links (links to pages on the World Wide Web). However, HoTMetal PRO does not automatically check the validity of those off-site links, nor does it show pages linked to those off-site Web pages. You can check your off-site hyperlinks by choosing **External Links...** from the **Site** menu. See [External links](#) for details.

Note: Since the **Web View** and **Page Links** windows show only files that can be reached by outward links starting at the home page, they will not show files in the project that aren't linked into the project via the home page or files linked to the home page. You can see those 'orphan' files in the **Project tab** because they do not have a chain on their file icon, and you can identify and group orphan files by choosing the command 'Orphan Files' from the **Site** menu (see [Finding Orphan Files](#) for details).

[More on this topic](#)

Viewing the file structure of your project

To see exactly what files are in your project and how they are arranged into folders, use the **Resource Manager**.

The Resource Manager is a file management system in HoTMetaL PRO that gives you access to images, cascading style sheets, scripts, dynamic HTML, and so forth. It also allows you to create and rename folders and files, choose different views, and move files into folders. For information on using the Resource Manager to put images, cascading style sheets, scripts, and dynamic HTML into your Web pages, see [Working with images](#).

To view the file structure of your project in the Resource Manager:

- Click on the  button to open the Resource Manager, if it isn't open already.
- Choose **Open...** from the **File** menu. The **Open** dialog box appears.
- Choose **Project Files (*.hpp)** from the **Files of type** pull-down list.
- Choose an **.hpp** file and click on **Open**. The project is loaded.

The **Project** () tab appears next to the **Assets** and **Desktop** tabs at the bottom of the Resource Manager window.

The top pane of the Resource Manager window is called the **Explorer pane**. It allows you to view the folders contained in your project.

The bottom pane of the Resource Manager window is called the **Contents pane**. The Contents pane displays the contents of the folder selected in the Explorer pane, and enables you to create new folders, create file filters, and display files in a number of different ways. This pane has its own toolbar:

The Resource Manager toolbar

Viewing options

There are several viewing options for the Contents pane.

To change the way files are displayed in the Resource Manager:

- Click on the  arrow in the **Resource Manager** toolbar.
- Choose **Large Icon**, **Small Icon**, **List**, **Details**, or **Thumbnail** from the pop-up menu.

Or:

- Click repeatedly on the  button to cycle through the different viewing options.

Or:

- Right-click in the Contents pane, choose **Arrange Icons**, and then choose a view from the fly-out menu.

Navigating

Click on the  icon in the **Resource Manager** toolbar to move one folder up in the folder tree.

Viewing specific files

You can select specific types of files to be viewed in the Contents pane using the **File Filter** menu. For example, if you want only **.gif** images to be displayed in the Contents pane:

- Click on the  button. The **Add New File Filter** dialog box appears.
- Type ***.gif** in the text box. The asterisk indicates that any file name with a **.gif** extension will be displayed in the Contents

pane. You can perform this operation for any particular file type. By default, all file types, (*.*), are selected for viewing in the Contents pane.

Click on the  icon to show all files in the folder.

The  icon opens a drop-down menu that lets you select file filters that have been added.

Viewing your project as it would appear on the Web

Web View

To check the validity of links in your document, get a sense of the overall shape of your project, and determine the pages that users can access when they access your information, use the Web View.

To display the Web View window, if it isn't displayed already:

- Choose **Web View** from the **View** menu or click on the  button in the **Views** toolbar.

The Web View window shows the link structure of your project as if it were sliding on the surface of a sphere. It's called the Web View because it looks like a web, and also because it most closely resembles the way that users will navigate your site when they encounter your pages on the World Wide Web.

The Web View uses a 'breadth-first' method for displaying links. This means that when displaying the links for a page, priority is given to displaying the direct links from that page, rather than displaying all the sub-links from individual pages.

To navigate around the Web View and move other files closer to or farther away from the center of the Web View, move your mouse cursor in the window until it becomes a hand (it must **not** be directly above a file). Clicking the left mouse button causes the hand to 'grip'; keeping the mouse button held down allows you to move the Web View over the surface of the sphere, moving different files into view.

Showing all links from a file

You can recalculate the Web View to show all links based on a selected file.

- Right-click on the desired file and choose **Show All Links** from the pop-up menu in the **Web View** window.

Choosing **Show All Links** shows all links that radiate out from the selected file, and not just the links that radiate outward from the home page. This is similar to the [Page Links window](#), which shows all the links both **into** and **out of** one particular file, except that **Show All Links** shows only the links going **out** of the current file (as well as the other links in the project).

[More on this topic](#)

Displaying links in the Web View

The labels for the file names and links in the Web View are displayed in different colors, which show how they are linked into the project.

The legend describing the different colors and their meaning appears at the bottom of the Web View.

You can show or hide the legend by right-clicking on the background of the Web View window and choosing **Show Legend / Hide Legend**.

The different colors of the files in the Web View indicate the different types of links in a project:

- Black – HTML file, image file, or other type of file.
- Green – Home page of the project.
- Red – Broken link.
- Blue – External (World Wide Web) link, outside the local file system or a file outside of the current project folder.
- Yellow – The currently selected file(s).

When you select any file in the Web View window, the path to that file is shown at the bottom of the window, and the corresponding file is highlighted in the Project tab.

See [Viewing options in the Web View window](#) for information on configuring the appearance of the Web View window.

Viewing options in the Web View

Right-clicking anywhere in the Web View window brings up a pop-up menu that lets you change some viewing options. (Many of the other commands in this menu also appear when you right-click in the other windows.) The following options are available:

- **Docking View** – Creates a larger viewing space. See [Docked and floating windows](#) for more information.
- [Show All Links](#) – Recalculates the links using the current file as the temporary 'home page'.
- **Full View/Minimal View** — **Full View** shows all linked files in the project; **Minimal View** shows only certain kinds of files: by default, it shows HTML, plain text, and MS Word documents.

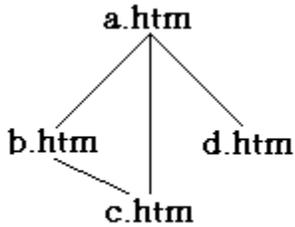

Note: The filetypes displayed in Minimal View can be configured by adding or deleting MIME-type entries in the 'Minimal Mime Types' section of the 'hmp5.ini' file.

- **Right Align** – Toggles between displaying files linked to the home page clustered at the right edge of the Web View 'sphere' and displaying them spaced around the entire sphere.
- **Display Long Text** – Toggles between full and truncated link names. Sometimes the Web View is easier to read if the link names are abbreviated.
- **Show Legend / Hide Legend** – Toggles between showing or hiding the legend at the bottom of the Web View.
- **Allow Docking** – Allows you to separate the Web View window from the HoTMetaL PRO interface as a separate floating window. You can drag the Web View window to wherever you like on your screen.
- **Hide** – Closes the Web View window. To open the window again, choose **Web View** from the **View** menu.

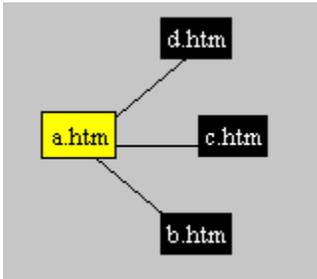

There is also a command called **Fix Broken Links...** in this menu. It is used only when there is a broken link in your project (displayed in red in the Web View). See [Fixing broken links](#) for more information.

Structure of the Web View

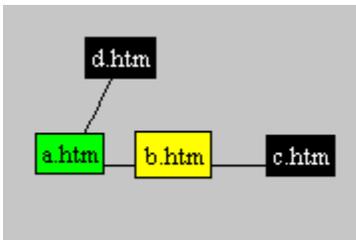

The Web View is based on a home page, and all links are shown relative to that home page, and 'outward' from the links on that home page. This means that 'sideways' links between documents are not immediately visible; only links that go outward from the home page are visible. For example:

In this diagram, there are 'outward' ('parent to child') links between file **a.htm** (the home page) and the files **b.htm**, **c.htm**, and **d.htm**. There is also a 'sideways' ('child to child') link between **b.htm** and **c.htm**. The Web View, working outwards from the home page, **a.htm**, would show the links to files **b.htm**, **c.htm**, and **d.htm**; however, it does not show the link between **b.htm** and **c.htm**:

You can recalculate the Web View to show all links based on a selected file. Choose **Show All Links** from the pop-up menu that appears when you right-click on a file in the Web View. Choosing **Show All Links** shows all links that radiate out from the selected file, and not just the links that radiate outward from the home page. If links are recalculated when the **b.htm** file is selected, the following Web View would be shown:

In this case, the links between **b.htm** and **c.htm** are shown, since the links have been recalculated based on **b.htm**.

Viewing all the links for a particular file

To get a quick summary of all the links going into and coming from a particular file, use the Page Links window.

To display the Page Links window for a particular file:

- Open the project.
- Click on the file whose links you want to see.
- Open the Page Links window by choosing **Page Links** from the **View** menu, or clicking on the  button from the **Views** toolbar.

The Page Links window lets you check all the links in one file:

- The index file or last file that you have currently selected is displayed at the **center** of the Page Links window.
- All the links leading into that file are shown on the **left** as file icons and names with arrows pointing **towards** the central file.
- All the links going out from that file are shown on the **right** as file icons and names at the end of arrows pointing **away from** the central file.

Note: Files can link to themselves: bookmarks (document-internal links) will be displayed in the Page Links window as links to a file icon for the same file.

The icons in the Page Links window give you some information about what kind of file is being represented.

-  – An HTML file on the local file system. This icon will vary depending on the program or version of the program you selected as your Web browser during installation (Internet Explorer or Netscape Navigator).
-  – An image file.
-  – A broken link.
-  – Other files, including external links, links to Usenet newsgroups, links to FTP sites, and mailto links (see [Links](#)).

For details of how to repair broken links, see [Fixing broken links](#).

To display all the links for a file that's already visible in the Page Links window:

- Double-click on that file. It becomes the central file, showing all the links into and out of that file. The file is also opened in the document window.

The **Show All Links** command in the Web View is similar to the Page Links view, but shows only the links **from** the selected file.

[More on this topic](#)

Web View and Page Links window options

By default HTML (**.htm**, **.html**, **.shtm**, and **.shtml**) files in the **Page Links** and **Web View** window are displayed using their titles (the content of their TITLE element, if there is any). Image files and other files linked to the project are displayed using their actual file names.

You can toggle between showing filenames and showing titles for HTML files by right-clicking in any view in the **Page Links** and **Web View** window and choosing **Show Filenames** or **Show Titles**. Files without TITLE elements will always be shown as file names.

Viewing file thumbnails

The Thumbnail View is useful for viewing thumbnails of HTML documents and image files (GIF, JPEG, PNG files) in your project. This is helpful when you want to see quickly what a particular file looks like.

Note: You must have Microsoft Active Desktop installed in order to use Thumbnail View. Active Desktop is available if you are running Windows 98, or if you installed Active Desktop when you installed Microsoft Internet Explorer 4.0.

To use the Thumbnail View:

- Open the **Resource Manager** by clicking on the  button or choosing **Resource Manager** from the **View** menu.
- If you want to view a project file, open the project. Project files will appear under the Project tab.
- Click on the appropriate tab and choose the file you want to view from the Contents pane.
- Choose **Thumbnail View** from the **View** menu. The file appears in the **Thumbnail View** window.

If you want to use the file as a link in your project:

- Click on the thumbnail in the **Thumbnail View** window and drag it onto the HoTMetaL PRO document window.
- Drop the file onto the area of your document that you want the link to appear in.

Note: If you have multiple windows open, the Thumbnail View window may be too small to view the file. You can make the Thumbnail view a floating window and then resize it as needed.

Creating new projects

To create a project based on an existing set of HTML files:

- Choose **New...** from the **File** menu, and then choose **Project From File...** from the fly-out menu. A dialog box in which you specify a **root page** (index page) for the new project appears.

You must specify the root page so that HoTMetaL PRO can build different views of the project. The root page is the starting page for the Web View; it is generally the page where many links to other pages are found. This file can be an index page, a table of contents page, or a welcome page in a group of HTML documents. Often, the root page of a project has a name such as **index.htm** or **home.html**.

- Choose the root page for the project.
- Click on **Open** to import the project and build the views.

When you create a new project, two files are created that store the information about the home page of the project, the link structure of the project, which files have been published, what Pockets have been created, and so on. These files have the same name as the root page of your project, with different file extensions (**.hpp** and **.hmp**). You should not edit these files directly.

Remapping a project after changes

If the file or link structure of a project has been updated—for example, if a file has been deleted or a new link added—the Project tab needs to be updated: this is called **remapping**. HoTMetaL PRO re-scans your project, and updates the windows and the **.hpp** and **.hmp** files.

If you make a change with HoTMetaL PRO, HoTMetaL PRO will prompt you to remap the site. Click on **OK**. To remap the links in a site:

- Choose **Remap Links** from the **Site** menu, press **F5**, or click on the  button from the **Site** toolbar.

HoTMetaL PRO will perform an immediate remap.

Opening an existing project

To open an existing project:

- Click on the  button to open the **Resource Manager**.
- Choose **Open...** from the **File** menu. The **Open** dialog box appears.
- Choose **Project Files (*.hpp)** from the **Files of type** pull down menu and click **Open**. The project is loaded.

The Project () tab will appear next to the **Assets** and **Desktop** tabs at the bottom of the Resource Manager window.

The last four previously opened or imported projects are listed in the **Recent Projects** fly-out menu in the **File** menu. Choosing a project file from that list will open it in the Project tab window.

Adding existing pages to a project

Use the **Import Site...** command from the **Site** menu to add an existing HTML page (and some or all of the pages linked to that page) to a project. This is useful when you want to expand your current project in some way, or merge two or more sites into a single project.

To import an existing HTML file or files:

- Have a project open.
- Choose **Import Site...** from the **Site** menu.
- Select the root page of the site that you want to import from the **Open** dialog box that appears.

When you have selected the home page, the **Import Site** dialog box appears.

The structure of the site that you are importing is shown in a view similar to the Web View. In this dialog box, you must specify:

- The level of associated files that you want to import.
 - The destination folder for the imported site.
 - Whether you want to import all files or selected files.
-
- Choose the destination folder (that is, the project that you want to copy the files to) by either entering the path to that folder in the **Import Destination** text box, or clicking on **Browse...** to navigate to the folder.

You can select the number of levels of files linked to the main file that you want in the site that you're importing. By clicking on the **Number of levels displayed** control, you can choose the number of levels, from zero (just the home page) to the maximum in the site. The level control will only go up to the maximum number of levels in your site (which, if you're just importing one file that's not linked to any other file, will be zero). Clicking on **Map Now** will redisplay the site with the selected level of files.

Note: Only links to local files are displayed in the 'Import Site' dialog. If there is a link to an external site, that page will not be displayed or imported.

You can import all of the files linked to the root page—to the maximum number of levels or to a selected level—or select individual files.

To import all of the linked files:

- Turn on **All Visible Levels**.
- Increase the **Number of levels displayed** as high as it will go.
- Click on **OK**.

To manually select which files you want to import:

- Turn on **Selected Files Only**.
- Click on a file in the Web View window of the **Import Site** dialog. As soon as you click on a file, all other files become blue (deselected). The file you are clicking on remains yellow (selected).
- To select more files, hold down the **Ctrl** key and click on the file icons.

To re-select all visible files in the site, turn on **All Visible Levels** and use the **Number of levels displayed** control to show as many levels as you want to import.

When you have chosen both the file to import and its destination folder, click on **OK** in the **Import Site** dialog box; the files you have selected will be copied to the specified folder. If you choose a file that is linked to files in subfolders, the same file and folder structure will be re-created in the new location. You will be warned of any name conflicts with existing files and folders and given the chance to cancel the import if that occurs. The site management functions will rebuild the views to show the new HoTMetal PRO file that you have imported.

Note: A file imported into your project might not have any links to other files in your project. You may need to add links that point to the new file in order to make it part of the link structure of the project. You can do this by editing files, or by dragging and dropping files in the site management view windows.

Creating a new folder

To create a new folder in your project:

- If the Resource Manager is not open, choose **Resource Manager** from the **View** menu.
- Click on the  button in the Resource Manager toolbar, or right-click in the Contents pane and choose **New Folder**, or choose **New Folder** from the **File** menu. The folder is created in the existing project folder.
- Type in a name for the folder and press **Enter**.

The **Site Doctor** dialog box appears, asking if you want to change all the links that refer to that file:

- Press **Enter** to say 'Yes'.

Managing files and links between files

You can cut, copy, paste, delete and rename files in the Contents pane, and HoTMetaL PRO will help you keep track of and maintain the links to those files.

You can move and copy files in the Explorer and Contents pane much as you would in the Windows Explorer, by dragging and dropping files and folders. You can also choose the cut, copy, paste, delete and rename commands from the **Edit** menu or from the right-click pop-up menu.

- **Cut** (or press **Ctrl+X**) – Cuts the selected file or folder. You can paste the file or folder using the **Paste** command.
- **Copy** (or press **Ctrl+C**) – Copies the selected file or folder.
- **Paste** (or press **Ctrl+V**) – Pastes a file that you have cut or copied.
- **Delete** (or press **Delete**) – Deletes the selected file or selected folder and all its contents. The file is sent to the Recycle Bin, and is not permanently removed from the disk until you empty the Recycle Bin.

To restore the file:

- Open the Recycle Bin.
- Right-click on the file and choose **Restore** from the pop-up menu.

The file will reappear in the folder you deleted it from. (You will need to choose **Remap links** from the **Site** menu, or press **F5**, to see the restored file in the HoTMetaL PRO.)

- **Rename** – Lets you rename the selected file. The name of the file becomes editable, and the name change takes effect when you click outside of the file name or press **Enter**. When you finish renaming a file that is linked to other files, the **Site Doctor** dialog box appears.

If you click on **Yes** in this dialog box, the Site Doctor automatically updates all links to the file in the current project with the new filename.

- You can create a new folder in the project by choosing **New Folder** from the **File** menu, or right-clicking on the Contents pane and choosing **New Folder** from the pop-up menu. This command creates a new folder within the selected folder of the Contents pane, which you can then rename.

When you move or rename a file, the Site Doctor is started; this will update the links as needed, so that they don't become broken.

When you move a file, the links within the file that refer to other documents are **not** updated; in other words, moving the file will correctly update the files that **refer to** the moved file, but may create broken links **within** that moved file.

Deleting a file can create broken links in your project; use the **Broken Links** command in the **Site** menu to check the link structure of your project.

Any of these operations can also be carried out by selecting the file and then choosing the cut, copy, paste, delete and rename commands from the **Edit** menu or the pop-up menu.

Creating links by dragging and dropping

You can create links by dragging a file in the Web View onto another file in the Web View, from the Page Links window onto a file in the Web View, or from Windows Explorer onto a file in the Web View. The Site Doctor will appear, asking you if you want to create a link in the file that you are dragging **onto**, **to** the file that you are dropping.

The link that you create by dragging and dropping will be inserted at the top of the document; the initial hot text will be the path to the file. If you want to change the hot text or position of the link, edit the file using HoTMetaL PRO.

Note: It is not possible to drag a link into the Web View from a browser window.

Changing your URLs for the Web

Before a completed HTML document is moved to a WWW server, all URLs should refer to documents that are available on some WWW server. (While the document is being created, they may refer to documents on your local system.)

For the most part, links in your HTML pages will have relative URLs, which won't be a problem on the WWW. However, in some cases (for example, when you create links to an unsaved document, or copy and paste links from other documents), your links may have absolute URLs that start with **file:///**. These links are not accessible over the WWW:

```
file:///c:/rodney/orwell/homage.htm
```

When the document is placed on your server, you must substitute URLs that refer to documents that are available on your server or some other server. For example:

```
http://www.sq.com/orwell/homage.htm
```

The **Find and Replace URLs...** command in the **Edit** menu gives you the opportunity to edit all the URLs, modifying them if necessary. This command is a form of 'find and replace' for URLs.

For information about replacing URLs in a project, refer to [Finding URLs](#).

To find and replace URLs:

- Launch HoTMetaL PRO.
- Open the document that you want to find and replace the URLs in.
- Choose **Find and Replace URLs...** from the **Edit** menu.

A dialog box will appear containing two text boxes.

The first box (labeled **Change URLs From**) contains a part of the URL that you want to change; the second box (labeled **To**) contains the text that you want to change it to. You can enter text in these boxes to replace the default text.

If there were a large number of URLs for which you needed to change a local folder such as **file:///c:/rodney** to a server address, such as **http://www.sq.com**, you could enter:

```
file:///c:/rodney
```

in the **Change URLs From** text box, and:

```
http://www.sq.com
```

in the **To** text box.

[More on this topic](#)

Finding and replacing URLs

When you click on **Find Next**, HoTMetal PRO finds the next element that has a URL matching the **Change URLs From** text. The insertion point is placed inside that element, and the document scrolls to its location. The search starts at the insertion point or selection.

Clicking on **Replace** will change the text you're searching for to the text in the **To** box.

Clicking on **Replace All** will make this change for all URLs in the document that contain the **Change URLs From** text. This also dismisses the dialog box. (The number of replacements is shown in the status bar at the bottom of the HoTMetal PRO window.)

This form of 'find and replace' matches only starting at the first character of the URL.

The values you enter in the **Change URLs From** and **To** text box will be saved and become the defaults.

For information on replacing URLs on the fly at publish time, see [URL Replacement](#) in the HoTMetal PRO online help.

Changing to relative URLs

You can change your URLs so that they are in relative rather than absolute form. What this generally involves is deleting the first part of all URLs; that is, the scheme, the host, and perhaps part of the path. For example, if your current links were all of the form **file:///c:/rodney/orwell/file.htm** and you wanted to put them in a directory on the Web, it could be useful to put them in relative form, if all your files were in a flat directory on your Website. In the **Change URLs From** text box, you would type **file:///c:/rodney/orwell**. You would not type anything in the **To** text box. The effect of that changing URLs operation would be to strip the scheme, host, and most of the path, and leave you with **file.htm** for all your URLs. For more details on relative and absolute URLs, see [Links](#) .

Publishing

Publishing a project means moving your documents to a server so that other users can have access to your project. The publishing component of HoTMetaL PRO lets you publish some or all of your files to a local or remote server. Once you have specified the destination server for your documents, HoTMetaL PRO will deliver the files to the location you specify, automatically logging into the server, if it's a remote site.

To publish a project:

- Choose **Publish...** from the **Site** menu or click on the  button in the **Site** toolbar. The **Publish Project to Web Site** dialog box appears.

There are two steps to publishing your project:

- 1 Specify the **destination server** that you want to move files to (see [Choosing the server](#)).
- 2 Mark which files in the project are to be published (see [Choosing which files to publish](#)).

[More on this topic](#)

Choosing the server

If you have defined one or more destination servers in previous publishing operations, a list of destination servers will appear in the **Select Site** drop-down list at the top of the **Publish Project to Web Site** dialog box. You can choose a server from that list or define a new destination.

Define a new destination

To define a new destination:

- Click on **Setup...**

The **Destination Site** dialog box appears.

The list of destinations that have already been created (if there are any) is at the bottom of the **Destination Site** dialog box in a scrollable list. To edit an existing destination, select it from the list; all of the details of that destination server will then be displayed in the upper half of the dialog box (the **Server** area). To delete a destination from the list, select it and click on **Delete**.

To create a new destination:

- Click on **New**.
- Now enter the information describing the destination server.

To edit a new or existing destination:

- Enter a descriptive name for this destination in the **Name** text box. The server will be identified by this name in the **Destination** list.
- If the destination is a server that is mounted on your PC's file system (that is, accessible through Windows Explorer), click on the **Local** radio button in the **Server** area of the dialog box. If the destination is a **remote** file server, which will require you to log into a different machine, choose the **Remote** radio button in the **Server** area of the dialog box.

Local server

If you have chosen a local server:

- Enter the path on the local server in the **Path** text box. You can also use the **Browse...** button to select the path: you will be presented with a dialog box where you can navigate to the folder on your local file system that you would like to publish to.

Remote server

If you have chosen a remote server, several text boxes appear.

- Enter the name of the server that you are publishing to in the **Host Name** text box; for example, **ftp.your_isp.com**
- Enter your **User Name** and **Password** for the server.
- You also need to specify the folder path to which your files will be published on the remote server: enter the path in the text box provided.
- Turn on the check box for **Passive FTP Mode** if you need to use that mode.
- When you have finished, click on **OK** to return to the **Publish Project to Web Site** dialog box.

If you do not know the information required in this dialog box, contact your ISP's technical support.

Choosing which files to publish

The **Mark files for Publishing** section of the **Publish Project to Web Site** dialog box lets you choose to publish some or all of the files in the current project. Note that you can't select files or publish until a server has been chosen.

The **Mark files for Publishing** window shows your project in an expandable hierarchical view of the actual files in your project, much like the Project tab. Check boxes appear to the left of the files in this window, indicating your selection of files to be published. To select all the files in the project for publishing, click on the **All** button to the right of this display: green check marks appear to the left of the files in this publishing window.

Clicking on **None** deselects all the files, and the checkmarks disappear.

You can also select or deselect individual files for publishing by expanding the display—clicking on the plus or minus sign to view the files within the folders—and then clicking on the check box changes the publishing status of the file. If you deselect some of the files in a folder, the folder checkmark color changes from green to gray, indicating that not all the files in that folder have been selected. If you wish to select all the files in that folder, click on that check box again and the check mark color will turn to green.

If desired, you can click on **Use Filters** to select or deselect certain files or file types: the set of files that this applies to is configurable .

Now you can send your files to the destination server.

Filtering file selections

In addition to selecting and deselecting certain files in the **Publish Project to Web Site** dialog, you can specify that certain files or file types will be selected or deselected at the press of a button. You can configure filtering options by choosing **Options...** from the **Tools** menu, then clicking on the **Publish** tab. In particular, you can include or exclude:

- Orphan files (turn on **Exclude orphan files** to exclude these)
- New or changed files (turn off **Exclude if up-to-date** to include these)
- Specific filenames and filetypes (to exclude these, turn on **Exclude by filename matching** and enter specific filenames, or wildcards such as ***.txt** and **project1.***, in the text box)

The choices you make are called **filters** because they filter out unwanted files. New and changed files are included by default. To apply this and other filters, click on **Use Filters** in the **Publish Project to Web Site** dialog.

URL replacement

The **Publish** dialog provides a general purpose URL replacement mechanism. This mechanism can, for example, be used to convert URLs that were used to test Miva scripts with HoTMetaL Personal Server to the URLs needed to run scripts on a server running HoTMetaL Application Server.

Two forms of URL replacement are supported:

- 1 Replacing part of a URL with some other text
- 2 Prepending some text to all URLs that end with a particular file extension

Replacing part of a URL

For example, to run scripts with HoTMetaL Personal Server, you might use a URL such as:

```
http://127.0.0.1/docs/quiz.mv
```

On a server running HoTMetaL Application Server, you'll need a URL such as:

```
http://www.sq.com/cgi-bin/hmappserver?docs/quiz.mv
```

Or:

```
http://www.sq.com/cgi-bin/hmappserver?~jsmith/docs/quiz.mv
```

The files that are published to your server will need to have all of your 'local' URLs converted. That is, in each URL, the characters '127.0.0.1/' will need to be replaced by 'www.sq.com/cgi-bin/hmappserver?' or 'www.sq.com/cgi-bin/hmappserver?~jsmith/'. Since you will probably continue to work with your files locally, it will be more convenient to just have the URLs changed in the published files.

You can have this conversion performed at publish time from the **Publish** dialog by carrying out the following steps:

- Choose **Publish...** from the **Site** menu.
- From the **Name** list, select the site that you want to publish to. (If the list is empty, proceed to the next step.)
- Click on the **Setup** button.
- If you haven't yet specified the **Name** and **Server** for your destination site, do so now.
- Turn on the **URL Changes** check box.
- Click on **Details....**
- In the **Change URL** dialog box, click on **New**.
- Turn on **Regular Expression Syntax**. This option enables you to enter a search string in the same way that you can with the regular Find and Replace.
- In the **Find** text box, enter the part of the URL that you want to replace, for example:

```
127.0.0.1/
```

- In the **Replace** text box, enter the text that you want to replace the **Find** string with, for example:

```
www.sq.com/cgi-bin/hmappserver?
```

- Click on **OK**.
- Click on **OK** in the destination site dialog.
- Now publish your files in the normal way. The replacements that you indicated will be performed **in the published files**; the files on your local system will be unchanged.

Prepending text to a URL

You can prepend a string of text to all URLs that have a particular file extension. For example, if all of your URLs are relative URLs you can convert them to absolute URLs by prepending the scheme and server address (for example, <http://www.softquad.com/>).

To do, this, display the **Change URL** dialog box as described above, and continue as follows:

- Turn on **Use File Extensions**. This option enables you to enter a search string in the same way that you can with the regular **Find and Replace**.
- In the **Find** text box, enter the file extension that terminates the URLs that you want to replace. For example, to specify all URLs ending with **.html**, enter:

*.html

(The '*' is required.)

- In the **Prepend** text box, enter the text that you want to be prepended to the URLs. For example:

http://www.softquad.com/cgi-bin/hmappserver?

- Click on **OK**.
- Click on **OK** in the destination site dialog.
- Now publish your files in the normal way.

Processing order

If you have specified more than one replacement pattern, each pattern in the list will be applied to each file that is published. Patterns are applied in the order they appear in the list, from top to bottom. For this reason, the order in which patterns appear is important. The replacement text produced by one substitution may then be affected by the next substitution, and so on. Whether this produces a desired effect depends on what you are trying to accomplish.

For example, if your documents contain relative URLs, some ending in **.htm** and some ending in **.html**, you can convert them all to end in **.html**, and then prepend your scheme and server address using two patterns: the first pattern will be a regular expression that matches all URLs ending in **.htm** and converts them to URLs ending in **.html**:

Find: (.*)\.htm
Replace: \1.html

The second pattern will prepend the scheme and server address to all URLs ending in **.html**:

Find: *.html
Replace: http://www.your_server.com/

Completing the publish operation

Once you have selected a host and marked the files that you want to publish, click on **Publish** at the bottom of the **Publish Project to Web Site** dialog box to copy the files to the selected server. The **Publishing Progress...** dialog box appears.

Status reports on the file transfer are shown at the bottom of this dialog box. Clicking on **Stop** stops the transfer. If you have specified directories in the path for publishing, they will be created: a dialog box will appear, asking you if you would like to create the specified directories.

Setting the default editor and browser, and other options

You can set the default cascading style sheet editor and viewer (Web browser) launched from the site management windows.

- Choose **Options** from the **Tools** menu.

These settings are also used in the document editing window.

In the **Helpers Apps** tab, you can select an HTML viewer (that is, a Web browser), and a cascading style sheet for your documents by clicking on **Choose...** and selecting the appropriate file.

You can choose whether the site management functions will map the links within MS Office 97 documents by turning on or off the **Map Microsoft Office 97 Documents** check box in the **General** section of the **Options** dialog box.

If you turn on **Web View Smooth Scroll**, in the **View** section of the **Options** dialog box, the Web View window will scroll more smoothly when you highlight a different file in the Project tab, and the Web View scrolls to display the highlighted file in the center of the window. This form of scrolling can be slower if you are displaying a large project.

If you make a change to the file or link structure of the project with HoTMetal PRO, you should remap the site.

You can also configure HoTMetal PRO to work with a proxy server.

Configuring a proxy server

Often, organizations with Internet access route their access through one machine, called a **proxy server** (or **gateway** or **firewall**), for security reasons. The proxy server, which is connected directly to the Internet, takes Internet requests and sends them out on the Internet, returning the responses to your computer.

In order to access the Internet from behind a firewall, you must configure your Internet software with the address of the proxy server. HoTMetal PRO can be configured to use a proxy server for publishing and checking external links.

To configure a proxy server:

- Choose **Options...** from the **Tools** menu, and click on the **Publish** tab.
- Click on the **Automatic** or **Manual** radio button if you want site management to route its Internet information requests through a proxy server.

If you have set a proxy in the **Internet** control panel (or from Microsoft Internet Explorer), you can use those settings automatically by turning on **Automatic**. If not, you may need to ask your system administrator for this information.

To configure a manual proxy:

- Turn on **Manual**.
- Enter the name or IP address of your proxy server in the **IP address** text box.
- Enter the port in the **Port** text box.

You can also set a list of **Exceptions** to both the manual and automatic proxy settings: these are locations that HoTMetal PRO can access directly without having to go through a proxy. The **Options** dialog allows you to set either local (intranet) addresses or use the bypass list from the registry.

If you have set a location for publishing that is in on a local intranet, selecting **Local intranet addresses** will allow publishing to that location without using a proxy. (Note that an address is considered to be local if it consists of exactly one word, without a domain. For example, **triptych** is considered a local address, but **triptych.com** is not.) If the selection of local intranet addresses does not have the desired effect, you can use a bypass list.

If you have set a bypass list of addresses that should be accessed without going through the proxy—in Microsoft Internet Explorer, or directly from the **Internet** control panel—you can use those settings automatically by choosing **Bypass list from registry**.

Some proxy servers use a **username@host** style of **ftp** addressing. In this situation, when you are configuring a **Destination Site** for publishing, make the following settings:

- **Host Name** – name of the proxy server.
- **User name** – **username@host**

Make sure that you have selected **No proxy** or that the proxy server name is in your bypass list.

Coding guidelines for Miva files

HoTMetaL PRO is a validating structured editor that can make editing Miva files easier. The special features that it brings to this process are:

- **Tag completion:** If you insert a paired tag such as [MVIF> in HoTMetaL PRO's **Tags On** mode, HoTMetaL PRO will always insert the corresponding end-tag (such as </MVIF]).
- **Attribute editing:** HoTMetaL PRO's Attribute Inspector presents a list of valid attributes for the current element and displays the required attributes in **bold**. All you have to do is enter the desired attribute values. The **Attribute Inspector** context sensitive help gives a description of each Miva (and HTML) attribute.
- Rules checking: By continuously checking your document against a **rules file** as you are editing it, HoTMetaL PRO ensures that you don't create any code or markup that has syntax errors.
- URL replacement: When you upload your files to a server, you can modify URLs on the fly (for example, to prepend or replace the server name).
- Previewing: run a Miva application by simply clicking on a browser preview button.

HoTMetaL PRO's site management functions help you organize your files, display links between them, and publish them to a server that runs HoTMetaL Application Server.

If you have already created some Miva documents and want to open and edit them with HoTMetaL PRO, these coding guidelines provide information on how to ensure that your code is compatible with HoTMetaL PRO.

[More on this topic](#)

Inserting Miva tags

HoTMetaL PRO has three editing modes that you can use to enter Miva tags: **WYSIWYG**, **Tags On**, and **HTML Source**. We recommend that you work in either **Tags On** mode (where you can take advantage of HoTMetaL PRO's tag and attribute editing functionality) or in **HTML Source** mode (in which you can enter Miva and HTML code directly).

To insert a Miva tag:

- You must be in **Tags On** mode (press **Ctrl+Alt+T**).
- Choose **Element...** from the **Insert** menu, or press **Ctrl+Shift+I**. The element list dialog is displayed.
- Click on the **Miva** tab in this dialog to see only the available Miva tags, or click on the **HTML** tab to see all available tags.
- Select the element that you want to insert from the list. You can scroll to an element quickly by typing the first few letters of its name.
- Click on **Apply**.

HoTMetaL PRO inserts start- and end-tag icons in the document. If the element is one such as <MVELSE> that doesn't have an end-tag, a blank end-tag icon will appear on the screen (for example,[MVELSE> <]) but will not be saved when you save the file.

Attributes

- 1 Attribute values must always be surrounded by double quotes in **HTML Source** mode. If you are entering attribute values in **Tags On** mode with HoTMetal PRO's **Attribute Inspector**, double quotes will be inserted for you automatically. If your document is valid, HoTMetal PRO will insert these for you if you open and save it.
- 2 An attribute value should not be specified simply as a value. For example, instead of:

```
<TABLE BORDER  
>
```

You should use:

```
<TABLE BORDER="BORDER"  
>
```

Again, if your document is valid, HoTMetal PRO will do this conversion for you.

Forming expressions and literals

An **expression** is a formula that can be evaluated to give a result.

```
<MVASSIGN NAME="price" VALUE="{ cost + markup }"  
>
```

In this example, '{cost + markup}' is an expression: when the <MVASSIGN> tag is executed, the values of the two variables **cost** and **markup** are added and the result is assigned to the variable **price**.

A **literal** is a string of text or a number, which needs no further evaluation.

```
<MVASSIGN NAME="organization" VALUE="United Nations"  
>
```

```
<MVASSIGN NAME="age" VALUE="22"  
>
```

'United Nations' and '22' are literals.

In Miva, literals and expressions occur in attribute values. The following rules govern the use of expressions and literals.

1 If you are entering an **expression**, always enclose it in curly brackets, '{' and '}'. For example:

```
<MVASSIGN  
  NAME="interest"  
  VALUE="{ principal * rate * time }"  
>
```

2 If you are entering a **literal** value (a number or text string that doesn't require evaluation), just enter it as is. For example:

```
<MVASSIGN  
  NAME="CEO"  
  VALUE="Mr Dithers"  
>
```

3 If an expression contains a literal text string in combination with other components, surround it with single quotes, not double quotes. For example:

```
<MVASSIGN  
  NAME="greeting"  
  VALUE="{ 'Dear Mr ' $ last_name $ ', ' }"  
>
```

4 Similarly, macros that evaluate to literal text strings should be surrounded with single quotes. However, if a macro evaluates to a string that is intended as a variable name in this context, it should **not** be surrounded by single quotes. For example:

```
<MVASSIGN NAME="firstname" value="Cynthia"  
>  
  
<MVASSIGN NAME="var" value="{ 'first' $ 'name' }"  
>  
  
<MVEVAL EXPR="{ 'Dear ' $  
&[firstname] }"  
>
```

```
>
<br
>

<MVEVAL EXPR="{ 'Dear ' $ '
&[firstname] }'"
>
<br
>

<MVEVAL EXPR="{ 'Dear ' $
&[var] }'"
>
```

This code will display:

```
Dear
Dear Cynthia
Dear Cynthia
```

After the macro is evaluated, the first <MVEVAL> is equivalent to:

```
<MVEVAL EXPR="{ 'Dear ' $ Cynthia }"
>
<br
>
```

In this situation **Cynthia** will be interpreted as a variable, but since it has no value, nothing will be displayed when it is evaluated. After macro evaluation, the second <MVEVAL> is equivalent to:

```
<MVEVAL EXPR="{ 'Dear ' $ 'Cynthia' }"
>
<br
>
```

Since **Cynthia** is in single quotes, it is interpreted as a literal and displayed. The third <MVEVAL>, after macro evaluation, is equivalent to:

```
<MVEVAL EXPR="{ 'Dear ' $ firstname }"
>
```

In this case **firstname** is a variable that evaluates to the literal string 'Cynthia', which is displayed.

Forming Miva macros

A Miva macro of the form **&[variable]** will be converted into the form **&[variable]** by HoTMetaL PRO. This form is executed the same as the original form by HoTMetaL Application Server. The following four forms for expressing a macro are equivalent:

`&[variable]`

`&[variable]`

`&[variable];`

`&[variable];`

Using tables

If you are using Miva code in conjunction with tables, you should avoid putting Miva tags directly inside a <TR> (table row) element. This generally results in HoTMetaL PRO not displaying the table correctly, and perhaps reporting spurious errors. It is acceptable to surround a <TR> (and its corresponding </TR> end-tag) with Miva tags, or to put Miva tags inside a <TD> or <TH> tag. The following two code fragments are acceptable:

```
<MVCOMMENT
>
| Case 1
|
<TR
>...
</TR
> tags inside
<MVIF
>...
</MVIF
>

</MVCOMMENT
>

<MVIF EXPR="{finished}"
>

<TR
>

<TD
>...
</TD
>

<TD
>...
</TD
>

</TR
>

</MVIF
>

<MVCOMMENT
>
| Case 2
|
<MVIF
>...
</MVIF
> tags inside
<TD
>...
</TD
>

</MVCOMMENT
>

<TR
>
```

```

<TD
>

<MVIF EXPR="{finished}"
>
...
</MVIF
>

</TD
>

<TD
>...
</TD
>

</TR
>

```

The following code is problematic because the <MVIF> is directly inside the <TR>:

```

<MVCOMMENT
>
| Case 3
|
<MVIF
>...
</MVIF
> tags inside
<TR
>...
</TR
>

</MVCOMMENT
>

<TR
>

<MVIF EXPR="{finished}"
>

<TD
>...
</TD
>

</MVIF
>

<TD
>...
</TD
>

</TR
>

```

If you have code like this, you should try to rewrite it in a way that gives the same or similar results, but conforms to these guidelines. For example, in many situations case 2 above can substitute for case 3, because an empty table cell is not displayed unless it has a visible border.

There are some insertions in and around tables that you'll have to do in HoTMetal PRO's **HTML Source** view (choose **HTML**

Source from the **View** menu or press **Ctrl+Alt+H**). For example, HoTMetal PRO doesn't let you select individual rows of a multi-row table in **WYSIWYG** or **Tags On** view, so if you want to surround a row with a tag such as `<MVF>`, you'll have to do it in **HTML Source** view.

Table rows that are surrounded by Miva tags are shown as separate tables without borders.

Markup to avoid

Some markup constructs should not be entered if you are creating documents with HoTMetaL PRO, and should be replaced with equivalent forms, if you want to open already-created documents with HoTMetaL PRO.

 [More on this topic](#)

Non-XML tags

Some tags that were inherently non-XML-compliant have been replaced by XML-compliant forms. Non-compliant markup cannot be entered in the **WYSIWYG** and **Tags On** views, and should not be entered in **HTML Source** view.

1 `<MVLET>` has been replaced by `<MVASSIGN>`. An `<MVLET>` tag of the form:

```
<MVLET var_name="{var_value}"
>
```

is equivalent to, and should be replaced by, the following `<MVASSIGN>` tag:

```
<MVASSIGN NAME="var_name" VALUE="{var_value}"
>
```

2 `<##...>` for inserting comments has been replaced by the tag pair `<MVCOMMENT>` and `</MVCOMMENT>`. A comment of the form:

```
<## Hey, look, I'm a comment!
>
```

is equivalent to, and should be replaced by, the following:

```
<MVCOMMENT
> Hey, look, I'm a comment!
</MVCOMMENT
>
```

You can also insert HTML-style comments with HoTMetaL PRO: to do so, choose **Comment** from the **Insert** menu, or press **F8**.

HTML comments are displayed in HoTMetaL PRO as `[.COMMENT> </.COMMENT]` tag icon pairs, and in the saved file appear as:

```
<!-- Hey, look, I'm a comment! --
>
```

Unlike Miva comments, HTML comments are passed to the browser, and can be viewed in the browser's source view. They are not displayed in the browser's normal view.

Non-standard names

In the interests of more consistent coding, HoTMetaL PRO has standardized on the following tag and attribute names:

- 1 <MVEVAL> should always be used instead of <MVEVALUATE>.
- 2 The attribute name EXPR of <MVEVAL>, <MVIF>, and <MVWHILE> should always be used instead of EXPRESSION.
- 3 <MVFUNCRETURN> should always be used instead of <MVFUNTIONRETURN>.

Macros for attribute assignment

Miva macros should not be used to specify both the name and value of an attribute. For example, don't do this:

```
<MVCOMMENT
>
| Avoid this!
</MVCOMMENT
>

<MVIF EXPR="{year EQ '1998'}"
>

<MVASSIGN NAME="attr" VALUE="SELECTED='SELECTED'"
>

<MVELSE
>

<MVASSIGN NAME="attr" VALUE=""
>

</MVIF
>

<OPTION NAME="year"
&[attr]
>1998
</OPTION
>
```

Instead, do this:

```
<MVCOMMENT
>
| Do this!
</MVCOMMENT
>

<MVIF EXPR="{year EQ '1998'}"
>

<OPTION NAME="year" SELECTED="SELECTED"
>1998
</OPTION
>

<MVELSE
>

<OPTION NAME="year"
>1998
</OPTION
>

</MVIF
>
```

You can, however, use macros to specify attribute **values** in Miva and HTML tags:

```
<MVASSIGN NAME="default" VALUE="Enter text here"  
>
```

```
<INPUT NAME="Text1" VALUE="  
&[default]"  
>
```

Improper nesting

You should strive to have properly nested tags. HoTMetaL PRO will enforce this in documents that it creates, but older documents may have to be fixed up. A good principle to follow is that the document should be valid as an HTML document if all the Miva tags are removed.

For example, if you wish to use a <FORM> in conjunction with a <TABLE>, you should not put the <FORM> start-tag inside the table, and the </FORM> end-tag after the table. This will cause HoTMetaL PRO to terminate the form prematurely and some form objects may not be recognized by the browser. In this situation you should either enclose the entire table between <FORM> and </FORM> tags, or put the <FORM> and </FORM> tags inside a single table cell (<TD>), whichever is appropriate.

Another construction to avoid is an <MVIF> ...</MVIF> block that surrounds a start-tag but not the corresponding end-tag, or vice versa. For example:

```
<MVIF EXPR="{color NE '#ff0000'}"
>

<TABLE BGCOLOR="
&[color]"
>

<MVELSE
>

<TABLE BGCOLOR="#ffffff"
>

</MVIF
>
....
</TABLE
>
```

Instead, you can use a construction such as the following:

```
<MVIF EXPR="{color NE '#ff0000'}"
>

<MVASSIGN NAME="tablecolor" VALUE="
&[color]"
>

<MVELSE
>

<MVASSIGN NAME="tablecolor" VALUE="#ffffff"
>

<MVIF
>

<TABLE BGCOLOR="
&[tablecolor]"
>
....
</TABLE
>
```

If all else fails

We have yet to find a case where you cannot do what you want with Miva and have valid HTML at the same time. However, if you find yourself in this situation, you can use the following mechanism to force HoTMetaL PRO to ignore the markup:

```
<!--webbot bot="HTMLMarkup" startspan --  
>  
...Markup here is ignored by HoTMetaL...  
<!--webbot bot="HTMLMarkup" endspan --  
>
```

This is compatible with the Microsoft FrontPage HTML Markup Webbot component.

Manipulating your text

What's covered in this chapter

This chapter describes using HoTMetal PRO to work with the text in your document. Topics include:

- Selecting, copying, cutting, and pasting text.
- Searching and replacing text.
- Moving between open documents.
- Printing your document.

Reference

You can work with your text in HoTMetal PRO much the same way you would in a word processing package, editing and moving words to reflect changes to the information in your document. There are, however, some minor differences that reflect the fact that you are working with a structured document that contains markup as well as text.

[More on this topic](#)

Working with selected text

In HoTMetaL PRO, it is easy to select and move around parts of the document structure in HoTMetaL PRO without having to worry about making the markup invalid. Each time you select a start- or end-tag when you drag-select text, the corresponding tag (and all the content in between) is automatically selected, too. This ensures that you never cut, or move, just part of the markup. There are also a number of ways to quickly select a whole element (and any sub-element).

To select an element, do **one of** the following:

- Choose **Select Element** from the **Edit** menu, or press **Ctrl+Shift+T**.
- Right-click anywhere in the element and choose **Select Element** from the pop-up menu.
- In Tags On view, you can also click once on either the start- or end-tag.

The element is selected.

To select several consecutive elements:

- Place the insertion point anywhere in the first element to be selected, and drag in the appropriate direction until all of the elements are selected.

The **Cut**, **Copy**, and **Paste** commands are similar to those in other Windows applications. The only difference is that in HoTMetaL PRO, a selection can contain elements. Removing or pasting certain elements can cause invalid markup in some circumstances.

HoTMetaL PRO will not paste a selection that would cause the markup to become invalid. **Cut** and **Delete** will become disabled if you select required elements, such as HTML, HEAD, and BODY.

To select all the content in a document:

- With the insertion point anywhere in the document, press **Ctrl+A**.

Indenting and outdenting selected text

You can indent and outdent blocks of text. This is useful, for example, when you want to insert quotes from a book or press release in your document. To indent:

- Highlight one or more blocks of text, such as paragraphs, headings, etc., or to select a single block for indenting, place the insertion point anywhere in the block.
- Click on the  toolbar button or choose **Indent** from the **Format** menu.

The text is now indented (indenting text surrounds it with a BLOCKQUOTE element).

To outdent text:

- If one or more blocks of text have been indented (that is, they are surrounded by a BLOCKQUOTE element), you can **outdent** them to reverse the indenting.
- Click on the  toolbar button or choose **Outdent** from the **Format** menu.

The selected text is now outdented in your document.

Searching and replacing text

You can find and replace text, elements, and patterns. Search and replace operations in HoTMetal PRO are similar to word processing applications with the following differences:

- Text searches will not find a match if part of the text is found in a separate element. For example, if you are searching for 'World Wide Web' and the word 'Web' is in an EM element, the text will not be matched.
- If rules checking is on, text will not be replaced if it will cause incorrect markup. If such a replacement occurs in a 'replace all' operation, it will be skipped.
- Choosing the **Undo** command after a 'replace all' undoes all of the replacements.

To find text:

- Choose **Find and Replace...** from the **Edit** menu, click on the  button, or press **Ctrl+F**. The **Find and Replace** dialog box appears. If text was selected, it appears in the **Find** text box.
- Type the text to be found in the **Find** text box. The maximum length is 255 characters.
- Specify replacement text in the **Replace** text box.
- If desired, use the **Find In** text box to restrict your search to a particular element.
- Click on the **Find** button. The first instance of the search text will be highlighted.
- Click on **Replace**, **Replace**, **Find** or **Replace All**, as appropriate.

To search again using the most recent search text:

- Choose **Find Next** from the **Edit** menu, or press **F3**.

Note: Turn on Use Pattern Matching to use search expressions.

[More on this topic](#)

Specifying search options

You may want to search forward or backward through your document, match only whole words, match upper- and lower-case exactly, wrap back to the beginning of the document, or do a pattern search. You can set any of these options and even use them in combination.

- Choose **Find and Replace...** from the **Edit** menu, click on the  button, or press **Ctrl+F**. The **Find and Replace** dialog box appears.

The following search options are available in the **Find and Replace** dialog box:

- **Match Case** – Searching will match text that is exactly as entered, matching upper case to upper case and lower to lower. For example, the search text 'maria' would not match 'MARIA' or 'Maria'. This option applies to patterns as well as text.
- **Whole Words** – Searching will match a sequence of one or more whole words only. For example, if you search for 'red' with **Whole Words** turned on, HoTMetaL PRO will not find it in 'Fred'.
- **Use Pattern Matching** – Enables the search ability to find patterns. If Use Pattern Matching is turned off, any special search characters in the search or replace text will be treated as ordinary characters.
- **Wrap** – Searching will wrap around to the top of the document and continue to the starting point (or to the bottom of the document for a backwards search), if **Wrap** is turned on.
- **Backwards Search** – Searches for the requested word starting at the end of the document, if **Backwards Search** is turned on.

Searching for elements

Both the search and replace text can consist of an element. Choose an element from the drop-down list or enter an open angle bracket (<), followed by a valid element name. Following the element name with a closing angle bracket (>) is optional. The angle bracket must be the first character. If the element is found, the insertion point is positioned to the right of the start tag for that element. For example,

<P

matches the element P. Element names are not case sensitive in HoTMetaL PRO, so '<p' would also find this element.

If the search and replace text are both elements, the element in the search text will be changed to the type specified in the replace text, if the HTML rules allow it. The contents of the element will be unchanged.

You can also search for instances of an element with certain attribute values, or search for text within a specific element type.

Searching for attributes

You can restrict the search text to an element with specific attribute values by following the element name with a space-separated list consisting of attribute names followed by an equal sign (=), followed by a value in double quotes (" "). For example:

```
<a name="donkey"
```

will search only for those A elements whose NAME attribute has the value 'donkey'.

You can specify replacement attribute values in the replace text in the same way. For example, to change the above name attribute to 'burro', type the following replacement text:

```
<a name="burro"
```

Searching for text within an element

In HoTMetaL PRO, you can restrict searches to a particular element type. Use the drop-down list beside the **Find In** text box to specify the element that you want to restrict searching to; specify the search text in the **Find** text box. For example, to find the word 'now' in an EM element, enter the text in the **Find** text box and specify the element in the **Find In** text box, as follows:

```
<EM  
>
```

Attribute values may also be specified in the **Find In** text box. For example:

```
<a name="donkey"
```

You can also search for specific text anywhere in a specific element type by entering the the element name, with opening and closing brackets, followed by the text in the **Find** text box. For example:

```
<EM  
>the
```

This search text would match the word 'the' anywhere within a EM element. This is similar to the restrictive searching that can be done using the **Find In** text. The two options can be used together to further restrict the search. In the above example, if the **Find In** text is set to:

```
<P  
>
```

the word 'the' would be matched if it appeared in a EM element within a paragraph, but not in any other context.

In the replace text, an element name cannot be followed by text: an error message will appear and the replacement will not occur.

If you have badly-formed search or replace text, an error message will appear, describing the error. For example, if you use the search pattern:

```
<QUAGMIRE
```

the following message appears:

```
Find: Invalid element name
```

because HTML rules do not allow an element called QUAGMIRE.

Possible errors include invalid attribute or element names, unmatched parentheses and brackets in search patterns, special search characters not preceded by a character, and invalid character ranges.

Using search patterns

If the **Find Patterns** option is turned on, the characters in the **Find** text box are interpreted as patterns. That is, the search text can contain special search characters that will match a class of text strings, or markup constructs. (If your search text does not contain any special characters, the text will be searched for exactly as entered.) The following special characters can be used:

. * ? + ^ \$ []

In addition, the character '<' is used to indicate an element search when it appears as the first character in the pattern.

To search for any special character as ordinary text when **Find Patterns** is turned on, precede it with a backslash. For example:

\.

will match a period.

Search patterns may be grouped by enclosing them in parentheses.

Matching any single character

To match any single character, including a blank space, use a period (.). For example

fo.d

would match 'food', 'ford', 'fond', 'fold', etc.

Matching zero or one

To match zero or one occurrences of a character, or series of characters enclosed in parentheses, follow the character with a question mark (?). For example:

colou?r

would match both color and colour.

Matching zero or more

To match zero or more occurrences of a character, or series of characters enclosed in parentheses, follow the character with an asterisk (*). For example:

l*ama

would match 'ama', 'lama', 'llama', 'lllama', etc.

b(an)*a

would match 'ba', 'bana', 'banana', etc.

You can combine the asterisk and period to match any text starting and ending with specified characters. For example:

s.*ch

would match 'search', 'such', 'stretch', 'stopwatch', as well as 'sch' and 'skip lunch'.

Matching one or more

To match one or more occurrences of a single character, or text enclosed in parentheses, follow the character with a plus sign (+). For example, the following search text would match 'ben', 'been', etc., but would not match 'bn':

```
be+n
```

Matching either/or

To search for either of two search patterns, separate them with a pipe or vertical bar (|). For example, to search for 'love' or 'money' use:

```
love|money
```

You can combine this with other search patterns. For example, to find truth or dare:

```
tr.th|d.*e
```

Matching just after markup

To search for text only when it immediately follows a start or end tag, start the search pattern with a caret (^). For example, to find the word 'Note' at the start of a paragraph use:

```
^Note
```

Matching just before markup

To search for text only when it is immediately followed by a start or end tag, end the search pattern with a dollar sign (\$). The dollar sign is not treated as a special search character unless it is at end of a search pattern. There cannot be white space between the text to be found and the tag. For example, to search for the word 'sub' immediately preceding a tag, use:

```
sub$
```

Matching character ranges

To define a range of characters to be matched, surround the group of characters with square brackets: '[' and ']'. The simplest form of character range matches any **one** of the characters within the brackets. For example:

```
t[ai]n
```

matches 'tan' and 'tin'.

A range of characters matches any character in that range of the alphabet. For example:

```
[b-d]
```

matches 'b', 'c', or 'd'. The pattern:

```
[A-Za-z0-9]
```

matches any alphanumeric character. If **Case Sensitive** is turned off, the character range a-z will match any upper- or lower-case letter.

To reverse the meaning of a character range—that is, to match characters **not** in the range—place a caret '^' before the range. For

example:

```
th[^ein]n
```

matches 'than', but not 'then' or 'thin'. The expression:

```
[^m-p]
```

would match any lower-case letter in the alphabet before 'm' or after 'p'.

Re-using search text

To use a sub-expression in the search text in the replace text, surround the sub-expression with parentheses—'(' and ')'. Then refer to the sub-expression in the replace text in the form '\n', where **n** is a number from 1 to 9. This will then be replaced with whatever the **n**th expression in brackets in the search text has matched. For example, if the search text is:

```
(.)read
```

and the replace text is:

```
\1ox
```

then if the text 'bread' is found, it will be replaced with 'box'. The expression \1 is replaced by the matched text for the first expression in parentheses in the search text: in this case '(.)' was matched by 'b'. Here's an example with more than one sub-expression. This time, let's say the search text is:

```
(v.*e) (v.*a)
```

and the replace text is:

```
\2 \1
```

Now, what happens if the text 'vice versa' is found? The first sub-expression, '(v.*e)', matches 'vice' and the second sub-expression, '(v.*a)', matches 'versa'. In the replace text, the second expression found is followed by the first, so the text becomes 'versa vice'.

You can even nest sub-expressions. The sub-expressions are numbered according to the order of their left parentheses. For example, if the search text is:

```
(cad(abra))
```

and the replace text:

```
\2 \1
```

'cadabra' will be replaced by 'abracadabra'.

To retain the entire matched text, use '\0' in the replace text. For example, if the search text is:

```
fish
```

and the replace text is:

gone \0ing

then, 'fish' will be replaced with 'gone fishing'.

You can use '\n' expressions in attribute replacement values: one application of this is to change a group of URLs. For example, if you want to change all of the filenames in your **A** elements to have the **.htm** file extension instead of **.html**, use the following find text:

```
<a href="(.*).html"
```

and the replace text:

```
<a href="\1htm"
```

The element is matched by '<a'; the attribute that contains the URL value is called HREF; the pattern '(.*)' matches everything in the URL up to the extension; that matched text is substituted for '\1' in the replacement text; and the new extension is added.

Search pattern summary

Expression	Matches
ordinary character	itself
<name or <name>	the element name
.	any single character
x*	0 or more occurrences of the character x
(pattern)*	0 or more occurrences of the pattern
x+	1 or more occurrences of the character x
(pattern)+	1 or more occurrences of the pattern
x?	0 or 1 occurrences of the character x
(pattern)?	0 or 1 occurrences of the pattern
pattern1 pattern2	pattern1 or pattern2
^pattern	pattern immediately following markup
pattern\$	pattern immediately before markup
[string]	any single character in the string
[^string]	any single character not in the string
[char1-char2]	any character in the range
[^char1-char2]	any character not in the range
\n	in a replace string, is replaced by the text matched by the nth subexpression in brackets in the search string
\0	in a replace string, is replaced by the text matched by the entire search string

Moving between documents

If you have more than one document open in HoTMetaL PRO, you can move between the open documents in a variety of ways. The **Window** menu contains a list of open documents in the order that you opened them.

To move between documents, do one of the following:

- Choose the appropriate file from the **Window** menu.

To move through the open documents in the order that you viewed them:

- Choose **Next**, or **Previous**, from the **Window** menu.

- Click on the  and

toolbar buttons, to move up and down the list of open documents.

- Press **Alt+Left arrow** or **Alt+Right arrow**, to move up and down the list of open documents.

HoTMetaL PRO also allows you to move between documents by following local links. If your current document contains a link to a file on your PC, you can use this anchor to view or edit the linked document.

To follow a link:

- Right-click on the link. A pop-up menu appears.
- To edit the linked file, choose **Edit Linked Item** from the menu. The file opens in HoTMetaL PRO.
- To view the linked file, choose **View Linked Item** from the menu. The file opens in your default browser.

You can use this feature of HoTMetaL PRO to edit or view external links (that is, to retrieve files from the Web). These commands are also available from the **Tools** menu.

Printing documents

You can print the HTML Source view of a document directly from HoTMetaL PRO, or you can print the document from a browser.

To print from HoTMetaL PRO:

- Switch to **HTML Source** view.
- Choose **Print...** from the **File** menu.

To print from a browser:

- Choose **Page Preview** from the **View** menu and choose **Print** from the pop-up menu.

Alternatively, you can launch an external browser and print from that application.

Working with images

What's covered in this chapter

Images are one of the reasons the Web has become so popular. While your pages don't require images, they can make them more interesting to look at, and can help you to communicate your ideas. Here's what you'll learn:

- Displaying images in HoTMetaL PRO.
- Browsing for images.
- Inserting images into your page.
- Editing image properties.
- Extended image properties.
- Images and accessibility.
- Creating 'hot' images.
- Creating clickable image maps.

Reference

In part, the Web is distinguished from other Internet applications (for example, Usenet) by its ability to display inline images. Images have become more important to creating Web documents as the layout and display capabilities of Web browsers has become more sophisticated. Using HoTMetaL PRO, you can insert and display many different image formats in the document window, then use the power of PhotoImpact SE to edit your images for the Web.

[More on this topic](#)

Displaying images in HoTMetaL PRO

HoTMetaL PRO can display graphics in many different formats, including BMP, PNG, JPEG, GIF, TIFF, and others. Images displayed in the HoTMetaL PRO document window are displayed as they would be in a browser, including image size and, if applicable, transparency. HoTMetaL PRO also displays background images.

All browsers that are capable of displaying images can display GIF files. Most newer browsers can also display JPEG images, and some browsers can display other platform-specific image types. If you want your Web pages to be viewed by the broadest possible audience, however, make sure that your images are in GIF or JPEG format.

You can configure HoTMetaL PRO to display or hide images and background graphics. The default settings for all documents are configured in the **View** tab of the **Options** dialog box (choose **Options...** from the **Tools** menu); you can choose whether inline and background images should be displayed in the window or not. This choice will then apply by default to all new documents.

You can override the inline images **Options** setting for individual documents using the **Show/Hide Inline Images** commands in the **View** menu. If you don't want images to be displayed in the document, choose **Hide Inline Images**. The command will then toggle to **Show Inline Images**: if you choose this command, HoTMetaL PRO will resume displaying inline images.

You cannot override the **Options** dialog for background images settings in individual documents.

Inserting images into your page

When you insert an image into your page you are actually creating a link to a graphic file using a URL. The Web browser puts the two together when you load the page. Similarly, HoTMetal PRO displays the image within the document window so you have an idea of how it will look in the Web browser, although the WYSIWYG view does not exactly match a browser display. If you look at a document containing an image in HTML Source View or Tags On view, however, you will see that the image is represented by an IMG element.

You can insert images into your page by dragging and dropping, or from the HoTMetal PRO [toolbars and menus](#). HoTMetal PRO also gives you two powerful ways to browse for images for your page, then drag and drop them where you like. These are the **Image Explorer** (not provided with the Evaluation version) and the [Resource Manager](#) .

[More on this topic](#)

Inserting images from the toolbars or menus

To insert an image using the toolbars or menu commands:

- Place the insertion point at the location where you want the image to appear in the document (the document cannot contain a selection).
- Click on the  (**Insert Image**) toolbar button or choose **Image...** from the **Insert** menu.

The **Image Properties** dialog box appears.

Because images in HTML are represented by links, you have to specify the location of the image file the same way you would for any other kind of link. This information is required.

To specify the image file location:

- Enter the Internet address (URL) for the file in the **Image File** text box. (If you need more information on URLs, see the Links help.)

Or:

- Click on **Choose...** and browse for the file.

In this dialog box you can specify alternate text, alignment, width, height, and border width. You can also click on Edit Image Map Name if an image map is associated with this image.

You can bring up this dialog to edit an **existing** image's properties in one of three ways:

- Double-click on the image.
- Right-click on the image and choose **Image Properties...** from the pop-up menu.
- Click on the image and then click on  again.

You can also edit all of the image's properties using the Attribute Inspector and edit the image map name.

Alternate text

The **Alternate Text** text box in the Image Properties dialog box is for entering some text that will be displayed if the document is being read with a browser that can't display images or one that has image loading turned off. Some browsers display alternate text while the images are loading, or in a pop-up window when the cursor is over the image. Even though this information is not required, it is good HTML style to include it for the benefit of users without graphical browsers. Since alternate text is indexed by some search engines, providing a short description of the image allows people to find it more easily. Using meaningful alternate text also makes your page accessible to people with visual impairments who use assistive technology to surf the Web.

Alignment

The default alignment for images is **BOTTOM**, meaning that the bottom of the image will be on the baseline of the adjacent text. You can choose an alignment value from the **Alignment** pull-down list in the [Image Properties](#) dialog box.

You can set the image alignment to the following:

- **MIDDLE** – Aligns the baseline of the current line with the middle of the image.
- **TOP** – Image aligns with the top of the tallest item in the line.
- **LEFT** – Image 'floats' on the left margin and text wraps around it to the right.
- **RIGHT** – Image 'floats' on the right margin and text wraps around it to the left.
- **TEXTTOP** – Image aligns with the top of the tallest text in the line.
- **BASELINE** – Same as **BOTTOM**.
- **ABSMIDDLE** – Aligns the middle of the current line with the middle of the image.
- **ABSBOTTOM** – Aligns the bottom of the image with the bottom of the current line.

Not all of these image alignments are supported by all browsers, so use them with caution and make sure that your page looks acceptable on several different browsers.

For left and right images, text wraps around the image, but the **IMG** tag remains inline to indicate its actual location in the document.

Note that there is no 'center' alignment: if you want to center an image, surround it with a block element (such as **P**) that you can then center-align. Some browsers also support the **CENTER** element, which you can put around the image.

Width and height

When you insert an image—by dragging and dropping or any other means—HoTMetal PRO will automatically set the height and width attributes. These properties are measured in pixels; they tell the browser how large an image is. This will speed download times and page formatting. Height and width are not supported by all browsers, but do make a large difference to how fast a web page formats in many browsers. If you wish to change these values, you can edit them using the **Height** and **Width** text boxes in the Image Properties dialog box.

Note: Some browsers accept percentage values for the height and width. The percentage value represents a percentage of the window size. This can be useful for graphics that resize with the window, such as graphical horizontal rules.

Border

The **Border** field in the [Image Properties](#) dialog box enables you to put a border around the image. Typing in a number value represents the width of the border, in pixels, around the image. The default value is 0; this indicates that there is no border around the image. One of the most common uses for the border value is setting it to 0 to remove the blue border that will appear around an image if it is surrounded by a link (A element).

- Enter the desired value.

Spacing

Some browsers support the image attributes VSPACE and HSPACE.

To edit these attributes:

- Right-click on the image and choose **Attribute Inspector** from the pop-up menu.

Or:

- Click on the image and choose **Attribute Inspector** from the **View** menu.

Or:

- Press **F6**.

You can specify blank space on the top and bottom (VSPACE) and on the sides (HSPACE) of an image. The value is in pixels. This can be very useful for trying to create a more precise layout.

Managing your assets

The Resource Manager is an asset management tool that gives you access to all kinds of **Web objects**: images, cascading style sheets, scripts, dynamic HTML, and more. It organizes Web objects into categories and enables you to perform 'intelligent' drag and drop operations into your documents. For example, if you drag and drop a background image it is inserted in your document as a background, not as an ordinary image. The Resource Manager also enables you to select different views, create file filters, and navigate through folders. You can also view images as thumbnails before you insert them into your Web page.

The Resource Manager contains two tabs: the **Assets tab** () and the **Desktop tab** (). If you have a project open, there will be a third tab, the [Project tab](#).

The **Assets** tab gives you access to a permanent and dynamic collection of Web objects of various kinds, from which you can perform 'intelligent insertion' operations.

The **Desktop** tab gives an Explorer-like view of your desktop, from which you can perform ordinary drag and drop of files into your document, and from which you can add your own assets to the collection in the Assets tab.

The top pane of the Resource Manager is called the **Explorer pane**. This is where you can browse through folders in a hierarchical tree view. Its navigation is similar to that of Windows Explorer.

The bottom pane of the Resource Manager is called the **Contents pane**. This is where you can view the contents of the selected folder in the Explorer pane, and drag and drop files into your document.

The Resource Manager toolbar lets you navigate through folders, create new folders, create file folders, and choose view formats for thumbnails.

The Resource Manager toolbar

For more information on using the Resource Manager toolbar, see [The Desktop tab](#).

Note: [Microsoft Internet Explorer](#) must be installed on your PC in order for the full Assets tab functionality to be available.

[More on this topic](#)

The Assets tab

The **Assets** tab gives you access to a permanent and dynamic collection of Web objects of various kinds, from which you can perform 'intelligent insertion' operations.

Note: Microsoft Internet Explorer must be installed on your PC in order for the full **Assets** tab functionality to be available.

The **Assets** tab contains four folders for organizing and categorizing Web objects:

- **cdrom** – gives you access to the Web objects on the HoTMetaL PRO CD.
- **Hmfx** – a library public domain of Web objects supplied with HoTMetaL PRO.
- **myassets** – a folder in which you can build up your own library of Web objects.
- **remote** – links to **hmfx.com**, SoftQuad's asset Website from which you can download from a continuously updated library of Web objects.

Note: The 'cdrom' and 'remote' mechanisms used here are extensible and can be used only by other vendors to create asset CDs or Websites. Contact SoftQuad for more information.

Navigating in the Assets tab

To navigate in the Explorer pane, you can:

- Click on a folder to open it in the Contents pane.
- Double-click on a folder to expand it.
- Click on the  icon to expand a folder, or click on the  icon to contract it.

Click on the scrollbars to scroll up or down in the Explorer pane.

Dragging and dropping from an Assets folder

The folders in the **Assets** tab enable you to access Web objects to insert into your documents. To use a sample from one of the **Assets** folders:

- Click on the  button, or choose **Resource Manager** from the **View** menu to open the **Resource Manager**, if it isn't open already.
- Click on the  **Assets** tab.
- Open a folder in the Explorer pane by double-clicking on the folder icon.

You can now navigate around the folder in the Explorer pane and choose images, cascading style sheets, scripts, and dynamic HTML to insert into your Web page. You can view the selected object in the Contents pane.

When you have found an object that you want to put into your Web page:

- If the object is one that will be inserted at a specific location in the document (for example, an arrow or bullet) drop it at the desired location.
- If the object is one that the Resource Manager intelligently inserts by generating the appropriate HTML markup (for example, a background image or color) just drop it anywhere in the document.

You can do an ordinary drag and drop with any image by **right-clicking** on the object and dragging and dropping it.

Downloading Web objects from hmfx.com

The **remote** folder enables you to connect to SoftQuad's **hmfx.com** Website to download Web objects to insert into your Web page (you must have an active Internet connection in order to reach this site). To connect to this site using the **remote** folder:

- Open the **remote** folder in the Explorer pane, by double-clicking on the folder icon.
- Open the **hmfx.com** folder. You will be connected to SoftQuad's **hmfx.com** Website.

You can now navigate around the **hmfX.com** Website and choose images, cascading style sheets, scripts, and dynamic HTML to insert into your Web page.

When you have found an object that you want to put into your Web page:

- Click on the object and drag it onto the HoTMetaL PRO document window just as you would from any of the other asset folders.

SoftQuad will update the **hmfX.com** Website with new Web objects for you to download and use in your Web pages. Check the **hmfX.com** Website often.

Creating your own assets

Over time you may wish to build up your own collection of assets and incorporate them into the Resource Manager collection, in order to take advantage of its 'intelligent insertion' capabilities. You should store these files in new or existing folders underneath the **myassets** folder.

Creating a new folder in the My Assets folder

In the **myassets** folder you can create your own folders to organize and categorize Web objects to insert into your documents. It is recommended that you add folders only to **myassets**. To create a new folder in the **myassets** folder:

- Click on the  tab in the **Resource Manager**. The Assets tab opens.
- Open the **myassets** folder.
- Right-click on the **myassets** folder and choose **New Folder** from the pop-up menu. The **New Assets Folder** dialog box appears.
- Enter a name for the new folder in the **Folder Name** text box.

When you create a new folder in **myassets**, you must specify what types of objects you are going to put in that folder.

- Choose an asset type from the **Type of Assets** pull-down menu. If you will be saving more than one type of object in this folder, choose **Assorted**.
- Click on **OK**. The new folder appears in the **myassets** folder.

You can now drag and drop objects from the Desktop tab or HoTMetaL PRO document window into the new folder.

The Asset tab's contents correspond to the folder **Assets** in the HoTMetaL PRO 5.0 folder. If you add a folder to this folder using Windows Explorer, and click on the new folder in the Explorer pane of the Assets tab, the Contents pane will display a 'Convert to Assets' page. Click on the **Convert** button in this page to perform the conversion. You will be prompted to choose specific files and the Asset type.

Note: You can change the top-level folder displayed in the Assets tab by changing the **assets_path** setting in the **Windows\hmp5.ini** file.

Renaming a folder in My Assets

To rename a folder in **myassets**:

- Click on the folder to select it.
- Choose **Rename** from the **Edit** menu, or right-click on the folder and choose **Rename** from the pop-up menu, or click on the name of the folder.
- Type in the new name for the folder and press **Enter**.

Deleting a folder in My Assets

To delete a folder in **myassets**:

- Click on a folder to select it.
- Right-click and choose **Delete** from the pop-up menu. The folder is deleted.

Storing objects in the My Assets folder

You can add assets to folders in the **myassets** folder. If the asset you wish to add doesn't fit into the existing categories in the **myassets** folder, you can create a new subfolder to contain them. To put an object in an folder in the **myassets** folder:

- Click on the  tab in the **Resource Manager**.
- In the Explorer pane, navigate through your system for the object that you want. Files are displayed in the bottom pane, the Contents pane.

- Click on the object and drag it onto the  tab. The **Assets** tab will open.

If the assets folder into which you want to drag the object is currently open in the Contents pane, you can simply drop it at the desired location. If the desired folder isn't open, you can navigate to it in the Explorer pane:

- Without releasing the mouse button, drag the pointer over the Explorer pane.
- If the folder you want is not visible, move the pointer to a position just above the bottom (or just below the top) of the pane, and the pane will scroll.
- When the desired folder is visible, move the pointer over it.
- If the pointer turns into a 'no' sign, you cannot drop the file directly into this folder (because it has sub-folders) but if you hover over the folder for several seconds, it will open up and display its subfolders.

You can repeat this process until you get to a drop-capable folder.

- Drop the object.
- If the folder has been assigned an asset type of **Assorted**, a dialog box will appear prompting you to select the type of asset the object is (for example, clip art). Enter a description for the object in the **Description** text box and click **OK**.
- For certain object types, you will be prompted to enter some extra information about the object; for example, alternate text for an image. Enter this information and click on **OK**.

The object that you selected will appear in the Contents pane.

You can put as many files as you like into a folder by dragging and dropping them.

Deleting Web objects in a folder

To delete Web objects (images, cascading style sheets, scripts, or dynamic HTML) in the **myassets** folder:

- Right-click on the Web object (image, cascading style sheet, script, or dynamic HTML) in the **Contents pane** and choose **Delete** from the pop-up menu. The Web object is deleted.

Note: Animated GIF images place a heavy resource load on the browser window used to display asset pages. It is strongly recommended that you place no more than 3-5 animated GIFs on any asset page, and that you do not 'Convert to Assets' any folder containing more than 3-5 animated GIFs. Displaying in rapid succession a series of pages with animated GIFs is also not recommended.

The Desktop tab

Desktop gives you access to your PC's desktop. You can choose Web objects from your system to put into your Web pages, or save in the collection in the **Assets** tab.

Note: Microsoft Internet Explorer must be installed on your PC in order for the full Desktop tab functionality to be available.

Browsing in the Desktop tab

To browse in the Desktop tab:

- Click on the  button, or choose **Resource Manager** from the **View** menu to open the **Resource Manager**, if it isn't open already. The **Resource Manager** window opens.
- Click on the  tab in the **Resource Manager**.

The top pane of the Desktop tab is called the Explorer pane. This is where you can browse for files on your system. Its navigation is similar to **Windows Explorer**.

The bottom pane of the Desktop tab is called the **Contents pane**. This is where you can view files in various formats.

The Resource Manager toolbar lets you navigate through folders, create new folders, create file filters, and choose view formats for thumbnails.

The Resource Manager toolbar

Navigating in the Explorer pane

To navigate in the Explorer pane, you can:

- Click on a folder to open it in the Contents pane.
- Double-click on a folder to expand it.
- Click on the  icon to expand a folder, or click on the  icon to contract it.

Use the scrollbars to scroll up or down in the Explorer pane.

Use the  button in the **Resource Manager** toolbar to go up one folder in the folder tree.

Creating a new folder

To create a new folder:

- Click on the  button, or right-click in the Contents pane and choose **New Folder** from the pop-up menu.
- Enter a name for the folder and press **Enter**.
- To move or copy files to the new folder, just select, drag, and drop them as you normally would.
- To update the **Desktop** tab, click on the  button, or right-click in the Contents pane and choose **Refresh** from the pop-up menu.

Creating file filters

You can select specific types of files to be viewed in the Contents pane using the **File Filter** menu. For example, if you want only **.gif** images to be displayed in the Contents pane:

- Select the Contents pane by clicking on it.

- Click on the  button. The **Add New File Filter** dialog box appears.
- Enter *.gif in the text box. The asterisk indicates that any file name with a .gif extension will be displayed in the Contents pane. By default, all file types (*.*) are displayed in the Contents pane.

Click on the  button to show all files in the folder.

The  button opens a drop-down menu that lets you select file filters that have been added.

Thumbnail view options

You can select different thumbnail view options from the Resource Manager toolbar. To select different thumbnail view options:

- Click on the  arrow icon from the **Resource Manager** toolbar.

You can choose the following views from the pull-down menu:

- **Large Icon** – shows the files with large icons.
- **Small Icon** – shows the files with small icons.
- **List** – shows the files in a list format.
- **Details** – shows each file's name, size, file type, modification date, and attributes.
- **Thumbnail** – shows image files as thumbnails.

- Choose **Thumbnail** to view the files as thumbnail images, or click repeatedly on the  button to cycle through the different viewing options.

You can increase the size of the thumbnails in the Contents pane:

- Click on the  icon in the menu to make the thumbnails bigger or click on the arrow beside the magnifying glass

and select the size that you want the thumbnails to appear. Click on

to make the thumbnails smaller.

The image pop-up menu

Ulead PhotoImpact SE is shipped with HoTMetaL PRO 5.0, but not with the Evaluation Version that you are now using. Therefore, when you choose **Edit Image File** or **View Image File**, HoTMetaL PRO will try to carry out one of the following actions, in the order given:

- If you have associated a [helper application](#) with the file extension of the current image, that application will be launched.
- If you have selected a default image editor by choosing **Image Editor** from the **Tools** menu, that application will be launched.
- Otherwise, you will be prompted to choose an application.

When you right-click on an image in the HoTMetaL PRO document window the image pop-up menu is displayed:

- **Edit Image File** – Starts the image editor and loads the image file. The default image editor is Ulead PhotoImpact SE. You can choose different [helper applications](#) for editing specific image types from the **Options** dialog .
- **View Image File** – Starts the image viewer and displays the image file. The default image viewer is Ulead PhotoImpact Viewer SE. You can choose different [helper applications](#) for viewing specific image types from the **Options** dialog.
- **Image Properties...** – Brings up the [Image Properties](#) dialog.
- **Select Element** – Selects the IMG element to cut or copy.
- **Attribute Inspector** – Lets you edit all of the properties of the IMG element, including [extensions](#).

[More on this topic](#)

Choosing helper applications

You can change the default editor and viewer for a particular image type from the **Options** dialog. These applications will be launched instead of the default when you choose **Edit Image File** or **View Image File** for a file of that type.

- Choose **Options...** from the **Tools** menu.
- Click on the **Helper Apps** tab.
- Enter the file extension for the image type in the **File Extension** text box. If files of that type could have more than one extension (for example, **.jpg** and **.jpeg**), you will have to make a separate entry for each.
- Click on **Add New Type**.
- You can choose an editor, viewer, or both. Enter the locations and filenames of the desired applications in the **Viewer** and **Editor** text boxes (you can use the **Choose...** button to select them).
- Click on **OK**.

Creating 'hot images'

A 'hot image' is a hypertext link from an image rather than from some text. You can use images to link to Internet destinations, start scripts, and other events that you can start by clicking in a browser.

To make an image 'hot':

- Do one of:
 - In Tags On view, select the image by clicking on the image tag.
 - In WYSIWYG view, right-click on the image and choose **Select Element** from the pop-up menu.
- Click on the  (**Insert Link**) toolbar button, choose **Link...** from the **Insert** menu, or press **Ctrl+K**.

This brings up the **Insert Link** dialog box.

- Type the destination of the link (URL) in the **Insert Link** dialog box.
- To prevent the browser from displaying a link color border around the 'hot' image, set the value of the image's BORDER attribute to 0 (zero) using **Attribute Inspector**.
- Double-click on the image to bring up the **Image Properties** dialog.
- Set **Border** to 0 (zero) if it doesn't have that value already.

Note: While you can have images outside of block elements such as paragraphs, you cannot have link elements outside of block elements. If HoTMetaL PRO prevents you from inserting the link around the image, first surround the image with a paragraph, header, or other block element.

Inserting multimedia files

HoTMetaL PRO supports elements and attributes for inserting multimedia files such as sound and video, as well other special formats (for example, ShockWave) that require plug-ins in order to be displayed in the browser.

To insert any element referred to here, choose **Element...** from the **Insert** menu.

To edit the attributes of an element, put the insertion point inside the element and choose **Attribute Inspector** from the **View** menu.

It is easiest to work with this kind of element if you switch to Tags On view.

Sound files

Some common sound formats are MIDI, WAV, and AU. Netscape browsers use the EMBED element to represent sound files. Microsoft Internet Explorer uses the BGSOUND element. BGSOUND must be inserted before any 'block' elements in the document. The attributes of BGSOUND are:

- SRC: the URL of the sound file.
- LOOP: how many times the file plays (the value -1 or INFINITE causes it to play over and over).
- DELAY: the number of seconds between each repetition.
- TITLE: an identifying title.

Normally you should use both EMBED and BGSOUND so that your file can be played by both types of browsers.

Video

Video files often require a browser plug-in in order to be displayed. If in doubt, you should contact the vendor for the file format that you wish to use, to obtain details on the markup (elements and attributes) required for that format, and any plug-in(s) required to display it.

Microsoft Internet Explorer and the Netscape browsers use the EMBED element to represent video files. Internet Explorer also supports the IMG element for playing some video formats. The following IMG attributes are used for video:

- DYN SRC – the URL of the video file.
- START – This attribute specifies when the video file will be played. The value FILEOPEN causes this to happen as soon as the HTML document is opened; the value MOUSEOVER causes the video to be played when the mouse cursor is over the animation. If you supply both values, the video will be played in both situations.
- CONTROLS – If this attribute has the value CONTROLS, a set of controls will be displayed under the video.
- LOOP – Specifies how many times the video should be played. The value '-1' or INFINITE will cause it to be played over and over.

Other multimedia formats

Other multimedia formats (for example, ShockWave) require a browser plug-in in order to be displayed. If in doubt, you should contact the vendor for the file format that you wish to use, and to obtain details on the markup (elements and attributes) required for that format, and any plug-in(s) required to display it.

Microsoft Internet Explorer and the Netscape browsers use the EMBED element to represent multimedia files.

[More on this topic](#)

Inserting multimedia files with EMBED

Web browsers let you use the EMBED element to insert a 'object' in an arbitrary format (sound, movie, etc.) into the document. These objects will be processed by 'plug-in' applications. The essential attributes of EMBED are:

- SRC – The URL of the file to be embedded.
- HEIGHT – The height of the displayed image.
- WIDTH – The width of the displayed image.
- NAME – giving the object a target name allows other objects and elements to refer to it.

The following EMBED element attributes are currently used only by Netscape Navigator:

- ALIGN – Sets the alignment of the text around the controls in the same way as the ALIGN attribute in the IMG element. It can have the same values: TOP, BOTTOM, CENTER, etc.
- BORDER – Specifies the width of the border (in pixels)
- FRAMEBORDER – If this attribute has the value NO, no border will be drawn around the object
- HSPACE – Specifies extra space that the browser draws to the right and left of the embedded object (in pixels)
- PALETTE – An embedded graphical object uses either the foreground or background color palette. Choose FOREGROUND or BACKGROUND. (The default is BACKGROUND.)
- PLUGINSOURCE – Allows you to specify a URL from which the user can download the necessary plug-in.
- TYPE – Specifies the MIME-type. Either this attribute or the SRC attribute must have a value.
- UNITS – Specifies whether WIDTH and HEIGHT values are to be interpreted as pixels or en dashes.
- VSPACE – Specifies extra space that the browser draws above and below the embedded object (in pixels)

The following EMBED element attributes apply only to Netscape Navigator's **LiveAudio** plug-in:

- AUTOSTART – Setting the attribute value to TRUE starts playing the sound automatically when the page is loaded into Netscape Navigator. The default is FALSE.
- STARTTIME – Designates where in the sound file to begin playback. For example, to start playing the file at the forty-five second mark, enter '00:45'. (This will work only for the Windows 95, Windows NT, and Macintosh versions of Netscape Navigator.)
- ENDTIME – Designates where in the sound file to end playback. For example, to finish playing at the one minute mark, enter a value of '01:00'. This is an absolute time measured from the beginning of the sound file; it is not the time elapsed from the STARTTIME attribute value. (This will work only for the Windows 95, Windows NT, and Macintosh versions of Netscape Navigator.)
- HIDDEN – Hides the controls for an embedded sound object (this attribute may work for other types of EMBED elements, as well). You should give this attribute a value of TRUE to hide controls and have the sound file load as a background sound. (The attribute FALSE is not valid—if you don't want to hide the object controls, do not include the HIDDEN attribute.)
- CONTROLS – Defines which control will appear in the Web browser for a given embedded object. This attribute can have the values CONSOLE, SMALLCONSOLE, PLAYBUTTON, PAUSEBUTTON, STOPBUTTON, and VOLUMELEVER. The default is CONSOLE. Only one control is allowed in each EMBED element. To have more than one control for a single sound or video, you must use separate EMBED elements with the same NAME attribute. Netscape's page on LiveAudio explains how to use multiple controls.
- HEIGHT – Sets the value of the height of the console or control, in pixels. The default values of the controls are:

```
CONSOLE 60
SMALLCONSOLE 15
VOLUMELEVER 20
BUTTON 22
```

- WIDTH – Sets the value of the width of the console or control, in pixels. The default values of the controls are:

```
CONSOLE 144
SMALLCONSOLE 144
VOLUMELEVER 74
BUTTON 37
```

- MASTERSOUND – When using multiple controls for a single embedded sound, this attribute denotes which EMBED element's SRC attribute refers to the main sound file. This attribute is required when you use multiple controls. Netscape's page on LiveAudio explains how to use multiple controls for that plug-in.
- NAME – Assigns a name to the embedded sound or control. In the case of multiple controls for a single sound, you must assign each of the controls the same name. Netscape's page on LiveAudio explains how to use multiple controls for that plug-in.

Netscape Navigator also allows you to insert variable or application-specific attributes in the EMBED element. These cannot be represented in SGML and therefore are not supported by HoTMetaL PRO's WYSIWYG view or Tags On view. If you want to insert such attributes, you should open the HTML file in HTML Source view and insert the attributes manually, inside the EMBED start-tag. The file will not validate if you switch to Tags On or WYSIWYG view; HoTMetaL PRO will attempt to 'fix' the application-specific attributes.

Images and accessibility

While images are part of what makes the Web so popular, many people either cannot, or do not wish to, view images on the Web. Some of these people do so by choice, either turning the image display options off in their browsers, or using text-only browsers such as Lynx. On the other hand, users with visual impairments require assistive technology, such as screen readers, which generally cannot interpret images. There are a few simple things you can do to ensure that you make your pages accessible to people who cannot or do not wish to view images.

If you have **Prompt for Accessibility** turned on in the **General** tab of the **Options** menu, the **Image Properties** dialog will contain an Accessibility panel. It also prompts you to enter an alternate description of the image. This description should be brief, but at the same time meaningful; that is, simply putting **graphic** in the alternate text box won't help users understand what the graphic's purpose is while putting **graphic: SoftQuad logo** will.

HoTMetaL PRO was designed with accessibility issues in mind. The Accessibility panel gives you the option of writing a more detailed description of the image. This description is saved in an HTML file; HoTMetaL PRO generates a link to this file and places it next to the image in your document.

To add a detailed description in the **Accessibility** panel:

- Click on **Description...** in the Accessibility panel; this brings up a text box.
- Type a detailed description of the image, including the information it conveys to the viewer.
- Type a file name for the image, the default is the image filename plus **'-desc'**.

The description is saved as an HTML file. You can also choose an existing file by clicking on the **Choose...** button. (Some authors prefer to keep all the descriptions in a single file, rather than adding a number of small files to the site.) HoTMetaL PRO will insert a small letter 'd' (which links to the description page) beside the image.

Creating clickable image maps

Image maps (or clickable image maps) are images that have been divided into regions; clicking in a region in a browser causes an action to occur (usually a link to another location). There are two types of image maps: client-side and server-side.

With client-side image maps, all of the information required for the browser to process the image map is contained in the document itself. This information includes a list of the co-ordinates that define the mapping regions, and the actions (for example, hypertext links) they are associated with. With server-side image maps, this information is in a separate **map file**.

Most Web browsers support server-side image maps, and client-side image maps are now also widely supported. You can use both a server-side and a client-side image map for the same image: if the browser accepts client-side image maps, then they will take precedence over server-side image maps.

Good HTML style involves giving users who do not have access to image map features an alternate way of accessing the pages that are linked to in an image map, for example, a text-only list. For more information see the accessibility help for [client side](#) and [server side](#) image maps.

[More on this topic](#)

Server options for server-side image maps

There are two different types of Web servers: NCSA and CERN, and they require slightly different server-side map file formats. Before you create any server-side image maps, specify your server type (you may need to obtain this information from your ISP or system administrator):

- Choose **Options...** in the **Tools** menu.
- Click on the **General** tab.
- In the **Image Map Files** group in the lower right corner of the tab, choose one of **Save in NCSA format** and **Save in CERN format**.
- Click on **OK**.

Creating image maps

To create an image map:

- Right-click in the background of the toolbar area and choose **Image Mapping** from the pop-up menu.
- Click on the image that you want to use as an image map.

The image mapping toolbar provides tools for defining 'hot' areas of different shapes: circle, rectangle, and polygon.

To define an image map area:

- Click on the toolbar button for the desired shape.
- Move the mouse pointer over the image; the pointer will turn into a crosshair.
- Click and drag the pointer to create the map area.
- When you have defined the area, release the mouse button.

The **Enter URL information** dialog box appears. The following fields are available:

- **URL:** the location of the document the area will link to.
 - **Comments:** a comment in the MAP element or map file to describe the link.
 - **Alternate Text:** alternate text describing the map areas, for text-only browsers and accessibility.
 - **Target Frame:** targets a particular frame of a FRAMESET to load the linked document.
- When you have entered the information in the dialog box, click on **OK**.

If this is the first region that you've defined for this image, the **Image Map Options** dialog appears.

The **Image Map Options** dialog specifies whether to save the image map information as a server-side image map (ISMAP), a client-side image map (USEMAP), or both.

Client-side

To create a client-side image map:

- Turn on the **UseMap** check box in the **Save Image Map** dialog box; the **UseMap name** text box will now accept text.
- You can give the image map a name in the **UseMap name** text box, or accept the default.
- Click on **OK**.

For more information on client-side image maps, see [Background: Client-side image maps](#) .

Server side

To create a server-side image map:

- Turn on the **Server-side Image Map** check box in the **Image Map Options** dialog box; the adjacent text box will now accept text.
- Type a file name and path for the mapping file or click on **Browse...** to choose an existing mapping file.

For more information on server-side image maps, see [Background: Server-side image maps](#) .

Changing an image map

To move an existing image map region:

- Click on the region and drag it to the desired new location in the image.

To edit the URL information for a region (that is, display the **Enter URL Information** dialog box again):

- Double-click on the region.

To display the **Image Map Options** dialog box for an existing image map:

- Right-click on the image and choose **Image Properties...** from the pop-up menu.
- In the **Image Properties** dialog box, click on the **Edit Image Map Name...** button.

To display all of the defined regions in an image map:

- Click on the  toolbar button.

Background: Client-side image maps

Client-side image maps are generally faster than server-side image maps because the browser does the work, not the server. All of the links for a client-side image map are specified in a MAP element, which is usually in the same HTML document as the image.

The MAP element contains one or more AREA elements, each of which defines a region in the image map. An AREA has the same function as a line in an image map file. AREA doesn't have any content: all of the information is contained in its attributes.

MAP has an attribute called NAME: the value of this attribute is the map name, a string of characters that is used to identify the MAP. The USEMAP attribute of the corresponding IMG element has the same value as the map name (with '#' prepended). This is how the browser knows which MAP to associate with a particular image.

If you create a client-side image map with HoTMetaL PRO, the program creates the MAP and AREA elements and map name for you, and sets the USEMAP attribute to point to the MAP element.

For example, if you defined areas on an image, specified the target links, and chose the default name **map1**, HoTMetaL PRO creates a MAP element with the NAME **map1** and sets the USEMAP attribute of the image to **#map1**.

For convenience, HoTMetaL PRO places the MAP element directly after the corresponding IMG element. The MAP is not displayed in the browser window.

Associating images with external MAP elements

It is possible to create and reference MAP elements in other documents. To do this you have to edit the USEMAP attribute of the image to point to the document containing the MAP element. For example, if you use the same image map in a number of documents, you may want to have the map element in just one of the documents. The USEMAP attribute of the image would consist of the URL followed by a '#' plus the name of the map. For example:

```
../public_html/index.html#map
```

Background: Server-side image maps

When you specify a server-side map, the image is surrounded by a link element (A) that associates the map file with the image. You are generally going to be creating a map file on your PC, and you will have to upload the file to your service provider so that it works on the Web. The following instructions apply to setting the URL (location) of the anchor which surrounds the image so that it points to the map file on the server.

In order to understand what's going on here you have to know that there is a program called **imagemap** on the server, which reads your image map file whenever someone clicks on the image. The browser sends the program the co-ordinates of the point that was clicked on. The **imagemap** program determines which **region** in the image was clicked on, and on the basis of this, tells the server which URL to access.

You use a URL to associate the image map file with your image. This URL tells the server two things:

- The location (server address and folder) of the **imagemap** program.
- The symbolic name for your image map file.

A typical location for the **imagemap** program is the **cgi-bin** folder on the server. In this case, the URL (in an A element) would look something like this:

```
http://www.my-isp.com/cgi-bin/imagemap/triptych
```

(Here 'triptych' may look like a filename, but it's actually the symbolic name of the image map file).

You will have to edit the URL of the anchor that has been created, so that it points to the correct position on the server.

- Change the URL of the A element surrounding the image to a value such as the one in the example above.

The image that you applied the mapping to will have its ISMAP attribute set. This tells the server that this element points to a server-side imagemap.

Server-side image maps: informing the server

Not all Web servers deal with image maps in exactly the same way. For this reason, the instructions given here **may not work** for your server. The following discussion is based on the Unix NCSA **httpd** server. You should consult your server's documentation if you're unsure whether something applies.

Once you've created the image map file, you need to tell the server where it is. If you're using the Unix NCSA **httpd** server, you would do this by making an entry in the file **imagemap.conf** in the **conf** folder on the server. (You'll have to find out from a local administrator where the server folder is located.) If you're using a different server, the filenames given in this section may not be correct: you should consult the server documentation or talk to an administrator.

The **imagemap.conf** file consists of entries that associate a **symbolic name** with every image map file known to your server. One line describes each map. You can choose whatever symbolic name you wish to use. In this example, the symbolic name is **triptych**, and the image map file is in **/home/iaain/public_html/heads.map**. You should put the following line in the **imagemap.conf** file:

```
triptych: /home/iaain/public_html/heads.map
```

If someone else is administering the server, you may not be able to update this file yourself. You'll still have to choose a symbolic name for your image map file, because this name is used in the next step.

Image tips and tricks

You can try lots of different things to make your pages work better and look better. Some of the following are supported only by specific browsers, so you should make sure they look acceptable in other browsers before you include them in public pages. The following are just a few tricks:

- **Resizing logos to speed download time** – If you have the same logo in different sizes throughout your site, try using the same source image for all of the tags, and set the HEIGHT and WIDTH properties to do the resizing for you. This works better with some images than others, so you should check to make sure it works. This means that users will only have to download a single image (which will be stored in their browser's cache) and let the browser do the work.
- **Removing borders for 'hot' images** – If you have created a 'hot' image (an image that is also a hyperlink), your image may be displayed with a link-color border around it in a Web browser. This is because if you don't specify a border for your images, the browser assumes that a border is implied and will display it for linked images. To remove the border, set the BORDER attribute to 0 (zero) using the **Attribute Inspector**.
- **Using the VSPACE and HSPACE attributes for layout** – The ability of some browsers to create absolute pixel spacing surrounding an image can give you greater control over how your pages appear. Experiment with different values for the VSPACE and HSPACE attributes to create 'whitespace' around your images.
- **Using percentage values for height and width properties** – Some browsers (for example, Netscape Navigator) accept percentage values for the HEIGHT and WIDTH properties. The percentage value represents a percentage of the window size. This can be useful for graphical horizontal rules that resize with the window; for example, you could use a **Height** of 3 (pixels) and a **Width** of 100%.

Scrolling 'marquees'

A scrolling marquee is a piece of text that scrolls across a rectangular area that you define in the browser window. You specify the height and width of the marquee area, and then (if desired) specify margins. The scrolling text will be visible between the margins. Surrounding text can be aligned with the marquee area as you wish.

Note: Marquees are not supported by all Web browsers. Use this feature with caution, and make sure that all marquee documents contain markup readable by all browsers.

To create a marquee:

- Insert a MARQUEE element (using **Element...** in the **Insert** menu).
- Between the tag icons, enter the text that you want scrolled.

The attributes of MARQUEE tell the browser exactly how the text will be displayed and scrolled. You can edit these attributes the **Attribute Inspector** in the **View** menu.

- ALIGNMENT – how the surrounding text is aligned with the marquee text (TOP, MIDDLE, or BOTTOM).
- BEHAVIOR – specifies the type of movement of the text. The choices are:
 - SCROLL – continuous scrolling on and off the screen (the default)
 - SLIDE – the text scrolls until one end reaches the margin
 - ALTERNATE – the text 'bounces' back and forth between the margins
- BGCOLOR – background color of the marquee area.
- DIRECTION – direction (LEFT or RIGHT) that the text scrolls. LEFT is the default.
- HEIGHT – height of the marquee area, in pixels (n), or as a percentage of the window height (n%).
- HSPACE – width of the left and right margins, in pixels.
- LOOP – the number of times the text will scroll. If this attribute has the value '-1' or INFINITE, the text will scroll 'infinitely'.
- SCROLLAMOUNT – the number of pixels between successive scrolls of the text.
- SCROLLDELAY – the time in thousandths of a second between successive scrolls of the text.
- VSPACE – the height of the top and bottom margins, in pixels.
- WIDTH – width of the marquee area, in pixels (n), or as a percentage of the window width (n%).

Working with tables

What you'll learn in this chapter

Tables in HTML documents are used to present information that is naturally tabular, and to perform [page layout](#).

All of HoTMetal PRO's commands for [inserting](#) and modifying tables are in the **Table** menu. These commands can also be accessed from the **Table** toolbar. You can edit some table properties by right-clicking on a table and choosing commands from the pop-up menu.

You can [add](#) and [delete](#) rows and columns from an existing table, [move](#) rows and columns, [resize](#) rows and columns, [merge](#) and [split](#) cells, and set various [table properties](#). HoTMetal PRO provides keyboard commands for [moving around](#) in a table. Tabular material in other applications can be [pasted or dragged](#) into a HoTMetal PRO document.

Reference

[More on this topic](#)

Inserting a table

To insert a table:

- Put the insertion point where you want to insert the table.
- Click on the  toolbar button, or choose **Insert Table...** from the **Table** menu.

In the **Insert Table** dialog box, you can insert the table and set some of its properties.

Each cell in a newly-created table will contain an nbsp character. This is a 'non-breaking space' character and ensures that the cell will be displayed in a browser even if it has no content. You can delete these characters if you wish. In HoTMetal PRO you can see these characters only in Tags On and HTML Source view.

- Enter the number of rows and columns that the table should have initially. You can add and delete rows and columns later.
- If desired, set the table properties. You can also [set them later](#).

Setting table properties

You can set table properties (that is, those that apply to the whole table) from the **Insert Table** dialog box when you insert a table, or you can edit the properties of an existing table.

To edit the properties of an existing table:

- Put the insertion point anywhere inside the table.
- Do **one of** the following:
 - Right-click and choose **Table Properties...** from the pop-up menu.
 - Click on the  toolbar button.
- Choose **Table Properties...** from the **Table** menu.
- Now click on the **Table** tab in the **Table Properties** dialog that appears.

You can also set the properties of individual rows, columns, and cells by clicking on the **Row**, **Column**, or **Cell** tabs, respectively.

You can set the following table properties:

- **Default Background Color** – The table's background color. Click on ... to bring up the Windows **Color** dialog. The color you select will be expressed as a hexadecimal red-green-blue value. You can also enter this hexadecimal value directly in the text box. You can enter a color name (red, green, etc.) in the text box, but remember that not all browsers support colors expressed in this way.
- **Width** – You can specify the table width as an absolute number of **Pixels** or as a **Percent** of the document width.
- **Border** – The lines that form the boundary of each table cell when the file is displayed in a browser.
 - Turn on **Grid**, and enter a **Width** of 1 or greater if you want to have a visible border.
 - Turn on **Grid**, and enter a **Width** of 0 if you want the lines in the border to have zero width.
 - Choose **None** if you want the border to be transparent.

Most browsers do not draw borders around empty table cells. A useful way of giving an empty cell 'invisible' content, thereby forcing the browser to display the border, is to insert a 'non-breaking space' into the cell, by pressing **Ctrl+Shift+Space**. A non-breaking space is displayed as an ordinary space in WYSIWYG view, and as an nbsp icon in Tags On view. HoTMetaL PRO inserts non-breaking spaces in the cells of new tables.

If a table has an 'invisible' border (that is, no border or a zero-width border) you can show or hide the dotted lines representing the border in the HoTMetaL PRO document window by choosing **Show/Hide Table Grid** from the **View** menu, or pressing **Ctrl+Alt+Q**. This does not affect how the table is displayed in a browser.

Some browsers support the FRAME and RULES attributes (see below) for more specific border drawing.

- **Cell Spacing** – This is the space (in pixels) between cells. If you want cells to touch (that is, there will be no space between cells), set both the cell spacing and the border to '0' (zero).
- **Cell Padding** – This is the space (in pixels) between the text of the cell and the cell border.

There are several other table properties that can be set by editing the attributes of the table.

[More on this topic](#)

Setting table properties by editing attributes

All table properties can be set by editing attributes. The most common properties can also be set by choosing [Table Properties...](#). This section describes table properties that can be set only by editing the attributes of the table.

To edit attributes, do one of the following:

- Place the insertion point to the right of the [TABLE> start-tag in [Tags On](#) mode and choose **Attribute Inspector** from the **View** menu.

Or:

- Place the insertion point anywhere in the table and choose **Attribute Inspector** from the **View** menu.
- Choose **TABLE** from the **Element** list at the top of the **Attribute Inspector** dialog box.

Not all attributes will be recognized by all browsers. The attributes that you can change are:

- NOWRAP – Text will not wrap in table cells if this feature is turned on. This can create some very large table cells that scroll off the Web browser's window, so use this feature with caution.
- BORDERCOLOR, BORDERCOLORLIGHT, BORDERCOLORDARK – Set the color of the border, or, for 3D (shadow-style) borders, set two different colors for the 'light' and 'dark' areas of the border.
- VALIGN – Sets the vertical alignment of all cells in the table to **top**, **middle**, or **bottom**. You can also set the vertical alignment of data within individual [rows](#), [columns](#), and [cells](#).
- HEIGHT – Sets the height of the table in pixels or in percentage of the document height.
- ALIGN – Tables can have alignment values of RIGHT, LEFT, CENTER, JUSTIFY (right and left alignment), BLEEDLEFT, and BLEEDRIGHT. These values determine how the entire table (**not** data within cells) is aligned in the document window. You can also set the alignment of data within individual [rows](#), [columns](#), and [cells](#).
- COLS – Specifies the number of columns in the table. This allows the browser to begin rendering the table before the whole table has been read.
- FRAME – Specifies which part(s) of the table border will be drawn by the browser. The possible values are:
 - VOID: no border
 - ABOVE: top border only
 - BELOW: bottom border only
 - HSIDES: top and bottom only
 - VSIDES: right and left sides only
 - LHS: left side only
 - RHS: right side only
 - BOX: all four sidesOnly one value for FRAME can be specified.
- HSPACE – Extra horizontal space around the table (in pixels).
- RULES – Specifies where rules (separators) will be drawn by the browser. The possible values are:
 - ALL: draw all separators
 - COLS: draw column (vertical) separators only
 - NONE: no separators
 - ROWS: draw row (horizontal) separator onlyOnly one value for RULES can be specified.
- VSPACE – Extra vertical space around the table (in pixels).

Setting table row properties

To specify the properties for a single table row:

- Put the insertion point inside the row whose properties you want to modify.
- Do one of the following:
 - Right-click and choose **Table Properties...** from the pop-up menu.
 - Choose **Table Properties...** from the **Table** menu.
- Click on the  toolbar button.
- Click on the **Row** tab in the **Table Properties...** dialog that appears.

You can set the following properties:

- **Color** –The background color of the row. Click on ... to bring up the Windows **Color** dialog box. The color you select will be expressed as a hexadecimal red-green-blue value. You can also enter this hexadecimal value directly in the text box. You can enter a color name (red, green, etc.) in the text box, but remember that not all browsers support colors expressed in this way. Most browsers do not display the background color of empty table cells. A useful way of inserting 'invisible' content in an empty cell, thereby forcing the browser to display the background, is to insert a 'non-breaking space', by pressing **Ctrl+Shift+Space**.
- **Vertical Alignment** – Where the cell contents are positioned vertically. **Top**, **Middle**, and **Bottom** are standard choices; if you choose **Other** you can enter an arbitrary vertical alignment value (this is to allow for enhancements to alignment support in various browsers; make sure that any value you enter is supported by the appropriate browser).
- **Horizontal Alignment** – Where the cell contents are positioned horizontally. **Left**, **Center**, and **Right** are standard choices; if you choose **Other** you can enter an arbitrary horizontal alignment value (this is to allow for enhancements to alignment support in various browsers; make sure that any value you enter is supported by the appropriate browser).
- **Height** – You can specify cell height as an absolute number of pixels. Setting the height in the **Row** tab automatically sets the heights of all cells in the current row. If you set the heights of individual cells, the browser will display the row using the height of the highest cell.
- **Cell Type** – You can specify that all cells in the row will be of the type **Data Cell** (the normal type of table cell) or **Header Cell** (the contents will be centered and displayed in bold). Header cells will most frequently be used in the top row and the left-most column.

Setting table column properties

To specify the properties for a single table column:

- Put the insertion point inside the column whose properties you want to modify.
- Do one of the following:
 - Right-click and choose **Table Properties...** from the pop-up menu.
 - Choose **Table Properties...** from the **Table** menu.
- Click on the  toolbar button.
- Click on the **Column** tab in the **Table Properties...** dialog that appears.

You can set the following properties:

- **Color** –The background color of the column. Click on ... to bring up the Windows **Color** dialog box. The color you select will be expressed as a hexadecimal red-green-blue value. You can also enter this hexadecimal value directly in the text box. You can enter a color name (red, green, etc.) in the text box, but remember that not all browsers support colors expressed in this way. Most browsers do not display the background color of empty table cells. A useful way of inserting 'invisible' content in an empty cell, thereby forcing the browser to display the background, is to insert a 'non-breaking space', by pressing **Ctrl+Shift+Space**.
- **Vertical Alignment** – Where the cell contents are positioned vertically. **Top**, **Middle**, and **Bottom** are standard choices; if you choose **Other** you can enter an arbitrary vertical alignment value (this is to allow for enhancements to alignment support in various browsers; make sure that any value you enter is supported by the appropriate browser).
- **Horizontal Alignment** – Where the cell contents are positioned horizontally. **Left**, **Center**, and **Right** are standard choices; if you choose **Other** you can enter an arbitrary horizontal alignment value (this is to allow for enhancements to alignment support in various browsers; make sure that any value you enter is supported by the appropriate browser).
- **Width** – You can specify cell width as an absolute number of **Pixels** or as a **Percent** of the document width. Setting the cell width in the **Column** tab automatically sets the widths of all cells in the current column. If you set the widths of individual cells, the browser will display the column using the width of the widest cell.
- **Cell Type** – You can specify that all cells in the column will be of the type **Data Cell** (the normal type of table cell) or **Header Cell** (the contents will be centered and displayed in bold). Header cells will most frequently be used in the top row and the left-most column.

Setting table cell properties

To specify the properties for a single table cell:

- Put the insertion point inside the cell whose properties you want to modify.
- Do one of the following:
 - Right-click and choose **Table Properties...** from the pop-up menu.
 - Choose **Table Properties...** from the **Table** menu.
 - Click on the  toolbar button.
- Click on the **Cell** tab in the **Table Properties...** dialog that appears.

You can set the following properties:

- **Color** –The background color of the cell. Click on ... to bring up the Windows **Color** dialog box. The color you select will be expressed as a hexadecimal red-green-blue value. You can also enter this hexadecimal value directly in the text box. You can enter a color name (red, green, etc.) in the text box, but remember that not all browsers support colors expressed in this way. Most browsers do not display the background color of empty table cells. A useful way of inserting 'invisible' content in an empty cell, thereby forcing the browser to display the background, is to insert a 'non-breaking space', by pressing **Ctrl+Shift+Space**.
- **Vertical Alignment** – Where the cell contents are positioned vertically. **Top**, **Middle**, and **Bottom** are standard choices; if you choose **Other** you can enter an arbitrary vertical alignment value (this is to allow for enhancements to alignment support in various browsers; make sure that any value you enter is supported by the appropriate browser).
- **Horizontal Alignment** – Where the cell contents are positioned horizontally. **Left**, **Center**, and **Right** are standard choices; if you choose **Other** you can enter an arbitrary horizontal alignment value (this is to allow for enhancements to alignment support in various browsers; make sure that any value you enter is supported by the appropriate browser).

Note: You can also set vertical alignment for table cells using the Formatting toolbar buttons for left, center, and right alignment.

- **Width** – You can specify cell width as an absolute number of **Pixels** or as a **Percent** of the document width. If you set the widths of individual cells, the browser will display the column using the width of the widest cell.
- **Height** – You can specify cell height as an absolute number of pixels. If you set the heights of individual cells, the browser will display the row using the height of the highest cell.
- **Cell Type** – You can specify that the current cell will be a **Data Cell** (the normal type of table cell) or a **Header Cell** (the contents will be centered and displayed in bold). Header cells will most frequently be used in the top row and the left-most column. You can also change the cell type for the current cell by right-clicking in the cell and choosing **Change to Header cell** or **Change to Data cell** from the pop-up menu.

Adding table rows and columns

You can add rows and columns to an existing table.

To add **one or more** rows or columns, from the **Table** menu:

- Put the insertion point in a row or column next to where you want to insert the new rows or columns.
- Choose **Insert Rows or Columns...** from the **Table** menu.
- Turn on one of **Insert Row Above**, **Insert Row Below**, **Insert Column Left**, and **Insert Column Right**.
- Enter the **Number of Rows** or **Number of Columns**.
- Click on **OK** or **Apply**.

To add **one** row or column, from the toolbar:

- Put the insertion point in a row or column next to where you want to insert the new row or column.
- Click on the appropriate toolbar button:
 -  – Add a new row above the current row.
 -  – Add a new row below the current row.
 -  – Add a new column to the right of the current column.
 -  – Add a new column to the left of the current column.

You can add a row to the bottom of a table by pressing **Tab** in the last cell of the last row in the table.

Deleting rows and columns

You can delete one row or column at a time from a table.

To delete a row from a table:

- Put the insertion point anywhere in the row that you want to delete.
- Click on the  (**Delete Row**) toolbar button, or choose **Delete Row** from the **Table** menu.

To delete a column from a table:

- Put the insertion point anywhere in the column that you want to delete.
- Click on the  (**Delete Column**) toolbar button, or choose **Delete Column** from the **Table** menu.

Moving rows and columns

You can move a table row up or down by one row, and move a table column left or right by one column.

To move a table row:

- Put the insertion point anywhere in the row that you want to move.
- Choose **Move Row or Column...** from the **Table** menu.
- In the dialog box that appears, turn on **Move Row Up** or **Move Row Down**.
- Click on **OK** or **Apply**.

Or:

- Put the insertion point anywhere in the row that you want to move.
- Click on the  (**Move Row Down**) or  (**Move Row Up**) toolbar button.

To move a table column:

- Choose **Move Row or Column...** from the **Table** menu.
- In the dialog box that appears, turn on **Move Column Left** or **Move Column Right**.
- Click on **OK** or **Apply**.

Or:

- Put the insertion point anywhere in the column that you want to move.
- Click on the  (**Move Column Left**) or  (**Move Column Right**) toolbar button.

Splitting cells

Splitting a cell means dividing one cell into two, either vertically (splitting into columns) or horizontally (splitting into rows).

To split a cell into two columns:

- Put the insertion point anywhere in the cell that you want to split.
- Click on the  toolbar button or choose **Split Cell into Columns** from the **Table** menu.

If the original cell had any content, it will be located in the left column after the split.

To split a cell into two rows:

- Put the insertion point anywhere in the cell that you want to split.
- Click on the  toolbar button or choose **Split Cell into Rows** from the **Table** menu.

If the original cell had any content, it will be located in the upper row after the split.

Merging cells

Merging cells means combining two adjacent cells into one cell.

To merge cells from the **Table** menu:

- Put the insertion point anywhere in one of the cells that you want to merge.
- Choose **Merge Cell...** from the **Table** menu.
- In the dialog box that appears, turn on one of :
 - **Merge Cell Up** – Merge with the cell above this one.
 - **Merge Cell Down** – Merge with the cell below this one.
 - **Merge Cell Left** – Merge with the cell to the left of this one.
 - **Merge Cell Right** – Merge with the cell to the right of this one.
- Click on **OK** or **Apply**.

To merge cells from the **Tables** toolbar:

- Put the insertion point anywhere in one of the cells that you want to merge.
- Click on one of:
 -  – Merge with the cell to the right of this one.
 -  – Merge with the cell to the left of this one.
 -  – Merge with the cell above this one.
 -  – Merge with the cell below this one.

The merge succeeds even if the current cell spans over two or more rows or columns. The reverse is not true, however: if the cell that the current cell is being merged with extends over more rows or columns (or a different set of rows or columns) than the current cell, the merge will not succeed, and HoTMetaL PRO will display an error message.

Contracting cells

Contracting a cell in a table pulls the boundary of a cell one cell to the left, right, top, or bottom. To contract a cell in a table:

- Right-click on the background of the toolbar area at the top of the HoTMetal PRO document window and choose **Table Advanced** from the pop-up menu to turn on the **Table Advanced** toolbar.
- Put the insertion point anywhere in the cell that you want to contract.
- Click on one of the **Table Advanced** buttons:
 -  – Pulls the left boundary of the cell one cell to the right
 -  – Pulls the right boundary of the cell one cell to the left
 -  – Pulls the bottom boundary of the cell one cell up
 -  – Pulls the top boundary of the cell one cell down

Inserting a table caption

A table caption is a title for the table.

To insert a table caption:

- Put the insertion point anywhere inside the table.
- Choose **Insert Caption** from the **Table** menu.
- Enter the caption text.

If the current table contains a caption, the menu item will toggle to **Select Caption**. Choosing **Select Caption** will highlight the caption text; if the caption is empty, the insertion point will move to the caption location.

By default, browsers will display the caption above the table. Some browsers will display the caption below the table if you set the CAPTION element's ALIGN attribute to BOTTOM:

- Put the insertion point inside the caption.
- Choose **Attribute Inspector** from the **View** menu, or press **F6**.
- Choose BOTTOM in the **ALIGN** field.
- Press **Enter**.

Moving around in a table

There are several ways to move around the insertion point in a table:

- You can move up, down, left, and right using the arrow (cursor) keys.
- To move to the next cell on the right, press **Tab**. If you press **Tab** in the last cell in a row, the insertion point will move down to the first cell in next row. (If you press **Tab** in the last cell in the table, a new row is inserted at the end of the table.)
- To move to the next cell on the left, press **Shift+Tab**. If you press **Shift+Tab** in the first cell in a row, the insertion point will move up to the last cell in the previous row.
- To move to the last cell in the current row, press **Alt+End**.
- To move to the first cell in the current row, press **Alt+Home**.
- To move to the last cell in the current column, press **Alt+PageDown**.
- To move to the first cell in the current column, press **Alt+PageUp**.

If a cell spans across two or more columns, the cell is considered to be contained in the leftmost of those columns for purposes of navigation. If a cell spans across two or more rows, the cell is considered to be in the topmost of those columns for purposes of navigation.

Because the **Tab** key is used for table navigation, if you want to insert the tab character itself in a table cell, you have to press **Ctrl+Tab**.

Resizing rows and columns

Row heights can be an absolute number of pixels; column widths can be an absolute number, or a percentage of the document width. Different browsers may handle table dimensions in different ways and may redraw tables differently when a reader changes the dimensions of the browser window.

You can resize rows and columns from the **Table Properties** dialog or by dragging the row and column boundaries in the document window.

To change the height of a row:

- Move the mouse cursor over the **bottom** horizontal boundary of the row until the cursor turns into a double-headed arrow.
- Drag the boundary up or down to resize the row height.

Or:

- Right-click anywhere in the row you would like to resize and choose **Table Properties...** from the pop-up menu.
- Click on the **Row** tab.
- Type the height, in pixels, in the **Height** text box.
- Click on **OK**.

To change the width of a column:

- Move the mouse cursor over either of the vertical boundaries of the column until the cursor turns into a double-headed arrow.
- Drag the boundary left or right to resize the column width.

Or:

- Right-click anywhere in the column you would like to resize and choose **Table Properties...** from the pop-up menu.
- Click on the **Column** tab.
- Turn on **Pixels** or **Percent** depending on which way you want to specify the width. A percent value means a percent of the total width of the table.
- Type the width (pixels or percent) in the **Width** text box.
- Click on **OK**.

Note: HoTMetaL PRO automatically calculates the column width based on content.

Pasting tables from other applications

You can copy and paste tabular material from other applications, such as spreadsheets and text editors, into HoTMetaL PRO. This material will be converted to a table. Non-tabular material will be converted into a list or a paragraph.

Converting to a table

HoTMetaL PRO will convert a pasted selection into a table if:

- There are at least two lines.
- Each line consists of items separated by tabs.
- Each line has at least two items.
- Each line has the same number of items. This does not mean that every cell in every line has to have content; to represent an empty cell, enter a tab to indicate that the cell is there, even though it is empty.

Selections from spreadsheets such as Excel are normally represented in the format described, so there is no problem with pasting them. Tabular material from text editors such as Notepad can also be pasted, and will be automatically converted into a table as long as it conforms to the above guidelines.

Using tables for page layout

Tables have two common uses in HTML documents:

- To present information that is naturally tabular, such as a table of products and prices, or a table of cities and their populations.
- To perform page layout.

The page layout role is not always an easy fit for tables, which, as a category of HTML elements, are fairly complex. In addition to the basic complexity of the problem, there are important variations in the way different browsers handle tables. If you are relying on tables to produce a particular 'look' for a page, be sure to view it in each major browser.

The basic idea behind using tables for layout purposes is that you can use a table row, column, or cell to define a region of the screen, and then insert some content in that region. One common use for tables is displaying information in multiple columns—each table column represents a column on the page.

Some techniques that are useful to know about when using tables to achieve various visual effects are:

- You can set the background color of cells, rows, columns, or the whole table.
- You can hide the table border, or make it wider or narrower.
- You can move cells closer together or farther apart by setting the cell spacing value.
- You can move the text closer to or farther from the cell boundary by setting the cell padding value.
- Most browsers will not display the border or background of a cell that has no content. A useful way of giving an empty cell 'invisible' content is inserting a 'non-breaking space' into the cell, by pressing **Ctrl+Shift+Space**.
- Some similar effects can be achieved using [frames](#).

Example

Here is a simple example: suppose you want to display several paragraphs, with a thick vertical yellow line to the left of the paragraphs. This can be laid out using a table, as follows:

- Create a table with one row and two columns.
- Make the table border invisible.
- Set the background color of the column (cell) on the left to yellow.
- Set the width of the cell on the left to the desired number of pixels.
- Insert a 'non-breaking space' into the cell on the left by pressing **Ctrl+Shift+Space**.
- Insert the paragraphs in the column (cell) on the right.

The cell on the left with the yellow background is displayed in the browser as a yellow line that extends from the top to the bottom of the text on the right.

Editing HTML markup

What's covered in this chapter

This chapter introduces the rules of HTML and describes how HoTMetaL PRO deals with them. Topics include:

- The basic structure of an HTML document.
- Inserting HTML elements.
- Changing, splitting, joining, and removing elements.
- Using attributes.
- Repairing invalid HTML.
- Fixing markup problems with the HTML wizard.
- Making your pages accessible to everyone.
- Inserting special characters.
- Editing HTML in source view.

Reference

If you use HoTMetaL PRO in WYSIWYG view, most of the time you don't need to concern yourself with completely understanding HTML. But the more you work with your Web pages, the more likely you are to want to add something that requires some knowledge of HTML. Or maybe you just want to know what all the fuss is about. Once you understand the basics, you'll see that it really is **elementary**!

[More on this topic](#)

Selecting text and elements

In HoTMetaL PRO, it is easy to select and move around parts of the document structure in the document window without having to worry about making the markup invalid. Each time you select a start- or end-tag, the corresponding tag (and all the content in between) is automatically selected, too. This ensures that you never cut or move just part of the markup. There are also a number of ways to quickly select a whole element (and any sub-elements).

When editing HTML markup, it is helpful to see the tags that are in your document so that you can more easily select and edit elements. To view the document in Tags On view:

- Choose **Tags On** from the **View** menu, if it isn't selected already, or click on the  button in the **Views** toolbar.

To select an element, do **one of** the following:

- Put the insertion point inside the element and choose **Select Element** from the **Edit** menu, or type **Ctrl+Shift+T**.
- Right-click anywhere in the element and choose **Select Element** from the pop-up menu.
- In Tags On view, click once on either the start- or end-tag.

The element is selected.

To select several consecutive elements:

- Place the insertion point anywhere in the first or last element that you want to select, and drag in the appropriate direction until all of the elements are selected.

The **Cut**, **Copy**, and **Paste** commands are similar to those in other Windows applications. The only difference is that in HoTMetaL PRO, a selection can contain elements. Removing or pasting certain elements can cause invalid markup in some circumstances.

HoTMetaL PRO will not paste a selection that would cause the markup to become invalid. **Cut** and **Delete** will become disabled if you select required elements, such as HTML, HEAD, and BODY.

To select all the content in the body of a document:

- With the insertion point anywhere in the document, type **Ctrl+A**. The entire content of the document is selected.

[More on this topic](#)

Empty tags

In HTML markup, there are some tags that differ from other tags based on content: **empty tags**. Empty tags cannot have any content between the tags. The only content that empty tags can have is their attribute values. For example, an empty tag looks like this, [TAGNAME> <]. Some examples of empty tags are [BR> <], [HR> <], [LINK> <], and [IMG> <].

Creating HTML: it's elementary

To see the HTML markup in a document in Tags On view:

- Open a document, or click on the  button to create a new document.
- Choose **Tags On** in the **View** menu or click on the  button from the **Views** toolbar.

The document is surrounded by an element called HTML. This element contains two sub-elements, HEAD and BODY. These are required elements. The HEAD element contains information about the document; the BODY element contains all the other elements that make up the document itself.

Inserting HTML elements

You can think of the elements in an HTML file in (at least) two different ways: you can think of them as formatting styles, or as structural elements. Since a document published on the Web will be formatted differently by each browser or another application that reads it, you may prefer to think of the elements as standing for parts of the document's structure—heading, paragraph, list item—without thinking explicitly about how they are formatted. On the other hand, if you are accustomed to working with desktop publishing or word processing applications, you may want to think of the elements as styles.

HoTMetaL PRO supports both approaches to HTML markup. Working in the WYSIWYG view is similar to applying word processing styles; the Tags On view is oriented toward thinking of elements as structural objects.

In [earlier topics](#), you learned how to use the toolbar and the **Enter** key to insert elements. When you did this, you were creating HTML elements that serve various functions in the document.

In this chapter, you'll learn how to use the **Element List** to insert specific elements.

There are several ways to insert an element:

- Choose **Element...** from the **Insert** menu.
- Press **Ctrl+Shift+I**.
- Click on the  toolbar button.

The **Element List** window appears.

Once you are comfortable enough with HoTMetaL PRO to attempt some of the more complex HTML features, you'll discover that there are some HTML elements that are available only using this method. There are three tabs for HTML elements: **Recent**, **Miva**, and **HTML**. The **Recent** tab contains the ten most frequently used elements in this editing session that are valid in this context. The **Miva** tab contains elements in the Miva programming language, supported by the HoTMetaL Personal Server and HoTMetaL Application Server. All of the elements available for editing HTML markup are available in the **HTML** tab. If you prefer to always have the full list of available elements visible, use the **HTML** tab. You can press the **Tab** key to switch between tabs.

For information about Miva, refer to [Coding Guidelines for Miva files](#) in the HoTMetaL PRO online help.

- Click on the **HTML** tab to display the full list of elements.
- To select an element, click on it, or type the first few letters of the element's name, until the selection moves to the desired element.
- To insert an element, double-click on the element that you want to insert, or select the element and click on **Apply** or press **Enter**. If the dialog is floating, pressing **Ctrl+Shift+Enter** will insert the selected element and dismiss the dialog.

If the document contains a selection, the new element will surround it.

If you try this with the insertion point in various places in your document, you will notice that the list of elements changes. HoTMetaL PRO automatically provides you with a list of elements appropriate to your location in the document. For example, if you have text selected, only character format elements appear. If the insertion point is inside a block element, elements that cannot be nested inside that element do not appear, helping you to avoid invalid markup.

For information on changing the appearance of the **Element List** window, see [Docked and floating windows](#).

In some circumstances, HoTMetaL PRO will automatically insert an element to conform with the HTML rules. If you type inside an element that cannot contain text directly, but normally contains a sub-element that can contain text, the text you type will automatically be surrounded by that sub-element. For example, if you insert a UL, as soon as you start typing an LI element is automatically created, and contains your text.

Types of elements

There are a large number of available HTML elements (some of which are rarely used). It may help you to remember the more commonly used elements if you think of them as being grouped into different types, as they are in this section. Some of the elements described in this section are available from the toolbar and **Element Style** drop-down list and have been described earlier.

- [Head elements](#)
- [Character formatting elements](#)
- [List elements](#)
- [Block elements](#)
- [Code elements](#), sometimes used to format text in technical manuals or papers
- [HTML comments](#)
- [Other character formatting elements](#)

Other elements—those that represent tables, forms, frames, links, and images—have specialized editing interfaces in HoTMetal PRO and don't have to be inserted directly in a document.

[More on this topic](#)

Using your HEAD

The HEAD element has sub-elements that define header material:

- TITLE – contains the document title, which appears in the title bar of a web browser when the file is displayed. This is a required element.
- BASE – can be used to record the document's location in the form of an absolute URL, which can be used to resolve a relative URL if the document is not accessed in its original location.
- ISINDEX – indicates to the browser that the document is an index document. This is used only if the document is on a server that does indexing.
- LINK – indicates a relationship between the document and another object on the Web, such as a cascading style sheet.
- META – gives information that appears in HTTP headers. This can also be used to store document information such as the author and creation date.

Using block elements

Block elements are those that are commonly displayed starting on a new line. Any of the following block elements can be inserted in the body of a document:

- Heading elements (H1 through H6) – Give headings to sections of the document.
- P (paragraph) – Paragraphs are the most common elements.
- ADDRESS – Used to include an address, such as the address of the author of the document.
- BLOCKQUOTE – Used for quotes from another source, requiring special block-style formatting.
- PRE (pre-formatted text) – Used to tell a browser to maintain the line breaks and spacing exactly as they were entered. The text will be formatted by a fixed-width, typewriter-style font.

You can insert a block element using **Element...** from the **Insert** menu to be able to add headings and paragraphs quickly.

Turn on the **Quick Tools** toolbar (using the **Toolbars...** command in the **View** menu) to be able to add new headings and paragraphs quickly.

Type **Return** to start a new line, then click on the appropriate toolbar button for the element you wish to insert.

Using character elements

Character elements are used to specify special formatting for text, usually to add emphasis. It is considered good practice to use the **STRONG** and **EM** elements, rather than **B** and **I**. This leaves browsers with the flexibility to display the text in the way that works best with the other display capabilities and settings of the browser. You can add the following elements to inline text:

- **STRONG** – Usually displayed by browsers as bold.
- **B** – Bold.
- **EM** – Emphasis, usually displayed by browsers as italic.
- **I** – Italic.
- **U** – Underline. Since linked text is usually underlined, this element should only be used where it will not cause confusion.
- **CITE** – Document citation.
- **TT** – Teletype, displayed in a fixed-width typewriter font, such as Courier.

To insert a character format element:

- With the appropriate text selected, choose **Element...** from the **Insert** menu. The **Element List** window appears.
- Click on the **HTML** tab to choose an element from the list.
- Select the element you wish to insert from the list, and click on the **Apply** button. The selected text is now enclosed by that element.

You can use the ,

, and

 toolbar buttons to make text bold, underlined, or italic quickly.

Inserting a line break

If you want to force a browser to break the current line in the text, insert a BR element. This element cannot contain text: it merely represents a line break.

To insert a line break:

- Put the insertion point at the point at which you want to break the line, and do one of the following:
 - Press **Shift+Enter**.
 - Choose **Element...** from the **Insert** menu. The **Element List** window appears. Click on the **HTML** tab. Select BR from the list, and click on **Apply**.

The text is now split at the insertion point.

Using list elements

There are five HTML elements for different types of lists. With the exception of DL, list elements contain one or more LI (list item) elements. You can nest lists (that is, create sub-lists), by inserting a list element (such as UL or OL) inside a list item (LI).

To insert a list element using the **Element List** window:

- With the insertion point in the body of the document (but not inside any other block element), choose **Element...** from the **Insert** menu. The **Element List** window appears. Click on the **HTML** tab. Select one of the following list elements:
 - OL – ordered list. Browsers will automatically number the items in this list element, reflecting nested levels.
 - UL – unordered list. Items in this list start with a list mark (bullet). Browsers usually use a different list mark for nested lists. You can set an attribute to specify a graphic to be used as the list mark.
 - DL – list of definitions. This type of unordered list is different from the others. Each item in a DL consists of one or more terms (DT elements), followed by definitions (DD elements).
 - DIR – folder list. This is an unordered list. Each LI element in a DIR should be no longer than 24 characters.
 - MENU – menu list. Also an unordered list. Each LI element should be no longer than one line.

You can change text to list items quickly using the **Style Element** drop-down menu, or use the  and  toolbar buttons for numbered or bulleted lists.

Inserting comments

You can add comments about the document or notes to yourself using the **Comment** command in the **Insert** menu. This inserts an HTML comment, which can contain only text (not other elements). Comments are not displayed by browsers, but can be viewed in HoTMetaL PRO if the **Show comments** option is turned on.

To insert a comment:

- Choose **Comment** from the **Insert** menu, or type **F8**.
- Type your text inside the tag.

To show comments:

- Choose **Options...** from the **Tools** menu. The **Options** dialog box appears.
- Click on the **View** tab.
- Turn on the **Show comments** option.
- Click on **OK**. Your comments will now display in the document window (but not in browsers).

Note: Because of the way comments are represented in HTML, you should not put two hyphens in a row (--) inside a comment. This could cause invalid markup.

Using code elements

Code elements represent a specific type of text and would normally be used in technical manuals or academic papers. You can insert any of these elements using the **Element List** window:

- CODE – Samples of code, usually displayed in a typewriter-style font.
- KBD – Used to display text that a user would enter at the keyboard (not to confused with INPUT, used in forms), usually displayed in a typewriter-style font.
- SAMP – Literal characters, usually displayed in a typewriter-style font.
- VAR – Represents a variable name (for example, **filename**).

Using advanced text formatting elements

There are a number of other text formatting elements available from the **Element List** window. Make sure that your pages look acceptable without these elements, because they are not supported by all browsers. Use them with caution to create:

- **Blinking text** – Surround text with the BLINK element to cause it to blink on and off in the browser. Remember that such text is inaccessible for some users.
- **Non-breaking text** – Surrounding text with the NOBR element prevents the browser from inserting line breaks. This element should be used only with short pieces of text that you wish to keep together (for example, a proper name).
- **Word breaks** – If there is a position inside a NOBR element where a line break is acceptable to you, put a WBR element at that position to tell the browser that it can break the line there, if necessary.
- **Large and small text** – Surrounding text with the BIG or SMALL element causes the text to be displayed in large or small type, respectively, compared to the surrounding text.
- **Strike-through text** – Surrounding text with the S element causes it to be printed with a line through the text.
- **Subscripts and superscripts** – Surrounding text with the SUB or SUP element causes the text to be displayed as a subscript or superscript, respectively.
- **Base font** – The BASEFONT element is used to increase or decrease the default font size for the whole document. This element must be placed inside the BODY element before any block elements. The possible values of the SIZE attribute are not specific font sizes: they are proportional sizes that range from 1 to 7, with 3 corresponding to the usual font size. The font size will not change in the document window but it will change when the document is displayed by browsers that support BASEFONT.

Changing the markup

Every Web page is a work in progress: modifications are always being made. Whether you are editing text on your page or changing layout, you will need to change the markup.

HoTMetaL PRO supports the following functions for modifying the markup:

- [Changing](#) the element type.
- [Splitting](#) elements.
- [Joining](#) elements.
- [Removing](#) elements.

[More on this topic](#)

Changing elements

Changing an element can be as simple as selecting a new element from the **Style Element** pull-down menu. For example, you change a level 1 heading to a level 2 heading just by placing the insertion point in the heading and choosing **Heading 2** from the pull-down menu of styles in the **Formatting** toolbar.

For ease-of-use, only the most commonly used elements appear on the pull-down menu. To change an existing P element to a more specialized HTML element such as DIV, use **Change Element...** from the **Edit** menu.

To change an element:

- Place the insertion point inside the element.
- Choose **Change Element...** from the **Edit** menu or, if the **Element List** window is already visible, click on the **Change** radio button at the bottom of the **Element List** window. The **Change Element** window appears.
- Click on the **HTML** tab.
- Select the desired element.
- Click on **Apply**.

Splitting elements

Splitting an element creates two elements of the same type as the current element. If there is content in the element, the first element will contain all the content before the insertion point and the second element will contain the remaining content. If the insertion point is just after the start tag, or just before the end tag, a new, empty element is created. The most common use for splitting elements is to place the insertion point just before the end tag and create a new, empty element after the current element.

To split an element:

- Place the insertion point where you want to split the element and do **one of** the following:
 - Press **Enter** (in a block element).
 - Type **Ctrl+Shift+P**.
 - Choose **Split Element** from the **Edit** menu.

Joining elements

To join two elements, do **one of** the following:

- Place the insertion point just after the start-tag for the second element and press **Backspace**.
- Put the insertion point anywhere in the second element, and choose **Join to Preceding** from the **Edit** menu or press **Ctrl+Shift+J**.

If the elements have attributes, then the attributes of the first element will be adopted for the new, combined element.

Removing elements

The easiest way to remove an element (that is, the tags, not the content) is to use the **Backspace** key in Tags On view, especially if you want to remove one of several nested elements (elements within elements). Some character formatting elements can also be removed by selecting the formatted text and clicking the appropriate button. For example, to remove the italics from a word, select the whole word and click on .

To remove the current element, do **one of** the following:

- Place the insertion point just after the start-tag for the element, and press **Backspace**.
- Put the insertion point anywhere directly in the element (that is, not in a subelement), and choose **Remove Tags** from the **Edit** menu or press **Ctrl+Shift+D**.

Using attributes

Elements can have **content** (the text and sub-elements you have placed inside the element) and **attributes**. An attribute is a **value**, or piece of information about the element that does not show in the content. Any element can have an attribute. For example, the URL part of an image anchor is an attribute, and you can use another attribute to specify the alignment of the image.

In **Tags On** view, you can choose to have **Tag Tips** appear when you hover the cursor over a tag in the document window. Tag Tips display any non-null attribute values for the element. Tag tips are visible by default. To turn Tag Tips on or off:

- Choose **Options...** from the **Tools** menu. The **Options** dialog box appears.
- Click on the **General** tab if it isn't selected already.
- Click on the **Show Tag Tips** check box.
- Click on **OK**.

When you hover over a tag in the document window, the attributes will be displayed in a small floating dialog box.

Note: In WYSIWYG view, **Tag Tips** display the attributes of images.

You can use the **Attribute Inspector** to [change the attributes of any element](#) (discussed in the next section), but some elements also have special dialog boxes that appear automatically when the element is created.

Some elements with special dialog boxes for editing common attributes are:

- An image (IMG element) has an **Image Properties** dialog box. To open this dialog box, double-click on the image or right-click inside the IMG element and choose **Image Properties** from the pop-up menu.
- The HREF attribute, which represents URLs in A elements, can be edited by choosing **Link...** from the **Insert** menu.
- Graphical FORM objects have customized attribute editing dialog boxes. Double-click on those objects to access the dialog boxes.
- Many attributes in tables, and table rows, columns, and cells, can be edited by right-clicking in the table and choosing **Table Properties** from the pop-up menu.
- You can change the attributes of the BODY element that set color and background images by choosing **Page Properties...** from the **File** menu.
- You can change the attributes of frames by right-clicking on a frame and choosing **Frame Properties...** from the pop-up menu, or by choosing **Frame Properties** from the **Frameset** menu.

[More on this topic](#)

Editing attributes with the Attribute Inspector

In the WYSIWYG and Tags On views, you can edit attributes for any element using the **Attribute Inspector**. You may find it easiest to make sure you are in the element whose attributes you want to edit by working in Tags On view and placing the insertion point directly to the right of the element's start-tag. If you prefer to work in WYSIWYG view, you can use the context display at the bottom of the window to confirm which element you are in.

To edit the attributes of an element:

- Place the insertion point inside the element.
- Choose **Attribute Inspector** from the **View** menu, type **F6**, or click on the  button from the **Views** toolbar.

The **Attribute Inspector** window appears.

The drop-down list at the top contains the current element and all of the elements that enclose it. If the element listed is not the element you wanted to edit (for example, if an inline element is listed, but you want to edit the block element that contains it), choose the element from the list and its attributes will appear in the **Attribute Inspector**.

The Attribute Inspector is divided into three tabs: the **All** tab contains all of the attributes of the element; the **Common** tab contains the most common attributes of the element; the **Events** tab contains all of the attributes of the element that correspond to actions that can be associated with a script (for example, a JavaScript script.).

- Click on the first attribute you wish to edit. The editing field associated with an attribute can be one of three types. If a drop-down arrow appears at the right edge of the field, you can choose a value from the drop-down list; if there is a ... button, you can click on it to browse for a file; otherwise, type an appropriate value in the field.
- You can use the arrow keys to scroll up and down through the window and edit other attributes. If you click on a ... button, your selection is applied when you click **OK**; other values are applied when you press **Enter**, move to another field, or close the dialog box. This enables you to see the effects of your changes in the document window before closing the **Attribute Inspector**.
- Click on the  button or press **Alt+F4** to dismiss the window.

Drag and drop

You can drag and drop objects into fields in the Attribute Inspector. You can create a link to a file displayed in the Resource Manager by dragging that file onto an appropriate attribute (for example, the **HREF** attribute of the **A** element). For example, if you wanted to have a sound played when you click on an image you would drag the sound file from the Resource Manager to the **ONCLICK** attribute of the image file in the Attribute Inspector.

Editing STYLE attributes

Most elements have a **STYLE** attribute that lets you attach cascading style properties to the element. Click on the ... in the **STYLE** field to bring up the [Cascading Style Sheet editor](#).

For more information about using cascading style sheets, see the topic [Using cascading style sheets](#).

In HTML Source view, attributes are displayed in the start-tag for each element. If you know HTML well enough, you can edit attributes directly in the [source view](#).

Creating valid HTML

One of the most important features of HoTMetaL PRO is automatic **rules checking**, which ensures that you do not break the required structure as you work with your document. As well, when you open or save a document, HoTMetaL PRO **validates** it—it checks that the markup is correct and complete.

Many HTML browsers permit a very loose, unstructured document format. However, this provides no guarantee that documents will be formatted the way you want when they are displayed on the Web, particularly given the wide range of browsers. You will get much better results with valid documents.

The document-structuring rules built into HoTMetaL PRO are designed to be flexible while at the same time maintaining a useful document structure. If you open an existing document that does not conform to these rules, HoTMetaL PRO will try to open it anyway, adjusting the markup so that it conforms as closely as possible to the rules of HTML. If there are serious errors, the [HTML wizard](#) will be launched.

HoTMetaL PRO prevents markup errors in a number of ways:

- Commands are grayed out (disabled) under circumstances that could cause errors. For example, commands on the **Insert** menu are gray whenever it would be invalid to insert the related object.
- A restricted list of elements is presented. For example, the **Element List** window will list only those elements that can correctly be inserted in the current location.
- In some cases, HoTMetaL PRO will not complete the command. For example, if you choose an element style from the **Style Element** drop-down list that cannot be correctly inserted at the current location, the element style will not be inserted.
- In other cases, you are given an opportunity to cancel a command that would create invalid markup. For example, if a **Paste** operation would leave the document incorrectly tagged, a warning pops up asking if you want to cancel the operation.

[More on this topic](#)

Checking the HTML

Use the **Check HTML** command to verify that the markup in a document is correct and complete. If the validation process finds an error in the document, a message appears and the insertion point will move to the error so that you can make the necessary change.

Validation will find and report any markup errors not caught by rules checking. It will check that:

- All required elements are present. For example, if the document contains an OL (ordered list) element that does not contain at least one LI (list item) element, validation will detect this problem.
- All required attributes are present. For example, an IMG element must have a value for the attribute SRC (this represents the URL for the image, and is filled in automatically if you choose an image when you create the IMG element). If an IMG element exists without one, validation will detect its absence.

To validate a document:

- Choose **Check HTML** from the **Tools** menu, or click on the  toolbar button.

One of the following appears:

- A message confirming that your document is valid.
- An error message describing the first instance of invalid markup. Click on **OK** and fix the problem. Repeat this step until the document is valid.
- If your document contains elements or attributes that are not defined in HTML 2.0 (a very basic HTML standard), you will get a warning informing you of this. Click on **More...** if you wish to see the details, in the **HTML Extensions Used** dialog box.

To determine which elements in your document will be understood in various browsers, choose a browser from the drop-down list. In the top panel, the elements specific to that browser will be listed. The bottom panel lists all the elements that are not understood by other browsers or found in commonly-used rules files. You can also select a browser or rules file from the drop-down list.

Learning when to turn off the rules

The current rules checking state is indicated in the lower right corner of the status bar. In WYSIWYG and Tags On views, rules checking is automatically on as much as possible. In HTML Source view, rules checking does not apply (HTML is invalid most of the time when you are entering it by hand). When rules checking is on, HoTMetaL PRO ensures that the document being edited will be correctly marked up—changes that would cause invalid markup are not allowed.

There are occasions when the changes you are making involves two or more steps, and one of the steps will leave the document temporarily invalid. In these situations rules checking can get in the way and can be turned off temporarily. It is possible to turn rules checking off in the **General** tab of the **Options** dialog box, but this is not recommended. You can also toggle rules checking on and off by typing **Ctrl+Shift+K**; HoTMetaL PRO will automatically turn it back on at the earliest opportunity. If you have reason to create invalid HTML or need to work with chunks of text that will temporarily result in invalid markup, work in HTML Source view.

[More on this topic](#)

Moving text around

You may have noticed that you cannot select text across element tags (that is, you cannot place your insertion point in the middle of a paragraph and select the second half of the paragraph and down into the next—the full paragraph is automatically selected). That is because a single start or end tag would be a markup error. Each time you select a tag, its partner (and all the content in between) is automatically selected, too.

If you are completely rearranging the content of your document, you may prefer to work with rules checking off (that is, either turn the option off or work in HTML Source view) while you cut and paste portions of the content, fix any broken markup, and then turn rules checking back on.

Fixing markup problems with the HTML wizard

HoTMetaL PRO has a built-in set of rules that determine which HTML elements and attributes are valid, and how they can be arranged with respect to one another. If you open an invalid document—one that violates the built-in rules—HoTMetaL PRO will try to silently auto-correct the problem in order to produce a valid document. Generally speaking, if your document contains valid HTML elements and attributes, but has them arranged incorrectly (for example, if an LI is not enclosed in a 'list' element such as OL or UL) HoTMetaL PRO will correct the problem for you.

HoTMetaL PRO checks for certain problems when you try to open a file, or when you switch between HTML Source and Tags On views. If some invalid markup is found, the **HTML wizard** starts.

The **HTML wizard** asks you how you would like to solve the problems found. The more knowledgeable about HTML you are, the easier it will be to make these choices, but the **HTML wizard** itself provides enough guidance for you to use it no matter what your level of expertise is.

This wizard is launched if HoTMetaL PRO finds:

- An element that it does not recognize.
- An attribute it does not recognize.

Note: You can undo the actions of the HTML Wizard by editing the file Rules\hmpro5.ux, in the HoTMetaL PRO 5.0 folder. This file is in XML.

[More on this topic](#)

Fixing unknown elements

A document might contain an unknown element, for example, PARA instead of P. In this situation, HoTMetal PRO will offer you the choice of letting the program attempt to auto-correct the problem, or launching the **HTML wizard**.

If you launch the HTML wizard, a dialog box appears with the following choices:

- HTML Element wizard – This is a wizard that guides you through correcting the invalid element.
- **Edit HTML Source** – Opens the document in HTML Source view, where you can correct the problem manually.
- **Discard this tag** – The tag (for example '<para>'), but not its contents, will be discarded.
- **Discard all unrecognized elements** – All unrecognized tags in the document will be discarded; you will not be asked individually about each tag.

The HTML Element wizard

If you choose to correct an invalid element with the **HTML Element wizard**, it appears and offers you several choices.

The simplest choices are:

- **Misspelled Element** – If the error is simply a typing error (for example, APPELT instead of APPLET) or a case of not knowing the correct HTML element name (for example, EMPH instead of EM) you can choose this option and enter the correction in the text box (some element names are available from the pull-down menu).
- **Text Only** – If the error occurred because the '<' character, which normally starts an HTML tag, was used in some other context (for example, the phrase 'Press <Return>') you should choose this option. The '<' will be replaced by the characters '<', which will be displayed as '<' in a browser, but will not start a tag.

If you choose either of these options and click on **Finish**, the wizard makes the desired change and terminates.

If you want HoTMetaL PRO to treat this element as a valid HTML element from now on, you have two choices:

- **Custom Element (Container)** – Choose this option if the new element consists of a start- and end-tag with some content (text and/or other elements) between them (for example, <para>...</para>).
- **Custom Element (Non-container)** – Choose this option if the new element consists only of a start-tag, and doesn't contain any text or elements (it can have attributes, however). For example, instead of an IMG element you could have:

```
<image src="logo.gif"  
>
```

Note: You should define the unknown element as a new element only if there is a browser or other HTML client application that supports that element. Otherwise, the element may be formatted as you wish only in HoTMetaL PRO.

If you choose one of these options and click on **Next>>**, you'll get another screen in which you can further customize the new element.

Configuring custom elements

If you add a new element to the list of valid elements, you will get a screen that lets you specify some properties of the element.

- **Name** – You can modify the element name (but if you do so, and you chose **Custom Element (Container)** in the previous screen, only the start-tag will be modified).
- **Description** – This description will appear in the **Description** field in the **Element List** window.

You can choose the following style properties:

- Turn on **Paragraph** if you want the new element to be displayed as a block-style element (the element will have line breaks before and after it), or **Character** if you want the element to appear inline.
- Turn on **Preserve white space** if you want the line-breaks, tabs, and spaces inside this element to be displayed in HoTMetaL PRO exactly as they appear in the HTML file.
- Turn on **Hide in WYSIWYG mode** if you want the contents of this element to be hidden in WYSIWYG view.

Note: You can undo the actions of the HTML Wizard by editing the file Rules\hmpro5.ux, in the HoTMetaL Pro 5.0 folder. This file is in XML format.

Fixing unknown attributes

A document might contain an unknown attribute, for example, the IMG start-tag might have an HREF attribute instead of SRC. In this situation, HoTMetal PRO will give you the choice of letting the program attempt to auto-correct the problem, or launching the **HTML wizard** dialog box. This will also occur if a new element that you defined using the **HTML Element wizard** has one or more attributes; each of these attributes has to be defined individually for the new element. If you choose **Auto-correct** in this situation, the attributes will be deleted.

If you choose **HTML wizard**, you will see a dialog box with the following choices:

- HTML Attribute wizard – This is a wizard that guides you through correcting the invalid attribute.
- **Edit HTML Source** – Opens the document in HTML Source view, in which you can correct the problem manually.
- **Discard this attribute** – The attribute and its value (the text between double quotes, if any) will be discarded.
- **Discard all unrecognized attributes** – All unrecognized attributes in the document will be discarded; you will not be asked individually about each attribute.

The HTML Attribute wizard

The **HTML Attribute wizard** lets you correct an unknown attribute or add it to the list of valid attributes.

To correct an attribute name:

- Choose the correct name from the **Attribute Name** drop-down list.
- Click on **Finish**.

To add the unknown attribute to the list of valid attributes:

- Leave the **Attribute Name** unchanged.
- Optionally, enter some descriptive text in the **Help string for Attribute Inspector** text box.
- Optionally, enter a space-separated list of values; this will restrict the allowed values for the new attribute.
- Click on **Finish**.

Note: You can undo the actions of the HTML Wizard by editing the file `Rules\hmpro5.ux`, in the **HoTMetaL Pro 5.0** folder. This file is in XML format.

Note: You should define the unknown attribute as a new attribute only if there is a browser or other HTML client application that supports that attribute. Otherwise, the attribute will be supported only in **HoTMetaL PRO**.

Authoring for accessibility

HoTMetaL PRO includes the following features to make accessible authoring easier and faster.

- Accessibility prompting dialog boxes
- Descriptive text editor
- Accessibility validation
- Pop-up warnings

HoTMetaL PRO helps you evaluate the accessibility of your markup by letting you check the markup according to the guidelines that follow. Please see the section on validating for accessibility for more information.

[More on this topic](#)

Guidelines for creating accessible pages

People access the Internet and intranets under a variety of circumstances. Some users cannot see graphics because they have visual impairments, use text-based browsers, or have slow modem connections; others cannot hear sound because they have auditory impairments, or use computers without sound capabilities; and some cannot operate a mouse or keyboard because they have mobility impairments. Accessible HTML authoring means writing pages and sites that take these different groups into consideration. Accessible pages do not have to be plain and text-based, but take special care to avoid presenting material in a manner that excludes potential users.

The following guidelines will help make your HTML pages more accessible to users with disabilities, particularly those who are 'reading' your pages with the aid of a screen reader and voice synthesizer. These guidelines also help keep your pages usable with all browsers, especially non-graphical browsers such as Lynx.

- Provide meaningful text for all links (A elements).
- Include alternate text (using the ALT attribute) for all images.
- Use client-side image maps instead of server-side image maps (to make them accessible to the visually impaired using the tab function in Internet Explorer 3.0).
- Include alternate (ALT) text for each image map AREA.
- Place a textual list of all image map links elsewhere on the page.
- Choose readable combinations of text and background colors.
- All tables should be accompanied by a link to a text-only presentation of their content.
- All forms should be accompanied by a link to a text-only presentation of their content.
- Text boxes in forms should have default content that suggests the kind of information the user should enter.
- Always include a NOFRAMES version of a page that uses frames.
- Avoid hyperlinks longer than ten words. Longer links may be cut off by screen readers.
- Ensure that there are separating spaces or characters between each hyperlink.
- Avoid using the MARQUEE and BLINK elements.
- Keep the color and font constant within each word.
- Include descriptive text for BGSOUND (background sound) files.
- Include descriptive text for audio files.
- Include descriptive text for video files.
- Include alternate and descriptive text for applets.
- Include alternate and descriptive text for ActiveX objects.
- Warn the user if Client-Server Push-Pulls are being used.

Note: These accessibility guidelines were provided by the Adaptive Technology Research Centre at the University of Toronto. More information about the ATRC is available at: <http://www.utoronto.ca/atrc>

Inaccessible Element: Missing link text

Link anchors (text in A elements) should provide a description of the content being linked. Avoid phrases such as 'Click here.'

Inaccessible Element: APPLET

Applets can take many forms, but they are often very visual and therefore inaccessible to users with visual disabilities. This inaccessibility can be compensated for with the addition of a short alternate text label and a longer descriptive text. HoTMetaL PRO prompts you to use both of these methods during the insertion process. For users whose browsers do not support Java, alternative content should be entered that is identical to the alternate text. It is important that all functions available within the applet also be listed in text format elsewhere in the document or site.

Inaccessible Element: BGSOUND

The BGSOUND element is used to define a background sound for a document. If the background sound includes instructions, announcements, or other important content, that content should also appear textually on the page. For added accessibility descriptive text can be used. The length, style, and content of background audio clips vary widely from one situation to the next and depend on the creative discretion of the author. Descriptions of these clips might include a detailed script of all dialogue, a written description of any music that can be heard, and a text-based representation of any sound effects that occur in the recording.

Inaccessible Element: BLINK or MARQUEE

Text is generally considered to be inaccessible if it cannot be interpreted by a screen reader program. Flashing or moving text is not only inaccessible to screen reading programs, but it is also difficult to read for users of screen magnifiers. Text that does not stay still is difficult to track, focus on, and read. Try drawing attention to text using emphasis, italics, or bold instead.

Inaccessible Style: Background Images or Colors

The wrong choice of background image or color can affect the readability of a page for everyone, but users with a variety of visual disorders are most affected. Graphical content, such as company logos, will be completely missed by users who use screen reading programs, and the reading process for users who must magnify the screen one small portion at a time is disrupted by the absence of a solid background. The enhanced background might also reduce, or eliminate, the readability of a document for users who are color blind, have problems focusing, or whose eyes tire and strain easily. These problems can be compounded by poor choices in foreground text colors. If background images and colors are used, special care must be taken to ensure that pages are readable and that all content appears elsewhere on the page in textual form.

Inaccessible Style: Text Color

The wrong combination of background and text colors can affect the readability of a page for everyone, but users with a variety of visual disorders, such as color blindness, focusing problems, or eyes that tire and strain easily, are most affected. Another problem is the practice of adding large blocks of white on white text to increase search engine scores. This is invisible to the average viewer, but the text will be picked up by a screen reader, much to the confusion of the user. When defining colors for text, ensure that the text is readable against the background and that links are easily recognized. The use of color is not always a problem: it can be used to make reading easier and aid comprehension.

Inaccessible Attribute: FONT Size

Font size is often used as an alternative to headings. One practice, called Drop Caps, is to use a larger font size for the first letter of a word than for the rest of the word.

Although this is a common practice in print, an HTML aware screen reader will read the first letter followed by the rest of the word. For example, the word "the" becomes "tee he". For better accessibility, headings should be used whenever possible. Headings also maintain and enhance the document structure.

Inaccessible Style: Forms

Forms are generally a very useful and user-friendly way of soliciting input from readers. However, despite technological improvements, browsers and assistive technologies may have trouble conveying the format and content of forms to their users. Therefore, it is suggested that a text-only version of the form, including both email and postal addresses, be available on a separate linked page. This will allow users with visual disabilities to save the file locally and reply by email, or to print out the form and reply by mail. This solution will also provide a way of accommodating users who are wary of sending personal information over the Internet.

Inaccessible Style: Text Boxes and Text Areas

Text boxes and text areas can be a problem for screen reader users because their labels may be on another line or cut off. It is helpful to include the field name as the default field text for edit boxes. For example: "your name" or "institution." This serves to clarify the function of edit boxes with text labels that may have been cut off by the screen.

Inaccessible Style: Frames

Frames offer a way to split up the screen into functional window-like panes. Some of these panes may remain displayed during an entire site visit, allowing site guides or other useful information to be permanently displayed. Although this can be very helpful to some users, screen reading programs typically read from left to right, ignoring pane boundaries and mixing content from both sections. This can be incredibly confusing and may render the entire site inaccessible. Also, not all browsers support the FRAMESET element. To ensure accessibility to all users, sites using frames should offer the option of turning off frames and displaying content in the normal fashion using the NOFRAMES tag.

Inaccessible Element: IMG

The most common way of dealing with the inaccessibility of images is by making use of ALT (alternate text) attribute of the IMG element. Alternate text provides a textual description which is displayed in place of the image by text-based browsers and graphical browsers whose image loading has been disabled. ALT text is particularly important to users with visual impairments, who use screen reading programs that are unable to interpret images of any kind, including pictures of words. Since the ALT text is displayed independently from the image, the description must be adequate enough to keep the user informed. For example: if the image depicts a company logo, the corresponding ALT text might consist of the company name, along with a short description of the logo, itself. If the image is anchored, it is important to emphasize the button's functionality rather than its overall appearance. For example: using a label such as 'home' or 'help' would be more informative than a description of the button's visual appearance.

Note: ALT text descriptions should be kept brief because many browsers display the text within a limited area. This means that a description that is too long will not appear in its entirety. In situations where a longer description is required, a short ALT text description should still be included with the image along with a descriptive text link. The Image Attributes, which appears during image insertion, includes a Description button for adding descriptive text.

Inaccessible Attribute: IMG-ISMAP (Server-Side Image Maps)

Image maps are a very popular and effective way of conveying information. However, they require that the user have a graphical browser with a fast connection, and the physical ability to see the image on the screen. Microsoft Internet Explorer 3.0 introduced a keyboard function that allows users to **TAB** through the AREA's of Client-Side image maps. If alternate text labels are provided for each AREA then these image maps become accessible to the visually impaired. Therefore, it is suggested that Server-Side image maps be avoided in favor of Client-Side image maps. However, it is still necessary to provide a text menu for users with other browsers or slow connections. This text menu should be located just below the image map and contain all the same options as the image map. The menu should also include a text-based title, such as "Image Map Options".

Inaccessible Attribute: IMG-USEMAP (Client-Side Image Maps)

A Client-Side Image Map is composed of hotspots called AREAs. Microsoft Internet Explorer 3.0 introduced a keyboard function that allows Client-Side Image Maps to be accessed as long as alternate text (ALT) labels are provided for each AREA. These text labels should provide the user with adequate information as to what will occur if a particular AREA is selected. For example: if the image is a button, it is important to emphasize the button's functionality. If the image is a hyperlink, it is important to emphasize the type of content of the linked site. An ALT text for the full image is also necessary to indicate that this image is an image map. It is still necessary to provide a text menu for users with other browsers or slow connections. This text menu should be located just below the image map and contain all the same options as the image map. The menu should also include a text-based title, such as "Image Map Options".

Inaccessible Element: OBJECT

Objects can take many forms, but they are often very visual and therefore inaccessible to users with visual disabilities. This inaccessibility can be compensated for with the addition of a short alternate text label and a longer descriptive text. Both of these methods are available on the **Object Attributes** dialog box, which appears during the insertion process. For users whose browsers do not support OBJECT, alternate content should be entered that is identical to the alternate text. It is important that all functions available within the object also be listed in text format elsewhere in the document or site.

Inaccessible Style: Client-Server Push-Pulls

In a Client-Side Push-Pull, images are pushed on top of each other in succession to form pages with dynamic content. Often this is used to construct changing billboards or animation. Unfortunately, this practice makes the page inaccessible to users who rely on ALT text because many assistive technologies assume a static page format. If a Client-Side Push-Pull is unavoidable, users should be warned of its existence by a short note at the top of the page. This warning may explain why their access device reacts strangely. In addition, all content contained within the Push-Pull should be presented elsewhere in textual format.

Inaccessible Element: TABLE

Tables are usually an excellent way of displaying large amounts of data in a way that is easy to understand. However, screen reading programs read lines of text that appear on the screen from left to right. This means that column breaks (blank spaces between columns) are ignored, and the text is read in one continuous, non-contextual stream from left to right. This problem becomes especially difficult to handle when table cells contain entries that are more than one line high. Since screen readers typically read line by line they may read the two lines of the cell at different times, making the table difficult to understand. It is suggested that all the information contained in the table be provided elsewhere in a purely linear, text-based format. This text can be placed in a separate file that can be accessed through a hyperlink if necessary. Recently, tables with invisible cell boundaries have begun to be used to organize the layout of pages, including integrating columns of text and images. This practice is also very inaccessible for the reasons stated above; most screen readers read left to right and ignore the column boundaries, merging the columns into an unreadable jumble.

Inaccessible Style: Wordy Links

Some visually impaired users use screen reading programs which allow them to cycle forwards and backwards through the hyperlinks on a page. This movement is achieved via the use of keyboard commands, and allows users of this technology to quickly obtain a link list without having to read the document line-by-line. It is important to avoid link names that are more than ten words long, or those links that take up more than one line. This not only makes the process of obtaining a link list more time effective for screen readers, but avoids problems with screen reading programs that are not capable of interpreting multi-line links correctly.

Inaccessible Style: Non-Separated Links

Some visually impaired users use screen reading programs which allow them to cycle forward and backward through the hyperlinks on a page. This movement is achieved via the use of keyboard commands, and allows blind readers to quickly obtain a link list without having to read the document line by line. Non-separated link names should be avoided because screen reading programs tend to read multiple links as a single link, making link selection ambiguous. This problem can be avoided by placing unlinked characters such as numbers or commas as well as line breaks between links.

Inaccessible Style: Missing Descriptive Text for Audio Files

Descriptive text is a very important way of making audio clips accessible to users in a variety of circumstances. Groups of individuals who can benefit from such descriptions include those with hearing impairments, slow modems or network connections, or computers that lack multimedia capabilities.

Inaccessible Style: Missing Descriptive Text for Video Files

Descriptive text is a very important way of making video clips accessible to users in a variety of circumstances. Groups of individuals who can benefit from such descriptions include those with visual impairments and slow modems or network connections.

Writing alternate (ALT) text

Alternate text can be associated with an image (IMG), image map area (AREA), Java applet (APPLET) and ActiveX object (OBJECT). This text (the contents of the ALT attribute) is displayed instead of the image or object when image loading is turned off and by text-only browsers such as Lynx. Some browsers also display alternate text while images are loading. The way alternate text is displayed also differs between browsers. Some browsers display the alternate text as a single line that may be cut off by the screen while others force the text into the dimensions of the image which is a problem when the image is very small. Consider the following guidelines to writing ALT text:

- Keep it short (less than ten words). If a longer description is necessary, use descriptive text .
- If the image is within an anchor emphasize the destination in the alternate text.
- If the image is an image map, make a note of this in the alternate text.
- Graphics that are being used as list bullets should have the letter 'o' for the alternate text.

Browsers that do not support Java or ActiveX cannot display ALT text for these objects, either. Alternative content that is identical to the alternate text should be provided for users of these browsers. If accessibility prompting is turned on, the **Applet Properties** and **Object Properties** dialog boxes provide space to write alternative content.

Writing descriptive text

Descriptive text is a longer, more detailed description of an inaccessible element than would be appropriate for alternate text. The descriptive text is contained in a separate file, accessed by a link containing the single letter 'D' (or 'd') immediately following the element in the document. HoTMetal PRO simplifies the process of authoring this text by handling the creation of the file, insertion of the D-link, and insertion of the descriptive text into the file. All you have to do is enter the descriptive text itself and change the default descriptive text file name if desired. The descriptive text editor makes the editing process more efficient by retrieving any descriptive text already authored for the description file. If changes are made, the old text is automatically replaced with the new text.

Using the descriptive text editor

Descriptive text is a relatively new practice that is meant to complement the short description provided by the alternate text and increase the accessibility of a site. Basically, a D-link (for description) is placed just after a potentially inaccessible element in the HTML file. This link connects to a text-only description of the element. Descriptive text is usually provided for applets, images, objects, audio files, and video files in order to make them accessible to users who are visually or hearing impaired, using text-only browsers, or using slow connections.

HoTMetaL PRO includes a built-in utility for writing descriptive text. This utility is available whenever one of these objects is inserted, as long as **Automatic accessibility prompting** is set to **On** or **Strict** in the HoTMetaL PRO **Options** dialog box.

To enter descriptive text:

- Click on **Description...**. The **Accessibility Description** dialog appears.
- Type a description in the text box.
- Enter a path and file name for the text in the **Descriptive file** text box, or click on **Choose...** to select an existing file.
- Click on **OK**.

Consider the following guidelines to writing descriptive text:

- Describe any text that appears in the object.
- Describe the size, look, and organization of the object.
- Describe the main function of the object.
- Transcribe any voices, sounds, or action.
- Do not include hyperlinks or other HTML markup.

Setting the accessibility prompting level

You can choose one of the following accessibility prompting levels in the **Options** dialog box:

- **Off** – Deactivates accessibility prompting. The dialog boxes and pop-ups that appear as you insert elements will not prompt you to create accessible alternatives.
- **On** – The attributes dialogs for elements that require alternative or descriptive text for complete accessibility will include prompts for such text.
- **Strict** – Activates the pop-up warning system, in addition to the prompts for alternative and descriptive text. This system will display warnings about the inaccessibility of the TABLE, BGSOUND, FRAMESET, MARQUEE, and BLINK elements as soon as they are inserted using the **Element List** window.

To change the accessibility prompting level:

- Choose **Options...** from the **Tools** menu. The **Options** dialog box appears.
- On the **General** tab of the **Options** dialog box, set the desired accessibility prompting level.

Validating for accessibility

People with disabilities often use special technology to give them access to HTML documents. As a result, HTML documents should conform to rules for accessibility. For example, many people assume that with the increasing number of users with graphical browsers, the alternative text (ALT) attribute for images is no longer necessary. Some accessibility technologies, however, make use of the **ALT** attribute for users with impaired vision.

You can ensure that your document is accessible to users with special assistive technology by choosing **Check Accessibility** from the **Tools** menu. HoTMetal PRO checks your document against a set of guidelines. If your document is not marked-up to be accessible to everyone, a message appears with a summary list of the accessibility problems:

Click on **OK** to open a succession of warning dialog boxes, which explain each problem. Click on **Cancel** to stop validating the document for accessibility. Dialog boxes appear for some problems that can be solved immediately; in these dialogs you can do the following:

- Correct the problem and click on **Apply**.
- Click on **Skip** to proceed to the next accessibility problem without making any changes.
- Click on **Stop** to quit the correction process.

If your document does not pass the accessibility check, it does not mean that the HTML markup is incorrect. However, it is advising you that your document could be marked up to be more accessible to people with disabilities.

Typing special characters and symbols

HoTMetal PRO supports the ISO 8859/1 character set (also called ISO Latin-1) and a number of other 'special' characters and symbols that do not have a corresponding key on the keyboard.

To enter a special character (a non-ASCII alphabetic character):

- With **NumLock** on, hold down the **Alt** key and type a zero (0) followed by the ANSI numeric code for the character. For example, **Alt+0233** will enter the character 'é'.

Or:

- Choose **Special Characters** from the **Insert** menu, press **Ctrl+Shift+E**, or choose **Toolbars...** from the **View** menu and turn on the **Special Characters** toolbar. The **Special Character** toolbar appears.
- Click on the character you want to insert.

To enter a symbol (a currency, mathematical, punctuation, or publishing symbol):

- Choose **Toolbars...** from the **View** menu and turn on the **Symbols** toolbar. The **Symbols** toolbar appears.
- Click on the symbol you want to insert.

Note: When you save a file, non-ASCII characters are converted to entities. For example, 'é' is converted to the entity definition that Web browsers will recognize: 'é'.

Non-breaking spaces

A **non-breaking space** looks like an ordinary space, but if you put this kind of space between two words, browsers will not break the line of text at that location. Another common use for non-breaking spaces is to force the browser to display the border or background color of empty table cells. A non-breaking space is displayed as an ordinary space in the HoTMetal PRO WYSIWYG view, and as an nbsp icon in the Tags On view.

To insert a non-breaking space, type **Ctrl+Shift+Space**.

Editing HTML source

HoTMetal PRO's HTML Source view lets you edit your document as a raw HTML file. You can use this to edit invalid HTML, or to create and edit raw HTML. HTML Source view displays all of the elements, attributes, and content that make up the document, using different colors to distinguish the content and various types of markup. You can change the display font and font colors for this view; you can also modify the layout of the source displayed.

To view HTML source, do **one of** the following:

- Choose **HTML Source** from the **View** menu.
- Click on the **HTML Source view** button (the left-most button in the  group) at the bottom left of the document window.

Not all of the menu commands and toolbar buttons are available in HTML Source view. Among those that are available are:

- **Element...**, **Horizontal Rule**, **Link...**, and **Image...** in the **Insert** menu.
- Most commands in the **Format** menu.
- **Insert Table...** and **Insert Caption** in the **Table** menu.
- All commands in the **Form** menu except **Form Field Properties...**

In general, in HTML source view you can use the menus or the toolbars to insert elements and surround the selection with an element, but not edit attributes or set properties that rely on attributes. This kind of editing must be done by entering HTML directly in the document window.

Context-sensitive rules checking is not turned on in HTML Source view. HoTMetal PRO will not prevent you from entering invalid HTML, but you can still choose **Check HTML** in the **Tools** menu to check the validity of your document.

You can indent or outdent blocks of text in HTML source view by pressing **Tab** or **Shift+Tab**.

HoTMetal PRO organizes the HTML by displaying the line numbers on the left side of the window in Source view. If a line is longer than the current width of the document window, it will wrap around. This is referred to as **soft wrapping**. You can configure the wrapping behavior in the Source View tab of the **Options** dialog box.

You will also notice that the HTML markup is displayed in different colors. This is to organize the markup so that you can easily identify elements, attributes, and text. By default, elements are in blue, attributes are in red, and text is in black.

The DOCTYPE declaration, visible at the top of the file in HTML Source view, specifies the DTD, the file that describes the how elements and attributes can validly be arranged.

[More on this topic](#)

Changing the HTML Source view display

You can change several display properties for the HTML Source view: fonts, colors, word wrapping, how tab characters are used, and line numbering. To set these properties:

- Choose **Options...** from the **Tools** menu.
- Click on the **Source View** tab in the **Options** dialog box.

(These options do not change the contents of the document, but rather how it is displayed in HTML Source view. To configure how the text and markup are laid out, click on the [Source Layout](#) tab.)

Fonts and colors

You can change the font and font size used in HTML Source view, and the colors used to display the following document components:

- Ordinary text (non-markup)
- Start-tags (including attribute names)
- End-tags
- Attributes (that is, attribute values)
- Scripts (the contents of SCRIPT elements)
- Comments
- The DOCTYPE declaration (located at the top of the document in HTML Source view).

These settings do not affect the way your document is displayed in a browser.

Set any of the following font options, which will apply to the entire HTML Source view:

- **Font** – changes the font. Choose a font from the drop-down list.
- **Size** – changes the font size. Choose a size from the drop-down list.

To change the colors used for ordinary text, set any of these options:

- **Foreground** – changes the text color. Click on the button to select a color.
- **Background** – changes the HTML Source view background color. Click on the button to select a color.

To change the colors of various components of the HTML markup:

- Make sure **HTML Colors** is turned on.
- Click on the button for any of the document components and choose a color.

To change the colors of various components of scripts embedded in the document via SCRIPT elements:

- Make sure **Script Colors** is turned on.
- Click on the buttons for any of the script components and choose a color.

Word wrapping

You can change word wrap options. This refers to how lines are displayed in the HTML Source window if they are longer than the current width of the window. The options are:

- **Off** – turns word wrap off, so that the lines extend past the right edge of the window.
- **Break within words** – long lines wrap onto the next line, and can be broken within words.
- **Break between words** – long lines wrap onto the next line, and can be broken only between words. If you choose this option you can also choose to allow or disable line breaking inside tags.

If a line wraps, it does not cause the line number in HTML Source view to increase.

Tab options

The **Tab** option lets you choose how tab characters will be treated in HTML Source view. Note that (except in PRE elements) a sequence of one or more tab or space characters will be collapsed to a single space if you switch to Tags On or WYSIWYG view and save the file; this is consistent with the rendering of 'white space' characters by most HTML browsers.

- Enter a **Size** value between 1 and 16 to specify the number of characters between tab positions in HTML Source view.
- By default, pressing **Tab** will cause HoTMetaL PRO to enter one or more characters to move the insertion point to the next tab

- position. You can turn on **Use tab character** to cause a tab character to be inserted instead.
- If **Auto-indent** is turned on, new lines created by pressing **Enter** will be automatically indented at the same level as the previous line.

Line numbering

Line numbering enables you to hide or show line numbering in the HTML source window.

Changing the HTML Source view layout

HoTMetal PRO uses indentation and line breaking to display HTML source in a way that helps users distinguish content and various kinds of markup. While the default settings should make it easier for you to work with source code (by comparison with a text editor), you may want to adjust the settings to make certain elements stand out. These settings also determine how the file is saved.

To change the HTML Source view layout:

- Choose **Options...** from the **Tools** menu. The **Options** dialog box appears.
- Click on the **Source Layout** tab.

Any options you choose are applied to files saved from Tags On and WYSIWYG views. If you turn on the **Enable automatic layout** checkbox, these options will also be applied when you switch from Tags On or WYSIWYG view to HTML Source view.

Files are saved from HTML Source view 'as-is'. To force layout options to be applied to HTML Source view, turn on **Enable automatic layout**, switch to Tags on or WYSIWYG view, and then switch back to HTML Source view. If you do not want automatic layout options to be applied to your files, turn off automatic layout, and do not save your files in Tags On or WYSIWYG view; from the **View** tab, you can also make HTML source view the default view in which files are opened and created.

Line endings

End of Line sets the line ending options. The options are:

- Each line ends with carriage return (CR) and line feed (LF), as in Windows.
- Each line ends with line feed (LF) only, as in UNIX.
- Each line ends with carriage return (CR) only, as in Macintosh.

Pretty-printing

You can also affect how specific types of elements will be laid out; this is sometimes referred to as **pretty-printing**.

- Choose an **Indent size**: this is the number of characters that the contents of an element will be indented if indent contents (see below) is turned on for that element.
- You can choose layout options for one or more elements (you don't have to click on Apply for each element—choose options for as many elements as you need to and then click on **Apply**).
 - Select the element from the **Elements** list (!-- stands for HTML comments).
 - Turn on **Indent contents** if you want the contents of the element to be indented. This option is commonly chosen for list elements such as OL and UL.
 - You can add a blank line or new line (line break) before or after the start-tags or end-tags.

To restore the Source Layout options to the defaults:

- Click on **Restore Defaults**.
- Close the window by clicking on **OK**.

Using WebBot components

WebBot™ components (also called FrontPage components) are a feature of Microsoft FrontPage™ and Web servers that support the FrontPage Server Extensions. WebBot components consist of some special markup, and sometimes other content. A WebBot component acts as an instruction to the client or server to process the content in a special way or take some other action. If you intend to use any of the server-side WebBot components, you should ask your ISP if their server supports the FrontPage Server Extensions.

HoTMetal PRO enables you to open pages containing WebBot components and enter your own WebBot component markup. HoTMetal PRO does not interpret and run WebBot components.

HoTMetal PRO supports the standard FrontPage WebBot components. If new WebBot components are added to the product, or you create your own, you can extend HoTMetal PRO's capabilities in order to support them.

WebBot components are invisible in WYSIWYG view; in Tags On view they are displayed as a pair of tags containing the WebBot name, with the WebBot markup between the tags. You can view and edit the WebBot markup directly in HTML Source view.

To enter a WebBot component, switch to HTML Source view, and enter the WebBot component markup directly. WebBot components are implemented using HTML comments. Usually there is a 'start comment' and an 'end comment'; between the comments there can be special content, such as an HTML form that interacts with the WebBot, or some non-standard HTML markup that is hidden and will be processed only by an application that understands the WebBot component. For example:

```
<!--webbot bot="HTMLMarkup" startspan -->  
  
<newtag>Interpret me, if you dare!  
</newtag>  
  
<!--webbot bot="HTMLMarkup" endspan -->
```

This example shows the 'HTMLMarkup' WebBot component, which enables you to hide non-standard markup (for example, ColdFusion markup); see SoftQuad's Support Center (<http://www.softquad.com/supportcenter>) for tips.

HoTMetal PRO provides partial support for Active Server Page (ASP) markup; however, any ASP markup that cannot be opened in the normal way requires the 'HTMLMarkup' WebBot component in order to be opened in HoTMetal PRO

Adding support for new WebBot components

HoTMetal PRO can open pages containing the standard [FrontPage WebBot components](#). If new WebBot components are added to the product, or you create your own, you can extend HoTMetal PRO's capabilities in order to support them. You do this by editing the **hmpro5.ini** file, in the HoTMetal PRO folder.

For each new WebBot component, there are three settings:

- non_SGML_start_comment_N
- non_SGML_end_comment_N
- non_SGML_tag_N (optional)

In each case, N is a number. For each group of settings, use the next available unused number: if there are already 10 groups, you would use **non_SGML_start_comment_11**, and so forth.

These settings are used as follows:

- **non_SGML_start_comment_N** should be set to some text or a pattern that defines the markup inside the 'start comment'. You can use the same special characters in patterns as are used in [search patterns](#) in HoTMetal PRO.
- **non_SGML_end_comment_N** should be set to some text or a pattern that defines the markup inside the 'end comment'. You can use the same special characters in patterns as are used in [search patterns](#) in HoTMetal PRO.
- **non_SGML_tag_N** should be set to the name of the tag that is will represent the WebBot component in the HoTMetal PRO Tags On view. If you don't make this setting, the name WEBBOT will be used.

You may find it helpful to use the existing settings in the **hmpro5.ini** file as models when creating new settings. In many cases, you may be able to implement the new settings by copying existing ones and simply changing the WebBot component name.

This extension mechanism does not have to be used only to define new WebBot components; it can also be used to define your own special markup.

Working with forms

What you'll learn in this chapter

You can create HTML forms, like paper forms, for users to fill out information according to your specifications. You can guide the user through:

- Single-line or multi-line text input.
- 'Yes' or 'no' choices made with a check box.
- 'One of the following'-style choices made with option (radio) buttons.
- Selections from drop-down lists or selection lists.
- Entering a password.
- Attaching (uploading) a file.
- Calling a script embedded in your document.

Usually forms contain a button that the user clicks on to submit the form data, and another button that the user can click on to reset the form fields to their default values.

When the user submits the form, it goes to either an email address or to a program on a Web server.

Reference

To create a form field, click on the appropriate button in the **Forms** toolbar, or choose the appropriate command in the **Form** menu. If the **Forms** toolbar is not visible, click on the toolbar area and choose **Forms** from the pop-up menu.

In HTML, all form fields must be enclosed in a FORM element. You can start creating your form by inserting a FORM element explicitly, or you can just insert any form field, and HoTMetaL PRO will create the FORM element automatically. In WYSIWYG view, the FORM element is not displayed. In Tags On view, the FORM start- and end-tag icons give you a useful visual cue to the form's boundaries.

To create a FORM element explicitly:

- Click on the  toolbar button or choose **Insert Form** from the **Form** menu.

[More on this topic](#)

Form field properties

Fields in a form have a number of properties that you can (or, in some cases, must) edit. Some common properties are:

- **Name** – Most form objects must have a name. Except with radio buttons, a name cannot be used twice in the same form. When the form is submitted, the name is sent along with the input data for that object, so that the receiving program will know which graphical object the data came from.
- **Value** – The value associated with a form object is normally the data that the user enters. Some objects—text boxes, password fields, drop-down lists, selection lists, multi-line text areas—let you specify a default value. Check boxes have a default value of 'off' or 'on', depending on whether the user checks them; this can also be overridden. Option (radio) buttons **must** be given a value when the form is created.
- **Size** – You can specify the default size of some objects. Widths are specified in characters; heights are specified in lines.
- **Checked** – You can specify that a check box or option (radio) button is checked (turned on) by default.

Once you have inserted a form object, you can edit its properties in three ways:

- 1 Double-click on the object.
- 2 Right-click on the object and then choose **Form Field Properties...** from the pop-up menu. (The menu item changes depending on what kind of object you click on: **Text Box Properties...**, **Option Button Properties...**, and so forth.)
- 3 Click once on the object and then choose **Form Field Properties...** from the **Forms** menu. (The menu item for this command also changes, depending on what kind of object you click on).

Each of these actions brings up a dialog box, specific to each type of object, in which you can edit the object's properties. Click on the **Help** button in each dialog box for more information on the properties for that kind of form object.

These properties correspond to attributes of the object: if you wish to edit the attributes directly, right-click on the object and choose **Attribute Inspector** from the pop-up menu.

Creating a text field

A text box lets the user enter a single line of text in a form.

To insert a text box:

- Click on the  button in the **Forms** toolbar or choose **Text Box** from the **Form** menu.

A text box appears in the form. You can get a good idea of what this form element will look like in your Web browser from how it looks in the HoTMetal PRO document window.

To set the properties of the text box:

- Double-click on the text box, or right-click on the text box and choose **Text Box Properties...** from the pop-up menu.

The **Text Box Properties** dialog box lets you set the most important properties of a text box.

- **Name** – This value is used when the browser sends the input data to the server, in order to identify which text box, drop-down list, etc. on the form, a particular piece of data came from. You should always set a value for **Name**; this value should be unique—it should not be used for any other object in the form. HoTMetal PRO will automatically generate a name of the form 'Text1', 'Text2', and so forth—you can keep this name or enter something more descriptive.
- **Value** – If you specify text here it will be displayed in the text box by default.
- **Size** – Specifies the text box size in characters. Entering a number here will change the size of the text box. If no number is entered, the text box will be 20 characters long.
- **Max. Length** – The maximum number of characters that can be entered in the text box in a browser.

Entering several lines of text (scrolling text area)

A text box in a form accepts just one line of text. If you need to let your users enter several lines of text at once (to enter an address, for example), you should use a scrolling text area. This is a rectangular area that has vertical and horizontal scrollbars so that the user can enter as many lines of text as are needed.

- Click on the  button, or choose **Text Area** from the **Form** menu.

HoTMetal PRO will insert a graphical representation of a scrolling text area, which looks similar to the way this object is displayed in most browsers.

To set the properties of the text area:

- Double-click on the text area, or right-click on the text area and choose **Text Area Properties...** from the pop-up menu. This brings up a dialog box that lets you set the most important properties of a text area.
 - **Name** – This value is used when the browser sends the form's data to the server, in order to identify which object in the form a particular piece of data came from. You should always set a value for **Name**; this value should be unique—it should not be used for any other object in the form. HoTMetal PRO will automatically generate a name of the form 'MultiText1', 'MultiText2', and so forth—you can keep this name or enter a more meaningful choice.
 - **Default Content** – The text you enter here will be the default text displayed in the text area by the browser.
 - **Width** – Enter the number of characters wide that you want the text area to be.
 - **Rows** – Enter the number of rows that you want.
 - **Text Wrapping** – You can choose virtual, physical, or no text wrapping.

Creating drop-down lists and list boxes

Drop-down lists and list boxes are two ways of letting a user make a choice from a list of choices. A drop-down list is a menu from which the user can make one choice; a list box is a scrollable list from which the user can make one (or sometimes more than one) choice. Which one you use depends on which graphical object you think works best in your form, and whether you want to offer more than one choice—if you do, you have to use a list box.

To create a drop-down list:

- Click on the  toolbar button or choose **Dropdown List** from the **Form** menu.

To create a list box:

- Click on the  toolbar button or choose **List Box** from the **Form** menu.

HoTMetaL PRO will display a graphical representation of the drop-down list or list box.

A drop-down box or list box contains one or more items (also called options).

To add items and edit the object's properties:

- Double-click on the object, or right-click on the object and choose **List Properties...** from the pop-up menu.

The **List Properties** dialog box appears, letting you create and edit a list of choices.

You can set the following properties:

- **Name** – This value is used when the browser sends the form's data to the server, in order to identify which object in the form a particular piece of data came from. You should always set a value for **Name**; this value should be unique—it should not be used for any other object in the form. HoTMetaL PRO will automatically generate a name of the form 'Select1', 'Select2', and so forth—you can keep this name or enter a name of your own choice.
- **Size** – This is the number of list items that are displayed in the browser. If this value is greater than 1, the list automatically becomes a list box, even if it was created as a drop-down list.
- **Allow Multiple Selections** – If you want the user to be able to choose more than one item from the list, turn on the check box. If you choose this option, the list automatically becomes a list box, even if it was created as a drop-down list.

Note: If 'Size' is set to '1' and 'Allow Multiple Selections' is turned off, the list automatically becomes a drop-down list.

Each list item consists of a label and a default value. The label is the text for that item that is displayed in the browser. The value is the text that the browser sends, if this item is selected when the form is submitted.

Adding items to the list

To add an item:

- Enter the label in the **List Item** text box.
- Enter a value in the **Value** text box. You should use a different value for each item.
- If you want this item to be selected automatically when the list is displayed, turn on the **Default Item** check box. There can be only one default item in the list.
- Click on **Add >>**.

To edit an existing item:

- Click on the item that you want to edit.
- Click on **Remove/Edit**. The item will 'jump out' of the list and become editable.
- Make the desired changes to **List Item**, **Value**, and **Default Item**.
- Click on **Add >>**. The item you just edited will move back into the list, at the end.

To delete an existing item:

- Click on the option that you want to delete.
- Click on **Remove/Edit**. The item will 'jump out' of the list.

To change the order of items in the list:

- Click on the item that you want to move.

- Click on the  button to move the item up or the  button to move the item down.

Creating check boxes

Check boxes let the user make a 'yes/no' choice. These are different from [option buttons](#) which let the user make one choice from a group of choices.

To insert a check box:

- Click on the  toolbar button or choose **Check Box** from the **Form** menu.

HoTMetaL PRO inserts a check box icon.

To edit the properties of a check box:

- Double-click on the check box, or right-click on the check box and choose **Check Box Properties...** from the pop-up menu.

You can set the following properties:

- **Name** –This value is used when the browser sends the form's data to the server, in order to identify which object in the form a particular piece of data came from. You should always set a value for **Name**; this value should be unique—it should not be used for any other object in the form. HoTMetaL PRO will automatically generate a name of the form 'CheckBox1', 'CheckBox2', and so forth—you can keep this name or enter a name of your own choice.
- **Value** – When the form is submitted, the default value associated with checked boxes is the word 'on' (unchecked boxes are not submitted with the form's data). If you want to override this default, enter the text to be associated with the check box in the **Value** text box.
- If you want this check box to be turned on (checked) by default, turn on the **Checked?** check box.

Creating option buttons (radio buttons)

A group of option buttons (also called radio buttons) lets the user make one (and only one) choice from a group of choices.

To insert an option button:

- Click on the  toolbar button or choose **Option Button** from the **Form** menu.

HoTMetaL PRO inserts an option button.

To edit the properties of an option button:

- Double-click on the option button, or right-click on the option button and choose **Option Button Properties...** from the pop-up menu.

You can set the following properties:

- **Name** – This value is used when the browser sends the form's data to the server, in order to identify which object in the form a particular piece of data came from. Each item in a group of related option buttons must have the same name, so that the browser will know that only one button in the group can be turned on at the same time. HoTMetaL PRO will automatically generate a name of the form 'Radio1'—you can keep this name or enter a name of your own choice. If you create another group of radio buttons in the same form, you must use a different name for that group.
- **Value** – All option buttons must have a value; this value is submitted by the browser if the option button is turned on when the form is submitted. These values should be unique within each group of buttons with the same name. HoTMetaL PRO will generate unique values of the form 'Value1', 'Value2', and so forth; if you want to override this default, enter a value of your choice in the **Value** text box.
- If you want this option button to be turned on (checked) by default, turn on the **Checked?** check box. Only one option button in a group can be turned on by default.

Creating a reset button

Forms usually contain a **reset button** that restores all the form's controls (text boxes, radio buttons, etc.) to their default values.

To create a reset button:

- Click on the  toolbar button, or choose **Reset Button** from the **Form** menu.

To set the properties of a reset button:

- Double-click on the reset button, or right-click on the reset button and choose **Reset Button Properties...** from the pop-up menu.

You can set the following properties:

- **Name** – Even though you can set this value, reset buttons don't generally need a name since they aren't submitted to the server.
- **Value** – If you enter text in this box it will become the label for the reset button, instead of the default, 'Reset'.

Creating a submit button

When the user clicks on the **submit button** the form's data is sent to the server or email address. There are two kinds of submit buttons:

- The most common kind of submit button looks like a button and has a text label.
- An **image submit button** consists of a graphical image.

To create a submit button:

- Click on the  toolbar button to insert an ordinary button or the

button to insert an image submit button, or choose **Submit Button** or **Image Button** from the **Form** menu.

To set the properties of a submit button:

- Double-click on the submit button, or right-click on the submit button and choose **Submit Button Properties...** or **Image Button Properties...** from the pop-up menu.

You can set the following properties:

- **Name** – If you have several forms (in this document or in different documents) whose data will be sent to the same recipient (this could be a program or an email address) you should use different values for the name of the submit button so that the recipient will have a way of easily knowing which form the data came from.
- **Value** – If you enter text in this box it will become the label for the submit button, instead of the default (usually 'Submit Query').
- **Image File** – If you've inserted an image submit button, use this text box or the **Edit...** button to enter the URL of the image.

Creating a file upload field

A **file upload field** enables the user to attach a file to the data submitted with the form. A file upload field consists of a text box and, depending on the browser, a button that brings up a file chooser dialog box: the user can specify a file with either of these controls.

To insert a file upload field:

- Click on the  toolbar button or choose **File Upload** from the **Form** menu.

To set the properties of the file upload field:

- Double-click on the file upload field, or right-click on the field and choose **File Upload Properties...** from the pop-up menu.

You can set the following properties:

- **Name** – This value is used when the browser sends the form's data to the server, in order to identify which object in the form a particular piece of data came from. You should always set a value for **Name**; this value should be unique—it should not be used for any other object in the form. HoTMetal PRO will automatically generate a name of the form 'File1', 'File2', and so forth—you can keep this name or enter a unique name of your own choice.
- **Size** – Specifies the size in characters of the text box part of the file upload field.
- **Max. Length** – Sets the maximum length of a filename (including the folder path) that be entered in the file upload field.
- **Acceptable File Types** – Enter the list of file (MIME) types that the field can be used to upload.

In order to allow a form to upload files, you must also change the form's 'MIME type':

- Place your insertion point just to the right of the [FORM> start-tag.
- Choose **Attribute Inspector** from the **View** menu, or press **F6**.
- Enter the value **multipart/form-data** for the FORM element's ENCTYPE attribute.

Creating push buttons to activate scripts

A form can contain **push buttons** that activate script commands.

To create a push button:

- Click on the  toolbar button or choose **Push Button** from the **Form** menu.

To edit the properties of a push button:

- Double-click on the push button, or right-click on the button and choose **Push Button Properties...** from the pop-up menu.

You can set the following properties:

- **Name** – This value is used when the browser sends the form's data to the server, in order to identify which object in the form a particular piece of data came from. You should always set a value for **Name**; this value should be unique—it should not be used for any other object in the form. HoTMetal PRO will automatically generate a name of the form 'Button1', 'Button2', and so forth—you can keep this name or enter a unique name of your own choice.
- **Value** – If you enter text in this box it will become the label for the push button, instead of the default (usually 'Button').

To set up a push button to run a script, you also have to:

- Select the push button.
- Press **F6** or choose **Attribute Inspector** in the **View** menu.
- Specify a script call as the value of **onBlur**, **onClick**, **onChange**, **onLoad**, or **onSelect**, as appropriate.

For more information, see the section [Scripts](#) and any available external documentation on the scripting languages (for example, JavaScript).

Creating a hidden input field

A **hidden input field** is not displayed in the browser or accessible to the user: it is used to send pre-set information that is use only by the recipient of the form's data. For example, it could identify to the recipient which form the data came from.

To create a hidden input field:

- Click on the  toolbar button or choose **Hidden Input** from the **Form** menu.

To edit the properties of a hidden input field:

- Double-click on the hidden field, or right-click on the button and choose **Hidden Input Properties...** from the pop-up menu.

You can set the following properties of a hidden input field:

- **Name** – This value is used when the browser sends the form's data to the server, in order to identify which object in the form a particular piece of data came from. You should always set a value for **Name**; this value should be unique—it should not be used for any other object in the form. HoTMetal PRO will automatically generate a name of the form 'Hidden1', 'Hidden2', and so forth—you can keep this name or enter a unique name of your own choice.
- **Value** – This is the value that will be submitted for the hidden input field when the form is submitted.

Creating a password entry

A password entry is similar to a [text box](#). It is intended for users to submit a password, so the text that the user enters will be blanked (replaced by asterisks) when the user types it; it will, however, be sent along with the other form data when the form is submitted.

To create a password entry:

- Click on the  toolbar button or choose **Password Entry** from the **Form** menu.

To edit the properties of a password entry:

- Double-click on the password field, or right-click on the button and choose **Password Entry Properties...** from the pop-up menu.

You can set the following properties:

- **Name** – This value is used when the browser sends the form's data to the server, in order to identify which object in the form a particular piece of data came from. You should always set a value for **Name**; this value should be unique—it should not be used for any other object in the form. HoTMetal PRO will automatically generate a name of the form 'Password1', 'Password2', and so forth—you can keep this name or enter a unique name of your own choice.
- **Size** – Specifies the size in characters of the password field.
- **Max. Length** – Sets the maximum length of the password that be entered in the field.

What happens when a form is submitted

After collecting information from the user, you will want to do something with it—even if you plan only to store it in a database for future use. More often, however, you will be interested in responding to your user. In fact, you should consider responding to your user within a few minutes, confirming that the input has been received and will be acted on. All of this implies some form of processing—probably, but not necessarily, automatic processing.

Typically this kind of processing is handled by programs running on the server. Though these may be written in any computer language and may communicate with the HTML serving processes in a couple of ways, two standards have become predominant: Perl is probably the most common programming language used to write user input processing programs, and Common Gateway Interface (CGI) is the way most server-side processes communicate with the HTML serving processes. If this is strange and new, you're not alone—and it doesn't mean that you have to stop right here in the face of a steep learning curve before you can use a form on your document. Most HTML document editors don't write Perl, or any other kinds of programs, and don't know much about CGI. Instead, they rely on their systems administrators and other programmers to provide the back-end processing that will handle the data flowing in from their HTML pages.

However, it is also possible to receive information from your form documents without preparing any server-side processing. If you want to use forms, but don't have a program set up on your server to process the data, you can send the raw content of the form to an email address, which is a quick and easy way to get form functionality. However, the content of that email may require editing. This may be useful in the short term, or for a small volume of responses that you are willing to deal with manually.

[More on this topic](#)

Specifying where the form is submitted

The form's **action** determines what happens to the data entered by the user when the submit button is pressed. The action can be either a program on a Web server that processes the data, or an email address that receives it. You specify an action by setting a value for the FORM element's ACTION and METHOD attributes.

In WYSIWYG view:

- Right-click on any form field and choose **Attribute Inspector** from the pop-up menu.
- Choose **FORM** from the drop-down list of elements at the top of the **Attribute Inspector** window.

In Tags On view:

- Put the insertion point immediately to the right of the [FORM> start-tag.
- Press **F6**, or right-click and choose **Attribute Inspector** from the pop-up menu.

At this point you should be editing the attributes of the FORM element. Check that **FORM** is the selected element—it will appear at the top of the dialog.

- In the **ACTION** field, enter the URL for the program or email address that you wish to submit the form data to, and then press **Enter**. (A URL for an email address must start with 'mailto'; for example: **mailto:charles@windsor.org**.)
- If the data is being submitted to a program, set the value for METHOD to either GET (the default) or POST, depending on the requirements of the program. Then press **Enter**.
- If the data is being submitted to an email address, set the value for METHOD to POST. Then press **Enter**.

How the data looks to the recipient

When a browser submits a form's data, it formats it in a standard way that all programs receiving the data should expect. The information is presented in pairs containing a 'name' (corresponding to the name of the text box, check box, etc.) and a 'value' (for text boxes or 'text areas', this will be the data entered; for check boxes the value 'on' is submitted—check boxes that aren't turned on are ignored; for radio buttons the **Value** is sent).

Each name and its corresponding value are separated by an equal, '=', sign. Each name/value pair is separated by an ampersand, '&'. Spaces are replaced by a '+' sign, and some special characters (notably newline, '=', and '&') are replaced by '%nn', where the **n**'s are digits from 0-9 and/or letters between 'A' and 'F'.

For example, if you have a text box named 'speak' that contains the text 'duck soup', a check box named 'english' that is turned on, and a submit button named 'Submit1' with the label 'Submit Query', the form's data will look like this when submitted by the browser:

```
speak=duck+soup  
&english=on  
&Submit1=Submit+Query
```

The HTML behind the form

This section briefly discusses the HTML markup that represents form objects. You can create and edit forms using the **Element...** and **Attribute Inspector** commands, but in most cases the frame editing commands will be faster and more convenient.

All form objects are surrounded by a FORM element.

Most form objects (text boxes, check boxes, radio buttons, submit buttons) are represented by INPUT elements. The value of the INPUT's TYPE attribute determines what type of object it represents; for example, if TYPE has the value TEXT (this is the default), a text box will be generated.

List boxes and drop-down lists are represented by the SELECT element; each item in the list is represented by an OPTION element. A SELECT element represents a drop-down list if its SIZE attribute is set to '1' (one) and its MULTIPLE attribute has no value. Otherwise it represents a list box.

A scrolling text area is represented by a TEXTAREA element.

Creating frames

What's covered in this chapter

This chapter describes how to use HoTMetaL PRO to create pages that divide the browser window into multiple regions using frames. Topics include:

- Creating frames to define areas of the window.
- Providing alternative pages.
- Using the WYSIWYG-Frames view.
- Targeting specific frames.

Reference

You can use frames to tell browsers to divide the window into multiple rectangular regions and display a different document or location in each region. You can also **target** frames (that is, use attributes to control which frame will display a linked document). HoTMetaL PRO provides a WYSIWYG Frames editing window for creating and formatting frames.

Note: Frames, while commonly used, are not part of the HTML 2.0 specification, and are not supported by all Web browsers. Use this feature with caution, and ensure that you have alternative pages for users of non-frame browsers and screen readers.

Note: Microsoft Internet Explorer must be installed on your PC in order for frame editing to be available.

[More on this topic](#)

Common uses for frames documents

By default, any anchor (A) in a frame will load a document into that same frame. This is the simplest application of a frame set document. More commonly, frame set documents are used to create interactive web sites, where clicking on menu items in one frame window causes documents to appear in another. For example, many sites on the Web use frames to create:

- Navigation bars – One frame displays a toolbar containing an image map or group of image anchors. Clicking on an image area causes content to display in another window (or windows).
- Footnotes – Used for technical or scholarly documents containing definitions or quotes. At least one document window with content contains an anchor element that jumps to specific points in a second footnote document. Clicking on an anchor causes the linked reference to display.
- Static title bar – A frame across the top of the browser window that keeps the title of the current document displayed can be combined with a navigation bar along the side that displays various portions of the document. This helps to orient the viewer, because the browser will show only the name of the frameset document in the title bar. An additional window below the main content frame could be used to display footnote information.
- Progressive detail – In this frame structure, the frame set is divided into any number of frames, with anchor elements providing 'choices' in each frame window. Each choice made would load a document in the next frame in the hierarchy containing more choices, with progressive levels of detail added with each choice.

Creating documents with frames

A frame-based document has two components:

- A **frameset** document that defines the frames.
- The individual documents (or document locations) that are displayed in the frames. These documents are associated with frames using URLs.

If you are setting up a frames-based document you can also optionally do the following:

- Supply some alternative content, in the frameset document, which will be displayed if the browser does not support frames.
- Assign names to frames so that you can specify that a document accessed by a link will be displayed in a specific frame.

If your document already contains frames, skip to the **Editing the frameset** section below.

To create a **new** frameset document:

- Choose **New...** in the **File** menu, then **Frames Page** from the fly-out menu, then choose one of the frame templates from the next fly-out menu.

If none of the templates correspond to the frame structure you want, you can pick the closest one and modify it, or you can create a new document with a single frame and modify that document:

- Choose **New...** in the **File** menu, then **New Page** from the fly-out menu.
- Choose **Convert to Frames** in the **Tools** menu.

To convert an existing document to a frameset document:

- Open an existing document.
- Choose **Convert to Frames** in the **Tools** menu.

Convert to Frames creates an initial frameset containing a single frame. If the original document had any content, it will be moved to an element called NOFRAMES: the content of this element is the alternative content that will be displayed if a browser cannot display frames.

At this stage the frameset contains a single frame that has no content. If you want the original content of your document to be displayed in a frame, you have to save that content in a separate file and assign that file to a frame.

Editing the frameset

Now you should carry out the following steps:

- 1 Refine the frame structure using the WYSIWYG-Frames view. The **Frames** toolbar enables you to specify the number and size of the frames, make frames resizable by the browser, display scrollbars in frames, and turn frameset borders on and off.
- 2 Assign to each frame a document that will be loaded in that frame initially when the frameset document is displayed .
- 3 If desired, assign names to the frames so that you can cause linked documents to be displayed in specific frames. If you do this, you also have to modify your links to refer to the desired frames.
- 4 If desired, insert some alternative content for non-frames browsers .
- 5 If you want to define frame spacing you have to do so using attribute values .

Defining frames in the WYSIWYG-Frames view

Once your document contains a frameset, you can start editing it as a frameset document.

Frame editing is carried out with three components of the HoTMetaL PRO interface: the WYSIWYG-Frames view, the **Frames** toolbar, and the **Frameset** menu. The **Frames** toolbar contains buttons and fields for creating frames and setting options for the currently selected frame.

To open the WYSIWYG-Frames view:

- Choose **WYSIWYG-Frames** from the **View** menu.

The **WYSIWYG-Frames** command is grayed out if the current document does not have a frameset.

The WYSIWYG-Frames view window represents the position and sizes of the frames in your frame document; you can add, delete, and resize frames in this area. If you click on a frame in the WYSIWYG-Frames view window, the properties of that frame are displayed in the **Frames** toolbar, and any changes you make from the toolbar are applied to that frame. The **active** frame has a blue border.

To move to the next frame or frameset in WYSIWYG-Frames view, press **Tab**; to move to the previous frame or frameset, press **Shift+Tab**.

Note: Microsoft Internet Explorer must be installed on your PC in order for the WYSIWYG-Frames view to be available.

To display the **Frames** toolbar:

- Right-click on the background of the toolbar area to bring up the pop-up menu for toolbars.
- If **Frames** is not turned on, turn it on to display the toolbar.

The **Frameset** menu offers all of the frame editing options. You can use this menu to edit the frame source, split the frame into columns and rows, delete frames, add scrollbars, toggle resizability, create borderless frames, refresh the display, and edit the frame's properties.

Note: You cannot switch directly from HTML Source view to WYSIWYG-Frames view; switch to WYSIWYG or Tags On view first, and then switch to WYSIWYG-Frames view.

[More on this topic](#)

Creating frames

You can create more frame areas in WYSIWYG-Frames view in several different ways:

- Click on the  button to split the currently selected frame into rows, or click on the  button to split the selected frame into columns.
- If you right-click on a frame, you can choose **Split Frame into Columns** or **Split Frame into Rows** from the pop-up menu.
- You can also choose **Split Frame into Columns** or **Split Frame into Rows** from the **Frameset** menu.

Each frame, when split, takes up half of the original frame's area.

To create custom-width frames, do **one of** the following:

- Using your mouse, hover over the edge of the window until the cursor becomes a double-headed arrow, drag in the direction necessary to size the frame, then release the mouse button.

Or:

- Create a new frame by splitting an existing frame, as described above.
- Enter the desired frame size in the **Size** text box in the **Frames** toolbar, and press **Enter**.

The default size unit for new frames, as shown in the **Size** text box in the **Frames** toolbar, is '%' (percent), unless the new frame was created by splitting a frame whose size was expressed as an absolute number of pixels, or a proportional (*) size.

Resizing frames

When you create a frame or manipulate its size, frame size values are generated automatically (as a percentage of the document window size). You can also specify the size of a frame as an absolute (specific) number of screen pixels or as a proportional size.

To resize a frame:

- Enter a size in the **Size** text box in the **Frames** toolbar, and then press **Enter**.

Or:

- Choose **Frame Properties...** from the **Frameset** menu, or right-click on the frame with your mouse and choose **Frame Properties...** from the pop-up menu. The **Frame Properties** dialog box appears.
- Enter a size in the **Size** text box, and then click on **OK**.

Absolute pixel sizes are not usually a good idea, since the browser window size can vary on different platforms and monitor sizes. A proportional size is specified with an asterisk (for example, 1* or *, 2*, or 3*). These are interpreted as follows: after all widths, or heights, specified as percentages or absolute amounts have been allocated to the corresponding frames, the remaining space will be allocated to frames, proportionally. For example, suppose your document was viewed in a browser window 800 pixels high and you had four horizontal frames within one frameset with the following size values:

50%, 100, *, 2*

The first frame would be 50% of the total height (400 pixels); the second frame would be the specified 100 pixels. The remaining 300 pixels would be divided between the other two frames. The fourth frame's height (2*) is set to twice that of the third frame (*), so the third frame would be 100 pixels high and the fourth would be 200 pixels high.

Resizable frames

Click on the  button to enable the browser to allow a frame to be resizable.

Adding scrollbars to frames

Frames can have scrollbars, no scrollbars, or you can tell the browser to add scrollbars automatically if the document in the frame is larger than the display size of the frame. Use the scrollbar buttons in the **Frames** toolbar to add or remove scrollbars (the default setting is to have scrollbars as needed).

To set the scrollbar options:

- Click on the appropriate frame in the WYSIWYG-Frames view window.
- To always have scrollbars, do **one of** of the following: click on the  button; right-click with your mouse on the frame and choose **Scrollbars - Always** from the pop-up menu; or choose **Always** from the **Scrollbars** fly-out menu in the **Frameset** menu.
- To never have scrollbars, do **one of** of the following: click on the  button; right-click with your mouse on the frame and choose **Scrollbars - Never** from the pop-up menu; or choose **Never** from the **Scrollbars** fly-out menu in the **Frameset** menu..
- To have the browser add scrollbars as needed, do **one of** of the following: click on the  button; right-click with your mouse on the frame and choose **Scrollbars - Automatic** from the pop-up menu; or choose **Automatic** from the **Scrollbars** fly-out menu in the **Frameset** menu.

Borderless frames

You can create **borderless frames**. This option makes all frames in the document appear without boundaries (borders).

To create borderless frames, do **one of** the following:

- Click on the  button from the **Frames** toolbar.
- Right-click and choose **Borderless Frames** from the pop-up menu.
- Choose **Borderless Frames** from the **Frameset** menu.

The frame borders in the WYSIWYG-Frames view window disappear.

To restore the frame borders, de-select **Borderless Frames** from the pop-up menu.

Deleting frames

There are several ways that you can delete a frame from the WYSIWYG-Frames view window.

To delete a frame:

- Click the frame in the WYSIWYG-Frames view window and do **one of** the following:
 - Click on the  button in the toolbar.
 - Right-click inside the frame and choose **Delete Frame** from the pop-up menu.
 - Choose **Delete Frame** from the **Frameset** menu.

Frame templates

HoTMetaL PRO provides frame templates that you can use to create new frame documents. The templates include some basic and commonly used frame layouts for Web pages. To use a frame template for your document:

- Choose **New...** from the **File** menu.
- Choose a frame template from the **Frames Page** fly-out menu.

The icon beside each frame template displays what the frames look like. Headers and footers are typically used to hold a logo or banner. The contents area may hold a table of contents, index, or the main content of the Web page. The available frame templates are:

-  – **Header and Contents**
-  – **Contents**
-  – **Footer**
-  – **Header**
-  – **Header, Footer and Contents**
-  – **Header and Footer**

After you have chosen a frame template from the fly-out menu, the WYSIWYG-Frames view window will display the frame template. Now you can use this view to specify the default controls, resize the frames, and do other frame editing.

Assigning a document to a frame

A frame will generally have a default document that is displayed in the frame when the frame document is initially loaded in the browser. The contents of a frame may change during a browsing session if the viewer clicks on a link that is targeted at that frame. If you do not specify a default document for a frame, it may be displayed as a blank area in the browser.

To specify the default document for a frame in the WYSIWYG-Frames view:

- Click on the frame to select it.
- Choose **Frame Properties...** from the **Frameset** menu, or right-click on the frame and choose **Frame Properties...** from the pop-up menu. The **Frame Properties** dialog box appears.
- Enter the URL for the document in the **Source** text box, either by typing it directly or by clicking on the **Browse...** button and selecting the file.

Dragging and dropping files onto a frame

You can also drag and drop files onto a frame. If the frameset document has been saved at least once, the URL of the dropped file will be relative to the location of the frameset document; if the frameset document has never been saved, the URL will be a full path. You can also drag and drop files from the **Assets** tab or **Desktop** tab in the **Resource Manager**, or from the **Thumbnail View**, onto a frame.

You can also use the SRC attribute of a FRAME element to specify the default document displayed in a frame:

- Click in the frame in WYSIWYG-Frames view.
- Choose **Attribute Inspector** from the **View** menu, or press **F6**.
- Enter the URL for the default document in the **SRC** field, either by typing it directly or by clicking on the ... button and choosing the file.
- Close the **Attribute Inspector**.

Editing a document in a frame

After you have supplied a source URL for a frame, you can edit the frame content. To edit the content of a frame in WYSIWYG-Frames view, do **one of** the following:

- Double-click in the frame.
- Click in the frame and choose **Edit Frame Contents** from the **Frameset** menu.
- Right-click in the frame and choose **Edit Frame Contents** from the pop-up menu.

The document will open in your default HoTMetal PRO document view.

Copying frame properties

You can drag and drop frame properties, including source URLs, between frames in WYSIWYG-Frames view:

- To **copy** one frame's properties—including its source URL—to another frame, hold down the **Ctrl** key, click and hold down the mouse button in the first frame, then drag and release in the second frame.
- To **swap** the properties—including source URLs—of two frames, hold down the **Shift** key, click and hold down the mouse button in one frame, then drag and release in the second frame.
- To **move** one frame's properties—including its source URL—to another frame, click and hold down the mouse button in the first frame, then drag and release in the second frame.

Refreshing the contents

The **Refresh** command in the **Frameset** updates the WYSIWYG-Frames view after a frame's content has changed.

- Click in the frame whose content you wish to edit.
- Choose **Edit Frame Contents** from the **Frameset** menu, or right-click and choose **Edit Frame Contents** from the pop-up menu.
The document opens in the HoTMetaL PRO document window.
- Make any changes needed to the document.
- Save your document.
- Choose **WYSIWYG-Frames** from the **View** menu.
- Choose **Refresh** from the **Frameset** menu, or right click and choose **Refresh** from the pop-up menu.

The WYSIWYG document display is updated with the current contents of the document you just edited.

To stop a frame's source document from loading, or a Web object (such as an animated GIF, or a JavaScript) from playing in the **WYSIWYG-Frames** view:

- Choose **Stop** from the **Frameset** menu, or right-click and choose **Stop** from the pop-up menu.

This is useful if the playing or loading of an object would be distracting or time-consuming.

Loading linked documents in specific frames

By default, if you click on a link in a document displayed in a frame, the linked document will be displayed in that same frame. To have a document referred to by a link display in a specific frame (called the **target** frame), do the following:

- 1 Give the frame a **name**.
- 2 Modify the link to refer to that frame name.

Assign a frame name

To give a frame a name:

- Choose **WYSIWYG-Frames** from the **View** menu.
- Click on the frame to make it active.
- Choose **Frame Properties...** from the **Frameset** menu, or right-click on the frame and choose **Frame Properties...** from the pop-up menu.
- Enter the name in the **Name** text box.

Or:

- Switch to Tags On view.
- Put the insertion point inside the FRAME element corresponding to the frame.
- Choose **Attribute Inspector** from the **View** menu, or press **F6**.
- Enter the name in the **NAME** field.

Referring to a frame name

To specify which frame a linked document will be displayed in:

- Put the insertion point inside the hot text for that link.
- Choose **Link...** from the **Insert** menu.
- Enter the frame name in the **Target frame** text box.
- Click on **OK**.

Or:

- Put the insertion point inside the link.
- Choose **Attribute Inspector** from the **View** menu, or press **F6**.
- Enter the frame name in the **TARGET** field.

When you click on the link in a browser, the document will be opened in the specified frame if that frame exists, otherwise, a new window will be created.

Special link targets

The following names have special meanings when used as link targets (notice that each of them starts with an underscore):

- **_self**: the document will be opened in the frame containing the link.
- **_top**: the document will be opened in the full browser window (if the window has been divided into frames, it will become a single pane again).
- **_blank**: the document will be opened in a new window.
- **_parent**: the parent frame set of the current frame will become a single frame, and the document will be displayed there.

[More on this topic](#)

Example of loading documents in specific frames

Here is an example of targeting specific frames using an anchor element.

```
<FRAMESET ROWS="33%,33%,33%"
>

<FRAME NAME="upper" SRC="blue.htm"
>

<FRAME NAME="middle" SRC="sources.htm"
>

<FRAME NAME="lower" SRC="blue.htm"
>

</FRAMESET
>
```

To create this document:

- Create a new document and choose **Convert to Frames** from the **Tools** menu.
- In WYSIWYG-Frame view, create the three frames.
- Click in each frame, choose **Frame Properties...** from the **Frameset** menu and enter the appropriate name: **upper**, **middle**, or **lower** in the **Name** text box.
- For the middle frame, choose **Frame Properties...** from the **Frameset** menu and enter **sources.htm** in the **Source** text box; for the top and middle frames, enter **blue.htm** in the **Source** text box.

Here is a fragment from the document **sources.htm**.

```
<P
>

<A TARGET="upper" HREF=http://www.sq.com/"
>
SoftQuad Home Page

</A
>

<A TARGET="lower" HREF=http://www.w3.org/"
>
W3 Consortium Home Page

</A
>
</P
>
```

To create this document:

- Create a new document.
- Choose **Link...** from the **Insert** menu. The **Insert Link** dialog appears.
- Type **http://www.sq.com/** in the **File or URL** text box and **upper** (the name of the first frame) in the **Target frame** text box.
- Insert a second anchor and give it the URL **http://www.w3.org/** and the target frame **lower**.
- Type the link text inside each anchor.

Since each frame should have a default document, create a file called **blue.htm** that has no content, but has the document background color set to blue.

When you load the frame document in a browser, three frames are displayed. The middle frame contains the document

sources.htm, and the other two frames are blue blanks. Clicking on the first anchor will cause the document <http://www.sq.com/> to be displayed in the upper frame; clicking on the second anchor will cause the document <http://www.w3.org/> to be displayed in the lower frame.

Frame spacing

The value of the **FRAMESPACING** attribute of a **FRAMESET** inserts additional space (in pixels) between all the frames in that frameset.

Frame spacing properties can't be set from the WYSIWYG-Frames view; to set these, use the **Attribute Inspector**:

- Click in any frame in the frameset in WYSIWYG-Frames view.
- Choose **Attribute Inspector** from the **View** menu, or press **F6**.
- Choose **FRAMESET** from the drop-down list of elements.
- Click on the **All** tab.
- Enter a value (the number of extra pixels between frames) in the **FRAMESPACING** field.

Using both rows and columns in a frameset

If your document contains a FRAMESET that has values for both the ROWS and COLS attributes, you cannot edit it in WYSIWYG-Frames view. In this case, you can manually convert it to an equivalent form using nested FRAMESETs with either ROWS or COLS, but not both, using the following procedure:

- Switch to Tags On view.
- Using the Attribute Inspector, make note of and then delete the COLS attribute value of the FRAMESET.
- Use the **Element...** command in the **Insert** menu to surround the FRAME elements corresponding to each row with a FRAMESET element. For example, if the original FRAMESET contains 6 FRAMEs, and you want them to display in 3 rows, surround the first two FRAMEs with a FRAMESET, then the next two, and the last two.
- Using the Attribute Inspector, give each of the new FRAMESETs the same COLS attribute value that the original FRAMESET had. (In our example, there would be attribute values for 2 columns.)

If you need more information about the HTML markup in a frameset document, see [The HTML behind the frames](#).

Adding alternative content

Since some browsers do not support frames, it is generally a good idea to provide alternative content that can be displayed in a non-frames browser.

Alternative content is contained in the NOFRAMES element; if present, this element is the last element in the outermost FRAMESET element in the document. NOFRAMES contains a BODY element, and therefore can contain any markup or content that you like.

If you use **Convert to Frames** to create the initial frameset, a NOFRAMES element will be inserted automatically. If the document contains any content when you perform the conversion, it will be placed inside the NOFRAMES element.

If a frame document is viewed by a browser that does not support frames, the browser will display only the content inside the NOFRAMES element. A browser that recognizes the FRAMESET element will ignore all content contained in the NOFRAMES element.

Note: the HoTMetaL PRO rules also allow the element 'NOFRAME' (with no 's'), because some sources appear to use this spelling of the element name. 'NOFRAMES' is more common.

The HTML behind the frames

HTML documents usually contain a BODY element as the top-level document content element. A document that contains frames begins with a FRAMESET element instead of a BODY element. A frameset divides the browser window into rectangular regions. Each of the regions can be:

- A **frame**, which displays one document. A frame is represented by a FRAME element. The SRC attribute for the frame specifies the default content of the frame.
- Another frame set, which is divided into frames.

For example, a frame set can contain a frame, plus another frame set containing two frames, resulting in three frames in all.

A frame document should also contain a NOFRAMES area, which itself contains a BODY element. The NOFRAMES element follows the FRAMESET element.

Browsers automatically ignore unrecognized markup and display only what they recognize, so if a frame document is viewed by a browser that does not support frames, the browser will display only what is recognized: the content inside the BODY element. Conversely, a browser that recognizes the FRAMESET element will ignore all content contained in the NOFRAMES element.

Note: the HoTMetaL PRO rules also allow the element 'NOFRAME' (with no 's'), because some sources appear to use this spelling of the element name. 'NOFRAMES' is more common.

The attributes of a frame determine its contents and appearance.

[More on this topic](#)

Frame attributes

The frame properties that you can set in WYSIWYG-Frames view correspond to attributes of the FRAME and FRAMESET elements. To edit these attributes, put the insertion point inside the appropriate element and choose **Attribute Inspector** in the **View** menu, or press **F6**.

FRAMESET attributes

A FRAMESET has COLS (columns) and ROWS attributes. These attribute names emphasize that a frame set can be thought of as a table or grid. These attributes may be blank, or consist of a list of one or more values separated by commas. Each such value determines the width (for columns) and height (for rows) of the regions; the number of width and height values supplied determines how many rows and columns, respectively, are created. The default for each is one. For example, if you set COLS to:

20%, 30%, 50%

and don't supply a value for ROWS, the frame set will be divided vertically into three regions: the first region's width will be 20% of the current frame set (or browser window if this frame set is at the top level), the second region's width will be 30%, and the third region's width will be 50%. If there is only one frame set in the document, these widths will apply to the entire browser window. Similarly, if you supply a value only for ROWS, the frame set will be divided horizontally into regions. If you supply values for both attributes, the frame set will be divided into a grid of rows and columns. However, WYSIWYG-Frames view supports FRAMESETs with either COLS or ROWS, but not both in the same FRAMESET. If your document has a FRAMESET with both attributes, you can convert it into an equivalent form that uses only one of these.

If you turn borderless frames on or off, HoTMetaL PRO sets the FRAMEBORDER attribute of FRAMESET to 1 or 0, respectively.

The FRAMESPACING attribute of FRAMESET specifies extra space between frames (in pixels).

FRAME attributes

Frame editing in the WYSIWYG-Frame view sets the following attributes of FRAME elements:

- The SRC attribute specifies the default document to be displayed in the frame.
- The NAME attribute is used for targeting specific frames.
- The MARGINWIDTH attribute sets the width of the frame margin in pixels.
- The MARGINHEIGHT attribute sets the height of the frame margin in pixels.
- SCROLLING can have any of following values: YES, NO, and AUTO. The default is AUTO.
- The default value for NORESIZE is NORESIZE. Remove the NORESIZE value to make the frame resizable.

Both FRAME and FRAMESET have other attributes that specify properties that can't be set from WYSIWYG-Frames view.

Using floating frames

HoTMetaL PRO also supports the IFRAME element, used by Microsoft Internet Explorer. This element is used to create 'floating' or 'in-line' frames that display in the browser window much as an image would.

To insert this element, choose **Element...** from the **Insert** menu, and select IFRAME.

This type of frame cannot be edited using the WYSIWYG-Frames view; use the **Attribute Inspector** to set any of the following attributes:

- **ALIGN** – Sets the alignment of the frame or the surrounding text. The default value is LEFT.
- **FRAMEBORDER** – Determines whether the floating or in-line frame will have a border. Values are 1 to give the frame a border and 0 for no border.
- **HEIGHT** – The height of the frame in pixels.
- **MARGINWIDTH** – The width of the left and right margins (in pixels).
- **MARGINHEIGHT** – The height of the top and bottom margins (in pixels).
- **NAME** – The target name for the frame. The default is none. Reserved names begin with an underscore (_).
- **NORESIZE** – If the default value, NORESIZE, is included, the frame can't be resized by dragging the frame border in the browser window. Remove the NORESIZE value to make the frame resizable.
- **SCROLLING** – Specifies whether the frame will always have scrollbars (YES), never have scrollbars (NO), or have scrollbars added by the browser if necessary (AUTO). The default is AUTO.

Maintaining your Website

HoTMetaL PRO has powerful site management functions for finding and replacing text across an entire site, finding orphan files, finding broken links, and finding external broken links. You can repair broken links with the Site Doctor. You can also group user-selected files into Pockets and perform further operations on them.

This chapter discusses:

- [Finding and replacing:](#)
 - [Finding text.](#)
 - [Finding tags.](#)
 - [Finding meta-data.](#)
- [Using pockets to manage files.](#)
- [Using the Site Doctor:](#)
 - [Finding broken links.](#)
 - [Fixing broken links.](#)
 - [Checking external links.](#)
 - [Finding orphan files.](#)
- [Using the Site Summary.](#)

[More on this topic](#)

Finding and replacing

One of the site management functions is a powerful search engine that lets you search an entire project for files containing particular text, and replace that text, if you wish. You can also find or replace HTML elements or attributes, or special header elements (META elements), which describe your document. The **Find** and **Replace** dialog box has four different tabbed sections—**Text**, **Tag**, **Meta**, and **URL**. The four tabs all work slightly differently, and are discussed in the following sections.

[More on this topic](#)

Finding text

To find text in your project files:

- Start HoTMetaL PRO.
- Click on the  button from the **Standard** toolbar to open the **Resource Manager**, if it isn't open already. The Resource Manager opens.
- Open a project. The **Project** tab in the Resource Manager appears.
- Choose **Web View** or **Page Links** from the **View** menu, if they aren't visible already, to view the files in your project.
- Choose **Find in Files...** from the **Edit** menu or click on the  button from the **Standard** toolbar.

The **Find** dialog box appears.

To perform a simple search, select the **Text** tab and enter the text that you want to find in the **Find what** text box. The last five searches that you made are available from the drop-down list.

Find and Replace options

There are several different ways to choose which files you would like to search in a project; from the list labeled **Search**, you can choose:

- **Project (all files)** – search in the entire project.
- **Site (linked files)** – search those files that are linked from the home page (that is, orphan files will not be searched).
- **Selected File(s)** – search only the files that are selected in the project. You can select files in the site management windows in the same way that you would in Windows: clicking on a file selects it, holding down the **Ctrl** key and clicking on a file adds it to the selection, and holding down the **Shift** key and clicking on a file in a list adds all the files from that point to the next or previous selected file in the list.

In addition to these options, you can **Find whole words only**, **Match case**, and **Use pattern matching**. You can use the same search patterns as you would in the HoTMetaL PRO document window: see [Using search patterns](#) for more information.

Finding tags

The **Tag** tab of the **Find** dialog box lets you search for particular HTML tags (elements) across a project or in selected files.

You can search for an HTML element (no matter what attribute it has), or an element, attribute, and attribute value combination.

To find an element:

- Choose an HTML element from the **Element** list or type the element name in the text box.
Once you have selected an element, the list of possible attributes for that element appears in the **Attribute** pull-down list.

To search for an attribute:

- Choose an HTML attribute from the **Attribute** list or type the attribute name in the text box.
If you haven't selected an element, no list of attributes will appear; you must select a particular element to perform a search.

To search for a particular attribute value, enter it in the **Attribute Value** text box.

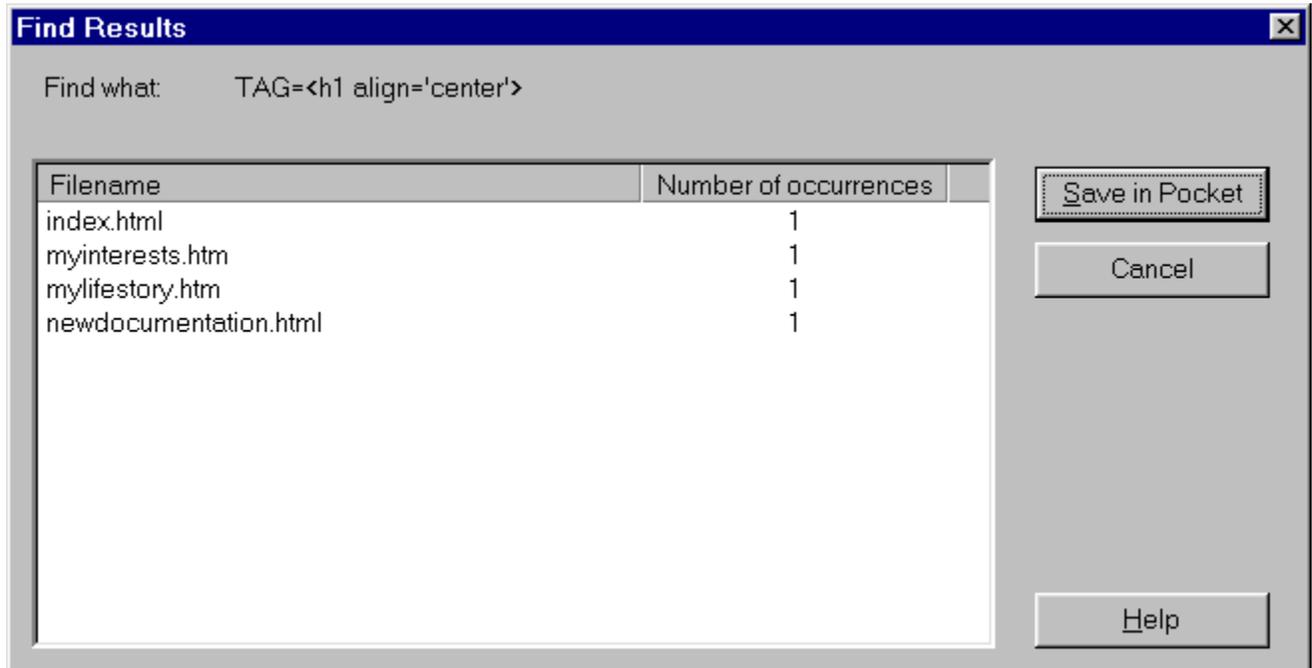

For example, suppose you wanted to search for all instances of H1 that are center-aligned. Center-aligned headers (and all other block elements) have the attribute ALIGN with the value CENTER.

- In the **Tag** tab of the **Find** dialog box, choose **h1** from the **Elements** drop-down list.

Once you have made the element selection, a list of possible attributes for the H1 element will appear in the **Attribute** drop-down list.

- Choose **align** from the **Attribute** drop-down list.
- Type **center** in the **Attribute Value** text box.
- Click on **Find** to start the search.

The results of your search are displayed in the **Find Results** dialog box. It displays the files that contain the searched for element and the number of occurrences in each file.

Finding meta-data (META elements)

The **Meta** tab of the **Find** dialog box lets you search for meta-data (META tags) with particular values for the **NAME** and **CONTENT** attributes, across a project or in selected files.

Meta-data is used to embed document meta-information; that is, information about the document. Meta-data is contained in the HEAD element as attributes and values of META elements. This kind of information is used by servers or browsers and is application and user specific; that is, meta-data is not found in all documents and there's no general agreement on the types of meta-data in common use. Some browsers use meta-data (for example, Netscape has an extension that allows a client-pull, where you set a page to load for a specified amount of time, then load another page). It's also used to index pages for many search engines.

Often, meta-data is specified by means of a META element's NAME and CONTENT attributes. The NAME defines what type of information is being specified, and the actual content is described in the CONTENT attribute. For example, a META element that describes the version number of a document might have its NAME attribute specified as VERSION and the CONTENT specified as 1.55.

For example, suppose your project contains META specifications for document authors, and you wanted to search for all files written by a specific author.

- In the **Meta** tab of the **Find** dialog box, type **Author** in the **Name** text box.
- Type the desired author name in the **Content** text box.
- Click on **Find** to search.

You can specify the search options for finding META in the same way that you can for finding text. See [Find and replace options](#) for details.

Finding URLs

The **URL** tab of the **Find** dialog box lets you search in URLs across a project or in selected files. This is different from the **Find Text** option because it looks only in attributes, not text and it's restricted to attributes that correspond to URLs (such as HREF of A, SRC of IMG).

To search in a URL:

- Type the search text in the text box.
- Select which files you want to search from the **Search** text box: **Selected files only**, **Site (linked files)**, or **Project (all files)**.
- Click on the **Find** button.
- The **Find Results** dialog box will appear, displaying the search results.
- You can choose to put the found URL file(s) into a pocket folder for working on later.

Find results

Once you have completed a search of any type, the **Find Results** dialog box will appear with your search results. If your search did not return any files, a dialog box will appear informing you of that.

The **Find Results** dialog box shows a list of **Filenames** and the **Number of occurrences** in each file of what you are searching for. You can resize the columns by dragging the divider between the column titles. You can group all the files that you have found into a Pocket and perform further operations on them by clicking on **Save in Pocket**. See [Using Pockets to manage files](#) for more information on Pocket operations.

Replacing text, tags, meta-data, and URLs

The **Replace in Files...** functionality is very similar to the **Find in Files...** functionality, except that you must fill in the replacement text, tags, or attribute values in the **Text**, **Tag**, **Meta**, or **URL** sections of the **Find and Replace** dialog box. Refer to [Other replace result operations](#) for information on other operations you can perform on replace results.

 [More on this topic](#)

Replacing text

To replace text:

- Choose **Replace in Files...** from the **Edit** menu.
- Click on the **Text** tab of the **Replace** dialog, if it isn't selected.
- Enter the text you wish to find in the **Find what** text box.
- Now, enter the replacement text in the **Replace with** text box.
- Make any selection of options from the **Search** section of the dialog (see [Find and replace options](#) for details).
- Click on **Find** to perform the search.

The **Replace Results** dialog box appears, showing the files that have the text you searched for.

- Click on **Replace All...** to replace the found text with the replacement text.

Replacing tags

To replace tags:

- Choose **Replace in Files...** from the **Edit** menu.
- Click on the **Tag** tab of the **Replace** dialog if it isn't selected.
- Choose a tag, and if desired, an attribute name and value that you wish to find from the **Element** and **Attribute** drop-down lists, and the **Attribute value** text box.
- Now, choose the replacement element, attribute, and attribute values in the **Replace with** section.

Note: You can leave the attribute and value blank in the 'find' tag; this matches all tags of the specified type.

- Make any selection of options from the **Search** section of the dialog (see [Find and replace options](#) for details).
- Click on **Find** to perform the search.

The **Replace Results** dialog box appears, showing the files that have the tags you searched for.

- Click on **Replace All** to replace the tags you searched for with the tags you chose to replace them with.

Note: Tag replacing should be used with caution: you could create invalid HTML if you replace a HTML element with an element that isn't allowed in that context. Using tag replacing to replace elements of the same type—for example, replacing 'H1' with 'H3' or replacing 'P' with 'DIV'—is safest.

Replacing meta-data

You can find and replace the **NAME** and **CONTENT** attributes of meta data (META tags) from the **Meta** tab of the **Replace** dialog box.

To replace meta-data:

- Choose **Replace in Files...** from the **Edit** menu.
- Click on the **Meta** tab of the **Replace** dialog if it is not selected.
- Enter the meta-data **Name** and **Content** in the **Find what** section.
- Now, enter the replacement **Name** and **Content** in the **Replace with** section.
- Make any selection of options from the **Search** section of the dialog (see [Find and replace options](#) for details).
- Click on **Find** to perform the search.

The **Replace Results** dialog box appears, showing the files that have the META elements you searched for.

- Click on **Replace All** to replace the meta-data **Name** and **Content** with the values you have chosen.

Replacing URLs

To replace text in URLs:

- Choose **Replace in Files...** from the **Edit** menu.
- Click on the **URL** tab of the **Replace** dialog, if it isn't selected.
- Enter the text you wish to find in the **Find what** text box.
- Now, enter the replacement text in the **Replace with** text box.
- Make any selection of options from the **Search** section of the dialog (see [Find and replace options](#) for details).
- Click on **Find** to perform the search.

The **Replace Results** dialog box appears, showing the files that have the text you searched for.

- Click on **Replace All...** to replace the found text with the replacement text.

Other replace result operations

From the **Find and Replace Results** dialog, you can choose to edit any of the files you have found or Pocket the find results without doing the replace.

To group all the files that you have found into a Pocket (and perform further operations on them), click on **Save in Pocket**. See [Using Pockets to manage files](#) for Pocket operations.

To edit any of the files that you have selected during the 'Find' part of the **Replace in Files...** operation, click on the file in the **Replace Results** dialog to select it, and then click on **Edit File...** HoTMetal PRO is launched with the file that you chose. (This may be useful if you want to do a more specific step-by-step find and replace within the document using HoTMetal PRO. See [Searching and replacing](#) .)

Using Pockets to manage files

Pockets—user-defined sets of files—are useful for managing projects. Pockets can help you delete, copy, or rename selected files as a group, rather than trying to find each file one-by-one in the Project tab, Web View or Page Links window. You can create Pockets based on a variety of criteria, such as search results, files with broken links, orphan files (files without any links to them), etc. See [Finding and Replacing](#) and [Repairing links with the Site Doctor](#) for details.

To open the Pocket View window, choose **Pocket View** from the **View** menu or click on the  button from the **Views** toolbar.

You can create pockets by selecting one or more files in the Project tab, Web View, or Page Links window and dragging them into the Pocket View window. The default name for Pockets you create by dragging is **New Pocket**, but you can [edit the name of the Pocket](#).

Once you have created a Pocket, you can then select one or more files in the Pocket and:

- Delete the files.
- Copy the files.
- Launch HoTMetal PRO (all selected files will be loaded).
- Do [find and replace](#) operations on the selected files (turn on **Selected File(s)** in the **Find and Replace** dialog).

Pockets are associated with specific projects, so they will disappear from the Pocket window if you display a different project.

Pockets are saved between HoTMetal PRO sessions. You can show or hide the files in a Pocket by clicking on the  icon to the left of the Pocket.

If you right-click on the Pocket window, you get a list of commands such as **Edit File**, **View in Browser**, **Properties**, **Remove From Pocket**, **Font...**, etc., which are common to all panels. See [Window commands](#) for details.

To add files to a Pocket:

- Drag selected files from the Project tab, Page Links window or Web View window and drop them on an existing Pocket.

Note: If you drag a folder into a Pocket, the Pocket will contain only the files that are in the folder, and not the folder itself, any subfolders, or files within subfolders.

To rename Pockets:

- Click on a Pocket once to select it and then click a second time, or right-click on the Pocket name and choose **Rename Pocket** from the pop-up menu. The name of the Pocket will become editable.
- Enter a new name. When you click outside the Pocket, or press **Enter**, the name change takes effect.

To remove files from a Pocket:

- Select the files, right-click on the selection and choose **Remove From Pocket** from the pop-up menu.

This does not delete the file; it just removes the file from the Pocket. To actually delete the file (that is, send it to the Recycle Bin), choose **Delete** from the **Edit** menu or right-click on the Project panel and choose **Delete** from the pop-up menu.

To delete a Pocket:

- Right-click on the Pocket and choose **Delete Pocket** from the pop-up menu.

Deleting a pocket does not delete the files it contains from your hard disk.

Repairing links with the Site Doctor

The Site Doctor helps you find problems in your site and repair them quickly and easily. The Site Doctor appears when you move a file around in a project, and asks if you want to repair links to that file. Additionally, there are three more commands that launch the Site Doctor. These commands let you find:

- [Files with broken links](#).
- [Files with broken links to external files](#).
- [Orphan files](#) (that is, files that can't be reached by following links outward from the home page of the project—files that are not part of the link structure of the project).

[More on this topic](#)

Finding broken links

A broken link is a link that points to a file that does not exist in the specified location. Users will not be able to navigate broken links; their Web browsers will return error messages when the page cannot be found. The site management functions enable you to fix the broken links and make sure that they point to pages that actually exist. To find broken links, choose **Broken Links** from the **Site** menu. The Site Doctor displays a list of broken links (if there are any) in your project.

From this dialog box, you can:

- Go to the Site Doctor's **Fix broken links** dialog by double-clicking on the broken link. This lets you change the link so that it points to an existing file.
- Put the broken links into a Pocket, by clicking on **Put in Pocket**. You can perform further operations on the broken links once they are pocketed.

Fixing broken links

Broken links are links that point to files that don't exist. This can happen if files are moved around without fixing links, for example. Broken links are displayed in the Web View window as file names shown in red, and in the Page Links window they have a red arrow pointing towards them with two vertical wavy lines ().

You can launch the **Fix Broken Links** Site Doctor from the [Find Broken Links](#) dialog, or by right-clicking on a broken link in the Pocket View, Web View, or Page Links window, and choosing **Fix Broken Link** from the pop-up menu. The **Site Doctor - Fix Broken Links** dialog appears.

The upper part of the **Fix Broken Links** dialog shows a list of files that contain the broken link. You can correct the broken link by typing in the correct path in the text box provided (you can type in either a relative or an absolute URL), or you can select a file by clicking on **Browse...**

Click on **Fix** to change the broken links to the link that you have specified. If the replacement link does not point to an existing file, a warning dialog appears and you will be asked to specify an existing file. Clicking on **Cancel** closes the dialog without fixing any links.

External links

An external link is a link outside of your project; for example, a link to a page on the World Wide Web. These kinds of links are usually specified by a URL of the form **http://...** (**ftp** links are not checked). HoTMetal PRO can check external links to find whether they are valid; that is, whether the links refer to 'live' locations on the Internet.

Links to files that are on your local drive but outside your project are also treated as external links (that is, URLs that start with **file://** or relative URLs that point to a file outside the current project; for example, **../././scratch.htm**). HoTMetal PRO does not validate these types of links when you choose **External links** from the **Site** menu.

Note: You may have to configure your proxy server before you can perform the operation described below. You also will need to connect to the Internet (that is, to your Internet Service Provider).

To check external links on your site, choose **External Links** from the **Site** menu. The Site Doctor starts searching the World Wide Web to resolve the external links in your project. When the checking is finished, the **Site Doctor - External Links** dialog box appears.

From this dialog box, you can choose to Pocket all the files containing external links, or Pocket only the files containing broken external links. You can edit those files to remove the broken links, delete them, etc. Clicking on **Stop** stops the search that is in progress and returns the current results.

Finding orphan files

Orphan files are files that are in the project folder, but not part of the link structure of the project. Sometimes that's because all the links leading to them are broken, in which case it's a good idea to keep those orphan files around, and sometimes the links to them have been removed, in which case the files can be safely deleted, since they aren't part of the project anymore.

To find orphan files in a project (that is, files that are in the project folder but aren't part of the link structure of the project).

- Choose **Orphan Files** from the **Site** menu.

The **Site Doctor - Find Orphan Files** dialog appears.

Clicking on **Put in Pocket** creates a Pocket called **Orphan Files** containing the results of the search.

Project summary

You can get a summary of your project by choosing **Summary** from the **Site** menu. The **Project Summary** dialog box appears.

The **Project Summary** dialog box has several columns. You can change the size of any of the columns by dragging the borders between the column titles. You can resize the dialog box by dragging the resize corner in the lower right corner of the dialog box. Click on **OK** to dismiss the dialog box.

You can see the file names and their titles in the **Path** and **Title** columns. The registered Windows type is displayed in the **Type** column, and the size of the file is shown in the **Size** column.

The **Links From** and **Links To** columns show the number of links into and out of the file, respectively. **Images** shows the number of images linked to the file. **Download Time** shows the number of seconds it would take to download this file at 28.8K bps rates (a standard high-speed modem).

You can sort the summary by any of these characteristics: click on a column title to sort and reverse the sort by clicking again. For example, if you click on the **Size** column title, the files will be sorted from smallest to largest. Clicking on the column title again sorts the files from largest to smallest.

The **Refresh** button refreshes the Project Summary to take any new changes into account.

The **Auto Sort** button automatically sorts the files into categories. For example, all image files are sorted together (GIF, JPEG, etc.), all web documents are sorted together (**htm**, **html**, etc.), all project files are sorted together (**hpp**, **hmp**), and text documents are sorted together (**doc**, etc.). Other recognized file types are: **.jpg**, **.ppt**, **.xls**, and **.css**.

The **Sort by Extension** button sorts the files in alphabetical order by extension type.

You can choose which columns to be displayed in the **Project Summary** dialog box by clicking on one or more check boxes under **Columns Shown**.

Show Orphan Files includes orphan files in the site summary.

Turn **Show Options** on or off in the **Site Summary** window's **Summary** menu to show or hide the controls for these various options.

Printing the Project Summary

You can print the project summary as an HTML file or as a text file.

Choose **Save As HTML...** from the **Site Summary** window's **Summary** menu to save the project summary as an HTML file.

Choose **Save As Text...** to save the project summary as a text file.

Before you save a text file, you can choose from three possible text formats by choosing **Save Options: Comma Separated** and **Tab Separated** separate fields with commas and tabs, respectively; **Fixed Field** uses tabs to line up columns vertically.

Objects, applets, and scripts

HoTMetal PRO provides support for applets, scripts, ActiveX controls, and Dynamic HTML code that can be inserted into your Web pages quickly and easily. This chapter gives you an overview of how to insert and use these objects.

- **Applets** – Programs written using the Java language. They are linked to a document, much like images.
- **ActiveX™ Controls** – Programs conforming to the Microsoft ActiveX standard that are registered on your PC and are only downloaded over the Internet when needed. (Unlike applets, if you already have the ActiveX program on your computer that is being requested in a Web page, there's no need to download a new copy, since the current copy will run on your PC.)
- **Scripts** – Programs that run in your browser when your Web page is loaded. These are generally written in JavaScript or VBScript. Scripts are usually embedded directly in a page; they are also interpreted, and do not need to be compiled (unlike ActiveX Controls and Java applets).
- **Dynamic HTML** – Can refer to many different things, but in this chapter, it refers to the combination of **scripts** and the ability of Microsoft Internet Explorer 4.0 to render HTML elements. These scripts change the way that HTML elements in a Web page are displayed; that is, you can directly affect the display of HTML elements with a script. While most Web browsers do render HTML dynamically to some extent, the current Microsoft browser has more dynamic rendering capabilities. You can insert dynamic HTML in HoTMetal PRO using [Design-Time Controls](#).
- The **Database Import wizard** (not provided with the Evaluation version) – a Design-Time Control that creates a table in your Web page based on the contents of a database or spreadsheet file.

Creating applets, scripts, ActiveX, Dynamic HTML and Design-Time Controls is beyond the scope of this manual.

[More on this topic](#)

Using the Resource Manager

The effects available from the Resource Manager in the Evaluation Version that you are now using are a subset of those shipped with HoTMetal Pro 5.0. Choose 'How To Purchase' in the Help menu for ordering information.

The Resource Manager is a quick way to insert scripts, applets, and Dynamic HTML into your document. When you insert one of these from the Resource Manager, a Design-Time Control will be launched, enabling you to configure the script, applet, or Dynamic HTML script. For more information on Design-Time Controls, see [Inserting Design-Time Controls](#).

To drag and drop applets, scripts, or dynamic HTML from the Resource Manager:

- Insert the HoTMetal PRO CD in the CD drive.
- Choose **Resource Manager** from the **View** menu.
- Click on the **Assets** tab. You can choose scripts, applets, or dynamic HTML from the **remote**, **hmf**, or **cdrom** folders.
- Navigate to the folder containing the applet, script, or dynamic HTML code that you want to insert into your Web page. Each object is visible in the contents (bottom) pane.
- Drag the object in the contents pane to the HoTMetal PRO document window.

The object that you selected will be inserted, and, if applicable, a DTC will be launched, so that you can configure the object.

Inserting Design-Time Controls

A Design-Time Control (DTC) is an ActiveX control that lets you configure the content of your page or an object of some type that is embedded in the page. DTCs are often used for configuring HTML, applets, and scripts in Web pages, they can also be created for more general purposes.

When you insert a DTC with HoTMetaL PRO, two things are inserted in your page:

- 1 The object or markup that the DTC configures.
- 2 Some code referring to the DTC itself, so that you can open it at a later time to reconfigure the object that was inserted. (This code is displayed only in HTML Source view.)

To insert a Design-Time Control in your document:

- Choose **Design Time Control...** from the **Insert** menu, or click on the  button in the **Advanced** toolbar.

A dialog box that lists the Design-Time Controls registered on your system appears. This list will have content only if one or more DTCs are registered.

- Double-click on a control in the list, or select a control and click on **Insert**.

A dialog box in which you can configure the applet, script, or Dynamic HTML code will appear. For some DTCs, a **Properties** dialog will automatically appear when you insert them. For other DTCs, you may need to right-click on the DTC and choose **DTC Properties** from the pop-up menu when you insert to access the DTC's **Properties** dialog.

If a DTC has been inserted into your document, you can re-open the **Properties** dialog for the DTC at any time.

To re-open the DTC **Properties** dialog:

- Select the object or code inserted by the DTC and choose **Design Time Control...** from the **Insert** menu, or right-click inside the DTC and choose **DTC Properties** from the pop-up menu.

To delete the DTC and the code that it inserted:

- Right-click inside the object or code inserted by the DTC and choose **Delete DTC** from the pop-up menu.

You can also insert DTCs using the [Resource Manager](#) .

Inserting applets

Java is a programming environment that operates in conjunction with certain browsers to allow you to insert programs, called **applets**, in an HTML document. Coding applets is beyond the scope of this manual; see one or more of the many available books and online references for more information.

Wherever an applet occurs in a document, it reserves an area on the browser screen in which it does some special processing, such as drawing a picture or interacting with the user.

HoTMetaL PRO supports the APPLET element for inserting applets. The APPLET element can appear inside certain 'block' elements—paragraphs, headings, list items, tables, and CENTER—or it can appear on its own, directly inside the BODY tag.

You can insert applets into HoTMetaL PRO in several different ways:

- Choose **Resource Manager** from the **View** menu. Navigate to the HoTMetaL PRO CD from the **Desktop** tab, open the **Hmfx** folder, choose the **applets** folder. This is the recommended way to insert the applets that are provided with HoTMetaL PRO.
- Click on the  toolbar button or choose **Java Applet...** from the **Insert** menu. This will bring up a file chooser dialog box that prompts you to choose the applet **.class** file that you want to insert. After you choose the file, a dialog box in which you can set various attributes of the applet will appear (see [Specifying the applet](#)).
- Drag and drop an applet **.class** file into the HoTMetaL PRO document window. An APPLET element with certain attributes set will be inserted into the document, and a dialog box in which you can set various attributes of the applet will appear (see below).
- Insert an APPLET element using **Element...** from the **Insert** menu, and edit its attributes manually by placing your insertion point inside the element and choosing **Attribute Inspector** from the **View** menu, or right-click and choose **Attribute Inspector** from the pop-up menu.

Sometimes applets are inserted and configured using Design-Time Controls. See [Inserting Design-Time Controls](#) for more information.

[More on this topic](#)

Specifying the applet

The attributes of the APPLET element specify the applet file and the area on the screen in which it operates. The following attributes are set automatically if you drag and drop an applet into the HoTMetaL PRO document window or use the applet toolbar button to choose an applet file. They can be set manually by editing the attributes of the APPLET.

- **ID** – The identifier for the applet.
- **CODEBASE** – Specifies the folder in which the applet file is located. If this attribute is blank, the applet is assumed to be in the same folder as the current document. This is generally a relative URL pointing to a local folder.
- **CODE** – The name of the file containing the applet. This attribute must specify a **filename** only (no directories). This information is required.

When you drag and drop an applet into the HoTMetaL PRO document window or use the applet toolbar button, the **Applet Properties** dialog box appears.

You can bring up this dialog box at any time by placing your cursor inside the APPLET, right-clicking, and choosing **Applet Properties...** from the pop-up menu, or choosing **Java Applet...** from the **Insert** menu. The following attributes can be set:

- **Alternate Text** – Text that will be displayed if the document is displayed in a non-Java environment.
- **Name** – A name that other applets in the same document can use to refer to this applet.
- **Width** – The amount of horizontal space (in pixels) reserved for the applet. This information is required.
- **Height** – The amount of vertical space (in pixels) reserved for the applet. This information is required.
- **Align** – This lets you align the portion of the screen that has been reserved for the applet. You can align applets using the alignment toolbar buttons.
- **Vspace** – Some extra space above and below the area reserved for the applet.
- **Hspace** – Some extra space to the left and right side of the area reserved for the applet.

Some other attributes of applets can be modified with the Attribute Inspector:

- **ARCHIVE** – Specifies a **zip** archive in which the browser will search for **.class** files. (Supported only by Netscape Navigator.)
- **MAYSCRIPT** – Enables **LiveConnect**, in order to interact with JavaScript. (Supported only by Netscape Navigator; see Netscape's documentation on their Web site for details.)

Applet subelements

If the applet code requires some input data, this can be provided in the document itself, by way of PARAM elements. A PARAM element doesn't have any content; the information it supplies is contained in its attributes:

- NAME – The name of an 'applet-specific attribute'. This must be a name that is known to the applet code.
- VALUE – The value associated with NAME.

There are two other attributes of PARAM: VALUETYPE and TYPE, which are used for PARAM within OBJECT. They are not used for PARAM within APPLET.

Applets in a non-Java environment

An APPLET can contain 'block' elements such as paragraphs, lists, and blockquotes. The content of these elements will be displayed only in a non-Java environment (either because the browser isn't Java-aware, or because Java display has been turned off).

Inserting scripts

SCRIPT elements contain code, written in one of several programming languages, that is executed by a script-aware browser. JavaScript and Visual Basic Script (VBScript) are two such programming languages. The SCRIPT element allows users to put code directly in an HTML document. JavaScript is supported by version 2.0 and higher of Netscape Navigator, and by Microsoft Internet Explorer. VBScript is supported by version 3.0 and higher of Microsoft Internet Explorer. Coding in JavaScript and VBScript is beyond the scope of this manual; many books and online references are available.

Note: SCRIPT is not supported by all Web browsers. Use this feature with caution, and make sure that your script documents are readable by all browsers.

Inserting ActiveX and other objects

The OBJECT element lets you insert a program—called an 'ActiveX Control' (formerly called 'OLE Control' or 'Internet Control')—into an HTML document.

Note: ActiveX and the OBJECT element are not supported by all Web browsers. Use this feature with caution, and make sure that your documents also contain markup readable by all browsers.

HoTMetal PRO supports the use of objects and provides an easy way to insert ActiveX Controls. ActiveX Controls can be sent over the Internet, or, if a copy exists on your PC already, run directly from a Web browser. You can insert an ActiveX Control object in several different ways:

- Click on the  toolbar button or choose **ActiveX Control...** from the **Insert** menu. This will bring up a dialog box that gives you a list of the ActiveX Controls installed on your system. **If there is nothing in this dialog box, then there are no ActiveX Controls registered on your system.** After you choose the control, the Object Properties dialog box in which you can set other attributes of the control will appear.
- Drag and drop an ActiveX Control (.ocx) file into the HoTMetal PRO document window. (These files generally reside in the **Windows\System** folder.) An OBJECT element will be inserted into the document, and the Object Properties dialog box in which you can set other attributes of the object will appear.
- Insert an OBJECT element using **Element...** from the **Insert** menu.

You can show or hide the code in an ActiveX Control; that is, display the Object tags or show the ActiveX Control as a graphical object.

- Right-click on the ActiveX Control and choose **Show Object Markup** or **Show ActiveX Control**.

[More on this topic](#)

Object properties

The dialog box for setting the properties of the ActiveX Control is very similar to the one used to set the properties of the APPLET element: it contains settings for such display parameters as **Width**, **Height**, **Alignment**, **Vspace** and **Hspace**. There is also a **Properties...** button which will take you to a Control-specific dialog box to set parameters for that particular ActiveX Control. You can bring up this dialog again at any time by placing your cursor inside the OBJECT element, right-clicking, and choosing **Object Properties...** from the pop-up menu. You can also open the **Object Properties** dialog by choosing **ActiveX Control...** from the **Insert** menu when you have an ActiveX Control already selected.

The following attributes of OBJECT are used for ActiveX (and other objects):

- ID – The identifier of the control.
- CLASSID – The unique ID of the code. For an ActiveX Control, it's a string in base 64.
- DATA – The URL pointing to the code.
- CODETYPE – The MIME (Internet Media) type of the code (here, **application/x-oleobject**).

There are several other attributes that are used with different types of OBJECT. Here is a brief description:

- BORDER – The border of the object in pixels. It functions the same as IMG's BORDER attribute.
- ISMAP – Tells the Web browser that the object is an image map. It functions the same as IMG's ISMAP attribute.
- USEMAP – Sets the location of a MAP definition. It functions the same as IMG's USEMAP attribute.
- NAME – An identifier used with form submissions.
- DECLARE – Declare but don't instantiate the object code.
- CODEBASE – Specifies the folder where the code is located.
- TYPE – Another way of specifying the MIME (Internet Media) type if the type of the DATA is distinct from the CLASSID type.
- STANDBY – A string that can be displayed in the Web browser while the OBJECT is loading.
- SHAPES – The object has shaped hypertext links.

Using cascading style sheets

The style in which a tag appears in a browser can come from three places:

- The browser's default styles.
- Explicit style information in the HTML code, such as **FONT** tags to specify text size and color.
- Cascading style sheets.

Cascading styles are a way of specifying styles using a combination of external style sheets, style sheets embedded in a document, and style information attached to specific elements.

Cascading style sheets provide the most versatile control over document styles, but not all Web browsers support them. Microsoft Internet Explorer, versions 4.0 and above, and Netscape Communicator, versions 4.0 and above, provide the most extensive support for cascading style sheets.

You can use the HoTMetaL PRO [cascading styles editor](#) to define your own cascading styles for displaying documents.

A cascading style sheet consists of one or more **rules**. These style sheets are said to be **cascading** because multiple style sheets can be applied to one document, and a set of [cascading rules](#) determine how style rules that apply to the same element are prioritized.

Browser support

Browser support for cascading style sheets is continually evolving; specific CSS properties are not guaranteed to work in any or all browsers. You should preview your documents in all browsers that you intend for them to be viewed with to determine the current level of support.

[More on this topic](#)

Cascading style sheet standards

There are two cascading style standards, called CSS1 (Level 1) and CSS2 (Level 2). CSS1 defines a wide range of style properties, and contexts in which they can be applied; CSS2 builds on CSS1 and describes more advanced formatting styles and contexts, such as absolute positioning, table styles, styles for elements with specific attribute values, styles for different output media, and styles for internationalized documents. These specifications can be found at the W3C Consortium's Web page at <http://www.w3.org/>. See the Microsoft and Netscape home pages for information on their support for the CSS standards. The HoTMetal PRO cascading style sheet editor provides extensive support for CSS1; CSS2 constructs can be entered in text mode.

Starting the cascading style sheet editor

To use the HoTMetal PRO cascading style sheet editor:

- Choose **Open...** from the **File** menu.
- Choose **CSS Documents** from the **Files of type** drop-down list.
- Navigate to and open a style sheet (**.css**) file.

Or:

- Choose **CSS Styles...** from the **Format** menu.

This command has a fly-out menu with four options:

- Choose **Element Styles** to edit styles for the current element.
- Choose **Document Styles** to edit styles embedded in the current document.
- Choose **External Styles** to edit an external style sheet (which can be linked to the current document).
- Choose **Refresh** to apply any style changes to the current document.

If you choose one of the first three options, the cascading style sheet editor dialog is displayed.

Attaching cascading styles to a document

There are three ways to attach cascading styles to a document:

- Attach an external style sheet file using a LINK element.
- Embed a style sheet in the document using the STYLE element.
- Assign an inline style rule for a specific occurrence of an element, using its STYLE attribute.

A set of cascading rules determine the precedence of rules occurring in more than one location.

More on this topic

Using external style sheets

Cascading style rules in a separate file can be linked to an HTML document.

- Choose **CSS Styles...** from the **Format** menu.
- Choose **External Styles** from the fly-out menu.
- The next fly-out menu has several options:
 - Choose **New...** to create a new external style sheet.
 - Choose **Open...** to edit an existing style sheet.
 - Choose a file name from the menu to open one of the recently-opened style sheets.
 - Choose **Add...** to choose an existing style sheet to link to the current document. This creates a LINK element pointing to the style sheet.

If you chose one of the first three options, the cascading style sheet editor is started; now you can edit the style sheet.

- Create or edit styles for one or more elements, as desired.
- Click on **OK** when done.

You can click on **Save** or **Save As...** to save the style sheet. Clicking on **Reset** discards all the changes you have made since the last save. You can open another style sheet by clicking on **Open**. Click on **OK** to finish; if the style sheet has not yet been linked to the current document, you will be asked if you want to link it now. Click on **Cancel** if you want to dismiss the CSS editor without saving any changes.

Editing styles for the current document

You can embed cascading styles directly inside an HTML document using the STYLE element, which is located in the document's HEAD element. A document can have more than one STYLE element.

- If your document has more than one STYLE element, put the insertion point in the one you want to edit. If the insertion point is not inside any STYLE element, the last one in the HEAD will be edited. If there is no STYLE element, one will be created.
- Choose **CSS Styles...** from the **Format** menu.
- Choose **Document Styles** from the fly-out menu. The cascading style sheet editor is started.
- Create or edit styles for one or more elements, as desired.
- Click on **OK** when done.

When you exit the cascading style sheet editor, the appropriate STYLE element will be created or updated.

You can also edit styles directly by typing inside a STYLE element. You should do this only if you're familiar with the syntax of CSS.

Because some browsers that are not CSS-compliant will display the contents of the STYLE element in the document window, it is a good idea to surround an embedded style sheet with an HTML comment. This will cause the content to be ignored by non-CSS browsers, but still interpreted by CSS-compliant browsers.

- Type '`<!--`' just after the [STYLE> start-tag, but before the style information.
- Type '`-->`' just before the </STYLE] end-tag, but after the style information.

Creating a style rule for a specific element

You can specify a style rule for an specific instance of an element, using its STYLE attribute.

There are two ways to do this:

- Put the insertion point inside the element to which you want to assign a style.
- Choose **CSS Styles...** from the **Format** menu.
- Choose **Element Styles** from the fly-out menu.

Or:

- Put the insertion point inside the element to which you want to assign a style.
- Choose **Attribute Inspector** from the **View** menu, or type **F6**.
- Click on the ... button in the **STYLE** field.

The cascading style sheet editor is started. Since you are editing styles for a single element only, you cannot choose a different element to edit.

- Use the tabbed 'style properties' section of the dialog to create or edit styles as desired.
- Click on **OK**; the style information becomes the value of the element's **STYLE** attribute.

Cascading precedence rules

Since cascading style properties for an element can be set in several places, the cascading style sheet standard specifies a set of rules that determine which of the available styles takes precedence. An outline of these rules is presented here; you should consult the CSS [standards](#) for detailed information.

- An 'inline' style property [set explicitly for an element instance](#) takes precedence over all other settings for that property.
- If there is a combination of [external style sheets](#) linked to the document via LINK elements, and [embedded style sheets](#) contained in STYLE elements, the setting for a particular property that occurs **last** takes precedence over earlier settings for that property. By default, HoTMetal PRO puts STYLE elements after LINK elements, but you can change the order of elements in the document window.
- If two or more settings for the same property occur in the same style sheet, the final one takes precedence.
- If a style sheet refers to an [imported style sheet](#), property settings in the imported style sheet have lower priority than settings explicitly located in the style sheet.

The HoTMetal PRO **WYSIWYG** and **Tags On** views display the document according to the styles contained in external style sheets, embedded style sheets, and inline styles. These views do not process imported style sheets, so occasionally the HoTMetal PRO display will not match the browser display.

Modifying HoTMetaL PRO display styles

HoTMetaL PRO's own formatting engine understands cascading style sheets. To modify the HoTMetaL PRO default display style of any element(s):

- Choose **CSS Styles...** from the **Format** menu.
- Choose **External Styles** from the fly-out menu.
- Choose **Open...** from the next fly-out menu.
- Open the file **hmpro5.css** in the **Display** folder underneath the **HoTMetaL PRO 5** folder.
- Make any desired changes.
- Save the style sheet.
- If you are prompted to link this style sheet to the current document, click on **No** unless you want this style sheet to also define the styles for this document when it is displayed in CSS-aware web browsers.
- Choose **CSS Styles...** from the **Format** menu.
- Choose **Refresh Styles** from the fly-out menu to apply the changed styles.

Using the cascading style sheet editor (overview)

The cascading style sheet editor has two modes, **simple** and **advanced**. Each mode lets you set the same style properties, but the advanced editor lets you specify more complex situations in which these style properties can be applied.

- The simple editor is the default mode when the style sheet editor is started. If the upper right corner of the dialog box contains the **More** button, the editor is in simple mode. In simple mode you can assign style properties to elements, classes of elements, and specific element instances.
- To put the editor in advanced mode, click on the **More** button in the upper right corner of the dialog box; if the button reads **Less**, the editor is currently in advanced mode. In advanced mode you can create context-sensitive style properties and apply styles to groups of elements.

To create a style for an element:

- Select an element from the **Element** drop-down list.
- Now you can use the tabbed 'style properties' section of the cascading style sheet editor to set the styles for the selected element.

Setting a cascading style for an element

To assign cascading style properties to an element (that is, **all** elements of a particular type, for example, 'all H1 elements'):

- Choose **CSS Styles...** from the **Format** menu.
- Choose **Document Styles** from the fly-out menu to edit styles embedded in the current document, or choose **External Styles** to edit an external style sheet.
- The cascading style sheet editor should be in simple mode: it is in simple mode if the button in the upper right corner reads **More**; if it reads **Less**, click on the button to return to simple mode.
- Select an element from the **Element** pull-down list.
- Now you can use the tabbed 'style properties' section of the cascading style sheet editor to set the styles for the selected element.

Classes and IDs

Classes provide a way of assigning a style to many element instances, possibly of different types. IDs provide a way of assigning a style to one specific occurrence of an element.

Classes

A class is simply a group of elements, possibly scattered throughout a document, all of which have the same value for their CLASS attribute. For example, if you want a document on some topic to contain both 'basic' and 'advanced' sections, you could give all the elements that contained advanced material the CLASS attribute value 'advanced'. You could then use a cascading style sheet to format the 'advanced' class differently: display it in a different color, or even make it invisible.

IDs

While many elements can have the same CLASS attribute value, only **one** element in any document can have a particular ID attribute value. IDs are intended to be unique identifiers for elements in a document: HoTMetaL PRO will not validate a file in which the same ID value is used for more than one element. Cascading style sheets let you associate an ID attribute with a set of style properties and values, so that you can format a particular element instance in a certain way.

[More on this topic](#)

Creating classes and IDs

Classes and IDs, which are groups of elements in a document, are **created** in HoTMetal PRO, and assigned styles in the cascading style sheet editor.

To create a class, you set the CLASS attribute of as many elements you wish to the **same value**.

- Put the insertion point inside an element that you want to add to a class.
- Choose **Attribute Inspector** from the **View** menu, or type **F6**.
- Insert a value in the **CLASS** field and type **Enter**.
- Repeat this for each element that you want to add to the class, using the same value for **CLASS** each time.

To create an ID, you set the ID attribute of **one** element to a unique value.

- Put the insertion point inside the element that you want to assign an ID to.
- Choose **Attribute Inspector** from the **View** menu, or type **F6**.
- Insert a value in the **ID** field and type **Enter**.

Use the cascading style sheet editor to [assign styles](#) to classes and IDs.

Note: CLASS and ID attribute values must start with a letter and can contain only letters, numbers, and '-' (hyphen).

Assigning styles to classes and IDs

To create a simple style rule associating a class or ID with a set of styles:

- Click on the **Add Class/ID...** button in the cascading style sheet editor.

The **Edit Simple Selector** dialog box appears.

To specify a class:

- Enter the CLASS attribute value in the **Class** text box.

The CLASS attribute will be displayed in the **Element** list with an initial period ('.') to indicate that it is a CLASS attribute rule and not an element rule.

To specify an ID:

- Enter an ID attribute value in the **ID** text box.

The ID will be displayed in the **Element** list with an initial number sign ('#') to indicate that it is an ID attribute rule.

- Now you can use the tabbed style properties section of the CSS Editor to set style properties for the selected class or ID.

Note: Class names and IDs that are to be used in style sheets must start with a letter and can contain only letters, numbers, and '-' (hyphen). Class names and IDs are not case-sensitive in a cascading style sheet: for example, classes called 'H1b' and 'h1B' are the same. A CLASS or ID rule that has no style properties associated with it will not be saved in the style sheet.

Setting style properties

The properties section of the CSS editor dialog box (on the left, just below the **Elements** list) is tabbed: set style properties by clicking on the tab and moving to the appropriate section. There are seven tabs in all; if the tab you want is not visible, click on the () left or right arrow button to bring it into view.

Click on the Font tab to edit font properties, the Text tab to edit text properties, the Background tab to edit background properties, the Box tab to edit box properties, the Border tab to edit border properties, the Classification tab to edit classification properties, and the Other tab for miscellaneous properties.

Many style properties have the default value **inherit**: this means that the value for that property will be inherited from the corresponding value (if any) for its surrounding (enclosing) element, or from the default value for that property in the browser. For example, if the **font-size** property of the P element were set to **default**, it would have the same **font-size** property as a DIV or BODY element that contained that P element.

Note: In properties where you must select a value and a unit measurement, you cannot enter any numeric values if the property is set to 'inherit'. You have to choose the unit of measurement first.

Style changes can be seen in the **Preview** area on the right side of the dialog. Click on the **Preview** button to toggle previewing on or off. If you want to 'reset' a style, do so manually; clicking on the **Reset** button reloads the entire style sheet.

[More on this topic](#)

Font properties

Click on the **Font** tab of the [cascading style sheet editor](#) to edit font properties in the cascading style sheet.

You can set the following properties:

- **font-family** – The fonts available on your system will be listed in the **primary** pull-down list. You can either choose a font from this list or type a font name (for example, **Times New Roman**). You can also specify a **font class** (such as **serif**). The default is **inherit**.

In addition to the primary font family specification, you can specify secondary font or font class specifications, which will be used if the browser viewing the file is unable to find the specified primary font family. For example, if you use the font **Gill Sans** as your primary font family specification, but a user is viewing your document on a PC that does not have the Gill Sans font, you may want to use a secondary specification such as **sans-serif**, so that even if the user is not viewing the document with the exact font that you specified, he or she is at least viewing it with a font of the same type, that is, a sans-serif font.

Make your secondary **font-family** choices from the **New secondary** pull-down list or enter them into the text box. Then click on **Add** to add the secondary font families to the **Secondary** list. These choices are ranked by order: that is, an item higher up in the **Secondary** list will be used first, if it is available. You can delete an entry from this list by clicking on an entry and then clicking on **Delete**.

- **font-size** – Choose a unit of measurement from the pull-down menu and enter a value for the font size; points are usually the most appropriate unit.
- **line-height** – Choose a unit of measurement from the pull-down menu and enter a value for the space between the baselines of lines of text. The **percent** unit means a percentage of the font size. For example, if the font size were 10 points, and the **line-height** value were 120%, the space between lines would be 12 points (120% of 10 points).
- **font-style** – Choose **inherit**, **normal**, or **italic** from the pull-down list.
- **font-variant**– Choose **inherit**, **normal**, or **small-caps** from the pull-down list.
- **font-weight** – The style sheet lets you set **levels** of font weight, so you can, in effect, make text 'more bold' and 'less bold'. Selecting **normal** uses the default weight; selecting **inherit** uses the same **font-weight** value as the containing element. Selecting **lighter** or **bolder** decreases or increases the font weight, respectively. You can also specify font weight on a numerical scale where 100 is the lightest weight and 900 is the heaviest.

Text properties

Click on the **Text** tab of the [cascading style sheet editor](#) to edit text properties in the cascading style sheet.

You can set the following properties:

- **text-indent** – Sets the indent for the first line of the element. Enter a numeric value and choose the units for the value you enter. (To indent the whole element, set a value for the **margin-left** property.)
- **word-spacing** – Sets the spacing between words. The value you enter will be **added** to the default word spacing.
- **letter-spacing** – Sets the spacing between letters. The value you enter will be **added** to the default letter spacing.
- **vertical-align** – Position the element relative to the baseline of its parent element. A **percent** value moves the element up or down from the baseline. This property is applied only to inline elements.
 - Choose how you would like your text vertically aligned from the pull-down list containing several alignment styles.
- **color** – Specifies the color of the text. There are three ways to specify font color:
 - Choose a pre-defined color from the pull-down list containing the standard 16 Windows colors.
 - Choose **RGB** from the pull-down list and enter a color in #RRGGBB format.
 - Choose a custom color by clicking on the **Custom** button: the Windows **Color** dialog appears.
- **text-align (justification)** – How the text is aligned within the element. You can choose from **inherit**, **left**, **center**, and **right**.
- **text-transform** – Display text with the first letter capitalized, all in uppercase, or all in lowercase.
- **text-decoration** – You can choose one or more of **underline**, **linethrough**, **overline**, **blink**. If **none** is chosen, any previous value for **underline**, **overline**, **blink**, or **linethrough** is overridden. The default is 'inherit'.

Background properties

Click on the **Background** tab of the [cascading style sheet editor](#) to edit background properties in the cascading style sheet.

In this section, you can set the following properties:

- **background-color** – Sets the background color for the specified element. There are three ways to specify background color:
 - Choose a predefined color from the pull-down list containing the standard 16 Windows colors.
 - Choose **RGB** from the pull-down list and enter a color in #RRGGBB format.
 - Choose a custom color by clicking on the **Custom** button: the Windows **Color** dialog appears. You can also use **background-color** to set a transparent background: just choose **transparent** from the pull-down list of colors.
- **background-image** – Enter the URL for an image file that you wish to use as a background (generally, this URL is given in relative format and specifies a file in the current directory). You can choose an image by clicking on **Browse**.
- **background-repeat** – Sets how the background image will repeat or 'tile'.
 - **repeat** (the default): the background image will repeat indefinitely in both directions
 - **repeat-x**: the background will repeat horizontally only
 - **repeat-y**: the background image will repeat vertically only
 - **no-repeat**: the background image will not repeat; it will only be seen once (useful for large images)
- **background-attachment** – Specifies whether the background image will **scroll** along with the browser window when the user scrolls, or whether it will remain **fixed**.
- **background-horizontal**, **background-vertical** – You can specify the position of the background image by choosing a value for either or both of these properties. **background-horizontal** can have the following values:
 - **left**: positions the left edge of the background image at the left side of the browser window
 - **center**: positions the background image in the center
 - **right**: positions the right edge of the background image at the right side of the browser window
 - **percentage**: you can specify the exact positioning of a background image by entering a percentage. 0% is the left edge of the browser window (and is equivalent to **left**); similarly, 100% specifies the right edge. 43%, for example, would position a background image just left of center.
 - **centimeters**, **inches**, **points**, or **pixels**: specify an exact positioning using any of these units. The background image will be positioned the specified distance from the left edge.**background-vertical** can have the following values:
 - **top**: positions the top edge of the background image at the top of the browser window
 - **center**: positions the background image in the center
 - **bottom**: positions the bottom edge of the background image at the bottom of the browser window
 - **percentage**: you can specify the exact positioning of a background image by entering a percentage. 0% is the top edge of the browser window (and is equivalent to **top**); similarly, 100% specifies the bottom edge. 75%, for example, would position a background image near the bottom.
 - **centimeters**, **inches**, **points**, or **pixels**: specify an exact positioning using any of these units. The background image will be positioned the specified distance from the top edge.

Box properties

Click on the **Box** tab of the [cascading style sheet editor](#) to edit element box properties.

In the CSS1 formatting model, all displayed elements are associated with a rectangular box area. This box consists of four concentric rectangles: the inner rectangle contains the element's content; this is surrounded by a padding area; the padding area is surrounded by a border; finally, the border is surrounded by a margin area. In practice, most elements have padding, border, and margin areas with a width of zero, so that the content area and total box area are identical.

The **Box** tab lets you set margin, padding, width, height, and contents properties. The **Border** tab lets you set [border properties](#).

In this section, you can set the following properties:

- **margin-top**, **margin-bottom**, **margin-right**, and **margin-left** – Set the margin sizes for each respective margin side.
- **padding-top**, **padding-bottom**, **padding-right**, and **padding-left** – Set the amount of space between the border and the element content.
- **width** and **height** – Set explicit dimensions for the box around the element content. For example, an image can be rescaled using **width** and **height** values for an IMG element.
- **float** – Allow the element to 'float' to the left or right until it abuts the margin, padding area, or border of a block-level element. For example, an image with a float value of 'left', contained in a paragraph, will be displayed in the upper left corner of the paragraph, provided that no other block elements were in the way.
- **clear** – Specify sides of the element's box on which other floating elements may not be displayed.

For all properties except **float** and **clear**, you must choose the units from the drop-down menu before you can enter a value.

Border properties

Click on the **Border** tab of the [cascading style sheet editor](#) to edit element border properties.

In the CSS formatting model, all displayed elements are associated with a rectangular box area. This box consists of four concentric rectangles: the inner rectangle contains the element's content; this is surrounded by a padding area; the padding area is surrounded by a border; finally, the border is surrounded by a margin area. The [Box](#) tab lets you set margin, padding, width, height, and contents properties.

To set the style properties for a specific border of the element:

- Click on the radio button for **Top**, **Right**, **Bottom**, or **Left**.
- Set the style properties.

To set the style properties for **all** borders of the element:

- Set the style properties.
- Click on **Apply to all**.

You can set the following properties:

- **border-width** – Sets the width of the specified border. Choose a unit of measurement from the pull-down menu and enter a value for the specified width.
- **border-style** – Sets the style of the specified border.
- **border-color** – Sets the background color for the specified border. You can choose a color in one of three ways:
 - Choose a predefined color from the pull-down list containing the standard 16 Windows colors.
 - Choose **RGB** from the pull-down list and enter a color in #RRGGBB format.
 - Choose a custom color by clicking on the **Custom** button: the Windows **Color** dialog appears.

Classification properties

Click on the **Classification** tab of the [cascading style sheet editor](#) to edit classification properties in the cascading style sheet. Classification properties enable elements to be classified as belonging to one of several types of elements: block elements, inline elements, and list item elements.

You can set the following properties:

- **display** – The basic element type: **block**, **inline**, **list-item**, or **none**. Elements with type **none** are hidden—they are not displayed by the browser.
- **white-space** – How white space is processed in elements with **display** set to **block**. The possible values are:
 - **inherit**: inherit the value from the parent element
 - **normal**: sequences of whitespace characters are each collapsed into a single space (as in paragraphs)
 - **pre**: treat whitespace as in PRE elements
 - **nowrap**: wrap text only when a BR (line break) tag occurs
- **list-style-type** – The style of list bullet for elements with **display** set to **list-item**.
- **list-style-position** – How the list bullet is positioned, for elements with **display** set to **list-item**. **outside** produces a 'hanging' bullet—all lines of the list item content are indented to the right of the bullet; **inside** causes the second and subsequent lines of the list item content to be indented at the same level as the bullet.
- **list-style-image** – Specifies an image to be used as the list bullet for elements with **display** set to **list-item**.

List properties are inheritable by the current element's sub-elements; therefore, properties such as **list-style-type** do not have to be set directly for an element with **display** set to **list-item**: they can be set for an enclosing element such as OL, UL, or even BODY or DIV, and will then be inherited by sub-elements of type **list-item**.

Note: Use the '[Other](#)' tab, '[Edit Style Text](#)', or '[Edit Rule Text](#)' to create a 'list-style' rule.

Miscellaneous properties

Click on the **Other** tab in the [cascading style sheet editor](#) to edit miscellaneous properties.

This section of the cascading style sheet editor is used to:

- Enter values for property types that are new extensions to the CSS standard or are not explicitly supported by the cascading style sheet editor.
- Assign priorities to rules.

Extensions

The [cascading style sheet standard](#) is continually being upgraded. Values for new property types can often be entered using the **Other** section of the cascading style sheet editor. In general, you can use **Other** to edit a property if it can be expressed in the form:

```
property : value
```

For example:

```
font-foundry : "Gill's Font Farm"
```

- Click on the **Other** tab.
- Enter the property (for example, 'font-foundry') in the **Other properties** text box.
- Enter the value in the **Value** text box (for example, "Gill's Font Farm").
- Click on the **Save** button in this section of the dialog box. You can delete these custom properties by clicking on the **Delete** button.

If an extension can't be expressed in this form (that is, it requires a different syntax), you can enter it in [text mode](#) using **Edit Style Text** or **Edit Rule Text**. In particular, if you need to specify a [selector](#) that doesn't have explicit support in the cascading style sheet editor, you will have to edit it in text mode.

Note: Style property values containing spaces should be surrounded by double quotes; the cascading style sheet editor will add these automatically. Values containing single quotes should also be surrounded by double quotes, and vice versa; you should add these manually.

Priorities

If certain elements are assigned styles in more than one way (for example, in the document itself and by means of an external style sheet), you can help to resolve style conflicts by choosing priorities for important styles.

- Click on the **Other** tab.
- Select a style property from the **Property** pull-down list.
- Enter a specification in the **Priority** text box. Entering **important** in this text box will make the style property you have specified more rigid and less able to be influenced by competing style specifications.
- Optionally, enter a comment in the **Comments** text box.

Editing styles as text

By clicking on **Edit Style Text** or **Edit Rule Text** in the [cascading style sheet editor](#), you can bring up a simple text editor to edit style rules in text mode. **Edit Style Text** lets you edit the whole style sheet; **Edit Rule Text** lets you edit the rule for the current element only. **Edit Style Text** is unavailable if you started the cascading style sheet editor by choosing **Element Styles**, or via the Attribute Inspector.

Style properties or values that are not recognized by HoTMetal PRO will be displayed in the [Other](#) tab in the cascading style sheet editor.

[Selectors](#) that don't have explicit support in the cascading style sheet editor must be edited in text mode.

Creating styles for elements with specific attribute values

The CSS2 standard enables you to create styles for elements with specific attribute values. The notation for specifying attribute values is not supported explicitly by the cascading style editor, but you can enter it using [Edit Style Text](#).

To specify an element with a specific value for an attribute, use the notation:

```
element[attr="value"] { style declaration }
```

For example:

```
P[lang="de"] { color : blue; }
```

This specifies that P elements with a LANG attribute value of 'de' will be colored blue.

To specify an element with any non-null value for an attribute, use the notation:

```
element[attr] { style declaration }
```

For example:

```
P[lang] { color : red; }
```

This specifies that P elements with a non-null LANG attribute value will be colored red.

Each of these rules can also be written without a specific element name, so that the rules will apply all element types whose attributes match.

These rules take the form:

```
*[attr="val"] { style declaration }  
*[attr] { style declaration }
```

For example:

```
*[lang="de"] { color : red; }
```

This specifies that all elements with a LANG attribute value of 'de' will be colored red.

Displaying text before an element

To display some text before the contents of an element in the HoTMetaL PRO Tags On and WYSIWYG views, use the **prefix-format** property. Text displayed in this way is also called 'prefix text' or 'generated text'. You can create rules for **prefix-format** using [Edit Style Text](#). **prefix-format** is a HoTMetaL PRO extension for formatting its own document window, and **is not** supported by web browsers.

Here is some examples:

```
H4 { prefix-format: "Warning!";}
H5 { prefix-format: "Please note:";}
```

There are special prefix text strings that display the attributes of an element. To display all of the attributes that have a value, use the string '%attribute-list;'. To display a specific attribute value, use '%attribute NAME;', where NAME is the attribute name. For example:

```
P {prefix-format: "[%attribute-list;"]}
A {prefix-format: "[%attribute HREF;"]}

```

The standard CSS (CSS2) method for specifying prefix (and suffix) text is with the **:before** and **:after** 'pseudo-elements'. For example, to specify prefix and suffix text for the P element:

```
P:before { content: "Paragraph starts!";}
P:after { content: "Paragraph ends!";}

```

You can create rules for **:before** and **:after** using [Edit Style Text](#). The HoTMetaL PRO document window does not display content specified with these pseudo-elements.

Examples of simple styles

The following sample style sheet contains three style rules that were created with the cascading style sheet editor in simple mode:

- 1** The first rule states that all H1 elements will have a font size of 20 points, line height of 22 points, and be displayed in green.
- 2** The second rule states that all elements in the class 'student' (that is, all elements, of any type, whose CLASS attribute has the value 'student') will be hidden.
- 3** The third rule states that the element with ID value 'para1' will be displayed in a bold, italic font.

```
H1 { font-size: 20pt; line-height: 22pt; color: green }  
.student { display: none }  
#para1 { font-style: italic; font-weight: bold }
```

Cascading styles: Advanced mode

Use the advanced mode of the [cascading style sheet editor](#) to:

- Create rules that [group together](#) several element types, elements in a particular context, classes, and IDs.
- Assign [style properties](#) to these rules.
- Create rules that [import other style sheets](#) and rules that specify [meta-information](#) about the style sheet.
- [Re-order](#) rules with respect to one another.

To use advanced mode, click on the **More** button in the upper right corner of the cascading style sheet editor dialog box. The dialog box expands into the advanced [cascading style sheet editor](#).

[More on this topic](#)

Creating and editing advanced rules

In simple mode you can create rules that assign style properties to a single element, a class, or an ID.

In advanced mode you can create rules that assign style properties to a group of several **selectors**. 'Selector' is a general term that refers both to simple items such as elements, and complex items such as an element in a specific context.

All of the defined rules are displayed in the **Edit Style Rules** list: that is, all of the selectors in these rules are displayed. This list also includes any rules that you created in simple mode.

To create a new rule (that is, assign selectors to the rule):

- Click on the **New** button.

To modify an existing rule (that is, add or delete selectors):

- Select a rule in the the **Edit Style Rules** list.
- Click on **Edit**.

When you click on **New** or **Edit** the **Edit Selectors in Rule** dialog box appears.

From this dialog box you can add the following selectors to the rule:

- An element.
- A class or ID.
- An element in a specific context.
- An element in a specific class.
- An element with a specific ID.

After you create a rule, you must specify style properties for it, or else it won't be saved when you save the style sheet.

To make a copy of an existing rule:

- Click on a rule in the the **Edit Style Rules** list.
- Click on **Copy**.

A copy of the rule is added to the **Edit Style Rules** list. The copy will, by default, have all of the style properties of the original.

To delete a rule:

- Click on the rule in the the **Edit Style Rules** list.
- Click on **Delete**.

Adding an element to a rule

Style rules can apply to a combination of elements, classes, IDs, elements in classes, elements with IDs, and 'elements in context'. For example, you can create a rule that applies to H4, H5, and H6 elements. To add an element to a rule:

- Make sure the cascading style sheet editor is in advanced mode (click on the **More** button if it's showing).
- Click on **New** to create a new rule, or select an existing rule from the **Edit Style Rules** list and click on **Edit**.
- In the **Edit Selectors in Rule** dialog box that appears, select an element from the **Elements** list.
- Move it into the **Selectors in Rule** list by clicking on **Add >>**.
- Repeat the previous three steps if you want to add other elements.

Adding a class or ID to a rule

Style rules can apply to a combination of elements, classes, IDs, elements in classes, elements with IDs, and 'elements in context'. To add a class or ID to a rule:

- Make sure the cascading style sheet editor is in advanced mode (click on the **More** button if it's showing).
- Click on **New** to create a new rule, or select an existing rule from the **Edit Style Rules** list and click on **Edit**.
- In the **Edit Selectors in Rule** dialog box that appears, click on **--Class/ID--** in the **Elements** list.
- Move it into the **Selectors in Rule** list by clicking on **Add >>**.
- Click on **Edit**.
- In the **Edit Simple Selector** dialog box that appears, enter the **Class** or **ID** that you want to add.
- Click on **OK**.
- Repeat the previous six steps if you want to add other classes and IDs.

Adding an element in a class (or with an ID) to a rule

Style rules can apply to a combination of elements, classes, IDs, elements in classes, elements with IDs, and 'elements in context'. When you add an element that's in a particular class to a rule, the style properties specified for this rule will apply to the element only when it has a particular CLASS attribute value. When you add an element with particular ID to a rule, the style properties specified for this rule will apply to the element only when it has a particular ID attribute value.

- Make sure the cascading style sheet editor is in advanced mode (click on the **More** button if it's showing).
- Click on **New** to create a new rule, or select an existing rule from the **Edit Style Rules** list and click on **Edit**.
- In the **Edit Selectors in Rule** dialog box that appears, select an element from the **Elements** list.
- Move it into the **Selectors in Rule** list by clicking on **Add >>**.
- Click on **Edit**.
- In the **Edit Simple Selector** dialog box that appears, enter the desired **Class** or **ID**.
- Click on **OK**.
- Repeat the previous six steps if you want to add other elements.

Pseudo-classes

Another way to refine the element that you are building a style rule for is to enter a **pseudo-class** or **pseudo-element**. Pseudo-classes are not attributes, but they are characteristics of certain elements that are recognized by programs that understand the CSS standard. Currently, there are three defined pseudo-classes that work with A elements, and can be selected from the pull-down list beside the **Pseudo-class** text box. They are **active**, **link**, and **visited**, and can be used to define different styles for the A element in its unvisited, visited, and active state; for example, different colors are generally used to differentiate these different link states. Defined pseudo-classes show up in the **Style rules** list or **Edit Selectors in Group** dialog box with a colon separating the element and the pseudo-class; for example, **A:active**.

Pseudo-elements are used to address sub-parts of elements. For example, the **P:first-letter** pseudo-element defines just the first letter of a paragraph (to be used for formatting drop capitals, for example).

Adding an 'element in context' to a rule

Style rules can apply to a combination of elements, classes, IDs, elements in classes, and 'elements in context'.

Sometimes you will want a style rule to apply to an element only when it has a particular ancestor (or ancestors). For example, you might want P within DIV to have a different style than just plain P. This kind of selector is called a **contextual selector**.

- Make sure the cascading style sheet editor is in advanced mode (click on the **More** button if it's showing).
- Click on **New** to create a new rule, or select an existing rule from the **Edit Style Rules** list and click on **Edit**.
- In the **Edit Selectors in Rule** dialog box that appears, select the element whose context you wish to specify in the **Elements** list.
- Move it into the **Selectors in Rule** list by clicking on the **Add >>**.
- Click on **Edit Context**.

The **Edit Contextual Selector** dialog box appears.

To specify that an element should be the ancestor of the current element (in order for the styles to apply):

- Select the desired 'ancestor' element from the **Elements** list on the left.
- Click on **Add Before >>**.

On the other hand, you can specify that an element should be the descendant of the current element:

- Select the desired 'descendant' element from the **Elements** list on the left.
- Click on **Add After >>**.

You can add as many elements as are needed to this sequence of ancestors and descendants:

- Select an element in each of the two lists.

Now:

- Click on **Add Before >>** to make the element in the **Elements** list the ancestor of the element in the **Contextual Selector** list.

Or:

- Click on **Add After >>** to make the element in the **Elements** list the descendant of the element in the **Contextual Selector** list.

If desired, you can further refine any element in the **Contextual Selector** list by clicking on **Edit** and specifying a class.

Examples of advanced styles

The following sample style sheet contains three style rules that were created with the cascading style sheet editor in advanced mode.

- 1 The first rule states that **both** H5 and H6 elements will have a font size of 14 and a line height of 16.
- 2 The second rule states that a P element that is contained in a DIV element will be indented by 0.5 inches.
- 3 The third rule states that a DD element in the class 'student' (that is, its CLASS attribute has the value 'student') will be hidden.

```
H5, H6 { font-size: 14pt; line-height: 16pt }
DIV P { text-indent: 0.5in }
DD.student { display: none }
```

Rule ordering

You can change the order of the rules in the advanced mode of the [cascading style sheet editor](#) by selecting a rule and then clicking

on the  'up' or

'down' arrow to move it higher or lower in the list. This ordering may affect how elements are displayed in the browser. See [Cascading precedence rules](#) for more information

Importing another style sheet

You can import another style sheet and all its rules and elements into the current style sheet. This can be quite useful in many ways; for example, if you have made a 'reference' style sheet for the basic styles of your project, and would like to modify only a few selected styles. Imported styles in a style sheet have lower precedence than styles set explicitly in the style sheet.

- Make sure the cascading style sheet editor is in advanced mode (click on the **Less** button if it's showing).
- Create a new style rule by clicking on **New**.
- Click on the **@import** radio button in the **Edit Selectors in Rule** dialog box. The **Edit @import** dialog appears.
- Enter the URL for the imported style sheet in the **URL** text box, or click on **Browse** to select it.
- Optionally, enter comments about this imported style sheet in the **Comments** text box provided.

Adding meta-information

A HoTMetaL PRO extension to cascading style sheets lets you enter information for keeping track of style sheets, versions of style sheets, etc. These 'rules' are informational only and don't affect how the browser displays documents.

To enter meta-information:

- Make sure the cascading style sheet editor is in advanced mode (click on the **Less** button if it's showing).
- Create a new style rule by clicking on **New**.
- Click on the **@meta** radio button in the **Edit Selectors in Rule** dialog box. The **Edit @meta** dialog appears.
- Enter the name of a particular kind of information you want to enter in the **Name** text box, or select one from the pull-down list.
- Enter the value for that piece of information in the **Value** text box.
- Optionally, enter a comment in the **Comments** text box.
- Optionally, enter comments on the entire '@meta rule' in the **General comments** text box.

Using macros

A macro is a set of actions associated with a keyboard accelerator (also called a keyboard shortcut or hot key). The macro facility in HoTMetaL PRO can be used to define your own macros. This is particularly useful when you have to carry out some repetitive task that doesn't have a built-in accelerator or command.

You can save your macros in one or more files and load them as needed.

Macros are not associated with a specific document, so any macros you load will be available for use with all documents that you edit.

Macros can be associated with text and/or elements to be inserted in a document, a single command, or a complex series of commands. Some actions that you can perform with macros are:

- Insert an element that doesn't have a toolbar button associated with it.
- Set an attribute or property in several elements.
- Insert a piece of text that is used repeatedly.
- Create a keyboard shortcut for a command that doesn't have a built-in shortcut, subject to certain restrictions.

[More on this topic](#)

Creating macros

To record a macro:

- Choose **Record New Macro** from the **Tools** menu or click on the  button in the **Macros** toolbar. This starts macro recording. The mouse cursor changes to a 'cassette' view. The command will then toggle to **Stop Recording...** and the status bar will read **Recording macro**.
- Enter the sequence of actions that you want the macro to carry out. These actions will not only be recorded, they will also be applied to the current document as you perform them. There are some restrictions on what can go into a macro.
- When you're finished, choose **Stop Recording...** in the **Tools** menu or click on the  toolbar button. This command ends the macro.

Now you will get a dialog box that lets you select a descriptive name and an accelerator for the macro. The accelerator is the sequence of keystrokes that will run the macro.

An accelerator can consist of any choice from the **Key** list (a letter, number, function key, or arrow key), alone or preceded by **Ctrl**, **Alt**, or **Shift** in any combination.

- Enter a descriptive name for the macro.
- Choose the keys for the accelerator.
- Click on **New Macro**.

If you re-use one of HoTMetaL PRO's built-in keyboard accelerators as a macro accelerator, its original functionality will be unavailable as long as that macro is loaded.

Restrictions on macros

A macro should be self-contained, that is, its completion must not depend on any user input at the time the macro is run, such as typing in a dialog box or making a selection from a list. Therefore, there are some sequences of actions that cannot successfully be included in a macro. As a general guideline, if a macro involves any of the commands whose name ends in '...', that command should be completed somewhere in the macro. So, for example, you can define a macro that inserts a particular element, but you cannot define a macro that simply brings up the **Insert Element** dialog box.

Mouse clicks in the document window are ignored during macro recording. The first time you attempt to use the mouse to change the selection, HoTMetaL PRO will beep. The second time, you will get a message saying that you should use the cursor (arrow) keys to change the selection.

Not all commands can be recorded in a macro. In general, a macro that was recorded in WYSIWYG view, WYSIWYG-Frames view, or Tags On view should not be played back in either of the other two views. Actions in the HTML Source view cannot be recorded in a macro.

The following other actions cannot be recorded in a macro:

- Actions that make a different document the 'active' document (for example, drag and drop between documents).
- Site management actions.
- Frame editing commands.
- Setting table properties.
- The **Check HTML** and **Check Accessibility** commands.
- Insertion of ActiveX controls and Design-Time Controls (DTCs).
- Spell checking operations.
- Most commands in the **File** and **View** menus.

If you use a toolbar button when recording a macro, note that even though a toolbar button can perform one of several actions (insert, change, split) only the action that was **actually performed** when you recorded the macro will be performed the next time you run the macro. For example, if the insertion point is inside a P element and you click on the  button, HoTMetaL PRO will split the P element. This action is recorded in a macro as 'split the current element', so when the macro is run, it will attempt to split the current element, even if it's not a P. (By contrast, if you create markup with the **Element...** or **Change Element...** command, it will be played back in the macro exactly as you entered it.)

Running a macro

The usual way to run a macro is to type its keyboard accelerator. You can also run macros by choosing **Macros...** from the **Tools** menu. This gives you a dialog box that lists all the macros that are currently available.

To run a macro:

- Choose **Macros...** from the **Tools** menu, or click on the  toolbar button. The **Macros** dialog appears.
- Select the appropriate macro from the list.
- Click on **Run**.

You can run only one macro at a time.

Changing a macro accelerator

To change the accelerator associated with a macro:

- Choose **Macros...** from the **Tools** menu. The **Macros** dialog appears and displays a list of currently loaded macros.
- Select the macro that you want to change.
- Choose a new accelerator using the **Ctrl**, **Alt**, and **Shift** check boxes and the **Key** list.
- Click on **Change**.

Deleting a macro

To delete a macro from the list of loaded macros:

- Choose **Macros...** in the **Tools** menu. This displays a dialog box with a list of currently loaded macros.
- Select the macro that you want to delete. (You can delete only one macro at a time.)
- Click on **Delete**.

If you delete a macro that has been loaded from a file, the macro is removed only from the list of available macros—it is not deleted from the file from which it was loaded, and can subsequently be re-loaded.

To delete a macro from a macro file:

- Delete the macro from the list of loaded macros, as described above.
- Click on **Save**. This saves the currently loaded macros to the file.

Saving and loading macro files

To save the currently loaded macros to a file:

- Choose **Macros...** from the **Tools** menu. This displays a dialog box with a list of currently loaded macros. The name of the current macro file (if there is one) is displayed at the bottom of the dialog box.
- Click on **Save** to save the macros to the current macro file.
- Click on **Save As...** to save the macros to another macro file.

A macro file saved in this way can later be loaded by clicking on **Load...**

If any macros are still unsaved when you attempt to exit HoTMetal PRO, you will get a warning message informing you of this and giving you the opportunity to save the macros before exiting.

To load a macro file:

- Choose **Macros...** from the **Tools** menu.
- Click on **Load...**
- Choose a macro (.mcr) file.

After a macro file is loaded, the previously loaded macros are unavailable. If any macros have been defined but not yet saved, these will be lost. Before the new macro file is loaded, you will receive a warning dialog giving you the opportunity to save any unsaved macros.

When you load a macro file, it becomes the default macro file and will be loaded the next time you launch HoTMetal PRO. The default macro file for HoTMetal PRO is **hmpro5.mcr**, located in the **macros** folder under the HoTMetal PRO folder. See the file **readme.htm** in this folder for more information.

Choosing the macro language

HoTMetaL PRO macro files are XML files that contain embedded code in either VBScript or JScript. You can choose which language is used for the embedded code by editing the **hmpro5.ini** file:

- Open **hmpro5.ini** in the HoTMetaL PRO 5.0 folder with a text editor.
- Set **default_macro_language** to **vbscript** or **jscript**. For example:

```
default_macro_language=vbscript
```

(If an existing settings exists, you can modify it; if none exists, create one.)

- Save the file and restart HoTMetaL PRO.

The HoTMetaL PRO macros work the same no matter which language they are expressed in.

Shortcut keys

Shortcut keys for HoTMetaL PRO menu items are indicated on their respective menus. All menus, menu items, and dialog box controls are accessible by pressing the **Alt** key and the **underlined letter** (also called an 'access key' or 'mnemonic') associated with that control. HoTMetaL PRO also supports shortcut keys for window and dialog box navigation.

[More on this topic](#)

File commands

These shortcut keys give you access to file manipulation commands.

Create a new blank document	Ctrl+N
Create a new document from a template	Ctrl+T
Open a document	Ctrl+O
Open a recently-opened document	Alt+F+number
Close a document	Ctrl+W, Ctrl+F4
Save a document	Ctrl+S
Save all documents	Ctrl+Q
Page Properties	Alt+Enter
Print	Ctrl+P
Quit HoTMetaL PRO	Ctrl+Q, Alt+F4
Preview in a browser	Ctrl+M
Access online help	F1

Editing commands

These shortcut keys give you access to common editing operations.

Find and Replace	Ctrl+F
Find Next Forwards	F3
Find Next Backwards	Shift+F3
Find Selection Forwards	Ctrl+F3
Find Selection Backwards	Ctrl+Shift+F3
Undo an action	Ctrl+Z, Alt+Backspace
Redo an action	Ctrl+Y
Cancel an action	Esc
Spell checking	F7
Thesaurus	Shift+F7
Turn Rules Checking On/Off	Ctrl+Shift+K
Check HTML	F9
Select all	Ctrl+A
Remap links in a project	F5

Switching between views and display modes

These shortcut keys switch between HoTMetaL PRO 's four editing views, and display invisible characters, the styles dialog, and the Visual Dynamic Keyboard.

Toggle between WYSIWYG and Tags On views	Ctrl+Space
Switch to HTML Source view	Ctrl+Alt+H
Switch to Tags On view	Ctrl+Alt+T
Switch to WYSIWYG view	Ctrl+Alt+W
Switch to WYSIWYG-Frames view	Ctrl+Alt+F
Switch to Page Preview	Ctrl+Alt+B
Hide/show table grid.	Ctrl+Alt+Q

Inserting, deleting, and moving text and markup

These shortcut keys enable you to perform common editing operations on text and markup.

Delete one character to the left	Backspace
Delete one character to the right	Delete
Cut selection (copy to clipboard)	Ctrl+X, Shift+Delete
Delete selection (don't copy to clipboard)	Delete
Copy selection	Ctrl+C, Ctrl+Insert
Paste from clipboard	Ctrl+V, Shift+Insert
Insert a link	Ctrl+K
Insert a bookmark	Ctrl+G
Insert a break (BR element)	Shift+Enter
Insert non-breaking space ():)	Ctrl+Shift+Space
Insert special character	Ctrl+Shift+E
Insert Tab character in a table cell	Ctrl+Tab
Toggles the Attribute Inspector open/closed	Shift+F6
Shows and sets focus to the Attribute Inspector window	F6
Split element	Enter, Ctrl+Shift+P
Join to preceding	Backspace, Ctrl+Shift+J
Remove markup	Ctrl+Shift+D
Change element	Ctrl+Shift+L
Select element	Ctrl+Shift+T
Insert element	Ctrl+Shift+I
Insert selected element from floating Element List dialog, and dismiss dialog	Ctrl+Shift+Enter
Insert a comment	F8

Formatting characters

These shortcut keys perform character formatting in HoTMetaL PRO.

Increase the font size

Ctrl+Shift+>

Decrease the font size

Ctrl+Shift+<

Apply bold formatting

Ctrl+B

Apply an underline

Ctrl+U

Apply italic formatting

Ctrl+I

Create a new cascading style sheet in the document

Ctrl+Shift+B

Formatting paragraphs

These shortcut keys perform paragraph (block) formatting.
Center a paragraph or table cell

Ctrl+E

Left align a paragraph or table cell

Ctrl+L

Right align a paragraph or table cell

Ctrl+R

Demote selected list items to sub-list

Tab

Promote selected list items out of list

Shift+Tab

Moving around in a document

These shortcuts move the insertion point in the HoTMetaL PRO document window. See the next section for shortcuts for moving around in tables.

Scroll to insertion point or selection	F4
One character to the left	Left Arrow
One character to the right	Right Arrow
One word to the left	Ctrl+Left Arrow
One word to the right	Ctrl+Right Arrow
One paragraph up	Ctrl+Up Arrow
One paragraph down	Ctrl+Down Arrow
Up one line	Up Arrow
Down one line	Down Arrow
To the end of a line	End
To the beginning of a line	Home
Up one screen (scrolling)	Page Up
Down one screen (scrolling)	Page Down
To the end of a document	Ctrl+End
To the beginning of a document	Ctrl+Home
To the next frame or frameset in WYSIWYG-Frames view	Tab
To the previous frame or frameset in WYSIWYG-Frames view	Shift+Tab

Moving around in tables

These shortcuts move the insertion point in tables. See the previous section for shortcuts for moving around in the rest of the document window.

Next cell in a row	Tab, Right Arrow
Previous cell in a row	Shift+Tab, Left Arrow
First cell in a row	Alt+Home
Last cell in a row	Alt+End
First cell in a column	Alt+Page Up
Last cell in a column	Alt+Page Down
Previous row	Up Arrow
Next row	Down Arrow

Making and extending selections

These shortcut keys enable you to make or extend selections (highlighted text or markup).

One character to the right

Shift+Right Arrow

One character to the left

Shift+Left Arrow

To the end of a word

Ctrl+Shift+Right Arrow

To the beginning of a word

Ctrl+Shift+Left Arrow

To the end of a line

Shift+End

To the beginning of a line

Shift+Home

One line down

Shift+Down Arrow

One line up

Shift+Up Arrow

One paragraph down

Shift+Page Down

One paragraph up

Shift+Page Up

To the beginning of a document

Ctrl+Shift+Home

Select the current element

Ctrl+Shift+T

Select the entire document

Ctrl+A

Select the next table cell's contents

Tab

Select the preceding table cell's contents

Shift+Tab

Choosing menu items

These shortcuts enable you to choose commands from the HoTMetaL PRO menus.
Show the shortcut (right mouse) menu

Shift+F10

Make the menu bar active

F10

Show the program icon menu (on the program title bar)

Alt+Space

Select the next or previous command on the displayed menu or sub-menu

Down Arrow, Up

Select the menu to the left or right; or, with a sub-menu visible, switch between the main menu and the sub-menu

Left Arrow or Rig

Close the visible menu and sub-menu at the same time

Alt

Close the visible menu; or, with a sub-menu visible, close the sub-menu only

Esc

Moving between windows and dialog boxes

These shortcuts enable you to move between windows, dialog boxes, and documents.
Switch to the next active program

Alt+Tab

Switch to the previous active program

Alt+Shift

Display the next document

Alt+Right

Display the previous document

Alt+Left

Show the Windows **Start** menu

Ctrl+Esc

Close the active document window

Ctrl+W

Return to document window

Shift+F6

Switch to the next document window

Ctrl+F6

Switch to the previous document window

Ctrl+Shift

Toggle between the two most recent windows

Alt+F6

Cycle through document and modeless windows

Alt+Shift

Navigating in a dialog box

These shortcut keys enable you to select and use dialog box controls (controls are groups of one or more related objects, such as a push button, or a group of radio buttons).

Switch to the next tab in a tabbed dialog box

Switch to the previous tab in a tabbed dialog box

Move to the next control

Move to the previous control

Move to control

Move between options in the selected drop-down list box

Move between radio buttons in selected group

Perform the action assigned to the selected button

Turn selected check box on or off

Turn any check box on or off

Move to an option a selected drop-down list box

Open selected drop-down list box

Close selected drop-down list box

Perform the action assigned to the default button in the dialog box (if no other push button is selected)

Select a folder in a folder list

Update the files visible in the **Open** or **Save As** dialog box

Cancel the command and close the dialog box

Glossary

This chapter defines many of the terms commonly heard when talking about the Web.

absolute URL

A URL that contains a scheme (for example, **http**) and a server address (for example, **www.softquad.com**.)

accessibility

HTML documents are said to be **accessible** if they have been optimized for use by:

- 1 Users with physical disabilities.
- 2 Users with a variety of hardware and software configurations.

For example, in an accessible document all images should be accompanied by alternate text; this text can be interpreted by a document reader with a voice synthesizer, and displayed instead of the images by a text-only browser. In HoTMetaL PRO you can check a document's accessibility by choosing **Check Accessibility** in the **Tools** menu.

Accessible applications are those that provide alternate modes of operation for users with disabilities. HoTMetaL PRO provides the Visual Dynamic Keyboard for this purpose.

ActiveX

ActiveX™ controls are programs that can be referred to in various types of documents and applications under Microsoft Windows, including HTML documents. These programs perform some action in the browser window. OLE is the mechanism under Windows by which ActiveX controls can communicate with a browser. Not all browsers support this feature. In HoTMetaL PRO you can insert an ActiveX control by dragging and dropping it into the document window, or by choosing **ActiveX Control...** from the **Insert** menu. See also Java.

adaptive (assistive) technology

The use of hardware and software to assist people who have difficulty accessing information systems using conventional methods. Examples of adaptive technology are screen readers and magnifiers for users with visual disabilities, and alternative keyboards (such as HoTMetaL PRO's Visual Dynamic Keyboard) and switches for people with little or no hand movement.

anchor

An element in an HTML document that points to another file, or to a specific location in the current file or another file. When the document is displayed in a browser, clicking on a link causes the browser to display the document and/or location that it points to.

applet

A program, written in the Java language, that is referred to in an HTML document. Applets perform some special processing in the browser window, such as drawing a picture or interacting with the user. In HoTMetaL PRO you can insert a an applet control by dragging and dropping it into the document window, or by choosing **Java Applet...** from the **Insert** menu. See also ActiveX.

attribute

A value that is associated with an element but is not part of the **content** of the element. Many formatting properties are represented by attributes: for example, background color, table width, and alignment; the URL part of an link is an attribute. HoTMetaL PRO has many specialized dialogs for editing these properties; you can also view and edit any attribute directly by choosing **Attribute Inspector** from the **View** menu.

bookmark

A specific, named location in a document that can be the target of a URL. A bookmark consists of an A element with its NAME attribute set to some text value (the bookmark name); bookmarks are created in HoTMetaL PRO using the **Bookmark...** command in the **Insert** menu.

broken link

A link to a file that does not exist or is not at the location indicated by the URL. The **Broken Links** command in the **Site** menu will find broken links in a project.

browser

A program that communicates with Web servers, and is used for retrieving and displaying documents from the World Wide Web or an intranet. Most browsers use a graphical interface to provide access to text, images, audio, and video. Compare this with editor. Some well-known browsers are Lynx, Microsoft Internet Explorer, Mosaic, and Netscape Navigator.

cascading style sheet (CSS)

A way to specify document formatting, supported by certain browsers such as Netscape Communicator 4.0 and Microsoft Internet Explorer 4.0. Cascading style sheet information can be applied to a document via an external style sheet attached to the document; via an embedded style sheet contained on a STYLE element, or via a style rule attached to an element instance in its STYLE

attribute. A cascading style sheet generally consists of one or more rules. Rules can associate an element, an element in a particular context, certain attributes, or a group of elements with settings for font size, indentation, margins, and many other formatting properties.

These style sheets are said to be 'cascading' because multiple style sheets can be applied to the same document, but there are cascading rules that specify which rules apply to a particular element. There are two levels of the CSS standard—CSS1 defines basic formatting and is most widely supported by browsers; CSS2 defines advanced properties and contexts. You can start the HoTMetaL PRO CSS editor by choosing **CSS Styles...** from the **Format** menu. See <http://www.w3.org/> and the topic [Styles](#) in the online help for more information.

CERN

The European Laboratory for Particle Physics near Geneva, Switzerland, where the [World Wide Web](#) was 'invented'. For more information, see <http://www.cern.ch/>

CGI

An acronym for Common Gateway Interface. This is a feature of [Web servers](#) that allows HTML [clients](#) such as browsers to communicate over the web with scripts installed on the server. HTML [forms](#) are often processed by such scripts. 'CGI scripts' can be written in any programming language that will run on the server; Perl is a common choice.

class; CLASS attribute

HTML 4.0 supports the CLASS attribute for many HTML elements. In general, a set of elements can be given the same CLASS attribute value to mark them for special processing. A set of elements (possibly including different types of elements) that have the same CLASS value is referred to as a 'class'. Style properties can be applied to members of a class using [cascading style sheets](#).

clickable image map

A **clickable image map** (or just **image map**) is an image that is divided into regions, each of them associated with a [URL](#). Clicking in a region causes the file referred to by the associated URL to be accessed. There are two kinds of image maps: **server-side** (ISMAP) image maps require an external **image map file** that defines the regions in an image map and assigns them to URLs. **Client-side** (USEMAP) image maps accomplish the same thing using special elements in the document itself. Client-side image maps are easier to implement but are not supported by all browsers.

client

In networking, any program that communicates with a server. An example of a client is a [browser](#), which communicates with a [Web server](#).

client-side image map

A type of image map for which the mapped regions and their associated [URLs](#) are defined in the document itself. Client-side image maps are not supported by all browsers. Also called a USEMAP.

decor

In HoTMetaL PRO's Site Maker wizard, a set of graphical objects—buttons, lines, bullets—that have a similar visual theme, and which you can choose to give your site a consistent visual appearance.

design time control

An [ActiveX](#) control that assists a document creator in designing various objects that can be inserted in an HTML document.

DNS

Domain Name System. This is the way in which the network turns a host or Internet domain (for example, **softquad.com**) into an Internet [IP](#) address for use with [TCP/IP](#). Internet applications use both domain names and IP addresses to connect to other computers on the Internet.

editor

A program, such as HoTMetaL PRO, used to create, or change the content of, [HTML](#) documents. Compare this with [browser](#).

element

Elements are the structural building blocks of [HTML](#) documents. Blocks of text in HTML documents are contained in elements according to their function in the document: for example, headings, lists, paragraphs, and [links](#) are all surrounded by specific elements. Many HoTMetaL PRO commands and features insert elements; the most general way is to choose **Element...** in the **Insert** menu.

extranet

- 1 An [intranet](#) that is linked to the intranet(s) of one or more other organizations.
- 2 An intranet that provides limited access from the outside world.

firewall

In networking, a firewall is a computer that prevents intruders from accessing all the computers on a network if they manage to break into one computer someplace. The firewall usually sits between your inside network and the outside Internet.

form

A group of graphical controls in an [HTML](#) document: text boxes, radio buttons, drop-down lists, check boxes, etc. A user browsing the document can enter information in a form and use the browser to submit it to an e-mail address or a program on a [Web server](#). In HoTMetaL PRO, you can insert form objects using the **Form** menu or the **Forms** toolbar. See also [CGI](#).

frame

A sub-window of a browser window; each frame can display a different document. In HoTMetaL PRO, you can display and edit frames in the WYSIWYG-Frames view.

FTP

The File Transfer Protocol; one of the [schemes](#) that can be specified in a [URL](#). This has traditionally been one of the most important of the network services. You can use this standard communications protocol to pick up a copy of a file from a remote computer, provided that you can connect to that computer (with [TCP/IP](#), for example).

GIF

A common graphics format used in [HTML](#) documents. This format is owned by CompuServe. See also [JPEG](#) and [PNG](#).

gopher

A line-mode Internet protocol that predates the Web. Web browsers can normally communicate with gopher servers.

home page

The top-level document of a site associated with a person, company, organization, or subject, usually containing introductory information and links to other relevant [pages](#).

hot image; hot spot; hot text

Hot text is text in a [hypertext](#) document (such as an [HTML](#) document) that is a link to some other file; a hot image is an image that is a link to some other file; a hot spot is hot text, or a region in an image map.

HTML

The HyperText Markup Language. This is the usual format for documents that are 'published' on the Web. HTML is an application of [SGML](#).

HTML Source editing

HoTMetaL PRO provides an editing window, the HTML Source view, in which you can edit the HTML source ('code') of the document directly, as a text file. This window provides visual cues to identify the various components of the HTML source. HoTMetaL PRO also provides [WYSIWYG](#), [Tags On](#) (structural), and frame editing windows.

HTTP, http

The HyperText Transfer Protocol. This protocol is used to transfer HTML documents over the network, between a [Web server](#) and an HTML browser, while you wait. The HTTP protocol is implemented by Web servers.

hypertext

Text that contains links to other documents or specific locations in documents. HTML documents are examples of hypertext.

ICADD

The International Committee for Accessible Document Design. Techniques created by ICADD and documented in ISO 12083 specify how to automatically transform [SGML](#) files (including [HTML](#) files) into input to a Braille, large print, or synthesized voice system. See also [accessibility](#).

ID (identifier)

The ID [attribute](#) was added to most HTML elements in HTML 3.0. It is used for constructing [cascading style sheets](#): an ID attribute uniquely identifies a single instance of an element so that a style rule can be constructed for that element in a [cascading style sheet](#). An ID must start with a letter, followed by letters and digits; it is not case-sensitive.

IETF

The Internet Engineering Task Force, responsible for the technical management of the Internet. The IETF coordinates the development of the [HTTP](#) standard.

image map; image map file

An **image map** is an image that is divided into regions, each of them associated with a URL. Clicking in a region causes the file referred to by the associated URL to be accessed. There are two kinds of image maps: **server-side** (ISMAP) image maps require an external **image map file** that defines the regions in an image map and assigns them to URLs. **Client-side** (USEMAP) image maps accomplish the same thing using special elements in the document itself. Client-side image maps are easier for document authors to implement, but are not supported by all browsers.

HoTMetaL PRO has a built-in image map editor, available from the **Image Mapping** toolbar when an image is selected in the document window.

interlaced image

An image that is first displayed in the browser at a low resolution, and then in successively higher resolutions, until the whole image has been downloaded. This is sometimes referred to as **progressive display**. [GIF](#), [JPEG](#), and [PNG](#) images can be interlaced. Not all browsers support this feature.

Internet Explorer

A popular browser developed by Microsoft Corporation.

intranet

An 'internal net', whose pages are available only on a local server. An organization can use Web technology, such as browsers, servers, and editors to share information among its members or employees, but not make this information accessible to the public over the WWW. See also [extranet](#).

IP address

An IP address is the specific address, in numerical form, of a computer on the Internet. Each IP address is unique to that computer, and consists of four numbers separated by periods.

ISP

An Internet Service Provider (ISP) provides access to the Internet for a fee, usually through a dialup connection.

ISMAP

Another name for [image map](#).

ISO

The International Organization for Standardization ('ISO' is not an exact acronym).

ISO 8859-1 character set

This is the character set for 'special' or 'accented' characters that is generally in use for HTML documents. This character set is also called 'ISO Latin 1'. It includes characters required for most western European languages. This character set is one of several in the ISO 8859 standard: others support, for example, Eastern European languages and Cyrillic-based languages such as Russian. HTML now specifies the much broader [Unicode](#) standard.

Java

Java is a programming environment that operates in conjunction with certain browsers. It lets you refer to and run programs, called **applets**, from an HTML document. Applets perform some special processing in the browser window, such as drawing a picture or interacting with the user. The Java programming language is a platform-independent object-oriented language, with some similarities to C and C++. See also [ActiveX](#).

JavaScript

JavaScript is a programming language that is loosely based on [Java](#). Instead of being **referred to** in an [HTML](#) document, as Java applets are, JavaScript code is usually embedded in the document itself, using the `SCRIPT` element.

JPEG

An image format that is commonly supported by Web browsers. JPEG is an acronym for Joint Photographic Expert Group. See also [GIF](#) and [PNG](#).

layout

- 1 The visual arrangement of components—text, images, tables, etc.—on a printed or virtual page.
- 2 In HoTMetaL PRO's [Site Maker](#) wizard, a choice of structure for the pages in the site that you're creating.

line-mode browser

An HTML browser that can be used on a 'dumb terminal' such as a VT100 or a PC with communications software. The most common is [Lynx](#).

link

An [element](#) in an HTML document that points to a document, or to a specific location in a document, using a [URL](#). Clicking on a link in a browser causes the browser to display the document and/or location that it points to. You can insert a link in HoTMetaL PRO by choosing **Link...** from the **Insert** menu.

Lynx

A common [line-mode](#) HTML browser. Lynx can be used over a slow dial-up line or if you don't have a windowing system.

mailto

A [scheme](#) that causes a browser to send a form to a particular e-mail address, or generate a mail-editing window.

markup

Special codes in a document that specify how parts of it are to be processed by an application. In a word-processor file, markup

specifies how the text is to be formatted; in an HTML document, the markup (the tags) specifies the text's structural function (heading, title, paragraph, etc.).

marquee

A piece of text that scrolls across a browser document window. Not all browsers support marquees.

meta-information

Information **about** a document that is read by a Web or intranet server. It could be indexing information for search purposes, document creation and expiry information, etc. Meta data is contained in META tags in the HEAD element.

MIME

The Multipurpose Internet Mail Extensions (RFC 1510): extensions that allow e-mail messages to contain audio, video, and multiple files. It is also the format that Web servers and browsers use to transfer files. The MIME **content type** of a file tells a browser how to process it. The content type for HTML files is 'text/html'.

Miva

A programming language that can be embedded in Web pages. Miva uses an XML-based syntax; Miva tags correspond to common programming language constructs such as assignment statements, conditional expressions, loops, and input/output statements. Miva also supports special database, email, and commerce functionality.

Miva is a 'server-side' programming language: Miva programs are run on the server, not by the browser. Miva is implemented by HoTMetaL Application Server (which runs as a CGI process or NSAPI module) and HoTMetaL Personal Server, a PC-based server that is mainly used as a development platform. HoTMetaL PRO can edit documents containing Miva code; Miva tags are available from the **Miva** tab of the **Element List** dialog.

HoTMetaL Personal Server is included with the full version of HoTMetaL PRO 5.0, but not with the Evaluation Version you are now using.

Mosaic

The first widely-used HTML browser, developed at the NCSA.

NCSA

The National Center for Supercomputing Applications, located at the University of Illinois at Urbana-Champaign, Illinois. The NCSA is an (indirectly) U.S. government-funded body that exists to try and make powerful computers more accessible to researchers. Mosaic was originally written at the NCSA.

Netscape Navigator, Netscape Communicator

Popular web browsers developed by Netscape Communications Corporation.

OLE

The mechanism under Windows by which ActiveX controls can communicate with a browser.

orphan files

Files in a HoTMetaL PRO project that cannot be reached by following links that start in the project's home page. The **Orphan Files** command in the **Site** menu can locate orphan files for you.

page

A single HTML document (which can be longer than one screen).

PNG

Portable Network Graphics; a graphics format supported by some browsers. PNG is a 'lossless' format; some of its advantages are better (24-bit) color support, compression, and anti-aliasing and transparency capabilities.

Pockets

User-defined sets of files that are useful for managing projects. You can create Pockets based on a variety of criteria, such as search results, files with broken links, orphaned files (files without any links to them), etc. Once you have created a Pocket with a certain type of file in it, you can then delete, copy, or rename listed files all together, rather than trying to find each and every file in the project display.

pretty printing

Saving an HTML file in such a way that it is easily readable by a human; for example, indenting nested lists to reflect their nesting structure. You can configure pretty printing options in the **Source Layout** tab of the HoTMetaL PRO **Options** dialog.

progressive display

How an interlaced image is displayed by a browser: first at a low resolution, and then in successively higher resolutions, until the whole image has been downloaded.

project

A defined group of files, consisting of linked HTML files, auxiliary HoTMetal PRO files, and linked files in other formats. Projects are displayed and managed in HoTMetal PRO.

proxy server

A proxy server is a computer that is directly connected to the Internet, allowing multiple users on a network to access the Internet. It may also be part of a [firewall](#), protecting the network from unauthorized access. The proxy server then acts as an agent (or proxy), to make the connection. To you, inside the firewall, it pretends to be the server that you're attempting to connect to; on the outside, it pretends to be the client, and talks to the real server, thus letting you talk to a server outside the firewall (or vice versa). See also [socks](#).

publishing

Publishing a HoTMetal PRO [project](#) means moving your documents to a server so that other users can have access to your project. The publishing component of HoTMetal PRO lets you publish some or all of your files to a local or remote server. Once you have specified the destination server for your documents, the publishing component will automatically log in to the server and deliver the files to the location you specify.

relative URL

A URL that is missing some information (such as the [scheme](#) or network location), which a browser is expected to inherit from the URL of the document that contains the relative URL.

scheme

The part of a URL that tells an HTML [client](#), such as a browser, which access method to use to retrieve the file specified in the URL. Common schemes are **http**, **file**, **ftp**, and **mailto**.

screen magnifier

Screen magnification software helps people with visual impairments to use computers by enlarging the image on the screen. The magnification program runs simultaneously with the computer's operating system and applications. An area of the screen, selected using the mouse or cursor keys, is enlarged to fill the whole screen or displayed in a magnifying window.

screen reader

A software package that enables people to use computers without having to see the monitor. The screen reader uses a sound card or speech synthesizer to speak the text on the screen and the user's keystrokes. Because screen readers produce a stream of spoken text, the user usually receives a top to bottom, line by line account of a page. This means that graphics, even those including words, are missed and columns are often misread.

server

A networked program that responds to requests from local or remote computers for [HTML](#) files. You give the Web server a file name (in the form of a URL) and it gives you back the file (which can be in any format, text or binary) over the same network connection.

SGML

An international standard for describing the [markup](#) of structured documents. The basic idea behind SGML is that information can be made independent of particular hardware and software. This is done by storing all documents as text-only files (with references to documents in other formats, such as graphics, when required), and using markup that describes the **structure** of documents, rather than their physical appearance. SGML is described by the ISO 8879 standard (1986). HTML is an application (a particular instance) of SGML.

Site Maker

A component of HoTMetal PRO; a wizard that lets you design a site by supplying some information about you and/or your company, specifying the purpose(s) of the site, and choosing a [decor](#) and [layout](#).

Site Maker is included with the full version of HoTMetal PRO 5.0, but not with the Evaluation Version you are now using.

socks

A protocol used to connect to servers outside a [firewall](#). Not all firewalls support socks, in which case a [proxy server](#) is used instead.

style sheet

A cascading style sheet—way to specify document formatting, supported by certain browsers such as Netscape Communicator 4.0 and Microsoft Internet Explorer 4.0. Cascading style sheet information can be applied to a document via an external style sheet attached to the document; via an embedded style sheet contained on a STYLE element, or via a style rule attached to an element instance in its STYLE attribute. A cascading style sheet generally consists of one or more rules. Rules can associate an element, an element in a particular context, certain attributes, or a group of elements with settings for font size, indentation, margins, and many other formatting properties.

These style sheets are said to be 'cascading' because multiple style sheets can be applied to the same document, but there are

cascading rules that specify which rules apply to a particular element. There are two levels of the CSS standard—CSS1 defines basic formatting and is most widely supported browsers; CSS2 defines advanced properties and contexts. See <http://www.w3.org/> and the topic [Styles](#) for more information.

tags

An [element](#) in an HTML file begins with a **start-tag** (for example, '<PRE>') and (usually) ends with an **end-tag** (for example, '</PRE>'). In HoTMetaL PRO's [Tags On](#) view, tags are represented by tag icons at the beginning and end of an element; you can see the tags directly in the HTML Source view. See also [markup](#).

Tags On editing

HoTMetaL PRO provides an editing window for structured editing. In this window tags are represented by tag icons at the beginning and end of an element. HoTMetaL PRO also has [WYSIWYG](#), [HTML Source](#) and frame editing windows.

TCP/IP

Transmission Control Protocol/Internet Protocol. This is the low-level protocol used by much of the Internet. It's really two protocols; IP packets are sent over a network that itself uses TCP. Other common variations include SLIP (pronounced 'slip'; Serial Line/Internet Protocol), and PPP (Point to Point Protocol).

transparent image

An image in which one color (usually the dominant background color) is designated as 'transparent', so that when the image is displayed in a browser, the image's background is colored with the browser's background color. The desired effect is an image that does not have a rectangular boundary.

Unicode

A standard for electronically encoding the characters of many of the scripts used to write the world's languages, as well as special symbols such as mathematical symbols. Unicode attempts to make it easier to create computer applications that can process multiple scripts and/or whose interface (menu commands, dialog box labels, and so forth) can be adapted to various scripts. To this end Unicode uses a 'fixed-width' character encoding in which all characters are represented by 16 bits, and no special 'control' codes are used. Unicode is the character encoding specified by HTML. For more information, see <http://www.unicode.org/>

URI

Uniform Resource Identifier. This is a generic name for any of a class of ways of identifying resources on the Internet. Three types of URIs are URCs (Uniform Resource Classification), URLs, and URNs (Uniform Resource Name). Implementations of URCs and URNs are still in an experimental stage. The basic idea is that a resource (for example, a document) is identified by a URN, a kind of 'public identifier' in the SGML sense. The URN is resolved into a URC, which is a collection of information about the resource (it could include, for example, the price of obtaining the resource, and one or more URLs).

URL

Uniform Resource Locator. A URL is the address of a file, written in a format that can be interpreted by a [Web server](#), which then retrieves the file. A URL can contain a [scheme](#) that tells how the file is to be retrieved, a server on which the file resides, a path and/or filename, and a [bookmark](#) name referring to a specific location in the file. For most files on Web servers, the scheme [http](#) is used.

USEMAP

Another name for a [client-side image map](#).

Visual Dynamic Keyboard (VDK)

An on-screen keyboard provided with HoTMetaL PRO that enables users with mobility impairments to use HoTMetaL PRO and other Windows applications. A variety of hardware can be used with the VDK, instead of a conventional keyboard and mouse. See also [accessibility](#).

The Visual Dynamic Keyboard is included with the full version of HoTMetaL PRO 5.0, but not with the Evaluation Version you are now using.

W3C

The World Wide Web Consortium, an industry association for the development of World Wide Web technologies. This organization is sponsored by the Massachusetts Institute of Technology (USA), Institut National de Recherche en Informatique et en Automatique (INRIA) (France), and Keio University (Japan). For more information, see <http://www.w3.org/>.

Web, the

An informal name for the [World Wide Web](#).

Web object

[HTML](#) code that makes up an image, script, or piece of dynamic HTML. These items are objects that can be used to make up the content of a Web page.

Web page

Another term for a page.

Website

A group of linked pages on the World Wide Web.

Web server

A networked program that responds to requests from local or remote computers for HTML files. You give the Web server a file name (in the form of a URL) and it gives you back the file (which can be in any format, text or binary) over the same network connection.

Web View

The Web View shows the link structure of your HoTMetal PRO project as if it were sliding on the surface of a sphere. The Web View starts from a root page: all links go 'outwards' from the home page. The various colors used to display the links give information about the type of link.

workspace

In HoTMetal PRO, a workspace saves state information about the current project, open files, window layout, and options.

World Wide Web

This is a generic term for the collection of Web servers and browsers that literally spans the world. Usually abbreviated WWW.

WWW

The World Wide Web.

WYSIWYG editing

What You See Is What You Get. HoTMetal PRO's WYSIWYG view displays HTML documents as they might appear in a browser. HoTMetal PRO also provides Tags On (structural), HTML Source, and frame editing views.

XML

The eXtensible Markup Language. It is designed to be an easy-to-implement subset of SGML, for use over the Internet. XML is an initiative of the W3C; for more information, see <http://www.w3.org/>.

Yuri Rubinsky Insight Foundation (YRIF)

A non-profit organization dedicated to making information more accessible to people with disabilities. YRIF was founded in memory of Yuri Rubinsky (1952-1996), co-founder and former president of SoftQuad Inc. For more information, see <http://www.yuri.org/>.

Glossary

This chapter defines many of the terms commonly heard when talking about the Web.

absolute URL

A URL that contains a scheme (for example, **http**) and a server address (for example, **www.softquad.com.**)

accessibility

HTML documents are said to be **accessible** if they have been optimized for use by:

- 1 Users with physical disabilities.
- 2 Users with a variety of hardware and software configurations.

For example, in an accessible document all images should be accompanied by alternate text; this text can be interpreted by a document reader with a voice synthesizer, and displayed instead of the images by a text-only browser. In HoTMetaL PRO you can check a document's accessibility by choosing **Check Accessibility** in the **Tools** menu.

Accessible applications are those that provide alternate modes of operation for users with disabilities. HoTMetaL PRO provides the Visual Dynamic Keyboard for this purpose.

ActiveX

ActiveX™ controls are programs that can be referred to in various types of documents and applications under Microsoft Windows, including HTML documents. These programs perform some action in the browser window. OLE is the mechanism under Windows by which ActiveX controls can communicate with a browser. Not all browsers support this feature. In HoTMetaL PRO you can insert an ActiveX control by dragging and dropping it into the document window, or by choosing **ActiveX Control...** from the **Insert** menu. See also [Java](#).

adaptive (assistive) technology

The use of hardware and software to assist people who have difficulty accessing information systems using conventional methods. Examples of adaptive technology are screen readers and magnifiers for users with visual disabilities, and alternative keyboards (such as HoTMetal PRO's Visual Dynamic Keyboard) and switches for people with little or no hand movement.

anchor

An element in an HTML document that points to another file, or to a specific location in the current file or another file. When the document is displayed in a browser, clicking on a link causes the browser to display the document and/or location that it points to.

applet

A program, written in the [Java](#) language, that is referred to in an HTML document. Applets perform some special processing in the browser window, such as drawing a picture or interacting with the user. In HoTMetaL PRO you can insert a an applet control by dragging and dropping it into the document window, or by choosing **Java Applet...** from the **Insert** menu. See also [ActiveX](#).

attribute

A value that is associated with an element but is not part of the **content** of the element. Many formatting properties are represented by attributes: for example, background color, table width, and alignment; the URL part of an link is an attribute. HoTMetal PRO has many specialized dialogs for editing these properties; you can also view and edit any attribute directly by choosing **Attribute Inspector** from the **View** menu.

bookmark

A specific, named location in a document that can be the target of a URL. A bookmark consists of an A element with its NAME attribute set to some text value (the bookmark name); bookmarks are created in HoTMetaL PRO using the **Bookmark...** command in the **Insert** menu.

broken link

A [link](#) to a file that does not exist or is not at the location indicated by the [URL](#). The **Broken Links** command in the **Site** menu will find broken links in a project.

browser

A program that communicates with Web servers, and is used for retrieving and displaying documents from the World Wide Web or an intranet. Most browsers use a graphical interface to provide access to text, images, audio, and video. Compare this with editor. Some well-known browsers are Lynx, Microsoft Internet Explorer, Mosaic, and Netscape Navigator.

cascading style sheet (CSS)

A way to specify document formatting, supported by certain browsers such as Netscape Communicator 4.0 and Microsoft Internet Explorer 4.0. Cascading style sheet information can be applied to a document via an external style sheet attached to the document; via an embedded style sheet contained on a STYLE element, or via a style rule attached to an element instance in its STYLE attribute. A cascading style sheet generally consists of one or more rules. Rules can associate an element, an element in a particular context, certain attributes, or a group of elements with settings for font size, indentation, margins, and many other formatting properties.

These style sheets are said to be 'cascading' because multiple style sheets can be applied to the same document, but there are cascading rules that specify which rules apply to a particular element. There are two levels of the CSS standard—CSS1 defines basic formatting and is most widely supported by browsers; CSS2 defines advanced properties and contexts. You can start the HoTMetaL PRO CSS editor by choosing **CSS Styles...** from the **Format** menu. See <http://www.w3.org/> and the topic [Styles](#) in the online help for more information.

CERN

The European Laboratory for Particle Physics near Geneva, Switzerland, where the World Wide Web was 'invented'. For more information, see <http://www.cern.ch/>

CGI

An acronym for Common Gateway Interface. This is a feature of Web servers that allows HTML clients such as browsers to communicate over the web with scripts installed on the server. HTML forms are often processed by such scripts. 'CGI scripts' can be written in any programming language that will run on the server; Perl is a common choice.

class; CLASS attribute

HTML 4.0 supports the CLASS attribute for many HTML elements. In general, a set of elements can be given the same CLASS attribute value to mark them for special processing. A set of elements (possibly including different types of elements) that have the same CLASS value is referred to as a 'class'. Style properties can be applied to members of a class using [cascading style sheets](#).

clickable image map

A **clickable image map** (or just **image map**) is an image that is divided into regions, each of them associated with a URL. Clicking in a region causes the file referred to by the associated URL to be accessed. There are two kinds of image maps: **server-side** (ISMAP) image maps require an external **image map file** that defines the regions in an image map and assigns them to URLs. **Client-side** (USEMAP) image maps accomplish the same thing using special elements in the document itself. Client-side image maps are easier to implement but are not supported by all browsers.

client

In networking, any program that communicates with a server. An example of a client is a browser, which communicates with a Web server.

client-side image map

A type of image map for which the mapped regions and their associated URLs are defined in the document itself. Client-side image maps are not supported by all browsers. Also called a USEMAP.

decor

In HoTMetal PRO's Site Maker wizard, a set of graphical objects—buttons, lines, bullets—that have a similar visual theme, and which you can choose to give your site a consistent visual appearance.

design time control

An ActiveX control that assists a document creator in designing various objects that can be inserted in an HTML document.

DNS

Domain Name System. This is the way in which the network turns a host or Internet domain (for example, **softquad.com**) into an Internet IP address for use with TCP/IP. Internet applications use both domain names and IP addresses to connect to other computers on the Internet.

editor

A program, such as HoTMetaL PRO, used to create, or change the content of, HTML documents. Compare this with browser.

element

Elements are the structural building blocks of HTML documents. Blocks of text in HTML documents are contained in elements according to their function in the document: for example, headings, lists, paragraphs, and links are all surrounded by specific elements. Many HoTMetaL PRO commands and features insert elements; the most general way is to choose **Element...** in the **Insert** menu.

extranet

- 1 An intranet that is linked to the intranet(s) of one or more other organizations.
- 2 An intranet that provides limited access from the outside world.

firewall

In networking, a firewall is a computer that prevents intruders from accessing all the computers on a network if they manage to break into one computer someplace. The firewall usually sits between your inside network and the outside Internet.

form

A group of graphical controls in an HTML document: text boxes, radio buttons, drop-down lists, check boxes, etc. A user browsing the document can enter information in a form and use the browser to submit it to an e-mail address or a program on a Web server. In HoTMetaL PRO, you can insert form objects using the **Form** menu or the **Forms** toolbar. See also CGI.

frame

A sub-window of a browser window; each frame can display a different document. In HoTMetaL PRO, you can display and edit frames in the WYSIWYG-Frames view.

FTP

The File Transfer Protocol; one of the schemes that can be specified in a URL. This has traditionally been one of the most important of the network services. You can use this standard communications protocol to pick up a copy of a file from a remote computer, provided that you can connect to that computer (with TCP/IP, for example).

GIF

A common graphics format used in [HTML](#) documents. This format is owned by CompuServe. See also [JPEG](#) and [PNG](#).

gopher

A line-mode Internet protocol that predates the Web. Web browsers can normally communicate with gopher servers.

home page

The top-level document of a site associated with a person, company, organization, or subject, usually containing introductory information and links to other relevant pages.

hot image; hot spot; hot text

Hot text is text in a hypertext document (such as an HTML document) that is a link to some other file; a hot image is an image that is a link to some other file; a hot spot is hot text, or a region in an image map.

HTML

The HyperText Markup Language. This is the usual format for documents that are 'published' on the Web. HTML is an application of SGML.

HTML Source editing

HoTMetaL PRO provides an editing window, the HTML Source view, in which you can edit the HTML source ('code') of the document directly, as a text file. This window provides visual cues to identify the various components of the HTML source. HoTMetaL PRO also provides WYSIWYG, Tags On (structural), and frame editing windows.

HTTP, http

The HyperText Transfer Protocol. This protocol is used to transfer HTML documents over the network, between a Web server and an HTML browser, while you wait. The HTTP protocol is implemented by Web servers.

hypertext

Text that contains links to other documents or specific locations in documents. HTML documents are examples of hypertext.

ICADD

The International Committee for Accessible Document Design. Techniques created by ICADD and documented in ISO 12083 specify how to automatically transform SGML files (including HTML files) into input to a Braille, large print, or synthesized voice system. See also accessibility.

ID (identifier)

The ID attribute was added to most HTML elements in HTML 3.0. It is used for constructing cascading style sheets: an ID attribute uniquely identifies a single instance of an element so that a style rule can be constructed for that element in a cascading style sheet. An ID must start with a letter, followed by letters and digits; it is not case-sensitive.

IETF

The Internet Engineering Task Force, responsible for the technical management of the Internet. The IETF coordinates the development of the HTTP standard.

image map; image map file

An **image map** is an image that is divided into regions, each of them associated with a URL. Clicking in a region causes the file referred to by the associated URL to be accessed. There are two kinds of image maps: **server-side** (ISMAP) image maps require an external **image map file** that defines the regions in an image map and assigns them to URLs. **Client-side** (USEMAP) image maps accomplish the same thing using special elements in the document itself. Client-side image maps are easier for document authors to implement, but are not supported by all browsers.

HoTMetaL PRO has a built-in image map editor, available from the **Image Mapping** toolbar when an image is selected in the document window.

interlaced image

An image that is first displayed in the browser at a low resolution, and then in successively higher resolutions, until the whole image has been downloaded. This is sometimes referred to as **progressive display**. GIF, JPEG, and PNG images can be interlaced. Not all browsers support this feature.

Internet Explorer

A popular browser developed by Microsoft Corporation.

intranet

An 'internal net', whose pages are available only on a local server. An organization can use Web technology, such as browsers, servers, and editors to share information among its members or employees, but not make this information accessible to the public over the WWW. See also [extranet](#).

IP address

An IP address is the specific address, in numerical form, of a computer on the Internet. Each IP address is unique to that computer, and consists of four numbers separated by periods.

ISP

An Internet Service Provider (ISP) provides access to the Internet for a fee, usually through a dialup connection.

ISMAP

Another name for image map.

ISO

The International Organization for Standardization ('ISO' is not an exact acronym).

ISO 8859-1 character set

This is the character set for 'special' or 'accented' characters that is generally in use for HTML documents. This character set is also called 'ISO Latin 1'. It includes characters required for most western European languages. This character set is one of several in the ISO 8859 standard: others support, for example, Eastern European languages and Cyrillic-based languages such as Russian. HTML now specifies the much broader Unicode standard.

Java

Java is a programming environment that operates in conjunction with certain browsers. It lets you refer to and run programs, called **applets**, from an HTML document. Applets perform some special processing in the browser window, such as drawing a picture or interacting with the user. The Java programming language is a platform-independent object-oriented language, with some similarities to C and C++. See also [ActiveX](#).

JavaScript

JavaScript is a programming language that is loosely based on Java. Instead of being **referred to** in an HTML document, as Java applets are, JavaScript code is usually embedded in the document itself, using the SCRIPT element.

JPEG

An image format that is commonly supported by Web browsers. JPEG is an acronym for Joint Photographic Expert Group. See also GIF and PNG.

layout

- 1 The visual arrangement of components—text, images, tables, etc.—on a printed or virtual page.
- 2 In HoTMetaL PRO's Site Maker wizard, a choice of structure for the pages in the site that you're creating.

line-mode browser

An HTML browser that can be used on a 'dumb terminal' such as a VT100 or a PC with communications software. The most common is Lynx.

link

An element in an HTML document that points to a document, or to a specific location in a document, using a URL. Clicking on a link in a browser causes the browser to display the document and/or location that it points to. You can insert a link in HoTMetal PRO by choosing **Link...** from the **Insert** menu.

Lynx

A common line-mode HTML browser. Lynx can be used over a slow dial-up line or if you don't have a windowing system.

mailto

A scheme that causes a browser to send a form to a particular e-mail address, or generate a mail-editing window.

markup

Special codes in a document that specify how parts of it are to be processed by an application. In a word-processor file, markup specifies how the text is to be formatted; in an HTML document, the markup (the tags) specifies the text's structural function (heading, title, paragraph, etc.).

marquee

A piece of text that scrolls across a browser document window. Not all browsers support marquees.

meta-information

Information **about** a document that is read by a Web or intranet server. It could be indexing information for search purposes, document creation and expiry information, etc. Meta data is contained in META tags in the HEAD element.

MIME

The Multipurpose Internet Mail Extensions (RFC 1510): extensions that allow e-mail messages to contain audio, video, and multiple files. It is also the format that Web servers and browsers use to transfer files. The MIME **content type** of a file tells a browser how to process it. The content type for HTML files is 'text/html'.

Miva

A programming language that can be embedded in Web pages. Miva uses an XML-based syntax; Miva tags correspond to common programming language constructs such as assignment statements, conditional expressions, loops, and input/output statements. Miva also supports special database, email, and commerce functionality.

Miva is a 'server-side' programming language: Miva programs are run on the server, not by the browser. Miva is implemented by HoTMetaL Application Server (which runs as a CGI process or NSAPI module) and HoTMetaL Personal Server, a PC-based server that is mainly used as a development platform. HoTMetaL PRO can edit documents containing Miva code; Miva tags are available from the **Miva** tab of the **Element List** dialog.

HoTMetaL Personal Server is included with the full version of HoTMetaL PRO 5.0, but not with the Evaluation Version you are now using.

Mosaic

The first widely-used HTML browser, developed at the NCSA.

NCSA

The National Center for Supercomputing Applications, located at the University of Illinois at Urbana-Champaign, Illinois. The NCSA is an (indirectly) U.S. government-funded body that exists to try and make powerful computers more accessible to researchers. Mosaic was originally written at the NCSA.

Netscape Navigator, Netscape Communicator

Popular web browsers developed by Netscape Communications Corporation.

OLE

The mechanism under Windows by which ActiveX controls can communicate with a browser.

orphan files

Files in a HoTMetal PRO project that cannot be reached by following links that start in the project's home page. The **Orphan Files** command in the **Site** menu can locate orphan files for you.

page

A single HTML document (which can be longer than one screen).

PNG

Portable Network Graphics; a graphics format supported by some browsers. PNG is a 'lossless' format; some of its advantages are better (24-bit) color support, compression, and anti-aliasing and transparency capabilities.

Pockets

User-defined sets of files that are useful for managing projects. You can create Pockets based on a variety of criteria, such as search results, files with broken links, orphaned files (files without any links to them), etc. Once you have created a Pocket with a certain type of file in it, you can then delete, copy, or rename listed files all together, rather than trying to find each and every file in the project display.

pretty printing

Saving an HTML file in such a way that it is easily readable by a human; for example, indenting nested lists to reflect their nesting structure. You can configure pretty printing options in the **Source Layout** tab of the HoTMetal PRO **Options** dialog.

progressive display

How an interlaced image is displayed by a browser: first at a low resolution, and then in successively higher resolutions, until the whole image has been downloaded.

project

A defined group of files, consisting of linked HTML files, auxiliary HoTMetaL PRO files, and linked files in other formats. Projects are displayed and managed in HoTMetaL PRO.

proxy server

A proxy server is a computer that is directly connected to the Internet, allowing multiple users on a network to access the Internet. It may also be part of a firewall, protecting the network from unauthorized access. The proxy server then acts as an agent (or proxy), to make the connection. To you, inside the firewall, it pretends to be the server that you're attempting to connect to; on the outside, it pretends to be the client, and talks to the real server, thus letting you talk to a server outside the firewall (or vice versa). See also socks.

publishing

Publishing a HoTMetaL PRO project means moving your documents to a server so that other users can have access to your project. The publishing component of HoTMetaL PRO lets you publish some or all of your files to a local or remote server. Once you have specified the destination server for your documents, the publishing component will automatically log in to the server and deliver the files to the location you specify.

relative URL

A URL that is missing some information (such as the scheme or network location), which a browser is expected to inherit from the URL of the document that contains the relative URL.

scheme

The part of a URL that tells an HTML client, such as a browser, which access method to use to retrieve the file specified in the URL. Common schemes are **http**, **file**, **ftp**, and **mailto**.

screen magnifier

Screen magnification software helps people with visual impairments to use computers by enlarging the image on the screen. The magnification program runs simultaneously with the computer's operating system and applications. An area of the screen, selected using the mouse or cursor keys, is enlarged to fill the whole screen or displayed in a magnifying window.

screen reader

A software package that enables people to use computers without having to see the monitor. The screen reader uses a sound card or speech synthesizer to speak the text on the screen and the user's keystrokes. Because screen readers produce a stream of spoken text, the user usually receives a top to bottom, line by line account of a page. This means that graphics, even those including words, are missed and columns are often misread.

server

A networked program that responds to requests from local or remote computers for HTML files. You give the Web server a file name (in the form of a URL) and it gives you back the file (which can be in any format, text or binary) over the same network connection.

SGML

An international standard for describing the markup of structured documents. The basic idea behind SGML is that information can be made independent of particular hardware and software. This is done by storing all documents as text-only files (with references to documents in other formats, such as graphics, when required), and using markup that describes the **structure** of documents, rather than their physical appearance. SGML is described by the ISO 8879 standard (1986). HTML is an application (a particular instance) of SGML.

Site Maker

A component of HoTMetaL PRO; a wizard that lets you design a site by supplying some information about you and/or your company, specifying the purpose(s) of the site, and choosing a decor and layout.

Site Maker is included with the full version of HoTMetaL PRO 5.0, but not with the Evaluation Version you are now using.

socks

A protocol used to connect to servers outside a firewall. Not all firewalls support socks, in which case a proxy server is used instead.

style sheet

A cascading style sheet—way to specify document formatting, supported by certain browsers such as Netscape Communicator 4.0 and Microsoft Internet Explorer 4.0. Cascading style sheet information can be applied to a document via an external style sheet attached to the document; via an embedded style sheet contained on a STYLE element, or via a style rule attached to an element instance in its STYLE attribute. A cascading style sheet generally consists of one or more rules. Rules can associate an element, an element in a particular context, certain attributes, or a group of elements with settings for font size, indentation, margins, and many other formatting properties.

These style sheets are said to be 'cascading' because multiple style sheets can be applied to the same document, but there are cascading rules that specify which rules apply to a particular element. There are two levels of the CSS standard—CSS1 defines basic formatting and is most widely supported browsers; CSS2 defines advanced properties and contexts. See <http://www.w3.org/> and the topic Styles for more information.

tags

An element in an HTML file begins with a **start-tag** (for example, '<PRE>') and (usually) ends with an **end-tag** (for example, '</PRE>'). In HoTMetaL PRO's Tags On view, tags are represented by tag icons at the beginning and end of an element; you can see the tags directly in the HTML Source view. See also markup.

Tags On editing

HoTMetaL PRO provides an editing window for structured editing. In this window tags are represented by tag icons at the beginning and end of an element. HoTMetaL PRO also has WYSIWYG, HTML Source and frame editing windows.

TCP/IP

Transmission Control Protocol/Internet Protocol. This is the low-level protocol used by much of the Internet. It's really two protocols; IP packets are sent over a network that itself uses TCP. Other common variations include SLIP (pronounced 'slip'; Serial Line/Internet Protocol), and PPP (Point to Point Protocol).

transparent image

An image in which one color (usually the dominant background color) is designated as 'transparent', so that when the image is displayed in a browser, the image's background is colored with the browser's background color. The desired effect is an image that does not have a rectangular boundary.

Unicode

A standard for electronically encoding the characters of many of the scripts used to write the world's languages, as well as special symbols such as mathematical symbols. Unicode attempts to make it easier to create computer applications that can process multiple scripts and/or whose interface (menu commands, dialog box labels, and so forth) can be adapted to various scripts. To this end Unicode uses a 'fixed-width' character encoding in which all characters are represented by 16 bits, and no special 'control' codes are used. Unicode is the character encoding specified by HTML. For more information, see <http://www.unicode.org/>

URI

Uniform Resource Identifier. This is a generic name for any of a class of ways of identifying resources on the Internet. Three types of URIs are URCs (Uniform Resource Classification), URLs, and URNs (Uniform Resource Name). Implementations of URCs and URNs are still in an experimental stage. The basic idea is that a resource (for example, a document) is identified by a URN, a kind of 'public identifier' in the SGML sense. The URN is resolved into a URC, which is a collection of information about the resource (it could include, for example, the price of obtaining the resource, and one or more URLs).

URL

Uniform Resource Locator. A URL is the address of a file, written in a format that can be interpreted by a Web server, which then retrieves the file. A URL can contain a scheme that tells how the file is to be retrieved, a server on which the file resides, a path and/or filename, and a bookmark name referring to a specific location in the file. For most files on Web servers, the scheme http is used.

USEMAP

Another name for a client-side image map.

Visual Dynamic Keyboard (VDK)

An on-screen keyboard provided with HoTMetaL PRO that enables users with mobility impairments to use HoTMetaL PRO and other Windows applications. A variety of hardware can be used with the VDK, instead of a conventional keyboard and mouse. See also [accessibility](#).

The Visual Dynamic Keyboard is included with the full version of HoTMetaL PRO 5.0, but not with the Evaluation Version you are now using.

W3C

The World Wide Web Consortium, an industry association for the development of World Wide Web technologies. This organization is sponsored by the Massachusetts Institute of Technology (USA), Institut National de Recherche en Informatique et en Automatique (INRIA) (France), and Keio University (Japan). For more information, see <http://www.w3.org/>.

Web, the

An informal name for the World Wide Web.

Web object

HTML code that makes up an image, script, or piece of dynamic HTML. These items are objects that can be used to make up the content of a Web page.

Web page

Another term for a page.

Website

A group of linked pages on the World Wide Web.

Web server

A networked program that responds to requests from local or remote computers for HTML files. You give the Web server a file name (in the form of a URL) and it gives you back the file (which can be in any format, text or binary) over the same network connection.

Web View

The Web View shows the link structure of your HoTMetaL PRO project as if it were sliding on the surface of a sphere. The Web View starts from a root page: all links go 'outwards' from the home page. The various colors used to display the links give information about the type of link.

workspace

In HoTMetal PRO, a workspace saves state information about the current project, open files, window layout, and options.

World Wide Web

This is a generic term for the collection of Web servers and browsers that literally spans the world. Usually abbreviated WWW.

WWW
The World Wide Web.

WYSIWYG editing

What You See Is What You Get. HoTMetal PRO's WYSIWYG view displays HTML documents as they might appear in a browser. HoTMetal PRO also provides Tags On (structural), HTML Source, and frame editing views.

XML

The eXtensible Markup Language. It is designed to be an easy-to-implement subset of SGML, for use over the Internet. XML is an initiative of the W3C; for more information, see <http://www.w3.org/>.

Yuri Rubinsky Insight Foundation (YRIF)

A non-profit organization dedicated to making information more accessible to people with disabilities. YRIF was founded in memory of Yuri Rubinsky (1952-1996), co-founder and former president of SoftQuad Inc. For more information, see <http://www.yuri.org/>.
