

## Visual Basic Multibutton Control

(c)1992 by Mark Gamber

This control provides a button to Visual Basic which acts as a number of small, independent buttons. To begin using the control, copy **VMBTTN.VBX** to your Visual Basic directory. Select "Add Files..." from the "File" menu and select the file from the listbox displayed. If successful, a new icon will appear in the toolbar.

### Properties:

Alpha: TRUE forces alphanumeric displays, FALSE displays numbers.

BackDown: Background color used for a pressed button.

BackUp: Background color used for a raised button.

NumBase: First number or letter in control. All other buttons are incremented from this value.

SubHeight: Pixel height of each individual sub-button.

SubWidth: Pixel width of each individual sub-button.

TextDown: Color used for text in a pressed button.

TextUp: Color used for text in a raised button.

Version: Version of this control. 100 is version 1.00, for example.

### Events:

Clicked: Called when a button is clicked. Provides button and state.

### Notes:

This is not the same as a "grid" control where data can be assigned to each cell. Instead, data is preassigned given the NumBase and size of the control and sub-buttons.

You **may not** have more than 256 sub-buttons per control. There is no error checking for this as it would slow the control unacceptably. If you use more than 256 sub-buttons in a single control, you will be cheerfully scolded with a Windows UAE.
