OUTLINE

TOPIC: OLE 2.0 Outline Sample Code FILE: readme.txt DATE: 11/11/93

OUTLINE SERIES --------------

This sample application set demonstrates taking a 'base' application (in this case OUTLINE.EXE) and extending it into an OLE 2 server and container (SVROUTL and CNTROUTL respectively) and into OLE 2 in-place (aka visual editing) container (ICNTROTL).

These applications attempt to implement the complete OLE 2 functionality and recommended user model. For example, these applications implement all of the OLE 2 User Interface dialogs. As such this is not a trivial sample application set.

All OUTLINE applications support loading/saving files; they all use docfiles for storage.

DIRECTORY STRUCTURE -------------------

The OUTLINE sample uses the following directory structure:

```
                        OUTLINE
                           |
      +-------------+-----------+--------+--------+
      |             |           |        |        |
   OUTLINE       OLE2UI       WRAPUI  BTTNCUR   GIZMOBAR
```

OUTLINE -- source directory for OUTLINE sample app series
OLE2UI -- source directory for common OLE 2 UI library using Unicode OLE.
WRAPUI -- source directory for common OLE 2 UI library using OLE2ANSI wrappers for the OLE 2 calls.

All five variations of the OUTLINE applications are built from common sources. All of the common source code (*.C and *.H files) is in the OUTLINE directory. Each variant of the application builds in the same directory for this release.

Files that begin with OUTL comprise the base version of the application. They are also used by OLE versions of the applicaton. Files that begin with CNTR are specific to the container version and files that begin with SVR are specific to the server version. Files that begin with OLE are common to both the container and server versions. This series of sample applications highlights the changes necessary to implement OLE into an existing application. The container version has the same functionality as the base (OUTLINE) and also allows you to embed objects.

Some of the major OLE features are organized into special files in order to group related code across the application variants:

DRAGDROP.C -- Drag/Drop implementation
CLIPBRD.C -- OLE 2 style copy/paste implementation (data transfer)
LINKING.C -- Linking and Moniker support implementation
CNTRINPL.C -- In-place container implementation
SVRINPL.C -- In-place server implementation
CLASSFAC.C -- IClassFactory implementation

Conditional compilation is used to control what code is used with which version. The following defines are used to control the compilation:

OLE_VERSION -- code common to all OLE versions
OLE_SERVER -- code used by both SVROUTL and ISVROTL
OLE_CNTR -- code used by both CNTROUTL and ICNTROTL

INPLACE_CNTR -- code used by ICNTROTL only

The following defines are used to identify code specific for a particular feature (NOTE: it is not really intended that these symbols should be turned of):

USE_DRAGDROP	-- drag/drop code
USE_FRAMETOOLS	-- formula bar and tool bar
USE_HEADING	-- row/column headings code
USE_STATUSBAR	-- status bar code
USE_CTL3D	-- use CTL3D.DLL to have 3D effect for dialogs
USE_MSGFILTER	-- IMessageFilter code
_DEBUG	-- debug code

HOW TO BUILD ------------

To build, simple do an nmake -a -i from the root of the outline directory.

This will first build a version of the OLE2UI library, using it's own ANSI to UNICODE translations. This library is a private version of the OLE2UI library to be used exclusively by the OUTLINE samples applications.

NO OTHER APPLICATION MAY SHIP A DLL CALLED "OUTLUI.DLL".

Every application that builds the OLE2UI library as a DLL must build it with a unique name for that application. See the OLE2UI\README.TXT for instructions on how to build the OLE2UI library.

NOTES ON WRAPUI ---------------

WRAPUI builds a dll with the same functionality as OLE2UI, except that it uses the OLE2ANSI wrappers provided in the ole2\ole2ansi directory instead of doing its own ANSI to UNICODE translation. In general we recommend that ISVs actually provide their own translation since it will improve the performance and reduce the size of your application. However we realize that for a large project this may not be a feasible solution, so we have provided WRAPUI to illustrate how you may use the OLE2ANSI wrappers in your own application. Please see the ole2\ole2ansi\readme.txt for further info- rmation regarding the wrappers.

MAKEFILE   (OUTLINE Sample)

```
#
# (c) Copyright Microsoft Corp. 1992 All Rights Reserved
#
# Makefile : Builds the OLE 2.0 Outline series sample apps
#        The Outline series includes:
#           Outline.exe -- base version of app (w/o OLE functionality)
#           SvrOutl.exe -- OLE 2.0 Server sample app
#           CntrOutl.exe -- OLE 2.0 Containter (Container) sample app
#        NOTE: apps are built in a subdir of same name as app.
#
# Usage:     NMAKE              (builds all executables)
#    or:     NMAKE APP=outline  (build outline.exe--non-OLE version)
#    or:     NMAKE APP=svroutl  (build svroutl.exe--server-only version)
#    or:     NMAKE APP=cntroutl (build cntroutl.exe--container-only version)
#    or:     NMAKE APP=icntrotl (build icntrotl.exe--InPlace container ver.)
#    or:     NMAKE APP=isvrotl  (build isvrotl.exe--InPlace server ver.)
#    or:     NMAKE clean        (erase all compiled files)
#

!include <$(MSTOOLS)\samples\ole\include\olesampl.mak>

!if "$(APP)" == ""
APPS = outline.exe svroutl.exe cntroutl.exe icntrotl.exe isvrotl.exe
!else
APPS = $(APP).exe
!endif

all: $(APPS)

$(APPS):
    nmake -a -f outline.mk APP=$*

##########################################################################
#
# clean (erase) generated files

clean:
    -del *.obj
    -del *.res
    -del *.exe
    -del *.map
    -del *.pch
```

   **    of formats that are registered for our app in the
   **    registration database. OLE provides a default enumerator
   **    which enumerates from the registration database. this default
   **    enumerator is requested by returning OLE_S_USEREG. it is NOT
   **    required that a user document (ie. non-DataTransferDoc)
   **    enumerate the OLE formats: CF_LINKSOURCE, CF_EMBEDSOURCE, or
   **    CF_EMBEDDEDOBJECT.
   **
   **    An object implemented as a server EXE (as this sample
   **    is) may simply return OLE_S_USEREG to instruct the OLE
   **    DefHandler to call the OleReg* helper API which uses info in
   **    the registration database. Alternatively, the OleRegEnumFormatEtc
   **    API may be called directly. Objects implemented as a server
   **    DLL may NOT return OLE_S_USEREG; they must call the OleReg*
   **    API or provide their own implementation. For EXE based
   **    objects it is more efficient to return OLE_S_USEREG, because
   **    in then the enumerator is instantiated in the callers
   **    process space and no LRPC remoting is required.

** -------------------------------------
**    forward the WM_PALETTECHANGED message (via SendMessage) to any
**    in-place objects that currently have their window visible. this
**    gives these objects the chance to select their palette as a
**    BACKGROUND palette.
**
**    SEE THE TECHNOTE FOR DETAILED INFORMATION ON PALETTE COORDINATION
**
**    OLE2NOTE: For containers and objects to manage palettes properly
**    (when objects are getting inplace edited) they should follow a
**    set of rules.
**
**    Rule 1: The Container can decide if it wants to own the palette or
**    it wants to allow its UIActive object to own the palette.
**    a) If the container wants to let its UIActive object own the
**    palette then it should forward WM_QUERYNEWPALETTE to the object
**    when it is received to the top frame window. also it should send
**    WM_QUERYNEWPALETTE to the object in its
**    IOleInPlaceFrame::SetActiveObject implementation. if the object
**    is given ownership of the palette, then it owns the palette until
**    it is UIDeactivated.
**    b) If the container wants to own the palette it should NOT send
**    WM_QUERYNEWPALETTE to the UIActive object.
**
**    Rule 2: Whether the container wants to own the palette or not, it
**    should forward the WM_PALETTECHANGED to the immediate child
**    inplace active objects in its documents. if it is an inside-out
**    style container then it must forward it to ALL objects that
**    currently have their windows visible. When the object recives the
**    WM_PALETTECHANGED message it must select its color palette as the
**    background palette. When the objects are in loaded state they will be
**    drawn by (OLE) by selecting their palettes as background palettes
**    anyway.
**
**    Note: IOleObject::SetColorScheme is not related to the palette
**    issue.

   **    the object to force a repaint in the future, we mark
   **    that the extents of the object may have changed
   **    (m_fDoGetExtent=TRUE), and we post a message
   **    (WM_U_UPDATEOBJECTEXTENT) to our document that one or more
   **    OLE objects may need to have their extents updated. later
   **    when this message is processed, the document loops through
   **    all lines to see if any are marked as needing an extent update.
   **    if infact the extents did change. this can be done by calling
   **    IViewObject2::GetExtent to retreive the object's current
   **    extents and comparing with the last known extents for the
   **    object. if the extents changed, then relayout space for the
   **    object before drawing. we postpone the check to get
   **    the extents now because OnViewChange is an asyncronis method,
   **    and we have to careful not to call any syncronis methods back
   **    to the object. while it WOULD be OK to call the
   **    IViewObject2::GetExtent method within the asyncronis
   **    OnViewChange method (because this method is handled by the
   **    object handler and never remoted), it is good practise to not
   **    call any object methods from within an asyncronis
   **    notification method.
   **    if there is already WM_U_UPDATEOBJECTEXTENT message waiting
   **    in our message queue, there is no need to post another one.
   **    in this way, if the server is updating quicker than we can
   **    keep up, we do not make unneccsary GetExtent calls. also if

      **    it is VERY important that an in-place container
      **    that also support linking to embeddings properly manage
      **    the running of its in-place objects. in an outside-in
      **    style in-place container, when the user clicks
      **    outside of the in-place active object, the object gets
      **    UIDeactivated and the object hides its window. in order
      **    to make the object fast to reactivate, the container
      **    deliberately does not call IOleObject::Close. the object
      **    stays running in the invisible unlocked state. the idea
      **    here is if the user simply clicks outside of the object
      **    and then wants to double click again to re-activate the
      **    object, we do not want this to be slow. if we want to
      **    keep the object running, however, we MUST Lock it
      **    running. otherwise the object will be in an unstable
      **    state where if a linking client does a "silent-update"
      **    (eg. UpdateNow from the Links dialog), then the in-place
      **    server will shut down even before the object has a chance
      **    to be saved back in its container. this saving normally
      **    occurs when the in-place container closes the object. also
      **    keeping the object in the unstable, hidden, running,
      **    not-locked state can cause problems in some scenarios.
      **    ICntrOtl keeps only one object running. if the user
      **    intiates a DoVerb on another object, then that last
      **    running in-place active object is closed. a more
      **    sophistocated in-place container may keep more object running.

/*************************************************************************
** class CONTAINERLINE : LINE
**    The class CONTAINERLINE is a concrete subclass of the abstract base
**    class LINE. The CONTAINERLINE maintains all information about the
**    place within the CONTAINERDOC that an OLE object is embedded. This
**    object implements the following OLE 2.0 interfaces:
**          IOleClientSite
**          IAdviseSink
**    In the CntrOutl client app either CONTAINERLINE objects or TEXTLINE
**    objects can be created. The CONTAINERLINE class inherits all fields
**    from the LINE class. This inheritance is achieved by including a
**    member variable of type LINE as the first field in the CONTAINERLINE
**    structure. Thus a pointer to a CONTAINERLINE object can be cast to be
**    a pointer to a LINE object.
**    Each CONTAINERLINE object that is created in added to the LINELIST of
**    the associated OUTLINEDOC document.

/*************************************************************************
** class CONTAINERAPP : OLEAPP
**    CONTAINERAPP is an extention to the base OLEAPP object (structure)
**    that adds special Container functionality. There is one instance of
**    CONTAINERApp object created per running application instance. This
**    object holds many fields that could otherwise be organized as
**    global variables. The CONTAINERAPP class inherits all fields
**    from the OLEAPP class. This inheritance is achieved by including a
**    member variable of type OLEAPP as the first field in the CONTAINERAPP
**    structure. OLEAPP inherits from OUTLINEAPP. This inheritance is
**    achieved in the same manner. Thus a pointer to a CONTAINERAPP object
**    can be cast to be a pointer to an OLEAPP or an OUTLINEAPP object
*************************************************************************/

/* m_arrSingleObjGetFmts array enumerates the formats that a
**    ContainerDoc object can offer (give) through a
**    IDataObject::GetData call when the selection copied IS a
**    single OLE object.
**    ContainerDoc objects accept data formats in the following order:
**                 1. CF_CNTROUTL
**                 2. CF_EMBEDDEDOBJECT
**                 3. CF_OBJECTDESCRIPTOR
**                 4. CF_METAFILEPICT  (note DVASPECT will vary)
**                 5. CF_LINKSOURCE *
**                 6. CF_LINKSRCDESCRIPTOR *
**
**    * OLE2NOTE: CF_LINKSOURCE and CF_LINKSRCDESCRIPTOR is only
**    offered if the OLE object is allowed to be linked to from the
**    inside (ie. we are allowed to give out a moniker which binds
**    to the running OLE object), then we want to offer
**    CF_LINKSOURCE format. if the object is an OLE 2.0 embedded
**    object then it is allowed to be linked to from the inside. if
**    the object is either an OleLink or an OLE 1.0 embedding then
**    it can not be linked to from the inside. if we were a
**    container/server app then we could offer linking to the
**    outside of the object (ie. a pseudo object within our
**    document). we are a container only app that does not support
**    linking to ranges of its data.
**    the simplest way to determine if an object can be linked to
**    on the inside is to call IOleObject::GetMiscStatus and test
**    to see if the OLEMISC_CANTLINKINSIDE bit is NOT set.
**
**    OLE2NOTE: optionally, a container that wants to have a
**    potentially richer data transfer, can enumerate the data
**    formats from the OLE object's cache and offer them too. if
**    the object has a special handler, then it might be able to
**    render additional data formats.

/* OleDoc_Init
```

```
 * -----------
 *
 *  Initialize the fields of a new OleDoc object. The object is initially
 *  not associated with a file or an (Untitled) document. This function sets
 *  the docInitType to DOCTYPE_UNKNOWN. After calling this function the
 *  caller should call:
 *      1.) Doc_InitNewFile to set the OleDoc to (Untitled)
 *      2.) Doc_LoadFromFile to associate the OleDoc with a file.
 *  This function creates a new window for the document.
 *
 *  NOTE: the window is initially created with a NIL size. it must be
 *        sized and positioned by the caller. also the document is initially
 *        created invisible. the caller must call OutlineDoc_ShowWindow
 *        after sizing it to make the document window visible.

    /* OLE2NOTE: it is ALWAYS necessary to make sure that the work we
    **    do in our OleDoc_Close function is performed before we
    **    destroy our document object. this includes revoking from the
    **    Running Object Table (ROT), sending OnClose notification,
    **    revoking from Drag/Drop, closing all pseudo objects, etc.
    **    There are some tricky scenarios involving linking and
    **    when IOleObject::Close is called versus when we get our
    **    final release causing us to call our OleDoc_Destroy
    **    (destructor) function.
    **
    **    SCENARIO 1 -- closing from server (File.Exit or File.Close)
    **                  OleDoc_Close function is called directly by the
    **                  server in response to the menu command
    **                  (WM_COMMAND processing).
    **
    **    SCENARIO 2 -- closed by embedding container
    **                  our embedding container calls IOleObject::Close
    **                  directly.
    **
    **    SCENARIO 3 -- silent-update final release
    **                  THIS IS THE TRICKY ONE!!!
    **                  in the case that our object is launched because
    **                  a linking client calls IOleObject::Update on
    **                  its link, then our object will be run
    **                  invisibly, typically GetData will be called,
    **                  and then the connection from the linking client
    **                  will be released. the release of this last
    **                  linking connection should cause our object to
    **                  shut down.
    **                  there are 2 strategies to deal with this scenario:
    **
    **                  STRATEGY 1 -- implement IExternalConnection.
    **                  IExternalConnection::AddConnection will be
    **                  called (by the StubManager) every time that an
    **                  external (linking) connection is created or
    **                  CoLockObjectExternal is called. the object
    **                  should maintain a count of strong connections
    **                  (m_dwStrongExtConn). IExternalConnection::
    **                  ReleaseConnection will be called when these
    **                  connections are released. when the
    **                  m_dwStrongExtConn transistions to 0, the object
    **                   should call its IOleObject::Close function.
    **                   this assumes that CoLockObjectExternal is used
    **                   to manage locks by the object itself (eg. when
    **                   the object is visible to the user--fUserCtrl,
    **                   and when PseudoObjects are created, etc.)
    **                   this is the strategy implemented by SVROUTL.
    **
    **                   STRATEGY 2 -- guard both the destructor
    **                   function and the Close function. if the
    **                   destructor is called directly without Close
    **                   first being called, then call Close before
    **                   proceeding with the destruction code.
    **                   previously SVROUTL was organized in this
    **                   manner. that old code is conditionaly compiled
    **                   away with "#ifdef OBSOLETE" below. this
    **                   method has the disadvantage that external
    **                   remoting is no longer possible by the time the
    **                   Close is called making it impossible for
    **                   the object to ask its container to save the
    **                   object if the object is dirty. this can result
    **                   in data loss. thus STRATEGY 1 is safer.
    **                   consider the scenario where an in-place
    **                   container UIDeactivates an object but does NOT
    **                   keep the object locked running (this is
    **                   required--see CntrLine_IPSite_OnInPlaceActivate
    **                   in cntrline.c), then, if a linking client binds
    **                   and unbinds from the object, the object will be
    **                   destroyed and will NOT have an opportunity to
    **                   be saved. by implementing IExternalConnection,
    **                   a server can insulate itself from a poorly
    **                   written container.
    */

/****************************************************************************
** class OLEDOC : OUTLINEDOC
**    OLEDOC is an extention to the base OUTLINEDOC object (structure)
**    that adds common OLE 2.0 functionality used by both the server
**    and container versions. This is an abstract class. You do not
**    instantiate an instance of OLEDOC directly but instead
**    instantiate one of its concrete subclasses: SERVERDOC or
**    CONTAINERDOC. There is one instance of an document
**    object created per document open in the app. The SDI
**    version of the app supports one ServerDoc at a time. The MDI
**    version of the app can manage multiple documents at one time.
**    The OLEDOC class inherits all fields from the OUTLINEDOC class.
**    This inheritance is achieved by including a member variable of
**    type OUTLINEDOC as the first field in the OLEDOC
**    structure. Thus a pointer to an OLEDOC object can be cast to be
**    a pointer to a OUTLINEDOC object.
```

**    global variables. The OLEAPP class inherits all fields
**    from the OUTLINEAPP class. This inheritance is achieved by including a
**    member variable of type OUTLINEAPP as the first field in the OLEAPP
**    structure. Thus a pointer to a OLEAPP object can be cast to be
**    a pointer to a OUTLINEAPP object.

** class TEXTLINE : LINE
**    The class TEXTLINE is a concrete subclass of the abstract base
**    class LINE. The TEXTLINE class holds a string that can be edited
**    by the user. In the base app version and the OLE 2.0
**    server-only version only TEXTLINE objects can be created. In the
**    OLE 2.0 client app version either TEXTLINE objects or CONTAINERLINE
**    objects can be created. The TEXTLINE class inherits all fields
**    from the LINE class. This inheritance is achieved by including a
**    member variable of type LINE as the first field in the TEXTLINE
**    structure. Thus a pointer to a TEXTLINE object can be cast to be
**    a pointer to a LINE object.
**    Each TEXTLINE object that is created in added to the LINELIST of
**    the associated OUTLINEDOC document.

    /* OLE2NOTE: the OLE 2.0 user model is that embedded objects should
    **    always be saved when closed WITHOUT any prompting to the
    **    user. this is the recommendation irregardless of whether the
    **    object is activated in-place or open in its own window.
    **    this is a CHANGE from the OLE 1.0 user model where it
    **    was the guideline that servers always prompt to save changes.
    **    thus OLE 2.0 compound document oriented container's should
    **    always pass dwSaveOption==OLECLOSE_SAVEIFDIRTY. it is
    **    possible that for programmatic uses a container may want to
    **    specify a different dwSaveOption. the implementation of
    **    various save options can be tricky, particularly considering
    **    cases involving in-place activation. the following would be
    **    reasonable behavior:
    **
    **      (1) OLECLOSE_SAVEIFDIRTY: if dirty, save. close.
    **      (2) OLECLOSE_NOSAVE: close.
    **      (3) OLECLOSE_PROMPTSAVE:
    **        (a) object visible, but not in-place:
    **              if not dirty, close.
    **              switch(prompt)
    **                 case IDYES: save. close.
    **                 case IDNO: close.
    **                 case IDCANCEL: return OLE_E_PROMPTSAVECANCELLED
    **        (b) object invisible (includes UIDeactivated object)
    **              if dirty, save. close.
    **              NOTE: NO PROMPT. it is not appropriate to prompt
```

```
   **                       if the object is not visible.
   **         (c) object is in-place active:
   **                if dirty, save. close.
   **                NOTE: NO PROMPT. it is not appropriate to prompt
   **                      if the object is active in-place.

** class SERVERDOC : OLEDOC
**    SERVERDOC is an extention to the abstract base OLEDOC class.
**    The OLEDOC class defines the fields, methods and interfaces that
**    are common to both server and client implementations. The
**    SERVERDOC class adds the fields, methods and interfaces that are
**    specific to OLE 2.0 Server functionality. There is one instance
**    of SERVERDOC object created per document open in the app. The SDI
**    version of the app supports one SERVERDOC at a time. The MDI
**    version of the app can manage multiple documents at one time.
**    The SERVERDOC class inherits all fields from the OLEDOC class.
**    This inheritance is achieved by including a member variable of
**    type OLEDOC as the first field in the SERVERDOC structure. Thus a
**    pointer to a SERVERDOC object can be cast to be a pointer to a
**    OLEDOC object or an OUTLINEDOC object

** class SERVERAPP : OLEAPP
**    SERVERAPP is an extention to the abstract base OLEAPP class.
**    The OLEAPP class defines the fields, methods and interfaces that
**    are common to both server and client implementations. The
**    SERVERAPP class adds the fields and methods that are specific to
**    OLE 2.0 Server functionality. There is one instance of
**    SERVERAPP object created per running application instance. This
**    object holds many fields that could otherwise be organized as
**    global variables. The SERVERAPP class inherits all fields
**    from the OLEAPP class. This inheritance is achieved by including a
**    member variable of type OLEAPP as the first field in the SERVERAPP
**    structure. OLEAPP inherits from OLEAPP. This inheritance is
**    achieved in the same manner. Thus a pointer to a SERVERAPP object
**    can be cast to be a pointer to an OLEAPP or an OUTLINEAPP object
*************************************************************************/

** class SERVERNAME : OUTLINENAME
**    SERVERNAME class is an extension to the OUTLINENAME base class that
**    adds functionallity required to support linking to ranges (pseudo
**    objects). Pseudo objects are used to allow linking to a range
**    (sub-selection) of a SERVERDOC document. The base class OUTLINENAME
**    stores a particular named selection in the document. The
**    NAMETABLE class holds all of the names defined in a particular
**    document. Each OUTLINENAME object has a string as its key and a
**    starting line index and an ending line index for the named range.
**    The SERVERNAME class, also, stores a pointer to a PSEUDOOBJ if one
**    has been allocated that corresponds to the named selection.
**    The SERVERNAME class inherits all fields from the OUTLINENAME class.
**    This inheritance is achieved by including a member variable of
**    type OUTLINENAME as the first field in the SERVERNAME
**    structure. Thus a pointer to an SERVERNAME object can be cast to be
**    a pointer to a OUTLINENAME object.

/*************************************************************************
** class SERVERNAMETABLE : OUTLINENAMETABLE
**    SERVERNAMETABLE class is an extension to the OUTLINENAMETABLE
**    base class that adds functionallity required to support linking
**    to ranges (pseudo objects). The name table manages the table of
**    named selections in the document. Each name table entry has a
**    string as its key and a starting line index and an ending line
**    index for the named range. The SERVERNAMETABLE entries, in
**    addition, maintain a pointer to a PSEUDOOBJ pseudo object if one
**    has been already allocated. There is always one instance of
**    SERVERNAMETABLE for each SERVERDOC object created.
**    The SERVERNAME class inherits all fields from the NAME class.
**    This inheritance is achieved by including a member variable of
**    type NAME as the first field in the SERVERNAME
**    structure. Thus a pointer to an SERVERNAME object can be cast to be
**    a pointer to a NAME object.
*************************************************************************/

SIMPCNTR

Simpcntr -------- This sample is the simplest OLE 2.0 container that can be written and still support the visual editing feature. The sample has no native file format, and can only support one OLE object at a time. The Insert Object command is used to create an object.

See the MAKEFILE for compilation instructions.

MAKEFILE   (SIMPCNTR Sample)

CSimpleApp::CSimpleApp (SIMPCNTR Sample)

```
//**********************************************************************
//
// CSimpleApp::CSimpleApp()
//
// Purpose:
//
//      Constructor for CSimpleApp
//
// Parameters:
//
//      None
//
// Return Value:
//
//      None
//
// Function Calls:
//      Function                    Location
//
//      OutputDebugString           Windows API
//      SetRectEmpty                Windows API
//
// Comments:
//
//      CSimpleApp has a contained COleInPlaceFrame.  On construction
//      of CSimpleApp, we explicitly call the constructor of this
//      contained class and pass a copy of the this pointer, so that
//      COleInPlaceFrame can refer back to this class
//
//********************************************************************

CSimpleApp::QueryInterface   (SIMPCNTR Sample)

```
//**********************************************************************
//
// CSimpleApp::QueryInterface
//
// Purpose:
//
//      Used for interface negotiation at the Frame level.
//
// Parameters:
//
//      REFIID riid         -   A reference to the interface that is
//                              being queried.
//
//      LPVOID FAR* ppvObj  -   An out parameter to return a pointer to
//                              the interface.
//
// Return Value:
//
//      S_OK    -   The interface is supported.
//      S_FALSE -   The interface is not supported
//
// Function Calls:
//      Function                    Location
//
//      OutputDebugString           Windows API
//      IsEqualIID                  OLE API
//      ResultFromScode             OLE API
//      COleInPlaceFrame::AddRef    IOIPF.CPP
//
// Comments:
//
//      Note that this QueryInterface is associated with the frame.
//      Since the application could potentially have multiple documents
//      and multiple objects, a lot of the interfaces are ambiguous.
//      (ie. which IOleObject is returned?).  For this reason, only
//      pointers to interfaces associated with the frame are returned.
//      In this implementation, Only IOleInPlaceFrame (or one of the
//      interfaces it is derived from) can be returned.
//
//********************************************************************

/* OLE2NOTE: forward the WM_QUERYNEWPALETTE message (via
**    SendMessage) to UIActive in-place object if there is one.
**    this gives the UIActive object the opportunity to select
**    and realize its color palette as the FOREGROUND palette.
**    this is optional for in-place containers. if a container
**    prefers to force its color palette as the foreground
**    palette then it should NOT forward the this message. or
**    the container can give the UIActive object priority; if
**    the UIActive object returns 0 from the WM_QUERYNEWPALETTE
**    message (ie. it did not realize its own palette), then
**    the container can realize its palette.
**    (see ContainerDoc_ForwardPaletteChangedMsg for more info)
**
**    (It is a good idea for containers to use the standard
**    palette even if they do not use colors themselves. this
**    will allow embedded object to get a good distribution of
**    colors when they are being drawn by the container)

COleClientSite::QueryInterface (SIMPDND Sample)

```
//**********************************************************************
//
// COleClientSite::QueryInterface
//
// Purpose:
//
//      Used for interface negotiation at this interface
//
// Parameters:
//
//      REFIID riid         -   A reference to the interface that is
//                              being queried.
//
//      LPVOID FAR* ppvObj  -   An out parameter to return a pointer to
//                              the interface.
//
// Return Value:
//
//      S_OK                -   The interface is supported.
//      E_NOINTERFACE       -   The interface is not supported
//
// Function Calls:
//      Function                    Location
//
//      OutputDebugString           Windows API
//      CSimpleSite::QueryInterface SITE.CPP
//
// Comments:
//
//********************************************************************

CPersistStorage::AddRef   (SIMPSVR Sample)

```
//***********************************************************************
//
// CPersistStorage::AddRef
//
// Purpose:
//
//      Increments the reference count on CPersistStorage and the "object"
//      object.
//
// Parameters:
//
//      None
//
// Return Value:
//
//      The Reference count on the Object.
//
// Function Calls:
//      Function                    Location
//
//      OuputDebugString            Windows API
//      CSimpSvrObj::AddRef         OBJ.CPP
//
// Comments:
//
//
//*********************************************************************
